aeronautics." The Federal enactment in 1926 of the Air Commerce Act, supplemented by the Uniform State Law, will tend to bring about uniformity if not exclusive Federal control. The Air Commerce Act follows mainly the rules of the International Flying Convention. The act provides for a Bureau of Civil Aeronautics in the Department of Commerce. This bureau, under an assistant secretary of commerce for air, has charge of Federal inspection of aircraft, crews and aerodromes and the establishment and enforcement of air navigation rules: It also furnishes aids to air navigation by approving and charting air routes, establishing air light-houses and signal stations, furnishing suitable weather reports and providing at the Government fields, in cases of emergency, supplies and repairs at their fair market value. Special provision is made for trials giving the individual complete freedom to test and fly new inventions, no matter how freakish, so long as they do not endanger the public safety. No machine, however, is permitted to carry passengers unless it has been inspected and licensed as a public carrier. European air laws carefully protect the public against the unproved freak machine but they in no manner prohibit the building and testing of any type of craft, from helicopters to tail-less and wingless machines.

Safe air travel will be the preliminary aim of the air board. Public confidence in air travel must be created. To accomplish this air accidents must be decreased, if not eliminated, to a percentage lower even than railroad casualties. In Germany a rigid system of inspections and licensing has helped to cut accidents to a negligible ratio. The following experts' list of "six requisites for safe flying," will serve as a basis for the new air regulations: (1) A machine sound aerodynamically and structurally; (2) a reliable engine of sufficient power; (3) a competent conservative pilot and navigator; (4) airports and emergency landing fields, sufficiently close together to insure gliding to safety; (5) nationwide weather forecast, specialized and adapted to the needs of flying; (6) adequate charts of air routes.

AERIAL NAVIGATION is the science of directing an aircraft in flight and of determining its position at any desired instant. The word "avigation" is used by some to denote "aerial navigation." Since "avis" means "bird" it follows that the word "avigation" signifies the science of directing the man-made bird in flight. The term "avigation" is shorter and more distinctive, but it is new, and not in general use. In practice, navigation consists of determining the position of aircraft from time to time and then laying its course to any desired destination.

In studying the subject of navigation it is convenient to divide it into the four well defined methods of *piloting*, *dead reckoning*, *radio position finding* and *celestial navigation*.

Each of these methods may in turn be subdivided into three parts:

1. Definitions and theoretical principles.
2. Equipment and instruments used.
3. Actual practice of the method.

An aviator who wishes to be able to direct his plane on long and hazardous flights over unfamiliar territory in all sorts and conditions of wind and weather should have a good working knowledge of each of these four methods and in addition should be familiar with applied meteorology and fog or blind flying.

While the actual knowledge of meteorology is essential for the safe navigation of aircraft, this subject is usually covered by separate texts, is not always included in navigation and will not be included here, except to state that there has been rapid advance in the science of meteorology within the past few years

based largely on the "air mass" theory and the elaborate weather observing and teletype and radio system of disseminating weather information.

Comparison of Sea and Aerial Navigation.— Modern high-speed ships are very little affected by the wind and the current is much less important in its relative effect on the ship's motion than is true for the old sailing ships and slower ships. Accurate gyro compasses and speed indicators give excellent account of the motion of the ship itself in the direction in which it is headed.

The aviator on the other hand is concerned with an entirely different ocean. His aircraft sails in the atmosphere above the surface of the earth. The position of his plane with respect to the surface of the earth is the resultant of two distinct motions; the motion of the plane in the direction in which it is headed due to the driving power of the engine, and the motions of the air itself which is commonly referred to as the wind. The aviator's compass and his air-speed meter give him a fairly good account of the motion of the plane in the direction in which it is headed. But his compass, while improving, is somewhat crude compared to the mariner's gyro compass and his air-speed meter is not so accurate as the patent log. The winds are far harder to predict than the ocean currents and their velocity is many times greater. It is seldom that a current of 4 m.p.h. (4 knots) is encountered, but the speed of the winds may range to 100 m.p.h. or even more.

Thus the motions which combine to cause the change of position of an aircraft are many times greater in amount and are less accurately known than those affecting a ship. Therefore the dead-reckoning position of an aircraft is more liable to be in error and the error far larger in amount. The aviator should check and correct this position whenever he can by reference to known objects on the surface of the earth, which is known as piloting; by radio bearings; and by observations of heavenly bodies.

In observations of heavenly bodies the aviator is troubled by his cramped position and by the vibration of his plane. On the other hand there are no rocks and shoals in the air and he can take short cuts which greatly reduce the work and give him his position within 5 to 10 mi. which is generally sufficient.

Importance of Mastering All Methods.— The ambitious student should understand clearly at the very start that it is not enough for him to be satisfied with a knowledge of piloting which will merely enable him to direct his plane from point to point on routine flights. He should master all methods.

While it is not essential for the beginner to have a college education, it is necessary for him to have good judgment, calm nerves, and the faculty of doing simple operations without delay. Three or four months of earnest work should equip the average student for serious navigation.

The total weight of navigation equipment for dead reckoning and piloting exclusive of the panel instruments and compass should not exceed about 10 pounds. The weight for radio equipment depends on the type and size of the equipment used. The weight of a celestial navigation outfit should not exceed 15 to 20 lb. including the books, sextant and other necessary equipment.

position, Direction and Distance on the Earth's Surface.
— Position on the earth's surface is determined by the co-ordinates of latitude and longitude. The direction is given in degrees from 0° at North around to the right (clockwise) to 360° . The north point is determined by magnetic compasses which indicate the direction in which the plane is heading.

Distance is given either in statute miles or nautical miles. The statute mile is an arbitrary distance of 5,280 feet.

Maps and Charts.— A map or chart is a representation of the earth's surface or a part of it on a flat piece of paper. An accurate chart is probably more important than any other item of equipment. If the destination is not in sight at the start, the navigator's first act is to look at the map to find the direction in which he must go to reach the desired destination. In the course of the flight, as the navigator fixes his position by any or all of the various methods, he plots his fix or determined position on the chart and checks the direction from this fix to the destination.

Systems of Projection.— Any boy who has knocked the cover

off his baseball and then tried to spread it out flat knows that it cannot be done without a good bit of stretching and wrinkling. Similarly the spherical surface of the earth cannot be represented on a flat piece of paper without some distortion of certain features. In an ideal chart, distances, bearings, shapes and areas would be shown in their true relation and the shortest distance between two points would be represented by a straight line. It

FROM P. V. H. WEEMS, "AIR NAVIGATION" (MC GRAW-HILL)

FIG. 1.—ILLUSTRATION OF AERONAUTICAL CHART PROJECTIONS

is possible to preserve one of these properties by sacrificing some of the others and maps are constructed by various methods of projection in order to preserve that feature which will be most useful for the particular purpose the map is to serve.

About 96% of aviation charts are on the Lambert projection, about 2% on the Mercator projection and 2% on other projections. Heretofore, the gnomonic or great circle chart was used more frequently, but these have been partially replaced by the stereographic projection for polar areas, since the latter gives less distortion. On the Mercator chart a straight line is the "rhumb line" course or Mercator course, as steered by a compass, although a straight line on the chart does not give the direct course between two points. Also, the distance scale on the Mercator chart is the expanding latitude scale. On the Lambert chart the distance scale is distorted very little and a straight line very closely represents the great circle or shortest distance course between two points on the earth's surface.

The stereographic chart is formed by projecting the earth's surface on a plane with the observer 180° away from the point of tangency of the plane. The stereographic chart is indicated for south polar area with observer standing at the north pole (fig. 1).

Practical Construction of a Mercator Chart.— Assuming that the earth is a sphere, which, for practical navigation, is true, a Mercator chart may be constructed as follows:

1. Draw parallel vertical lines to represent the longitude to the desired scale.
2. For the lowest latitude, say 40° N. or S., draw a horizontal line for the bottom of the chart.
3. From the intersection of the left vertical line and Lat. 40° , draw a line AB making an angle of $40\frac{1}{2}^\circ$ with the 40° parallel of latitude.

4. Ground illumination for TWA transport loading at Grand Central Air Terminal, Los Angeles

4. The portion of AB intercepted between two adjacent longitude meridians is the scale of the latitude between 40° and 41° .

5. Repeat the procedure for 41° and 42° of latitude by drawing CD at angle of $41\frac{1}{2}^\circ$ to the 41st parallel of latitude, and continue the construction as desired. Number the longitude and latitude parallels as required for the area covered.

The universal plotting sheet is a partially constructed Mercator chart. One line drawn for the selected latitude completes a local chart.

Special Aeronautical Charts.— By international consent, the earth has been charted and indexed for general aeronautical charts, for local aeronautical charts and charts for special purposes. For example, the aeronautical charts for the continental United States consist of 87 sectional aeronautical charts, scale 1:500,000; and 17 regional charts, scale 1:1,000,000. On these charts are shown aids to navigation, the variation of the compass, the elevation of the terrain, the lighted airways, the radio ranges and beacons and other important information of the area covered. In addition, there are published Radio DF charts giving special radio data.

Air Pilotage.— Air pilotage, or piloting, is the method of directing aircraft from place to place by referring to visible landmarks on the earth's surface such as church spires, lighthouses, beacons, railroads, rivers, mountains and lakes. In normal flight over land, with a suitable map and good visibility, the pilot guides his plane much as a tourist directs his automobile from a road map, that is by simple piloting, which is nothing more nor less than comparing objects observed from the plane with objects shown on the map.

Preparation for Air Pilotage.— Before taking off, even for a comparatively short and simple flight, the proper charts should be studied, the course or courses laid down, the route subdivided either by distances or by time of flight, and the necessary data plainly marked on the chart. The route should be divided into 20-min. runs, 50-mi. intervals, or other convenient divisions. The charts should be carefully folded and laid out in the order of use.

The Theory of Dead Reckoning.— Dead reckoning is the method of determining a position by keeping an account, or reckoning, of the course and distance run from a previously known position called the point of departure.

Dead reckoning requires a knowledge of the direction and the speed of flight. In still air, *i.e.*, in the absence of wind, direction is obtained from the compass reading, the speed is read from the air-speed indicator, and the navigator's task is simple. Generally, however, the position of an aircraft on the surface of the earth is the resultant of two distinct motions: the motion of the plane in the direction in which it is headed, due to the driving power of the engine; and the motion of the air ocean itself relative to the earth, which is commonly referred to as the wind.

Hence, the navigator needs to keep an estimate of the velocity and direction of the wind at the height at which he is flying and to compute his dead-reckoning position accordingly.

Triangle of Velocities.— The speed and direction of an aeroplane flying through the air, which itself is moving bodily in some direction, are given by the triangle of velocities.

Any velocity may be represented by a straight line with an arrow, by making the direction as shown by the arrow represent the direction of the motion, and by making the length of the line proportional to the speed. The resultant of two simultaneous velocities can then be found by starting from any point and drawing a line so that its length and direction represent one of the velocities, and from the end of this line drawing another line to represent the second velocity; the resultant velocity is found by closing the triangle in the reverse direction.

In fig. 2 let the line $E \rightarrow W$ represent a wind of 30 m.p.h. from the west; and let the line $W \rightarrow P$ represent the heading and air speed of an aeroplane flying south-east through the air at 70 miles per hour. These two velocities form two sides of the triangle EWP, starting from E to W for the wind direction and speed and going from W to P for the heading and air speed. The resulting motion due to the combination of these two velocities can be represented by the line $E \rightarrow P$, which closes the triangle in the re-

verse direction; in other words, $E \rightarrow P$ represents the track and ground speed. This triangle of velocities is of the utmost importance in all problems of dead reckoning, and it must be thoroughly understood.

In the chosen lettering: E=earth, W=wind, P=plane.

For example, $E \rightarrow P$ indicates the speed and direction of the plane relative to the earth—in other words, the plane's track and ground speed; $W \rightarrow P$ represents the speed and direction of the plane relative to the wind, which is the heading and air speed.

FIG. 2.— TRIANGLE OF VELOCITIES SHOWING DEAD-RECKONING TERMS. THE ANGLE NWP IS THE HEADING;

ANGLE NWP', THE TRACK; ANGLE NWW', THE WIND DIRECTION; ANGLE PWP', THE DRIFT ANGLE; LINE WP, THE AIR SPEED; LINE EP OR WP', THE GROUND SPEED; LINE EW OR PP', THE WIND SPEED

Due to high speeds of modern aircraft, the drift indicator should provide observations inside the plane. An instrument of this type is the Gatty Drift Indicator, in which a collimated lens is mounted in the periscope, making it unnecessary for the eye to move to an uncomfortable position.

The compass, altimeter, air-speed meter, turn-and-bank indicator, rate-of-climb indicator, directional gyro and gyro horizon are mounted in fixed positions on the instrument panel.

The directional gyro and gyro

horizon are important gyroscopic instruments most necessary to blind flying. These instruments worked in conjunction with radio

ranges, and other aids to navigation, make it possible for modern planes to take off, accomplish a mission and land with zero visibility.

Radio.— With constant decrease in cost and weight, and with increase in reliability and effectiveness, radio equipment for aircraft is rapidly and steadily growing in importance. Radio aids are of great and increasing value to the navigator. These aids are: (1) Radio-range beacons; (2) two-way radio-telephone; (3) aircraft direction finders, compasses and homing devices; (4) airway broadcasts of meteorological information and notices to airmen; (5) instrument approach and blind-landing aids, including airway markers and airport-approach markers.

All the preceding aids contribute largely to safety in flight, the principal problem in aviation.

Fundamental Principles.— The basic principle of radio, as applied to air navigation, is that Hertzian waves sent from a transmitting station may be detected at a distant receiving station.

A second principle is that the direction from which radio waves are received may be determined to within 1° to 3° by means of the directional characteristics of the loop aerial. This same directional characteristic of a loop (though not yet fully developed) is also applicable, to a limited extent, to transmission as well as to reception, thus making it possible to direct the radio waves in a path. The field patterns of loops, discussed later, are essentially the same whether used for reception or transmission.

Radio signals may be sent and received in the form of Morse (or other code) dot-and-dash signals, this method being known as radio-telegraphy. By certain additions to the radiotelephone equipment, the human voice, or any other sounds, may be transmitted and received in the same way as a conversation is carried on with a house telephone.

A so-called "radio compass" is merely a useful application of the well known directional characteristics of a loop antenna. When the edge of the loop is pointed toward the transmitting station, the reception is of maximum strength; and when the transmitting station is in a direction perpendicular to the plane of the loop, little or no signal will be heard. Therefore, if a dial is mounted on the loop, the direction from which an incoming signal is received may be determined by swinging the loop back and forth until the point of minimum reception strength is found.

The point of minimum signal strength is used because that point is much sharper and easier to detect than the point of maximum receptive strength.

Aircraft Radiotelephone.— The use of aircraft radio for communication from plane to plane, from plane to ground, and for summoning aid in an emergency has been greatly facilitated by the development of the radiophone. Radiophone, for aeronautical use, has been a goal sought since commercial air lines began scheduled operations calling for flying irrespective of weather conditions and at night.

Until recently, various obstacles, now solved, baffled attempts to maintain voice contact with the aeroplane for more than a few miles. With the development, however, of short-wave telephony and recent advances made in shielding practices, a practical radio-telephone installation is an accomplished fact.

The ground-plane and plane-to-plane telephone service calls for complicated engineering installation, but its use by the pilot is simplicity itself. The entire equipment is nearly automatic in operation, requiring no adjusting on the part of the pilot, whose full attention can be directed to the operation of the engine and to keeping the aeroplane on its course.

As soon as the pilot takes off, the ground station operator checks on the pilot and adjusts his mechanism to tune in with the pilot, who does not adjust his set in flight. The pilot turns the switch to receive and waits for the periodic reports, approximately every zomin., giving him the latest reports on the weather, on wind velocity at various altitudes, despatching company orders and other helpful information. If he wants to talk to the ground he switches to *send* on the panel board.

Distance range of transmitters in planes and at stations is about 200mi. and, when half that distance away from the ground station last passed, the pilot picks up the next ground station ahead, and so on during the flight. The device is set to receive at all times the pilot does not wish to call, and at neutral only when the plane is on the ground. No extra pilot or helper is required to operate the radiophone, although transport planes have a pilot and a copilot, who can also fly the plane.

Blind Flying.— Blind flying is the term applied to the art of flying and navigating aircraft under atmospheric conditions where neither the earth nor the sky is visible to the pilot.

Physical Reactions to Blind Flying.— Under normal conditions of visibility a pilot controls his aircraft mainly by responding to his own sensory reactions. The senses most important to him are sight; the sensations of the vestibular labyrinths, from which is derived the sense of balance; deep muscle sensations consequent upon the shifting of the bodily weight; and, to a smaller extent, the sense of hearing. Sight is, of course, the chief guide, and while he is able to retain a view of the horizon or of the earth itself he can manoeuvre his aircraft accurately without reference to any of the instruments on his dashboard. With any diminution of visibility it may be necessary to make occasional reference to certain of his instruments, but it is only when he is completely deprived of external vision that he has to apply an entirely different technique in order to maintain control. It is now incontrovertibly accepted that man cannot fly blind without the aid of suitable instruments and special training in their use. Even birds will not venture on the wing out of sight of the ground in thick fog.

Celestial Navigation.— A sextant, timepiece, almanac and a set of tables or other means for reducing the observation of time and altitude are required. The weakest link in celestial navigation is the aircraft sextant which utilizes a bubble to replace the sea horizon used by marine navigators. Since the bubble is subject to acceleration, it is necessary to take ten or more altitudes and average them in order to get reasonable accuracy, say within five miles.

In addition to the method by the *Line of Position Book* and that by the *Star Altitude Curves*, the U.S. Hydrographic Office publishes several different methods including H.O. 214 (only partially completed in 1940), a shorter method than the *Line of Position Book*, but not as short as the *Star Altitude Curves*. The method by the *Line of Position Book* solves the

spherical triangle by convenient tables. H.O. 214 provides a ready solution except for one interpolation. The *Star Altitude Curves* provide a fix by three stars without calculations other than one subtraction of time.

The Theory of Celestial Navigation.— An observer at any point on the earth's surface, except the poles, sees the altitude of any heavenly body change with time. The altitude can be calculated for any instant of time by methods to be described later.

The altitude of a heavenly body also changes with a change in the position of the observer. The amount of this change depends on the direction in which the observer moves relative to the geographical position (G.P.) of the observed body. If he moves one mile directly toward the observed body, the altitude is increased by 1'; while if he moves in any other direction the altitude is changed by a predictable amount.

The converse is also true, namely, that, if the altitude of a heavenly body is known, the distance from the geographical position of the body for the instant of observation is known. Celestial navigation is based on the application of this principle. Therefore we may say that the work of the navigator in celestial navigation consists in finding his geographical co-ordinates of latitude and longitude by locating himself with reference to the geographical position of one or more celestial bodies.

The exact position of a body, in terms of declination and Greenwich hour angle, may be taken from the almanac for any instant of time, and this position may be plotted on a globe or chart as latitude and longitude. A circle with this position as centre, and with a radius equal to the observer's distance from this position as determined by the sextant (*i.e.*, 60° —altitude), would be the observer's circle of position; the observer must lie somewhere on this circle called "circle of equal altitude." If two bodies were observed, the intersections of the circles of position would determine the position (or two possible positions) of the observer.

Since the circle of position as determined above would be very large, a small arc of the circle may be considered as a straight line, at some point on which is the observer's position. If it were possible to lay off on a chart with sufficient accuracy the distance of the observer from the geographical position of the body, celestial navigation would be easy. The observer would doubtless use a sextant graduated to read zenith distance (instead of altitude) in minutes, or nautical miles, and this distance would simply be used as the radius of an arc to be laid off on a chart from the plotted position of the body. Unfortunately, the great distances—up to 5,400mi.—to be plotted makes this simple and obvious method impracticable, but the desired effect is secured by the means about to be described.

The Line of Position.— It is not usual to include the whole earth on any one chart; only that part of immediate interest to the navigator is shown. Hence the whole circumference of circles of equal altitude would not appear; as the radius of the circle is usually large, the small, slightly curved arc in which the navigator is interested may be replaced by a straight line without appreciable error. This line is called a *line of position* or *position line* or *Sumner line* after Captain Thomas H. Sumner, an American shipmaster, who discovered it in 1827.

FROM P. V. H. WEEMS, "AERIAL NAVIGATION (MC GRAW-HILL)"
FIG. 3.—PLOTTING ALTITUDE DIFFERENCE AND LINE OF POSITION

Plotting a Position Line on a Chart.—To lay down a line of position on a chart by the method of Marcq St. Hilaire, it is necessary to take the dead-reckoning position, or some convenient point close to it, and to compute for this assumed position the altitude and azimuth of the observed body at the time at which the observation was made. If the altitude observed with the sextant agrees exactly with the computed altitude, the altitude

difference is zero. Then it is only necessary to draw from the assumed position A (fig. 3) a line of bearing AB along the computed azimuth of the body and a line CAD at right angles to this; then CAD is the required line of position.

If, however, the observed altitude is greater than the computed altitude, say by $15'$, which equals 15 nautical miles on the earth's surface, the observer is nearer to the geographical position of the heavenly body than the assumed dead-reckoning position would indicate. In this case the position line must be moved closer to the geographical position of the heavenly body by the amount of the altitude difference. Hence the intercept AE is laid off 15 nautical miles toward the body along the computed azimuth, and the position line FEG is drawn, as before, at right angles to the azimuth line AB.

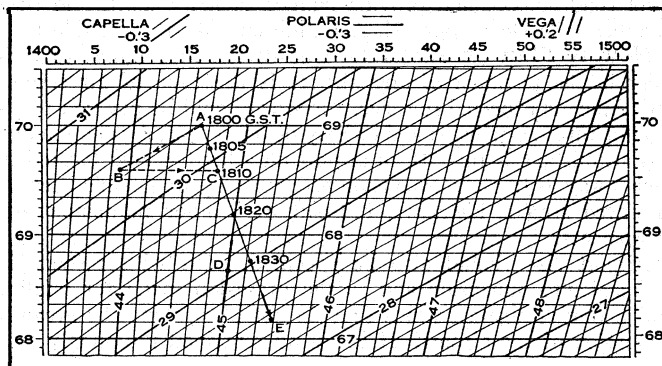

Summary.—Briefly, celestial navigation consists in finding and plotting on a chart one or more lines of position. One line of position gives the navigator certain useful information. Two or more lines of position determine by their intersection a definite position or fix. To determine a line of position, the navigator must take the following principal steps:

1. Observe the sextant altitude of a known heavenly body.
2. Note the exact time of the above observation.
3. Take the declination and Greenwich hour angle of the observed body from the almanac for the GCT of observation.
4. Apply the assumed longitude to the Greenwich hour angle to find the local hour angle.
5. Compute the altitude, using an assumed position, by solving the spherical triangle formed by the earth's pole, the geographical position of the observed body, and the observer's assumed position.
6. Compute the azimuth, using the same assumed position.
7. Compare the computed and observed altitudes to obtain the altitude difference.
8. Set off the altitude difference along the computed azimuth and draw the line of position at right angles to it.

Star Altitude Curves.—Using the principles for computing a line of position previously described, altitude curves for so-called "fixed" stars may be plotted against the co-ordinates latitude and sidereal time. Sidereal time is similar to civil time except it is based on the motion of the fixed stars, which causes it to differ from civil time by 3min. 57sec. daily.

Actually, the stars move by a small amount in various directions, which, when referred to the earth, causes a displacement of stars from 0 to about .8 of a mile annually and this correction must be made in the use of the curves. A portion of a page of the curves is shown in fig. 4 with a plotted example showing how they may be used.

Suppose a plane making 300 m.p.h. on course 240° true is at A,

FROM P. V. H. WEEMS, "AIR NAVIGATION" (MC GRAW-HILL)

FIG. 4.—SAMPLE *Star Altitude Curves* SHOWING METHOD OF USE

Lat. 70° N., Long. 56° W. at 1800 GST, or 1416 LST (1800 less 3^h44^m for 56° W. Longitude). In *romin.* the plane would travel 50mi. on 240° and, with a page of the curves used as a Mercator chart, as shown in fig. 4, would arrive at point B, in Lat. $68^\circ 36'$ N. Because of the distance travelled in *romin.*, the altitude of Vega would change from $44^\circ 36'$ at A to $43^\circ 55'$ at B. In the elapsed

romin. Vega's altitude increases at point B from $43^\circ 55'$ to $44^\circ 48'$ at C. The combined effect of change of position and *romin.* of elapsed time would change Vega's altitude from $44^\circ 36'$ to $44^\circ 48'$. If Vega's altitude at 1800 GST is $44^\circ 36'$ and at 1810 GST is $44^\circ 48'$, then for 1805 GST Vega's altitude is shown at once to be $44^\circ 42'$. In other words, the line AE is the loci of simultaneous altitudes of Vega, Capella and Polaris, provided the plane remains on its schedule. If at 1830 GST Vega's altitude is $45^\circ 00'$, the plane is at some point D about 12mi. off course to right. If an observation of Polaris gives an altitude of $67^\circ 40'$ at 1830, the intersection with Vega gives D as the definite fix, and the plane is shown to be 13mi. 247° true from the scheduled 1830 position.

The only limitation to the Star Altitude Curves is that observations are restricted to stars for which the curves have been plotted. An accurate solution may be made in about two minutes without the use of an almanac, without plotting lines of position and without knowing the latitude, declination or hour angle of the body. Simply find the intersection of the altitude of two or more stars, refer this to the latitude scale direct for latitude and to the time scale for the local time. This, subtracted from the Greenwich time, gives the longitude.

AERODROME, AIRPORT or AIR STATION. Whether called by any of these three names or by others such as air park, air base, or flying field, the areas now set aside in every country on earth for the regular use of aircraft form one of the basic and most important elements in the conduct and development of aviation.

As of Jan. 1, 1940, there were in the United States alone no less than 2,451 airports, landing fields and seaplane bases recognized as such by governmental authorities. This total includes 643 municipal and 456 commercial airports, 266 Civil Aeronautics Authority intermediate fields, 21 naval air stations, 59 army fields and 170 miscellaneous Government, private and State airports and landing fields. In a survey conducted in the spring of 1939 the U.S. Civil Aeronautics Authority estimated that the total investment up to Jan. 1, 1939 in civil airports in the United States amounted to \$330,782,111, and of this amount \$6,549,057 was contributed by States, \$101,459,232 by municipalities, \$79,208,544 privately, and \$143,565,278 by the Federal Government, most of which has been in the shape of relief projects initiated since 1933.

What the eventual needs will be in the United States, and in proper scale throughout the world, is difficult to estimate, but the Civil Aeronautics Authority in 1939 estimated that \$128,000,000 would be required to develop the airports at 236 designated air-mail stops to the point where they would be fully adequate to meet the increasing needs of air transportation. Inclusive of the above, it was also estimated that \$290,000,000 would be required similarly to develop 860 airports having special reference to air transportation, and that to provide an entire system of approximately 3,500 airports designed to meet the full requirements of free movement by air throughout the United States, would, inclusive of the above, cost approximately \$500,000,000.

Airport Requirements.—When flying emerged from the purely experimental stages of 1910, the problem of providing landing fields and landing areas was a minor one. The relatively small size of the aircraft then in use, coupled with their slow take-off and landing speeds, made almost any open and level area a potential landing field. Many flights were made in the early days from country pastures, baseball parks, race tracks, State fair grounds and the like. However, this is no longer the case, The

Airport Site Planning Standards

Recommended minimum Standards	Class 1	Class 2	Class 3	Class 4
Length* of Landing Strips (in feet)	1,800 to 2,500	2,500 to 3,500	3,500 to 4,500	4,500 and over
Width of usable landing strips (in feet)	300	500	500	500
Length of runways (in feet)	None	2,500 to 3,500	3,500 to 4,500	4,500 and over
Width of runways (in feet)	None	150 (Night oper.) 100 (Day oper. only)	200 (Instrument) 150 (Night oper.) 100 (Day oper. only)	200 (Instrument) 150 (Night oper.) 100 (Day oper. only)
Number † of landing strips and runways determined by percentage of winds, including calms ‡, covered by landing strip and runway alignment	75%	80%	90%	90%

Two-way radio Visual traffic control Instrument approach system, when required

*All of the above landing strip and runway lengths are based on sea level conditions; for higher altitudes increases are necessary. One surfaced runway is recommended for the effective length of each landing strip for airports in Classes 2, 3, and 4.

†Landing strips and runways should be sufficient in number to permit take-offs and landings to be made within $22\frac{1}{2}^\circ$ of the true wind direction for the percentage shown above of winds 4 m.p.h. and over, based on at least a 10-year Weather Bureau wind record where possible.

‡Calms: Negligible wind conditions of 3 m.p.h. and under.

transition and the trend of aircraft design from smaller aeroplanes with light wing loadings to the larger fast transports of today with their heavy wing loadings, higher landing speeds and slower climb ratios, has seriously complicated and rendered obsolete former conceptions of adequate airport size.

The proper size of modern airports, and especially the length and width of runways for the operation of all types of land planes, both day and night, has been the subject of much discussion and study by the entire aviation industry and the various organizations whose interests lie in airports.

While airports in the United States are no longer rated or licensed according to their size or facilities provided, there have been formulated tentative standards governing airport size which were used by the U.S. Civil Aeronautics Authority in making its national survey of airports. These tentative standards were developed from data which had been gathered from photographic studies of aircraft landings and take-offs and from the recommendations of representative sections of the aviation industry. For planning purposes, therefore, landing areas can be tentatively classified as being either Class 1, Class 2, Class 3 or Class 4 airports.

To gain admission to any of the three highest classes, the airport landing strips must be paved and there must be proper lighting. For all four classes it is specified that the "effective" length of landing strip should be determined by the stipulation that a line drawn from the end of the strip on a minimum slope of 20ft. horizontally to every foot of rise shall clear the highest obstruction in the neighbourhood. Thus "clear approaches" means that in the case of a Class 1 airport, the approach to the landing strip or runways should be clear within a glide path of 20 to 1 from the ends of the runways and 30 to 1 in the case of Class 2, 3, and 4 airports. For instrument landing runways the ratio should be 40 to 1 from a point 4,500ft. from the beginning of the runway.

All runway lengths referred to in the following classification and set forth in the accompanying table apply to airports located at sea level. For those appreciably above sea level, the minimum length of landing strip for each class must be increased enough to compensate for the decrease of density with altitudes. Thus an airport 6,000ft. above sea level needs in general a runway length almost 50% greater than would be needed for a field of the same class near to sea level.

Class 1 Airport.—Small communities having a population up to 5,000 which are not located either on the present or proposed air carrier system should provide airports which can safely accommodate aircraft of the small private owner type. It is recommended that under sea level conditions the airport should be equipped with landing strips having a minimum length of 1,800ft.

to 2,500ft. together with "clear approaches." (Additional data see Table.)

Class 2 Airport.—In larger communities having a general population range of from 5,000 to 25,000, located on present or proposed feeder line airways where considerable aeronautical activity is present, the airport should safely accommodate the larger sized private owner type planes and small sized transport planes. For such airports it is recommended that under sea level conditions they provide landing strips of at least 2,500ft. to 3,500ft. in length, together with "clear approaches." (Additional data see Table.)

Class 3 Airport.—Important cities having a general population range of from 25,000 to several hundred thousand, located on feeder line airway systems or serving as intermediate points on main line airways, should provide airports which can safely accommodate the present day transport planes. To do this such airports under sea level conditions should provide landing strips 3,500ft. to 4,500ft. in length together with clear and unobstructed approaches. (Additional data see Table.)

Class 4 Airport.—Cities representing the major industrial centres of the nation and serving as the most important junction points or terminals on the airway system, should provide airports which can safely accommodate the largest aircraft now in use and those planned for the immediate future. Such airports under sea level conditions should provide landing strips 4,500ft. and over together with clear approaches. (Additional data see Table.)

How to Plan an Airport.—One of the first things to consider in the planning of any airport is the type of air service the airport is expected to serve. Airports should be planned to allow for future expansion and orderly development. A common and serious mistake is to start an airport on a limited area located in such a way as to make expansion economically impossible because of paved streets, highways, railroads and other permanent developments.

Airport size should also be specified, both with respect to its maximum dimension and to the provision made for landing and taking off against winds that do not blow along the greatest dimension of the airport. If the wind remained unfaithfully true to one point of the compass, as it comes very near doing in some parts of the tropics, the airport could be reduced to a single runway, but the typical case is that of winds coming from any quarter, and the airport must be planned accordingly. Even though it is on only one day or night that the winds blow strongly from one particular direction, a pilot approaching the airport on that day or night should be able to make a safe landing.

There are, of course, other factors having important bearing upon the necessary size of an airport. Its altitude above sea

level is of special significance, and mean temperatures and other climatic factors have their effects. Special care should also be given in planning to the surfacing of runways or of the whole field area, its drainage, the buildings to be provided for storage of aircraft and other purposes, and to the availability of equipment and qualified persons for various servicing operations.

One more remark should be made in general terms, and that is that airports should be planned and designed for long-continued use. The airport planned in 1940 should be planned not merely for the aircraft and the operating methods of 1940, but also for the needs of at least five or ten years hence, as well as can be anticipated.

Locating the Airport.—In the selection of an airport site and particularly in weighing the relative merits of several locations, the facilities of ground transportation to and from the area in question assume considerable importance. To assure uninterrupted transportation service, the selection of a site which is conveniently located with respect to the existing highway system and other means of transportation is an important factor in enabling a city to obtain the maximum benefits from air travel. The frequency, speed and cost of existing or proposed means of transportation should be considered more than the distance in miles of the proposed site from the city.

Proposed sites must also be carefully investigated as to wind, fog and smoke affecting general visibility in the vicinity; prevalence of ground fog due to adjacent swamp land or bodies of water; adverse wind currents and directions as influenced by earth configuration; direction of wind-blown industrial smoke and fumes as they affect visibility in the vicinity of the airport site must also be considered. A study should also be made of wind direction and duration at the proposed sites, as the direction of prevailing winds influences the layout and alignment of the runways and also the location and layout of the building area. Before finally selecting a site where obstructions of a serious nature exist, such as power lines, high trees, stacks and so forth, the practicability of removing or reducing all obstructions to a safe permissible height should also be assured.

Drainage and Soil.—One of the most important considerations governing the location and selection of an airport site is the nature and composition of the soil and subsoil upon which it is to be built. For the economical development of the area for aviation purposes, and especially for the life and durability of paved runways, taxi strips and aprons, detailed knowledge of the soil at the site, and especially its behaviour in contact with water, is vitally important.

Adequate drainage is especially essential to the proper maintenance of paved runways, for experience shows that more runway paving failures occur from unstable subsoil conditions caused by lack of proper drainage than for any other reason.

Grading.—In view of the fact that one of the few permanent features involved in the construction of an airport is the grading, a complete grading plan of the entire area ultimately to be included in the airport should be prepared, which will take into consideration the contemplated finished grades. Since excessive grades, particularly, make night landings more difficult, longitudinal and transverse landing areas in runway grades not to exceed $1\frac{1}{2}\%$ are preferable on major airports. Obviously, however, it is not always feasible to adhere to this figure as a maximum, since wide topographical variations on a site often involve excessive quantities of earth movement. From the standpoint of aircraft operations alone, however, field grades should be held as close to $1\frac{1}{2}\%$ as possible.

Airport Surfaces.—In sections of the country where the soil and climatic conditions permit the growth and maintenance of firm turf surfaces, it may be possible for airports with light and limited traffic to maintain continuous operations throughout all seasons of the year without resorting to artificial surfacing. However, under the strain of heavy traffic, turf is likely to become rutted, especially if exposed to alternate freezing and thawing.

Paved Runways.—The term "runway paving" is applied to

the process of preparing a firm, stable, all-year, all-weather runway surface, free from dust or aggregate which may be blown or picked up by aircraft engine propellers, and designed to support the static and dynamic loads occurring in the landing and taking off of aircraft.

Hard surfacing may be divided roughly into the general types, rigid and flexible. Rigid type pavements include Portland cement concrete of varying dimensions, with or without steel reinforcing, and certain asphaltic concretes and asphaltic or water-bound macadams which may approach rigid characteristics. Flexible paving includes virtually all of the bituminous types of construction with cutbacks, emulsions, planed or blade mixes, built up penetrations and bituminous soil stabilization.

Rough non-skid wearing surfaces are avoided because of the excessive tire wear which such surfaces impose on landing aircraft. The preferable finishes for concrete surfaces are those approaching a smooth trowelled finish.

Lighting.—Airports vary so widely that each airport will present a separate problem. The size and shape of an airport, the terrain, the amount of traffic, the types of aircraft to be used and the nature of the soil or runway surface all will play important parts in affecting the number, type and extent of the lights which should be used. The following types of lights are, however, considered standard equipment on all major air terminals in the U.S.:

The Airport Beacon.—This is a beam light having a beam intensity of at least 1,000,000 candle power, thus making it visible for miles to the pilot of an aeroplane and telling him that there is a lighted field available. Beacons are generally mounted on towers set either on the ground or on top of one of the airport buildings. In any case, the beacon should be mounted at least 20ft. above any buildings or surrounding structures.

The Illuminated Wind Direction Indicator.—Two basic types of illuminated wind direction indicators are in general use, the illuminated wind cone and the illuminated wind tee. Their primary function is to give the true direction of the wind at all times. They should also be readily visible at all times to aircraft approaching from any direction.

Boundary Lights and Range Lights.—As the name implies, boundary lights outline the entire available landing area of the airport. Such lights are spaced not more than 300ft. apart and are served by an underground distribution system. Clear lights are used as boundary lights and green range lights are set in the line of the boundary lights to mark the ends of runways or favourable landing directions. These range lights are arranged in groups having the identical number of lights at both ends of the same runway.

Contact Lights.—Contact lights are used on major air terminals to assist pilots in effecting landings and take-offs. They consist of white lights, flush with the ground along the runways, spaced 200ft. apart, along each side of the runway. Their installation is always arranged in pairs opposite one another on both sides of the runways. They are controlled so that only one runway at a time is illuminated. Runways used for instrument landings have rows of lights at least 200ft. apart, and the contact lights in the rows are spaced 200ft. apart along both sides of the pavement. On instrument landing runways, yellow contact lights are used from the approach end to a point 3,000ft. from the remote end and white lights from this point to the remote end. In instrument landings, this system serves to give the pilot the assurance that if he comes down between the yellow lights he has at least 3,000ft. of runway ahead of him for use in a landing.

Approach Lights.—Approach lights are lights located outside the landable area and arranged to indicate a favourable or preferred direction of approach. The principal use of approach lights is to mark a lead-in or approach lane for instrument landing.

Obstruction Lights.—Obstruction lights clearly mark with red lights all obstructions surrounding an airport. High obstructions like radio towers which extend more than 70ft. above their surroundings are marked by lights at the top and at the

one-third and two-third levels.

Ceiling Projector.—A projector concentrating a narrow beam of light and mounted at a fixed angle of elevation, generally 60° , is used to determine the height of the ceiling (the under surface of the lowest cloud or mist layer) above the airport at night by a simple system of triangulation. The ceiling projector is located at a fixed distance, generally 1,000ft., from the point at which the clinometer readings are to be made.

Landing Area Floodlight System.—This system is so designed as to provide an even distribution of illumination free from abrupt changes in intensity and shadow areas over the portion of the landing area to be used in making a landing.

Air Marking.—The air marker is one of the simplest and least expensive aids to air navigation in common use in the United States but it is, at the same time, most effective and necessary, particularly in so far as the private or itinerant flyer is concerned. Perhaps the chief hazard concerned in "contact flying" is the danger of becoming lost due to poor visibility or other reasons and it is obvious that this hazard is considerably lessened if the flyer can ascertain his exact whereabouts and orient himself by merely looking down as he passes over a town or city and reads a sign giving this information. Since this is the chief function of air marking, the markers should be of a letter size 10 to 20ft., and legible under good visibility conditions from a height of at least 3,000 feet. Such markers are either painted or constructed on roofs, on the ground or are painted directly on highways.

Intermediate or Safety Fields.—Airports of all the groups so far enumerated are located with primary reference to the convenience of a community. There are also to be considered other groups which are established solely as a contribution to the safety of air navigation and for which convenience plays almost no part at all. They are the intermediate fields and safety fields strategically placed to meet the needs of a pilot finding himself forced to an early descent either by stress of weather or by threats of mechanical failure. Along the 24,250mi. of Federally established lighted airways of the United States, such intermediate fields are located at irregular intervals but placed so that it is seldom that jomi. intervene along any airway between marked and lighted landing places. While their number has tended to diminish in recent years because of the lessened liability of aircraft to forced landings, there are still some 273 intermediate fields under Federal control and maintenance and they still play an important part in ensuring airway safety.

Seaplane Bases.—The word airport has been used for convenience to describe bases for land planes alone. Airports less narrowly defined, and seaplane bases should, however, be considered together as they provide essentially the same purpose. The limiting dimensions of a landing area for seaplanes are customarily determined by natural conditions. Open sea take-offs are usually dangerous and frequently impossible and the greatest possible length of operating area is usually fixed by the width or depth of a harbour except where the whole body of water (lake, river, sound or bay) is so protected as not to become very rough. In an ideal seaplane base adequate rules governing the use of channels and the mooring of craft would leave several straight runways of adequate length clear of any fixed obstructions or any great congestion of water traffic.

Major Air Terminals.—While there are a number of major air terminals scattered throughout the United States, only one has been selected to illustrate the development and growth and the requirements which must be met by a modern major air terminal.

North Beach Airport, New York City.—The New York Municipal airport, comprising as it does a landplane administration building, six mammoth hangars, office buildings, a seaplane hangar and marine terminal building, is one of the largest projects of its kind in the world. It was constructed at a cost of \$44,119,299, of which \$27,430,332 represented the Federal contribution and \$16,688,967 the contribution of the city of New York.

The airport itself provides four asphalt macadam-surfaced runways for landplanes, the longest of which, running NW and SE, is 6,000ft. long and 200ft. wide. Running NE and SW is runway No.

2, 5,000ft. long and 200ft. wide. Runway No. 3 is 4,500ft. long and 150ft. wide, and runs east and west. Running north and south is runway No. 4, having a length of 3,532ft. and 150ft. in width.

These runways were designed in strict accordance with the "wind rose" or diagram constructed from the meteorological records showing the prevailing winds at the site, the longest runway being built in the line of direction of the most frequent prevailing winds, and so on down the line. Taxi runways 100ft. wide intersect the runways, connecting them with one another and with the apron 400ft. wide and 6,200ft. in length which extends in an arc in front of the landplane hangars and buildings. This apron of concrete construction provides ample space for the loading and unloading of 15 21-passenger transport planes at the same time. The apron is illuminated by floodlights mounted on hangars, five on each hangar. When a plane is landed on a runway, the floodlights and runway contact lights go out and the taxi lights go on, showing the pilot the best taxi lane to the apron. The runways are bordered by contact lights spaced 200ft. apart. The ends of the four runways are also marked by green range lights and at the end of each runway there are two narrow beam floodlights, each 7,500,000 candlepower. The field is outlined by approximately 85 boundary lights spaced 250ft. apart. Numerous other lights, including taxi strip lights, floodlights, etc., are installed about the field.

The airport control tower is on the roof of the administration building, 64ft. above the ground. Here, every modern facility for directing the flow of incoming and outgoing traffic has been provided. On top of this tower is a rotating beacon of 13,500,000 candlepower.

The airport also provides six large hangars, together with a marine terminal building provided with complete facilities for hauling giant trans-Atlantic ships from the water, placing them on miniature railroad flat cars, and wheeling them into the hangar on tracks for repairs or maintenance.

Radio Facilities.—The centre of the whole network of lights is the control desk in the airway traffic control tower. This control desk has the airport in miniature laid out on its top. Tiny lights go on and off with the contact lights, traffic lights, and floodlights on the field. The most modern of radio equipment, receivers and transmitters, is provided.

Airports in Europe.—It is the general rule in Europe that the major airports serving international traffic are financed and operated by the central government. In some cases, as in Great Britain, there are only a very few such ports and most areas are cared for by airports provided at municipal expense as in the United States. In other instances, as in Germany, the central government plays a much larger part. Commercially operated fields are extremely rare, although in the Netherlands the major airports are under the control of the leading Dutch air transport company which serves as operating agent to the Dutch Government.

Some European countries have a substantially greater density of airport distribution than the United States as a whole. In 1939 Great Britain and Northern Ireland listed 180 airports, Royal Air Force stations and landing fields, including 75 public civil airports and 38 private fields. The 113 civil and private airports allow on the average one for every 788 sq.mi. of area as against a civil airport for 1,587 sq.mi. in the United States. France in 1939 listed 185 airports, 51 of them private, and Germany listed 99 civil airports, which obviously does not include airports used partially or wholly for military purposes.

Under the combined influence of military consideration and the rapid growth of air transport, the European governments were, at the outbreak of hostilities, engaged in hasty revisions of their ideas of adequacy of airports. The major international terminals have been the subject of a great enlargement program. The standard set in the United States for a Class 4 airport, with the exception of the newly completed New York Municipal airport at North Beach and the Washington National airport at Washington, D.C., seems quite modest when compared with the most advanced European thought. The Tempelhof airport at Berlin, for example

(see TEMPELHOF FIELD), was listed in 1939 as having a landing area 4,600ft. by 2,600 feet. The enlargement program now nearing completion substantially quadruples the area and provides one runway 6,500ft. long. The new terminal building covers 137,000 square meters of ground area and has a main waiting room 330ft. by 160ft., restaurants to serve several thousand people and a long stretch of hangars under one cantilever roof under which aeroplanes are to be drawn up for loading and which is approximately a mile in length. There, 100,000 people may gather in comfort on the hangar roof to observe airport activities, and 60,000 may be seated at tables on the roof and served from special restaurants entirely separate from the main restaurant over the waiting room. The daily total of arrivals and departures at Tempelhof in the summer is reported to be over 300 planes. At Le Bourget, Paris' terminal airport, the landing area is currently being increased to 800ac. with a runway more than 8,000ft. long in one direction and 5,000ft. in another. The plans for the terminal building are only slightly less impressive than those for Tempelhof. By any other standard, they would be spectacular. The new terminal building at Le Bourget (see LE BOURGET AIRPORT) which cost between 12,000,000 and 14,000,000fr., is rectangular in design, 722ft. by 115ft., with a height, exclusive of the centre section, of 40ft. and a span of approximately 3,300,000 cu.ft., or three times the cubical content of the Croydon terminal. Other airports, such as the one at Schipol at Amsterdam and the Croydon terminal in England, display similar ideas and ambitions but move more modestly toward their realization. The prevailing European idea seems to be that a first-class airport should have (at least one runway 6,000ft. in length. (E. M. E.)

AERODYNAMICS. The word is

both to the study of the disturbances generated in air by the passage of solid bodies, such as aircraft, and to the study of the motion of free aircraft under the influence of air reactions. The former is a specialized development of *fluid dynamics* and the latter of *rigid dynamics*, i.e., the dynamics of rigid bodies under the action of external forces. (See DYNAMICS and HYDRODYNAMICS.)

The equations of motion of a slightly viscous fluid such as air can be formulated, but have not in general been solved, and in no instance has the complete motion of the air passing a body, such as a wing, been calculated directly from the laws of motion. Aeronautics is thus dependent for its data mainly upon direct experiment, and since quantitative experiments upon the full scale are difficult and costly, the bulk of the data available has been obtained upon small models of the parts concerned suspended in artificially induced currents of air. The technique of the measurement of air reactions upon models suspended in "wind tunnels," (see AERONAUTICS) as the tunnels containing these air currents are called, has reached a high development and many tunnels of great size and power have been built in all countries seriously concerned with aeronautics. The largest wind tunnel in the world is at Langley Field, Virginia; it has a cross section of 30 feet by 60 feet and is operated by two fans 35 feet 5 inches in diameter, driven by a 4,000 horse power slip-ring induction motor. The tunnel can accommodate a moderate sized aeroplane, one, for example, that would carry two or three passengers. New tunnels in England and Germany approach the size of the one at Langley Field.

It is clearly of importance to determine how nearly similar is the manner in which the air flows around such models to the manner in which it flows around the corresponding full scale aeroplane. In many aeronautical problems air can be treated as though it were an incompressible and inviscid fluid. In these cases it can be shown that *similar bodies moving in a similar manner will generate similar air flows*, no matter what the size of the body, the density of the fluid, or the speed of the motion. Even the nature of the fluid, whether liquid or gas, is of no consequence, and experiments intended to relate to air may equally well be carried out in water, or in any other fluid which, for the purpose in hand, can be treated as incompressible and inviscid. The simple laws of aeronautics, such as that the pressure varies in proportion to the density of the air and to the square of the speed, are based upon

this assumption.

Effects of Compressibility and Viscosity.—In aeronautics air can generally be treated as though it were incompressible, unless velocities exceeding some 300 or 400 miles per hour are involved. When velocities higher than this occur, compressions and expansions of the air as it passes the solid body may seriously influence the flow; the rule for similarity of flow becomes less simple. It is then necessary that corresponding velocities in the motions to be compared should all bear the same ratio to the velocity of sound in the fluid in which the motion takes place. For example, if high speed experiments in air and water are to be strictly comparable, the experiments in water must be carried out at speeds four times as great as the corresponding speeds in air, because sound travels some four times as fast in water as in air; but when both the model and the full scale body move through air the actual speed of the model must be the same as that of the full scale body. Such high speeds as 300 to 400 miles per hour are not yet commonly met in aeronautics, except in racing aeroplanes and at the tips of the blades of high speed airscrews, and hence it is unnecessary to obey this law of similarity, except in connection with the tests of such screws.

For fluid flows which are appreciably influenced by viscosity yet another condition must be fulfilled to ensure similarity between two motions. Let μ be the viscosity of the fluid, ρ its density, V the velocity of the body through the fluid, and let l be some length which defines the size of the body—for instance the diameter, if the body be a sphere, or the length, if it be an airship. Then the quantity $\frac{\rho V l}{\mu}$ must have the same value in each of the

motions to be compared, otherwise viscosity will play a different part in each motion, and strict similarity will be impossible. This quantity $\frac{\rho V l}{\mu}$ has zero dimensions and is therefore a pure number or ratio, independent of the units in which its separate factors are expressed, provided that those units form a dynamically consistent

FROM NAYLER AND FRAZER, "REPORTS AND MEMORANDA OF THE ADVISORY COMMITTEE FOR AERONAUTICS" BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE

FIG. 1.—THE TURBULENT FLOW OF FLUID PAST A CYLINDER

This illustrates the flow round all bodies which offer a high resistance to rapid motion through fluids. The motion of the fluid, which is from left to right, is characterized by a dead region *a*, followed by a turbulent wake *b*. Such a flow exerts a powerful drag upon the body

system, i.e., a system of units which allows Newton's laws of motion to be expressed in the form:—Force = mass \times acceleration, the pound-poundal-foot-second and the gram-dyne-centimetre-second systems being examples. It is universally known as the *Reynolds number*, after the celebrated scientist Osborne Reynolds. When the Reynolds number of a flow is small, viscosity will play a predominating part in the motion, which will be of the kind usually associated with the flow of oils or treacle. When the number is large, the flow will be of the kind usually associated with water, and will approximate to that of an inviscid fluid. Thus the same fluid may act in a highly viscous manner when flowing slowly past small objects, and yet behave almost as though inviscid when flowing rapidly past large bodies. The Reynolds numbers which are of interest in aeronautics are of the order of a million; in these circumstances the air behaves almost as though it were inviscid, and the simple laws of comparison between model and full scale, to which reference has been made, can generally be applied without serious error. Certain flows, which are of great

interest in aeronautics (e.g., the flow about a wing at the stalling angle which is defined later) are, however, highly critical, in the sense that small disturbances may cause an entire change in the type of flow. These critical flows may be sensitive to changes in the Reynolds number, even though the value of the number is very large, and hence the greatest caution must be used in applying the results of small model experiments on these critical phenomena. The highly practical importance of some of these critical flows has led to great efforts being made to devise laboratory experiments in which the Reynolds number will be the same as that of the full scale flow to be represented. One way in which this has been successfully accomplished, though at great cost, is to enclose the whole wind tunnel in an air-tight chamber pumped up to a pressure of some 20 atmospheres; this increases ρ some 20 times, which compensates for the reduction in V and l necessary to bring the experiment within the scope of laboratory methods.

FLUID MOTION

The forms taken by the flow of air past a solid body can in general be classified as belonging to one of two characteristic types. Fig. 1 is typical of the flow around the majority of bodies not specially shaped to move easily through fluids. The motion, which in this figure is from left to right, is characterized by a dead region *a*, of small velocity and low pressure, followed by a turbulent wake *b*. Such a flow exerts a powerful drag upon the body, and much energy will be required to force the body rapidly through the fluid. Fig. 2 is typical of the flow around bodies which move easily through fluids, the dead region *a* is absent, whilst the wake has become very small. Flows of this type are generally called *streamline* flows, and bodies which generate them are called *streamline* bodies. The turbulent flow, as in fig. 1, is not yet susceptible to precise mathematical analysis, but streamline flows, as in fig. 2, approximate, when the Reynolds number is large, to the flow of a hypothetical inviscid fluid, the analysis of which has been thoroughly studied.

Bernoulli's Theorem.— This famous theorem relates to the steady flow of the hypothetical inviscid fluid, and states that the pressure p and the velocity v at all points on a single streamline are connected by the relation:

$$p + \frac{1}{2}\rho v^2 = \text{constant.}$$

In most aeronautical problems the air at all points far from the body is assumed to be undisturbed, so that its velocity relative to the body and its pressure are uniform; if these are called V and P respectively, then Bernoulli's equation leads easily to:

$$p - P = \frac{1}{2}\rho V^2 \left[1 - \left(\frac{v}{V} \right)^2 \right]$$

from which the pressure at any point can be deduced from the velocity at that point, or vice versa. The maximum pressure will thus occur where v is zero, and will have the value of $P + \frac{1}{2}\rho V^2$; this maximum pressure occurs on the surface of the solid body at the point where the streamlines divide. (See figs. 1 and 2.) This fact is used to measure the velocity of air in aeronautical experiments. If a tube, closed at one end and open at the other, is placed with the open end facing the air stream, the pressure within it will have the maximum value $P + \frac{1}{2}\rho V^2$. If the difference between this pressure and the pressure P of the undisturbed stream can be measured and if the density is known, the velocity V can be determined. The undisturbed, or static pressure P can be obtained within a closed tube placed with its axis parallel to the wind and having small holes punctured in its sides at some distance from the closed end. These two tubes are known respectively as the *pitot* and *static pressure* tubes; and together with some form of manometer, for measuring the difference between the pressures within them, they provide the standard speed measuring unit both in the laboratory and on aeroplanes in flight.

The Flow About a Streamline Body.— The theoretical study of a hypothetical inviscid fluid leads to the conclusion that when a solid body starts from rest to move through such a fluid, which is otherwise undisturbed, the form of the flow around the body is uniquely determined by its shape and mode of motion. This

FIG. 1.—THE FLOW OF FLUID PAST A —STREAMLINE— BODY

In contrast to the turbulent flow round a body not especially shaped to move easily through fluids as in Fig. 1, this illustrates the flow round a body which offers small resistance to rapid motion through fluids

flow has the remarkable property that, although it may cause variations of pressure which tend to rotate the body, it exerts no resultant force upon the body, no matter what the shape of the body may be. The actual air flow about a streamline body, such as an airship (fig. 2) is a very close approximation to this theoretical flow, and hence the resultant of the pressures upon the surface of the body is almost zero—the small remaining drag, or resistance to motion, being nearly all due to *skin friction*, i.e., the tangential forces on the surface due to the friction of the air. When the Reynolds number is large, as in aeronautics, the fluid mechanism which exerts these skin friction forces is confined to a very thin sheath, or layer, enveloping the body. This is called the *boundary layer*; the motions within it are very complex and are known to provide the determining factor which decides whether the flow will be streamline or turbulent. Outside this very thin boundary layer the flow, if streamline, behaves very closely as though the fluid were absolutely inviscid.

A wing may be loosely described as a flattened streamline body. Its cross section in one plane containing the direction of motion has a typical streamline form, as in fig. 3 (see also *AEROPLANE*) which shows a modern wing section. So long as the incidence, or inclination of this section to the direction of motion is not too great, the flow about the wing will be streamline, the drag will be small and the wing will exert a lift perpendicular to the direction of motion which increases progressively with the incidence. If the incidence becomes too large the flow changes, more or less

FIG. 3.— AN EXAMPLE OF AN AEROPLANE WING SECTION

The modern type of wing is more or less a flattened streamlined body. The actual air flow about a body of this shape is such a close approximation to the theoretical flow that the pressure upon its surfaces is almost zero

suddenly, to a form similar to that in fig. 1. The wing is then said to *stall* and its resistance to motion is greatly increased, whilst its lift no longer increases with incidence, but may even fall slightly.

Below the *stalling angle* the flow, though streamline, differs from that unique flow which could be generated from rest in an inviscid fluid, and approximates more nearly to one of a series of flows, which are possible to the inviscid fluid, but which could not be generated in it without the action of some additional agency. The way in which these flows are generated is still somewhat obscure, but it is known that their development is made possible by the slight trace of viscosity in the air, which allows eddies to be shed from the trailing edge of the wing, and that as these eddies are shed the flow about the wing changes until the appropriate flow has developed. When these changes have ceased and the flow has become steady the viscosity plays no further appreciable part in the motion, except in the boundary layer. Theoretically

there are, for each wing at each incidence, a series of such flows which could exist steadily in the inviscid fluid but could not be generated in it, and a question arises as to which one of them will occur in any given instance. Unlike the flows which could arise from rest in an inviscid fluid, these flows give theoretically, a lift upon the wing, and if the actual lift of the wing can be measured, the particular flow of this series which is occurring can be identified as that one which theoretically gives the measured lift. It is thus possible, by merely measuring the total lift of a wing, to calculate, with considerable accuracy, the direction and velocity of the flow at all points in its neighbourhood and from Bernoulli's equation the distribution of pressure over its surface. If the lift cannot be measured, the flow can be approximately identified as that one of the series in which the streams flow smoothly off the trailing edge of the wing without sharp changes of direction. This method of identification is not so accurate as the former.

Induced Drag.—Calculations such as the foregoing can most conveniently be made in relation to wings of infinite span, or length perpendicular to the direction of motion. For such wings the theoretical drag in the inviscid fluid is zero; the real drag is almost entirely due to skin friction and is so small that it may, in favourable circumstances, be less than one-fiftieth of the lift. When the span of the wing is finite, circulations are set up around the tips, the air flowing round them from the high pressure region beneath to the low pressure region above the wing. Vortices are thus generated, which trail from the wing tips and remain in the air long after the wing has passed. These vortices require power for their generation and consequently the power required per running foot to propel a finite wing, and the drag on the wing, are greater than for a wing of infinite span: for this reason the drag of a wing of practicable shape is seldom less than one-twentieth of the lift. L. Prandtl has developed approximate mathematical methods of calculating this drag, which he calls the induced drag. The difference between the actual and the induced drag is called the profile drag, because it depends upon the profile, or cross section, of the wing and is not dependent on the span.

For a given wing arrangement, the induced drag is proportional to the ratio, weight supported/span; this ratio is now called the span loading. The induced drag varies in inverse proportion to the air density and the square of the speed. The profile drag, for a given incidence and profile, depends upon the total wing area and varies in direct proportion to the density and the square of the speed. When calculating the drag of an aeroplane wing, it is now normal practice to divide the drag into these two parts and to study them separately. Induced drag can be calculated, not only for single wings, but for multiple wings, as in a bi-plane, or for wings in the presence of plane boundaries, such as the walls of a wind tunnel or the surface of the earth. Such calculations are used extensively in all modern laboratories and design offices.

FREE FLIGHT

Stability.—An aeroplane which, on being disturbed from a condition of steady flight in equilibrium, ultimately returns to the condition from which it was disturbed, is said to be stable. Complete stability in this sense can be achieved by correct proportioning of the parts of the aeroplane, but is by no means necessary for successful flight; for if the pilot has effective control over his aeroplane he can easily check any tendency to depart from equilibrium flight, which may result from a moderate instability. It is, however, important for the designer to know, not only whether his aeroplane will be stable or unstable, but the degree of stability or instability to be expected, for its behaviour in the hands of the pilot will depend upon this factor. The subject has therefore been extensively studied mathematically, but is so complicated that it is impossible here to do more than refer the reader to standard books on the subject.

Stalling.—As the speed of an aeroplane falls the lift falls, and sufficient lift to balance the weight can be obtained only by an increase of incidence. But it has been shown in a previous paragraph that when the incidence of a wing passes a certain critical angle the character of the air flow changes, and the lift ceases to increase. There is thus a minimum speed, associated with the

above critical angle, at which any aeroplane can fly steadily. This minimum speed of steady flight is called the stalling speed, the incidence at which it occurs is called the stalling incidence, and an aeroplane flying at an incidence greater than the stalling incidence is said to be flying stalled. With this change of flow at the stalling incidence is associated a complete change in the characteristics which determine the stability of aeroplanes and the action of their controls. For the effect of this change upon practical aviation see **AEROPLANE**.

AERO ENGINES. The term "aero engines" encompasses any and all prime movers designed for or actually used in the propulsion of aircraft. It therefore includes steam engines, electric engines, internal combustion engines, and jet propulsion mechanisms.

It is more restricted than the term "aero power plant" in that the latter encompasses not only the aero engine but all of its appurtenances such as fuel and oil systems, cooling systems and air-screws (air-screw termed propeller in the U. S.).

HISTORICAL

Early Airship Engines.—In 1851, a French engineer, Henri Giffard, developed the first aeronautical engine. He chose the steam engine for his purpose and constructed an engine which with its boiler weighed 351lb. and developed only 3 horse power. Nevertheless, it provided the means for the first controlled navigation of the air and on Sept. 4, 1852, Giffard piloted his airship from Paris to Trappes.

Twenty years elapsed from this epochal flight to the first flight with an internal combustion aero engine. In 1872, the German engineer, Paul Hærlen, piloted an airship powered with a four-cylinder internal combustion engine which used the lifting gas of the airship, coal gas, for fuel.

The first internal combustion aero engine using gasoline as fuel was the two-cylinder engine used by Schwarz in 1897 to propel the first rigid airship.

Early Aeroplane Engines.—The engine used by the Wright brothers in the first flight of man in a heavier-than-air machine on Dec. 17, 1903, was a four-cylinder internal combustion engine using gasoline as fuel. (See Plate I, fig. 1.) The engine was designed and constructed by the Wright brothers who succeeded in constructing an engine which exceeded their own expectations by delivering 12 h.p. for a weight of 179 pounds. Its form was similar to that of the contemporary automobile engines with four cylinders mounted in line. The barrels only were liquid-cooled and the heads were air-cooled.

The most noteworthy early aeroplane engine was designed and constructed in 1902 by Charles M. Manly for the Langley "aerodrome," which, though it failed to fly in its first attempts due to failures of the catapulting gear, did fly some years later without modification.

This remarkable engine developed 52.4 h.p. with a weight of only 151lb., giving a weight-power ratio of 2.88. It had five water-cooled cylinders arranged radially around a central single throw crank-shaft. This form of construction, known as the radial type, was later to become the most popular type for aeroplane propulsion. (See Plate I, fig. 2.)

Aero Engines of the World War Period, 1914-18.—The advent of the World War in 1914 greatly stimulated the development of aero engines. World War engines of note were of various types, but it was in this era particularly that the rotary types found favour. The rotary engine was of the general form of the radial engine designed by Manly in that the cylinders radiated outwardly from a common centre. It differed from Manly's engine in that the cylinders and crank-case rotated around a crank-shaft rigidly mounted in the aeroplane fuselage. The advantage of these engines over others available early in the war period was light weight. The disadvantage was excessive gyroscopic force

which made aeroplane control difficult.

The type did not survive due to the above disadvantage and to an inherent limitation in speed and power and high fuel and oil consumption. Notable examples used in the war were the Gnôme, Le Rhône, Bentley B.R.2 and Clerget all used by the Allies, and the Oberursel and Goebel used by the Central Powers. These engines were all air-cooled and weighed from 2 to 3lb. per horse-power. (See Plate I, fig. 3.)

The weight advantage of the rotary engines at the start of the war was soon eliminated by the refinement of the automobile type of liquid-cooled engine with 8 or 12 cylinders in two banks of four or six cylinders arranged in "Vee" form.

Most noteworthy of the 8-cylinder engines was the Hispano-Suiza manufactured in France, England and the United States. This engine had its cylinders cast of aluminium in two blocks of four cylinders each with individual steel cylinder liners with closed ends shrunk and screwed into place. The sizes mostly used were from 150 to 220 horse-power. These engines weighed approximately 2.3lb. per horse-power.

In the 12-cylinder types, the two outstanding engines were the English Rolls Royce and the American Liberty. Both of these engines had individual steel cylinders with steel water jackets welded thereto. The Rolls Royce developed 360 h.p. with a weight of 836lb., giving a weight-power ratio of 2.32. The Liberty developed 420 h.p. with a weight of 845lb., resulting in a 2.11 weight-power ratio.

The Liberty was particularly noteworthy in the short time elapsing from the start of work on the design to its quantity production in a number of American automobile factories which had not previously engaged in aviation work. However, it should be noted that the Rolls Royce engine was also the product of an automobile manufacturer.

While the Allies were concentrating their engine development on the "Vee" type engines, the Central Powers concentrated their attention on the development of the 6-cylinder in-line type of which the outstanding engines were the Mercedes, Benz and Maybach. These engines ranged in power from 160 to 220 h.p., and weighed over 3.5lb. per horse-power.

Noteworthy in the war period was the development in England of two radial air-cooled engines which were about ready to go into service at the end of the war.

One was the Cosmos Jupiter, developed by the Cosmos Engineering Co., Ltd., and the other the A.B.C. Dragon Fly, developed by the A.B.C. Motors, Limited. The former was a 9-cylinder radial which developed 450 h.p. with a weight of only 662lb. or 1.47lb. per horse-power. The cylinders were closed end steel forgings with a poultrice aluminium head bolted on to carry the valve mechanism and inlet and exhaust passages. Two inlet and two exhaust valves were used.

The Dragon Fly was also a 9-cylinder radial with closed end steel cylinders. They had one inlet and two exhaust valves each with individual cast aluminium ports bolted to the heads. The rocker arms were carried on steel frames also bolted to the heads. This engine developed 340 h.p. with a weight of 600lb., giving a weight-power ratio of 1.76.

This engine was unusual in that it used a roller bearing in the master connecting rod and did not provide for oil circulation, the oil pumps supplying oil only at the rate oil was consumed by the engine.

GENERAL REQUIREMENTS

There are certain peculiarities of aerial transportation which demand a higher performance from the aero engine than is required of engines for any other service.

The principal requirements are reliability, low weight, low fuel consumption, small size and maintenance of power at high altitudes.

Reliability. — Of all forms of transportation, aerial transportation demands the most in reliability of its power plant. The failure of an engine in land transportation results only in inconvenience and some engine repair expense. The failure of an engine in water transportation is generally no more serious in its consequences, as the boat will usually stay afloat until help is

secured.

No help can be sent to an airship or aeroplane. If the power plant of an airship fails, it must be navigated and landed as a free balloon, a hazardous undertaking. If the power plant of an aeroplane fails, it must immediately glide to a landing in the most suitable field within gliding range. If this field is inadequate, or the pilot's judgment bad, damage to the aeroplane if not to the passengers is inevitable.

It is because of the seriousness of power plant failures in air transportation that it has long been customary to duplicate parts in the aero engine which are most likely to cause failures such as sparking plugs and magnetoes, and to use multiple power plants whenever possible and practicable so that flight may be continued if one unit fails.

Low Weight. — The requirement of low weight in the aero engine is more stringent in the case of the aeroplane than it is in the case of the airship, but in both it is greater than in other means of transportation. The problem in the aeroplane is more acute because in the aeroplane only is power required to counteract the force of gravity.

The percentage of the total power so used varies between aeroplanes and with the speed of each aeroplane, the greater the speed the less power required to counteract gravity. At zero speed, as in the case of the hovering helicopter, all of the power is so used.

The importance of light-weight aero engines for aeroplanes is perhaps best illustrated by considering its effect on pay-load (weight of passengers and cargo). In a given aeroplane any reduction in weight of the power plant can be added to the pay-load without any change in the performance of the aeroplane. A typical 24-passenger air transport aeroplane in 1940 had a useful load (pay-load plus fuel, oil, crew, etc.) of 8,000lb., with a gross weight of 24,400lb. and two 1,200 h.p. engines. These engines weighed approximately 1,300lb. each or just over one pound per horse-power.

Assuming a weight of 200lb. for each passenger and his baggage, the 24 passengers would account for 4,800lb. of pay-load, or exactly 2lb. per horse-power. From this it will be at once apparent that if the engines in this aeroplane weighed 3lb. per h.p., all of the passengers would have to be taken out to compensate for the increased engine weight.

The above figures are, of course, based on retaining the same performance of the aeroplane considered and it should not be assumed therefrom that an engine weighing 3lb. per h.p. cannot be used as such weights were not uncommon in the smaller engines used in private aeroplanes in the same year. The added engine weight can be accommodated without sacrifice in useful load by increasing the wing area and reducing the aeroplane performance. However, the performance of the transport aeroplane cited was considered as economically justified, and the high performance of the military aeroplane was, of course, essential. As the performance of the aeroplane is reduced, the engine weight becomes of less importance.

A contemporary small two-place aeroplane had a pay-load of 275lb. with a 65 h.p. engine weighing 160 pounds. The pay-load was therefore over 4lb. per h.p. as compared to an engine weight of 2.5lb. per horse-power.

The importance of light weight in this case can best be illustrated by comparing weight reduction with range of operation. A reduction in the weight of this engine to 2lb. per h.p. would have permitted increasing the range of operation of this aeroplane from 380 to 480 miles.

Low Fuel Consumption. — The requirement of low fuel consumption goes hand in hand with the requirement of low weight because to the cost of fuel must be added the cost of transporting it in the air. As in the case of reductions in engine weight, reductions in fuel weight can be directly added to pay-load. The importance of fuel consumption increases directly with the range of operation of the aeroplane and becomes of paramount importance for transoceanic travel. This will be apparent when it is realized that even the best of the aero gasoline engines in 1940 consumed in service between .45 and .50lb. of fuel per h.p. hour. At the usual cruising power of 65% of maximum power, this re-

sults in a fuel consumption of approximately .3lb. per maximum h.p. per hour. In the case of the transport aeroplane cited above, the engines would consume a weight of fuel equal to the total weight of the passengers in less than seven hours.

Small Size.—The over-all dimensions of aero engines are in most installations of paramount importance. If the engine cannot be placed within the framework of the aeroplane as dictated by other requirements, then it necessarily adds to the projected area of the aeroplane, and hence to the power required to propel the aeroplane through the air. The importance of keeping the projected area to a minimum increases with increase in aeroplane speed. The power required to overcome the parasitic drag varies with the cube of the speed and, other things being equal, is proportional to the projected area.

Power at Altitude.—The density of the atmosphere decreases rapidly with increase in altitude, so much so that the air at 18,000 ft. altitude has a density of only one-half of that at sea level. The indicated power of any internal combustion engine, *i.e.*, the actual delivered power plus the power required to overcome engine friction, varies directly with the weight of the air it consumes in unit time. As the displacement of the engine per unit time is constant in volume, it follows that its displacement in weight, and hence its indicated power, varies directly with the air density. The delivered power varies even faster because the friction horse-power remains substantially constant.

An engine without some means of counteracting the effect of altitude would therefore develop less than one-half its ground power at 18,000ft. altitude.

TYPES

Although these general requirements are applicable to all uses of aero engines, the relative importance of these requirements varies greatly with different uses of the aero engine. To meet the widely varying requirements for different services many types of aero engines have been developed and with a few exceptions have found a place in service. They are classified in several different ways, *e.g.*, according to use, heat cycle, fuel, cooling system, mechanical arrangement, etc.

Air-Cooled Radial Gasoline Engine.—Vieing for first place with the liquid-cooled ("Vee") type is the air-cooled radial engine, widely used in military and non-military, and in commercial and private flying. With but few exceptions, they are of the four-stroke cycle type, and have an odd number of cylinders operating on each crank-pin to secure equal firing intervals. They are made with both one and two banks of cylinders. In Plate II are shown two views of a typical two-row radial engine, the Wright Double Row Cyclone, and the crankshaft assembly and the crankcase of this engine.

The engine is provided with a two-speed centrifugal supercharger. It has a displacement of 2,603 cu.in., and is rated commercially at 1,600 h.p. at 2,400 r.p.m. for take-off. Its maximum, except take-off, ratings are 1,350 h.p. from sea level to 5,000ft. with low gear supercharger drive, and 1,275 h.p. from 6,700ft. to 12,000ft. with high gear supercharger drive. Its compression ratio is 6.85 to 1. and 95 octane fuel is required for the above ratings. The engine weighs 1,950lb. or 1.2lb per hp. take-off rating. The air-screw gear reduction is .5625 to 1. The bore and stroke are 6.125in., and 6.312in. respectively. The over-all dimensions are, diameter 55in., length 62 inches.

Water-Cooled "Vee."—A typical example of the water-cooled "Vee" type, the Rolls Royce Merlin, is shown in Plate III, figs. 1 and 2. It has 12 cylinders of 5.4in. bore and 6in. stroke, giving a displacement of 1,647 cubic inches. It also has a two-speed centrifugal supercharger and is rated 1,075 h.p. at 3,000 r.p.m. for take-off. Its international rating is 1,035 h.p. at 2,600 r.p.m. at 2,250ft. with low gear supercharger and 960 h.p. at 2,600 r.p.m. at 13,000ft. with high gear supercharger. Weighing 1,394lb., the weight per horse-power is 1.3 pounds. The over-all dimensions are, length 75in., width 30in., height 41.2 inches.

Air-Cooled "Vee."—Plate III, fig 3, illustrates the air-cooled "Vee" type, the engine being the Ranger SGV-770B. Its displacement is 773 cu in. and weight 640 pounds. It is rated 500 h.p. at 2,950 r.p.m. for take-off, and 420 h.p. at 2,850 r.p.m. at its critical

altitude of 5,700 feet. The over-all dimensions are, length 61.3in., width 28in., height 32.25 inches. The weight per take-off horse-power is 1.28 pounds.

Air-Cooled "H."—An unusual type of engine is that shown in Plate III, fig. 4, the Napier Dagger VIII. It is an excellent example of the use of small cylinders at very high rotation speeds. The 24 cylinders are of $3\frac{1}{8}$ in. bore and $3\frac{1}{2}$ in. stroke, giving a displacement of 1,027 cubic inches. The rated take-off power is 955 h.p. at 4,200 revolutions per minute. Its maximum power of 1,000 h.p. is developed at 4,200 r.p.m. at 8,750ft. altitude. The engine weighs 1,390lb., giving a weight-power ratio of 1.39. Its over-all dimensions are, length 74in., width 26in., height 47 inches.

Water-Cooled Flat Type.—Developed primarily to permit mounting within the contours of the aeroplane wing, the horizontally opposed or flat type engine is illustrated in Plate IV, fig. 1. The engine illustrated is the Lycoming 1,230, having a displacement of 1,230 cu.in., and weight of 1,325 pounds. The engine is rated at 1,200 h.p. for take-off, or almost 1 h.p. per cu.in. displacement. The weight per h. is 1.10 pounds. The over-all dimensions are, length 90in., width 44in., height 37 inches.

Sleeve Valve Radial.—The manufacturers of the well-known Bristol Jupiter radial engine produced in 1932 a 9-cylinder air-cooled radial engine employing a single sleeve valve of the Burt-McCullom type. This consists of a relatively thin cylinder sleeve operating between the piston and the cylinder wall to control inlet and exhaust ports. It has an oscillatory movement in which each point in the sleeve has an approximately circular motion. In 1936 a larger engine, the Bristol Hercules, was produced and placed in service in the Royal Air Force. This engine is of the two-bank 14-cylinder type with a $5\frac{3}{4}$ in. bore and a $6\frac{1}{2}$ in. stroke. Its total displacement is 2,360 cubic inches. It is rated at 1,290 h.p. at 2,800 r.p.m. for take-off, and 1,100 h.p. at 2,400 r.p.m. at 5,000 feet. It weighs 1,680lb., giving a weight-power ratio of 1.3. Its dimensions are, diameter 52in., length 67 inches. See Plate IV, fig. 3.

Barrel Type.—The barrel type engine or, as it is variously known, the round engine, the wobble plate engine or the swash plate engine, has always attracted interest due to its extreme compactness. None had been sufficiently well developed to be ready for service at the start of the war which began in Europe in 1939. In this type the cylinders are arranged in a circle around a central shaft with their centre lines parallel to each other and to the shaft. Various methods of transmitting the power from the pistons to the shaft have been used; one arrangement of pistons and shaft is as shown in Plate IV, fig. 2. The compactness of such designs is well illustrated by one design having 4,070 cu.in. displacement with an over-all diameter of 36in., and over-all length of 79 inches. These dimensions should be compared with those for other types given herein.

Two-Stroke Cycle Gasoline.—The two-stroke cycle gasoline engine has also attracted many engineers due to its promise of delivering more power per cu.in. displacement than the four-stroke cycle engine, but up to 1940 none had been sufficiently developed to attain any general acceptance. However, in the years just prior to 1940, research projects carried out particularly by the National Advisory Committee for Aeronautics in the United States had shown such favourable results that interest in this type was renewed. In addition, the almost universal use of superchargers on the four-stroke cycle engines had by this time removed one of the older objections to the two-stroke cycle—that of the added complication of the scavenge pump. There had also been developed, particularly in Germany, very satisfactory gasoline injection systems for four-stroke cycle engines. These are considered as almost essential for a two-stroke cycle engine and had also been objected to on the grounds of complication.

Diesel Engines.—Diesel engines have received more attention in Germany than in any other country, and they have been in regular aeroplane service in that country, including use in trans-Atlantic flights. The first such engine to receive any great amount of service use and used in trans-Atlantic service was the Junkers Jumo, shown in Plate IV, fig. 4. The construction is novel. Each of the six cylinders has two opposed pistons, eliminating cylinder heads completely. The opposing pistons are connected

to crank-shafts placed at opposite ends of the cylinders, and geared together at the end. The piston controlling the exhaust port is given a slight lead over the piston controlling the inlet port to permit supercharging. One of the principal advantages of this form of construction is through or uniflow scavenging obtained thereby. The bore of the cylinders of the Jumo 205-C was 4.13 in., and each piston had a stroke of 6.3 in., giving a total displacement of 1,104 cubic inches. The engine was rated at 610 h.p. at 2,200 r.p.m. for take-off and 600 h.p. maximum except take-off at the same speed. It weighed 1,124 lb., giving a weight-power ratio of 2.04. The specific fuel consumption was claimed to be .381 lb. per h.p. hour.

Radial oil engines which have attained some degree of success have been developed by Packard and Guiberson in the United States, Bristol in England, and Clerget and Salmson in France. They have shown no gain in power-weight ratio, however, over the Junkers. A "Vee" type oil engine was developed by Daimler Benz in Germany for airship use.

Steam Engines.—Although the first controlled flight was made with a steam power plant, no such power plants had enjoyed more than experimental flights up to 1940. Their disadvantage as compared to internal combustion engines is that much of the heat rejected in the steam power plant must be transferred to the air by radiation, and this usually entails increased drag; whereas, in the internal combustion engine, the heat rejected in the exhaust requires no additional expenditure of power for its rejection.

At the time when regular trans-Atlantic flights were being inaugurated, serious consideration was given to combinations of internal combustion and steam power plants, and it is likely that such power plants will be developed. The internal combustion engine rejects about two-thirds of the heat supplied to it in the fuel it consumes. Approximately one-fifth of this could be converted into useful work by a steam power plant. In the case of the auxiliary steam plant, no fuel is required, and hence its weight-power ratio is constant irrespective of range of operation. Therefore, it becomes of interest whenever the range of operation is such that this weight is less than the weight of the internal combustion engine plus its fuel.

Jet Propulsion.—As speeds of aeroplane operation increase, the possibilities of jet propulsion increase. In this type of propulsion, fuel is burned in a chamber under pressure, and the escape of the combustion products from this chamber at high velocity provides the desired thrust. This is not materially different than propulsion by an engine-driven air-screw, and is subject to the same general laws. The thrust obtained from a jet is proportional to the mass of fluid moved in unit time and the velocity imparted to it. The energy consumed in the process is, however, proportional to the mass and square of the velocity. Jet propulsion necessarily involves the use of very high jet velocities and its efficiency is therefore akin to that which would be attained from extremely small air-screws.

Rocket Propulsion.—Some efforts have been made to use the equivalent of the sky rocket with which everyone is familiar to propel aircraft, and at least one flight of an aeroplane so propelled has been reported.

Gas Turbines.—Many efforts have been made to develop a satisfactory internal combustion turbine, or something approximating a turbine, but up to 1940 none had achieved any measure of success.

The extremely high temperatures and velocities which must be used to secure reasonable fuel consumption have been the universal stumbling block.

One exception which must be noted has been the successful development of exhaust-driven turbines in which this problem is partially avoided by taking most of the energy out of the charge in the reciprocating engine before it reaches the turbine. These turbines have been very successfully used to drive superchargers, and have very definite advantages over gear drives for this purpose.

Not only do they conserve some of the excessive exhaust energy loss, which otherwise occurs with a supercharged engine at high altitudes, but their capacity automatically varies with the requirements therefor.

FUELS AND LUBRICANTS

The improvements made in the maximum power output and in the low weight of aero engines can be attributed in no small degree to improvements in fuels and lubricants. In the case of gasoline, or petrol, as it is called in Great Britain, improvements made in its characteristics from the World War (1914-18) period to 1940 have of themselves permitted an increase in power output per cu.in. displacement at the same r.p.m. of 2 to 1. Not so startling, but nevertheless material improvements have also been made in lubricants and in Diesel fuels.

Gasoline.—The remarkable increase in permissible power output of gasoline engines mentioned above has been accomplished by the development of gasolines which are more resistant to a combustion process which has been termed "detonation." This can best be described as the almost instantaneous combustion of a part of the air-fuel mixture in the cylinder after some part of it has been burned as the result of the normal progress of the flame front from the point of ignition. It results in the development of extremely high temperatures which cannot long be endured by any engine without serious damage or complete failure ensuing. It is usually accompanied by an audible knock. Fuels vary widely in their susceptibility to this type of combustion, and for each there is a critical temperature and pressure at which it occurs. They are rated by comparing their detonating characteristics with reference fuels. Mixtures in varying proportions of normal heptane, which detonates at low temperature-pressure conditions, and iso-octane, which detonates only at quite high temperature-pressure conditions, have been universally adopted as reference fuels. The detonating characteristics of other fuels are then designated by so-called "octane numbers," which are the percentages of iso-octane in the reference fuel having like detonating tendency.

Diesel Fuel.—Diesel engine fuel, called distillate or fuel oil, has not been developed particularly for aviation use, but such special development will probably be made necessary by the fact that in no other service are the fuel requirements so severe. For aviation use it has the advantage of reduced fire hazard and, as it is used without high tension ignition systems, it eliminates the problem of shielding such systems to minimize their interference with radio reception.

Lubricants.—The lubricants used in aero engines are generally of a much higher viscosity than those used in other services due to the very high bearing loads in aero engines. The need for a higher viscosity at operating temperatures makes more important the rate of change in viscosity with change in temperature. In all mineral oils the viscosity increases with decreases in temperature, and the differences between the viscosities of various oils are much greater at low temperatures than at high. Oils with a large viscosity temperature change and having sufficient viscosity at operating temperature would make the starting of a cold engine almost impossible.

This change in viscosity with change in temperature creates a difficult problem in the cooling of the oil. The oil flowing through a radiator whose metal surfaces are over-cooled, congeals on these surfaces and provides an excellent heat insulator. The result is that the hot oil passes through the centre with little reduction in temperature. This characteristic of oil coolers has frequently created the anomaly of requiring the temperature air control shutters to be partially closed to accomplish a reduction in the oil temperature, although this direction of movement is normally expected to increase the temperatures.

DESIGN PROBLEMS--GENERAL

Weight.—The attainment of minimum weight for the cycle used is a problem common to all types of aero engines. Minimum weight is attained by reducing to a minimum the distances through which stresses must be carried, making every part work as hard as it can as much of the time as possible, and choosing materials and sections which are capable of carrying the loads with a minimum of weight.

An example of what is meant by the statement relative to working time is found in the comparison of the radial type to the in-line type of construction. For the same bore and stroke the forces

- 4. Junkers "Jumo" 6-cylinder diesel engine

transmitted by the connecting rods are the same in the two engines. However, the maximum of force occurs in only one rod at a time, and the sum of all of the forces does not begin to equal the product of the number of rods by their maximum loads. As a result, the crank throw of the 9-cylinder radial engine is nowhere near as heavy as would be the sum of nine individual crank throws. The same power is transmitted through less material because the material is made to work more uniformly, *i.e.*, the ratio of maximum stress to mean stress is reduced.

In the matter of choosing the most desirable form to secure minimum weight, as in practically every other decision which must be made, there are conflicting influences. Although it may be noted from the description of engines under the heading Types that the radial air-cooled engine is lighter in pounds per cubic inch displacement than are the "Vee" water-cooled types, it will also be apparent that in the attainment of low weight per horsepower they lose all or part of this advantage by reason of a lower power output per cubic inch displacement. This same conflict occurs between small and large cylinders, the latter weighing less for a given displacement, but able to produce less power for that displacement. These conflicts account for the wide divergence in the forms of equally successful engines.

DESIGN PROBLEMS—GASOLINE ENGINE

The limitation placed upon the design of gasoline aero engines by the detonating characteristics of the fuel has been mentioned under the heading of Fuels and Lubricants. That these limitations give the engine designer many problems will be apparent from the following.

Compression Ratio.—A major factor in determining the detonating characteristics of an engine—*i.e.*, the maximum temperatures and pressures attained in the cylinders, is the compression ratio. This is the ratio of the volume of the fuel-air mixture in the engine cylinder before compression to its volume after compression. Increases in compression ratio increase the detonating tendencies, and vice versa. The compression ratio also directly affects the specific fuel consumption in conventional engines. It has a quantitatively equal effect on power output. Unfortunately, the direction of change is such that an increase in compression ratio is required for a decrease in fuel consumption and increase in power which is in conflict with the requirements for the suppression of detonation.

Supercharging.— There is introduced at this point the subject of supercharging as it has a direct bearing on permissible compression ratio. Supercharging is the process of pumping into the engine cylinder a greater weight of fuel-air mixture than the cylinder could otherwise aspirate. It was introduced originally to compensate for reduction in air density at high altitudes. For the present, so-called ground supercharging, *i.e.*, the use of supercharging at sea level, will be considered. This has a direct bearing on the detonating characteristics of an engine as it determines the pressure and temperature at the start of compression, and hence the temperatures and pressures at the end of compression for any given compression ratio. It will be immediately apparent, therefore, that for a given fuel the designer has a choice of high compression ratio and low, or even negative supercharging, and low compression ratio and high supercharging. As the power varies more rapidly with the degree of supercharge than it does with the compression ratio, high supercharge and low compression ratio will give the maximum power output for a given fuel. However, supercharging does not directly affect specific fuel consumption, and therefore the best fuel economy will be attainable with a high compression ratio and a low supercharge.

Further complicating the problem is the original object of supercharging, that of maintaining the power of the engine up to some prescribed altitude. For a given supercharger design it is evident that the greater the ground supercharging the less will be the supercharger capacity left for altitude use, and hence the lower the altitude to which ground power may be maintained.

Air-Fuel Ratio.—A third factor affecting both the specific fuel consumption and the tendency of the engine to detonate is the air-fuel ratio used. There is a reasonably wide range of air-fuel mixtures that ignite satisfactorily, and within this range a

choice must be made between a rich mixture giving a high fuel consumption but a decrease in detonation and a lean mixture giving a low fuel consumption but increasing the detonation tendencies. Fortunately, in practically all non-military and in some military operations, maximum power is required for only relatively short periods of time, and it is customary to provide means of supplying an extremely rich mixture at full power to suppress detonation, and a lean mixture at cruising power to secure good fuel economy. The magnitude of the fuel-air ratio effect on detonation is of such an order that in some cases the operational margin over detonating conditions is no greater at cruising power with lean mixture than at full power with rich mixture.

Cooling Systems.—Also affecting detonation tendencies and greatly affected by detonation is the cooling system used for the cylinders. The temperatures of the cylinder walls and cylinder heads naturally have a direct effect upon the increase in temperature of the fuel-air mixtures during compression. In the reverse order, detonation in the cylinder with the resulting high temperatures greatly increases the amount of heat which the cooling system must dissipate. Here again, we find conflicting interests. The higher the cylinder wall temperature the greater the tendency toward detonation, but the lower the power loss due to the drag of the cooling system and, within limits, the lower the fuel consumption.

The importance of the power loss due to the drag of an improperly designed cooling system can be well illustrated by the fact that the entire power of the engine would have been required to overcome the drag of the radial air-cooled engine at air speeds commonly attained in 1940 with the engine uncowled as was the common practice in 1930. Only through the development of very elaborate cowls and cylinder baffle-plates to secure the maximum cooling effect with the minimum drag were the higher speeds made possible with the air-cooled engine.

Less critical are these problems to the designer of the liquid-cooled engine as he has greater control of the factors involved in their solution. Freed from the necessity of fitting his radiating elements to the aerodynamically imperfect cylinder, and not limited in available area of the radiator, he can design his radiator for the most efficient dissipation of the heat. To offset this advantage, liquid-cooling is generally heavier, more prone to failure, and more susceptible to gun fire. It does, however, have an additional advantage of being better able to cope with temporary overloads due to detonation and such engines are therefore less liable to failures from this cause.

In efforts to reduce the weight of liquid-cooling systems, as well as their drag, steam and chemical cooling systems are used. In the former, the heat rejected by the cylinder is taken up for the most part by the latent heat of evaporation of the liquid, and the radiator becomes in effect a condenser. As it is for the most part filled with steam rather than liquid, the weight is less. It also has the advantages of reduced area by reason of the higher temperature drop from the radiator to the air, and hence a reduction in drag. Chemicals have been substituted for water in many liquid-cooled engines to secure the reduction in area obtainable by using a coolant temperature higher than that permissible with water. The chemical usually used is ethylene glycol which has a boiling point of about 350° Fahrenheit.

In all cooling systems, the increase in speeds and in altitudes of operation has necessitated the use of some method of controlling the amount of cooling. If this were not done, a cooling system adequate to take care of the engine at the low speeds during take-off and climb would over-cool at cruising, especially at high altitudes and, in addition, it would add an unnecessarily high cooling drag.

DESIGN PROBLEMS—DIESEL ENGINE

The greatest problem in the development of the Diesel aero engine is that of securing satisfactory combustion of the fuel. The constant pressure cycle, approximated by slow speed Diesel engines, actually has a higher ratio of mean pressure to maximum pressure, and should of itself permit the Diesel engine to weigh less than the gasoline engine. However, to secure low weight it is essential that high rotative speeds be used, and at high speeds

the maintenance of the constant pressure cycle together with full utilization of all the air has not been attained. Unfortunately, the cycle tends to approach the constant volume cycle of the gasoline engine, and gives rise to excessively high pressures due to the high compression ratio used in the Diesel engine. In the Packard aviation Diesel engine the peak pressures were reported to have been above 1,200 lb. per sq.in.

The Diesel cycle lends itself more readily to the use of the two-stroke cycle than does the Otto cycle since there is no problem of fuel loss through the exhaust ports nor of securing sufficient time for evaporation of the fuel. Ground supercharging also has more advantages and fewer disadvantages in the Diesel than in the Otto cycle.

perhaps on some early failure to imitate the birds. Leonardo da Vinci thought and wrote about it, and there are some references to the subject in the works of Francis Bacon. In 1617, Fleyder of Tiibingen lectured on flying; while in Italy, again, in his book *De Motu Animalium* (1680), G. A. Borelli discussed the question in connection with the strength of man's muscles and came to the conclusion that such flight was impossible.

Early History of Artificial Flight.—We are here concerned mainly with the flight of bodies heavier than air; for the early history of airships, see BALLOON and AIRSHIP. The first attempts, limited in all cases to the flight of models, were generally based on the endeavour to imitate the action of a bird's wings. Sir George Cayley, however, in 1796, constructed a tiny helicopter in which two windmills made of gull feathers were caused to revolve about a vertical axis. Figs. 1 and 2 illustrate two models due to Pénaud, constructed in the early '70s of last century; in the first of these the motive power is obtained from a screw driven by the torsion of an india rubber cord; in the second an attempt is made to imitate the action of a bird's wings. Stringfellow in 1842 had already constructed a model in which the supporting force was obtained from the wings while the motive power came from a screw, and from that time on some of the fundamental principles underlying flight began to be more generally recognized.

Principles of Flight.—A bird's wings have two functions to perform: they support the body in the air and they provide the

to the article on FLIGHT, NATURAL. It would appear that support is given by the portions of the wing nearer the body, while the propulsive power comes from the more rapidly moving tips.

Imagine a Bat surface in the form of a long rectangle, with its long edge horizontal and its surface inclined downwards from front to back, to be moved forward in a horizontal direction at right angles to its length. The pressure of the air on the under surface exceeds that on the upper; the plane thus experiences a force directed upwards and backwards. This can be resolved into one force, the "lift," acting vertically upwards, in a direction, that is, opposite to the weight of the plane, and into one directed backwards, the "drag," tending to stop the motion.

Measurement would show that approximately these forces are proportionate to the area of the plane and the square of the speed with which it is moved.

Now support on the plane an engine driving a screw propeller. If the motion thus produced be sufficiently rapid, the lift will exceed the weight of plane and engine, and, omitting for the moment considerations of balance, the plane will fly.

Early Mechanical Machines.—It was on principles such as

the first machine was first shown by Sir George Cayley in 1842 and Crystal Palace a model for which he received a prize of £100. Langley, of the Smithsonian institute of Washington, worked on similar lines. It had been realized by this time that greater lifting power could be obtained by shaping the supporting surfaces correctly, i.e., by giving them a convex shape on the upper side and a concave on the lower. A steam-driven model flew, in 1896, for a distance of about 4m. along the Potomac river near Washington. At a later date, Langley built a large machine which was intended for passengers. It was fitted with a remarkably light steam engine designed by Manley and driven by two propellers; this was launched into the air from a vessel in the river. On each of the two occasions in 1903 on which it was tried, something went wrong with the launching arrangements and the machine was wrecked. Another early machine was that of Sir Hiram Maxim; this too was damaged in a trial in 1894.

Gliders.—Meanwhile, it had been realized that before success was reached more knowledge as to the conditions of balance in the air was necessary and, further, that much could be learned by the aid of gliders depending for their support on natural air currents.

The experimenters, suspended from their wings, jumped from natural or artificial heights and allowed the wind to carry them through the air. Lilienthal in Germany, who first showed the advantage of curved over flat surfaces, was killed after making over 2,000 safe flights; he endeavoured in these to maintain his balance by shifting his position relative to the wings. Chanute, in America, made the surfaces of the aeroplane movable; he constructed a number of machines.

The Modern Era.—Wilbur and Orville Wright, of Dayton in Ohio, began their epoch-making work in 1900 with gliders. They introduced two great improvements: the elevator, or horizontal rudder for steering the machine in the vertical plane, which they placed in front of the main planes (in nearly all modern machines it is attached to the tail); and the flexing of the rear edge of the main planes so as to vary the lift on either or both at will and thus maintain the balance in the air. A petrol motor driving a screw was added in 1903. In 1905 they made 45 flights, in the longest of which they remained in the air for half an hour and travelled 24½ miles. A little later, 1906, Santos-Dumont constructed a machine in which he flew a distance of about 250yd. in 21 seconds.

In 1908, Henry Farman, at Issy-les-Molineaux, made a circular flight of 1km. and on Sept. 29 he covered 24½m. in 42min. Meanwhile the Wrights had continued their work at Dayton. On Sept. 12, 1908, Orville made a flight of 45m. in 1hr. 14½min.; but a few days later he had an accident in which he was seriously injured and his passenger was killed. Wilbur Wright, on Sept. 21, 1908, at Le Mans, beat all previous records by a flight of 56m.

in 1hr. 31min. 25 $\frac{1}{2}$ sec. On Dec. 31 he remained in the air for 2hr. 20min. 23sec.

These great advances had been rendered possible by the improvement of the petrol engine.

In 1909, a number of notable flights were made, several of them in monoplanes. On July 25 Bleriot crossed the Channel from Calais to Dover, and later Latham nearly achieved the same feat.

In November, Farman covered a distance of about 134 $\frac{1}{4}$ m. in 4hr. 17min. 53sec.

Next year Paulhan, at Los Angeles, in a biplane, reached a height of 1,383yd. and on April 27–28, 1910, the same pilot won the Daily *Mail* prize of £10,000 by flying within 24 hours from London to Manchester with one stop.

Table I., printed herewith, gives some details, approximately correct, of the principal experiments made with flying machines from 1879 to Wilbur Wright's flight in France.

Since that day the advance has been enormous. In place of the toy models of Henson and Stringfellow we have machines weighing as much as 60 tons and with wing spans up to 140 feet. Even these giants can reach speeds of 200 m.p.h. Small modern pursuit planes fly at 400 m.p.h. Engines have been developed with outputs of more than 2,000 h.p.

For details of modern aircraft see Table II on page 243.

See also TRANS-OCEANIC AND TRANS-CONTINENTAL FLIGHTS.

THE SCIENCE OF AERONAUTICS

The year 1909 opened a new era in the history of aeronautics. Towards the end of 1908, the Wrights had made their flights. The value of the aeroplane as a weapon became obvious; how valuable, it was left for the World War to show. Little was known of the forces affecting aircraft in motion; of the laws regulating the flow of air in their neighbourhood; the conditions required for balance and safety; the relation between the form and dimensions of the supporting planes and the weight carried; or the mechanism necessary for the control of the machine in flight.

The internal combustion engine had made flight possible, but the way to combine efficiency and lightness was but vaguely understood. The propeller brought problems of its own; naval architects had made a study of the action of the screw in a ship; to what extent did the conclusions they had reached apply to an airscrew? It was clear that there was much to learn and many directions in which research and experiment, conducted under proper supervision, could help.

Experiments in aerodynamics had been made by Langley in 1891. Zahm at a later date (1902–03) had measured the air velocity, pressure and friction on surfaces of various forms. Stanton, at the national physical laboratory, had experimented on the resistance of surfaces in a current of air and the pressure of the wind on plates. Lanchester, in his *Aerodynamics*, had described similar measurements. Lord Rayleigh, in various papers of great importance dating from 1876, had discussed questions of the resistance of fluids and, in 1899, contributed to the *Manchester Memoirs* a paper on the mechanical principles of flight; but no organized attack on the questions raised by the flight of a body heavier than air had been made.

Abroad, the airship had attracted more interest. In 1906 the society for the study of airships was formed in Germany, divided into branches dealing respectively with meteorology, dynamics, construction and engineering. Their first report, March 1907, describes in full detail programmes of the work proposed in these various branches; specially interesting is the account it gives of the method of testing resistance to the motion of an airship by means of a model in a wind tunnel and other proposals by Prof. Prandtl for testing model airships by means of towing by automobile.

Advisory Committees for Aeronautics. — Early in 1909, R. B. (later Lord) Haldane suggested that a section devoted to research in aeronautics might be established at the national physical laboratory. In May of that year the prime minister, H. H. Asquith, announced that this had been done and that, for the superintendence of the investigations and to advise on scien-

tific problems arising in connection with the work, he had appointed a special committee—the advisory committee for aeronautics.

Meanwhile, work of a similar character was in progress elsewhere: at Gottingen, under Prandtl; at Koutchino in Russia, where Riabouchinsky was director; at a somewhat later date in America under the national advisory committee for aeronautics; and in Italy by Crocco; while papers on stability had been published by B. F. Lanchester and Soreau.

Aerodynamics. — In studying the forces to which aircraft are subject in flight, mathematics alone are of but little help; the dynamics of the air are too complex for a complete theory, and recourse must be had to experiment.

In the case of a body heavier than air an upward force, or lift, must be provided which, when the motion is horizontal, will just balance the weight. As the aircraft moves forward various actions produce a resistance to its motion, and unless a force is provided to balance that resistance, the drag on the machine, it will come to rest; the mechanism must provide a propelling force which for uniform speed must just balance the drag.

Now we have seen already that when a flat surface inclined at a small angle to the direction of motion is moved forward through the air it experiences a resistance—drag—opposing the motion and a force—the lift—at right angles to that motion.

To carry a given weight how large must this surface be, at what speed must it move and at what angle to the direction of motion should it be placed? What will be the resistance to its motion and what horse power must be supplied? What is the best form of surface for the purpose both in section and in plan? How must matters be arranged so as to secure controllability and reasonable safety to the flyer? Such were some of the questions to be answered.

Since 1909, many, perhaps all, of these and similar questions have been answered in part by observation and experiment on full scale machines, in part by the use of suitable models in a wind tunnel.

The Wind Tunnel. — W. Froude had shown that by towing the model of a ship in a tank and measuring the force required to tow it, the resistance to the motion of the ship at sea and the horse power required to propel it could be calculated.

In tank experiments the model is towed through water, but the problem is one of relative motion. If it were possible to obtain

a steady stream of water free from eddies and turbulence, the model might be stationary and the water stream past it. This was the method adopted by those investigating the pressure of moving air on surfaces exposed to its action. Arrangements were devised to produce a steady flow of air through a closed channel and measure its speed. The model was placed in this stream and attached to a balance specially designed to measure the forces acting on it.

Imagine the air stream in the tunnel to be horizontal, and take as an example a narrow rectangular plate placed with its longer edge horizontal and at right angles to the direction of the wind and its plane inclined at a definite angle to the same. This angle is known as the angle of attack. The balance is such that the horizontal force or drag, the vertical force or lift at right angles to the wind direction, and the couple tending to turn the model about an axis parallel to its length can all be measured. The last observation enables the position of the centre of pressure, or point in which the resultant of the wind forces intersects the model, to be determined.

In fig. 3, ACB represents a section of the model by a vertical plane through the wind direction. C is the centre of pressure through which acts the resultant force; the balance measures its components, the lift, the drag, and also the couple tending to rotate the model about an axis perpendicular to the paper through some point depending on the attachment to the balance.

FIG. 3.—DIAGRAM SHOWING RESULTANT OF LIFT AND DRAG ON A RECTANGULAR SURFACE

Details of the various forms of wind tunnel in use and of the balances and their method of attachment to the model will be found in the article on AERODYNAMICS, to which reference should be made.

It is found that, so long as the angle of attack remains the same, the lift, the drag and the couple are approximately proportional to the product of the density of the air, the square of the speed and the area of the surface on which it acts; so we may write

$$L = K_L \rho S V^2$$

$$D = K_D \rho S V^2$$

$$M = K_M \rho S V^2$$

where M represents the couple; the coefficients K_L , K_D , K_M are constant so long as α the angle of attack is not varied; ρ is the air density, S the area of the plane and V the air speed.

The three coefficients depend on the angle of attack; by making observations at various inclinations of the surface to the wind we can draw a curve for each of the quantities L , D , M and thus read off their values at any angle of attack.

Scale Effect.—But this is for the model. How can we step from it to the actual machine? Froude had shown that for a ship there was a definite relation depending on the size and speed of model and ship. Lord Rayleigh investigated the condition, which must hold in order that the motion of the air round the model should be similar to that near the machine. He found that, assuming the medium in which the motion takes place to be identically the same in both cases, the condition was expressed by the statement that vl should be the same for model and machine, v being the speed and l some length determining the scale in each case. Now, clearly this condition cannot be satisfied; for both the speed and size of the model are necessarily less than those of the machine itself. Experiment, however, has shown that in many cases it is not necessary to fulfil the strict condition; we may apply the equations already given to the machine using the value of the coefficients, K_L , etc., found from

while in fig. 5 are shown some wing sections. In addition to the lift and drag curves, the ratio of lift to the drag is also plotted and it will be noted that this has a minimum value for a low angle of incidence and increases somewhat rapidly with the incidence. The lift, it is true, increases up to a certain value as

FIG. 5.—TYPICAL WING SECTIONS
(1) R.A.F. 15. (2) R.A.F. 32

the angle of attack is increased; but the drag increases more rapidly. Thus, while a much greater lift is obtained by increasing the angle of the planes to the horizontal the thrust given by the airscrew necessary to do this increases in a much more rapid ratio.

Stalling.—The curves for different shaped wings are different and, while we may note that increasing the camber of the upper surface within limits increases the lift, reference for the detailed effect of the shape of the section on the properties of the wing must be made to the article AERODYNAMICS. All curves of the lift have one property in common. As the angle of attack increases still further the lift suddenly falls; the aeroplane can no longer fly; its power to carry its load has gone and it must fall; it is said to be stalled. If the engine power be sufficient to maintain the speed, then by increasing the angle of attack at which the machine is flown the weight carried can be increased, or alternatively, if the load remain the same while the angle is increased, the speed can be reduced until at last a limit is reached, the stalling angle is exceeded and the machine, becoming uncontrollable, nose dives and spins to the ground.

A very large proportion of the accidents which occur arise from this; it may be an engine failure or a lapse on the part of the pilot causing him to attempt a turn when going at too slow a speed; the machine is stalled at too low an altitude and falls; before control can be regained it strikes the ground and is wrecked.

Wind Tunnel Results.—For a full discussion of the equations giving the lift and drag and the consequences to be deduced from them—reference must be made to AERODYNAMICS. A few of the more obvious consequences may be mentioned here.

Besides its wings, an aeroplane has a tail and elevator, a body fitted with a fin and rudder, an engine and airscrew, with tanks for petrol and oil; all of these contribute to the drag and some to a small extent to the lift, but neglecting these, let us see what conclusions we can draw directly from the equations.

When an aeroplane is flying horizontally at uniform speed the total lift will just balance the weight W . The lift is mostly carried by the wings; so neglecting for the present the effect of the tail and body we have the result that the weight carried is found by multiplying together the lift coefficient, the density of the air, the area of the wing and the square of the speed.

The loading, the average weight carried by each unit of area of the wings, will be given by dividing this quantity by the area of the wings.

Again, the conditions which must be satisfied if the machine is to climb well can be worked out, and we see how experiments in the wind tunnel can be utilized to predict the performance of the machine.

Conditions for Stalling.—Before passing on to consider other problems, it will be useful to look a little further into the question of stalling. Observations in the wind tunnel made by the aid of smoke or in a water channel show that for a wing of good shape, flying at a small or moderate angle of incidence, the motion of the air is approximately stream line; it flows smoothly past the wing, there is very little eddying or turbulence. As the incidence is increased the eddies formed behind the wing increase also and for a time the lift and drag increase until a condition of affairs is reached in which there is little or no semblance of stream line motion; the wake behind the wing is a mass of turbulent eddies; the drag is very large while the lift falls and is quite uncertain as to its value.

The changes outlined are illustrated by the figures 6 and 7. The figures show too why the drag increases as the incidence

FIG. 4.—CHART OF LIFT COEFFICIENT SHOWING IN ADDITION TO THE LIFT AND DRAG CURVE, THE RATIO OF THE LIFT TO THE DRAG

the model experiments. With the need for higher accuracy the investigation of scale effect has become of great importance, and reference should be made to the article AERODYNAMICS.

Lift and Drag.—The curves for lift and drag depend on the form of the aerofoil under test. For a given incidence the value of K_L , the lift coefficient, will be much less for a plane surface than for a wing of good form. Fig. 4 gives the curves for a wing,

becomes larger. It is known that in a frictionless fluid, and air is nearly frictionless, there would be no resistance to the motion of a smooth stream-lined body, a body that is, round which the air would flow in stream lines without eddies; that in any actual case there is some small resistance is due to the slight friction between the body and the air; but when the motion becomes turbulent, energy is necessary to support the turbulence and some of the power required to propel the body is used in supplying this energy; the drag on the body is increased and more power is needed to maintain the speed.

Stability.— Before turning to this section of our subject it is necessary to consider what is meant by stability.

A pendulum, such as a ball hung by a string, or a rod balanced

vertically on a finger, when at rest, are both in equilibrium. So long as they are undisturbed the rod and the string both remain vertical, but the effect of a slight disturbance differs in the two cases; if the pendulum

be disturbed it oscillates about its equilibrium position for a short time, finally coming to rest as before; the rod when disturbed falls to the ground unless by skilful movements of the finger it is possible to restore the balance.

The pendulum exemplifies a case of stable equilibrium, the rod of unstable; similar considerations apply to a body in a state of steady motion, an aeroplane (say) moving horizontally with constant speed. Imagine that by some means—a sudden downward gust for example—the motion is slightly disturbed and the nose takes a downward direction. Suppose too that the pilot does nothing to counteract this, then two things may happen, the nose may rise again—of its own accord as it were—and after a few oscillations up and down the machine may recover its horizontal path. Like the pendulum it is stable, it can be flown without touching the controls, unless of course the initial disturbance is too violent. When the engine has once been adjusted to give the power necessary to maintain horizontal flight at the specified speed the machine will continue to fly thus of itself. On the other hand, the initial disturbance may increase, the nose may continue to drop, the machine like the rod on the finger is unstable and action is required on the pilot's part in order to recover the steady horizontal flight. It is not possible here to discuss the conditions necessary for stability; it must suffice to state that they require the knowledge of a

IBID
FIG. 7.— EDDIES FORMED IN THE WAKE OF A FLYING WING
The increased angle of incidence of the wing to the air current creates appreciable air eddies

number of quantities known as stability derivatives which can be determined by suitable experiments in an air tunnel.

As to the relative advantages of stability and instability much might be written; stability brings with it consequences which for some purposes are disadvantageous. The machine has, as it were, a will of its own, once set to a certain course it tries to keep to it; it is less easy to manoeuvre, to be deflected by the pilot from its course and forced into the sudden changes of motion and aspect needed, say, for military purposes.

For a fighting machine too great stability is a disadvantage; on the other hand, for a civil machine designed to go from one aerodrome to another at a given speed, stability is a marked advantage; it adds to the safety of the aircraft and it diminishes greatly the strain on the pilot.

Modern Theories.— So far, we have been discussing the elements of aerodynamics and the manner in which wind tunnel experiments may be used to determine, the characteristics of a machine.

Reference must be made to the article on AERODYNAMICS for a description of the various forms of wind tunnel now in use,

and an account of how, following up some very early work by Lanchester the lift and drag of an aeroplane wing have been derived in the first instance by Prandtl and his school at Gottingen, from the fundamental equations giving the circulation set up in the air around the wing and the vortices shed from its tips and trailing edge. Much work on the same lines has been done under research committees working in England and America. Fig. 8 (p. 247) shows a modern wind tunnel developed in Great Britain.

THE AEROPLANE

Fig. 9 on p. 247 gives a diagram of an aeroplane indicating its principal parts and their names.

The main purpose of the various parts is clear from the figure which represents a biplane; the wings support the machine; to secure steady motion in a vertical plane a *tail plane* is necessary, and in order that the motion in that plane may be controllable part of the tail is hinged and can be raised and lowered thus forming the *elevator*.

Steady motion in the horizontal direction calls for a *vertical fin* at some distance behind the main planes and, to control the direction of that motion, a *rudder* is added to guide the machine.

The tail plane and fin are connected to the wings by the *fuselage*, in the fore part of which is the *cockpit* containing the pilot's seat and the controls. A portion of the rear extremity of each wing is hinged about an axis parallel to the length of the wing, thus forming an *aileron*. Lowering an aileron increases the angle of incidence and therefore the lift of that portion of the wing; raising it has the opposite effect. The pilot is thus able to control any rocking of the aeroplane about a longitudinal axis.

Control wires pass from these movable parts to the pilot's seat, those from the rudder going to the *rudder bar* worked by his feet, while those from the elevator are connected to the *control column* or *joy stick*, a rod fixed in front of the pilot by a universal joint at its lower end. The connections are such that the longitudinal motion of the column raises or lowers the elevator while a transverse motion affects the aileron.

In a *tractor machine*, as shown in the drawing, engine and airscrew are in front of the pilot; in a *pusher machine* they would be placed at his back. The planes are connected by *struts*, while rigidity is secured to the structure by a series of wires arranged to keep the two planes in fixed relative position. The *longerons* are the lower main members of the body structure which are prolonged forward so as to support the engine; the machine is carried on the *landing chassis*, an under carriage on wheels fitted with springs so as to absorb shock on landing. At the rear is the *tail skid*, which rests on the ground when taxiing.

The distance between the wings is the *gap*. In many machines the upper wing is not set exactly above the lower but either rather in front when the machine is set to be positively *staggered* or behind when the stagger is negative.

In a *monoplane* there is only one pair of wings.

Details of Structure.— We turn now to the actual design and structure of aircraft, remembering that a fuller account appears in the article AEROPLANE.

For most purposes the design must be such that the aeroplane will fly safely with a minimum expenditure of power. Since the total weight carried is fixed, the structure must be light in order that the useful load, that part of the load not made up of the weight of the machine including the engine, petrol, oil and necessary equipment, may be as large as possible; the machine must be controllable; the stability and manoeuvrability desirable will depend on the purposes for which it is required.

Landing is made more easy if the speed is slow, hence the stalling speed, the minimum speed of flight, should be kept as low as other requirements permit; precaution against fire should be taken, and, for a civil machine, the comfort of the passengers is of great importance; steps have recently been taken to reduce the noise, often most trying to passengers, to about the same as that met with in an express train.

In the earlier machines the main structure was of wood and the wings were covered with linen cloth painted or doped with a kind of varnish to secure stiffness and protect the material.

FIG. 8.—THE 24 FT. WIND TUNNEL AT THE ROYAL AIRCRAFT ESTABLISHMENT. SHOWING AEROPLANE IN POSITION ON MAIN BALANCE

In more modern machines much of the main structure is of metal, while in a few, particularly sea-planes and flying boats, metal in the form of a thin sheet is used for the covering of the wings. The need to combine lightness and strength in aircraft has led to much metallurgical and engineering research, and by the use of new alloys many desirable changes in the structure have become possible.

The functions of the various parts of the machine are discussed in full detail in the article AEROPLANE and their use in controlling the flight at the will of the pilot described.

prevention of **Stalling**.—By these means, so long as the machine has sufficient speed to produce the necessary lift, it is under control: but, if from any cause stalling incidence is passed, the lift is suddenly reduced, controls cease to be fully effective and the machine falls rapidly. If this takes place at a sufficient altitude the pilot may be able to prevent the accident by diving the machine, increasing the speed and bringing the controls into action again or, on the other hand, the machine may develop a spin, which it is difficult to stop, and be wrecked, before the pilot can regain control.

Now we have seen that the stalling speed is inversely propor-

tional to the maximum lift coefficient. By increasing this, we reduce the stalling speed, *i.e.*, we enable the machine to be flown at a speed at which it would otherwise be uncontrollable. Various attempts have been made to put it into the power of the pilot to increase the lift in case of emergency; the *Handley Page* slot is one of these. This consists of a slot or narrow aperture cut in each wing, parallel to its length; the slot is ordinarily closed but the pilot has the means of opening it and thus the lift is increased. In a more recent form, also due to Handley Page, the slot opens automatically when stalling incidence is passed.

The use of the slot alone has certain concurrent disadvantages. These, however, can be overcome by a suitable adjustment of the ailerons, and mechanism has been devised combining the two, so that when the slot is opened the ailerons simultaneously take up the correct position.

Fig. 10 (p. 248) shows a wing fitted with a Handley Page slot.

Loading: Load Factor.—In a modern engineering structure the stresses to which each component member will be subjected can usually be calculated and the necessary strength provided. In an aeroplane the stresses depend on the velocity and acceleration of the machine, its position in the air, the gusts of wind to which it may be subjected, etc. While it is possible to calculate them for steady horizontal flight and for certain other definite conditions of motion, the calculation, which for modern machines is specially complicated, cannot embrace all conditions.

To allow for this a load factor determined as the result of experience is assigned to each member of the structure; the calculated stress, including as usual a factor of safety, is multiplied by the load factor and the result is the stress which the member is designed to bear.

METHODS OF PROPULSION

The failure of the early attempts to fly was due in no small degree to the want of a proper engine; there was little knowledge of the power necessary. Models were devised, worked by india-rubber cords or clockwork, and in 1842 Phillips built a steam-driven model which, according to his account, rose to a great altitude and flew across two fields. Steam was used by Henson (1843), and Stringfellow (1847), who, in 1868, obtained a prize of £100 at an exhibition of the aeronautical society held at the Crystal Palace. The engine was estimated to give $\frac{1}{3}$ horse power.

FIG. 9 —DIAGRAM OF BIPLANE ILLUSTRATING NOMENCLATURE

The weight of the complete model was under 12 lb. and the area of the wings and tail about .36 sq. feet.

The steam engine used by Langley (1903) was remarkable; it was designed by Manley and its weight was extremely small for the horse power produced.

In his earlier model the weight of the engine was 60 oz. and the power developed 1h.p.; the four boilers weighed 7 lb. each.

Maxim, in his experiments of 1894, employed a pair of two-cylinder compound engines, each weighing 600 lb. and giving 363h.p.

The whole problem was changed by the invention of the internal combustion engine burning petrol.

Santos-Dumont employed a light and powerful petrol engine in 1906; about a year later Henry Farman used an eight-cylinder Antoinette petrol motor developing 40h.p. at 1,100 revolutions per minute.

In 1908, Wilbur Wright, in his notable flights in France, employed a four-cylinder petrol engine of 24h.p., making 1,200 revolutions per minute and connected by chain gearing to two wooden propellers which revolved at 450 revolutions per minute. The weight of this motor was stated to be about 200 lb.

Engine Requirements. — From this time onward progress has been rapid and reference should be made to the article on AERO ENGINES for the details. The problem for the designer has been to reduce the ratio of weight to horse power; and this implies not merely a reduction in the weight of the engine itself but also in that of the fuel consumed.

Modern engine weights vary from 100 up to 1,000 or 1,200 pounds and their power from 20 horse power up to 820 horse power, with a weight per horse power of 1.5 pounds, or even distinctly less, and a fuel consumption of under 0.5 pounds per horse power hour.

Again, in the design of an engine, attention must be paid to its head resistance; the aeroplane itself, with its wings, body and under carriage, offers considerable resistance to the motion, and this is increased in a marked degree, unless great care is taken in the design, by the resistance due to the engine itself, placed as it usually is in the extreme front of the machine. In designing a machine it is clearly of great importance to have regard to the engine with which it is to be fitted.

In the endeavour to combine lightness and power many problems await the designer; thermodynamic reasoning shows that the efficiency—the ratio of the energy given to the propeller to the heat, measured as energy, supplied to the engine—increases as the compression in the cylinder is increased, but too great a compression produces detonation—knocking—in the engine, and delicate experiments are required to investigate the cause of this. Much has been accomplished by special distillation of fuels for aeronautical engines and the use of chemicals, especially tetra-ethyl lead, to produce a fuel in which this tendency to detonate is reduced to a minimum. As a result higher compressions are practical and outputs per unit of cylinder volume have been increased.

Another difficulty arises from the high temperatures involved. A material is needed which will combine strength and the power to resist great heat, especially in the moving parts, the valves and valve spindles exposed to the outrush of the exhaust gases. Some of this difficulty may be met by sleeve valve construction.

The sparking plugs, again, are a source of difficulty; every motorist knows of the trouble caused from time to time by a faulty plug. In a modern high-power aero engine the troubles are multiplied many times, and much care and thought are being spent in devising improvements.

Petrol is a source of danger, and for airships especially the use of a high compression engine of the Diesel type would have marked advantages. Such an engine, if light enough, would also be of undoubted value in an aeroplane.

Power and Height. — The energy fed into an engine comes from the combustion of the oxygen drawn into the cylinder at each alternate stroke of the piston, and the volume drawn in is the same whether the engine be on the ground or at an altitude. But the air density falls as the machine rises. The quantity of oxygen ready for burning in each stroke is thus reduced and the power of the engine falls off. The exact proportion in which this occurs varies with different engines, but approximately the power is proportional to the density of the air drawn into the cylinder.

Supercharging. — To remedy this a device is added in certain cases whereby the density of the air supplied is maintained constant; this takes the form of a blower or pump which forces into the cylinder more air than would normally be drawn in; the engine is said to be supercharged.

Carburation. — The petrol is supplied to the engine through the carburettor and the amount of petrol needed for most efficient working depends on the amount of air drawn in; the ratio of petrol to air should remain constant. Thus, as the machine rises and the air density falls, it is desirable to reduce the supply of petrol proportionately. Various devices have been developed to do this automatically and many engines in transport service are now equipped with such "automatic mixture control."

Engine Instruments. — As engines grow steadily more complex and are with increasing frequency mounted in wings or outboard nacelles, more instruments of high sensitivity are required to indicate to the pilot the exact performance of each powerplant. Upon his instrument board, the pilot of a transport plane now must have an indication of each engine's speed and manifold pressure, temperature indications from several different critical points, the amount of fuel available and, for long flights, the rate at which each engine is consuming fuel.

Modern Engines. — The article AERO ENGINES indicates how these numerous requirements are being met. Aero engines fall into two main classes: (1) water-cooled and (2) air-cooled; in the one the cylinders are cooled as in an ordinary motor car engine by water which circulates round their jackets and is itself cooled by passing through the radiator, placed usually in the extreme front of the machine, but in the case of modern extra high speed aircraft in the wings. For an air-cooled engine, the outside of each cylinder is fitted with a number of webs or flanges, thus increasing the cooling surface, and the engine itself, placed so as to catch the full draught of air, is fitted with NACA cowls or Townend rings to reduce the resistance. The air-cooled engine again falls into two classes; in the one the cylinders are fixed, the motion is conveyed to the airscrew by the shaft; in the other the cylinders rotate about a fixed shaft and carry the propeller round. Details as to a few typical engines are given in Table III.

THE AIRSCREW OR PROPELLER

The use of a screw as an instrument of propulsion has long been familiar, and various theories have been proposed to account for its action.

The earliest of these, due originally to Froude and Rankine, is known as the momentum theory; the screw is regarded as a disk which in some way imparts momentum to the column of fluid which passes through it.

Imagine the machine to be at rest and the air where uninfluenced by the screw to be approaching it with velocity V .

In reality, of course, the air is at rest, and the machine moves forward with velocity V_1 but the forces brought into play are identical in the two cases. The velocity of the column of air which passes through the airscrew disk—the area of the circle swept out by its blades—is increased according to Froude by an amount v so that the column leaves the screw with a velocity $V+v$. It follows as a further consequence of the theory that half the additional velocity is acquired before the screw is reached. So that the velocity with which the air arrives at the screw is $V+\frac{1}{2}v$.

Thus we have a column of air of density ρ and area of cross section A approaching the screw with speed $(V+\frac{1}{2}v)$ and the mass which traverses the disk in 1 sec. will thus be $A\rho(V+\frac{1}{2}v)$. This mass gains a velocity v , and the momentum generated in one second is $A\rho(V+\frac{1}{2}v)v$. This must be the force exerted by the

screw on the air and therefore the thrust or force driving the screw through the air.

The Aerofoil Theory.—A more modern theory regards the action of a screw as an aerofoil or aeroplane wing in rapid rotation about one end. An aerofoil moving forward in a straight line at right angles to its length experiences a lift perpendicular to the direction of motion and a drag opposing the motion.

Imagine now that the aerofoil, instead of moving uniformly forward, is spinning about one end round an axis parallel to the direction of lift, a similar result will follow, each section perpendicular to the length of the aerofoil is moving forwards, though with a velocity which varies as its distance from the axis; each section therefore experiences a "lift" parallel to the axis and a "drag" acting so as to check the motion of rotation.

The lifts combine to produce a resultant thrust on the aerofoil in the direction of the axis, the drags to form a torque about the same. To maintain the motion a torque must be applied sufficient to overcome the drag and the action of the aerofoil transforms the torque into a thrust on the air. We have an elementary screw.

In order that the thrust may act along the axis and not at a point on the aerofoil which changes its position as the blade rotates, a second aerofoil is added on the other side of the axis and with its front edge pointing in the opposite direction to that of the first.

Again, if the blade were of the same section from root to tip, since the tip is moving very much faster than the root, the thrust on an element at the tip would greatly exceed that near the root. To obtain a more uniform grading of the thrust the shape of the blade is altered as we pass from root to tip in such a way that the angle of attack, the angle between the blade and the direction of motion relative to the air, is greater at the root than the tip and thus we arrive at the two-bladed screws in common use.

Reference has been made in the section dealing with aerodynamics to the vortex theory of the aerofoil; this theory has been applied by Glauert to the action of the airscrew with results which explain most of the outstanding difficulties of the earlier theories.

Airscrew Efficiency.—The above account will serve to show in a general way how the energy supplied by the rotation of the engine is transformed into that required to drive the aircraft; by the efficiency of the screw we mean the ratio of the power developed as thrust to the horse power delivered by the engine.

FIG. 11.—AIR SCREW OR PROPELLER

To utilize the power of the engine to the greatest advantage the pitch of the airscrew employed should change with changes in the speed of the machine; for if an airscrew be designed to be most efficient when the engine is running at its normal rate, and the machine flying at full speed, it follows both from theory and experiment that when stationary on the ground the rate of rotation is very appreciably less than that required for efficiency under these conditions and the airscrew is not giving its full thrust; it is therefore advantageous to vary the pitch of the screw so as to permit the engine to exert full power on the ground as well as in flight at various altitudes; almost all modern transport and military planes are consequently equipped with "adjustable pitch" airscrews. Formerly, almost all airscrews were made of hard wood. Now blades of duralumin or steel are almost invariably used with engines of more than 200 h.p.

NAVIGATION AND INSTRUMENTS

The pilot has to find his way in the air as well as control his machine, and for this, like the sailor, he needs special instruments. These are fixed to the dash board of his cockpit.

Here it must suffice to refer to the more important of these, but before doing this, a difficulty peculiar to flight when the horizon is invisible and the ground cannot be seen, must be noted.

Finding the Vertical.—The pilot, then, has no means of determining the vertical or of knowing for certain whether he is flying straight or in a curve. When the machine is at rest on the ground the bubble of the level fixed in the machine at right angles to its length occupies its central position or a pendulum, a heavy bob suspended from some point in the machine hangs vertically. The same is true if the machine is moving horizontally at uniform speed. Again, if the machine still moving in the same way rolls over to one side the pendulum swings to that side and the pilot can correct the list by the proper use of his controls.

But suppose the machine begins to turn in a horizontal plane (say) to the left. The pendulum bob swings outwards to the right until the direction of the string lies along the resultant of the weight and the centrifugal force now acting on the bob. The pilot, ignorant of the change to curved motion, alters his controls to bring the bob back to its central position, thinking thereby to put the machine on even keel. Instead of this, however, he has merely given the machine the "bank" appropriate to the curve in which he has commenced to fly and proceeds to describe a circle.

Turn Indicator.—To avoid this difficulty an instrument known as a turn indicator has been devised, and this warns the pilot when his machine begins to deviate from its straight course. By the aid of a compass and a turn indicator he can maintain his direction.

Compass, Altimeter, Speedometer and Gauges.—The compass has its own difficulties and for a discussion of these reference must be made to the article on AERIAL NAVIGATION.

To know his height or to fly at constant height the pilot uses an altimeter, a form of aneroid barometer specially designed and corrected for his use (see ALTIMETER).

The speed is given by the speedometer, which acts on the principle that the pressure on a surface opposed to wind of velocity V exceeds by $\frac{1}{2}\rho V^2$ that on a surface tangential to the direction of motion. A rotation counter registers the engine revolutions, while there are gauges to indicate the quantity of petrol in the tanks and the temperature of the water in the radiator system.

Sextant: Wireless.—To determine his latitude and longitude when over an unknown country or at sea he must use a sextant and a chronometer. The horizon is often invisible; this and the unsteady movements of the machine make the use of an ordinary sextant difficult, and the R.A.F. bubble sextant has been devised to overcome these.

Wireless telegraphy enables the pilot to fix his position, to fly blind between stations, and to land, using wireless direction finding and marker beacons.

Instruments for Research.—For research work, the measurement of the forces on the various parts of an aircraft in flight due to the pressure of the air and to its rapid changes of motion, many most valuable recording instruments have been devised, some of which will be found described in the appropriate sections.

Seaplanes and Flying Boats.—For seaplanes and flying boats see SEAPLANE.

The Hump Speed.—As the speed increases from rest when starting, the resistance on the hull increases rapidly until a certain speed known as the hump speed is attained. When this is passed there is a marked drop in the resistance and the machine rises and planes or skims over the surface, the speed increases until the lift on the wings is sufficient to carry the weight, and the aircraft rises from the water and continues its flight through the air. The determination of this *hump* speed and the proper adjustment of airscrew and engine to attain a full efficiency at this speed constitute a serious problem for the designer. Much work has been done in the William Froude tank at Teddington on seaplane problems, the conditions of stability, the form of float or boats, the hump speed for various designs, the strength obtained by the different methods of construction and other matters. In a new tank at Farnborough a number of important problems were in 1935 under investigation. Observations in the wind tunnels have been of great value in reducing the air resistance. The high speed attained in the Schneider trophy race of 1929 was due to changes in shape made in consequence of such experiments. (See TRANSPORT BY AIR.) (R. T. GL.; X.)

AEROPLANE. The main problem that confronts the designer of any means of transport is to find a working compromise between the various demands of those who maintain and use the service. There is no conflict between the interests of the operator and those of the user. Their common requirements are safety, speed, comfort and adherence to a published time-table. While it cannot as yet be maintained that air transport is as safe, or as reliable as other comparable methods, it is rapidly reaching that goal. As regards both safety and reliability, recent improvements in radio, the establishment of radio beacons, the installation of de-icing apparatus, tremendous forward strides in instruments and aeroplanes, and improvements in operating facilities have had great effects.

The cost of air transport is comparatively high and it is in terms of cost only that all the four requirements mentioned above can be expressed. That the slight extra cost, however, is balanced by time saving and ease of travel, is being demonstrated by the ever increasing passenger traffic.

For reasons which are explained in the article AERODYNAMICS a normal aeroplane cannot be maintained in flight at a speed less than a certain minimum "stalling" speed, which for a modern commercial aeroplane varies between 40 and 80 miles per hour. On the other hand, it is possible to give it enough engine power to drive it at between 90 and 250 m.p.h., while leaving a margin of some 20% of its total weight for passengers or goods. The aeroplane's permanent way, the air, is the only medium of transport which connects without interruption all places on the globe. It

may be anticipated that the consequent possibility of transit free from the necessity of making transfers may prove to be as valuable as the speed which can be maintained.

From the point of view of DESIGN, with which this article deals, safety is discussed below, comfort is comparable to that of other types of travel and in the opinion of many air travel furnishes superior comfort; and reliability (in so far as it depends on design) presents no special problems.

In what follows we shall discuss (1) the Minimum Speed of Flight and its influence on the design of aeroplanes; (2) The

FIG. 1.—DIAGRAM SHOWING HOW THE WING LOADING, IN POUNDS PER SQUARE FOOT, VARIES WITH THE LIFT COEFFICIENT AND THE SPEED

Power Required for Flight, including both that necessary to drive the aircraft through the air and also—the unique feature of transport by aircraft heavier-than-air—that expended in sustaining it in flight; (3) The possibilities of Improvement of Performance by reduction of resistance; (4) the *Origin* of Aerodynamic data of Design; (5) the Distribution of Weight among the component parts; (6) the *External Form* of Aeroplanes, commenting on the most conspicuous features of modern aircraft; (7) Stability and Control and their influence on (8) the Safety of Air Travel; concluding with notes on (9) Structural Design and (10) Materials used in Construction.

1. MINIMUM SPEED OF FLIGHT

It is the impossibility of steady flight below the stalling speed that constitutes the chief danger of air travel. Many attempts have been made to avoid this source of danger by devising an aeroplane which would be capable, as a whole, of remaining stationary in the air. Such machines have generally employed either flapping or rotating wings, the so-called ORNITHOPTERS and HELICOPTERS. The former have shared the legendary fate of Icarus. The latter have been recently proven possible of construction and flight. However, their reliability and practicability are still to be proven. See GYROPLANE.

There is no fundamental obstacle to reducing the minimum speed of a normal aeroplane to some 25 m.p.h., instead of the 40 to 80 m.p.h. quoted above as typical of modern practice. In fact the earliest flying machine had minimum speeds of this order. But the general proportions of such a machine would be uneconomical from every other point of view. In particular almost the whole of the available weight would be absorbed by the structure and power plant, leaving no margin for paying load.

The relation between the total weight (W lb.), the area of the wing (S sq. ft.) and the aerodynamic coefficient (k) which determines their lift at any given speed (V ft./sec.) (see AERODYNAMICS) is

$$W = k_L \rho S V^2,$$

being the density of the air.

This may be put, for average ground level density, in the form

$$V = 14 \sqrt{\frac{W}{k_L}} \text{ miles per hour}$$

where $w = W/S$ and is called the wing loading, in pounds per square foot. Fig. 1 shows the possible combinations of w and k , which will give any selected speed. Fig. 2 shows the cross section by a vertical plane parallel to the direction of flight of some modern wing sections. For these the maximum value of k_L (which in virtue of the above relation corresponds to the minimum flying speed) is between 0.55 and 0.65, represented by the shaded band in fig. 1. Modern commercial aircraft using such wings have loadings between 9 and 20 lb. per square foot. A reduction in the stalling speed can be made only by reducing the wing loading or by using a shape of wing section which will give a higher maximum value of k_L . The former course leads to a reduction in the paying load. Much attention has therefore been devoted to the latter method.

A most effective high lift wing section is the "slotted" wing of F. Handley Page (fig. 3). With this the maximum lift coefficient can be increased some 50% or more. The action of the device is, broadly speaking, to cause the flow characteristic of stalling (see AERODYNAMICS) to occur at a larger angle of incidence. The increase in lift is dependent on the relative position of the main and auxiliary wings, *i.e.*, on the size and shape of the slot between them, which can be varied in flight. With the slot closed the characteristics are nearly the same as those of a normal wing. In this respect form a (fig. 3) is superior to form b, but in practice there are, with both, constructional difficulties in the way of ensuring a smooth and unbroken surface when the slot is closed.

Another method which has been widely used, is to vary the curvature, or "camber," of the wing (fig. 4). In general, the greater the curvature of a wing section the higher is the maximum lift, but the lower the efficiency at high speeds. This device attempts to secure both high lift and high efficiency by enabling the pilot to alter the curvature to suit the conditions of flight. The increase of lift attainable in this way is much less than can be achieved with a slot, the maximum being about 10%. An automatic form of this device has also been used, the trailing flap being held down by elastic cord and therefore rising as the air pressure increases, *i.e.*, as the speed increases. By combining both these methods very high maximum lifts have been obtained.

A variation of the system of changing the camber is the use of flaps. Their use is now standard on the majority of airliners, having been necessitated by the greatly increased speeds. The increase in high speed and in cruising speed has inevitably increased the stalling speed and thus the landing speed. The employment of flaps has kept the landing speed at a practical figure. The use of flaps on the take-off also increases the lift and makes shorter take-off possible at the expense of speed. They are constructed by hinging the under surface of the trailing edge of the wing in such a manner that the trailing edge may be opened by forcing down the under surface by a system of control from the pilot's seat for landings and take-offs. Flaps have now been developed of several types. Those which have thus far proved most practical increase the lift at stalling speed by about 25%.

2. POWER REQUIRED FOR FLIGHT

When an aeroplane of conventional design and normal proportions is flying horizontally (in air of a given density) the power

Angle of the chord to the longitudinal axis of the aeroplane. The chord of the wing sections in fig. 2 is indicated by a straight line.

FIG. 2.—CROSS SECTIONS OF RECENT TYPES OF AEROPLANE WINGS

FIG. 3.—CROSS SECTION OF THE HANDLEY PAGE SLOTTED WING. WITH IT THE MAXIMUM LIFT COEFFICIENT CAN BE INCREASED SOME 50% OR MORE

FIG. 4.—METHOD OF VARYING THE CURVATURE OF THE WING. IN GENERAL, THE GREATER THE CURVATURE THE HIGHER IS THE MAXIMUM LIFT

of the engine is disposed of in the following ways:

(a) About 25% is lost owing to the inefficiency of the airscrew.

(b) From 30% to 45% is used in overcoming the resistance of the air to the passage of the body, including the engine itself, the undercarriage and the exposed part of the wing structure, etc.

(c) From 45% to 30% is similarly absorbed by the resistance of the wings.

The choice between the alternative figures in (b) and (c) depends on the speed of flight, the former corresponding to low, and the latter to high speeds. The resistance of the parts included in (a) varies practically as the square of the speed of flight, and the corresponding power therefore as the cube. The resistance of the wings (c) may be further subdivided as follows:

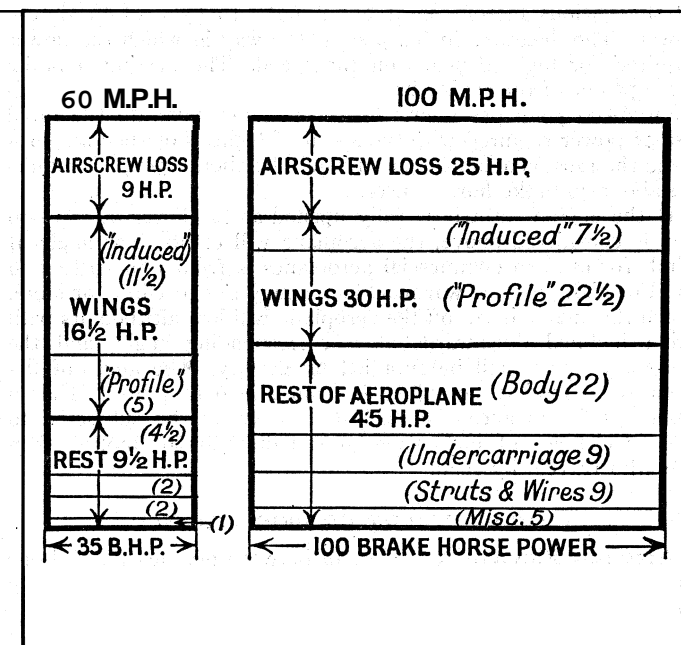

FIG. 5.—DIAGRAM SHOWING HOW THE POWER REQUIRED VARIES WITH THE SPEED AND THE PROPORTIONS IN WHICH IT IS ABSORBED BY THE LOSS IN THE AIR SCREW AND BY THE RESISTANCE OF THE VARIOUS PARTS OF THE AEROPLANE

(c. 1) From a third to three-quarters is due to the equivalent of friction of the air on the surface of the wings (the profile drag). This varies as the square of the speed, and the power as the cube. If the area of the wing is changed, the profile drag changes in proportion. Each wing section has a typical coefficient of profile drag, and, apart from maximum lift, this is in fact nearly all that distinguishes one section from another.

(c. 2) From two-thirds to a quarter is due directly to the action of the wings as generators of a lifting force (the induced drag of Prandtl; see AERODYNAMICS). This varies inversely as the square of the speed, and the power therefore inversely as the speed. It does not depend on the shape of the wing section, or on the area of the wings, but (for a given lifting force, *i.e.*, weight) only on their overall width or span, being inversely proportional to the square of the span. This induced resistance is the essential feature in which transport by aircraft heavier than air differs from all other methods, for in no other is it necessary to expend energy in order to sustain the vehicle. About 8% of the fuel used by a normal aeroplane is used in this way (fig. 5).

This division of the resistance of the wings into two parts—one of which increases with the speed of flight, while the other decreases, the former dependent (broadly speaking) only on the section and shape of the wings, the latter independent of these factors and governed by the extent to which the span of the wings allows the aeroplane to "grip" the air (see AIRSCREW)—was originally suggested by F. W. Lanchester. It lay dormant for some years, largely because there was not forthcoming any adequate theory by means of which it would be given quantitative

expression in terms of the dimensions of the wings. This expression has been rendered possible by the work of L. Prandtl of Gottingen and his collaborators, with great advantage to the technique of aeroplane design. Its chief merit is that it enables a designer to examine the economics of wing proportions without continual resort to model experiments. It has been abundantly verified by comparison with experiments.

In normal flying conditions, as opposed to the special conditions characteristic of arising from and alighting on the ground, the speed of an aeroplane may vary from 1.2 to 3.5 times its stalling speed. The upper of these two figures can be raised by the provision of more power. At its top speed the engine is working at its full power, which is not an economical condition from the point of view either of the life of the engine or of fuel consumed per ton-mile. The most economical speed, taking into consideration all the various factors, is at about 60% to 75% of maximum power. The diagrams in fig. 5 show the way in which the power required for flight depends on the speed. The maximum brake horse-power of the engine has been taken to be 100 and the minimum speed 50m. per hour. These diagrams illustrate the rapid rise of power required with the speed of flight. For such an aeroplane the most economical speed would be about 75m.p.h., requiring about 50 brake horse-power.

If the engine throttle is fully opened at the lower of the two speeds considered above, the aeroplane will climb. The angle of climb for modern commercial aeroplanes is from 1 in 10 to 1 in 15. For high-powered war machines it may rise to 1 in 6, or more. When the engine is cut off the aeroplane will lose altitude, its path being inclined downwards at a corresponding angle, and the necessary power will be supplied by gravity. The angle of descent for a modern aeroplane is from 1 in 6 to 1 in 8. Thus a passenger in an aeroplane will not in general be subjected to greater changes of inclination of the direction of motion than one who travels by road.

3. IMPROVEMENT OF PERFORMANCE

Airscrew Efficiency.—A loss of between one quarter and one third of the power of the engine in the transmission assembly would hardly be tolerated in road or rail transport. Transport by water, however, is burdened by a loss identical in character and similar in amount. It arises from the fact that the propulsive force is obtained by driving a fluid backwards. This condition cannot be entirely overcome, but propeller efficiency can be and is being greatly increased. Commercial aeroplanes have an altitude operating range from sealevel to about 15,000 feet. At 15,000 feet the air density is slightly more than half the air density at sealevel. It is obvious that a constant pitch propeller cannot have high efficiency throughout that marked range of air density. If it is designed for high efficiency at the surface, where maximum power is desired for take-off, it will have low efficiency at normal cruising altitudes. To meet the changing densities with changing altitudes, resort has been made to adjustable pitch, controllable pitch, and automatic propellers. The first is adjustable on the surface with motors dead. The second is capable of control by the pilot while in flight. The last is automatic. All these types are at present in use as standard equipment. (See AIRSCREW.)

Resistance of the Body.—The majority of aeroplanes have in the nose of the body an air-cooled engine, or a water-cooled engine with a radiator. With this arrangement the resistance of the body cannot be separated from that which is incurred in cooling the engine. This latter is equivalent to a reduction in the power of the engine of from 15% to 25% at the cruising speed of a normal commercial aeroplane. At higher speeds the loss is greater.

It is natural to try to recover some of this by placing as much as possible of the load carried (fuel, crew, passengers) behind the radiating surfaces. But a large part of the loss remains, because such parts as these could, at least in principle, be placed in a stream-line body of very low resistance. Such bodies would, however, be heavy, and the conventional tractor aeroplane is by no means a bad compromise, especially when an air-cooled engine is used.

When a very high speed is required, as for example in racing

aeroplanes, the cooling resistance can be eliminated by using a water-cooled engine in combination with a radiator whose cooling surface is part of the smooth surface of the wings. Such a radiator has been used in the Schneider Cup and Pulitzer Trophy races. The consensus of the opinion of designers appears to be that it is as yet unsuitable for employment in commercial aeroplanes.

Resistance of the Undercarriage.—The undercarriage of an aeroplane has a high resistance, mainly due to the wheels. This condition has been met in two ways. The wheels and landing gear may be covered with cowling in a streamline shape or the landing gear may be retractable. In the latter case the landing gear is hinged in such a manner as to permit it to fold into the wings, fuselage, or engine nacelles. The retraction is usually activated by hydraulic or electric systems. Both methods of resistance reduction are in current use. The cowling (commonly called "breeches") is more common for small aeroplanes and the retractable gear for large ones.

Resistance of the Bracing of the Wings.—A few years ago the aeroplane was a mass of external struts and bracing with cables between wings, from wings to fuselage and engine bed, and between the various fixed and movable controls. The tendency at present is toward "clean" design. Modern construction methods and materials permit all bracing for monoplanes to be internal. Whereas this requires increase in weight, it is largely balanced by increase in aerodynamic efficiency. All modern high speed transports and military aeroplanes are aerodynamically "clean" and highly streamlined. As speed requirements increase even rivet heads are made flush with the surface.

Super Atmospheric Manifold Pressure.—Of recent years much has been done in the development of superchargers. They were originally designed to avoid power loss with increases in operating altitude. As an unsupercharged engine is taken to high altitudes with consequent decreases in atmospheric pressure, power decreases rapidly. The supercharger increases the manifold pressure and prevents undue power losses. Many modern engines operate at the surface with a manifold pressure well in excess of atmospheric pressure with a resulting improvement in sealevel performance.

4. ORIGIN OF AERODYNAMIC DATA OF DESIGN

The designer bases his calculations on data derived from four main sources: (1) Theoretical investigations, such as the Lanchester-Prandtl theory of the action of wings. (2) Experiments on models in wind tunnels. (3) Experiments on full scale aeroplanes in flight. (4) Analysis of the measured performance of aeroplanes. References to the first of these divisions will be found in the article on AERODYNAMICS, where also the principles underlying experiments on models are dealt with.

Wind Tunnel.—The wind tunnel has played a great part in the development of aeronautics. Many manufacturing firms possess their own tunnels, used mainly for measurements of the resistance of aeroplane bodies, etc., with a view to improving performance. National wind tunnels exist in many countries, generally reserved in principle for research on problems of wide interest and application.

The main advantage of model experiments is the ease with which the experimenter can control the conditions.

Full Scale Experiments.—Most of the leading aircraft-producing countries carry out full scale experiments. In Great Britain they are made at the Royal Aircraft establishment under the control of the director of scientific research at the Air Ministry. In the United States they are carried out by the National Advisory Committee on Aeronautics, by The Material Division of The Army Air Corps and by certain manufacturers.

Analysis of Performance Tests.—The measurements of speed and climb which are made during the acceptance tests of aeroplanes are a valuable source of information for the designer. Their analysis enables an overall comparison between various types to be made on a rational basis, but necessarily lacks something in precision. For each type differs from the others in many features, so that, for example, an observed difference in speed cannot safely be ascribed to any one peculiarity. But with suitable

precautions reliable information can be obtained in a convenient form. It is found that the factors which have the greatest influence on the speed and climb of an aeroplane are the horse-power per unit of total weight and the total weight carried per unit of wing surface. For further details of the method, and its limitations, reports of the National Advisory Committee on Aeronautics (U.S.) or of the Aeronautical Research Committee (British) should be consulted.

5. DISTRIBUTION OF WEIGHT

Figure 6 illustrates the relative proportions of the total weight taken up by the various sections into which it is convenient to divide the component parts. The figures apply to an average commercial aeroplane of moderate size. The distribution of weight varies from one machine to another.

FIG. 6.—DISTRIBUTION OF TOTAL WEIGHT OF COMMERCIAL AEROPLANE

Structure.—The "structure" includes a great deal which is not part of the essential structure of the aeroplane. A change in the specified strength affects about 60 to 70% only of the nominal structure weight.

Power Plant.—The weight of the power plant depends mainly on the desired maximum speed of the aeroplane, and on the weight of the engine and its equipment per brake horse-power. There is generally a reduction in this item if an air-cooled engine is used instead of a water-cooled engine.

Fuel, etc.—The weight of fuel and tanks is dependent on the speed and duration of flight specified, and on the standard of fuel economy reached by the engine. The latter factor varies little for modern engines, both air- and water-cooled engines now giving one brake horse-power hour for about 1/2 lb. of petrol.

Crew, etc.—The crew and equipment tend naturally to absorb a progressively smaller proportion of the total weight as the size of the aeroplane increases.

Paying Load.—The paying load, being the balance after the above items have been accounted for, is from 13 to 20% of the gross loaded weight of the aeroplane. For slower aeroplanes it may reach a much higher percentage. Compared with other means of transport this is a high proportion. Both a passenger railway train and an ocean liner carry a much smaller percentage of paying load. That these means of transport are able to offer lower fares than aircraft is due partly to the higher running costs of an aeroplane per passenger mile, but mainly to the fact that the volume of passenger traffic is as yet small compared to that of other common carriers.

The essential need for economy of weight in aircraft is due, not only to the fact that but one-fifth of its weight is available for paying load, but to the higher cost of carrying this load by air, as compared with other ways. A saving in the weight of some part of the aeroplane of 1% of the whole allows a reduction of the cost of transport by about 5%.

6. EXTERNAL FORM OF AEROPLANES

Wings.—There is a striking lack of variation in the appearance as seen in plan of all modern aeroplanes. The main wings have

a large span (fig. 7 a) in relation to their chord, the average ratio of span to chord being about seven. This is a direct consequence of the fact that the resistance due to the generation of lift varies inversely as the square of the span (S^2). In some aeroplanes the chord diminishes towards the tip of each wing (fig. 7 b) and occasionally the wings, although of uniform chord, are "swept back" (fig. 7 c). Neither of these modifications affects the aerodynamic efficiency appreciably.

Near the tip of each wing is an aileron or wing flap hinged about axes 1-1 (fig. 7 a) and interconnected so that an upward movement of one is accompanied by a downward movement of the other. They are operated by a sideways movement of the pilot's control column, and are the means by which the wings are kept level in straight flight, or banked for a turn, as may be required. (See also AILERON.)

Tail plane.—At a distance of some three chords behind the leading edge of the wings is the tail plane, in area about one-ninth that of the wings. In steady flight its function is to balance or trim the aeroplane, *i.e.*, to ensure that the resultant of all the air forces on the aeroplane passes through the centre of gravity. (See AERODYNAMICS.) It is generally in two parts. The front part, some 60% of the whole, is normally fixed, though means may be provided by which the pilot can alter its angle of incidence by rotating it about an axis such as 2-2 (fig. 7 a), thus enabling the aeroplane to be trimmed for flying at various speeds. This operation is analogous to trimming the sails of a ship so that it carries no weather or lee helm. In a modern aeroplane a movable tail plane is generally considered indispensable, unless trimming planes such as Flettner controls (described later) are used in which case the stabilizer need not be adjustable.

The rear part of the tail, or elevator, is hinged on an axis such as 3-3 (fig. 7 a), and connected to the control column in such a way that a forward movement of the pilot's hand depresses the trailing edge of the elevator and causes the machine to dive, and vice versa. The elevator is the primary control organ of an aeroplane, since by it the pilot alters the angle of incidence of the wings and hence in conjunction with the engine power controls the rate of climb or descent and the speed. (Fig. 9 of article AERONAUTICS shows control organs, and the forms which they take in more modern machines will be seen in the articles, AERIAL NAVIGATION; AVIATION, CIVIL.)

Number of Planes.—The appearance of aeroplanes in front and side elevation is more varied than that in plan, owing mainly to the use of one or more planes. As many as four planes have

FIG. 7.—THE RELATIVE SIZES AND AREAS OF AEROPLANES, SHOWING THE SPAN OF THE MAIN WINGS IN RELATION TO THEIR CHORD. WHENCE THE AVERAGE RATIO OF SPAN TO CHORD MAY BE DEDUCED

been used on aeroplanes, but the great majority of existing machines have either one or two planes.

An analysis of the aeroplanes described in Jane's *All the World's Aircraft* for 1934 shows that, out of a total of nearly 1100 types, 52% were monoplanes and 48% biplanes, with no triplanes or quadraplanes. A similar analysis for 1927 gives, for about 600 types, 31% monoplanes and 69% biplanes. In 1922 there were 22% monoplane types to 78% biplanes with 8 triplanes and one quadraplane. This trend is due partly to the development of wing sections of great depth in relation to their chord, and partly to a desire to eliminate external wing bracing, but principally to the fact that the structural strength of the biplane is no longer a primary consideration in view of recent developments in stressed

skin wing and fuselage construction.

In fig. 8, separate analyses are shown diagrammatically for aeroplanes produced in Great Britain, France, Germany, the United States and other countries. It should be noted that the figures given above refer to types and include both commercial and war aeroplanes and seaplanes. Some of these naturally exist only in small numbers, and some may be confined even to one experimental machine, but there is evidence that all have actually been made and flown. Complete comparable data was not available in 1940 but a general survey indicated that monoplane outnumbered biplane designs by a ratio of at least nine to one.

FIG. 8.—SHOWING PERCENTAGE OF AEROPLANE TYPES PRODUCED IN 1922 AND 1934

Confining attention to monoplanes and biplanes, the chief variations in front elevation are shown in fig. 9. The high wing monoplane (a) is used mainly where it is desired to have some of the advantages of external bracing. The low wing monoplane (b) has rather less resistance and is less liable to damage by wind when on the ground, an important advantage. The latter type is the more numerous in military aircraft.

The biplane with wings of equal span (c) is the most common form of aeroplane, but wings of unequal span (d) (sometimes called sesquiplane, *i.e.*, $1\frac{1}{2}$ plane) have many advantages. The monoplane is rapidly taking the leading role. Fig. 9 (e) shows a large biplane with two or more engines. The right and left hand wings are generally not in line, but form a very flat upward Vee. This dihedral angle (which is generally given as the angle between either wing and the horizontal, and varies from 0° to 5°) is introduced in order to improve the lateral stability of the machine.

The corresponding side elevations of these aeroplanes are given in fig. 10. In a biplane the relative position of the planes as seen in this view varies as shown in (c), (d) and (e). In (c) and (d) the planes are staggered, *i.e.*, the line joining the leading edge of the upper and lower planes is not perpendicular to their chords. The angle of stagger is generally between 0° and 30° and a variation over this range has little if any effect on the efficiency of the wings. In (d) the chord of the lower wing is smaller than that of the upper wing, a common variant, especially when the spans are also unequal (fig. 9). In (e) the wings have equal chords and no stagger. The tail plane is here shown as a biplane, in which form its weight can be made low for a considerable area.

Set of the Wings.—The wing setting is the same as the angle of incidence and is the acute angle between the plane of the wing chord and the longitudinal axis of the aeroplane. In British terminology the angle of incidence is equivalent to the American term angle of attack, which is the acute angle between the reference line in a body and the line of the relative wind direction projected on a plane containing the reference line and parallel to the plane of symmetry.

Fin and Rudder.—The vertical stabilizing and controlling surfaces, a fixed fin and a movable rudder connected to foot pedals on which the pilot's feet rest, are situated near the tail plane.

They perform practically the same function as the rudder of a boat and can be seen in more detail in fig. 9 of article AERONAUTICS. The fixed fin is usually made adjustable for modern multiengine aeroplanes. The range of adjustment is sufficiently great to permit a setting such that the aeroplane will fly straight, when one of the wing engines is not operating, without undue exertion on the part of the pilot. This is particularly important on multiengined aeroplanes since many accidents have resulted from the inability of the pilot to hold a straight course after one engine has failed at low altitude. The operating engine has a tendency to lift the wing on its side and pull the aeroplane into a power spin.

A comparatively recent and highly efficient method of "trimming" the aeroplane for flight is the Flettner Control. This is a hinged section of the trailing edge of the rudder which is adjustable from the pilot's seat. As the Flettner control is moved to the right, the airflow on its surface forces the rudder to the left. A sufficient movement of the control is permitted to compensate for the loss of one engine's power as far as directional stability is concerned. When the Flettner Controls are used the fixed surfaces need not be adjustable.

As aeroplanes increase in size the amount of pressure which must be applied to the controls by the pilot increases to such an extent that his strength may be overtaxed in sharp manoeuvres. To reduce the effort required auxiliary control surfaces have been in certain instances introduced. In appearance they are similar to the Flettner controls but, instead of being operated by the pilot, are automatic. As the right foot pedal is pressed by the pilot and the rudder moves to the right, the auxiliary control automatically moves to the left. The airflow thus assists the pilot in making his turn by relieving pressure on the foot pedal.

Both the Flettner controls and the automatic auxiliary controls are used on elevators (movable horizontal control surfaces) as well as rudders and could be used on ailerons if size of the aeroplane warrants.

Automatic Pilot.—Many modern transport aeroplanes are equipped with an automatic gyroscopic pilot. The device is so designed to pilot the aeroplane on a given heading. It can be adjusted for climb, descent or for turns. It is so arranged that the pilot can over control by the normal use of control column and rudder.

The automatic pilot has many advantages. It produces more steady flight than is otherwise possible and permits the pilot to attend his radio and navigational duties with greater freedom. Although it is not a normal practice, it may be set for takeoff or landing.

Position of Airscrews and Engines.—In the three sketches the airscrews indicate the position of the engines. In modern

FIG. 9.—VARIATION IN THE FRONT ELEVATION OF MONOPLANES AND BIPLANES

aeroplanes the "pusher" position of the airscrew is seldom used except in single-engined flying boats, and in some extremely light sport planes such as the "Pou du Ciel" (Flying Flea), the vast majority of modern aeroplanes using tractor airscrews. When two or more engines are used, it is customary to distribute them along the wings, as the transmission of their power by means of shafts and gearing from a central engine-room to airscrews in suitable positions involves a prohibitive weight, and an unnecessary chance for mechanical failure. As seen in front elevation the

arrangements shown in fig. 11 have been used. Considerations of rudder control in the event of the failure of one engine make it desirable to place the engines as near to one another as the airscrews permit. Overlapping airscrews have been used, but have generally given rise to troublesome vibrations. It is also desirable that the axes of the airscrews should be, as far as possible, on the same horizontal level as the centre of gravity, in order to avoid giving rise to couples tending to make the aeroplane rotate in a vertical plane when the throttles are altered (see fig. 11).

7. STABILITY AND CONTROL

The general principles of stability and control are dealt with in the article AERODYNAMICS, and the stabilizing and controlling

FIG. 10.— THE SIDE ELEVATIONS OF THE AEROPLANES IN FIG. 9

surfaces have been referred to above. The necessary disposition and dimensions of these surfaces are decided in practice chiefly by direct comparison with previous designs. Since, however, aeroplanes are not merely scale copies of one type, some rational means of using the accumulated experience of previous work is essential, and it is this that research into the fundamentals of stability and control is able to supply. Needless to say, even these methods break down when the aeroplane in question is not broadly similar to those from which the data are derived, and then nothing short of a thorough investigation, assisted by model experiments, will suffice. Very often, even with the best that can be done in this way, uncertainties remain, and the designer is forced, as in other branches of engineering design, to rely upon his ability to draw conclusions from insufficient premises.

Stability.— Stability, the property of returning to a steady state of motion when deliberately or accidentally disturbed, implies as a necessary preliminary of the existence of equilibrium, or "trim," in that state. An aeroplane is trimmed for a steady condition of flight by an adjustment of its tail plane, or adjustment of the Flettner controls, the elevators being left free. The degree of stability generally considered desirable for a commercial aeroplane can be attained by arranging the size of tail plane and the fore and aft position of the centre of gravity within certain limits. The further back the centre of gravity, the larger is the necessary tail area. The fore and aft position of the centre of gravity in relation to the wing is defined by its distance from a plane passing through the leading edge of the wing perpendicular to the chord, for a monoplane; for a biplane an equivalent monoplane wing is substituted. In normal aeroplanes this distance is usually about one-third the chord, though it has varied between one-quarter and one-half. The height of the centre of gravity of an aeroplane in relation to the wings has a secondary effect on its stability. In particular a low centre of gravity is not necessary for stability. With the centre of gravity in the first-mentioned position, stability will be secured providing the product of the ratios

$$\frac{\text{area of tail plane and elevator}}{\text{area of wings}} \text{ and } \frac{\text{distance of tail plane from centre of gravity}}{\text{chord of wings}}$$

is greater than about 0.35. The latter ratio is usually about 3, and the former one-eighth.

The fore and aft control required can generally be obtained if the ratio $\frac{\text{area of elevator}}{\text{area of fixed tail plane}}$ is about two-thirds.

Lateral stability depends mainly on the provision of an adequate fin and dihedral angle. While desirable for comfort, lateral stability is of minor importance compared with lateral control.

Aileron Control.— Ailerons of an area between $\frac{1}{2}$ and $\frac{1}{3}$ of that of the wings are usually provided, and give adequate control at all normal flying speeds. At low speeds, however (more accurately, at angles of attack of the wings in the neighbourhood of stalling), not only are normal ailerons ineffective, but they may actually become a source of danger, their use aggravating an inherent tendency of the stalled wings to force the aeroplane into a spiral dive or spin. (See AILERON.)

Rudder Control.— An effective rudder is as essential for safety at low speeds as effective ailerons. The efficiency of any given rudder depends on its being arranged so that the body does not shield it, but it is found that when the product of the ratios

$$\frac{\text{area of rudder and fin}}{\text{area of wings}}$$

and

$$\frac{\text{distance of rudder from centre of gravity}}{\text{semi-span of wings}}$$

is above $\frac{1}{20}$, a satisfactory control is obtained. The latter ratio is usually about 1, so that the former should not be less than one-twentieth. The area of the rudder is generally about $\frac{2}{3}$ that of the rudder and fin combined.

The efficiency and sensitivity of control surfaces have been materially increased by placing tabs on the trailing edges. The tabs are quite small pieces of comparatively thin metal so located on the trailing edges as will furnish the greatest effect. Tabs smooth out the effect of the controls and increase control stability. They are used on ailerons, rudder and elevators.

8. SAFETY OF AIR TRAVEL

Air travel would have been much more quickly adopted except for a general public apprehension of the risks involved. These risks are associated with the following causes: (1) physical failure of the pilot, (2) fire when in flight, (3) collision when in flight, (4) breakage of the structure, (5) forced landing. Dangers of the first four types are not peculiar to aircraft and the precautions they involve are common to transport by road, rail and sea. The measures adopted in air transport have practically eliminated them. It is mainly the dangers which may arise when an aeroplane is forced to land that loom large in the minds of those who might otherwise travel by air. While it cannot be said that these fears are entirely unwarranted, yet in so far as the design of aircraft is involved the position is rapidly improving.

Forced Landings.— Forced landings may be necessitated by engine trouble, structural failure, fuel shortage, weather, ice forming on the aeroplane or loss of knowledge by the pilot of location. A well qualified pilot with a properly equipped aeroplane should not experience forced landings caused by loss of bearings, and should never experience fuel shortage. Forced landings caused by weather, while annoying, are not dangerous in a country well equipped with emergency landing fields. Structural failures are extremely rare in normal flight. Ice forming on the wings and propellers is a serious problem. The danger of ice is two-fold. It adds considerable weight to the structure and at the same time decreases the normal efficiency thereof by spoiling the lifting qualities of the wings and the traction qualities of the propellers. Some trouble has also been experienced by ice forming in carburettors and reducing engine power output. However, invention as well as the development of efficient meteorological services and weather broadcasting systems has largely if not completely met the situation. It would be a rare phenomenon if ice forming conditions existed throughout the altitude range of the aeroplane. Altitudes for flight should be sought which do not favour icing. To arrive at such altitudes, however, it may be necessary to pass through icing layers. Since clear ice, under severe condi-

tions, can form at the rate of 3 inches per minute, it is an important problem which has given much cause for thought and experimentation. Its importance has been more keenly felt in recent years since the development of instrument flying. Formerly little cloud flying was attempted but with modern methods cloud flying is nearer the rule than the exception.

To prevent ice from forming in carburettors, heaters are installed to warm the incoming air. There has recently been devised a de-icer for propellers. It consists of a container holding sev-

FIG. 11.—FRONT ELEVATIONS SHOWING ARRANGEMENTS OF ENGINES

eral gallons of a mixture of alcohol and glycerine. This is fed by gravity into a rotating slinger ring and thence to absorbent pads at the blade roots. The solution moistens the surface of the blade and prevents adhesion of ice thereto.

Various systems of preventing ice from forming on wings and struts have been used. The one which appears at present to have most promise is that of using vibrating rubber pads in the leading edge. The vibration cracks the ice and it is carried off by the air.

Aeroplane engines are at present remarkably reliable and forced landings due to this cause are infrequent. With the use of two or more engines in aeroplanes, capable of sustentation with one engine dead, an immediate forced landing due to engine failure is, although not altogether impossible, worthy of little consideration and no apprehension. Instruments usually give some indication of impending engine failure and thus permit the pilot to land and correct the difficulty before complete loss of power results.

From the height of about 3,000 feet approximately four minutes are available in which the pilot may choose a landing place. If the failure occurs before the aeroplane has reached its cruising altitude, the time and the corresponding area of ground in which this landing place is to be found are reduced in proportion. These considerations unfortunately may result in the pilot having to execute somewhat sharp turns in order to place the aeroplane correctly, and it is during these that the controllability of the machine is most severely tested. The ultimate danger lies in the fact that the speed of horizontal travel at the moment of landing cannot possibly be less than the stalling speed. In practice with a typical commercial aeroplane it will be between 55 and 70 miles per hour. The pilot, therefore, endeavours to make the most of what space is available. This consideration, combined with the psychological effect of the apparent increase in the aeroplane's speed as the ground is approached' may lead an inexperienced pilot to carry out manoeuvres at a low speed, where the inherent characteristics of the aeroplane are least favourable and the controls least effective. (See above §7.)

9. STRUCTURAL DESIGN

The General Problem. — The aeroplane shown in fig. g, article AERONAUTICS, was designed about 1914; in general aerodynamic and structural design it is not fundamentally different from most modern aeroplanes. Regarded as a problem in structural design, a normal aeroplane wing, such as that illustrated, is a double cantilever, *i.e.*, two similar cantilevers joined at their roots, carrying a load distributed approximately uniformly over its span. The intensity of the loading begins to diminish appreciably at about one chord from the tip, but is still $\frac{2}{3}$ of its value at the centre, at a dis-

To a passenger in an aeroplane 1,000 or 2,000ft. up, there is generally no sensation of speed relative to the ground.

tance of $\frac{1}{3}$ chord from the tip. The wing itself is essentially a lamina, the wing sections most commonly used (*see* fig. 2) having a greatest depth of from $\frac{1}{4}$ to $\frac{1}{8}$ chord. The resultant loading is nearly perpendicular to the chord, but its line of action (as seen in side elevation) intersects the chord at a point (the so-called "centre of pressure") whose distance from the leading edge of the wing varies from $\frac{1}{3}$ to $\frac{1}{2}$ chord in normal flight, but may travel much further to the rear—even beyond the trailing edge—in special conditions. As a whole, therefore, the wing structure must be capable of taking torsion.

From general principles it would appear that the lightest way of bracing such a lamina would be to stiffen it internally by longitudinal and transverse beams (spars and ribs), and to support these by external bracing. The arrangement of two planes, one above the other, connected by struts and wires to form a braced tubular girder, suggested itself to the earliest experimenters in flight. Such a solution (*see* fig. g of AERONAUTICS) is typical of the modern biplane.

Alternatively, by tapering the wing in plan (fig. 7 b) and thus both reducing the intensity of loading outwards from the centre (though not, it appears, in proportion to the reduction of the chord), and increasing the available depth at the root, the whole of the necessary structure may be contained inside the covering. This is the principle of the internally braced wing characteristic of nearly all modern monoplanes. It has the advantage of avoiding the resistance of the exposed bracing which is involved in the first solution.

Comparison of Monoplane and Biplane. — Many variants of these two main schemes have been used, but in general there is a clear division between them. The first undoubtedly produces a lighter structure and a more compact aeroplane. For, with the same total weight and wing area, the biplane has a smaller span and chord and requires a shorter body and smaller tail.

With the aid of the Prandtl theory it is possible to arrive at

FIG. 12.—COMPARISON OF PLAN VIEWS OF MONOPLANE AND BIPLANE OF SAME TOTAL WEIGHT AND PERFORMANCE

comparative overall dimensions for a normal biplane and a monoplane of otherwise similar characteristics. Such a comparison is shown in fig. 12. The span of the monoplane (full lines) is about 10% larger than that of the biplane (thin lines), and its chord 65% larger. Both the length of the body and the tail area required by the monoplane are greater by about 28%. Each type has other advantages and disadvantages, but the ever increasing relative number of monoplanes indicates that, all in all, they are superior. (*See* also BIPLANE and MONOPLANE.)

Refinement in Details. — The details of the structural design depend largely on the materials used (*see* below). But the main problems are not essentially different from those of the design of ordinary engineering structures, except in one particular. The importance of saving weight in every item of an aeroplane (§ 5) makes it economically possible to carry refinement in design to a point not usually attempted in any other structure. For the same reason elaborate calculations are made during the design, and the effect of every minor strengthening is carefully considered. All aeroplane structures are highly redundant and initial stresses are imposed on the members by tightening the bracing wires, in order to increase the stiffness of the structure. The design of modern aeroplane structure takes account of these features as far as it is possible to do so, in contrast to the general tendency of bridge design, for example, which tends to avoid

them as sources of uncertainty (*see* BRIDGES). Where saving of weight is a prime consideration such a course is not possible.

Strength of Aeroplane Structures.— Since an aeroplane must be able to manoeuvre rapidly, many systems of air pressure, differing both in distribution and in intensity, must be taken into account. How rapidly it should manoeuvre depends on its class, *e.g.*, a small war machine must be able to execute safely any manoeuvre of which an aeroplane is capable, whereas less exacting conditions suffice for a large commercial machine. Spins, rolls, loops have all to be considered and experiments have been made in order to ascertain the distribution of the air pressure in such manoeuvres. The fundamental manoeuvre is, however, that of rapid recovery from a steep dive at a high speed, and here the combined effect of centrifugal force and gravity produces an "equivalent gravity" (*see* AERODYNAMICS) several times the normal. Given the necessary control power and indifference to his own safety, the pilot of an aeroplane could impose in this way forces up to 10 or 12 times those which the structure has to bear in the normal flight. As much as seven times normal gravity has been recorded in experiments under war conditions.

Most pilots "blank out" or temporarily lose control of certain senses, including sight, at less than 8 times normal gravity. The amount which an individual can stand depends upon physique and training. However, except for fighting aeroplanes the individual can usually stand more than can the aeroplane.

The ratio between the effective and the normal value of gravity, is termed the *load factor* for the whole machine under the stated conditions. A normal commercial aeroplane need never experience a load factor of as much as two in flight. In practice it is designed to bear a factor of from four to six, dependent on its size and class. The ratio between the maximum load factor considered in the design, for any stated form of distribution of air pressure, and the factor in any actual condition of flight appropriate to that distribution, is the nearest approach to the *factor of safety* commonly used in engineering.

For a commercial aeroplane the factor of safety, as thus defined, seldom falls below three. In normal level flight it is of the order of five. For a war aeroplane it may fall to $1\frac{1}{2}$, so that the most highly stressed member is loaded to two-thirds of its breaking load, or even more, but only in extremely rapid manoeuvres.

A commercial aeroplane has a *true* factor of safety, a margin of strength not called upon under the worst conditions which it normally experiences. The load factors corresponding to irregularities in the air are very small. So long as it is in the air, an aeroplane is exposed to much smaller risk of the failure of its structure by stress of weather than is a ship at sea. Any commercial aeroplane which conforms to the official criterion of strength, and has been licensed, without which it may not carry passengers, is capable of performing many manoeuvres such as looping and spinning with complete safety.

10. MATERIALS USED IN CONSTRUCTION

Composite Structures.— The materials which have been most commonly used hitherto for the main structural members of aeroplanes are wood and steel, with a fabric covering for the wings. The wood used was chiefly spruce of the highest grade, and in many aeroplanes the whole of the main structure, with the exception of ties and joints, was of this material. Ties and the joints or fittings by which they were attached to the other members were generally of steel. Steel tubes were used in some parts, either, as in the undercarriage, on account of their robustness, or, as in the control mechanism, because of their efficiency in transmitting torsion.

The arrangement of the members of a conventional aeroplane structure of this composite character will be seen in fig. 9 of AERONAUTICS. The cross section of the wing spars has the I section used in general structural engineering, though the thickness of the web and flanges is much larger in proportion to the overall dimensions of the section than is usual in steel I girders.

The wings of the aeroplane shown in fig. 9 are in biplane form with external bracing. Composite construction has also been applied to wings with no external bracing, generally, but not invari-

bly, monoplanes.

In aeroplane construction the primary requirement is lightness, and a modern composite aeroplane structure is on the whole nearly as light as one of any other type of construction so far developed, for the same strength. In so far as it embodies wood composite construction suffers from the following disadvantages:

(1) Wood of a suitable grade cannot be freely obtained. (2) When exposed to the atmosphere, particularly to large changes in temperature and humidity, wood deteriorates more rapidly than steel or other metals. (3) Wood is not a reliable material. Its external appearance is often misleading as an indication of its internal condition. (4) In aeroplane structures glue and wood-screws cannot be entirely avoided. Both are sources of weakness and uncertainty. (5) When a wooden structure is involved in an accident, many of its members break completely and splinter, and the structure disintegrates, whereas metal members often merely bend, and an all-metal structure generally preserves much of its original shape. The passengers in a wooden aeroplane are thus exposed to greater danger in case of an accident. (6) Wood has no inherent resistance to fire.

These disadvantages of wood have been the chief incentive to the development of all-metal construction for aeroplanes.

All-metal Structures.— The development of all-metal structures was originally mainly confined to replacing each of the wooden members of the composite structure described above by a metal member, using either steel or duralumin. In such a structure the load to be borne by each member is of a fairly simple character and can be estimated fairly closely. Hence a comparison of the merits of a composite and an all-metal structure on these lines can be reduced to a comparison of typical members.

However, recent tendency is toward Monocoque or Semi-Monocoque construction with the entire outer surface of the aeroplane of the metal stressed skin construction. Recent developments in the production of large, thin, uniform sheets of aluminium alloys, and in the art of welding and riveting have made desirable the Monocoque type of construction in which the covering of the fuselage furnishes the strength. In the Semi-Monocoque type part of the stress is borne by the stressed skin and part by reinforcement.

The metal used in fuselage and wing construction of this type is usually an aluminium alloy. Alclad, a very thin sheet aluminium alloy which has been coated with pure aluminium, is very satisfactory in that the necessity for painting is obviated. It also gives excellent results when used about salt water where salt corrosion usually gives trouble.

The change from wood construction to all-metal has been pronounced during the past 15 years. In modern all-metal aeroplanes aluminium alloys represent from 80 to 85% of the total weight of the structure.

Physical Properties of Materials.— The disadvantages of wood as a material for the structure of an aeroplane, outlined above, give an idea of what should be the characteristics of a satisfactory material. There is the usual difficulty, common to most problems of engineering design, of assessing the relative importance of each of these characteristics. In fact, their relative positions in the scale change with time and circumstances. But, owing to the low weight of the composite structures characteristic of modern aeroplanes, the technical problem is simplified into that of finding means of making, at the worst equally light, and preferably lighter structures from materials that do not share with wood the disadvantages mentioned. Table I. (p. 258) gives the strength and specific gravity of various materials which have been, or are likely to be, used for the main structural members of aircraft. They fall into three classes: wood, steel and light non-ferrous metals. The comparatively short life of wood has been quoted as one of its main disadvantages. Both steel and aluminium alloys need protection against corrosion. Of the former spot-welded stainless steel appears to have great promise. Of the latter alclad has proven highly satisfactory. Although it would be misleading to suggest that all the problems of protection of metal structures have been solved, the experience gained suggests that effective protection can be given against all the

FIG. 13—EXAMPLES OF METAL CONSTRUCTION OF SPARS AND RIBS FOR AEROPLANE WINGS

- A. Section of corrugated steel spar, showing method of attaching rib by means of spring steel clips riveted to struts, pressing into corrugations in the spar
- B. Inner end of wing in steel, showing wide rib and attachment of wing to aeroplane
- C. Corrugated steel spar using transverse tubes to stiffen webs, and duralumin strips to stiffen flanges
- D. Internal construction of wing in duralumin. Spar built up from sheet and angles. Ribs made from tube and channels
- E. Simplified wing spar in duralumin. The greatest depth of each of the spars is about 5 inches

ordinary causes of corrosion.

Struts and Beams of Thin Metal.—It is customary to regard the single figure obtained by dividing the strength by the specific gravity as a figure of merit on which the material can be judged. Such figures are not given in Table I. as they are not, in fact, a reliable criterion for all types of structural members.

The types of members responsible for the larger part of the weight of the structure of an aeroplane are two, struts and beams, the latter very often having to serve also as struts. Such members have essentially a variation of stress over their cross section, so that when the most heavily stressed point reaches the *limiting* stress of the material (this may be taken to mark the failure of the member as a whole), the majority of the material is under a lower stress. Hence the density of the material divided by its limiting stress is not in general proportional to the weight of the member.

In general, for a given area of cross section and a given limiting stress, the more the material can be spread out, *e.g.*, in the form of a circle, the greater will be the strength of the strut or beam, but the thinner will the material become. It appears, however, that a limit is reached for steel when the thickness is about $\frac{1}{50}$ the radius, beyond which an increase in the radius causes a decrease in strength. The member will then fail owing to local buckling of the material, at a load which corresponds to a maximum stress in the material, as calculated in the conventional way, which is below the limiting stress. The design of metal structures for aircraft hinges round the discovery of shapes of cross section which will enable the limiting stress of the material to be reached, and will be convenient for manufacture. The members must also be robust to ensure that ordinary handling does not damage them, a serious problem with thin sheets or tubes.

Limiting Stress.—The limiting stress in question is probably what is termed the yield point in compression, the stress at which plastic strain begins, for materials such as mild steel. For high tensile steel and light alloys (in practice the aluminium alloy known as *duralumin* is the one most used), there is no definite yield point and the limiting stress is accordingly somewhat un-

certain. Shapes for members (see fig. 13) have been devised in which the greatest stress at failure is some 60 to 70% of the ultimate tensile strength of the materials (see Table I., column headed "Effective Strength in Compression"), and there is reason to suppose that this is not far from the best that can be achieved. Some improvement may be anticipated from an extension of these results to still higher grades of steel, or from the development of a light alloy stronger than duralumin.

The ruling principle in the shapes of cross section which have achieved these results with steel is *corrugation* of the thin sheet

TABLE I.

Material.	Specific gravity.	Ultimate Tensile Strength (tons/sq. in.)	Effective strength, in compression (tons/sq. in.)
Wood—			
Spruce.	0.45	about 3	2
Steel—			
Mild (soft)	7.8	26	15
Plain carbon steel bar for ties (cold-rolled)	7.8	70	..
Plain carbon steel strip (cold-rolled and blued)	7.8	60	50
3½% nickel steel strip (hardened and tempered)	7.8	90	60
Light metals—			
Aluminium (cold-rolled)	2.6	10	8
Duralumin	2.85	27	17

material used. The theory of the collapse of corrugated material awaits development, design being at present largely empirical. But the general nature of the strengthening effect of corrugation is well understood. A flat sheet of thin metal buckles readily under compressive stresses. Corrugation, in any direction which does not make too great an angle with the direction of the stress, stiffens it against such buckling. It greatly reduces the influence of the inevitable local irregularities in actual materials, and gives robustness to what would otherwise be a very easily damaged member. It is essential in struts and beams of thin metal, to corrugate *longitudinally*. Transverse corrugations have proved ineffective.

Steel strip of thickness as low as $\frac{1}{100}$ in. has been used in aeroplane spars and ribs. The material is either cold-rolled medium carbon steel, whose essential properties have been improved by a process known as blueing (heating to some 350°C.), but is otherwise not heat treated, or a nickel chromium alloy steel, hardened and tempered. Hitherto the strip has been formed into the final shape cold and without any subsequent treatment. This restricts the sections which can be produced and the materials which can be used owing to the need for ductility in order to avoid cracks. Progress has been made in the direction of forming the shapes while the material is in an annealed state and heat treating subsequently. This method will probably supersede "hard" drawing and rolling.

For spars of the size shown in fig. 13, it has been found that the low specific gravity of duralumin makes it possible to use material of such a thickness that corrugation is not always necessary. The resulting shapes resemble those used in bridge construction, though the lattice girder seen in fig. 13 *d* is found in practice to be heavier than the simpler shape in *e*. It is probable that, for the size of spar required in the largest present-day aeroplanes of the type under discussion, it is more economical of weight to use a spar composed of a few parts (such as *a*, *c* and *e*) than to build it up from many pieces. On the other hand for larger beams, such as are used in airships, a lattice construction is lighter. Probably the lightest all-metal construction for a wing structure using spars and ribs, etc., combines both steel and duralumin, the former for the main members (spars and struts) and the latter for the subsidiary ribs and edges. With the methods outlined above it is now possible to make an all-metal aeroplane as light as, and lighter than, the corresponding composite machine.

AEROTHERAPEUTICS. In addition to the general use of open air and sunshine, there are several particular ways of using air for therapeutic purposes. Thus oxygen enriched air is used for those made ill through breathing irritating gases such as were used in warfare. These gases evoke oedema of the lungs and danger of suffocation through want of oxygen. So, too, in cases of pneumonia, shock and failing circulation, oxygen inhalation is useful. It is administered either by a mask or in a special chamber in which the patient is put. In the latter case great precaution must be taken against the danger of fire.

Oxygen containing 5% of carbon dioxide provokes deep breathing, and is useful in cases when the lungs require expanding, as after operations for empyema, when hypostatic congestion of the lungs threatens, and in cases of poisoning by carbon monoxide, as in ordinary coal-gas poisoning, etc. This mixture is particularly useful for breathing during induction of and after anaesthesia with ether, since the deep respiration induces anaesthesia quickly, and washes the ether out of the body at the end of the anaesthetic period. The breathing of nitrous oxide and oxygen in a compressed air chamber at half an atmosphere extra pressure gives deep and safe anaesthesia.

Certain dusts in the air act as irritants to those affected with hay fever and asthma, e.g., the pollen of plants, spores of aspergillus mould. It has been found possible to relieve such patients by sending them to the high Alps.

In a mercurial or sulphur bath, the patient, enveloped in a sheet, sits on a chair beneath which a lamp is placed both to volatilize the drug and produce a steamy atmosphere. The vapour is absorbed by the skin. This treatment is used for syphilis and also for scabies and other affections of the skin. (See THERAPEUTICS.)

Air at a low pressure is used locally for cupping and thus producing local congestion, the blood being drawn into the part to which the cupping apparatus is applied at the expense of other organs. A similar result is got by local application of heat, poultices, etc. In operations where the chest cavity is opened air is blown into the lungs through a tube introduced through the larynx in order to keep the lungs distended.

Ozonized Air.—Ozonized air has been used in treatment of phthisis and wounds. Ozone is an irritant to the lungs and can be used safely only in very weak concentrations, e.g., in a concentration just perceptible to the smell. It takes away the power to smell bad odours, but otherwise has no valuable properties which have been proven. Its chief use, then, is for deodorizing offensive smells. (L. E. H.)

AERSCHOT, PHILIPPE DE CROY, DUKE OF (1526-1595), prince of Chimay, governor-general of Flanders, was born at Valenciennes, and inherited the estates of the ancient and wealthy family of Croy. He was appointed governor of the citadel of Antwerp when the Spanish troops withdrew in 1577. After a period of vacillation he deserted Don John towards the end of that year. Jealous of the prince of Orange, he was then the head of the party which induced the archduke Matthias (afterwards emperor) to undertake the sovereignty of the Netherlands, and soon afterwards was appointed governor of Flanders by the state council. A strong party, including the burghers of Ghent, distrusted the new governor; and Aerschot, who was taken prisoner during a riot at Ghent, was only released on promising to resign his office. He then sought to regain the favour of Philip of Spain, and having been pardoned by the king in 1580 shared in the government of the Netherlands; but he refused to serve under the count of Fuentes when he became governor-general in 1594, and retired to Venice, where he died on Dec. 11, 1595.

See J. L. Motley, The Rise of the Dutch Republic.

AERTSZEN (or AARTSEN), **PIETER** (1507-1573), called "long Peter" on account of his height, Dutch historical painter, was born and died at Amsterdam. When a youth he distinguished himself by painting homely scenes, in which he reproduced articles of furniture, cooking utensils, etc., with marvellous fidelity. An excellent specimen of his style on a small scale, a picture of the Crucifixion, may be seen in the Antwerp Museum. Aertszen was a member of the Academy of St. Luke, in the books of which he is entered as *Langhe Peter*, schilder. Three of his sons attained to some note as painters.

AESCHINES (5th century B.C.), an Athenian philosopher and orator and a friend of Socrates. Diogenes Laertius preserves a tradition that it was he, not Crito, who offered to help Socrates to escape from prison. He was always a poor man. He started a perfumery shop in Athens on borrowed capital, became bankrupt and retired to the Syracusan court. According to Diog. Laert. (ii. 61), Plato, then at Syracuse, pointedly ignored Aeschines, but this does not agree with Plutarch De adulatore et amico (c. 26). On the expulsion of the younger Dionysius, Aeschines returned to Athens, and, finding it impossible to profess philosophy publicly owing to the contempt of Plato and Aristotle, was compelled to teach privately. Besides forensic speeches, noted for their purity of style, he wrote several philosophical dialogues: (1) Concerning *virtue*, whether it can be taught; (2) *Eryxias*, or *Erasistratus*: concerning riches, whether they are good; (3) *Axiochus*: concerning death, whether it is to be feared,—but those extant are not genuine remains.

J. le Clerc has given a Latin translation of them, with notes and several dissertations, entitled *Silvae Philologicae*, and they have been edited by S. N. Fischer (Leipzig, 1786), and K. F. Hermann De Aeschin. Socmt. relig. (Gött. 1850). An amusing passage of a genuine dialogue is quoted by Cicero in the *De inventione* (i. 31). Hirzel Der Dialog. i. 129-140; T. Gomperz Greek Thinkers, vol. iii. p. 342 (Eng. trans. G. G. Berry, London, 1905).

AESCHINES (389-314 B.C.) Athenian orator, the political opponent of Demosthenes. Aeschines and Demosthenes were both members of the first embassy to Philip (Feb.-March 346 B.C.). Philip's envoys appeared in the Assembly on April 15 and 16, and between these two meetings Aeschines appears to have been won over to Philip's interest; on the 15th he refused, with Demosthenes, to accept a clause excluding Phocis; on the 16th he supported a peace in which the question was left vague. The same ambassadors went to administer the oaths to Philip, but, after so delaying on their journey that Philip had time to make conquests in Thrace, Philocrates and Aeschines (out-voting Demosthenes), allowed him to exclude the Phocians. But on his return Aeschines falsely assured the Assembly that he had private information that Philip meant to support Phocis. The Athenians believed him and Phocis, left without support, surrendered.

In 345, Demosthenes accused Aeschines of misconduct, but Aeschines saved himself by an attack on Demosthenes' supporter (in Timarchum). In 343, Demosthenes renewed the attack, and Aeschines secured a bare acquittal (De Falsa Legatione).

In 340, war broke out again with Philip, and thanks to Aeschines, who stirred up a Sacred War in 339, he managed to enter Greece unopposed, as general of the Amphictyonic forces. Athens and Thebes, united by Demosthenes, resisted desperately, but were decisively defeated at Chaeroneia (338).

Aeschines' party secured favourable terms from Philip, and prosecuted Demosthenes on various charges, but the Athenians loyally supported him, and in 337 it was proposed to crown him for public services. Aeschines brought a *graphē paranomōn* against the proposer (in Ctesiphontem), but the case was not tried till 330. Demosthenes' speech on the Crown (a vindication of his whole policy) secured the condemnation of Aeschines, who withdrew to Rhodes.

AESCHYLUS (525-456 B.C.), Greek poet, the first of the only three Attic tragedians of whose work entire plays survive, and in a very real sense the founder of the Greek drama, was born at Eleusis in 525 B.C. His father, Euphorion, belonged to the "Eupatridae" or old nobility of Athens, as we know on the authority of the short Life of the poet given in the Medicean Manuscript (see note on "Authorities" at the end). According to the same tradition he took part as a soldier in the great struggle of Greece against Persia; and was present at the battles of Marathon, Artemisium, Salamis and Plataea, in the years 490-479. At least one of his brothers, Cynaegirus, fought with him at Marathon, and was killed in attempting a conspicuous act of bravery; and the brothers' portraits found a place in the national picture of the battle which the Athenians set up as a memorial in the Stoa Poecile (or "Pictured Porch") at Athens.

The vigour and loftiness of tone which mark Aeschylus' poetic work were partly inspired by the personal share he took in the great actions of a heroic national uprising. In the same way, the poet's brooding thoughtfulness on deep questions—the power of the gods, their dealings with man, the dark mysteries of fate, the future life in Hades—though largely due to his turn of mind and temperament, was doubtless connected with the place where his childhood was passed. Eleusis was the centre of the most famous worship of Demeter which was intimately connected with the Greek beliefs about the human soul and the underworld.

His dramatic career began in 499 B.C. when he first exhibited at Athens; and his last work, the trilogy of the *Oresteia*, was exhibited in 458. The total number of his plays is stated by Suidas to have been 90; and the seven extant plays, with the dramas named or nameable which survive only in fragments, amount to over 80, so that Suidas' figure is probably based on reliable tradition. In the 5th century each exhibitor at the tragic contests produced four plays; and Aeschylus must therefore have competed (between 499 and 458) more than 20 times. His first victory is recorded in 484, 15 years after his earliest appearance on the stage; but in the remaining 26 years of his dramatic activity at Athens he was successful at least 12 times. Perhaps the most striking evidence of his exceptional position among his contemporaries is the well-known decree passed shortly after his death that whosoever desired to exhibit a play of Aeschylus should "receive a chorus," *i.e.*, be officially allowed to produce the drama at the Dionysia. The existence of this decree, mentioned in the *Life*, is strongly confirmed by two passages in Aristophanes: first in the prologue of the *Acharnians* (acted in 427), where the citizen relates his great disappointment, when he took his seat in the theatre "expecting Aeschylus," to find that when the play came on it was Theognis; and secondly in a scene of the *Frogs* (acted 405 B.C.), where the throne of poetry is contested in Hades between Aeschylus and Euripides, the former complains (Fr. 866) that "the battle is not fair, because my own poetry has not died with me, while Euripides' has died, and therefore *he* will have it with him to recite"—a clear reference, as the scholiast points out, to the continued production at Athens of Aeschylus' plays after his death.

The only other incidents recorded of the poet's life that deserve mention are connected with his Sicilian visits, and the charge preferred against him of revealing the "secrets of Demeter." This tale is mentioned by Aristotle (*Eth.* iii. 2), and Eustratius (12th century) quotes from one Heracleides Pontius the following version:

AESCHYLUS, FATHER OF THE GREEK DRAMA
Head now in the Capitoline Museum, Rome, believed to be that of Aeschylus, probably B.C. about the 5th century.

The poet was acting in one of his own plays, where there was a reference to Demeter. The audience suspected him of revealing the inviolable secrets, and rose in fury; the poet fled to the altar of Dionysus in the orchestra and so saved his life for the moment. He was afterwards charged with the crime before the Areopagus; and his plea "that he did not know that what he said was secret" secured his acquittal. The commentator adds that the prowess of the poet (and his brother) at Marathon was the real cause of the leniency of his judges. In the above shape the story dates back to the 4th century; and as the main fact seems accepted by Aristotle, it is probably authentic.

As to his foreign travel, the suggestion has been made that certain descriptions in the *Persae*, and the fact that he wrote a trilogy on the story of the Thracian king, Lycurgus, seems to point to his having visited Thrace. This, however, remains at best a conjecture. For his repeated visits to Sicily, on the other hand, there is conclusive ancient evidence. Hieron the First, tyrant of Syracuse (478-467), who invited to his court famous poets and men of letters, had founded a new town, Aetna, on the site of Catana. About 476 Aeschylus was entertained by him, and at his request wrote and exhibited a play called *The Women of Aetna* in honour of the new town. He paid a second visit about 472, the year in which he had produced the *Persae* at Athens; and the play is said to have been repeated at Syracuse at his patron's request. Hieron died in 467, the year of the *Seven against Thebes*; but after 458, when the *Oresteia* was exhibited at Athens, we find the poet again in Sicily for the last time. In 456 he died, and was buried at Gela; and on his tomb was placed an epitaph in two elegiac couplets saying: "Beneath this stone lies Aeschylus, son of Euphorion, the Athenian, who perished in the wheat-bearing land of Gela; of his noble prowess the grove of Marathon can speak, or the long-haired Persian who knows it well." The *Life* says this epitaph was inscribed on his grave by the people of Gela, while Athenaeus and Pausanias attribute it to Aeschylus. Probably most people would agree that only the poet himself could have praised the soldier and kept silence about the poetry.

Of the marvellous traditions which gathered round his name little need be said. Pausanias' tale, how Dionysus appeared to the poet when a boy and bade him write a tragedy—or the account in the *Life*, how he was killed by an eagle letting fall on his head a tortoise—clearly belong to the same class of legends as the story that Plato was son of Apollo. Less supernatural, but hardly more historical, is the statement in the *Life* that the poet left Athens for Sicily in consequence of his defeat in the dramatic contest of 468 by Sophocles; or alternatively because Simonides' elegy on the heroes slain at Marathon was preferred to his own. Neither story fits the facts; for in 467, the next year after Sophocles' success, we know that Aeschylus won the prize of tragedy with the *Septem*; and the *Marathon* elegy must have been written in 490 about 14 years before his first visit to Sicily.

Aeschylus' Plays.—In passing from Aeschylus' life to his work, we have obviously far more trustworthy data, in the seven extant plays (with the fragments of more than 70 others), and particularly in the invaluable help of Aristotle's *Poetics*. The real importance of our poet in the development of the drama (see *DRAMA: Greek*) as compared with his predecessors is shown by the fact that Aristotle, in his brief review of the rise of tragedy (*Poet.* iv. 13), names no one before Aeschylus.

Tragedy grew out of the old choric song to Dionysus, to which was added first a spoken interlude by the chorus-leader, and later one actor (at first the poet), whom the mask enabled to appear in more than one part. But everything points to the fact that in the development of the drama Aeschylus was the decisive innovator. The two things that were important, when the 5th century began, if tragedy was to realize its possibilities, were (1) the disentanglement of the dialogue from its position as an interlude in an artistic and religious pageant that was primarily lyric; and (2) its general elevation of tone. Aeschylus, as we know on the express authority of Aristotle (*Poet.* iv. 13), achieved the first by the introduction of the second actor; and though he did not begin the second he gave to it the decisive impulse and consum-

mation by the overwhelming effect of his serious thought, the stately splendour of his style, his high dramatic purpose, and the artistic grandeur and impressiveness of the construction and presentment of his tragedies.

As to the importance of the second actor no argument is needed. The interacting personal influences of different characters on each other are indispensable to anything that can be called a play, as we understand the word; and, without two "personae dramatis" at the least, the drama in the strict sense is clearly impossible. The number of actors was afterwards increased; but to Aeschylus is due the essential step; and therefore, as was said above, he deserves, in a very real sense, to be called the founder of Athenian tragedy.

Of the seven extant plays, *Supplikes*, *Persae*, *Septem contra Thebas*, *Prometheus*, *Agamemnon*, *Choephoroe* and *Eumenides*, five can be dated with certainty, as the archon's name is preserved in the Arguments; and the other two approximately. The dates rest, in the last resort, on the *didaskalia*, or the official records of the contests, of which Aristotle (and others) compiled catalogues; and some actual fragments have been recovered. The order of the plays is probably that given above; and certainly the *Persae* was acted in 472, *Septem* in 467, and the trilogy in 458. The *Supplikes* is generally regarded as the oldest; and the best authorities tend to place it not far from 490. The early date is strongly confirmed by three things: the extreme simplicity of the plot, the choric (instead of dramatic) opening, and the fact that the percentage of lyric passages is 54, or the highest of all the seven plays. The chief doubt is in regard to *Prometheus*, but the very low percentage of lyrics (only 27, or roughly a quarter of the whole), and still more the strong characterization, a marked advance on anything in the first three plays, point to its being later than any except the trilogy, and suggest a date somewhere about 460, or perhaps a little earlier. A few comments on the extant plays will help to indicate the main points of Aeschylus' work.

Supplikes.—The exceptional interest of the *Supplikes* is due to its date. Being nearly 20 years earlier than any other extant play, it furnishes evidence of a stage in the evolution of Attic drama which would otherwise have been unrepresented. It probably resembles in general structure the lost works of Choerilus, Phrynichus, Pratinas and the 6th century pioneers of drama.

The plot is briefly as follows: the 50 daughters of Danaus (who are the chorus), betrothed by Aegyptus (their father's brother) to his 50 sons, flee with Danaus to Argos, to escape the marriage. They claim the protection of the Argive king, Pelasgus; and he (by a pleasing anachronism) refers the matter to the people, who agree to protect the fugitives. The pursuing fleet of suitors is seen approaching; the herald arrives, orders off the cowering Danaids to the ships and finally attempts to drag them away. Pelasgus interposes with a force, drives off the Egyptians and saves the suppliants. Danaus urges them to prayer, and the grateful chorus pass away to the shelter offered by their protectors.

It is clear that we have here the drama just developing out of the lyric pageant. The interest still centres round the chorus. Character and plot—the two essentials of drama—are both here rudimentary. The play is a single situation. It should not be forgotten, indeed, that the play is one of a trilogy—an act, therefore, rather than a complete drama. But we have only to compare it with those later plays of which the same is true, to see the difference. Even in a trilogy, each play is a complete whole in itself, though also a portion of a larger whole.

Persae.—The next play that has survived is the *Persae*, the only extant Greek historical drama. The plot is still severely simple, though more developed than that of the *Supplikes*. The opening is still lyric, and the first quarter of the play brings out, by song and speech, the anxiety of the people and queen as to the fate of Xerxes' huge army. Then comes the messenger with the news of Salamis, including a description of the sea-fight itself which can only be called magnificent. The play is not a tragedy in the true Greek sense; its real aim is not the "pity and terror" of the developed drama; it is the triumphant

glorification of Athens, the exultation of the whole nation gathered in one place, over the ruin of their foe; and one effective incident is the raising of Darius's ghost, and his prophecy of the disastrous battle of Plataea. But in the ghost's revelations there is a mixture of audacity and naïveté, characteristic at once of the poet and the early youth of the drama.

Septem Contra Thebas.—Five years later came the Theban tragedy, which is (like the *Supplikes*) one of a connected series, dealing with the evil fate of the Theban house, and traces the fate through three generations, Laius, Oedipus and the two sons who die by each other's hands in the fight for the Theban sovereignty. This family fate, where one evil deed leads to another after many years, is a larger conception, strikingly suited to Aeschylus' genius, and constitutes a notable stage in the development of the Aeschylean drama. In the last extant work, the *Oresteia*, the poet traces the tragedy of the Pelopid family, from Agamemnon's first sin to Orestes' vengeance and purification. And the names of several lost plays point to similar handling of the tragic trilogy.

The *Seven against Thebes* is the last play of its series; and again the plot is severely simple. Father and grandfather have both perished miserably; and the two princes both claim the kingdom. Eteocles has driven out Polyneices, who fled to Argos, gathered a host under seven leaders (himself being one), and when the play opens has begun the siege of his own city. The king appears, warns the people, chides the clamour of women, appoints seven Thebans, including himself, to defend the seven gates, departs to his post, meets his brother in battle and both are killed. The other chieftains are all slain, and the enemy beaten off. The two dead princes are buried by their two sisters, who alone are left of the royal house.

Various signs of the early drama are here manifest. Half the play is lyric; there is no complication of plot; the whole action is recited by messengers; and the predicted mutual slaughter of the princes is brought about by no accidental stroke of destiny, but by the choice of the king, Eteocles himself. On the other hand, the opening is no longer lyric (like the two earlier plays) but dramatic; the main scene, where the king appoints the seven defenders, must have been an impressive spectacle. One novelty should not be overlooked. There is here the first passage of *dianoia*, or general reflection of life, which later became a regular feature of tragedy. Eteocles muses on the fate which involves an innocent man in the company of the wicked so that he shares unjustly their deserved fate (*Theb.* 597–608). The whole part of Eteocles shows a new effort of the poet to draw character, which may have something to do with the rise of Sophocles, who in the year before (468) won the prize of tragedy. There remain only the *Prometheus* and the *Oresteia*, which show such marked advance that (it may almost be said) when we think of Aeschylus it is these four plays we have in mind.

Prometheus.—The Prometheus-trilogy consisted of three plays: *Prometizeus the Fire-bringer*, *Prometheus Bound*, *Prometheus Unbound*. The two last necessarily came in that order; the *Fire-bringer* is probably the first of the trilogy. That Prometheus sinned against Zeus, by stealing fire from heaven; that he was punished by fearful tortures for ages; that he was finally reconciled to Zeus and set free—all this was the ancient tale indisputably. Those who hold the *Fire-bringer* (*Πυρρόφορος*) to be the final play, conjecture that it dealt with the establishment of the worship of Prometheus under that title, which is known to have existed at Athens. But the other order is on all grounds more probable; it keeps the natural sequence—crime, punishment, reconciliation, which is also the sequence in the *Oresteia*. And if the reconciliation was achieved in the second play, no scheme of action sufficing for the third drama seems even plausible.¹

The play that survives is a poem of unsurpassed force and impressiveness. Nevertheless, from the point of view of the

¹The *Eumenides* is quoted as a parallel, because there the establishment of this worship at Athens concludes the whole trilogy; but it is forgotten that in *Eumenides* there is much besides—the pursuit of Orestes, the refuge at Athens, the trial, the acquittal, the conciliation by Athena of the Furies; while here the story would be finished before the last play began.

development of drama, there seems at first sight little scope in the story for the normal human interest of a tragedy, since the actors are all divine, except Io; and between the opening where Prometheus is nailed to the Scythian rock, and the close where the earthquake engulfs the rock, the hero and the chorus, action in the ordinary sense is *ipso facto* impossible. This is just the opportunity for the poet's bold inventiveness and fine imagination.

Oceanus, the well-meaning palaverer old mentor, and Hermes, the blustering and futile jack-in-office, gods though they be, are vigorous, audacious and very human character-sketches; the soft entrance of the consoling nymphs is unspeakably beautiful; and the prophecy of Io's wanderings is a striking example of that new keen interest in the world outside which was felt by the Greeks of the 5th century, as it was felt by the Elizabethan English in a very similar epoch of national spirit and enterprise 2,000 years later. Thus, though dramatic action is by the nature of the case impossible for the hero, the visitors provide real drama.

Another important point in the development of tragedy is what we may call the "balanced issue." The hero is both a victim and a rebel. He is punished for his benefits to man; but though Zeus is tyrannous, the hero's reckless defiance is shocking to Greek feeling. As the play goes on, this is subtly indicated by the attitude of the chorus. They enter overflowing with pity. They are slowly alienated by the hero's impiety; but they decline, at the last crisis, the mean advice of Hermes to desert Prometheus; and in the final crash they share his fate.

Oresteia.—The last and greatest work of Aeschylus is the *Oresteia*, which also has the interest of being the only complete trilogy preserved to us. As in Prometheus, the plot, at first sight, is such that the conditions of drama seem to exclude much development in character-drawing. The gods are everywhere at the root of the action. The inspired prophet, Calchas, has demanded the sacrifice of the king's daughter, Iphigeneia, to appease the offended Artemis. The inspired Cassandra, brought in as a spear-won slave from conquered Troy, reveals the murderous past of the Pelopid house, and the imminent slaughter of the king by his wife. Apollo orders the son, Orestes, to avenge his father by killing the murderess, and protects him when after the deed he takes sanctuary at Delphi. The Erinyes ("Furies") pursue him over land and sea; and at last Athena gives him shelter at Athens, summons an Athenian council to judge his guilt, and when the court is equally divided gives her casting vote for mercy. The last act ends with the reconciliation of Athena and the Furies; and the latter receive a shrine and worship at Athens, and promise favour and prosperity to the great city. The scope for human drama seems deliberately restricted by such a story so handled. Nevertheless, the growth of characterization is not only visible but remarkable. Clytaemnestra is one of the most powerfully presented characters of the Greek drama. And there is one other noticeable point. In this trilogy, Aeschylus, for the first time, has attempted some touches of character in two of the humbler parts, the watchman in Agamemnon, and the nurse in the *Choephoroe*. These two are veritable figures drawn from contemporary life; and though both appear only once, the innovation is most significant, and especially as adapted by Aeschylus.

Aeschylus' Characteristics.—It remains to say a word on two more points: the religious ideas of Aeschylus and some of the main characteristics of his poetry. The religious aspect of the drama in one sense was prominent from the first. But the new spirit imported by the genius of Aeschylus was religious in a profounder meaning of the term. The sadness of human lot, the power and mysterious dealings of the gods, their terrible and inscrutable wrath and jealousy (aga and phthonos), their certain vengeance upon sinners, all the more fearful if delayed—such are the poet's constant themes, especially in the *Oresteia*. And at times, particularly in the *Trilogy*, in his reference to the divine power of Zeus, he almost approaches a stern and sombre monotheism.

One specially noteworthy point in the *Agamemnon* is his ex-

PLICIT repudiation of the common Hellenic view that prosperity brings ruin. In other places he seems to share the feeling; but here (Ag. 730) he goes deeper, and declares that it is not ἄλβος but always wickedness that brings about men's fall. All through there is a recurring note of fear in his view of man's destiny. In one remarkable passage of the *Eumenides* (j17-52 j) this fear is extolled as a moral power which ought to be enthroned in men's hearts, to deter them from impious acts or from the pride that impels them to such sins.

Of the poetic qualities of Aeschylus' drama and diction, both in the lyrics and the dialogue, the briefest word must here suffice. He is everywhere distinguished by grandeur and power of conception, presentation and expression, and most of all in the latest works, the Prometheus and the *Trilogy*. He is pre-eminent in depicting the slow approach of fear, as in the Persae; the imminent horror of impending fate, as in the broken cries and visions of Cassandra in the Agamemnon (1072-1177), the long lament and prayers to the nether powers in the *Choephoroe* (315-478), and the gradual rousing of the slumbering Furies in the *Eumenides* (117-130). The fatal end in these tragedies is foreseen; but the effect is due to its measured advance, to the slowly darkening suspense which no poet has more powerfully rendered. Again, he is a master of contrasts, as when the floating vision of consoling nymphs appears to the tortured Prometheus (115-135); or the unmatched lyrics which tell (in the Agamemnon, 228-247) of the death of Iphigeneia; or the vision of his lost love that the night brings to Menelaus (410-426). And not least noticeable is the extraordinary range, force and imaginativeness of his diction. One example of his lyrics may be given which will illustrate more than one of these points. It is taken from the lament in the *Septem*, sung by the chorus and the two sisters, while following the funeral procession of the princes. (*Sept.* 854-860):—

Nay, with the wafting gale of your sighs, my sisters,
Beat on your heads with your hands the stroke as of oars,
The stroke that passes ever across Acheron,
Speeding on its way the black-robed sacred bark,—
The bark Apollo comes not near,
The bark that is hidden from the sunlight—
To the shore of darkness that welcomes all! (A. S.)

BIBLIOGRAPHY.—*Authorities:* The chief authority for the text is a single ms. at Florence, of the early 11th century, known as the Medicean or M., written by a professional scribe and revised by a contemporary scholar, who corrected the copyist's mistakes, added the scholia, the arguments and the *dramatis personae* of three plays (*Theb.*, *Agam.*, *Eum.*), and at the end of the *Life of Aeschylus* and the *Catalogue of his dramas*. The ms. has also been further corrected by later hands. In 1896 the Italian Ministry of Public Instruction published the ms. in photographic facsimile, with an instructive preface by Signor Rostagno. Besides M. there are some eight later mss. (13th to 15th century), and numerous copies of the three select plays (*Sept.*, *Pers.*, *Prom.*) which were most read in the later Byzantine period. These later mss. are of little value.

Editions.—The three first printed copies (Aldine, 1518; Turnebus and Robortello, 1552) give only those parts of Agamemnon found in M., from which ms. some leaves were lost; in 1557 the full text was restored by Vettori (Victorius) from later mss. After these four, the chief editions of the seven plays were those of Schutz, Porson, Butler, Wellauer, Dindorf, Bothe, Ahrens, Paley, Hermann, Hartung, Weil, Merkel, Kirchoff and Wecklein. Editions of separate plays, special studies, etc. Wilamowitz-Moellendorf, Enger, Conington, Blaydes, Cobet, Meineke, Madvig, Ellis, W. Headlam, Davies, Tucker, Verrall, Haigh and Hoernle. The Fragments have been edited by Nauck and also by Wecklein. The Aeschylean staging is discussed in Albert Müller's *Lehrbuch der griechischen Bühnenalterthümer*; in "Die Bühne des Aeschylus," by Wilamowitz (Hermes, xxi.); in Smith's *Dict. of Antiquities*, art. "Theatrum" (R. C. Jebb); in Dorpfeld and Reisch (Das griechische Theater), Haigh's *Attic Theatre*, and Gardner and Jevons' *Manual of Greek Antiquities*. English verse translations: Agamemnon, Milman and R. Browning; *Oresteia*, Suppliants, Persae, Seven against Thebes, *Prometheus Vincitus*, by E. D. A. Morshead; Prometheus, E. B. Browning; the whole seven plays, Lewis Campbell. *Oresteia* by G. Murray; by R. C. Trevelyan; by G. M. Cookson; prose translation by W. G. and C. E. S. Headlam.

AESCULAPIUS, the Latin form of ASKLEPIOS (Ἄσκληπιος) the name of the Greek god of medicine, the son of Apollo and the nymph Coronis. He probably came from Thessaly. The centaur Cheiron taught him the art of healing. At length Zeus, who, being afraid that he might render all men immortal, slew him with a thunderbolt (Apollodorus iii. 10; Pindar, *Phthia*, 3; Diod. Sic. iv.

71). Homer mentions him as a skilful physician, whose sons, Machaon and Podaleirius, are physicians in the Greek camp before Troy (Iliad, ii. 731). Temples were erected to Asklepios in many parts of Greece, near healing springs or on high mountains. The practice of sleeping (incubatio) in these sanctuaries was very common, it being supposed that the god effected cures or prescribed remedies to the sick in dreams. All who were healed offered sacrifice (especially a cock) and hung up votive tablets, recording their names, their diseases, and the manner in which they had been cured. Many of these tablets have been discovered at Epidaurus, the god's most famous shrine. Herodas (Mimes, 4) gives a description of one of his temples, and of the offerings made to him. The cult of Asklepios was introduced into Rome by order of the Sibylline books (293 B.C.), to avert a pestilence. The god was fetched from Epidaurus in the form of a snake and a temple assigned him on an island in the Tiber (Livy x. 47; Ovid, *Metam.* xv. 622). Asklepios is commonly represented standing, dressed in a long cloak, with bare breast; his usual attribute is a club-like staff with a serpent coiled round it. He is often accompanied by Telesphorus, the boy genius of healing, and his daughter, Hygieia, the goddess of health. Votive reliefs representing such groups have been found near the temple of Asklepios at Athens.

AESERNIA (mod. *Isernia*, Italy), Samnite town 58 mi. N.E. of Beneventum on the road to Corfinium, at the junction of a road past Venafrum to the Via Latina. These routes are all followed by railways to Campobasso, Sulmona and Caianello. A Roman colony from 263 B.C., it became the headquarters of the Italian revolt after the loss of Corfinium, and was only recovered by Sulla at the end of the war, in 80 B.C. Massive ancient walls serve as foundation to modern ones.

AESOP (Gr. *Ἄσωπος*), author of *Fables* about animals, generally with a didactic purpose, which have given their name to a whole class of stories, is supposed to have lived from about 620 to 560 B.C. The place of his birth is uncertain. He was the slave of Iadmon of Samos and met with a violent death at the hands of the inhabitants of Delphi. When a pestilence came upon them, the Delphians offered compensation for his death, and the award was claimed by Iadmon, grandson of his old master. Herodotus, who is authority for this (ii. 134), does not state the cause of Aesop's death; various reasons are assigned by later writers—his insulting sarcasms, the embezzlement of money entrusted to him by Croesus for distribution at Delphi (Schol. Ar. *Vesp.* 1446), the theft of a silver cup.

Aesop must have been freed by Iadmon, or he could not have conducted the public defense of a Samian demagogue (Aristotle, *Rhetoric*, ii. 20). Legend says that he afterwards lived at the court of Croesus, where he met Solon, and dined in the company of the Seven Sages of Greece with Periander at Corinth. But it is impossible to say whether there is any grain of fact in this confused chronology. During the reign of Peisistatius he is said to have visited Athens, on which occasion he related the fable of The Frogs asking for a *King*, to dissuade the citizens from changing Peisistratus for another ruler.

The current stories about him are derived from a life, or rather

romance, prefixed to a book of fables, purporting to be his, collected by Maximus Planudes, a monk of the 14th century. This describes him as ugly and deformed, as he is represented in the marble figure in the Villa Albani at Rome. That this life, however, was in existence a century before Planudes, appears from a 13th-century ms. of it found at Florence. In Plutarch's *Symposium of the Seven Sages*, at which Aesop is a guest, there are jests on his original servile condition, but nothing derogatory is said about his personal appearance. We are further told that the Athenians set up a noble statue of him by Lysippus, which furnishes a strong argument against the fiction of his deformity. The obscurity in which the history of Aesop is involved has induced some scholars to deny his existence altogether.

It is probable that Aesop did not commit his fables to writing (Wasps, 1259; Plato, *Phaedo*, 61 b). Demetrius of Phalerum (345–283 B.C.) made a collection in ten books, probably in prose, which has been lost. Next appeared an edition in elegiac verse, cited by Suidas, but the author's name is unknown. Babrius, a Roman, turned the fables into choliambics in the earlier part of the 3rd century A.D. The most celebrated of the Latin adapters is Phaedrus, a freedman of Augustus. Avianus (of uncertain date, perhaps the 4th century) translated 42 fables into Latin elegiacs. The collections, which we possess under the name of Aesop's *Fables*, are late renderings of Babrius's version, or Babrius was translated into Syriac, and back again into Greek. Ignatius Diaconus, in the 9th century, made a version of 53 fables in choliambic tetrameters. Stories from Oriental sources were added, and from these collections Maximus Planudes made and edited the collection which has come down to us under the name of Aesop, and from which the popular fables of modern Europe have been derived.

BIBLIOGRAPHY.—For further information see the article **FABLE**; Bentley, *Dissertation on the Fables of Aesop*; Du Ménil, *Poésies inédites du moyen âge* (1854); J. Jacobs, *The Fables of Aesop* (1889); i. The history of the Aesopic fable; ii. The Fables of Aesop, as first printed by William Caxton (1484), from his French translation; Hervieux, *Les Fabulistes Latins* (1893–99). Before any Greek text appeared, a Latin translation of 100 *Fabulae Aesopicae* by an Italian scholar named Ranuzio (Renutius) was published at Rome, 1476. About 1480 the collection of Planudes was brought out at Milan by Buono Accorso (Accursius), together with Ranuzio's translation. This edition, which contained 144 fables, was frequently reprinted and additions were made from time to time from various mss.—the Heidelberg (Palatine), Florentine, Vatican and Augsburg—by Stephanus (1547), Nevelet' (1610), Hudson (1718), Hauptmann (1741), Furia (1810), Coray (1810), Schneider (1812) and others. A critical edition of all the previously known fables, prepared by Carl von Halm from the collections of Furia, Coray and Schneider, was published in the Teubner series of Greek and Latin texts. A *Fabularum Aesopiarum sylloge* (233 in number) from a Paris ms., with critical notes by Sternbach, appeared in a Cracow university publication, *Rozprawy akademii umiejtnosci* (1894).

AESOPUS, a Greek historian who wrote a history of Alexander the Great, a Latin translation of which, by Julius Valerius, was discovered by Mai in 1816. He is known as the pseudo-Callisthenes.

(See the references *s.v.* CALLISTHENES.)

AESOPUS, CLODIUS, Roman tragedian, flourished in the first century B.C.

Cicero was on friendly terms with him. Aesopus made a last appearance in 55 B.C.—when Cicero tells us that he was advanced in years—on the occasion of the splendid games given by Pompey at the dedication of his theatre.

Horace (*Sat.* iii. 3. 239) mentions his taking a pearl from the ear-drop of Caecilia Metella and dissolving it in vinegar, that he might have the satisfaction of swallowing eight thousand pounds' worth at a draught.

AESTHETICS. If we examine a poem in order to determine what it is that makes us feel it to be a poem, we at once find two constant and necessary elements: a complex of images, and a *feeling* that animates them. Let us, for instance, recall a passage learnt at school: Virgil's lines (*Aeneid*, iii., 294, *sqq.*), in which Aeneas describes how on hearing that in the country to whose shores he had come the Trojan Helenus was reigning, with Andromache, now his wife, he was overcome with amazement

italica," etc., printed in Venice, March
27, 1492

and a great desire to see this surviving son of Priam and to hear of his strange adventures. Andromache, whom he meets outside the walls of the city, by the waters of a river renamed Simois, celebrating funeral rites before a cenotaph of green turf and two altars to Hector and Astyanax; her astonishment on seeing him, her hesitation, the halting words in which she questions him, uncertain whether he is a man or a ghost; Aeneas's no less agitated replies and interrogations, and the pain and confusion with which she recalls the past—how she lived through scenes of blood and shame, how she was assigned by lot as slave and concubine to Pyrrhus, abandoned by him and united to Helenus, another of his slaves, how Pyrrhus fell by the hand of Orestes and Helenus became a free man and a king; the entry of Aeneas and his men into the city, and their reception by the son of Priam in this little Troy, this mimic Pergamon with its new Xanthus, and its Scaean Gate whose threshold Aeneas greets with a kiss—all these details, and others here omitted, are images of persons, things, attitudes, gestures, sayings, joy and sorrow; mere images, not history or historical criticism, for which they are neither given nor taken. But through them all there runs a feeling, a feeling which is our own no less than the poet's, a human feeling of bitter memories, of shuddering horror, of melancholy, of homesickness, of tenderness, of a kind of childish *pietas* that could prompt this vain revival of things perished, these playthings fashioned by a religious devotion, the *parva Troia*, the Pergama *simulata magnis*, the *arentem Xanthi cognomine rivum*: something inexpressible in logical terms, which only poetry can express in full. Moreover, these two elements may appear as two in a first abstract analysis, but they cannot be regarded as two distinct threads, however intertwined; for, in effect, the feeling is altogether converted into images, into this complex of images, and is thus a feeling that is contemplated and therefore resolved and transcended. Hence poetry must be called neither feeling, nor image, nor yet the sum of the two, but "contemplation of feeling" or "lyrical intuition" or (which is the same thing) "pure intuition"—pure, that is, of all historical and critical reference to the reality or unreality of the images of which it is woven, and apprehending the pure throb of life in its ideality. Doubtless, other things may be found in poetry besides these two elements or moments and the synthesis of the two; but these other things are either present as extraneous elements in a compound (reflections, exhortations, polemics, allegories, etc.), or else they are just these image-feelings themselves taken in abstraction from their context as so much material, restored to the condition in which it was before the act of poetic creation. In the former case, they are non-poetic elements merely interpolated into or attached to the poem; in the latter, they are divested of poetry, rendered unpoetical by a reader either unpoetical or not at the moment poetical, who has dispelled the poetry, either because he cannot live in its ideal realm, or for the legitimate ends of historical enquiry or other practical purposes which involve the degradation—or rather, the conversion—of the poem into a document or an instrument.

Artistic Qualities.—What has been said of "poetry" applies to all the other "arts" commonly enumerated; painting, sculpture, architecture, music. Whenever the artistic quality of any product of the mind is discussed, the dilemma must be faced, that either it is a lyrical intuition, or it is something else, something just as respectable, but not art. If painting (as some theorists have maintained) were the imitation or reproduction of a given object, it would be, not art, but something mechanical and practical; if the task of the painter (as other theorists have held) were to combine lines and lights and colours with ingenious novelty of invention and effect, he would be, not an artist, but an inventor; if music consisted in similar combinations of notes, the paradox of Leibniz and Father Kircher would come true, and a man could write music without being a musician; or alternatively we should have to fear (as Proudhon did for poetry and John Stuart Mill for music) that the possible combinations of words or notes would one day be exhausted, and poetry or music would disappear. As in poetry, so in these other arts, it is notorious that foreign elements sometimes intrude themselves; foreign either *a parte*

objecti or a parte *subjecti*, foreign either in fact or from the point of view of an inartistic spectator or listener. Thus the critics of these arts advise the artist to exclude, or at least not to rely upon, what they call the "literary" elements in painting, sculpture and music, just as the critic of poetry advises the writer to look for "poetry" and not be led astray by mere literature. The reader who understands poetry goes straight to this poetic heart and feels its beat upon his own; where this beat is silent, he denies that poetry is present, whatever and however many other things may take its place, united in the work, and however valuable they may be for skill and wisdom, nobility of intellect, quickness of wit and pleasantness of effect. The reader who does not understand poetry loses his way in pursuit of these other things. He is wrong not because he admires them, but because he thinks he is admiring poetry.

Other Forms of Activity As Distinct from Art.—By defining art as lyrical or pure intuition we have implicitly distinguished it from all other forms of mental production. If such distinctions are made explicit, we obtain the following negations:

1. Art is not philosophy, because philosophy is the logical thinking of the universal categories of being, and art is the unreflective intuition of being. Hence, while philosophy transcends the image and uses it for its own purposes, art lives in it as in a kingdom. It is said that art cannot behave in an irrational manner and cannot ignore logic; and certainly it is neither irrational nor illogical; but its own rationality, its own logic, is a quite different thing from the dialectical logic of the concept, and it was in order to indicate this peculiar and unique character that the name "logic of sense" or "aesthetic" was invented. The not uncommon assertion that art has a logical character, involves either an equivocation between conceptual logic and aesthetic logic, or a symbolic expression of the latter in terms of the former.

2. Art is not history, because history implies the critical distinction between reality and unreality; the reality of the fact and the reality of a fancied world: the reality of action and the reality of desire. For art, these distinctions are as yet unmade; it lives, as we have said, upon pure images. The historical existence of Helenus, Andromache and Aeneas makes no difference to the poetical quality of Virgil's poem. Here, too, an objection has been raised: namely that art is not wholly indifferent to historical criteria, because it obeys the laws of "verisimilitude"; but, here again, "verisimilitude" is only a rather clumsy metaphor for the mutual coherence of images, which without this internal coherence would fail to produce their effect as images, like Horace's delphinus in *silvis* and aper in *fluctibus*.

3. Art is not *natural* science, because natural science is historical fact classified and so made abstract; nor is it mathematical science, because mathematics performs operations with abstractions and does not contemplate. The analogy sometimes drawn between mathematical and poetical creation is based on merely external and generic resemblances; and the alleged necessity of a mathematical or geometrical basis for the arts is only another metaphor, a symbolic expression of the constructive, cohesive and unifying force of the poetic mind building itself a body of images.

4. Art is not the play of fancy, because the play of fancy passes from image to image, in search of variety, rest or diversion, seeking to amuse itself with the likenesses of things that give pleasure or have an emotional and pathetic interest; whereas in art the fancy is so dominated by the single problem of converting chaotic feeling into clear intuition, that we recognize the propriety of ceasing to call it fancy and calling it imagination, poetic imagination or creative imagination. Fancy as such is as far removed from poetry as are the works of Mrs. Radcliffe or Dumas père.

5. Art Is Not Feeling in Its *Immediacy*.—Andromache, on seeing Aeneas, becomes *amens*, dirigit visu in medio, labitur, longo vix tempore fatur, and when she speaks *longos ciebat incassum fletus*; but the poet does not lose his wits or grow stiff as he gazes; he does not totter or weep or cry; he expresses himself in harmonious verses, having made these various perturbations the object of which he sings. Feelings in their immediacy are "expressed"

for if they were not, if they were not also sensible and bodily facts ("psycho-physical phenomena," as the positivists used to call them) they would not be concrete things, and so they would be nothing at all. Andromache expressed herself in the way described above. But "expression" in this sense, even when accompanied by consciousness, is a mere metaphor from "mental" or "aesthetic expression" which alone really expresses, that is, gives to feeling a theoretical form and converts it into words, song and outward shape. This distinction between contemplated feeling, or poetry, and feeling enacted or endured, is the source of the power, ascribed to art, of "liberating us from the passions" and "calming" us (the power of *catharsis*), and of the consequent condemnation, from an aesthetic point of view, of works of art, or parts of them, in which immediate feeling has a place or finds a vent. Hence, too, arises another characteristic of poetic expression—really synonymous with the last—namely its "infinity" as opposed to the "finitude" of immediate feeling or passion; or, as it is also called, the "universal" or "cosmic" character of poetry. Feeling, not crushed but contemplated by the work of poetry, is seen to diffuse itself in widening circles over all the realm of the soul, which is the realm of the universe, echoing and re-echoing endlessly: joy and sorrow, pleasure and pain, energy and lassitude, earnestness and frivolity, and so forth, are linked to each other and lead to each other through infinite shades and gradations; so that the feeling, while preserving its individual physiognomy and its original dominating motive, is not exhausted by or restricted to this original character. A comic image, if it is poetically comic, carries with it something that is not comic, as in the case of Don Quixote or Falstaff; and the image of something terrible is never, in poetry, without an atoning element of loftiness, goodness and love.

6. *Art is not instruction or oratory*: it is not circumscribed and limited by service to any practical purpose whatever, whether this be the inculcation of a particular philosophical, historical or scientific truth, or the advocacy of a particular way of feeling and the action corresponding to it. Oratory at once robs expression of its "infinity" and independence, and, by making it the means to an end, dissolves it in this end. Hence arises what Schiller called the "non-determining" character of art, as opposed to the "determining" character of oratory; and hence the justifiable suspicion of "political poetry"—political poetry being, proverbially, bad poetry.

7. As art is not to be confused with the form of practical action most akin to it, namely instruction and oratory, so *a fortiori*, it must not be confused with other forms directed to the production of certain effects, whether these consist in pleasure, enjoyment and utility, or in goodness and righteousness. We must exclude from art not only meretricious works, but also those inspired by a desire for goodness, as equally, though differently, inartistic and repugnant to lovers of poetry. Flaubert's remark that indecent books lacked *vérité*, is parallel to Voltaire's gibe that certain "poésies sacrées" were really "sacrées, car personne n'y touche."

Art in Its Relations.—The "negations" here made explicit are obviously, from another point of view, "relations"; for the various distinct forms of mental activity cannot be conceived as separate each from the rest and acting in self-supporting isolation. This is not the place to set forth a complete system of the forms or categories of the mind in their order and their dialectic; confining ourselves to art, we must be content to say that the category of art, like every other category, mutually presupposes and is presupposed by all the rest: it is conditioned by them all and conditions them all. How could the aesthetic synthesis, which is poetry, arise, were it not preceded by a state of mental commotion? *Si vis me flere, dolendum est*, and so forth. And what is this state of mind which we have called feeling, but the whole mind, with its past thoughts, volitions and actions, now thinking and desiring and suffering and rejoicing, travailling within itself? Poetry is like a ray of sunlight shining upon this darkness, lending it its own light and making visible the hidden forms of things. Hence it cannot be produced by an empty and dull mind; hence those artists who embrace the creed of pure art or art for

art's sake, and close their hearts to the troubles of life and the cares of thought, are found to be wholly unproductive, or at most rise to the imitation of others or to an impressionism devoid of concentration. Hence the basis of all poetry is human personality, and, since human personality finds its completion in morality, the basis of all poetry is the moral consciousness. Of course this does not mean that the artist must be a profound thinker or an acute critic; nor that he must be a pattern of virtue or a hero; but he must have a share in the world of thought and action which will enable him, either in his own person or by sympathy with others, to live the whole drama of human life. He may sin, lose the purity of his heart, and expose himself, as a practical agent, to blame; but he must have a keen sense of purity and impurity, righteousness and sin, good and evil. He may not be endowed with great practical courage; he may even betray signs of timidity and cowardice; but he must feel the dignity of courage. Many artistic inspirations are due, not to what the artist, as a man, is in practice, but to what he is not, and feels that he ought to be admiring and enjoying the qualities he lacks when he sees them in others. Many, perhaps the finest, pages of heroic and warlike poetry are by men who never had the nerve or the skill to handle a weapon. On the other hand, we are not maintaining that the possession of a moral personality is enough to make a poet or an artist. To be a *vir bonus* does not make a man even an orator, unless he is also *dicendi peritus*. The *sine qua non* of poetry is poetry, that form of theoretical synthesis which we have defined above; the spark of poetical genius without which all the rest is mere fuel, not burning because no fire is at hand to light it. But the figure of the pure poet, the pure artist, the votary of pure Beauty, aloof from contact with humanity, is no real figure but a caricature.

That poetry not only presupposes the other forms of human mental activity but is presupposed by them, is proved by the fact that without the poetic imagination which gives contemplative form to the workings of feeling, intuitive expression to obscure impressions, and thus becomes representations and words, whether spoken or sung or painted or otherwise uttered, logical thought could not arise. Logical thought is not language, but it never exists without language, and it uses the language which poetry has created; by means of concepts, it discerns and dominates the representations of poetry, and it could not dominate them unless they, its future subjects, had first an existence of their own. Further, without the discerning and criticizing activity of thought, action would be impossible; and if action, then good action, the moral consciousness, duty. Every man, however much he may seem to be all logical thinker, critic, scientist, or all absorbed in practical interests or devoted to duty, cherishes at the bottom of his heart his own private store of imagination and poetry; even Faust's pedantic *famulus*, Wagner, confessed that he often had his "grillenhafte Stunden." Had this element been altogether denied him, he would not have been a man, and therefore not even a thinking or acting being. This extreme case is an absurdity; but in proportion as this private store is scanty, we find a certain superficiality and aridity in thought, and a certain coldness in action.

The Science of Art, or Aesthetics, and Its Philosophical Character.—The concept of art expounded above is in a sense the ordinary concept, which appears with greater or less clarity in all statements about art, and is constantly appealed to, explicitly or implicitly, as the fixed point round which all discussions on the subject gravitate: and this, not only nowadays, but at all times, as could be shown by the collection and interpretation of things said by writers, poets, artists, laymen and even the common people. But it is desirable to dispel the illusion that this concept exists as an innate idea, and to replace this by the truth, that it operates as an *a priori* concept. Now an *a priori* concept does not exist by itself, but only in the individual products which it generates. Just as the *a priori* reality called Art, Poetry or Beauty does not exist in a transcendent region where it can be perceived and admired in itself, but only in the innumerable works of poetry, of art and of beauty which it has formed and continues to form, so the logical *a priori* concept of art exists nowhere but in the par-

ticular judgments which it has formed and continues to form, the refutations which it has effected and continues to effect, the demonstrations it makes, the theories it constructs, the problems and groups of problems, which it solves and has solved. The definitions and distinctions and negations and relations expounded above have each its own history, and have been progressively worked out in the course of centuries, and in them we now possess the fruits of this complex and unremitting toil. Aesthetic, or the science of art, has not therefore the task (attributed to it by certain scholastic conceptions) of defining art once for all and deducing from this conception its various doctrines, so as to cover the whole field of aesthetic science; it is only the perpetual systematization, always renewed and always growing, of the problems arising from time to time out of reflection upon art, and is identical with the solutions of the difficulties and the criticisms of the errors which act as stimulus and material to the unceasing progress of thought. This being so, no exposition of aesthetic (especially a summary exposition such as can alone be given here) can claim to deal exhaustively with the innumerable problems which have arisen and may arise in the course of the history of aesthetics; it can only mention and discuss the chief, and among these, by preference, those which still make themselves felt and resist solution in ordinary educated thought; adding an implied "et cetera," so that the reader may pursue the subject according to the criteria set before him, either by going again over old discussions, or by entering into those of to-day, which change and multiply and assume new shapes almost daily. Another warning must not be omitted: namely that aesthetics, though a special philosophical science, having as its principle a special and distinct category of the mind, can never, just because it is philosophical, be detached from the main body of philosophy; for its problems are concerned with the relations between art and the other mental forms, and therefore imply both difference and identity. Aesthetics is really the whole of philosophy, but with special emphasis on that side of it which concerns art. Many have demanded or imagined or desired a self-contained aesthetics, devoid of any general philosophical implications, and consistent with more than one, or with any, philosophy; but the project is impossible of execution because self-contradictory. Even those who promise to expound a naturalistic, inductive, physical, physiological or psychological aesthetics—in a word, a non-philosophical aesthetics—when they pass from promise to performance surreptitiously introduce a general positivistic, naturalistic or even materialistic philosophy. And anyone who thinks that the philosophical ideas of positivism, naturalism and materialism are false and out of date, will find it an easy matter to refute the aesthetic or pseudo-aesthetic doctrines which mutually support them and are supported by them, and will not regard their problems as problems still awaiting solution or worthy of discussion—or, at least, protracted discussion. For instance, the downfall of psychological associationism (or the substitution of mechanism for a *priori* synthesis) implies the downfall not only of logical associationism but of aesthetics also, with its association of "content" and "form," or of two "representations," which (unlike Campanella's *tactus intrinsecus*, effected *cum magna suavitate*) was a *contactus extrinsecus* whose terms were no sooner united than they *discedebant*. The collapse of biological and evolutionary explanations of logical and ethical values implies the same collapse in the case of aesthetic value. The proved inability of empirical methods to yield knowledge of reality, which in fact they can only classify and reduce to types, involves the impossibility of an aesthetics arrived at by collecting aesthetic facts in classes and discovering their laws by induction.

Intuition and Expression.—One of the first problems to arise, when the work of art is defined as "lyrical image," concerns the relation of "intuition" to "expression" and the manner of the transition from the one to the other. At bottom this is the same problem which arises in other parts of philosophy: the problem of inner and outer, of mind and matter, of soul and body, and, in ethics, of intention and will, will and action, and so forth. Thus stated, the problem is insoluble; for once we have divided the inner from the outer, body from mind, will from

action, or intuition from expression, there is no way of passing from one to the other or of reuniting them, unless we appeal for their reunion to a third term, variously represented as God or the Unknowable. Dualism leads necessarily either to transcendence or to agnosticism. But when a problem is found to be insoluble in the terms in which it is stated the only course open is to criticize these terms themselves, to inquire how they have been arrived at, and whether their genesis was logically sound. In this case, such inquiry leads to the conclusion that the terms depend not upon a philosophical principle, but upon an empirical and naturalistic classification, which has created two groups of facts called internal and external respectively (as if internal facts were not also external, and as if an external fact could exist without being also internal), or souls and bodies, or images and expressions; and everyone knows that it is hopeless to try to find a dialectical unity between terms that have been distinguished not philosophically or formally but only empirically and materially. The soul is only a soul in so far as it is a body; the will is only a will in so far as it moves arms and legs, or is action; intuition is only intuition in so far as it is, in that very act, expression. An image that does not express, that is not speech, song, drawing, painting, sculpture or architecture—speech at least murmured to oneself, song at least echoing within one's own breast, line and colour seen in imagination and colouring with its own tint the whole soul and organism—is an image that does not exist. We may assert its existence, but we cannot support our assertion; for the only thing we could adduce in support of it would be the fact that the image was embodied or expressed. This profound philosophical doctrine, the *identity of intuition and expression* is, moreover, a principle of ordinary common sense, which laughs at people who claim to have thoughts they cannot express or to have imagined a great picture which they cannot paint. *Rem tene, verba sequentur*; if there are no *verba*, there is no *res*. This identity, which applies to every sphere of the mind, has in the sphere of art a clearness and self-evidence lacking, perhaps, elsewhere. In the creation of a work of poetry, we are present, as it were, at the mystery of the creation of the world; hence the value of the contribution made by aesthetics to philosophy as a whole, or the conception of the One that is All. Aesthetics, by denying in the life of art an abstract spiritualism and the resulting dualism, prepares the way and leads the mind towards idealism or absolute spiritualism.

Expression and Communication.—Objections to the identity of intuition and expression generally arise from psychological illusions which lead us to believe that we possess at any given moment a profusion of concrete and lively images, when in fact we only possess signs and names for them; or else from faulty analysis of cases like that of the artist who is believed to express mere fragments of a world of images that exists in his mind in its entirety, whereas he really has in his mind only these fragments, together with—not the supposed complete world, but at most an aspiration or obscure working towards it, towards a greater and richer image which may take shape or may not. But these objections also arise from a confusion between *expression* and *communication*, the latter being really distinct from the image and its expression. Communication is the fixation of the intuition-expression upon an object metaphorically called material or physical; in reality, even here we are concerned not with material or physical things but with a mental process. The proof that the so-called physical object is unreal, and its resolution into terms of mind, is primarily of interest for our general philosophical conceptions, and only indirectly for the elucidation of aesthetic questions; hence for brevity's sake we may let the metaphor or symbol stand and speak of matter or nature. It is clear that the poem is complete as soon as the poet has expressed it in words which he repeats to himself. When he comes to repeat them aloud, for others to hear, or looks for someone to learn them by heart and repeat them to others as in a *schola cantorum*, or sets them down in writing or in printing, he has entered upon a new stage, not aesthetic but practical, whose social and cultural importance need not, of course, be insisted upon. So with the painter; he paints on his panel or canvas, but

he could not paint unless at every stage in his work, from the original blur or sketch to the finishing touches, the intuited image, the line and colour painted in his imagination, preceded the brush-stroke. Indeed, when the brush-stroke outruns the image, it is cancelled and replaced by the artist's correction of his own work. The exact line that divides expression from communication is difficult to draw in the concrete case, for in the concrete case the two processes generally alternate rapidly and appear to mingle, but it is clear in idea, and it must be firmly grasped. Through overlooking it, or blurring it through insufficient attention, arise the confusions between *art* and *technique*. Technique is not an intrinsic element of art but has to do precisely with the concept of communication. In general it is a cognition or complex of cognitions disposed and directed to the furtherance of practical action; and, in the case of art, of the practical action which makes objects and instruments for the recording and communicating of works of art; e.g., cognitions concerning the preparation of panels, canvases or walls to be painted, pigments, varnishes, ways of obtaining good pronunciation and declamation and so forth. Technical treatises are not aesthetic treatises, nor yet parts or chapters of them. Provided, that is, that the ideas are rigorously conceived and the words used accurately in relation to them it would not be worth while to pick a quarrel over the use of the word "technique" as a synonym for the artistic work itself, regarded as "inner technique" or the formation of intuition-expressions. The confusion between art and technique is especially beloved by impotent artists, who hope to obtain from practical things and practical devices and inventions the help which their strength does not enable them to give themselves.

Artistic Objects: the Theory of the Special Arts, and the Beauty of Nature.—The work of communicating and conserving artistic images, with the help of technique, produces the material objects metaphorically called "*artistic objects*" or "*works of art*": pictures, sculptures and buildings, and, in a more complicated manner, literary and musical writings, and, in our own times, gramophones and records which make it possible to reproduce voices and sounds. But neither these voices and sounds nor the symbols of writing, sculpture and architecture, are works of art; works of art exist only in the minds that create or recreate them. To remove the appearance of paradox from the truth that beautiful objects, beautiful things, do not exist, it may be opportune to recall the analogous case of economic science, which knows perfectly well that in the sphere of economics there are no naturally or physically *useful* things, but only demand and labour, from which physical things acquire, metaphorically, this epithet. A student of economics who wished to deduce the economic value of things from their physical qualities would be perpetrating a gross *ignoratio elenchi*.

Yet this same *ignoratio elenchi* has been, and still is, committed in aesthetic, by the theory of special *arts*, and the limits or peculiar aesthetic character of each. The divisions between the arts are merely technical or physical, according as the artistic objects consist of physical sounds, notes, coloured objects, carved or modelled objects, or constructed objects having no apparent correspondence with natural bodies (poetry, music, painting, sculpture, architecture, etc.). To ask what is the artistic character of each of these arts, what it can and cannot do, what kinds of images can be expressed in sounds, what in notes, what in colours, what in lines, and so forth, is like asking in economics what things are entitled by their physical qualities to have a value and what are not, and what relative values they are entitled to have; whereas it is clear that physical qualities do not enter into the question, and anything may be desired or demanded or valued more than another, or more than anything else at all, according to circumstances and needs. Even Lessing found himself slipping down the slope leading to this truth, and was forced to such strange conclusions as that actions belonged to poetry and bodies to sculpture; even Richard Wagner attempted to find a place in the list for a comprehensive art, namely Opera, including in itself by a process of aggregation the powers of all the arts. A reader with any artistic sense finds in a single solitary line from a poet at once musical and picturesque qualities, sculptural strength and

architectural structure; and the same with a picture, which is never a mere thing of the eyes but an affair of the whole soul, and exists in the soul not only as colour but as sound and speech. But when we try to grasp these musical or picturesque or other qualities, they elude us and turn into each other, and melt into a unity, however we may be accustomed to distinguish them by different names; a practical proof that art is one and cannot be divided into arts. One, and infinitely varied; not according to the technical conceptions of the several arts, but according to the infinite variety of artistic personalities and their states of mind.

With this relation (and confusion) between artistic creations and instruments of communication or *objets d'art* must be connected the problem of *natural beauty*. We shall not discuss the question, raised by certain aestheticians, whether there are in nature other poets, other artistic beings, beside man; a question which ought to be answered in the affirmative not only out of respect for the song-birds, but, still more, out of respect for the idealistic conception of the world as life and spirituality throughout; even if (as the fairy-tale goes) we have lost the magic herb which when we put it in our mouth, gives us the power of understanding the language of animals and plants. The phrase *natural beauty* properly refers to persons, things and places whose effect is comparable to that of poetry, painting, sculpture and the other arts. There is no difficulty in allowing the existence of such "*natural objets d'art*," for the process of poetic communication may take place by means of objects naturally given as well as by means of objects artificially produced. The lover's imagination creates a woman beautiful to him, and personifies her in Laura; the pilgrim's imagination creates the charming or sublime landscape, and embodies it in the scene of a lake or a mountain; and these creations of theirs are sometimes shared by more or less wide social circles, thus becoming the "*professional beauties*" admired by everyone and the famous "*views*" before which all experience a more or less sincere rapture. No doubt, these creations are mortal; ridicule sometimes kills them, satiety may bring neglect, fashion may replace them by others; and—unlike works of art—they do not admit of authentic interpretation. The bay of Naples, seen from the height of one of the most beautiful Neapolitan villas, was after some time described by the Russian lady who owned the villa as *une cuvette bleue*, whose blue encircled by green so wearied her that she sold the villa. But even the *cuvette bleue* was a legitimate poetical creation.

Literary Kinds and Aesthetic Categories.—Effects at once greater and more detrimental upon the criticism and historical study of art and literature have been produced by a theory of similar but slightly different origin, the theory of *literary and artistic kinds*. This, like the foregoing, is based on a classification in itself justifiable and useful. The foregoing is based on a technical or physical classification of artistic objects; this is based on a classification according to the feelings which form their content or motive, into *tragic, comic, lyrical, heroic, erotic, idyllic, romantic* and so on, with divisions and subdivisions. It is useful in practice to distribute an artist's works, for purposes of publication, into these classes, putting lyrics in one volume, dramas in another, poems in a third and romances in a fourth; and it is convenient, in fact, indispensable, to refer to works and groups of works by these names in speaking and writing of them. But here again we must deny and pronounce illegitimate the transition from these classificatory concepts to the poetic laws of composition and aesthetic criteria of judgment, as when people try to decide that a tragedy must have a subject of a certain kind, characters of a certain kind, a plot of a certain kind and a certain length; and, when confronted by a work, instead of looking for and appraising its own poetry, ask whether it is a tragedy or a poem, and whether it obeys the "*laws*" of one or other "*kind*." The literary criticism of the 19th century owed its great progress largely to its abandonment of the criteria of kinds, in which the criticism of the Renaissance and the French classicists had always been entangled, as may be seen from the discussions arising out of the poems of Dante, Ariosto and Tasso, Guarini's *Pastor fido*, Corneille's *Cid*, and Lope de Vega's *comedias*. Artists have profited by this liberation less than critics; for anyone with

artistic genius bursts the fetters of such servitude, or even makes them the instruments of his power; and the artist with little or no genius turns his very freedom into a new slavery.

It has been thought that the divisions of kinds could be saved by giving them a philosophical significance; or at any rate one such division, that of lyric, epic and dramatic, regarded as the three moments of a process of objectification passing from the lyric, the outpouring of the ego, to the epic, in which the ego detaches its feeling from itself by narrating it, and thence to the drama, in which it allows this feeling to create of itself its own mouthpieces, the *dramatis personae*. But the lyric is not a pouring-forth; it is not a cry or a lament; it is an objectification in which the ego sees itself on the stage, narrates itself, and dramatizes itself; and this lyrical spirit forms the poetry both of epic and of drama, which are therefore distinguished from the lyric only by external signs. A work which is altogether poetry, like *Macbeth* or *Antony and Cleopatra*, is substantially a lyric in which the various tones and successive verses are represented by characters and scenes.

In the old aesthetics, and even to-day in those which perpetuate the type, an important place is given to the so-called categories of beauty: the *sublime*, the *tragic*, the *comic*, the *graceful*, the *humorous* and so forth, which German philosophers not only claimed to treat as philosophical concepts, whereas they are really mere psychological and empirical concepts, but developed by means of that dialectic which belongs only to pure or speculative concepts, philosophical categories. Thus they arranged them in an imaginary progress culminating now in the Beautiful, now in the Tragic, now in the Humorous. Taking these concepts at their face value, we may observe their substantial correspondence with the concepts of the literary and artistic kinds; and this is the source from which, as excerpts from manuals of literature, they have found their way into philosophy. As psychological and empirical concepts, they do not belong to aesthetics; and as a whole, in their common quality, they refer merely to the world of feelings, empirically grouped and classified, which forms the permanent matter of artistic intuition.

Rhetoric, Grammar and Philosophy of Language.— Every error has in it an element of truth, and arises from an arbitrary combination of things which in themselves are legitimate. This principle may be confirmed by an examination of other erroneous doctrines which have been prominent in the past and are still to a less degree prominent to-day. It is perfectly legitimate, in teaching people to write, to make use of distinctions like that between simple style, ornate style and metaphorical style and its forms, and to point out that here the pupil ought to express himself literally and there metaphorically, or that here the metaphor used is incoherent or drawn out to excessive length, and that here the figure of "preterition," there "hypotyposis" or "irony," would have been suitable. But when people lose sight of the merely practical and didactic origin of these distinctions and construct a philosophical theory of form as divisible into simple form and ornate form, logical form and affective form, and so forth, they are introducing elements of rhetoric into aesthetics and vitiating the true concept of expression. For expression is never logical, but always affective, that is, lyrical and imaginative; and hence it is never metaphorical but always "proper"; it is never simple in the sense of lacking elaboration, or ornate in the sense of being loaded with extraneous elements; it is always adorned with itself, *simplex munditiis*. Even logical thought or science, so far as it is expressed, becomes feeling and imagination, which is why a philosophical or historical or scientific book can be not only true but beautiful, and must always be judged not only logically but also aesthetically. Thus we sometimes say that a book is a failure as theory, or criticism, or historical truth, but a success as a work of art, in view of the feeling animating it and expressed in it. As for the element of truth which is obscurely at work in this distinction between logical form and metaphorical form, dialectic and rhetoric, we may detect in it the need of a science of aesthetics side by side with that of logic; but it was a mistake to try to distinguish the two sciences within the sphere of expression which belongs to one of them alone.

Another element in education, namely the teaching of languages, has no less legitimately, ever since ancient times, classified expressions into periods, propositions and words, and words into various species, and each species according to the variations and combinations of roots and suffixes, syllables and letters; and hence have arisen alphabets, grammars and vocabularies, just as in another way for poetry has arisen a science of prosody, and for music and the figurative and architectural arts there have arisen musical and pictorial grammars and so forth. But here, too, the ancients did not succeed in avoiding an illegitimate transition *ab intellectu ad rem*, from abstractions to reality, from the empirical to the philosophical, such as we have already observed elsewhere; and this involved thinking of speech as an aggregation of words, and words as aggregations of syllables or of roots and suffixes; whereas the *prius* is speech itself, a continuum, resembling an organism, and words and syllables and roots are a *posterius*, an anatomical preparation, the product of the abstracting intellect, not the original or real fact. If grammar, like rhetoric in the case above considered, is transplanted into aesthetic, the result is a distinction between expression and the means of expression, which is a mere reduplication; for the means of expression are just expression itself, broken into pieces by grammarians. This error, combined with the error of distinguishing between simple and ornate form, has prevented people from seeing that the philosophy of language is not a philosophical grammar, but is wholly devoid of grammatical elements. It does not raise grammatical classifications to a philosophical level; it ignores them, and, when they get in its way, destroys them. The philosophy of language, in a word, is identical with the philosophy of poetry and art, the science of intuition-expression, aesthetics; which embraces language in its whole extension, passing beyond the limits of phonetic and syllabic language, and in its unimpaird reality as living and completely significant expression.

Classical and Romantic.— The problems reviewed above belong to the past—a past extending through centuries—rather than to the present; of their mis-stated questions and misconceived solutions there now remain mere relics and superstitions which affect academic treatises more than they do the consciousness and culture of ordinary people. But it is necessary to watch carefully for new shoots from the old stock, which still appear from time to time, in order to cut them down. Such is, in our own time, the theory of styles applied to the history of art (Wolfflin and others) and extended to the history of poetry (Strick and others), a new irruption of rhetorical abstractions into the judgment and history of works of art. But the chief problem of our time, to be overcome by aesthetics, is connected with the crisis in art and in judgments upon art produced by the romantic period. Not that this crisis was not foreshadowed by precedents and parallels in earlier history, like Alexandrian art and that of the late Roman period, and in modern times the Baroque art and poetry which followed upon that of the Renaissance. The crisis of the romantic period, together with sources and characteristics peculiar to itself, had a magnitude all of its own. It asserted an antithesis between *naïve* and *sentimental* poetry, *classical* and *romantic* art, and thus denied the unity of art and asserted a duality of two fundamentally different arts, of which it took the side of the second, as that appropriate to the modern age, by upholding the primary importance in art of feeling, passion and fancy. In part this was a justifiable reaction against the rationalistic literature of classicism in the French manner, now satirical, now frivolous, weak in feeling and imagination and deficient in a deep poetic sense; but in part, *romanticism* was a rebellion not against *classicism* but against the classical as such: against the ides of the serenity and infinity of the artistic image, against catharsis and in favour of a turbid emotionalism that could not and would not undergo purification. This was very well understood by Goethe, the poet both of passion and of serenity, and therefore, because he was a poet, a classical poet; who opposed romantic poetry as "hospital poetry." Later, it was thought that the disease had run its course and that romanticism was a thing of the past; but though some of its contents and some of its forms were dead, its soul was not: its soul consisting in this tendency on the part of art towards

an immediate expression of passions and impressions. Hence it changed its name but went on living and working. It called itself "realism," "verism," "symbolism," "artistic style," "impressionism," "sensualism," "imagism," "decadentism," and nowadays, in its extreme forms, "expressionism" and "futurism." The very conception of art is attacked by these doctrines, which tend to replace it by the conception of one or other kind of non-art; and the statement that they are fighting against art is confirmed by the hatred of the extremists of this movement for museums and libraries and all the art of the past—that is, for the idea of art which on the whole corresponds with art as it has been historically realized. The connection of this movement, in its latest modern form, with industrialism and the psychology produced and fostered by industrialism is obvious. What art is contrasted with is practical life as lived to-day; and art, for this movement, is not the expression of life and hence the transcending of life in the contemplation of the infinite and universal, but the cries and gesticulations and broken colours of life itself. The real poets and artists, on the other hand, rare at any time, naturally continue, nowadays as always, to work according to the old and only idea of what art is, expressing their feelings in harmonious forms; and the real connoisseurs (rarer, these also, than people think) continue to judge their work according to this same idea. In spite of this, the tendency to destroy the idea of art is a characteristic of our age; and this tendency is based on the *proton pseudos* which confuses mental or aesthetic expression with natural or practical expression—the expression which passes confusedly from sensation to sensation and is a mere effect of sensation, with the expression which art elaborates, as it builds, draws, colours or models, and which is its beautiful creation. The problem for aesthetics to-day is the reassertion and defence of the classical as against romanticism: the synthetic, formal theoretical element which is the *proprium* of art, as against the affective element which it is the business of art to resolve into itself, but which to-day has turned against it and threatens to displace it. Against the inexhaustible fertility of creative mind, the gates of hell shall not prevail; but the hostility which endeavours to make them prevail is disturbing, even if only in an incidental manner, the artistic taste, the artistic life and consequently the intellectual and moral life of to-day.

The Criticism and History of Art and Literature.—Another group of questions raised in works on aesthetics, though not unsuitable to such works, properly belongs to logic and the theory of historical thought. These concern the aesthetic judgment and the history of poetry and the arts. By showing that the aesthetic activity (or art) is one of the forms of mind, a value, a category, or whatever we choose to call it, and not (as philosophers of various schools have thought) an empirical concept referable to certain orders of utilitarian or mixed facts, by establishing the *autonomy of aesthetic value*, aesthetics has also shown that it is the predicate of a special judgment, the *aesthetic judgment*, and the subject-matter of history, of a special history, the history of poetry and the arts, *artistic and literary history*.

The questions that have been raised concerning the aesthetic judgment and artistic and literary history are making allowance for the peculiar character of art, identical with the methodological questions that arise in every field of historical study. It has been asked whether the aesthetic judgment is *absolute* or *relative*; but every historical judgment (and the aesthetic judgment affirming the reality and quality of aesthetic facts is an historical judgment) is always both absolute and relative at once: absolute, in so far as the category involved in the construction possesses universal truth; relative, in so far as the object constructed by that category is historically conditioned: hence in the historical judgment the category is individualized and the individual becomes absolute. Those who in the past have denied the absoluteness of the aesthetic judgment (sensationalistic, hedonistic or utilitarian aestheticians) denied in effect the quality, reality and autonomy of art. It has been asked whether a knowledge of the history of the time—the whole history of the time in question—is necessary for the aesthetic judgment of the art of that time; it certainly is, because, as we know, poetic creation presupposes

all the rest of the mind which it is converting into lyrical imagery, and the one aesthetic creation presupposes all the other creations (passions, feelings, customs, etc.) of the given historical moment. Hence may be seen the error both of those who advocate a merely historical judgment upon art (historical critics) and of those who advocate a merely aesthetic (aesthetic critics). The former would find in art all the rest of history (social conditions, biography of the artist, etc.), but would omit that part which is proper to art; the latter would judge the work of art in abstraction from history, depriving it of its real meaning and giving it an imaginary meaning or testing it by arbitrary standards. Lastly, there has appeared a kind of scepticism or pessimism as to the possibility of understanding the art of the past; a scepticism or pessimism which in that case ought to extend to every part of history (history of thought, politics, religion and morality), and refutes itself by a *reductio ad absurdum*, since what we call contemporary art and history really belong to the past as much as those of more distant ages, and must, like them, be re-created in the present, in the mind that feels them and the intellect that understands them. There are artistic works and periods that remain to us unintelligible; but this only means that we are not now in a position to enter again into their life and to understand them, and the same is true of the ideas and customs and actions of many peoples and ages. Humanity, like the individual, remembers some things and forgets many others; but it may yet, in the course of its mental development, reach a point where its memory of them revives.

A final question concerns the form proper to artistic and literary history, which, in the form that arose in the romantic period, and still prevails to-day, expounds the history of works of art as a function of the concepts and social needs of its various periods, regarding them as aesthetic expressions of these things and connecting them closely with civil history. This tends to obscure and almost to render invisible the peculiar character of the individual work of art, the character which makes it impossible to confuse one work of art with any other, and results in treating them as documents of social life. In practice no doubt this method is tempered by what may be called the "individualizing" method, which emphasizes the individual character of the works; but the mixture has the defects of all eclecticism. To escape this, there is nothing to do but consistently to develop individualizing history, and to treat works of art not in relation to social history but as each a world in itself, into which from time to time the whole of history is concentrated, transfigured and imaginatively transcended in the individuality of the poetic work, which is a creation, not a reflection, a monument, not a document. Dante is not simply a document of the middle ages, nor Shakespeare of the English Renaissance; as such, they have many equals or superiors among bad poets and non-poets. It has been objected that this method imposed on artistic and literary history the form of a series of disconnected essays or monographs; but, obviously, the connection is provided by human history as a whole, of which the personalities of poets constitute a part, and a somewhat conspicuous part (Shakespearian poetry is an event no less important than the Reformation or the French Revolution), and, precisely because they are a part of it, they ought not to be submerged and lost in it, that is, in its other parts, but ought to retain their proper proportions and their original character.

History of Aesthetics.—From the character of aesthetics as a philosophical science (*see* above) it follows that its history cannot be separated from that of philosophy at large, from which aesthetics receives light and guidance, and gives back light and guidance in its turn. The so-called subjectivist tendency which modern philosophy acquired with Descartes, for instance, by promoting enquiry into the creative power of the mind, indirectly promoted enquiry into the aesthetic power; and conversely, as an example of the influence of aesthetic on the rest of philosophy, it is enough to recall the effect which the mature consciousness of creative imagination and poetic logic had in liberating philosophical logic from the traditional intellectualism and formalism, and raising it to the level of speculative or dialectical logic in

the philosophies of Schelling and Hegel. But if the history of aesthetics must be seen as a part of the entire history of philosophy, it must on the other hand be enlarged-beyond its boundaries as ordinarily defined, which would restrict it almost entirely to the series of works by so-called professional philosophers and of the academic treatises known as "systems of philosophy." Genuine and original philosophical thought is often to be found, alive and energetic in books not written by professional philosophers and not outwardly systematic; ethical thought, in works of asceticism and religion; political, in the works of historians; aesthetic, in those of art-critics, and so forth. Further, it must be remembered that, strictly speaking, the subject-matter of the history of aesthetics is not the problem, the single problem, of the definition of art, a problem exhausted when that definition has been or shall have been attained; but the innumerable problems which are perpetually springing up in connection with art, in which this one problem, the problem of defining art, acquires particularity and concreteness, and in which alone it truly exists. Subject to these warnings, which must be carefully borne in mind, a general sketch of the history of aesthetics may be given, to provide a preliminary orientation, without running the risk of being understood in an unduly rigid and simplifactory manner.

A sketch of this kind must accept, not merely as convenient for purposes of exposition but as historically true, the common statement that aesthetics is a modern science. Graeco-Roman antiquity did not speculate about art, or speculated very little; its chief concern was to create a method of artistic instruction, not a "philosophy" but an "empirical science" of art. Such are the ancient treatises on "grammar," "rhetoric," "institutions of oratory," "architecture," "music," "painting" and "sculpture"; the basis of all later methods of instruction, even those of to-day, in which the old principles are restated and interpreted *cum grano salis*, but not abandoned, because in practice they are indispensable. The philosophy of art did not find favourable or stimulating conditions in ancient philosophy, which was primarily "physics" and "metaphysics," and only secondarily and intermittently "psychology" or more precisely "philosophy of mind." To the philosophical problems of aesthetics it only referred in passing, either negatively, in Plato's denial of the value of poetry, or positively, in Aristotle's defence, which attempted to secure for poetry a realm of its own between that of history and that of philosophy, or again in the speculations of Plotinus, who for the first time united the previously disconnected concepts of "art" and "the beautiful." Other important thoughts of the ancients were that to poetry belonged "tales" (*μῦθοι*) and not "arguments" (*λόγοι*), and that "semantic" (rhetorical or poetical) propositions were to be distinguished from "apophantic" (logical). Lately an almost wholly unexpected strain of ancient aesthetic thought has come to light, in the Epicurean doctrines expounded by Philodemus, in which imagination is conceived in what seems almost a romantic way. But these observations remained, for the time being, practically sterile; and the ancients' firm and sure judgment in artistic matters was never raised to the level and consistency of a theory, owing to an obstacle of a general nature—the objectivistic or naturalistic character of ancient philosophy, whose removal was only commenced, or demanded, by Christianity when it brought the problems of the soul into the focus of thought.

But even Christian philosophy, partly through its predominant transcendence, mysticism and asceticism, partly through the scholastic form which it borrowed from ancient philosophy and with which it remained content, while it raised the problems of morality in an acute form, and handled them with delicacy, did not penetrate deeply into the mental region of imagination and taste, just as it avoided the region which corresponds to it in the sphere of practice, the region of passions, interests, utility, politics and economics. Just as politics and economics were conceived moralistically, so art was subordinated to moral and religious allegory; and the germs of aesthetics scattered through the ancient writers were forgotten or only superficially remembered. The philosophy of the Renaissance, with its return to naturalism, revived, interpreted and adapted the ancient poetics

and rhetorics and treatises on the arts; but though it laboured long at "verisimilitude" and "truth," "imitation" and "the idea," "beauty" and the mystical theory of beauty and love, ('catharsis" or the purgation of passion, and the problems of the literary kinds, traditional and modern, it never reached a new and fruitful principle. No thinker arose capable of doing for the Renaissance treatises on poetry and art what Machiavelli did for political science, Asserting with emphasis, not merely by the way and as an admission, its original and autonomous character.

Much more important in this respect, though its importance was long overlooked by historians, was the thought of the later Renaissance, known in Italy as the *seicento*, Baroque, or the literary and artistic decadence. This was the time at which the distinction was first insisted upon between the "intellect" and a faculty called *ingegno, ingenium*, "wit" or "genius," as especially inventive of art; and, corresponding to this, a faculty of judgment, which was not ratiocination or logical judgment, because it judged "without discourse" or "without concepts," and came to be called "taste." These terms were reinforced by another, which appeared to denote something not determinable in logical concepts and in some way mysterious: "*nescio quid*" or "*je ne sais quoi*"; an expression particularly frequent in Italy (non so che), and imitated in other countries. At the same time were sung the praises of the enchantress "imagination," of the "sensible" or "sensuous" element in poetic imagery, and of the miracles of "colour," in painting, as opposed to "drawing" which seemed not altogether free from an element of cold logic. These new intellectual tendencies were somewhat turbid, but at times were purified and raised to the level of reasoned theory, e.g., Zuccolo (1623), who criticized "metric art" and replaced its criteria by the "judgment of sense," which to him meant not the eye or the ear but a higher power united to the senses; Mascardi (1636), who rejected the objective and rhetorical distinction between the styles, and reduced style to the particular individual manner arising out of the particular "wit" of each writer, thus asserting the existence of as many styles as there are writers; Pallavicino (1644), who criticized "verisimilitude" and assigned to poetry as its proper domain that of "first apprehensions" or imaginations, "neither true nor false"; and Tesauro (1654), who tried to work out a logic of rhetoric as opposed to the logic of dialectic, and extended the rhetorical forms beyond merely verbal form, to pictorial and plastic form.

Cartesianism, to which we have already referred, though, in the hands of Descartes and his successors, hostile to poetry and imagination, from another point of view, as stimulating enquiry into the subject or the mind, helped these scattered efforts (as we have said) to consolidate themselves into a system and to search for a principle to which the arts could be reduced; and here too the Italians, welcoming Descartes' method but not his rigid intellectualism or his contempt for poetry, art and imagination, wrote the first treatises on poetry in which the concept of imagination played a central or leading part (Calopreso 1691, Gravina 1692 and 1708, Muratori 1704 and others). These had considerable influence on Bodmer and the Swiss school, and, through them, on the new German criticism and aesthetics and that of Europe at large; so that a recent writer (Robertson) could speak of "the Italian origin of romantic aesthetics."

These minor theorists led to the work of G. B. Vico, who in his *Scienza nuova* (1725-1730) propounded a "poetic logic" which he distinguished from "intellectual logic"; regarded poetry as a mode of consciousness or theoretic form preceding the philosophical or reasoning form, and asserted as its sole principle the imagination, which is strong in proportion as it is free from ratiocination, its enemy and destroyer; praised as father and prince of all true poets the barbaric Homer, and with him, though impaired by theological and scholastic culture, the half-barbaric Dante; and attempted, though without success, to discern English tragedy and Shakespeare, who, though undiscovered by Vico, would, had he known him, certainly have been his third barbaric and supreme poet. But in aesthetics as elsewhere, Vico in his lifetime founded no school, because he was before his time, and also because his philosophical thought was concealed

beneath a kind of historical symbolism. "Poetic logic" only began to make progress when it reappeared in a far less profound shape, but in a more favourable environment, in the works of Baumgarten, who systematized an aesthetics of a somewhat hybrid Leibnizian origin, and gave it various names, including *ars analogi rationis*, *scientia cognitionis sensitivae*, *gnoseologia inferior*, and the name it has retained, *aesthetica* (*Meditationes*, 1735; *Aesthetics*, 1750-58).

The school of Baumgarten, or (more correctly) of Leibnitz, which both did and did not distinguish imaginative from logical form (for it regarded it as *cognitio confusa* and none the less ascribed to it a *perfectio* of its own), and the current of English aesthetics (Shaftesbury, Hutcheson, Hume, Home, Gerard, Burke, Alison, etc.), together with the essays on beauty and art which abounded at this time, and the theoretical and historical works of Lessing and Winckelmann, contributed to provide the stimulus, partly positive and partly negative, to the formation of the other masterpiece of 18th century aesthetics, the *Critique of Judgment* (1790) by Immanuel Kant, in which the author (after doubting it in the first *Crizque*) discovered that beauty and art afford subject-matter for a special philosophical science—in other words, discovered the autonomy of the aesthetic activity. As against the utilitarians he showed that the beautiful pleases "without interest" (*i.e.*, utilitarian interest); against the intellectualists, that it pleases "without concepts"; and further, against both, that it has "the form of purposiveness" without "representation of a purpose"; and, against the hedonists, that it is "the object of a universal pleasure." In substance, Kant never went further than this negative and generic assertion of the beautiful, just as, in the *Critique of Practical Reason*, once he had vindicated the moral law, he did not go beyond the generic form of duty. But the principles he had laid down were laid down once for all. After the *Critique of Judgment*, a return to hedonistic and utilitarian explanations of art and beauty could (and did) take place only through ignorance of Kant's demonstrations. Even the return to Leibnitz and Baumgarten's theory of art as confused or fanciful thinking would have been impossible, had Kant been able to link up his own theory of the beautiful, as pleasing apart from concepts, and as purposiveness without representation of purpose, with Vico's imperfect and inconsistent but powerful theory of the logic of imagination, which was to some extent represented in Germany at this time by Hamann and Herder. But Kant himself prepared the way for the reassertion of the "confused concept" when he ascribed to genius the virtue of combining intellect and fancy, and distinguished art from "pure beauty" by defining it as "adherent beauty."

This return to the tradition of Baumgarten is apparent in post-Kantian philosophy when it regards poetry and art as a form of the knowledge of the Absolute or the Idea, whether equal to philosophy, inferior and preparatory to it, or superior to it as in Schelling's philosophy (1800) where it becomes the organ of the Absolute. In the richest and most striking work of this school, the *Lectures on Aesthetic* of Hegel (1765-1831), art, with religion and philosophy, is placed in the "sphere of absolute mind," where the mind is set free from empirical knowledge and practical action, and enjoys the beatific thought of God or the Idea. It remains doubtful whether the first moment in this triad is art or religion; different expositions of his doctrine by Hegel himself differ in this respect; but it is clear that both, art and religion alike, are at once transcended and included in the final synthesis which is philosophy. This means that art, like religion, is substantially an inferior or imperfect philosophy, a philosophy expressed in imagery, a contradiction between a content and a form inadequate to it which only philosophy can resolve. Hegel, who tended to identify the system of philosophy, the dialectic of concepts, with actual history, expressed this by his famous paradox of the death of art in the modern world, as incapable of subserving the highest interests of the age.

This conception of art as philosophy, or intuitive philosophy, or a symbol of philosophy, or the like, reappears throughout the idealistic aesthetics of the first half of the 19th century, with rare exceptions, *e.g.*, Schleiermacher's *Lectures on Aesthetic* (1825, 1832-33) which we possess in a very incomplete form. In spite of the high merit of these works, and the enthusiasm for poetry and art which they express, the reaction against this type of aesthetics was, at bottom, a reaction against the artificial character of the principle on which they were based. This reaction took place in the second half of the century, simultaneously with the general reaction against the idealistic philosophy of the great post-Kantian systems. This anti-philosophical movement certainly had its significance as a symptom of discontent and of a desire to find new paths; but it did not produce an aesthetics correcting the errors of its predecessors and carrying the problem a stage further. In part, it was a breach in the continuity of thought; in part, a hopeless attempt to solve the problems of aesthetics, which are philosophical problems, by the methods of empirical science (*e.g.*, Fechner); in part, a revival of hedonistic and utilitarian aesthetic by a utilitarianism resting on association of ideas, evolution and a biological theory of heredity (*e.g.*, Spencer). Nothing of real value was

added by the *epigoni* of idealism (Vischer, Schasler, Carriere, Lotze, etc.), or the followers of the other early 19th century philosophical movements, *e.g.*, the so-called formalistic aesthetics (Zimmermann) derived from Herbart, or the eclectics and psychologists, who, like all the rest, laboured at two abstractions, "content" and "form" ("aesthetics of content" and "aesthetics of form"), and sometimes tried to fasten the two together, failing to see that by so doing they were only uniting two fictions into a third. The best thoughts on art in this period are to be found not in the professional philosophers or aestheticians but in the critics of poetry and art, *e.g.*, De Sanctis in Italy, Baudelaire and Flaubert in France, Pater in England, Hanslick and Fiedler in Germany, Julius Lange in Holland, etc. These writers alone make amends for the aesthetic trivialities of the positivistic philosophers and the empty artificiality of the so-called idealists.

The general revival of speculative thought led to greater successes in aesthetics in the first decades of the 20th century. Especially noteworthy is the union which is taking place between aesthetics and the philosophy of language, facilitated by the difficulties under which linguistic, conceived as the naturalistic and positivistic science of the phonetic laws of language and similar abstractions, is labouring. But the most recent aesthetic productions, because they are recent and still in process of development, cannot as yet be historically placed and judged.

BIBLIOGRAPHY.—The chief monuments of aesthetic thought have already been referred to in the foregoing outline. It may be added that the latest revision of the text of Aristotle's *Poetics*, together with a commentary, is that of A. Rostagni (Turin, 1927), and that the fragments of the Epicurean aesthetic of Philodemus (polemic against Neoptolemus of Parium) have been edited by Jensen (*Philodemus über die Gedichte Funftes Buch*, Berlin, 1923). Of Vico's second *Scienza nuova* the complete critical edition is that of F. Nicolini (Bari, 1911-16). Of Baumgarten, there is a reprint of the *Meditationes philosophicae de nonnullis ad poema pertinentibus* (1735), edited by Croce, Naples, 1900; but the *Aesthetica*, a very rare book, has unfortunately not been reprinted, though a previously unpublished course of Baumgarten's lectures on aesthetics has been published by B. Poppe (*A. G. Baumgarten: Berne-Leipzig, 1907*). Of Hegel's *Vorlesungen über die Aesthetik*, which we possess in Hotho's redaction (ed. 2, Berlin, 1842-43).

For the history of aesthetics, R. Zimmermann, *Geschichte der Aesthetik als philosophischer Wissenschaft* (Wien, 1858), and M. Schasler, *Kritische Geschichte der Aesthetik* (Berlin, 1872), may be consulted, though their standards of judgment are now out of date. See also B. Bosanquet, *A History of Aesthetic* (London, 1892). A history of aesthetics is contained in the second part of B. Croce's *Estetica come scienza dell' espressione e linguistica generale* (Bari, 1902; ed. 5, 1922; Eng. trans., abridged, London, 1913; 2nd ed., complete, 1922), and an essay completing and correcting this work, entitled *Inizio, periodi e caratteri della Estetica*, in the same author's *Nuovi saggi di Estetica* (ed. 2, Bari, 1926), which contains the most mature form of the writer's theoretical and historical thought on the subject. For ancient aesthetics Ed. Muller, *Geschichte der Theorie der Kunst bei den Alten* (Breslau, 1831-37), is still very useful; among recent works, E. Panovski, *Idea* (Leipzig, 1924), and A. Rostagni, "Per un' estetica dell' intuizione presso gli antichi" (in *Atene e Roma*, a review of classical philology, Florence, 1920); *Aristotele e l'aristotelismo nella storia dell' Estetica antica* (Florence, 1921). For mediaeval aesthetics the best work is contained in books on Dante, *e.g.*, Vossler's; *cf.* also Compagnoni, *Virgilio nel medio evo* (ed. 2, Florence, 1896) vol. i. For Renaissance aesthetics, J. E. Spingarn, *A History of Literary Criticism in the Renaissance* (New York, 1899); K. Borinski, *Die Poetik der Renaissance und die Anfänge der literarischen Kritik in Deutschland* (Berlin, 1896). For the Italian *seicento*, Croce, *Storia, cit.*, and essays in *Problemi di Estetica* (ed. 2, Bari, 1923) and *Storia dell' età barocca in Italia* (Bari, 1928); J. M. Robertson, *Studies in the Genesis of Romantic Theory* (London, 1923); H. Quigley, *Italy and the Rise of a New School of Criticism in the 18th Century* (Glasgow, 1921). For Vico's aesthetics, B. Croce, *La filosofia di G. B. Vico* (ed. 2, Bari, 1922; Eng. trans. London, 1913). For German 18th century aesthetics, R. Sommer, *Grundzüge einer Geschichte der deutschen Psychologie und Aesthetik von Wolf-Baumgarten bis Kant-Schiller* (Würzburg, 1892). For the origin of Kant's aesthetics, O. Schlapppe, *Kants Lehre vom Genie und die Entstehung der Kritik der Urtheilskraft* (Göttingen, 1901). For that of Schiller, V. Basch, *La poétique de Schiller* (ed. 2, Paris, 1911). For the Hegelian aesthetics the old but penetrating study of Th. W. Danzel, *Über die Aesthetik des hegelischen Philosophie* (Hamburg, 1844), must not be forgotten. For English aesthetics, A. E. Powell (Mrs. Dodds), *The Romantic Theory of Poetry* (London, 1926). For the *Epigoni* of idealism, E. v. Hartmann (who was one of them), *Die deutsche Aesthetik seit Kant* (Berlin, 1886). For recent aesthetics: H. Wildon Carr, *The Philosophy of B. Croce: The Problem of Art and History* (1917); E. F. Carritt, *The Theory of Beauty* (ed. 2, London, 1923); R. G. Collingwood, *Outlines of a Philosophy of Art* (1925). For the history of the philosophy of language in the idealistic period (Hamann, Herder, Humboldt) *cf.* H. Steinthal, *Ursprung der Sprache* (ed. 4, Berlin, 1888); *Geschichte der Sprachwissenschaft bei den Griechen und Römern* (ed. 2, Berlin, 1890-1891). For recent philosophy of language as aesthetics, Croce, *opp. cit.*, and Vossler, Spitzer, Lersch, Bertoni, Bartoli, etc. (B. CR.)

AESTHETICS, EXPERIMENTAL. Great artists throughout the centuries have contributed to an empirical aesthetic in the broad sense of the term. Some of them have given us extensive treatises based upon an analysis of their own methods of artistic production, or upon an investigation of existing works of art. Hogarth, for example, examined many forms of architecture, as well as the lines of the human figure, in a search for a norm of beauty which he thought he had found in the serpentine line, and Goethe in his *Farbenlehre* has made keen observations in regard to the aesthetics of colour. From the long list of names might also be mentioned Leonardo da Vinci, Sir Joshua Reynolds and M. E. Chevreul. G. Th. Fechner, however, is generally considered the founder of experimental aesthetics. He not only discussed the formal, or direct, and the associative factors underlying beauty on the basis of his experience of works of art, but he devised experiments in order to settle scientifically the question of the most pleasing proportions in geometrical forms and in line division. This problem had engaged the attention of a number of writers, whose results are in strong disagreement. Wolff insisted upon the proportion of 1:1, while Adolf Zeising thought the proportion of the golden section (1:1.618) to be the most pleasing, on the principle that it gives the greatest possible diversity in a harmonious unity. It was the proportion of the golden section that Fechner desired to put to experimental proof. He spread figures of different sizes, such as ellipses, before the observer, with instructions to choose the one which seemed the most pleasing or he had the person construct a figure according to the most pleasing proportion. It was these two methods of choice and construction, together with that of use, which he proposed as the proper empirical methods of investigation, and these methods have continued to be employed up to the present day. Fechner found the golden section to hold in many instances, but he also found the proportions of 1:1 and 1:3 to be pleasing under certain circumstances. Lightner Witmer thought that Fechner used too few figures, and that the experiments were not properly controlled. He therefore used a serial order of figures with the least perceptible difference of proportion between them. He also had the figures compared in pairs. His results do not always agree with those of Fechner, but he established the importance of the golden section for rectangles, ellipses and line division. An interesting fact came to light in experiments conducted by R. P. Angier. His subjects divided a line at what seemed to them the most pleasing point. Although several persons came near the golden section, no one actually chose it. Nevertheless, the average of all observers was almost exactly the golden section. His results served as a warning not to place too much weight upon averages in the search for an aesthetic norm. In general, however, it may be said that the golden section and symmetry are pleasing, that a division very near the middle and one which makes the shorter line less than a quarter of the length of the whole line are displeasing.

Numerous experiments have been made upon form and balance, with the principal aim of obtaining a psychological explanation of the pleasing effects. T. H. Haines and A. E. Davies, from their work with a series of cards having a constant length and varying width, decided that eye-movements, associations, balance between forces of attention, and suggestion, were the factors which determined the aesthetic effect. Ethel D. Puffer made an extensive study of balance by the use, among other objects, of lines of various sizes and in various positions. She found that the best aesthetic balance generally corresponded to the mechanical balance, and explained the results in terms of interest which, in the last analysis, meant for her a balance of motor impulses. L. J. Martin asserted that our preference for lines and shapes depends very much upon our attitude toward the objects we are judging. A slanting line, when interpreted as a bad vertical, is displeasing, but when we think of it as a horizontal line which is raising itself to a vertical, it is pleasing. F. Sander believes that absence of feelings of tension produces a restful effect such as is experienced in viewing Greek architecture, while vivid tensions underlie our reactions to Romanesque and Gothic architecture.

The theory of empathy made famous by Th. Lipps has also been offered frequently as an explanation of the aesthetic feelings aroused by lines, forms and other properties of art objects. A modern psychological interpretation of this theory is that the individual imitates in terms of his own reactions the patterns suggested by the art object. These reactions are projected by the individual into the external object and are perceived not as his own but as the dynamic qualities of the object. Experiments furnish some support for this theory of empathy in that implicit or nascent muscular activity related to the stimulus-situation has been detected during the act of perception.

The empathic value of lines in expressing emotional moods has been demonstrated in experiments in which subjects have been asked to draw lines indicative of emotional states and qualities or in which they have been asked to match various types of lines with descriptive adjectives. The agreement concerning the expressiveness of lines is much greater than chance expectation. For example, moods with little motor expression such as sadness and quietness are represented in the subject's drawings by wide sweeping curves whereas moods of excitement are represented by sharp curves and acute angles. Investigations of the ability of children to approximate adult judgment in this field show that even kindergarten pupils do better than chance, that there is a positive correlation between this ability and age and that artistic children do better than non-artistic children. The early recognition of the expressive qualities of pure lines argues against an associational explanation and suggests an empathic basis in the type of bodily response occurring in a given emotional condition.

The modern trend, however, is to emphasize the relationship of the line to the form of which it is a part, or the relationship of the figure to the total pattern in which it appears. As early as 1903 Legowski concluded from his experiments on preferences for the same type of figures of varying proportions that the comprehensibility of the relationships was the cause of their pleasantness. More recently Birkhoff has studied form preference and used as a measure of aesthetic pleasure the relation between order and complexity. The elaborations of his basic formula, $M = \frac{O}{C}$ (M = aesthetic measure, O = order and C = complexity) are not as objective as their mathematical expression might suggest, but Birkhoff's results do indicate that the degree of pleasure is related to ability to resolve complex relationships into a unified pattern—a very old aesthetic doctrine.

Colour.—Goethe in his *Farbenlehre* discussed the moods aroused by colours, and the different psychological effects of different colour combinations. Chevreul studied colours from the aesthetic standpoint, and remarked that complementary colours form the most pleasing combinations, as there is a harmony in the contrast, and half a century later Bezold stated that the colours which are very nearly, but not quite, complementary form the best combinations. Towards the end of the last century, Jonas Cohn and August Kirschmann performed controlled experiments on colour in the manner advocated by Fechner. Both men found contrast to be pleasing, and Cohn's results led him to conclude that saturated colours are in most instances preferred. From about this time the number of treatises on colour preferences began to grow rapidly, and the papers have covered a large field of investigation. The effects of hue, saturation and brightness, together with such factors underlying preference as the time of exposure of the colours, suggestion and association, have been studied. A large number of treatises deal with the colour preferences of infants and school children, and the changes in colour preference which occur with age. Comparative studies have also been made of the colour preferences of the sexes and of races. The experiments were done under such widely different conditions that in many cases they are hardly comparable, and the results are so numerous and varied that they are difficult to summarize. In no instance was there any great agreement in regard to the preference either for single colours or for combinations, and often there was not even a great constancy in the choice of the individual observer. All that one can indicate are general tendencies. Red and blue seem to be the favourite colours, and orange and yellow usually rank low. It appears from the mass of information that has been collected that men have the strongest preference for blue and women for red. A typical order of preference is blue, red, purple, green, orange, yellow, which would mean that the colours at the ends of the spectrum have the best chance of being chosen as the most pleasing. Also, saturated colours have a strong attraction, but are not always preferred. As Titchener has remarked, there seem to be two types of observers, one of which prefers saturated colours, the other definitely prefers unsaturated or what are popularly called artistic colours. E. Bullough has made an analysis of the psychological attitude of persons toward colours, and has found that there are four main types of judgments: the objective, where the peculiarities of the colours such as clarity are observed; the physiological, where the aspects of warmth, hardness, etc., are noted; the associative, where the colours remind the observer of some experience; and the character judgment, where the colours are expressive of mood. It seems, then, that our preference depends very much upon our attitude. Indeed, as von Allessch has stated, the old talk of beauty and ugliness of colours has only relative meaning. All colours can be all things at the right moment and at the right place. Nevertheless, we may say that in general complementary colours seem to be pleasing in combination, and probably also those colours which are nearly complementary. On the other hand, colours which are neighbouring in the spectrum do not seem to go together. Harmony, however, can generally be obtained from the inharmonious combination of two colours by the proper selection of a third colour to form a triad.

Sound.—The most important work on the psychology of music is that of Carl Stumpf. His book *Tonpsychologie* (1890) is a classic in this field and contains, among many theories and facts of importance, his psychological theory of consonance, which is based upon an empirical study of the perception of tonal combinations. For Stumpf, degree of consonance is correlated with degree of fusion of

the two tones of a musical interval. In his subsequent writings, he has vigorously attacked the physical theory of consonance of Herman v. Helmholtz and F. E. Kruger. Stumpf has also done extensive work upon the tonal quality of vowels and consonants. One of his latest investigations in the auditory field is a comparison of singing and talking, which he finds not fundamentally different. In speaking we use for the most part a continuous change in tone, while in singing we use discrete tonal steps. H. T. Moore has shown experimentally that, up to a certain point, the pleasantness of tonal intervals grows with our experience of them, which accounts for the gradual change in our attitude toward consonance and dissonance. O. Abraham and E. M. von Hornbostel, in their analysis of tonal intervals, have discovered two factors underlying the experience, one a qualitative, the other a quantitative, which they call distance or width of interval, and accord quality, respectively. C. E. Seashore has devised a series of tests which can be given by means of phonograph records. In his latest work he describes the results obtained by photographing the vibrations of the singing voice. He has detected the presence of the vibrato, or synchronous oscillations of pitch and intensity at the rate of five to eight per second in artistic singing.

In experiments upon the appreciation of pictures the introspective method has usually been employed. O. Kulpe showed pictures for three seconds each to a number of persons, and recorded their reports. He did not find evidence of empathy to support Lipps's theory. On the other hand, muscular sensations in a form which, according to Karl Groos, is called inner mimicry are present at times, but not always. A unique method of investigating the effect of pictures upon children was used by R. Schultze, who photographed the children while they were looking at the pictures. One was often able to judge from the photographs which picture the child had been looking at, as well as the mood which had been aroused.

A laboratory research in the field of literature which is suggestive, both from the point of view of method and content, is that of R. C. Givler. He showed conclusively the importance of the mere sound of words in conveying the meaning as well as the moods of poetry. Most of the investigations of the aesthetics and psychology of prose and poetry, however, have been in the nature of a direct analysis of the works themselves, or a study of the life of the artist, and do not come under experimental aesthetics in the narrow sense of that term, as used in this article. J. L. Lowes' *The Road to Xanadu* (1927) might, however, be mentioned as a model piece of research of this nature. Comparing the contents of a note-book left by Coleridge with the text of *The Rhyme of the Ancient Mariner* and *Kubla Khan*, Lowes has been able to analyse most convincingly the subconscious mind of that poet. Freud and his followers have also made numerous analyses of the subconscious minds of artists. Their results will undoubtedly be of interest to those persons who believe in the psycho-analytic method, and even the sceptic will find some suggestive material in their writings.

A promising modern development in experimental aesthetics is the genetic investigation of artistic creation and appreciation. The fundamentals of preference for form and pattern are well on their way toward assimilation by the time children enter grade school. Children between the ages of two and five years prefer balance in tri-dimensional designs to imbalance. Controlled observation confirms the popular belief in the sensitivity of young children to rhythm in music. Graphic rhythm (regular repetition in two-dimensional form) is preferred in pictorial presentation by five-year olds. Children of this age even show an appreciation of rhythm in abstract design. One study of talented children, aged five to seven years, definitely established the presence of creative artistic imagination at this age level. The pictures painted by the children were not generalized depictions of simple objects or stereotyped forms but were of a compositional character. Moreover, these talented novices showed a critical attitude toward their work characteristic of the professional. They were seldom satisfied with their first efforts and usually expressed in specific terms a critical evaluation of each stage of the production as they went along.

An interesting problem in the psychology of art is the relationship among the various fields of artistic expression (music, painting, etc.). Critics with a classical bias have affirmed the uniqueness of each of the arts, whereas artists of a less conservative bent have sometimes assumed a common basis and a common method of appeal to all the arts. An extreme example is the colour organ which attempts to use the temporal presentation of music in the visual field. The writings of Gertrude Stein and the paintings of some surrealists are likewise attempts to cut across the conventional bounds of the art fields in the belief in the unity of all psychological experience. The problem has been approached experimentally by comparing the moods aroused by painting with those aroused by music and by comparing the qualities of the various sensory modalities. J. Cowles presented 33 subjects with seven pictures as they listened to seven successive musical selections. They were asked to specify the picture which best suited each musical selection. A fairly high degree of agreement was found in the pairing of the visual and the auditory stimuli. Pictures suggestive of activity were nearly always paired with musical selections of prominent dynamic changes. That similar moods can be established in the individual through appeals to the different senses does not mean, however, that sensory qualities of the various sensory modalities have

even a rough equivalence. The eye and the ear as well as the other sense receptors give rise to distinctive qualities and even the intensive attributes of these qualities are not strictly comparable. Moreover, Karwoski and Odbert in a study of colour music have challenged the absolute nature of coloured hearing (that form of synaesthesia in which people experience a definite and a constant colour sensation when a certain tone is sounded). They found no constant relationship between tone and colour which held for all subjects and even the individual subject showed considerable variability in his visual response. The photism reported depended upon the total stimulus-situation and upon the familiarity with the musical selection as well as upon the tones themselves. Experimental psychology corroborates those critics who would keep apart the various arts in their objective techniques though not necessarily in their appeal to affective experience.

(H. S. L.; D. KA.)

AESTIVATION, literally "summer residence," a term used in zoology for the condition of torpor into which certain animals pass during the hottest season in hot and dry countries, contrasted with the similar winter condition, hibernation. In botany the word is used of the folded arrangement of the petals in a flower before expansion in the summer, contrasted with "vernation" of leaves which unfold in the spring. See **HIBERNATION**.

AETA, a Negrito tribe of the Philippine islands, woolly-haired, dark-skinned, dwarfish (the male stature is about 4ft. gin.) inhabiting the mountainous districts of the larger islands and some of the smaller. They are characterized by a large and clumsy foot with abnormally divergent great toe. The social unit is the family; polygamy is permitted, but monogamy prevails. The dead are normally buried, but the bodies of those whom it is wished to honour are exposed on platforms or in trees. Bows and poisoned arrows are used, long spears and darts barbed with flint or shell. Fire is made by means of a flexible thong pulled to and fro in a notch in a cleft stick. They pray to a great serpent to show them yams and honey.

The Aeta were long recognized as the owners of the soil in spite of the arrival of Malayan settlers, and in Luzon they levied taxes upon the Tagalog and other tribes (until these arrived in such numbers as to push them back into the hills) taking the heads of defaulters. For much longer, perhaps even yet, they kept a debit and credit account of heads with the Igorots and other neighbours.

(J. H. H.)

AETHELBALD, king of Mercia, succeeded Ceolred, A.D. 716, at the beginning of the period of Mercian supremacy. His activities as a warrior were slight; in 733 he raided Somerset as far as Somerton, and led unimportant campaigns against the Northumbrians and the Welsh. In 752 Cuthred of Wessex led a successful raid into Oxfordshire against him. Aethelbald encouraged the development of the church, making large grants of land, and publishing a decree in 749 which freed ecclesiastical lands from all obligations to the king except the *trinoda necessitas*.

See Bede, *Hist. Ecc.* (ed. Plummer), v. 23 and *Continuatio s.a.* 740, 750, 757; *Saxon Chronicle* (Earle and Plummer), s.a. 716, 733, 737,

740, 741, 743, 755; Mabillon, *Acta Sanctorum*, ii. pp. 264, 275-276, 279, 283-284; P. Jaffé, *Monumenta Moguntiacae*, iii. pp. 168-177; W. de G. Birch, *Cartul. Saxon.*, 178 (1885-93).

AETHELBALD, king of Wessex, was the son of Aethelwulf, with whom he led the West Saxons to victory against the Danes at Aclea, 851. According to Asser he rebelled against his father on the latter's return from Rome in 856, and deprived him of Wessex, which he ruled until his death in 860. On his father's death in 858 he married his widow, Judith.

See Asser, *Life of Alfred* (W. H. Stevenson, 1904), 12; *Saxon Chronicle*, s.a. 851, 855, 860.

AETHELBERT, king of Kent, son of Eormenric, came to the throne in A.D. 560. Aethelbert's supremacy, described by Bede as extending in 597 to the Humber, can have been little more than nominal, though he exercised stricter sway over Essex, where his nephew, Sabert, was king. An attempt to extend his kingdom westwards was defeated in 568 by Ceawlin at Wibbandune. Aethelbert's reign is chiefly remarkable for the introduction of Christianity. He married a Christian princess, Berta, daughter of Charibert, king of Paris, who brought over a bishop as private confessor. When in 597 Augustine landed in Thanet, the king treated his mission tolerantly, gave him a dwelling in Canterbury and allowed monks to preach there, afterwards being baptized himself, but making no attempt to force conversion on his subjects. In 604 he founded the see of Rochester, and his influence established Mellitus at London in the same year. He published a code of laws, the first of its kind, containing a list of money fines for various offences against the clergy.

BIBLIOGRAPHY.—See Stubbs, *Dict. of Christian Biog.* Ethelbert; Bede, *Hist. Ecc.* (Plummer i. 25, 26, ii. 3, 5); *Saxon Chronicle* (Earle and Plummer), s.a. 568.

AETHELBERT, king of the West Saxons, succeeded to the under-kingdom of Kent during the lifetime of his father, Aethelwulf, and retained it until the death of his elder brother, Aethelbald, in 860, when he became sole king of Wessex and Kent till his death in 865. His reign was marked by two serious attacks by the Danes, who were repelled in 860 by the levies of Hampshire and Berkshire, though not before they had sacked Winchester, while in 865 they ravaged Kent after agreeing to take money for peace. Aethelbert was buried at Sherborne.

BIBLIOGRAPHY.—See the *Saxon Chronicle* (Earle and Plummer), s.a. 860, 865; King Alfred's Will; W. de G. Birch, *Cartul. Saxon.*, 553.

AETHELFLAED or **ETHELFLEDA**, the "Lady of the Mercians," the eldest child of Alfred the Great, was married about 886 to Aethelred, earl of Mercia, to whom Alfred entrusted the control of Mercia. On the accession of her brother Edward, Aethelflaed and her husband continued to hold Mercia. In 907 they fortified Chester, and in 909 and 910 either Aethelflaed or her husband must have led the Mercian host at the battles of Tettenhall and Wednesfield (or Tettenhall-Wednesfield, if these battles are one and the same). It was probably about this time that Aethelred fell ill, and the Norwegians and Danes from Ireland unsuccessfully besieged Chester. Aethelflaed won the support of the Danes against the Norwegians, and seems also to have entered into an alliance with the Scots and the Welsh against the pagans.

In 911 Aethelred died, and Edward took over Middlesex and Oxfordshire. Except for this, Aethelflaed's authority remained unimpaired. In 912 she fortified "Scergeat" and Bridgnorth, Tamworth and Stafford in 913, Eddisbury and Warwick in 914, Cherbury, "Weardbyrig" and Runcorn in 915. In 916 she sent an expedition against the Welsh, which advanced as far as Brecknock. In 917 Derby was captured from the Danes, and the next year Leicester and York both submitted to her. She died in 918 at Tamworth (June 12), and was buried in St. Peter's Church at Gloucester. This noble queen, whose career was as distinguished as that of her father and brother, left one daughter, Aelfwyn. For some 18 months Aelfwyn seems to have wielded her mother's authority, and then, just before the Christmas of 919, Edward took Mercia into his own hands, and Aelfwyn was "led away" into Wessex. Aethelflaed and her husband wielded almost kingly authority; the royal title is often given them by the chroniclers.

See The *Saxon Chronicle*, s.a. (especially the Mercian register in MSS. B, C and D); Florence of Worcester; Fragments of Irish Annals (ed. O'Connor), pp. 227-237; D.N.B., s.v. (A. M.)

AETHELFRITH, king of Northumbria, is said to have come to the throne in A.D. 593, being the son of Aethelric (probably reigned 568-72). He married Acha, daughter of Ella (Aelle), king of Deira, whom he succeeded, probably in 605, expelling his son Edwin. In 603 he repelled the attack of Aidan, king of the Dalriad Scots, at Daegsastan, defeating him with great loss. Later in his reign, probably in 614, he defeated the Welsh in a great battle at Chester, and massacred the monks at Bangor who were assembled to aid them by their prayers. This war had a strategic importance in the separation of the North Welsh from the Strathclyde Britons. In 617 Aethelfrith was defeated and slain at the river Idle by Raedwald of East Anglia, whom Edwin had persuaded to take up his cause.

See Bede, *Chronica Maiora*, §531; *Hist. Ecc.* (Plummer) i. 34, ii. 2; *Saxon Chronicle*, s.a. 593, 603, 605, 616; *Hist. Brittonum*, 557, 63; *Annales Cambriae*, s.a. 613.

AETHELING, an Anglo-Saxon word meaning originally "of noble descent," but soon restricted to members of a royal family, and in the Anglo-Saxon Chronicle used almost exclusively for members of the royal house of Wessex. It was occasionally used after the Norman Conquest to designate members of the royal family. In the 10th century, the wergild of an aetheling was equal to that of an archbishop and one-half of that of a king.

AETHELNOTH (d. 1038), archbishop of Canterbury, known also as EGELNODUS or EDNODUS, was a son of the ealdorman Aethelmaer, and a member of the royal family of Wessex. He became a monk at Glastonbury, then dean of the monastery of Christ Church, Canterbury, and chaplain to King Canute, and on Nov. 13, 1020, he was consecrated archbishop of Canterbury. He appears to have exercised considerable influence over Canute, largely by whose aid he restored his cathedral at Canterbury. Aethelnoth, who was called the "Good," died on Oct. 29, 1038.

AETHELRED, king of Mercia, succeeded his brother Wulfhere in A.D. 675. In 676 he ravaged Kent, destroying the monasteries and churches and taking Rochester. Aethelred married Osthryth, the sister of Egfrith, king of Northumbria, but a quarrel arose between the two kings, presumably over the possession of the province of Lindsey, which Egfrith had won back at the close of the reign of Wulfhere. In a battle on the banks of the Trent in 679, the king of Mercia was victorious and regained the province. Aelfwine, the brother of Egfrith, was slain, but at the intervention of Theodore, archbishop of Canterbury, Aethelred agreed to pay a wergild for the Northumbrian prince and so prevented further hostilities. Osthryth was murdered in 697 and Aethelred abdicated in 704, choosing Coenred as his successor. He then became abbot of Bardney, and, according to Eddius, recommended Wilfrid to Coenred on his return from Rome. Aethelred died at Bardney in 716. See WILFRID.

BIBLIOGRAPHY.—Eddius, *Vita Wilfridi* (Raine), 23, 40, 43, 45-48, 57; Bede, *Hist. Ecc.* (ed. Plummer), iii. 11, iv. 12, 21; *Saxon Chronicle*, s.a. 676, 679, 704, 716. (F. G. M. B.)

AETHELRED I., king of Wessex and Kent (866-871), was the fourth son of Aethelwulf of Wessex, and should, by his father's will, have succeeded to Wessex on the death of his eldest brother Aethelbald. He seems, however, to have stood aside in favour of his brother Aethelbert, king of Kent, to whose joint kingdoms he succeeded in 866. Aethelred's reign was one long struggle against the Danes. In the year of his succession a large Danish force landed in East Anglia, and in the year 868 Aethelred and his brother Alfred went to help Burgred, or Burhred, of Mercia, against this host, but the Mercians soon made peace with their foes. In 871 the Danes encamped at Reading, where they defeated Aethelred and his brother, but later in the year the English won a great victory at "Aescdesun." A fortnight later they were defeated at Basing, but partially retrieved their fortune by a victory at "Maeretun" (perhaps Marden, in Wiltshire), though the Danes held the field. In the Easter of this year Aethelred died, perhaps of wounds received in the wars against the Danes, and was buried at Wimborne.

BIBLIOGRAPHY.—The *Saxon Chronicle*, *sub ann.*; Birch, *Cartul. Saxon.* vol. ii. Nos. 516-526; D.N.B., *s.v.*; *Eng. Hist. Review*, i. 218-234.

AETHELRED II. or **ETMELRED** (c. 968-1016), king of the English (surnamed **THE UNREADY**; *i.e.*, without *rede* or counsel), son of King Edgar by his second wife, Aelfthryth, was born in 968 or 969 and succeeded to the throne on the murder of his half-brother Edward (the Martyr) in 978. In the year after his accession the Danish invasions recommenced, though as yet their object was plunder only, not conquest. For an account of the repeated invasions, which gathered strength as time went on, see **ENGLISH HISTORY**. Aethelred's policy of buying off the raiders failed, and the massacre of Danes in England carried out by his orders on St. Brice's Day (Dec. 2, 1001) only made matters worse. Next year Sweyn returned, his hostility fanned by the desire for revenge. For two years he ravaged and slew; in 1003 Exeter was destroyed; Norwich and Thetford were sacked in 1004. No effectual resistance was offered, despite efforts here and there; disorganization of the country was complete. In 1005 the Danes were absent in Denmark, but they came back next year, and emboldened by the utter lack of resistance, they ranged far inland. In 1007 Aethelred bought them off for a larger sum than ever (£36,000), and for two years the land enjoyed peace. In 1009, however, in accordance with a resolution made by the witan in the preceding year, Aethelred collected such a fleet "as never before had been in England in any king's day"; but owing to a miserable court quarrel the effort came to nothing. The king then summoned a general levy of the nation, with no better result. Just as he was about to attack, the traitor Edric prevented him from doing so, and the opportunity was lost. In 1010 the Danes returned, to find the kingdom more utterly disorganized than ever. "There was not a chief man in the kingdom who could gather a force, but each fled as he best might; nor even at last would any there resist another." Incapable of offering resistance, the king again offered money, this time no less than £48,000. While it was being collected, the Danes sacked Canterbury and slew the archbishop Alphege. The tribute was paid soon afterwards; and about the same time the Danish leader Thurkill entered the English service.

From 1013 an important change is discernible in the character of the Danish attacks, which now became definitely political in their aim. In this year Sweyn sailed up the Trent and received the submission of northern England, and then, marching south, attacked London. Failing to take it, he hastened west and at Bath received the submission of Wessex. Then he returned northwards, and after that "all the nation considered him as full king." London soon acknowledged him, and Aethelred, after taking refuge for a while with Thurkill's fleet, escaped to Normandy. Sweyn died in Feb. 1014, and Aethelred was recalled by the witan. At once he hastened north against Canute, Sweyn's son, but Canute sailed away, only to return next year, when the traitor Edric joined him and Wessex submitted. Canute and Edric harried Mercia, and were preparing to reduce London, when Aethelred died there on April 23, 1016. Weak, self-indulgent, improvident, he had pursued a policy of opportunism to a fatal conclusion.

Aethelred's wife was Emma, or Aelfgifu, daughter of Richard I. the Fearless, duke of the Normans, whom he married not later than 985. After the king's death Emma married Canute the Great, and after his death in 1035 she struggled hard to secure England for her son, Hardicanute. In 1037, however, when Harold Harefoot became sole king, she was banished; she went to Flanders, returning to England with Hardicanute in 1040. In 1043 Edward the Confessor seized the greater part of Emma's great wealth, and the queen lived in retirement at Winchester until her death on March 6, 1052. By Aethelred Emma had two sons, Edward the Confessor and the aetheling Aelfred (d. 1036), and by Canute she was the mother of Hardicanute. Her marriage with Aethelred was an important step in the history of the relations between England and Normandy, and J. R. Green says "it suddenly opened for its rulers a distinct policy, a distinct course of action, which led to the Norman conquest of England.

From the moment of Emma's marriage Normandy became a chief factor in English politics."

Pertz in the *Scriptores Rerum Germanicarum*, Band xix., Hanover, 1866) for the latter part of the reign. See also J. M. Kemble, *Codex Diplomaticus aevi Saxonici* (London, 1839-48); and B. Thorpe, *Ancient Laws* (London, 1840).

AETHELSTAN (c. 894-940), Saxon king, was the son (probably illegitimate) of Edward the Elder. He had been the favourite of his grandfather Alfred, and was brought up in the household of his aunt Aethelflaed, the "Lady of the Mercians." On the death of his father in 924, Aethelstan succeeded him, and was crowned at Kingston shortly after.

One of Aethelstan's first public acts was to hold a conference at Tamworth with Sihtric, the Scandinavian king of Northumbria, and as a result Sihtric received Aethelstan's sister in marriage. In the next year Sihtric died and Aethelstan took over the Northumbrian kingdom. He now received, at Dacre, in Cumberland, the submission of all the kings of the island; viz., Howel Dda, king of West Wales, Owen, king of Cumbria, Constantine, king of the Scots, and Ealdred of Bamburgh, and henceforth he called himself "rex totius Britanniae." About this time (the exact chronology is uncertain) Aethelstan expelled Sihtric's brother Guthfrith, destroyed the Danish fortress at York, received the submission of the Welsh at Hereford, fixing their boundary along the line of the Wye, and drove the Cornishmen west of the Tamar, fortifying Exeter as an English city. In 934 he invaded Scotland by land and sea, perhaps owing to an alliance between Constantine and Anlaf Sihtricsson. The army advanced as far north as Dumottar, in Kincardineshire, while the navy sailed to Caithness. Simeon of Durham speaks of a submission of Scotland as a result; if it ever took place it was a mere form, for three years later we find a great confederacy formed in Scotland against Aethelstan. This confederacy of 937 was joined by Constantine, king of Scotland, the Welsh of Strathclyde, and the Norwegian chieftains, Anlaf Sihtricsson and Anlaf Godfredsson, who, though they came from Ireland, had powerful English connections. A great battle was fought at Brunanburh (perhaps Brunswark or Birrenswark hill in south-east Dumfriesshire), in which Aethelstan and his brother Edmund were completely victorious. England had been freed from its greatest danger since the days of the struggle of Alfred against Guthrum.

Aethelstan was the first Saxon king who could claim in any real sense to be lord paramount of Britain. In his charters he is continually called "rex totius Britanniae," and he adopts for the first time the Greek title *basileus*. This was not merely an idle flourish, for some of his charters are signed by Welsh and Scottish kings as *subreguli*. Further, Aethelstan was the first king to bring England into close touch with continental Europe. By the marriage of his half-sisters he was brought into connection with the chief royal and princely houses of France and Germany. His sister Eadgifu married Charles the Simple, Eadhild became the wife of Hugh the Great, duke of France, Eadgyth was married to the emperor Otto the Great, and her sister, Aelfgifu, to a petty German prince. Embassies passed between Aethelstan and Harold Fairhair, first king of Norway, with the result that Harold's son Haakon was brought up in England, and is known in Scandinavian history as Haakon Adalsteinsföstri.

Aethelstan died at Gloucester in 940, and was buried at Malmesbury, an abbey which he had munificently endowed during his lifetime. Apparently he was never married, and he certainly had no issue. A considerable body of law has come down to us in Aethelstan's name. The chief collections are those issued at Grately, in Hampshire, at Exeter, at Thunresfeld, and

AFTER G. M. COLLEN'S BRIT. SAXONICA
SHIELD OF AETHELSTAN
The cross boutoné, on a field of red and blue, is surmounted by a crest coronet of gold. The circle at the base is gold

the *Iudicia civitatis Lundonie*. In the last-named one personal touch is found when the king tells the archbishop how grievous it is to put to death persons of 12 winters for stealing. The king secured the raising of the age limit to 15.

(A. M.)

AETHELWEARD or **ETHELWARD**, Anglo-Saxon historian, was the great-grandson of Aethelred, the brother of Alfred, and ealdorman or earl of the western provinces (*i.e.*, probably of the whole of Wessex). He was the author of a Latin chronicle extending to the year 975. Up to the year 892 he is largely dependent on the Saxon Chronicle, with a few details of his own; later he is largely independent of it. He was the friend and patron of Aelfric, the grammarian.

AETHELWULF, king of the West Saxons, succeeded his father, Egbert, in A.D. 839. Aethelwulf's reign was chiefly occupied with struggles against the Danes. After the king's defeat 843-44, the Somerset and Dorset levies won a victory at the mouth of the Parret (c. 850). In 851 Ceorl, with the men of Devon, defeated the Danes at Wigganburg, and Aethelstan of Kent was victorious at Sandwich; despite this the Danes wintered in England that year for the first time. In 851 also Aethelwulf and Aethelbald won their great victory at Aclea, probably the modern Ockley. In 853 Aethelwulf subdued the North Welsh, in answer to the appeal of Burgred of Mercia, and gave him his daughter Aethelswith in marriage. The year 855 is the date of the Donation of Aethelwulf and of his journey to Rome with Alfred. On his way home he married Judith, daughter of Charles the Bold. According to Asser he was compelled to give up Wessex to his son Aethelbald on his return, and content himself with the eastern under-kingdom. He died in 858.

See Asser, *Life of Alfred* (W. H. Stevenson, 1904), 1-16; *Saxon Chronicle*, s.a. 823, 836, 840, 851, 853, 855.

AETHER: see **ETHER** (PHYSICS).

AETHICUS (= **ETHICUS**) **ISTER**, "the philosopher of Istria," the supposed but unknown author of a description of the world written in Greek. An abridgment, under the title of *Cosmographia Ethici*, written in barbarous Latin, and wrongly described as the work of St. Jerome, probably belongs to the 7th century.

The name Aethicus is also attached to a geographical treatise probably dating from the 6th century, a reproduction of the cosmography of Julius Honorius.

AETIOLOGY or **ETIOLOGY**, strictly, science or philosophy of causation, but generally used to denote the part of any special science (and especially of that of medicine and disease) which investigates the causes and origin of its phenomena. An aetiological myth is one which is regarded as having been invented *ex post facto* to explain some fact, name, or coincidence, the true account or origin of which has been forgotten. Such myths were often based on grotesque philological analogies, according to which an existing connection between two personalities (cities, etc.) was traced back to a common mythical origin. The preferred spelling of the word in the United States is *Etiology*.

AETION or **EETION**, a Greek painter, mentioned by Cicero, Pliny, and Lucian. His most noted work, described in detail by Lucian (Herodotus or Eetion, 5), was a picture representing the marriage of Alexander and Roxana. Through a misunderstanding of the words of Lucian, Aetion has been supposed to belong to the age of Antonines; but there can be little doubt

that he was a contemporary of Alexander and of Apelles (Brunn, *Geschichte der griechischen Künstler*, ii. p. 243). Pliny gives his date as 350 B.C.

AETIUS (ah-ët'ī-ooos) (fl. 350), surnamed "the Atheist," founder of an extreme sect of Arians, was a native of Coele-Syria. He studied successively under the Arians, Paulinus, bishop of Antioch, Athanasius, bishop of Anazarbus, and the presbyter Antonius of Tarsus. At the first synod of Sirmium he won a dialectic victory over the homoiousian bishops, Basilius and Eustathius, who sought in consequence to stir up against him the enmity of Caesar Gallus. In 316 he went to Alexandria with Eunomius (*q.v.*) in order to advocate Arianism, but he was banished by Constantius. Julian recalled him from exile, bestowed upon him an estate in Lesbos, and retained him for a time at his court in Constantinople. At the accession of Valens (364) he retired to his estate at Lesbos, but soon returned to Constantinople, where he died in 367. The Anomoean sect of the Arians, of whom he was leader, are sometimes called after him Aetians. His work *De Fide* has been preserved in connection with a refutation written by Epiphanius (Haer., lxxvi. 10).

See A. Harnack, *History of Dogma*, vol. iv. *passim*.

AETIUS (died 454), a Roman general of the closing period of the Western empire, born at Dorostolus in Moesia, late in the 4th century. He was the son of Gaudentius, who, although possibly of barbarian family, rose in the service of the Western empire to be master of the horse, and later, count of Africa. Aetius passed some years as hostage, first with Alaric and the Goths, and later in the camp of Rhuas, king of the Huns, acquiring in this way the knowledge which enabled him afterwards to defeat them. In 424 he led into Italy an army of 60,000 barbarians, mostly Huns, which he employed first to support the *primicerius* Ioannes, who had proclaimed himself emperor, and, on the defeat of the latter, to enforce his claim to the supreme command of the army in Gaul upon Placidia, the empress-mother and regent for Valentinian III. His clamours against his rival, Count Boniface, which were at first believed by the emperor, led Boniface to revolt and call the Vandals to Africa. Upon the discovery of the truth, Boniface, although defeated in Africa, was received into favour by Valentinian; but Aetius came down against Boniface from his Gallic wars, and in the battle which followed wounded Boniface fatally with his own javelin. From 433 to 450 Aetius was the dominating personality in the Western empire. In Gaul he won his military reputation, upholding for nearly 20 years, by combined policy and daring, the falling fortunes of the empire. His greatest victory was that of Châlons-sur-Marne (Sept. 20, 451), in which he led the Gallic forces against Attila and the Huns. This was the last triumph of the empire. Three years later (454) Aetius presented himself at court to claim the emperor's daughter in marriage for his son Gaudentius; but Valentinian, suspecting him of designs upon the crown, slew him with his own hand.

"That he was the one prop and stay of the Western empire during his life is the unanimous verdict of his contemporaries; but whether he was a really great general or statesman we cannot tell. He was beaten by Boniface; and it was not he, but the Goths and their king, who really triumphed in the Mauriac plain; yet he recovered Gaul in a series of campaigns, and he kept the Visigoths in check. . . . If he was less Roman than his predecessor Constantias, he was far more Roman than his successor Ricimer; and if he had occasionally used the arms of the Huns for his own ends, he had also used them to maintain the empire. One merit he had which must count for much—the merit of recognizing and encouraging men of ability. Majorian and Marcellinus, two of the finest figures in the history of the fallen empire, were men of his training." (Ernest Barker in *Cambridge Mediaeval Hist.*, vol. i., I., 418-419.)

See T. Hodgkin, *Italy and her Invaders*, vols. i. and ii. (1880).

AETIUS, a Greek physician, born at Amida in Mesopotamia, flourished at the beginning of the 6th century A.D. He was court physician at Byzantium. He wrote a large medical work in 16 books, founded on Oribasius and compiled from various sources, especially Galen (Galenos). Eight books of the Greek original were printed in Venice in 1534, and a complete Latin translation by Cornarius at Basel, 1542.

See Weigel, *Aetianarum exercitationum specimen* (1791); Danelius, *Beitrag zur Augenheilkunde des Aetius* (1889); Zernos, *Aetii sermo sextidecimus et ultimus*, editio princeps (1901).

AETNA, a Latin hexameter poem of 644 lines ascribed by the mss. to Virgil. This ascription is now universally rejected, but it is obvious that the author was an imitator of Virgil who was familiar with the Aeneid as well as the Bucolics and Georgics, and therefore lived at least as late as the time of Augustus. As there is no mention of the famous eruption of Vesuvius which destroyed Pompeii and Herculaneum it is safe to presume that the work was composed before A.D. 79. The poem has been attributed by various authorities to Claudian, Cornelius Severus and Manilius, but modern opinion assigns it to Lucilius Junior, the friend of Seneca, whose interest in, and knowledge of scientific matters is alluded to in the philosopher's correspondence. He is known to have been a governor of Sicily and also to have written poems. Aetna discusses the possible scientific explanation of the volcano's action.

Text edited (1920) by Robinson Ellis in J. P. Postgate's *Corpus Poetarum Latinorum*.

AETOLIA, a district of northern Greece, bounded on the south by the Corinthian Gulf, on the west by the river Achelous, on the north and east by the western spurs of Parnassus and Oeta. The land naturally falls into two divisions. The basins of the lower Achelous (mod. Aspropotamo) and Euenus (*Phidharis*) form a series of alluvial valleys intersected by detached ridges which mostly run parallel to the coast. This district of "Old Aetolia" lacks a suitable sea-board, but the inland, and especially the plain of central Aetolia lying to the north of Lakes Hyria and Trichonis and Mount Aracynthus, forms a rich agricultural country. The northern and eastern regions are broken by an extensive complex of chains and peaks, whose rugged limestone flanks are clad at most with stunted shrubs and barely leave room for a few precarious mule-tracks. These heights often rise in the frontier-ranges of Tymphrestus, Oxia and Corax to more than 7,000 ft.; the snow-capped pinnacle of Kiona attains to 8,240 ft. A few defiles pass through this barrier to the other side of the north Greek watershed.

In early legend Old Aetolia, with its cities of Pleuron and Calydon, figures prominently. During the great migrations (see DORIANS) the population was largely displaced, and the old inhabitants long remained in a backward condition. In the 5th century some tribes were still living in open villages under petty kings, addicted to plunder and piracy, and hardly recognized as Hellenes at all. Yet their military strength was not to be despised: in 426 their archers and slingers easily repelled an Athenian invasion under Demosthenes. In the 4th century the Aetolians began to take a greater part in Greek politics, and, in return for helping Epameinondas (367) and Philip of Macedon (338), recovered control of their sea-board, to which they annexed the Acarnanian coast and the Oeniadae. Aetolia's prosperity dates from the period of Macedonian supremacy. It may be ascribed partly to the wealth and influence acquired by Aetolian mercenaries in Hellenistic courts, but chiefly to the formation of a national Aetolian league, the first effective institution of this kind in Greece. Created originally to meet the peril of an invasion by the Macedonian regents Antipater and Craterus, who had undertaken a punitive expedition against Aetolia after the Lamian War (322), and by Cassander (314-311), the confederacy grew rapidly during the subsequent period of Macedonian weakness. Since 290 it had extended its power over all the uplands of central Greece, where its command over Heracleia (280) provided it with an important defensive position against northern invaders, its control of Delphi and the Amphictyonic council with a useful political instrument. The valour of the Aetolians was conspicuously displayed in 279, when they broke the strength of the Celtic irruption by slaughtering great hordes of marauders. The commemorative festival of the Soteria, which the league established at Delphi, obtained recognition from many leading Greek states. After annexing Boeotia (by 245) the Aetolians controlled all central Greece. Endeavouring next to expand into Peloponnesus, they allied themselves with Antigonos Gonatas of Macedonia against the

Achaean league (*q.v.*), and besides becoming protectors of Elis and Messenia won several Arcadian cities. Their naval power extended to Cephalonia, to the Aegaeon islands and even to the Hellespont. The league at its zenith had thus a truly imperial status.

Later in the century its power began to be sapped by Macedonia. To check King Demetrius (239-229) the Aetolians joined arms with the Achaeans. In 224 they held Heracleia Trachis against Antigonos Doseon, but lost control of Boeotia and Phocis. Since 228 their Arcadian possessions had been abandoned to Sparta. At the same time a new enemy arose in the Illyrian pirate fleets, which outdid them in unscrupulousness and violence. The raids of two Aetolian chiefs in Achaean territory (220) led to a coalition between Achaia and Philip V. of Macedon, who assailed the invaders with great energy, driving them out of Peloponnesus and marching into Aetolia itself, where he surprised and sacked the federal capital Thermon. After buying peace by the cession of Acarnania (217) the league concluded a compact with Rome. In the great war of their Roman allies against Philip the federal troops took a prominent part, their cavalry being largely responsible for the victory of Cynoscephalae (197). The Romans in return restored central Greece to the league, but by withholding its former Thessalian possessions excited its deep resentment. The Aetolians now invited Antiochus III. of Syria to European Greece, and so precipitated a conflict with Rome. But in the war they threw away their chances. In 192 they wasted themselves in an unsuccessful attempt to secure Sparta. In 191 they supported Antiochus badly, and by their slackness in the defence of Thermopylae made his position in Greece untenable. Having thus isolated themselves the Aetolians stood at bay behind their walls against the Romans, who refused all compromises, and, after the general surrender in 189, restricted the league to Aetolia proper and assumed control over its foreign relations. By the time of Sulla, the functions of the Aetolian league had become purely nominal. The federal constitution closely resembled that of the Achaean league (*q.v.*), for which it doubtless served as a model. The general assembly, convoked every autumn at Thermon to elect officials, and at other places in special emergencies, shaped the league's general policy; it was nominally open to all freemen, though no doubt the Aetolian chieftains really controlled it. The council of deputies from the confederate cities undertook the routine of administration and jurisdiction. The *strategus* (general), aided by 30 *apocleti* (ministers), had complete control in the field and presided over the assembly, though with restricted advisory powers. The Aetolians also used the Amphictyonic synod for passing solemn enactments. The league's relation to outlying dependencies is obscure; many of these were probably mere protectorates or "allied states" and secured no representation. The federal executive was certainly much more efficient than that of the Achaeans, and its councils suffered less from disunion; but its generals and admirals, official or otherwise, enjoyed undue licence; hence the league deservedly gained an evil name for the numerous acts of lawlessness or violence which its troops committed. But as a champion of republican Greece against foreign enemies no other power of the age rendered equal services. In the 15th century Aetolia passed under the rule of Scanderbeg and the Venetians, but was finally conquered for the Turks by Mohammed II. In the War of Independence it was the scene of severe fighting, including the sieges of Missolonghi.

AFARS (DANAKIL), a tribe of African "Arabs" of Hamitic stock. They occupy the arid coast-lands between Abyssinia and the sea. They claim to be Arabs, but are more akin to the Galla and Somali. The tribe is roughly divisible into a pastoral and a

coast-dwelling group. Their religion is chiefly fetich and tree-worship; many, nominally, profess Mohammedanism. They are distinguished by narrow straight noses, thin lips and small pointed chins. They wear, generally, nothing but a waist-cloth. They are divided into many sub-tribes, each having an hereditary sultan.

See Fr. Sczamucci and E. H. Giglioli, *Notizie sui Danakil* (1884); P. Paulitschke, *Ethnographie Nordost-Afrikas* (2 vols., Berlin, 1893-1896), and *Die geographische Erforschung der Addl-Länder und Hardrs in Ost-Afrika* (Leipzig, 1884).

AFER, DOMITIUS, a Roman orator and advocate, was born at Nemausus (Nimes). He became an informer and gained the favour of Tiberius by accusing Claudia Pulcra, a cousin of Agrippina, of treason. He was consul under Caligula (39) and superintendent of the water supply under Nero. He died in A.D. 60. His pupil, Quintilian, who calls him the greatest orator he had ever known, quotes some of his witty sayings (*dicta*), collections of which were published, and mentions two books by him *On Witnesses*.

See Quintilian, *Instit.* vi. 3. 42, viii. 5. 16, x. 1 118, etc.; Tac. Ann. iv. 52, 68, xiv. 19; Dio Cassius lix. 19, lx. 33; Pliny, *Épp.* ii. 14, viii. 18.

AFFECTION, literally, a state resulting generally from an external influence. The term was at one time employed to denote the states even of material bodies, but is now confined to certain mental states only, in fact, to certain feelings. It is popularly used of a sentiment between persons amounting to more than good will or friendship. By ethical writers the word has been used generally of distinct states of feeling, both lasting and spasmodic; some contrast it with "passion," as being free from the distinctively sensual element. More specifically the word has been restricted to emotional states which are in relation to persons. In the former sense, it is the Gr. *πάθος*, and as such it appears in Descartes and most of the early British ethical writers. On various grounds, however—*e.g.*, that it does not involve anxiety or excitement, that it is comparatively inert and compatible with the entire absence of the sensuous element—it is generally and usefully distinguished from passion. In this narrower sense the word has played a great part in ethical systems, which have spoken of the social or parental "affections" as in some sense a part of moral obligation. For a consideration of these and similar problems, which depend ultimately on the degree in which the affections are regarded as voluntary, see H. Sidgwick, *Methods of Ethics*, pp. 345-349.

In psychology the terms "affection" and "affective" are used for the characteristic quality of experiences that are neither cognitive nor conational. As all intellectual phenomena have by some psychologists been reduced to sensation, so all feeling has been regarded as reducible to simple mental affection, the element of which all emotional manifestations are ultimately composed. The nature of this element is a problem which has been provisionally, but not conclusively, solved by many psychologists; the method is necessarily experimental, and all experiments on feeling are peculiarly difficult. The solutions proposed are two. In the first, all affective phenomena are primarily divisible into those which are pleasurable and those which are the reverse. The main objections to this are that it does not explain the infinite variety of phenomena, and that it disregards the distinction which most philosophers admit between higher and lower pleasures. The second solution is that every sensation has its specific affective quality, though by reason of the poverty of language many of these have no name. W. Wundt, *Outlines of Psychology* (trans. C. H. Judd, Leipzig, 1897), maintains that we may group under three main affective directions, each with its negative, all the infinite varieties in question; these are (a) pleasure, or rather pleasantness, and the reverse, (b) tension and relaxation, (c) excitement and depression.

Two methods of experiment have been tried. The first, introduced by A. Mosso, the Italian psychologist, consists in recording the physical phenomena which are observed to accompany modifications of the affective consciousness. Thus it is found that the action of the heart is accelerated by pleasant, and retarded by unpleasant, stimuli; again, changes of weight are found to accompany modifications of affection-and so on.

The second is Fechner's method; it consists in recording the changes in feeling-tone produced in a subject by bringing him in contact with a series of conditions, objects or stimuli graduated according to a scientific plan and presented singly, in pairs or in groups. The result is a comparative table of likes and dislikes.

(See FEELING.)

AFFETTUOSO (Ital.), a musical direction signifying that the composition or particular passage so marked is to be played with much expression and feeling. *Espressivo* and *con espressione* are other terms having much the same significance.

AFFIDAVIT, a written statement sworn or affirmed to before some person who has authority to administer an oath or affirmation. Evidence is chiefly taken by means of affidavits in the chancery division of the High Court of Justice in England on a petition, summons or motion. Interlocutory proceedings before trial are conducted by affidavits, *e.g.*, for discovery of documents, hence called *affidavit* of documents. Affidavits are sometimes necessary as proof that certain legal formalities have been duly and legally performed. On special application to the court a deponent may be cross-examined on the statements contained in his affidavit. In Scotland the testimony of witnesses by affidavit is almost unknown, except in proceedings in the Sheriff Court of Chancery, and petitions for the sequestration of bankruptcy, where affidavits are enjoined by statute. In the rules of the Supreme Court (R.S.C. Ord. XXXVIII.) certain formal requirements are laid down for all affidavits and affirmations in causes or matters depending in the High Court. An affidavit must consist of title, body or statement and jurat. It must be written or printed on foolscap, bookwise, in the first person; give correctly the names of the parties to the action; and the description and true place of abode of the deponent. An affidavit is confined, except on interlocutory motions, to such facts as the witness is able of his own knowledge to prove. The signature of the deponent must be written opposite to the jurat, which must contain the place, date and time of swearing, and this signed by the officer or magistrate before whom the affidavit is sworn. An affidavit sworn on a Sunday is not invalid. Quakers, Moravians and Separatists were first privileged to make a solemn declaration or affirmation, and by the Common Law Procedure Act, 1852, and other statutes all persons prevented by religious belief from taking an oath were allowed to affirm; and, finally, by the Oaths Act, 1888, every person who objects to be sworn is allowed to affirm in all places and for all purposes where an oath is required by law. By an act of 1835 justices are permitted to take affidavits in any matter by declaration, and a person making a false affidavit in this way is liable to punishment. The same act prohibited justices of peace from administering oaths in any matter in which they had not jurisdiction as judges, except when an oath was specially authorized by statute, as in the bankruptcy law, and excepting criminal inquiries, parliamentary proceedings and instances where oaths are required to give validity to documents abroad. Scottish justices can act in England and vice versa. The Oaths Act, 1888, and the Commissioner of Oaths Act, 1889, consolidated all previous enactments relating to oaths and gave the lord chancellor power to appoint commissioners for oaths to take affidavits for all purposes (see OATH).

In the United States affidavit has the same meaning as in England and its general uses are the same, but it is not substituted for oral evidence in court to anything like the extent to which that is done in the English courts of chancery. The statutes of each State designate the persons before whom affidavits may be made outside the State, and special commissioners are appointed for that purpose by each State. Affidavits made abroad must be made before such commissioners or persons so designated, who are usually diplomatic and consular officials, justices, notaries public or mayors.

AFFILIATION, in law, the procedure by which the paternity of a bastard child is determined, and the obligation of contributing to its support enforced. In England a number of statutes on the subject have been passed, the chief being the Bastardy Act of 1845, the Bastardy Laws Amendment Acts of 1872 and 1873, the

Affiliation Orders Act, 1914, the Affiliation Orders Act, 1918, and the Bastardy Act, 1923. The mother of a bastard may summon the putative father to petty sessions within 12 months of the birth (or at any later time if he is proved to have contributed to the child's support or ceased to reside in England within 12 months after the birth), and the justices, after hearing evidence on both sides, may, if the mother's evidence be corroborated in some material particular, adjudge the man to be the putative father of the child, and order him to pay a sum not exceeding 20 shillings a week for its maintenance, together with a sum for expenses incidental to the birth, or the funeral expenses, if it has died before the date of order, and the costs of the proceedings. An order ceases to be valid after the child reaches the age of 13, except as regards arrears, but the justices may in the order direct the payments to be continued until the child is 16 years of age. An appeal to quarter sessions is open to both the mother and the defendant, and a further appeal on questions of law to the King's Bench. Should the child afterwards become chargeable to the parish, the sum due by the father may be received by the relieving officer. When a bastard child whose mother has not obtained an order, becomes chargeable to the parish, the guardians may proceed against the putative father for a contribution, and such an order may be varied and continued in favour of the mother or person having custody of the child. Any woman who is single, a widow, or a married woman living apart from her husband, may make an application for a summons. The Bastardy Act, 1872, makes due provision for the enforcement of an order of affiliation, and commitment is governed by the Summary Jurisdiction Act, 1879, and the Criminal Justice Act, 1914. In the case of soldiers an affiliation order cannot be enforced in the usual way, but by the Army Act 1881, as amended in 1883, 1891, 1904 and 1915, if an order has been made against a soldier of the regular forces, a portion of the soldier's pay may be retained. There is similar legislation with regard to sailors in the Royal Navy, by the Naval Discipline Act, 1915.

It having been found in practice that affiliation orders became ineffective owing to the unwillingness or inability of the mother to make continual appearances before the justices, under the Affiliation Orders Act, 1914, collecting officers may be appointed.

In the United States the father is primarily responsible for the support of a bastard child. The mother is responsible in the event of the father's death.

In the British colonies there is some procedure (usually termed filiation) akin to that described above, by means of which a mother can obtain a contribution to the support of her illegitimate child from the putative father. On the continent of Europe, however, the legislation of the various countries differs rather widely. (See ADOPTION; also BASTARD; POOR LAWS.)

AFFINE GEOMETRY. An affine geometry, as distinguished from a projective geometry, involves a definition of parallelism. Thus, when from the definitions and theorems of the ordinary euclidean geometry of the plane all those involving euclidean measurement of length and angle are eliminated, the residue is an affine geometry. In this case the line at infinity is unique, in that any two lines meeting in a point of the former are parallel. In the projective geometry of the plane there is no such preferred line; when any line is designated as preferred in this sense, we have a corresponding affine geometry. For example, in affine geometry there is a distinction between an ellipse, a parabola and a hyperbola, but not in projective geometry; moreover, only when the geometry is metrical is there a distinction between circles and ellipses.

The euclidean affine geometry is given analytic form by means of coordinates x and y referred to two intersecting lines of the plane in the usual manner. In this case the equations

$$\begin{aligned} x_1 &= a_{11}x + a_{12}y + a_1, \\ y_1 &= a_{21}x + a_{22}y + a_2, \end{aligned} \tag{1}$$

where the a 's are arbitrary constants subject to the condition

$a_{11}a_{22} - a_{12}a_{21} \neq 0$, define the most general transformation of points of the plane among themselves which transforms parallel lines into parallel lines. Such a transformation is called *affine*. The transformations (1) form a group, and we may say, following Klein, that the body of definitions and theorems expressing properties of quantities invariant under this group is an affine geometry. If $x', y'; x'', y''; x''', y'''$ are the coordinates of three non-collinear points, the quantity

$$\begin{vmatrix} x' & y' & 1 \\ x'' & y'' & 1 \\ x''' & y''' & 1 \end{vmatrix} \tag{2}$$

is invariant under transformations (1) for which $a_{11}a_{22} - a_{12}a_{21} = 1$. These transformations are called *equiaffine*. There is a considerable body of theorems concerning properties of plane curves which remain invariant under equiaffine transformations. In particular, there is a metric theory based upon a certain invariant of the type (2) associated with a curve.

The foregoing concepts are readily generalized to spaces of higher order. Thus there is for spaces of three dimensions a theory of curves and surfaces analogous in many respects to the theory for euclidean space of three dimensions. The developments of these ideas have been made by many geometers, notably Klein, Mobius, Sylvester and lately by Blaschke and Pick.

Any n independent variables x_i , where i takes the values 1 to n , may be thought of as the coordinates of a general n -dimensional space, or variety, in the sense that each set of values of the x 's defines a point. In a space thus defined there is not a basis for the comparison of directions at different points. Such a basis is provided when a definition of parallelism is added. In Riemannian geometry we say, following Levi-Civita, that at points of a curve, defined by $x_i = f_i(t)$, ($i = 1, \dots, n$), a set of functions ξ^i of t satisfying the system of equations

$$\begin{aligned} \xi^i \left(\frac{d\xi^j}{dt} + \sum_{k,l} \Gamma_{kl}^j \xi^k \frac{dx_l}{dt} \right) \\ - \xi^j \left(\frac{d\xi^i}{dt} + \sum_{k,l} \Gamma_{kl}^i \xi^k \frac{dx_l}{dt} \right) = 0 \quad (i, j = 1, \dots, n) \end{aligned} \tag{3}$$

are the components of a family of vectors parallel with respect to the curve; in this case Γ_{jk}^i are functions of the x 's determined by the metric of the space (see RIEMANNIAN GEOMETRY). As thus defined, parallelism is relative to a curve, and not absolute, as in euclidean space. If the Γ 's in (3) are taken as n^3 arbitrary functions of the x 's, equations (3) may be taken as the definition of parallelism for a general V_n , thus generalizing Levi-Civita's concept of parallelism for spaces with a Riemannian metric. In this case we say that the space is *affinely* connected, following Weyl; the Γ 's are called the coefficients of the affine connection.

When $\Gamma_{jk}^i = \Gamma_{kj}^i$, the connection is called symmetric, otherwise asymmetric. When, and only when, the connection is symmetric, there exist preferred coordinate systems, with a given point as origin, with respect to which corresponding components of a vector at the given point and of a parallel one at a nearby point are the same. When the connection is asymmetric, there are other connections giving an equivalent definition of parallelism; the definition is unique for symmetric connections.

The fundamental curves of an affinely connected space are those whose tangents are parallel with respect to the curves; *i.e.*, they are the straight lines of the space. They are the integral curves of the differential equations obtained when $\xi^i = dx_i/dt$ in (3). Some writers call them the paths of the space, others geodesics, since they are the generalizations of the geodesics of Riemannian spaces. There are many affine connections with the same paths, so that the theorems dealing with the paths and not with a particular affine connection constitute a projective geometry. A theory of affinely connected spaces, in many respects analogous to Riemannian geometry, has been developed recently, notably by Cartan, Eddington, Einstein, Schouten, Joseph M. Thomas, Tracy Y. Thomas, Veblen and Weyl.

sungen über Differential Geometrie, vol. ii. (1923); J. A. Schouten, *Der Ricci-Kalkül* (1924); L. P. Eisenhart, "Non-Riemannian Geometry," *American Mathematical Society* (1927); O. Veblen, "Invariants of Quadratic Differential Forms," *Cambridge Tracts in Mathematics* (1927) (L. P. E.)

AFFINITY, in law, as distinguished from consanguinity (*q.v.*), the term applied to the relation which each party to a marriage, the husband and wife, bears to the kindred of the other. Affinity is usually described as of three kinds: (1) direct, that relationship which subsists between the husband and his wife's relations by blood or between the wife and the husband's relations by blood. The marriage having made them one person, the blood relations of each are held as related by affinity in the same degree to the one spouse as by consanguinity to the other. But the relation is only with the married parties themselves, and does not bring those in affinity with them in affinity with each other; so a wife's sister has no affinity to her husband's brother. This is (2) secondary affinity. (3) Collateral affinity is the relationship subsisting between the husband and the relations of his wife's relations. (See CONSANGUINITY; MARRIAGE.)

AFFINITY, CHEMICAL, the property or relation in virtue of which substances are capable of entering into chemical combination with each other. (See CHEMISTRY; CHEMICAL ACTION; VALENCY.)

AFFIRMATION, the declaration that something is true; in logic, a positive judgment, the union of the subject and predicate of a proposition; particularly, in law, the solemn declaration allowed to those who conscientiously object to taking an oath.

AFFORESTATION: see FORESTS AND FORESTRY.

AFFRAY is the misdemeanour of breaking the peace in public to the terror of the king's subjects. Fighting in public is an affray, but no actual violence is necessary, and the offence is committed even where a man arms himself with weapons so as to cause terror to the public. Abusive and threatening words alone will not amount to an affray. In 1903 at the Carnarvon assizes before Mr. Justice Wills a conviction was obtained in *Rex v. Meade* where the accused went about armed and discharged a loaded revolver in a public street. He was also indicted under a statute of 1328 (2 Edw. III. c. 3). (See also RIOT.)

In the United States the English common law as to affray applies, subject to certain modifications by the statutes of particular States (Bishop, *Amer. Crim. Law*, 9th ed., 1923, vol. i. § 535). The Indian penal code (§159) adopts the English definition of affray, with the substitution of "actual disturbance of the peace" for "causing terror to the lieges."

AFFRE, DENIS AUGUSTE (1793-1848), archbishop of Paris, was born at Saint-Rome-de-Tarn, on Sept. 27 1793. He became archbishop of Paris in 1840. His episcopate is chiefly remembered for its tragic close. During the riots of June 23-26, 1848, the archbishop mounted a barricade in the Faubourg St. Antoine and was hit by a stray bullet.

AFFREIGHTMENT. Payment for the carriage of goods by water, more especially by sea, is called freight, and a bargain made between the carrier and the person whose goods are to be so carried is called a contract of affreightment. The law does not require that a contract of this kind shall be made in writing, but usually it is expressed in that form. The terms on which goods are carried by sea are, except in coasting trade, ordinarily expressed in a charter-party or a bill of lading or both. The former may be shortly described as a contract between a shipowner and a merchant for the hire or use of a ship, and the latter as a receipt for goods, stating the terms on which they are delivered to and received by a ship. A charter-party usually relates to the full cargo of a ship, and a bill of lading may do the same, but it is more often given with reference to a particular parcel of goods.

Terms Implied by Law.—The parties to a contract of affreightment are assumed by law (unless the contract expressly negatives or qualifies the assumption) to have dealt with each other on the footing of certain obligations included among the terms of contract. In the unusual case of no terms being expressly agreed, the implied terms alone would regulate the relations of the parties. In the common case of terms being expressly agreed, the

implied terms are included, subject to any modification of them specifically and explicitly made by the express terms. It should be mentioned in passing that, where the goods are carried under bills of lading, certain terms are by statute (as explained below) included in the contract which the parties are not free to exclude even if they wish.

Subject then to any modification made by the contract, a person who for payment carries goods by sea is under an implied obligation to exercise due care and diligence. Except possibly in a case where the sea carrier is not a common carrier (*i.e.*, where he does not profess himself ready to carry goods for everybody) he has a further degree of responsibility, in that he is liable for every accident, unless caused by act of God, or of the king's enemies, or by inherent defect of the goods themselves, or by their having been sacrificed for the general safety. He also impliedly undertakes absolutely that the ship is seaworthy at the beginning of the voyage, and that he will proceed on the voyage with reasonable dispatch, and without unnecessary deviation. Seaworthy has a special meaning as explained later. The carrier may in some circumstances be entitled to claim statutory limitation of the amount of his liability.

On the part of the shipper an undertaking is implied not to ship dangerous goods without notice, and he or the person entitled to take delivery of the goods is impliedly under obligation (1) to be prepared, without notice from the carrier, to take delivery within a reasonable time after the arrival of the ship at the place of delivery, and (2) to pay freight and general average contribution (if any) before he can claim delivery of the goods. In some circumstances where performance of the contract becomes impossible the parties may be released from performance under terms deemed to be implied in the contract.

Parties to the Contract.—As already mentioned, the terms of contract are ordinarily expressed in a charter-party (shortly, a charter) or a bill of lading, or both. A bill of lading may be more fully described as "a receipt for goods shipped on board a ship, signed by the person who contracts to carry them, or his agent, and stating the terms on which the goods were delivered to and received by the ship. It is not the contract, for that has been made before the bill of lading was signed and delivered, but it is excellent evidence of the terms of the contract" (Scrutton). Usually the printed form of the particular carrier is filled up in writing and signed by the captain, broker or other agent of the carrier, and the terms of the contract made or deemed to have been made before the bill of lading was given are thus reduced to documentary form. Though in form a receipt, a bill of lading is also a transferable document of title representing the goods to which it relates.

Where the contract is between a shipper and a carrier who is himself the shipowner the bill of lading binds the shipowner. In the case of a chartered ship—*i.e.*, a ship hired by a charterer—the bill of lading may, according to the circumstances, bind the shipowner or the charterer. Charters are varied in form. Under some, where the shipowner parts with the whole possession and control of the ship (so that the charter amounts to a demise, a form rare in modern practice) the contract would be between the shipper and the charterer. Under other charters the charterer may merely undertake that a full cargo shall be shipped and guarantee payment of a certain freight. There the contract would be between shipper and shipowner. Where, in intermediate cases, the shipper is a person other than the charterer, the bill of lading may, according to the terms of the charter, bind the shipowner or the charterer.

Charter-parties.—**Charters** (apart from the unusual form amounting to a demise of the ship) are entered into for a voyage (or series of voyages) or for a period of time. A voyage charter commonly provides that the ship, as described, shall proceed to a named place, and there load a cargo, and shall then proceed to a named place of discharge, where the cargo is to be delivered. Freight is to be paid in a lump sum, or at a rate named on the cargo carried, or calculated in some other way. The number of days within which the charterers are to load and discharge (called lay days) is specified, and also a rate for demurrage

should the ship be longer detained, with provisions to apply in the event of stoppages occurring. "Days" in a charter is understood to mean calendar days of 24 hours commencing at midnight. Sundays and holidays are included unless expressly excepted. "Working days" means all days on which work is ordinarily done at the port, excluding Sundays and holidays. Provisions as to time are frequently expressed in hours instead of days. Further clauses deal with issue of bills of lading, exceptions from liability, discharge of cargo, payment of freight, general average, ceasing of charterer's liability, brokerage, etc.

By a time charter the ship is hired to the charterers for a specified time, commencing on a certain date, when the ship is to be placed at the disposal of the charterers, at some specified place, or place to be named, to be employed in lawful trades between certain limits. The clauses deal with various matters in connection with the employment of the ship, such as payments for stores, provisions, wages, insurance, fuel, port and other charges, the appointment and giving of directions to the master of the ship, stevedoring, exceptions from shipowner's liability, arbitration, etc. A number of common forms of charter are in use containing clauses adjusted to the requirements and conditions of particular trades.

In determining the effect to be given to a charter it may be necessary to take into consideration along with its express terms other terms which, as already explained, are implied by law. Thus if a charter contains no express provision as to seaworthiness there is underlying the contract, and implied and involved in it, a warranty by the shipowner that the ship is seaworthy. The special meaning attached to this word is that the ship shall have that degree of fitness which an ordinarily careful and prudent owner would require his ship to have at the commencement of her voyage, having regard to all the probable circumstances of it. Not only must the ship be tight, staunch and strong, but also fit for the carriage of the particular kind of cargo to be carried. This implied absolute warranty of seaworthiness is fulfilled if the ship is seaworthy when she leaves her moorings, and does not include any undertaking that the ship shall continue seaworthy; but where the voyage is in stages the ship must be fit for each stage when entered upon.

There may also have to be taken into consideration, in construing a charter, trade usages or customs with reference to which the parties are presumed to have made their contract. The express terms often refer to custom (which in a charter means a settled and established practice of the port) and they may be explained by evidence of usage or custom short of alleging anything inconsistent with them. For example, stipulations as to loading or discharging cargo in a port may be thus construed. Evidence of custom may be given to explain the meaning of working day at the port.

When a ship has reached the place where (under a voyage charter) she is to be ready to load, and is ready to load, and the charterers have been notified of this, the ship is an arrived ship and the lay days (for loading) begin to run.

Subject to any express or implied qualification, a charterer undertakes absolutely to furnish a cargo. When he fails to furnish a full cargo the damages which the shipowner is entitled to recover for this breach of contract are called dead freight. It is the duty of the master of the ship on behalf of the owner to receive and properly stow on board the cargo to be carried, which ordinarily is to be delivered to him alongside, but this duty may be subject to modification by custom or contract.

Should a ship be detained beyond the lay days the charterer will become liable to pay for the detention. If the basis for payment has been agreed by the charter the payment is known as demurrage. If it has not been agreed or if the charter refers to a fixed number of demurrage days which has been exceeded, then the payment, or part of it, will be damages for detention, the rate of which may have to be ascertained and may be different from the demurrage rate.

A common provision in a charter is the cesser clause, which is to the effect that the charterer's liability shall cease on the shipment of the cargo to the extent to which the charter gives

the shipowner a lien. Under common law the shipowner's lien on the cargo is in respect only of freight and general average contributions. The cesser clause ordinarily confirms this, and gives a lien for demurrage, and sometimes also for dead freight.

Bills of Lading.— Though either a charter or a bill of lading or both together may express the terms of a contract, the transactions in which no bill of lading is issued are few, because the bill of lading, in addition to its primary purpose of expressing terms of contract, serves in commerce as a transferable document of title representing the goods to which it relates. Where the charterer is also the shipper, the bill of lading, as between shipowner and charterer, is regarded as no more than a receipt which does not alter the contract contained in the charter. It is merely a receipt until used by the charterer as a transferable document of title, *i.e.*, until negotiated. Where the shipper is a person other than the charterer, the bill of lading is the evidence of the contract and does not, except by plain words, incorporate or impose on the shipper the obligations of the charter. Where the shipper (whether he is the charterer or not) has indorsed the bill of lading to a holder for value, the bill of lading is the only evidence of the contract.

Apart from statutory limitations on freedom of contract presently to be referred to, a common form of bill of lading (as set out in Carver, Carriage of Goods by Sea), was as follows:—

"Shipped, in good order and condition, by....., in and upon the good ship called the, whereof is master for this present voyage, now riding at anchor in the port of and bound for (description of goods) marked and numbered as in the margin, and are to be delivered in the like good order and condition at aforesaid (the act of God, the king's enemies, fire, and all and every other dangers and accidents of the seas, rivers, and navigation of whatever nature and kind soever excepted) to his assigns, he or they paying freight for the said goods at the rate of, with primage and average accustomed. In witness whereof, the master or agent of the said ship hath affirmed to bills of lading, all of this tenor and date, the one of which bills being accomplished the others to stand void. "Dated in the day of (Signed)"

Many "negligence clauses" (exceptions from liability formerly inserted to protect sea carriers) have disappeared from bills of lading as a result of legislation. In the United States the Harter Act was passed in 1893. It requires the exercise of due diligence properly to equip the ship and make it seaworthy, and, subject to this being done, gives exemption from navigation risks as distinguished from carrier's risks which the act compulsorily imposes on the carrier by prohibiting the insertion in any bill of lading or shipping document of any clause whereby obligations carefully to handle and stow the cargo and to care for and deliver the same may be lessened, weakened or avoided. Similar legislation was afterwards passed by some of the British dominions.

More recent legislation has attempted to define by its express terms the liabilities as well as the immunities of the carrier. The Carriage of Goods by Sea Act, 1924, was formulated in this way. Scheduled to it is a series of rules which are in effect standard clauses to be deemed part of the terms of bills of lading. This act is applicable to these documents when issued in Great Britain or Northern Ireland. Similar legislation has been passed in Australia, India, most of the British colonies and Belgium.

The Carriage of Goods by Sea Act requires that (subject to limited exceptions) the bill of lading shall expressly incorporate as part of its terms the provisions of the rules scheduled to the act. These impose on the carrier an irreducible minimum of responsibility for the safe carriage of the goods.

Though the Act thus defines the carrier's liabilities, it does not (except in the case of the implied absolute undertaking to provide a seaworthy ship) expressly exclude the implied obligations referred to above. Though an alternative basis of liability is

expressly laid down, the question apparently might arise whether those obligations (other than that of seaworthiness) still exist underlying the contract and implied and involved in it. In any event the compulsory minimum of responsibility is a protection to third persons (such as endorsees) who, though not parties to the contract, may be affected by it, as well as to shippers.

As the rules scheduled to the act become part of the terms of British and Belgian bills of lading they are important, but it is not practicable to give here more than a summary.

Under the definitions in Article I "Goods" includes articles of every kind except live animals and deck cargo and "carriage of goods" covers the period from the time when the goods are loaded on to the time when they are discharged from the ship.

By Article II the carrier is subject to the responsibilities and liabilities, and entitled to the rights set forth in the rules.

The carrier's responsibilities and liabilities detailed in Article III are to exercise due diligence to (1) make the ship seaworthy, (2) properly man, equip and supply the ship, (3) make the holds fit and safe for goods. He must also properly and carefully load, handle, stow, carry, keep, care for and discharge the goods, and issue a bill of lading showing certain particulars of quantity and condition of goods. This document becomes prima facie evidence of receipt by the carrier of the goods as therein described. Unless notice of loss or damage is given on delivery (or, if not apparent, within three days) delivery is prima facie evidence of delivery and, in any event, carrier is discharged from all liability unless suit is brought within one year. Nothing may be added lessening carrier's liability, but clauses increasing it are allowable, e.g., clause making bill of lading conclusive evidence of shipment.

Article IV relieves the carrier from liability for loss or damage resulting from (1) unseaworthiness, unless caused by want of due diligence, (2) a number of specified perils (e.g., act or neglect of the servants of the carrier in the navigation or in the management of the ship, fire, perils of the sea, act of God, etc.) which are mostly perils arising without the actual fault or privity of the carrier. Reasonable deviation is allowed. The carrier is not liable for loss or damage to goods in an amount exceeding £100 per package or unit unless value is declared before shipment and inserted in bill of lading.

Under the form of bill of lading set out above the goods are to be delivered to a named person "or to his assigns." A document in this form is by English law a negotiable instrument, in the sense that it is transferable by indorsement and delivery. A bill of lading may be indorsed by the person named in it (the shipper or the consignee) either in blank, by a simple signature on the back, or specially by indorsing and signing a direction to deliver to some other person or order. The indorsee may then transfer by indorsing in blank or specially. If indorsed in blank, or made out to a name left blank, or to bearer, a bill may be dealt with by mere delivery.

The indorsement and delivery of a bill of lading transfers such property as it was the intention of the parties to the indorsement to transfer, and, by the Bills of Lading Act, 1855, also transfers to the indorsee, to whom the property in the goods passes, the rights and liabilities of the shipper under the bill of lading. A pledgee is however not an indorsee to whom the property passes, and does not incur liabilities unless he takes delivery of the goods.

Performance of the Contract.—Reference has already been made to the implied undertakings by the carrier that he will proceed on the voyage with reasonable dispatch and without unnecessary deviation, and to the doubt whether these obligations still underlie the contract where a bill of lading has been issued subject to the statutory rules.

To complete the voyage the sea carrier should, if necessary, repair the ship, or tranship the cargo in order that it may be forwarded to its destination.

If necessary for the common safety a shipmaster may jettison cargo properly stowed. Any such extraordinary sacrifice or expenditure intentionally and reasonably made or incurred for the common safety, for the purpose of preserving from peril the property involved in a common maritime adventure, is a general average act. Damages, losses and expenses which are the direct

consequence of a general average act are borne by ship, freight and cargo as contributing interests. The contributions are adjusted by a general average statement. If, as is commonly the case, the charter or bill of lading incorporates by reference the York-Antwerp Rules, 1924, the adjustment is made as provided by those rules. (See further as to this under AVERAGE.)

Should the contract prove impossible of performance owing to circumstances which were unforeseen, and to which no provision in the contract is applicable (in particular where circumstances arise from the occurrence of war or in some other way, involving such delay as to frustrate the commercial purpose of the adventure) the contract may be held by the court to have come to an end by virtue of a provision implied in it. Cases of this kind are, of course, quite different from those where the contract, when made, cannot be performed without breaking the law. It is then void from the beginning for illegality.

Under the contract the ship is bound to proceed (unless prevented by an excepted peril) to the agreed place of discharge. On the ship's arrival there the charterer or consignee is bound to take delivery. Unless, under express provision, or by custom, notice of arrival is to be given, none is required. In the case of goods imported from abroad into Great Britain, if the owner of the goods fails to make entry of them at the Customs, or to take delivery, the goods may, under and subject to compliance with the provisions of the Merchant Shipping Act, 1894, sections 492-501, be landed and warehoused. Delivery should not be made except to a person producing a bill of lading making the goods deliverable to that person. By custom bills of lading are made out in sets, usually of three copies, but the carrier is justified in delivering to the first person producing a bill of lading making the goods deliverable to him, if without notice or knowledge of anything making it wrong to do so.

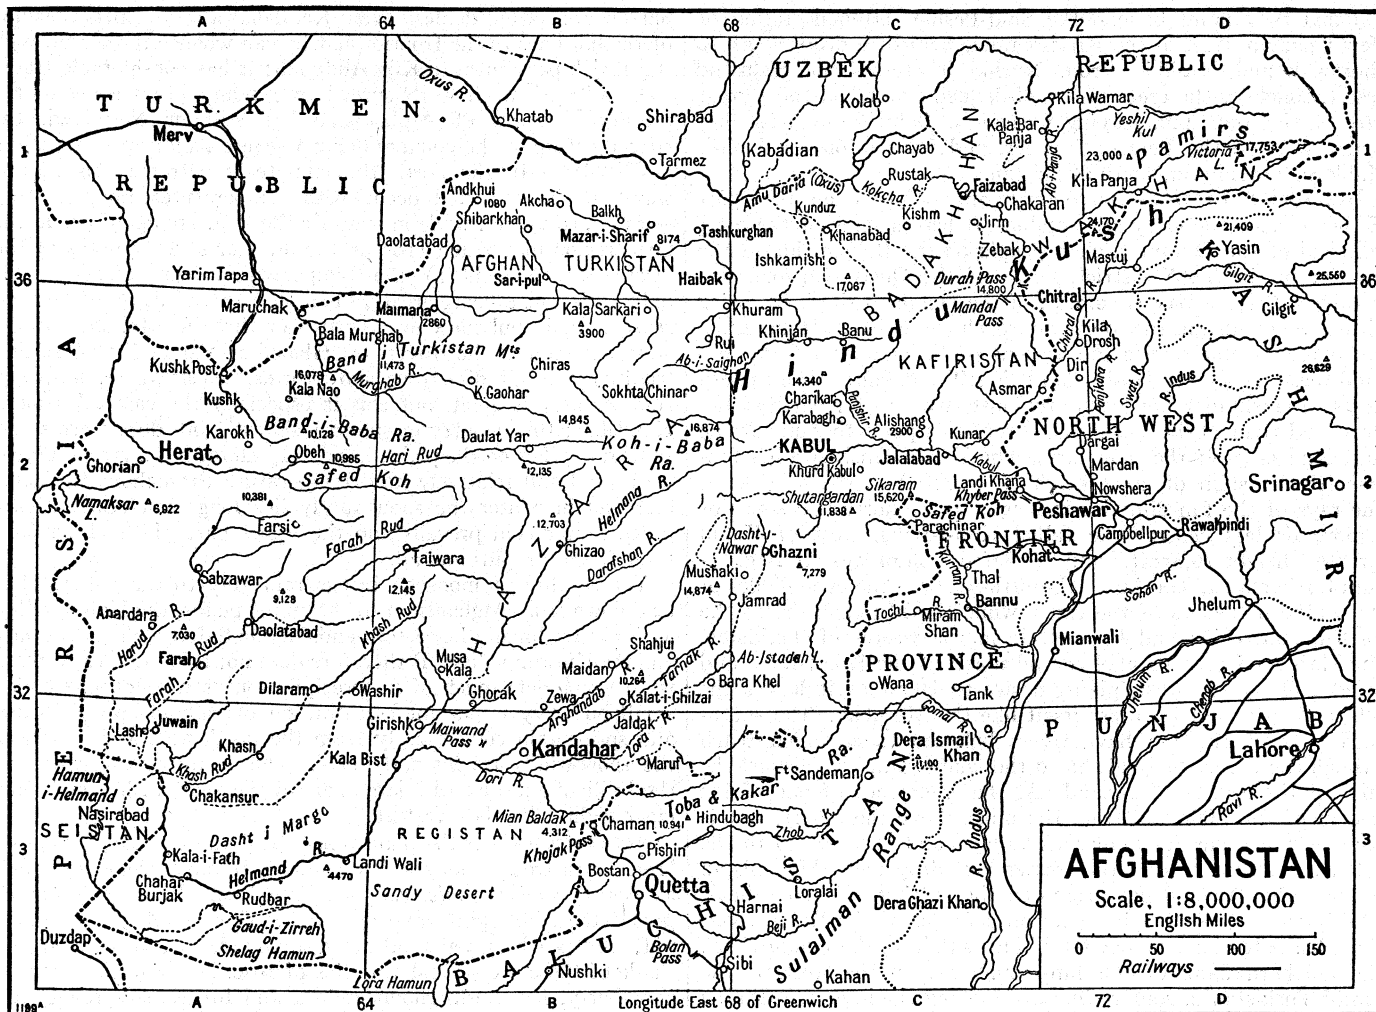

If goods are carried to the place where the voyage is to end, and, though damaged, are in a merchantable condition and ready for delivery, freight is payable. For delivery short of destination no freight is due unless the parties have taken steps justifying the conclusion that they intended to make a fresh contract whereby the owner of the goods has agreed to accept the goods at an intermediate port. English law in this respect differs from some continental laws under which proportional distance freight is payable. For short delivery at destination pro rata freight is payable. The carrier is entitled to a lien for freight payable on delivery. This is a possessory lien entitling him to withhold delivery until payment. It extends also to a general average contribution and to expenses incurred in the protection and preservation of the goods. If expressly so provided by the contract, the lien may extend to other matters, e.g., demurrage, damages for detention and dead freight.

See T. G. Carver, *Carriage of Goods by Sea* (1925); T. E. Scrutton, *Charter-parties and Bills of Lading* (1925). (S. D. C.)

AFFRETTANDO (Ital.), a musical term having just the same significance as *accelerando*, i.e., a quickening of the tempo or speed, but with a suggestion of hurry and agitation in addition.

AFGHANISTAN, a country of Asia. Estimated area is 245,000-270,000 sq.mi. (including Badakshan and Kafiristan). Pop. (est. 1938) 7,000,000. It is bounded on the north by Russian Turkistan, on the west by Persia, and on the east and south by Kashmir and the north-west frontier of India and Baluchistan. Surveys from 1872 to 1905 delimited the frontier which was accepted by Afghanistan in a treaty of 1921.

Boundaries.—From the town of Zulfikar on the Hari Rud river the boundary between Afghanistan and Russia is roughly parallel to the Paropamisus, and about 35m. N. of it, till it strikes the Kushk river in Jamshidi territory at a point once known as Chahil Dukteran, but now the Russian post Kushkinski, terminus of a branch railway from Merv. Kushkinski is about 20m. below the old Jamshidi settlement of Kushk, the capital of Badghis. From Kushkinski the boundary runs north-east, crossing the Murghab river near Maruchak (an Afghan fortress), and passing through the hills of the Chul, and the undulating deserts of the Aleli Turkmans, to the Oxus, leaving the valleys of Charshamba and of Andkhui (to which it runs approximately parallel) within Afghan

JOHN BARTHOLOMEW & SON, LTD., EDINBURGH

THE LAND OF THE AFGHANS HAS BEEN SUCCESSIVELY, IN ITS LONG AND INTERESTING HISTORY, A CONGERIES OF PETTY STATES. THE CENTRE OF GREAT EMPIRES RULED BY FOREIGNERS AND A DISMEMBERED COUNTRY, FURNISHING PROVINCES TO THREE MONARCHIES. IT IS NOW A DISTINCT POLITICAL ENTITY RULED BY AN INDEPENDENT NATIVE SOVEREIGN. THE AMIR, AS A COUNTRY FROM WHICH THE KHYBER PASS GIVES ADMISSION TO INDIA. AFGHANISTAN HAS ALWAYS POSSESSED A STRATEGIC IMPORTANCE IN EASTERN AFFAIRS

limits. These valleys define the limits of cultivation in this direction. Throughout this region the boundary is generally marked by pillars, but here and there local water-partings or watercourses are used. The boundary meets the Oxus at Khamiab at the western extremity of the cultivated district of Khwaja Salar and from that point to the eastern end of Lake Victoria in the Pamirs the main channel of the Oxus river forms the northern limit of Afghanistan. (See Oxus.) Eastwards from Lake Victoria the frontier was determined by the Pamir Boundary Commission (1895). A part of the little Pamir is Afghan, but the boundary crosses this Pamir before the great bend northwards of the Aksu takes place, and passing over a series of crags and untraversable mountain ridges, is lost on the Chinese frontier in the snowfields of Sarikol. Bending back westwards the frontier now follows the water-parting of the Hindu Kush; and as the Hindu Kush absolutely overhangs the Oxus nearly opposite Ishkashim, it follows that, at this point, Afghanistan is about 10m. wide. Thus a small high portion of the State extends eastwards from its north-eastern corner and is attached to the great Afghan quadrilateral by the thin link of the Panja valley. These narrow limits (called Wakhan) include the lofty spurs of the northern flank of the Hindu Kush, an impassable barrier at this point, where the glacial passes reach 19,000ft. in altitude, and the enclosing peaks 24,000ft. The backbone or main water-divide of the Hindu Kush continues to form the boundary between Afghanistan and the North-West Frontier Province of India until it reaches Kafiristan. From near the Dorah pass (14,800ft.), which connects Chitral with the Panja

(or Oxus) river, a long, straight, snow-clad spur reaches southwards, which divides the Kafiristan valley of Bashgol from that of Chitral, and this continues to define the eastern limits of Afghanistan till it nearly touches the Chitral river opposite the village of Arnawai, 45m. south of Chitral. Here the Bashgol and Chitral valleys unite and the boundary passes to the water-divide east of the Chitral river; along this water-divide it extends to a point nearly opposite the quaint old town of Pashat in the Kunar valley (the Chitral river has become the Kunar in its course southwards), and then divides the Mohmand country till it strikes the Kabul river near Palosi. Thence following a course nearly due south it reaches Landi Kotal. From the abutment of the Hindu Kush on the Sarikol in the Pamir region to Landi Kotal, and throughout its eastern and southern limits, the boundary of Afghanistan touches districts which were brought under British political control with the formation of the North-West Frontier Province of India in 1901. From the neighbourhood of Landi Kotal the boundary is carried to the Safed Koh overlooking the Afridi Tirah, and then, rounding off the cultivated portions of the Kurram valley below the Peiwar, it crosses the Kaitu and passes to the upper reaches of the Tochi. Crossing these again, it is continued on the west of Waziristan, finally striking the Gomal river at Domandi. South of the Gomal it separates Afghanistan from Baluchistan, which here adjoins the North-West Frontier Province. From Domandi (the junction of the Kundar river with the Gomal) the Afghan boundary marches with that of Baluchistan. (See BALUCHISTAN.) It is carried south-west mainly along the Kundar and

Kadanai to a point beyond the Sind-Peshin terminal station of New Chaman, west of the Khojak range, and then drops south to Shorawak and Nushki. From Nushki it crosses the Helmand desert, touching the crest of a well-defined watershed for a great part of the way and, leaving Chagai to Baluchistan, it strikes nearly west to the Persian frontier, and joins it on the Koh-i-Malik Siah mountain, south of Seistan.

Indefinite Limits.—Two important points upon this part of the Afghan boundary are notable. It leaves some of the most fanatical of the Durani Afghan people on the Baluch side of the frontier in the Toba district, north of the Quetta-Chaman line of railway; and it passes 50m. S. of the Helmand river, enclosing within Afghanistan the only approach to Seistan from India which is available during the seasons of Helmand overflow. Beyond these lagoons to Hashtadan it is still indefinite. The eastern limits of Hashtadan had been previously fixed as far north as the Hari Rud river at Toman Agha. From this point to Zulfikar the Hari Rud is itself the boundary. The Hindu Kush spreads fanwise from a stem of great height (24,000ft.) in the north-east. The rays of the fan diminish in height to the north and south of a more or less central one called Koh-i-Baba, west of Kabul (greatest height 16,870ft.) and the Safed Koh of western Afghanistan farther west. On the north-north-west are the deep defiles of the southern feeders of the Oxus, while the Murghab drains the north-western hills and loses itself in the wastes of Turkistan. The Hari Rud runs parallel to and north of the Koh-i-Baba and Safed Koh of the west, giving a site to Herat as it leaves the hills, and turns north to lose itself like the Murghab. The southward rays of the fan have rivers between them which reach through the desert of Registan to the lake-swamp of Seistan; the chief of these is the Helmand. At the emergence of one of the feeders of the Helmand from the hills, above the desert, stands Kandahar, a focus for numerous valleys, and also related to the Bolan pass. On the east the tremendous drop from Afghanistan to the Indus lowland has promoted the cutting of deep valleys, notably that of the Khyber pass on a feeder of the Kabul river, which has eaten back among the hill lines right to the Hindu Kush. The northern flank of the fan-mountains, on the west, is the Band-i-Turkistan, a sombre line overlooking the immense Chul, a loess area stretching away northwards to the Oxus.

The complexity of the Kabul river feeders is an important factor of the existence of the historic city of Kabul. From the city one may follow lines between the ridges southwards to Ghazni and to Kandahar, or the line of the Hari-Rud westwards to Herat, or one may go north over either the Hindu Kush (via the Unai pass) or Koh-i-Baba (via the pass of Irak) and so down the tremendous defiles of the Balkh river or one may skirt round the north-east of the Koh-i-Baba at a lower level via Charikar and the Shibar pass. By taking the last route one avoids getting more than 10,000 ft. above sea-level and this route is not often snowbound for long. It is the historic way. In the 19th century somewhat more direct ways from the Oxus to Kabul have been developed farther east. From Kabul into India one route much used in historic times left the Kabul river above Jalalabad and went north-east across the Kunar, thence into Bajaur and so via Malakand or some route near it into the Indian plains. The famous Khyber pass is entered beyond the fort of Jamrud, 11m. W. of Peshawar: it follows the Khyber stream up to Landi Kotal, debouching on to the Kabul river at Dakka whence the route goes along to Jalalabad, beyond which are alternative ways to Kabul. The Khyber pass is the part of the route between the entry to the mountains west of Jamrud and the emergence above at Landi Kotal and it lies within the North-West Frontier Province of India.

The Bara route farther south leads up into the heart of the Tirah country. The Kurram river route with the Peiwar (8,600ft.) and Shutargardan (10,800ft.) passes across the southern extensions of the Safed Koh (note the resemblance to the name of the range in western Afghanistan) is the next route southwards. The Tochi river route leads to Ghazni whence, in the days of its power, many raids were made upon the Indian plains. The Gomal river route has considerable commercial importance as it involves no very difficult pass though it is forced to leave the river because of very

narrow precipitous defiles. From Kandahar a route skirts the ends of the hill lines to the frontier at Chaman whence it goes through the Kojak pass down to Kila Abdullah; it has considerable trade.

In spite of much work spread over many years some of the physical features of Afghanistan are still undetermined, the rugged nature of the country being a severe handicap to research.

Climate.—In the north the climate is extreme. In winter, waves of intense cold occur with temperatures ranging from -12° F. to 17° F., while in summer the shade temperature in the Oxus region may reach 110° or 120° F. For seven months of the year (May–November) the temperature-range exceeds 30° F. daily, this range being greater than that of the days in the cold season. In Kabul snow lies for two or three months and people stay indoors near the stoves. At Ghazni also snow lasts long and tradition tells of disastrous snowstorms. Everywhere, however, summer heat is great, but this is especially the case all around Kandahar; this country in summer suffers from dust storms and snow rarely lies on the plains in winter. Herat has a strong north-west wind and relatively mild temperature throughout the summer and in winter the snow rarely lies long; but above Herat fierce winter cold prevails and the upper part of the Hari Rud river freezes, rapids and all.

The south-west monsoon brings rain only to the valleys that lead down from Afghanistan to the Indus plains, the Kabul valley as far as Laghman, the eastern ends of the Safed Koh, of the east and the Kurram valley. It therefore does not bring rain to Afghanistan which gets much of its precipitation as winter snow and a small but very important contribution of rain in spring. Snow and spring rain come largely from the north-west and in winter the snow-winds are intensely cold. The atmosphere is dry and the brilliant sunshine of a large part of the year, with very bright clear nights also, is a feature.

Vegetation.—On the main ranges at 6,000 to 10,000 ft. grow large forest trees, among which conifers are most prominent, such as *Cedrus deodara*, *Abies excelsa*, *Pinus longifolia*, *P. pinaster*, *P. pinea* (the edible pine) and the larch. Yew, hazel, juniper, walnut, wild peach and almond are also found. Growing under the shade of these are several varieties of rose, honeysuckle, currant, gooseberry, hawthorn, rhododendron and luxuriant herbage, the Ranunculaceae being abundant and rich in genera. The lemon and wild vine are commonest on the northern mountains. The walnut and oak (evergreen, holly-leaved and kermes) descend to the secondary heights, where they become mixed with alder, ash, khinjak, *Arbor-vitae*, juniper, *Indigoferae* and dwarf laburnum, with species of *Astragalus*, etc. Lower again and down to 3,000ft. grow wild olive, species of rock-rose, wild privet, acacias and mimosas, barberry and *Zizyphus*; and, in places, *Chamaerops humilis* (which is applied to a variety of useful purposes), *Bigonia* or trumpet flower, sissu, *Salvadora persica*, verbena, acanthus, varieties of *Gesnerae*. The lowest terminal ridges, especially towards the west, are naked in aspect. Their scanty vegetation is almost wholly herbal; shrubs are only occasional; trees almost non-existent. Labiate composite and umbelliferous plants are most common. Ferns and mosses are almost confined to the higher ranges. On the dreary Kandahar table-lands grow many vigorous plants, such as papilionaceous *Leguminosae*, and the camel-thorn (*Hedysarum Alhagi*), *Astragalus* in several varieties, spiny rest-harrow (*Ononis spinosa*), the fibrous roots of which often serve as a tooth-brush; plants of the sub-family Mimosae, such as the sensitive mimosa; a plant of the rue family, called by the natives *lipad*; the common wormwood; also certain orchids, and several species of *Salsola*. Rue and wormwood give domestic medicines—the former for rheumatism and neuralgia; the latter for fever, debility and dyspepsia, as well as for a vermifuge. The *lipad*, of heavy nauseous odour, is believed to keep off evil spirits. On some sides and hollows of ravines are found rose-bay (*Nerium Oleander*), called in Persian *khar-zarah*, or assbane, wild laburnum and various *Indigoferae*.

The chief cultivated trees are mulberry, willow, poplar, ash, and occasionally the plane.

Of commercial value is the gum-resin of *Narhex asafetida* of the high and dry plains of western Afghanistan, especially between

Kandahar and Herat. The Kakar clan collects this gum-resin; and the depot is Kandahar, whence it finds its way to India, for use as a condiment. It is not used in Afghanistan, but the Seistan people eat the green stalks preserved in brine. In the highlands of Kabul edible wild rhubarb is an important local luxury. The bleached rhubarb, which has a very delicate flavour, is obtained by covering the young leaves as they sprout with loose stones or an empty jar. Leaf-stalks are gathered and carried down for sale. Bleached and unbleached rhubarb are both largely consumed, both raw and cooked. Walnut and edible pine-nut are both wild growths, which are exported. The *sanjît* (*Elaeagnus orientalis*), common on the banks of watercourses, furnishes an edible fruit. The dried tuber of a mountain orchis affords the nutritious mucilage called *salep*; a good deal of this goes to India. *Pistacia khinjak* affords a mastic. The fruit, mixed with its resin, is used for food by the Achakzais in southern Afghanistan. The true pistachio is found only on the northern frontier; the nuts are imported from Badakhshan and Kunduz. Mushrooms and other fungi are largely used as food, especially by town Hindus as a substitute for meat. Manna, of at least two kinds, is sold in the bazaars. One, called *turanjbin*, appears to exude, in small round tears, from the camel-thorn, and also from the dwarf tamarisk; the other, *sir-kasht*, in large grains and irregular masses or cakes with bits of twig imbedded, is obtained from a tree which the natives call *siah chob* (black wood), thought by Bellew to be a *Fraxinus* or *Ornus*.

Agriculture.— In most parts of the country there are two harvests, as generally in India. One of these, called by the Afghans *bahdrak*, or the spring crop, is sown in the end of autumn and reaped in summer. It consists of wheat, barley and a variety of lentils. The other, called *pâizah* or *tirmâi*, the autumnal, is sown in the end of spring and reaped in autumn. It consists of rice, varieties of millet and sorghum, of maize, *Phaseolus mungo*, tobacco, beet, turnips, etc. The loftier regions have but one harvest. Wheat is the staple food; rice is not largely distributed. In the eastern mountains *bdjra* (*Holcus spicatus*) is the chief grain. Most English and Indian garden-stuffs are cultivated, turnips in some places very largely, as cattle food. The growing of melons, watermelons and other cucurbitaceous plants is very important near towns. Sugar-cane is grown only in the rich plains; and though cotton is grown in the warmer tracts, most of the cotton cloth is imported.

Madder is part of the spring crop near Ghazni and Kandahar and in the west and supplies the Indian demand. It is said to be very profitable, though it takes three years to mature. Saffron is grown and exported. The castor-oil plant furnishes most of the oil of the country. Tobacco is very general; that of Kandahar is exported to India and Bokhara. Two crops of leaves are taken.

Lucerne and a trefoil called *shaftal* form important fodder crops in the west, and, when irrigated, are said to afford ten or 12 cuttings in the season. The *komal* (*Prangos pabularia*) is abundant in the hill country of Ghazni, and is said to extend through the Hazara country to Herat. It is stored for winter fodder. Others are derived from the *Holcus* sorghum, and from two kinds of panick. It is common to cut down the green wheat and barley before the ear forms, for fodder, and the repetition of this, with barley at least, is said not to injure the grain crop. Bellew gives the following statement of the manner in which the soil is sometimes worked in the Kandahar district:—Barley is sown in November; in March and April it is twice cut for fodder; in June the grain is reaped, the ground is ploughed and manured and sown with tobacco, which yields two cuttings. The ground is then prepared for carrots and turnips, which are gathered in November or December.

European fruits are of many varieties and excellent quality. Fresh or preserved, they form a principal food of a large class of the people, and the dry fruit is largely exported. In the valleys of Kabul mulberries are dried, and packed in skins for winter use. This mulberry cake is often reduced to flour, forming in some valleys the staple food. Vines are sometimes trained on trellises, but most frequently over ridges of earth 8 or 10 ft. high; the produce round Kandahar must be enormous.

Open canals are usual in the Kabul valley, and in eastern Afghanistan generally; but in the west much use is made of the *karez*, a subterranean aqueduct uniting waters of several springs and conducting their combined volume to the surface at a lower level.

Wild mammals include the tiger in the north, the common leopard and other cats, wolves, jackals, foxes and hyenas among the dog tribe, goats, wild sheep, gazelles, deer, Himalayan varieties of markhor and ibex, wild hogs, wild asses (*Equus onager*). Afghanistan seems to furnish a retreat for the breeding season for many Indian and perhaps some African birds, while in winter its bird life is akin to that of lands farther north.

Of domestic animals, the one-humped camel is cared for and is a stronger breed than the taller one used in India. The two-humped camel is used in the north. The *yabu*, an indigenous horse, is strong and heavy-shouldered and about 14 hands high; it cannot do fast work nor stand great heat. The breed was improved by Abdur Rahman and those bred in the north are exported to India. Humped cows are kept for milk in the south and south-west, pressed and dried curd being largely eaten; it is said to be a Mongol introduction. Fat-tailed indigenous sheep are either white or russet; the white fleeces are exported to Persia and to Europe via Bombay. Mutton salted and dried in the sun is one of the chief foods of the nomad people who also use beef and camel's flesh in the same way. Goats and dogs (pointers and greyhounds) are also noteworthy.

Minerals.— A little gold is taken from the streams in Laghman and the adjoining districts. Famous silver mines were formerly worked near the head of the Panjshir valley in Hindu Kush. Kabul gets iron from the Permuli (or Farmuli) district, between the Upper Kurram and Gomal. Iron ore is most abundant near the passes leading to Bamian, and in other parts of Hindu Kush. Copper ore from various parts of Afghanistan has been seen, but it is nowhere worked. Lead is found in Upper Bangash (Kurram district), and in the Shinwari country; also among the branches of the Safed Koh of eastern Afghanistan and in the Kakar country. There are reported to be rich lead mines near Herat scarcely worked. Lead, with antimony, is found near the Arghandab, 32 m. N.W. of Ghazni, and in the Ghorband valley, north of Kabul. Most of the lead used, however, comes from the Hazara country, where the ore is described as being gathered on the surface. A large and elaborate ancient mine exists at Feringal, in the Ghorband valley. Antimony is obtained at Shah-Maksud, about 30 m. N. of Kandahar. Sulphur is said to be found at Herat, dug from the soil in small fragments, but the chief supply comes from the Hazara country and from Pirkisri, on the confines of Seistan, where there would seem to be a crater, or fumarole. Sal-ammoniac is brought from the same place. Gypsum is found in large quantities in the plain of Kandahar, being dug out in fragile coralline masses from near the surface. Coal (perhaps lignite) is found at least in the Ghorband valley and near the Khurd Kabul pass. Nitre abounds in the soil over all the south-west of Afghanistan, and often affects the water of the *karez* or subterranean canals. Rubies, turquoises and first-quality lapis lazuli come from Badakhshan. This last material, especially, is smuggled to the north.

People.— The term Afghan really applies to one section only of the people, but this is the dominant section known as the Durani. The Ghilzai (almost as powerful as the Durani) claim to be of Turkish origin; the Hazaras, the Chahar-Aimak, Tajiks, Uzbeks, Kafirs and others are more or less subject races. Popularly any inhabitant of Afghanistan is known as Afghan on the Indian frontier without distinction of origin or language; but the language division between the Parsiwan (or Persian-speaking Afghan) and the Pathan of the Indian frontier is a very distinct one. The predominance of the Afghan in Afghanistan dates from the mid-18th century, when Ahmad Shah carved out Afghanistan from the previous conquests of Nadir Shah and called it the Durani empire.

The Durani Afghans claim to be Ben-i-Israel, and insist on their descent from tribes carried away captive from Palestine to Media by Nebuchadrezzar. Yet they also claim to be Pukhtun (or Pathan) in common with all other Pushtu-speaking tribes, whom they

do not admit to be Afghan. The bond of affinity between the various peoples who compose the Pathan community is simply the bond of a common language. All of them recognize a common code or unwritten law called Pukhtunwali, which appears to be similar in general character to the old Hebraic law, though modified by Mohammedan ordinances, and strangely similar in some points to Rajput custom. Besides their division into clans and tribes, the whole Afghan people may be divided into dwellers in tents and dwellers in houses; and this division is apparently not coincident with tribal divisions, for of several of the great clans at least a part is nomad and a part settled. Such is the case with the Durani and with the Ghilzai.

Dominant Stock.—Afghans have fine figures, aquiline profiles, fair complexions, and a small group yielded an average cephalic index of 74.8, a value nearer to that found among Rajputs in India than to that among the Pukhtun (Pathan) groups (av. ceph. ind. 80–83) of the Indian frontier or to that among some of the subject peoples. Among the latter, the Hazaras are tall, very broad-headed (average cephalic index 85.0), and akin in feature to peoples of parts of Turkistan and Mongolia; they are said to have been planted in Afghanistan by Jenghiz Khan and they inhabit especially the mountains west of Kabul. The Tajiks are as broad-headed as the Hazaras but belong to the pale rosy-skinned rather than to the yellow-skinned stock; they seem to be an old established, settled, agricultural people.

Tribal law, with the custom of hospitality, and the vendetta in many forms are rules of life, and even the settled Afghan is very much a soldier. They are able to endure great privation and are sober and stern, and may often become cruel. They have long been free of law and have looked upon taxation as interference to be resisted by force, but now the "modernization" of Afghanistan is said to be proceeding apace.

The cultivators, including owners, tenants, labourers and slaves, are skilled irrigators, utilizing every fragment of profitable land; some of the Ghilzai are specially skilled in building underground water-channels (karez). The settled folk live chiefly in village communities and leave handicraft and commerce largely to subject races save that some Ghilzai are wandering traders (*powindaks*). Afghanistan is a stronghold of Islam, of the Sunni sect for the most part, though the Hazaras and others are Shiah. The Kafirs, as the name implies, are non-Mohammedans, living in Kafiristan (E.N.E.); other tribes of the Indian border are recent converts to Islam. Some of the Durani Afghans of Kandahar and Zamindawar districts are very fanatical "Ghazis," that is, men who have vowed their lives to the extinction of other creeds.

Language and Administration.—The official language of Afghanistan is Persian, which is also the vernacular of the people west of the Helmand; Pushtu is more widely spoken, especially to the east, but is unknown in the west; Turki is spoken in the north. There is a respectable amount of Afghan literature. The oldest work in Pushtu is a history of the conquest of Swat by Shaikh Mali, a chief of the Yusufzais, and leader in the conquest (A.D. 1413–24). In 1494 Kaju Khan became chief of the same clan; during his rule Buner and Panjkora were completely conquered, and he wrote a history of the events. In the reign of Akbar, Bayazid Ansari, called Piri-i-Roshan, "the saint of Light," the founder of an heretical sect, wrote in Pushtu, as did his chief antagonist, a famous Afghan saint called Akhund Darweza. The literature is richest in poetry. Abdur Rahman (17th century) is the best known poet. Another very popular poet is Khushal Khan, the warlike chief of the Khattaks in the time of Aurangzeb. Many other members of his family were poets also. Ahmad Shah, the founder of the monarchy, likewise wrote poetry. Ballads are numerous. Much of the literature is in Persian. The village Mullah or priest teaches the boys reading and writing and religion through the Koran; the Afghan noble has long known Persian and there is an old-established traditional lore in religion and medicine. But of late a good deal has been done to modernize education, by teaching agriculture, by developing free secondary schools including one under French and one under German supervision, by opening two colleges in Kabul, one for army officers and one for administrators, as well as other colleges elsewhere. Afghan stu-

dents in recent years have been sent to France and Germany. The Government was an absolute monarchy until 1922 when a legislative and a State assembly were organized with a cabinet under the presidency of the king, Amanullah Khan (born 1892, succeeded to the throne 1919), who took the title of king in 1926 in place of that of Amir. Ministers are appointed for foreign affairs, internal affairs, education, commerce, justice, revenue and war. There are five major provinces: Kabul, Kandahar, Herat, Mazar-i-Sharif, and Kataghan-Badakhshan, and four minor provinces Jalalabad, Khost, Farah and Maimana. Each province is under a governor. The law is that of Islam with courts in each seat of Government and appeals to higher courts and ultimately to a supreme one at Kabul. The army is a short service conscript one, but tribal groups also count for a great deal; there are armament factories at Kabul, and, by a treaty of 1921, the Afghans may import munitions through India. Herat in the west and Dehdadi near Balkh in the north are strongly fortified. A new currency was established in 1926, and revenue is mainly from customs. A subsidy was formerly paid by the Indian Government to the Amir but that ceased, by agreement, in 1919. There is no regular budget but the public revenue is still under £1,000,000. There are neither banks nor railways, nor is Afghanistan as yet in the International Postal Union, but some waterfalls, notably that of Djebel-us-Seradj, are utilized as sources of hydro-electric power. Railways reach the Afghan frontier at various points from the British side and also from the Russian side. The Khyber railway goes up to Landi Kotal.

Communications and Industries.—There are no railways, but telegraphic communication exists between Kabul and Peshawar; telephones exist in some of the towns, and Kabul has a wireless installation.

Great Britain, France, Germany, Italy, Persia, Russia and Turkey have legations at Kabul. Kabul (pop. 80,000) is the historic centre and the limits of its authority have varied greatly from time to time, some mountain regions being practically independent. Herat (pop. 50,000) is largely Persian in character and has often been in rebellion. Kandahar (pop. 60,000) in the south and Mazar-i-Sharif (pop. 30,000) in the north are other important centres.

Silks, felts, carpets, articles made from camels' and goats' hair, sheepskin coats, soap, clothing, boots, etc., are produced at Kabul, chiefly for the army, in factories that are partly instructional. Herat and Kandahar have long been famed for their silks, felts and carpets, though these are not comparable to true Persian ones. Herat and Kandahar gather fine wool from the nomad shepherds. Commerce across the frontiers has been limited by high duties. India sends to Afghanistan cotton goods, dye-stuffs, hardware, etc., while Afghanistan sends into India timber, dried fruits, provisions, drugs (especially asafetida), madder, spices, wool, silk, hides, cattle, tobacco. Merchandise is still carried chiefly on camel or pony back, but timber is floated down the streams where that is possible. Cattle go in greater number into Soviet territories and food stuffs are also exported in that direction, while imports from Russian lands into northern Afghanistan include wool and cotton. Trade with Persia is of little account.

The basin of the Kabul river especially abounds in remains of the period when Buddhism flourished. Bamian is famous for its wall-cut figures and at Haibak (on the route between Tashkurghan and Kabul) there are some most interesting Buddhist remains. In the Koh-Daman, north of Kabul, are the sites of several ancient cities, the greatest of which, called Begram, has furnished coins in scores of thousands, and has been supposed to represent Alexander's Nicaea. Nearer Kabul, and especially on the hills some miles south of the city, are numerous topes. In the valley of Jalalabad are many remains of the same character.

In the valley of the Tarnak are the ruins of a great city (Ulan Robot) supposed to be the ancient Arachosia. About Girishk, on the Helmand, are extensive mounds and other traces of buildings; and the remains of several great cities exist in the plain of Seistan, as Pulki, Peshawaran and Lakh, relics of ancient Drangiana. An ancient stone vessel preserved in a mosque at Kandahar is almost certainly the same that was treasured at Peshawar in the 5th

century as the begging pot of Sakya-Muni. In architectural relics of a later date than the Graeco-Buddhist period Afghanistan is remarkably deficient. Of the old city of Ghazni, the vast capital of Mahmud and his race, no substantial relics survive, except the tomb of Mahmud and two remarkable brick minarets. A vast and fruitful harvest of coins has been gathered in Afghanistan and the adjoining regions. The concession for archaeological exploration in Afghanistan has been given to France. Regarding the proprietorship of finds, it may be noted that the adoption of regulations such as are in force in Egypt is being considered.

Present-day Army.—The present military system dates from the days of Abdur Rahman who in 1896 introduced semi-compulsory service which provided that one man in every eight between the ages of 16 and 70 should take his turn in undergoing military training. In 1917 an organization was introduced to provide corps (Urdu) of all arms with a personnel of about 24,000 combatants, divisions of all arms with about 12,000 and mixed brigades with about 4,000, all with mounted troops in the proportion to infantry of one to six, with a six- or four-gun battery attached to each infantry "battalion." Recruitment is practically for life, but nominally discharge can be obtained after 3 years if a substitute is forthcoming. The king is head of the army, with a commander in chief as executive commander, and subordinates for the army formations. The headquarters of the military districts are Kabul, Jalalabad, Kost, Ghazni, Mukur, Kandahar, Farak, Herat, Maimana, Mazar-i-sharif and Faizabad. The distribution of troops is irregular. Kabul has the most. Practically all Afghans being armed with modern rifles, estimates of fighting strength are misleading. Taking the population at 6,000,000, an estimate of about 1,200,000 of fighting age would be somewhere near the mark. The size of mobile formations would depend upon success in collecting transport. Some motor transport is kept at Kabul. There are military academies at Kabul and Herat, military schools for cadets at Kabul, Ostalif and Jalalabad, but the majority of officers seem to be drawn from other sources. Kabul and other places have defences. Herat and Dehdali near Balkh are credited with being the chief fastnesses in Northern Afghanistan, the latter covering the roads leading from the Oxus into Afghan Turkistan. According to travellers' reports, attention is being directed to the development of air forces. Visits to Kabul of Russian aircraft and negotiations for their purchase have been reported, the Russians desiring to provide the pilots.

BIBLIOGRAPHY.—Afghanistan is one of the few countries for which information about armaments is not to be found in the League of Nations Armaments' Year Books. Foreign travellers were not encouraged by the present King's predecessors. The preceding notes are from the best accessible reports, culled from many sources. Among the most recent is an English translation by B. K. Featherstone of *Through the heart of Afghanistan* by Emil Trinkler (Faber and Gwyer, 1928). (G. G. A.)

HISTORY

The geographical term Afghanistan ("land of the Afghans") is an anachronism as applied to the country before 1747, when it first became a separate and independent state, and though it is now the official name of the kingdom it is not in common use among the Afghans.

The Afghan chroniclers call their people *Ben-i Israil*, or "Children of Israel," and claim for them descent from King Saul, whom they call *Tālūt*, through a son named Jeremiah, who is said to have had a son named Afghana; but this legend assumes so many conflicting and improbable forms that it may be safely regarded as a late invention. According to one account Afghana was settled by Sulaiman (Solomon) in the Sulaiman Mountains, and according to another, evidently connected with the account of the captivity of the Ten Tribes, his descendants were removed

from Palestine by Nebuchadrezzar and found their way to the mountainous country about Herat. Another legend related that in pre-Islamic times Bilo (father of the Biluchis), Uzbak (father of the Uzbaks) and Afghana were considered as brethren. The historian Firishta cites a legend which makes the Afghans Copts, of the race of Pharaoh; and the Afghans explain their conversion to Islam by a story to the effect that nine years after Mohammed's announcement of his mission a holy man named Kais, sent to Medina to make inquiry of him, became a zealous Muslim and on his return converted his countrymen, adding that all true Afghans are descended from Kais and his three sons, but ignoring the other descendants of Afghana. Omitting the legend which attributes to the Afghans a Coptic descent we find the grandson of King Saul made contemporary with Mohammed Uzbak Khan, who flourished in the 14th century, as well as with King Solomon; and Kais, whose name suggests Kish, Saul's father, made contemporary with the prophet Mohammed.

Despite these and other discrepancies some intelligent British officers, well acquainted with the Afghans, have accepted the story of their Hebrew descent. Their belief has been based on certain Afghan customs and on the fancied resemblance of a well-known type of Afghan physiognomy to the physical characteristics of the Jews; but the Afghans, as Muslims, have many customs similar to those of the Hebrews, and they share their physical resemblance to the Jews with other races in no way connected with them.

Early Period.—Until 500 B.C. Afghanistan formed part of the Achaemenian empire, and comprised the ancient provinces of Aria, or Hari Rud; *Bactria*, or Balkh; Drangiana, or Seistan and the Helmand Valley; *Arachosia*, or Kandahar; and *Paropamisus*, the region of the Hindu Kush and Kabul. The population in the north was Iranian, and in the south contained a large Indian element; but the most interesting people mentioned in the Greek records are the Paktyes in Arachosia, which Herodotus calls *Pakt-yike*, for in their name we may trace that of the *Pakhtun* or *Push-tun*, by which the Afghans still describe themselves. The story of Alexander's campaign in the eastern provinces of the Persian empire need not be repeated here, but the cities of Herat (Alexandria Arion) and Kandahar (Alexandria Arachosion) were either founded or restored by him.

He was succeeded in the eastern provinces of his empire by Seleucus Nicator, the founder of the Seleucid dynasty, but the Indian provinces and the Kabul valley fell to Chandragupta (*Sandracottus*), the founder of the Maurya dynasty.

Greek Dynasty.—As the power of the Seleucids waned an independent Greek dynasty was established, about 246 B.C., in Eactria, and about 50 years later annexed a great part of north-western India, but Afghanistan passed from its possession into that of the Parthians (who occupied its western provinces), and the Sakas, a Scythian tribe, who conquered the eastern provinces about 130 B.C. and gave their name to Seistan (*Sakastan* or *Sakastene*). Within 200 years the Yue-chi (*q.v.*), another central Asian tribe, expelled the Parthians and founded the Kushan dynasty, which ruled Afghanistan, and, at the height of its power, northern India, as far as Benares on the east and Malwa on the south. This dynasty adopted the Buddhist religion, and Kanishka, the greatest king of the line, convened the great council which settled the canon of northern Buddhism, and is mentioned as a champion of Buddhism by Hiuen Tsang, the Chinese pilgrim; al-Biruni, the Mohammedan traveller, philosopher, and geographer; and in the Mongol versions of the Buddhist story.

The empire of Kanishka did not long survive his death, but kings of his race, known as the Turki Shahs, were found by Hiuen Tsang reigning in the Kabul valley in the 7th century, and were not overthrown until the end of the 9th century, when a Hindu dynasty known as the Hindu Shahi ousted them.

The Caliph Empire.—The title of Arab conquest and Islamic propaganda in the 7th century reached western Afghanistan, which was included in the empire of the Caliphs, but did not touch the kingdom of Kabul, which remained independent under the Turki Shahi and Hindu Shahi kings. As the power of the Caliphs declined their provincial governors founded dynasties owning a

nominal allegiance to them but virtually independent. One of the earliest of these was the Arab dynasty of the Tahirids, who included Herat and Balkh in their kingdom of Khurasan, in which they were succeeded by a native Persian dynasty, the Saffarids, who were overcome in the 9th century by the Samanids of Balkh and Bukhara, another Persian house. Alptigin, a Turkish slave of this house, established himself in Ghazni, where he was succeeded, after a short interval, by another Turkish slave, Sabuktigin, who threw off the yoke of the Samanids and annexed to his dominions not only the Hindu kingdom of Kabul, but the territory lying between it and the Indus. Assistance given by him to the Samanids was rewarded with the government of Khurasan, to which he appointed his elder son Mahmud, and Afghanistan became the nucleus of a great empire. Sabuktigin died in 997, and his son Mahmud, after deposing a younger brother, ascended the throne in 998. The tale of his predatory raids into India need not be repeated here. He added to his empire Baluchistan, and, later in his reign, the Indian kingdom of the Punjab, the province of Multan, and the greater part of western Persia, and divided with Ilak Khan, the founder of a Turkish dynasty in Transoxiana, the dominions of the house of Saman, which came to an end during his reign.

The hitherto obscure town of Ghazni now became a great and splendid city, for Mahmud was no mere ravager and despoiler. It is in Mahmud's reign that we first hear of the small state of Ghor, in the southern ranges of the Safid Kuh, which Mahmud reduced to vassalage, and the rulers of which, eventually, extinguished his dynasty. He himself paved the way for the destruction of his empire by admitting into Khurasan the Seljuk Turks, who afterwards stripped his descendants of their possessions in the north and west and founded a great empire on the ruins of that of Ghazni.

Mahmud died in 1030 and his descendants continued to reign over a gradually diminishing empire, with Ghazni as their capital, until 1153, when Alauddin Husain, chief of Ghor, to avenge the death of his brother, Saifuddin, who had been treacherously put to death by the sultan of Ghazni, captured and burnt the city, driving Mahmud's descendant, Khusrav Shah, into the Punjab. The destruction of the great city of Ghazni earned for its author the cognomen of *Jahansuz*, "the World-Burner."

Ghor Dynasty. — In 1186 the World-Burner's nephew, Muizzuddin Mohammed, commonly known as Mohammed Ghori, treacherously enticed Khusrav Malik, the last of the Ghaznavids, from Lahore, and imprisoned him for the short remainder of his life. Having secured the Punjab, Mohammed invaded India, and founded there a Muslim empire which endured, in name at least, until 1858.

This dynasty of Ghor is commonly believed to have been of Afghan origin, but the belief rests on a very slender foundation of evidence. Legend also assigns it descent from Zahak; and though this is no better attested than their Afghan genealogy, it seems to be probable that they were Tajiks of Persian race. The Afghans themselves are Indo-Iranian by race, and their antiquity as a separate people is uncertain. Firishta's statement that the inhabitants of the Sulaiman mountains were known as Afghans in the 1st century of the *Hijra* (the 7th century of the Christian era) carries no weight, but the name occurs in al-'Utbi's *History of Sultan Mahmud*, written about A.D. 1030, coupled with that of the Khalaj or Khaljis, who were apparently a Turkish tribe domiciled in western Afghanistan, but always antagonistic to the true Afghans. Both names occur in the history of India during the 13th and 14th centuries, and the Indian historians are not careful to distinguish between the two peoples. Hence it is, probably, that some Europeans have carelessly classed all the five dynasties which preceded the Timurids on the throne of Dihli as "Pathans," or Afghans, though in fact two of them were Turkish, one was Khalji, and one was of Arab descent.

The Muslim empire in India was founded by a manumitted slave of Mohammed Ghori, and shortly after Mohammed's death his great empire fell to pieces and was divided between provincial governors and members of his own family holding small principalities in Afghanistan. These petty princes were subdued by

the shahs of Khvarazm, or Khiva, of whose great but ephemeral empire Afghanistan for a time formed part.

Mongol Rule. — In the 13th century Afghanistan, like Persia, suffered the dreadful calamity of invasion by the heathen Mongols of Jenghiz Khan, who settled to the north of the Hindu Kush; but the rest of the country, owing to its inhospitable nature, suffered less than more fertile and populated lands. It was here, however, that the gallant Jalaluddin, last of the shahs of Khvarazm, made his most strenuous efforts to avenge on these savages the annexation and devastation of his kingdom.

The greater part of Afghanistan remained under Mongol rule until the rise of Timur Lang (Tamerlane), who established himself in northern Afghanistan in the latter part of the 14th century, wresting Herat from the Rurts, a family which claimed descent from the princes of Ghor (see MONGOLS).

The **Moghul Empire**. — In 1504, Babur, fifth in descent from Timur, having been expelled from his ancestral dominions in Transoxiana, occupied Kabul and made it the capital of a kingdom which he established in Afghanistan; and in 1522 he captured Kandahar from the Afghans, a Moghul family which had long held it, but he did not remain long content with his Afghan kingdom. In 1526 he invaded India, defeated Ibrahim Lodi, the Afghan Sultan of Delhi, on the field of Panipat, and founded the state which is usually known to Europeans as the Moghul empire, though Babur was no Moghul, and would have resented the designation. Kabul and Kandahar remained for the time merely provinces of Babur's Indian empire, and Herat fell into the hands of the Safavi shahs of Persia.

Babur's son, Humayun, was expelled from India by the Afghan, Sher Khan, and was compelled to seek an asylum with Shah Tahmasp of Persia, who helped him to recover Kandahar, held by his rebellious brother. From Kandahar Humayun proceeded to Kabul, from which city he ousted another brother, and after spending seven years in re-establishing his authority in Afghanistan was able, in 1554, to recover his Indian empire, but died shortly afterwards, as the result of an accident, leaving the task of extending and consolidating the dominions of his house in India to his young son Akbar (*q.v.*), the real founder of the "Moghul" empire of India.

Afghanistan was then divided, Kabul remained a province of India, and Herat a province, of Persia; Balkh fell to the Uzbaks of Transoxiana, and Kandahar, after remaining for a time in the possession of the Timurids, was taken by the Persians. Akbar's grandson, Shah Jahan, made a disastrous attempt to recover Balkh and twice endeavoured to recover Kandahar, but without success.

In 1708 the Ghilzais of Kandahar, who perhaps represented the Khalaj, provoked by the oppressive rule of the Persian governor, Shahnavaz Khan, a Georgian prince of the Bagratid house, rose under Mir Vais and expelled the Persians. Mir Vais defeated the Persian armies sent against him and established his independence, but died in 1715. His son Mahmud, carrying out a project of his father's, invaded Persia, besieged Isfahan, and in Oct. 1722, compelled Shah Husain, the feeble Safavid, to surrender his crown to him, but the rule of the Ghilzais in Persia was brief—Mahmud died mad and his successor, Ashraf, was defeated by Nadir Kuli, the Afshar, who shortly afterwards ascended the throne. In 1737–38 Nadir Shah, one of Persia's greatest monarchs, recovered Kandahar and conquered the Indian province of Kabul, but conciliated the Afghans and enlisted many in his army—among them Ahmad Khan, a young chieftain of the Sadozai family of the Abdali tribe. Ahmad Khan rose to high rank in the Persian army, and after the assassination of Nadir Shah in 1747 was chosen by the Afghan chiefs at Kandahar as their leader and assumed the royal title. Among his titles was that of *Durr-i-Dauran*, "the Pearl of the Age," from which his tribe received the name of Durrani.

The land of the Afghans had been successively a congeries of petty states, the centre of great empires ruled by foreigners, and a dismembered country, furnishing provinces to three monarchies. It now became, for the first time, a distinct political entity, ruled by an independent native sovereign.

Ahmad Shah Abdali extended his kingdom westward nearly to the Caspian and eastward over the Punjab and Kashmir, which he wrested from the feeble successors of Babur on the throne of Delhi. He claimed and commanded the allegiance of Sind, which had been ceded by Mohammed Shah of Delhi to Nadir Shah. His northern boundary was the Oxus, and Baluchistan and Khurasan were tributary states of his kingdom. At the third battle of Panipat, fought on Jan. 6, 1761, he inflicted on the confederate Maratha chiefs, who were then at the zenith of their power and were the real masters of the great empire founded by Babur and Akbar, a crushing defeat, and with inferior numbers nearly annihilated their great army.

Foreign Influences.— Ahmad Shah died in 1773 and was succeeded by his son Timur, who transferred his residence from Kandahar to Kabul. In his reign Sind was lost, Balkh and other districts in Afghan Turkistan became virtually independent, and the seeds of revolt were sown in Khurasan and Kashmir. He died in 1793, leaving 23 sons, of whom the fifth, Zaman Mirza, by the help of Payinda Khan, head of the Barakzai family of the Durranis ascended the throne. His reign was short and troubled and was marked by one act destined to have momentous consequences—the grant of Lahore, in 1799, to the Sikh adventurer, Ranjit Singh. In the same year Mahmud, another son of Timur, ousted Zaman Shah and ascended the throne, but in 1803 was deposed by conspirators who placed his brother, Shuja-ul-Mulk, on the throne. In 1809 the East India Company's government in India, alarmed by the intrigues of Napoleon in Persia, sent Mr. Hfountstuart Elphinstone as envoy to Shah Shuja at Peshawar, but Napoleon's ambitious eastern schemes came to nought and the British mission at Peshawar was unable to effect anything, for Shah Shuja's rule was unpopular, and while his army was engaged in quelling a rebellion in Kashmir his deposed brother, Mahmud, rose in rebellion, defeated him and put him to flight, and ascended the throne for the second time. In 1815 Shah Shuja took refuge in India and remained a pensioner of the Indian Government until, at a later date, a use was found for him. Mahmud ruled until 1818 but the real ruler of the kingdom was Fath Khan the Kingmaker, the eldest son of Payinda Khan Barakzai. It was he who recovered Herat, which had been seized by the Persians, and in the insolence of his power he ventured to offer a gross outrage to the Sadozai family. Mahmud, already chafing under Fath Khan's yoke, avenged the insult by causing him to be blinded, and Mohammed Azim and Dost Mohammed, the minister's brother and half-brother, rose in arms against Mahmud, who retorted by causing Fath Khan to be put to death with torture. The Barakzais prevailed and in 1818 drove Mahmud from Kabul and dethroned him. A period of anarchy then ensued. Mohammed Azim ruled Kabul, but his brothers and other Afghan chiefs, the provincial governors, withheld their allegiance from him and the kingdom fell to pieces. Herat, always a Persian rather than an Afghan town, was alienated; Afghan Turkistan and Badakhshan regained their independence, and Ranjit Singh, who had already conquered Kashmir, Multan, Dera Ghazi Khan and Attock, was threatening Peshawar, which he secured by defeating the Afghan army at Naushahra in 1823. In the same year Mohammed Azim died, and the remaining Barakzai brothers plunged into a fratricidal war. Three years later Dost Mohammed established himself in Kabul, Ghazni and Jalalabad, and, having secured this fragment of the Afghan kingdom, assumed the title of Amir, after having, in 1835, defeated an attempt by Shah Shuja to regain his throne.

Russia had succeeded France as the bugbear of British administrators in the East, and the fear of Russian intrigue, as well as the prospect of active hostilities between the Amir Dost Mohammed and Ranjit Singh, induced the Company's government to despatch an envoy, Sir Alexander Burnes, to the court of the Amir. His mission was ostensibly commercial, but he was instructed to oppose the attempt of the shah of Persia to recover Herat. He was well received, but the Amir was disappointed by his refusal to pledge his Government to aid him against Ranjit Singh, and consequently held himself in no way bound

to refuse to receive Captain Vikovitch, a Russian officer who then arrived in Kabul. The Governor-General, Lord Auckland, peremptorily demanded his dismissal and the renunciation of all claims to the Punjab and Kashmir, which Ranjit Singh had recovered from the Afghans, and rashly decided to make Dost Mohammed's natural refusal of these demands a *casus belli*, and to attempt to restore the fugitive Shah Shuja, who had already been tried and found wanting. Ranjit Singh, whose material interests were involved, bound himself to co-operate with the British, but when all was ripe for the invasion declined even to permit British troops to cross his territories, though a Sikh force, with Sir Claud Wade and a small British detachment, advanced through the Khyber Pass.

The "Army of the Indus," numbering 21,000, assembled in Upper Sind in 1838 and advanced through the Bolan under the command of Sir John Keane. It met with hardly any resistance and in April, 1839, occupied Kandahar, where Shah Shuja was crowned in his grandfather's mosque. On July 21 Ghazni was taken by storm and Dost Mohammed, deserted by his troops, fled northwards. On Aug. 7 Shah Shuja, escorted by the British army, entered Kabul. It was believed that the war was over, and Sir John Keane, who received a peerage for his services, returned to India with the greater part of the army, leaving Sir William Macnaghten as envoy and Sir Alexander Burnes as his colleague, with 8,000 British and Company's troops and the contingent which had been raised for the service of Shah Shuja for their protection. The trouble was in fact only beginning, for the best of rulers is not acceptable to a free people when imposed upon them by foreign arms, and Shah Shuja had already rendered himself odious to the Afghans. He now, acting on the advice of the British Resident, attempted to raise a regular army to take the place of the tribal militia under its hereditary leaders; but the opposition of the chiefs, who apprehended the diminution of their own power and influence and the extinction of their country's independence, ensured the failure of this design. Shah Shuja was obliged to rely more and more upon British assistance, and his rule grew daily more unpopular. A danger was removed by the surrender of Dost Mohammed, who was sent to India, but it was impossible to save Shah Shuja, and in Nov. 1841, discontent at Kabul culminated in a revolt in which Burnes and other officers were massacred. Akbar Khan, the son of Dost Mohammed, placed himself at the head of the national party, and at a conference with the British authorities stabbed Sir William Macnaghten with his own hand. The British agreed to evacuate the country, and, in accordance with a convention with the Afghans, the garrison, then reduced to 600 British and 3,810 Indian troops, with the enormous number of 12,000 followers, marched out of Kabul on Jan. 6, 1842. The Afghans made no pretence of observing the terms of the convention, and the retreat of the demoralized army in the depth of a severe winter was a scene of confusion and massacre. On Jan. 13 the survivors of the force mustered at Gandamak only 20 muskets, and Dr. Brydon, the sole survivor of the Army of Kabul, except those whom the Afghans had captured, reached Jalalabad alone. The garrison of Ghazni had been obliged to surrender, but Kandahar was held by General Nott and Jalalabad by General Sale. In April, 1842, Shah Shuja was assassinated.

Preparations were made in India to avenge these disasters and to recover the prisoners. In April, 1842, General Pollock forced the Khyber Pass and relieved Jalalabad, and in September re-occupied Kabul, where he was joined by General Nott from Kandahar, who had recaptured and dismantled Ghazni. The prisoners were recovered from Bamiyan, where the Afghans had lodged them, and the army evacuated Afghanistan in Dec. 1842, after destroying the citadel and the central bazaar of Kabul. Dost Mohammed was permitted to return to his country and assumed the government, with the title of Amir.

In 1848, during the second Sikh War, Dost Mohammed was induced to go to the aid of the Sikhs. The adventure was unfortunate for him, for at the battle of Gujarat, in Feb. 1849, his cavalry was ignominiously routed and pursued as far as the hills, and the Peshawar territories were annexed to British India

and thus lost to Afghanistan. Balkh was recovered in 1850 and Kandahar in 1855, in which year also a treaty of peace was concluded between him and the British Government at Peshawar. In 1856 the Persians captured Herat but were obliged to surrender it to an independent ruler after the British expedition to Persia. In 1857 the Amir met, at Peshawar, Sir John Lawrence, who promised him arms and a subsidy to aid him in defending his country against Persia, and a British mission under Major Lumsden was received at Kandahar. During the Indian Mutiny the Amir declined to listen to those who instigated him to aid the rebels, and remained faithful to his alliance.

In 1863 Dost Mohammed captured Herat after a long siege, and, dying almost immediately afterwards, was succeeded by his son Sher Ali Khan, the early years of whose reign were disturbed by contests with his brothers. Early in 1873 the British Government succeeded in obtaining from the Russian Government a declaration that Afghanistan was beyond the field of Russian influence, and the recognition of the Oxus as the northern frontier of the State. Later, the Amir's failure to secure a British guarantee for his sovereignty and family succession, and his refusal to admit British agencies into Afghanistan led to estrangement between him and the British Government, and when, in July, 1878, he ostentatiously received a Russian mission at Kabul and shortly afterwards refused to permit a British mission to cross the frontier, his attitude was regarded as definitely hostile. After some warnings the Government of India delivered an ultimatum, his disregard of which led to the decision to invade Afghanistan. In Nov. 1878, the British forces inflicted severe defeats on the Afghan troops and occupied the Khyber pass and the Kurram valley, and early in 1879 occupied Kandahar, Kelat-i-Ghilzai, and Girishk. The Amir, with the Russian mission, had fled from Kabul, and he died, a fugitive, in March, 1879. His second son, Yakub Khan, who was recognized by the people of Kabul as Amir, voluntarily visited the British camp at Gandamak in May, 1879, and there concluded a treaty, by the terms of which he ceded the Kurram valley, Pishin, and Sibi, and the control of the Khyber and Michni passes and of the tribes in their neighbourhood. He also agreed to receive a British resident at Kabul and to subordinate the foreign affairs of Afghanistan to British influence. Major Sir Louis Cavagnari was well received by him as Resident, but the Amir was either unable or unwilling to control the fanatical element in Kabul, and in Sept. 1879, the Residency was attacked by a mob of townspeople and soldiers, and the Resident and his escort were murdered after a gallant defence.

Abdur Rahman Khan.—The Kandahar force then concentrated at Kandahar, and a force under General (afterwards Field-Marshal Earl) Roberts advanced through the Kurram valley, defeated an Afghan force at Charasia, and occupied Kabul in 1879. Yakub Khan, having entered the British camp, abdicated, and was sent to India, where he lived for the rest of his life. The British force under Roberts remained at Kabul, and in July, 1880, the British Government recognized a new Amir, Abdur Rahman Khan, a grandson of Dost Mohammed and nephew of Sher Ali.

Sardar Sher Ali Khan, a Barakzai of Kandahar, had already been recognized as independent ruler of that province, but in July, 1880, Ayub Khan, a younger brother of Yakub Khan, advanced from Herat, inflicted a crushing defeat on a brigade of British troops at Maiwand and invested Kandahar. On Aug. 8 General Roberts left Kabul with a relieving force, which reached Kandahar on the 31st, and on Sept. 1 defeated the besiegers and captured their camp, artillery, and baggage. Ayub Khan fled with a few followers, and, peace having been restored in southern Afghanistan, the British forces evacuated the country in 1881. Sher Ali was unable to maintain his authority in Kandahar and retired to India, where he ended his days as a pensioner. Ayub Khan again took the field, defeated Abdur Rahman's troops, and occupied Kandahar, but in Sept. 1881, Abdur Rahman utterly defeated him and drove him to seek refuge in Persia. In 1888 he went to India, and lived there as a pensioner of the British Government until his death.

Abdur Rahman had been recognized as Amir of Kabul only, but within a year of ascending the throne had made himself master of Kandahar and Herat also, and he succeeded in quelling tribal disturbances and in establishing his rule on a firm basis. No attempt was made to fetter his independence except with regard to his foreign relations, which he agreed to conduct subject to the control of the Government of India, from whom he received an annual subsidy to be devoted to the payment of his troops and the defence of his north-western frontier, and considerable supplies of war material, together with facilities for importing arms through India at his own cost.

In 1884 it was agreed that a joint commission of British and Russian officers should demarcate the northern boundary of Afghanistan, but the Russian commissioners did not immediately arrive on the scene, and in March, 1885, while the Amir was conferring with Lord Dufferin, the Viceroy of India, at Rawal Pindi, Russian troops attacked and drove from Panjdeh, a small town on the frontier, an Afghan force. In 1888 the Amir's authority was seriously menaced by the revolt of his cousin, Ishak Khan, who held a quasi-independent position as governor of Afghan Turkistan and caused himself to be proclaimed Amir, but the rebellion was crushed. Ishak was expelled and settled at Bukhara as a pensioner of the Russian Government, and Abdur Rahman's authority was established in the northern province. In 1895 he completely subjugated Kafiristan, a wild mountainous tract to the north-east of Kabul, the inhabitants of which had hitherto successfully resisted all attempts to destroy their independence.

In 1901 Abdur Rahman died, after a reign of 21 years, in the course of which he gave Afghanistan a government such as it had never known before. This he effected, first, by substituting for a feudal militia under tribal chiefs a standing army, well trained, well armed, and regularly paid, owing allegiance to none but himself. By means of this force he was able to establish an efficient central administration, retaining all power in his own hands, and to improve the public revenues not only by increasing the burden of taxation, but by ensuring the collection of all assessed taxes. He was harsh and ruthless, but he relieved his subjects from the petty tyranny of local chieftains and he suppressed highway robbery and violent crime. It is probable that he fully appreciated the advantages which his country might gain from projects of a commercial or strategical nature, such as railways, telegraphs, and mines; but it was his settled conviction that these advantages would be purchased at too high a price by the necessary employment of large numbers of foreigners, whose activities in the country might have amounted to peaceful penetration and menaced Afghan independence.

Habibullah.—Two days after the death of Abdur Rahman his eldest son was recognized as his successor. Habibullah introduced the reduction of taxation, the establishment of a council of state for tribal affairs, and the association of tribal chiefs with provincial governors for the adjudication of tribal cases. He also inaugurated military reforms. He loyally observed the condition regarding the control of the foreign affairs of Afghanistan on which the Government of India had recognized his father as Amir, but on all questions relating to the development of his country's trade and more intimate relations with the Government of India he proved to be as wary and suspicious as his father had been. He consented, indeed, to receive a special mission under Sir Louis Dane, foreign secretary to the Government of India which reached Kabul in Dec. 1904, but the mission failed to obtain any concessions, and the result of its work was merely the confirmation and ratification of existing agreements and the concession to him in the treaty of the title of "Majesty." After the failure of this mission an endeavour was made to remove his prejudices and to enlarge his mind by arranging for him a visit to India, in the course of which he could meet the leading administrators of the country. His acceptance of the invitation was viewed with disfavour by the more bigoted and ignorant of his subjects, but the manner of his reception by Lord Minto in Jan. 1907, and the good will displayed towards him, undoubtedly did much to improve the relations between the two Governments.

By the Anglo-Russian convention signed on Aug. 13, 1907, Great Britain disclaimed any intention of altering the political status of Afghanistan, and Russia declared Afghanistan to be beyond her sphere of influence.

Nabibullah, though as suspicious as his father, was more susceptible to modern influences, and among the many mixed blessings of civilization which he introduced into an unappreciative country were motor-cars, telephones, newspapers, a hydro-electric scheme, and the Habibia college, a high school in Kabul, the staff of which was chiefly composed of teachers from India. Many of these were regarded by the ignorant clerics of Afghanistan as inventions of the devil and the seed of infidelity, and it was partly from a sense of the antagonism which their introduction had aroused and partly with a view to conciliating the hereditary enemies of his house that Habibullah treated with great and unusual leniency the Ghilzais and Mangals of Khost, the district lying immediately to the west of the Kurram valley, who in 1912 had been goaded into rebellion by the rapacity of the local governor.

The World War.—On the outbreak of the World War in 1914 the Amir declared his intention of abiding by his agreement with the British Government and maintaining the neutrality of his country, but the entry of Turkey, the chief Islamic power, whose ruler was regarded by many Muslims as their Caliph, encouraged the anti-British party in Afghanistan and induced the Amir to receive a German mission, which contrived to reach his western frontier by way of Persia and entered the country as fugitives, having left in the hands of the Russians their confidential papers and that which was most likely to make them welcome in Afghanistan, their gold. They were admitted to Kabul, but their manners and bearing were not calculated to conciliate their hosts. They were regarded as state prisoners rather than as guests, and, in 1916, becoming apprehensive, on misleading information, of the Amir's intentions towards them, they retired hastily from Afghanistan, and some of them, falling into the hands of the Russians, were treated as prisoners of war. Habibullah preserved his neutrality until the end of the war, and would doubtless have received substantial recognition of his loyalty, in most difficult circumstances, to his obligations, had he not been assassinated on Feb. 20, 1919. His brother Nasrullah Khan, caused himself to be proclaimed Amir, but after a reign of six days was ousted by his nephew, Amanullah, who was recognized by the nobles and people as king. He was unfortunately not strong enough to resist the popular demand for war with Great Britain, regarded as Turkey's chief enemy, and on May 2, 1919, Afghan troops crossed the Indian frontier. Immediate steps were taken to expel them, and British and Indian troops, after encountering some resistance, occupied Dakka, beyond the Khyber; but before the concentration of the British troops was complete Amanullah, brought to his senses by the appearance of the first aeroplane over Kabul, made overtures for peace. Negotiations ended in a Treaty of Peace signed at Rawal Pindi on Aug. 8, 1919, by the terms of which the annual subsidy which the Amir had received since 1879 was discontinued, and Afghanistan was released from the control of her relations with foreign states. A conference at Mussoorie in 1920 prepared the way for the Treaty of Nov. 22, 1921, by which the two Governments agreed to respect one another's independence in domestic and foreign affairs; to recognize existing frontiers, subject to a slight readjustment near the Khyber, and to receive legations at London and Kabul, and consular officers at Delhi, Calcutta, Karachi and Bombay, and Kandahar and Jalalabad respectively. The Afghan Government retains the privilege of importing through India, free of duty, arms and munitions of war; and all restrictions on the export of goods from Afghanistan to British territory have been removed. A trade convention has since been concluded, and one to deal with posts and telegraphs is contemplated.

Russo-Afghan Treaty.—Afghanistan has proved that she may be trusted to control her relations with other states with credit to herself, for she has dealt successfully with three difficult and delicate situations. The first arose from a clause in the Russo-Afghan Treaty of Feb. 28, 1921, permitting the establishment

of Russian consulates at Ghazni and Kandahar—places so remote from the sphere of Russia's legitimate interests that it was obvious that the consulates could serve no purpose but that of facilitating hostile intrigue on the Indian frontier. The British commissioner declined to discuss the terms of a treaty unless Afghanistan annulled a concession so prejudicial to British interests, and she satisfied his demand without dangerously offending Russia. The second arose in 1924, out of the murder of two British officers by two Afghan subjects within a mile of the Afghan frontier, and this outrage was closely followed by the flight into Afghanistan of some ruffians who had murdered an English lady and abducted her daughter. The third, which nearly led to a rupture with Italy, arose from the shooting of an Afghan policeman by an Italian named Piparno in the employ of the Afghan Government. The procedure at the trial was prejudicial to the accused and violated the principles of at least one school of Muslim jurisprudence by ignoring the prior settlement of the case, with the cognizance of the State, by the payment of blood-money to relatives. In these circumstances the execution of Piparno aroused a dangerous feeling in Italy, but Amanullah's success in handling this and the other two cases cited proved that he had inherited a large share of his grandfather's strength of character and political sagacity.

In opening up his country to Western civilization Amanullah departed from the traditional policy of his dynasty, and he was in many respects so far more enlightened than the generality of his subjects as to be in some danger of alienating them, as in the case of his scheme for female education, which led the clerics to foment the dangerous rebellion which broke out in Khost early in 1924, and was not suppressed until the following spring.

Amanullah seemed to be making some progress in overcoming the ignorant prejudices of his subjects. The establishment of Afghan Legations in Moscow, Berlin, Paris, Rome, Tehran, Angora and London, and the reception of foreign legations in Kabul made them more familiar with the life of the outside world. In addition to a wireless station at Kabul, which is in regular communication with Peshawar and Tashkent, Kabul and neighbouring towns are linked with the Indian telegraph system and it is possible that Kabul may soon be linked, through Kandahar and Herat, with the Russian system. Since 1910 the introduction of motor-cars has had its natural result in the improvement of the roads. Those in the neighbourhood of the capital have already been completed, and the projected roads from Kabul to the Khyber, and from Kabul to Kandahar, and thence to Chaman will influence profoundly the economic and political development of the country. The extension, in 1925, of the Khyber railway from Jamrud to the head of the pass has stimulated trade by this route. The Hindu Kush, with its steep ascents and difficult passes, for the present effectively blocks communication by mechanical transport between Kabul and the north.

The extensive employment of Europeans on technical, educational, and other work can hardly be said to be popular, but its necessity, for the present at least, is gradually coming to be recognized. The wisdom of entrusting the development of the air force and some other essential services exclusively to Russians may well be doubted, but there seemed little doubt of Amanullah's ability to rid himself of Soviet agents should he find himself embarrassed by their intrigues.

A trade convention signed at Kabul on June 5, 1923, provided for three transit routes across British India for the forwarding of goods to and from Indian ports. Late in 1927 Amanullah left Afghanistan for an extensive tour of India, Egypt, and Europe. On his return he tried to introduce unpopular reforms, and late in 1928 the country revolted. Amanullah abdicated in Jan. 1929. After an interim rule by Habibullah Ghazi, Nadir Shah became king on Oct. 16, 1929, and after his assassination in Nov. 1933 he was succeeded by his son, Mohammed Zahir Shah.

AFGHAN LANGUAGE: see PUSHTU.

AFGHAN TURKISTAN, province of Afghanistan, bounded east by Badakshan, north by the Oxus river, north-west and west by Russia and the Hari Rud river, and on the south by the Hindu Kush, the Koh-i-Baba and the northern watershed of the Hari Rud basin. It is joom. long, north-east to south-west, and averages 114m. in width between the Russian frontier and the Hindu Kush. The area is about 7,000sq.m.—two-ninths of Afghanistan. The population is about 750,000, mainly cultivators in towns and villages, the chief being Mazar-i-Sharif (30,000), the modern supplanter of Balkh. The lowland has much loess and the riverine lands of the Oxus are highly cultivated, but to the west the Turkoman area is waste, and to the south are rough mountains. The people are Persian and Uzbeg with Turkoman, Hazara (Mongol) and Hindu elements. Ancient Balkh or Bactriana belonged to the Achaemenian empire. About 250 B.C. Diodotus (Theodotus), governor under the Seleucidae, made himself independent and founded the Graeco-Bactrian dynasties which succumbed to Parthian and nomad movements about 126 B.C. The succeeding Buddhist era has left us huge sculptures at Bamian and the rock-cut topes of Haibak. Jenghiz Khan laid waste the land; later it belonged for a century to the Delhi empire, then became Uzbeg, and in the 18th century came under Ahmad Khan and his son Timur (Durani Afghans). Next the Khanates fell apart during strife between Timur's sons, and the Uzbeg khans came under the rule of Bokhara. Under Dost Mohammed (1850-1859) the Afghans occupied the province, and boundary disputes were settled (1873) by the Anglo-Russian agreement awarding Andkhui, Shibarghan, Saripul and Maimana to Afghanistan. The Russo-Afghan commission delimited the boundary in 1885.

AFIUN QARAHISAR or **AFYON KARAHISAR**, popular name of Kara-hissar Sahib, the chief town of a vilayet in Asiatic Turkey, nearly 200 mi. east of Smyrna, and 50 mi. south-southeast of Kutaiah. Pop. (1935) 50,065. Called Nicopolis by Leo III after his victory over the Arabs in 740, its name was changed by the Seljuk Turks to Kara-hissar. It stands partly on level ground, partly on a declivity, and above it rises a precipitous trachytic rock (400 ft.) on the summit of which are the ruins of a Byzantine castle. The town is an important centre of trade. Opium in large quantities is produced in its vicinity and forms the staple article of its commerce; and there are, besides, manufactures of black felts, carpets, arms and saddlery. Afiun contains several mosques (one of them a very handsome building). The town is connected by railway with Smyrna, Konia, Angora and Istanbul.

See V. Cuinet, *Turquie d'Asie* (Paris, 1894), vol. iv.

A FORTIORI (Lat. "from a stronger [reason]"), a term used of an argument in which the conclusion is supported by a ground that is stronger than another that has already been accepted, or is commonly accepted, as sufficient justification for asserting the predicate of the conclusion of that kind of subject. For example, if in a right-angled triangle the side opposite the right angle must be greater than either of the other sides (because the right angle is greater than either of the other angles),

"how much more so" (a *fortiori*) must this be the case in an obtuse-angled triangle (which is even greater than a right angle).

AFRANIUS, LUCIUS, Roman general, lived in the times of the Sertorian (79-72 B.C.), third Mithridatic (74-61 B.C.) and Civil Wars. In 60 B.C. chiefly by Pompey's support, he was raised to the consulship. In the following year, while governor of Cisalpine Gaul, he obtained a triumph, and on the allotment of Spain to Pompey (55 B.C.), Afranius and M. Petreius were sent to govern it as legates. On the rupture between Caesar and Pompey they were compelled, after a short campaign in which they were at first successful, to surrender to Caesar at Ilerda (49 B.C.), and were dismissed on promising not to serve again in the war. Afranius, however, joined Pompey at Dyrrhachium, and at the battle of Pharsalus (48 B.C.) had charge of Pompey's camp. Despairing of pardon from Caesar, he went to Africa, and was present at the disastrous battle of Thapsus (46 B.C.). He was afterwards taken prisoner and handed over to Caesar, whose veterans put him to death.

See Hirtius, *Bell. Afric.*, 95; Plutarch, *Pompey*; Dio Cassius xxxvii., xli.-xliii.; Caesar, *B.C.* i. 37-87; Appian, *B.C.* ii.; CAESAR and POMPEY.

AFRANIUS, LUCIUS, Roman comic poet, flourished about 94 B.C. He dealt chiefly with everyday subjects from Roman middle-class life, and tells us that he borrowed freely from Menander and others.

See Horace *Epp.* ii. 1.57; Cicero, *Brutus*, 45. *de Fin.* i. 3; Quintilian x. 1. 100; fragments, about 400 lines, in Ribbeck *Scenicae Romanorum Poesis Fragmenta*, i. (1898).

AFRICA, the name of a continent which is the largest of three great southward projections of the main land-mass of the earth's surface, joined to Asia by the isthmus of Suez, 80m. wide. From its northern extremity, Ras ben Sakka, a little west of Cap Blanc in 37° 21' N. to the southern, at Cape Agulhas, 34° 51' 15" S., it is about 5,000m. long while west to east it is about 4,600m. from Cap Verde, 17° 33' 22" W., to Ras Hafun, 51° 27' 52" E. Length of coastline is 16,100m. for a mainland area of 11,262,000 square miles.

GEOGRAPHY

Africa is largely a plateau, broken and elevated in the south and lower towards the north, with fold mountains adhering to the northern flank, and it thus contrasts very strikingly with Euro-Asia in which fold mountains of successive series in diverse stages of denudation occupy a large proportion of the surface. The mean elevation of Africa is about 2,000ft., that of Asia 3,117ft. Asia has much quite low as well as very high land. Africa, as a plateau, has little at either extreme and in particular the land over 10,000ft. in Africa is merely small groups of peaks.

The high southern part of the plateau reaching north almost to lat. 10° S. has sharp slopes around its edges on the west, south and east, with a narrow coastal plain below, broadening in the north-west and especially the north-east in Angola and Portuguese east Africa respectively. Towards the south this plateau has a high rim, over 6,000ft. above sea near Windhoek in the west and in Basutoland on the south-east. The southern edge is stepped, with the Nieuwveld range above the Great Karroo, the Little Karroo as the step next below and the coastal plain next below that. Within the high rim are considerable areas of centrally placed lower land, the South Kalahari in the south, the depression draining into Lake Ngami (now practically dry) and the Barotse-land depression, but all keep above the 1,500ft. contour and each is a local depression in a table-land most of which is at more than 3,000ft. above the sea. Generally speaking the plateau-edge dips down, with a small coastal ledge, into fairly deep water, but towards the Cape of Good Hope there is a fair area of shallow water off-shore.

The steepness of the edge of the plateau is important as a determinant of the character of the rivers, long sections of which flow in deep slots cut back into the plateau from its edge. The Orange river is fed from the rains that fall on the Drakenberg range and flows west through lands of drought; the Limpopo and Zambezi, the two largest on the east flow out to the broad sandy alluvial flats of Portuguese East Africa and the slot-like character

of a large part of the Zambezi-channel is generally known from the occurrence of the famous Victoria Falls. In the south-west the Zambezi system interlaces with that of the Taukhe or Tioghe and receives surplus water from it at times. The rest of the Taukhe water loses itself in the swamps and salt-pans of the former Lake Ngami basin. The lower parts of the three great rivers have contributed to the lowering of considerable areas of the plateau below the 3,000ft. level. The Zambezi river, about 2,000m. long, drains an area of half a million square miles, the Orange river, about 1,300m. long and with a drainage area of about 170,000sq.m. but more than that amount must be added if we define the basin orographically and so include in it larger waterless tracts. Towards the north this southern plateau tends to run rather higher and there is a continuous belt of highland across the continent from the coastal plain on the west to Lake Nyasa on the east, in which region the typical form of the southern plateau is interfered with by important rifts to be considered next. Allowing for complexities the southern plateau of Africa is thus essentially an elevated surface with still higher edges for the most part and with, also, considerable depressions, usually deserts in character, near the median north to south axis of the plateau. North of this southern plateau, on the west, is the basin depression, largely flooded by younger rocks and now occupied by the Congo and its numerous feeders. The basin is almost enclosed by land over 1,500ft. in height, for the main river escapes through a deep cut between the hills out to sea; there is general agreement that the basin is a depression in the original plateau surface that has been an inland sea. To the east of the basin are series of physical features that together constitute one of the major physical problems of the earth's surface. They are collectively designated the Rift valley system and have been the subject of much discussion, for which reference may be made especially to the files of the Geographical Journal (London, especially 1916-21) and to Krenkel *Geologie Afrikas* (1925). In this region in later tertiary and early Pleistocene times great movements occurred and earthquakes are still a feature. Often a block has sunk between parallel fractures and thence has come the name of Rift valley. A western rift may be traced from Lake Nyasa via Tanganyika and Lake Albert to Gondokoro. Many of the fractures run either north-west to south-east (the so-called "Erythraean" direction) or, in the north, north-east to south-west (the "Somali" direction). A middle rift line goes north-north-east from Nyasa via Lake Nai-

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

NATIVES OF WEST AFRICA ENGAGED IN MAKING SPOONS IN THEIR TRADITIONAL MANNER

vasha to Lake Rudolf, with branchings and changes *en route*; though its general direction is north to south, its component fractures are generally north-west to south-east and north-east to south-west, with some north to south ones in the north. The easterly rift line is less important and goes on the whole north-eastwards from about the middle of Lake Nyasa. In the floors of the rifts lie the long narrow lakes, Nyasa 1,645ft. above sea-level but with a maximum depth of 2,580ft. so part of its floor is over 900ft. below sea-level, Tanganyika, also very deep and normally 2,624ft. above sea-level but this level is so variable that the outflow from Tanganyika is quite intermittent, and Rudolf at only 1,180ft. Some other lakes are small; that of Naivasha is over 6,100ft.

Many portions of these lakes have sharp walls and are obviously filling depressed zones. The western rift is the youngest and sharpest; the most important movements may have been as late as the Pleistocene period. The rifts all show volcanic activity which is most marked along the eastern sides of the middle one, where occur the great peaks of Kenya (17,007ft.) and Kilimanjaro, on which Kibo peak (19,321ft.) has long been held to be the culmination of Africa but Nilsson (1927) claims to have found points on Kilimanjaro 1jft. and 17ft. higher, respectively, than the highest previously known. Ruwenzori, on the eastern side of the western rift is 16,794ft. high and has a block structure apparently with faulted sides; interestingly enough it is in about the same latitude as the other great peaks mentioned and they are all on a belt of land, higher than most of the flanking territory, that stretches from the volcanic Cameroons (*v. inf.*) to the east coast. This cross-line scheme is noticeable in great basins (Niger, Chad and Bahr-el-Ghazal) to the north-west and is evidently of some importance in the story of the deformations that Africa has undergone.

It seems clear that at Lake Albert there was faulting on a large scale both before and after the country was arched up into a wrinkled dome while, farther east, the middle rift may be connected with faulting near the median axis of a long arch. Faulting of domed and arched structures, supplemented by vulcanicity on a large scale, both occurring so recently as to leave features extremely sharp, are thus the characteristics of the country. Between the arched areas of Lake Albert and the middle rift in a downfold lies Lake Victoria of area approximately 26,000sq.m. and more or less rectangular but fractures determine only a small part of its outline and its shores are not high-cliffed. Unlike the rift lakes, it is less than 50 fathoms deep. It is at 3,720ft. above sea-level.

It is well known that the zone of fractures extends northwards marking the east and west edges of the Abyssinian highland, the series of cliff lines bordering the Gulf of Aden and the Red Sea, and the rift lines along the Gulf of Aqaba to the Dead Sea and the Jordan valley. All through this zone one finds systems of parallel fractures and a considerable number are north-west to south-east, others are north-east to south-west, others apparently north to south.

The relations of land and water, both inland waters and the ocean, have naturally varied a lot with the great changes of land levels, but apparently since present levels were reached, and therefore probably well on in the Pleistocene period, lakes of immense size existed in the rift valleys of East Africa. Shore lines 600ft. above present water-levels have been traced over long distances and there is not much doubt that during the major glacial phases of the Pleistocene ice age in Europe the mountains of East Africa were glaciated much farther down than at present.

The northern extension of the rift system to Lake Rudolf and beyond it north-westwards to the lowlands of the White Nile divides east Africa from Abyssinia and Somaliland. The latter is a plateau sloping south but broken sharply on the north, where a steep slope marks the coast of the Gulf of Aden, and less sharply on the south-east to the Indian Ocean as well as on the south-west towards the Juba river basin which may be described as a widening of the coastal plain. Socotra is essentially a broken off projection of Somaliland. Abyssinia on the other hand is a remarkable mountain land bounded east and west by great fractures of remarkable sharpness giving steep cliffs down to the Red Sea and to the White Nile lowland. The rift system of the Red Sea and that of the Gulf of Aden both enter into relationship with an Abyssinian rift which runs from the sea to Lake Rudolf and divides Abyssinia from Somaliland. Abyssinia differs entirely from any folded mountain range; it is a high and deeply dissected block full of evidences of volcanic activity and provided with powerful rivers, feeders of the White Nile (Sobat, etc.) the Blue Nile and the Atbara, indicating its high (largely summer monsoonal) rainfall. It lies for the most part more than 5,000ft. above sea-level and reaches up to nearly 15,100ft. at Ras Dashan in the north. Lake Tana (Tsana) in the highlands is actually 5,690ft. above sea-level.

The Nile may be said, in a way to begin as the Kagera, the chief feeder of Lake Victoria. It leaves that lake on the north and after passing through the lake swamp of Kioga it goes to the north-eastern end of Lake Albert. Issuing again from the northern end of that lake, it emerges in due course from the rift system into a great flat area less than 1,500ft. above sea-level and framed by higher land save in the north-east and giving so little fall on the river that it becomes obstructed by floating vegetation. It is noteworthy that this upper Nile basin, the Lake Chad basin and the main Niger basin, all more or less enclosed, are nearly in the same latitude, with the still more enclosed basin of the Congo to the south. Basins of this kind are thus a marked feature of the geography of the old block of Africa. After the Nile (Bahr-el-Jebel) has received the Sobat from the east it flows north through increasingly barren country into a slot cut in the great desert. The transition from the fertile slot up the, often steep, slope to the desert plateau is a very sharp one and the river has no tributaries in its desert section. It thence follows that, though the Nile is 4,037m. long from the Kagera source to the sea, its basin-area is only 1,107,227sq.m., whereas the Congo, rather under 3,000m. long but very rich in tributaries, has a basin area of about 1,425,000 square miles.

North of the Congo basin one may go from the Gulf of Guinea across to the extreme east without touching a point less than 1,500ft. above sea. This rise or swell of the land surface has, on its north-west border, the high line (north-east to south-west) of the Cameroons, apparently an old mountain structure rejuvenated by volcanic outpourings. On this line stands the great peak of the Cameroons (13,370ft.) at the corner of the Gulf of Guinea, and it is continued into the sea giving the island of Fernando Po (Spanish) and those of S. Thomé and Principe (Portuguese). On Fernando Po, Clarence Peak is over 9,000ft. high.

North of the Gulf of Guinea the land soon rises above the 600ft. level and towards the west there is a fairly marked slope up from the sea to over 1,500ft. above its level, the slope faces south-west and above it towards the north is a patch above 3,000ft. in height while one small area near the northeast border of Liberia reaches nearly 10,000ft. This region, with a heavy, monsoonal, summer rainfall is the birthplace of the feeders of the Niger. Thence that river flows north-east demonstrating the general slope of the land down to the Sudan and Sahara, then east and south-east and south to reach the gulf in the lowland between the eastern end of the West African coastal edge and the highland of the Cameroons. Its length is about 2,600m. and basin-area about 800,000 square miles.

Between the main Niger basin and that of the Bahr-el-Ghazal and White Nile lies a basin of internal drainage with the shallow, shrinking Lake Chad in its southern half and a depressed area with some swamps in the north-east. Lake Chad is about 850ft. above sea-level, and receives drainage from the south-east and west. The other depressed area is, in parts, less than 600ft. above sea but the drainage to it is of very small account. North of the Niger and Chad basins is the immense arid belt of the Sahara. It reaches the Atlantic along a low practically waterless coast 1,000m. long from the mouth of the Senegal to the streams of the Atlas. The western part of the Sahara is generally low and has no heights reaching 1,500ft. but in the northern centre is the Ahaggar plateau, connected with the eastern end of which are north-west to south-east lines of higher land one going north-west to the Gulf of Qabes and one south-east crowned by the Tibesti highlands. Eastward, heights diminish again but there is practically a continuous cliff edge along the Nile slot on both sides and the continuation of the desert plateau on the east stands for the most part more than 1,500ft. above sea with a considerable area over the 3,000ft. line.

The desert has large sandy areas especially in the west with regions of stony desert (*hammada*) in the northern centre and a good deal of stony desert to the east. A number of oases break the monotony of the desert, some being north of Lake Chad; some of the land around the Tibesti highland (reaching 8,000ft.) also gets more moisture and has a population aggregated in certain centres. Wadis from the Ahaggar plateau and elsewhere in the desert are

interesting evidences of a former greater rainfall and from a study of animal remains as well as of finds of human implements it seems that the Sahara was more or less a grassland during some phases at any rate of the early ages of man. The probability is that periods of greater rainfall in the Sudan more or less coincided with periods of Pleistocene glaciation in Europe. The desert area is estimated at 3,500,000 square miles. The Nile slot cuts the desert without modifying it appreciably, and opens out north to the famous delta west of which the coast is not high save in the Barca or Cyrenaica plateau which reaches 1,500ft. not far from the sea.

The Atlas range, the north-western part of the continent, is orographically a part of the mountain arcs that frame the basins of the western Mediterranean. It reaches a height of 14,000ft. at Bu Uriul and Ari Aiaschi and runs, generally, east-north-east to west-south-west. The eastern half has the Tell Atlas on the north and the Sahara Atlas on the south side with the plateau of the Shotts, several lakes without outlets, between them. The western region has the Mid Atlas continuing the first and the Great Atlas continuing the second; the Anti Atlas is parallel to and south of the Great Atlas. To the north of the Mid Atlas the separate coastal mountain range of Er Rif curves north-west to the Strait of Gibraltar beyond which the curved high line is continued in the Sierra Nevada of southern Spain.

South of the eastern ends of these highlands is a more or less east to west line of low land containing the Shott el Jerid (about 52ft. above sea-level) and the Shott Melrir (nearly 100ft. below sea-level) both without outlet. Africa is remarkable for the extent of land, 3,750,000m. in basins of inland drainage.

Africa is singularly poor in islands. Madagascar 229,820sq.m., is one of the large islands of the world (smaller than New Guinea and Borneo); it is separated from Africa by the rather deep Mozambique Channel and in structure it resembles Africa. Biologically it has links both with Africa and with the East Indian archipelago. Socotra, east-north-east of Cape Guardafui, a continuation of the Somaliland plateau is the only other African island of any size. The Canary and Cape Verde archipelagoes of the north-west and the Comoro archipelago of the east are volcanic (but pebbles of continental, or plutonic, material have been sent to Europe from Anjovan, one of the lesser Comoro Islands); the Seychelles are a continental remnant. There are coral islets between the Comoros and the Seychelles. Mauritius, Reunion and Rodriguez, the two last entirely, the first mainly volcanic, lie in the Indian Ocean east of Madagascar; Ascension, St. Helena and Tristan da Cunha in the south Atlantic far to the west. (X.)

CLIMATE

Extending from latitude 37° N. to 35° S., the greater part of Africa lies within the tropics, and except on mountains and plateaux the average annual temperature is high, ranging from 62° at Cape Town to 86° at Massaua on the Red Sea. On the other hand there are great extremes of rainfall; in the Egyptian desert appreciable falls occur only once in a number of years, while the western slopes of the Cameroon mountains are among the wettest parts of the world, Debundscha at the foot of Cameroon Peak having an average of 369in. a year. Africa may be conveniently divided into five climatic divisions, of which four run roughly parallel with the lines of latitude, while the fifth occupies a large part of the eastern coastal districts. On either side of the equator is a belt of heavy rainfall which is distributed fairly uniformly throughout the year, but with a tendency for April and October to be the wettest months, those following the annual passage of the sun across the equator. This belt roughly coincides with the Congo valley and Gabon. Northwards the first rainy season is retarded into May and June, while the second rainy season is advanced into September and August, giving a long dry season, a principal wet season, a short dry season and a secondary wet season which is not much inferior in intensity to the first. In latitude 8° or 9° N. these two rainy seasons coalesce into one wet season lasting from May or June until September, while the rest of the year is dry; at the same time the total rainfall decreases. North of 15° N. the rainfall is small and irregular and

we pass into the belt of desert which includes the Sahara and Sudan. This extends to the Mediterranean in the north-east, but in the north-west there is a coastal strip in Algeria and Morocco which has a long dry summer but an appreciable winter rainfall and forms part of the Mediterranean climatic province.

In South Africa there is a similar succession, the April rainfall maximum of the equatorial belt advancing into March and February, while the October maximum is retarded into November and December, until the two coalesce into the summer rainfall region of the southern hemisphere, which includes Angola and southern Rhodesia. South of this is the Kalahari desert, the counterpart of the Sahara, while in the extreme south-west is a small area round Cape Town with a dry summer but appreciable rainfall in winter (April to September). This zonal division does not apply to eastern Africa south of the equator, which has summer monsoon rains and a winter dry season over its whole extent.

BY COURTESY OF THE AMERICAN BOARD OF FOREIGN MISSIONS

A RAIN-MAKER, AN IMPORTANT MEMBER OF WEST AFRICAN COMMUNITIES, WITH THE REQUISITES OF HIS MAGIC

The **Equatorial Rainfall Belt**.—This region includes the greater part of the Congo basin above Leopoldville, Gabon, Cameroon and the coast of Nigeria as far as the mouth of the Niger. Its characteristics are uniformly high temperature and humidity, a large amount of cloud and a rainfall generally exceeding 60in. a year and rarely falling below 2in. in any month. The temperature is rarely extreme, and probably many parts of the region have never reached the Greenwich maximum of 100°, but on the other hand the temperature rarely falls below 60° on the low ground. The annual average may be taken as 80°, rising to 87° during the day and falling to 73° at night. The hottest months generally fall in the early part of the year, while July and August tend to be coolest, but the annual range is rarely as much as 10°. The relative humidity averages 80%, and this continual moist heat is very enervating to Europeans. The greater part of the region is densely forested.

Savanna Belts.—North and south of the equatorial rain forest is a zone of moderate rainfall, the whole of which falls in a short summer rainy season, while the remainder of the year is dry. These belts may be regarded as extending as far as the isohyet of 20 inches. The northern belt includes Senegal, Bathurst, Sierra Leone, the Gold Coast, Dahomey, the greater part of Nigeria, the Sudan and Abyssinia. The rainfall varies greatly, rising to as much as 154in. a year at Sierra Leone, but even there the months of December to March are almost rainless. The drier parts are occupied by open grass-land but the wetter areas are forested. The rainy season from May or June to September inclusive, in spite of being summer in the astronomical sense, is the coolest part of the year, the temperature being kept down by the great cloudiness and heavy rainfall. This season is unpleasant because of the high humidity, the small daily range of temperature and the frequent thunderstorms and tornadoes, especially at the beginning and end of the season. The prevailing wind is south-westerly at the surface, but is very light; at a height of a few thousand feet the wind becomes north-easterly, and the thunderstorms advance from the north-east. From late October until the end of February is the most pleasant season, with hot days but cool nights, dry air and clear skies; the prevailing wind is north-easterly except on the coast, where sea-breezes occur during the day. Over the interior the wind is often laden with penetrating fine dust (Harmattan wind). In March, April and the beginning of May, the temperature is very high, maxima sometimes exceeding 100° even on the coast, and reaching 110° in the interior. The humidity of the air is still low but is rising steadily, and the wind is light and variable. The rainfall of the Abyssinian plateau is of great importance as the source of the annual Nile floods, and so of the fertility of Egypt. The annual rainfall of

Addis Ababa averages 50in., but more than three-fifths of this amount falls in July, August and September, while October to January inclusive are almost rainless. In spite of the position of Abyssinia near the eastern margin of Africa, it is believed that most of the moisture which falls as rain is derived from the Atlantic ocean, and is carried across the whole width of the continent by the south-west winds, and that only a comparatively small part of the rainfall is derived from the Indian Ocean. The southern savanna belt includes Angola and Rhodesia; the climate is generally similar to that of the northern belt, but the summer rainy season occurs from December to February. The rainfall nowhere exceeds 60in. and owing to the generally high elevation the climate is comparatively pleasant and healthy. The amount of cloud is comparatively small, and the lowest temperatures occur in winter and not, as in the north, in the rainy season.

Deserts.—The greater part of Africa north of 16° N. is occupied by an arid climate which gives rise to the deserts of the Sahara and Egypt. The rainfall is less than 10in. a year, and over a large part of the area is probably less than an inch, being confined to a few drops once or twice a year and isolated heavy falls at intervals of many years; under these conditions the term "average" has no meaning. The temperature is very high in summer, the average in July exceeding 90° over a large part of the interior; it remains very hot from April to September inclusive, but the winter months are relatively cool. The daily range of temperature is very great, exceeding 30° at many places; for example at El Obeid in the Anglo-Egyptian Sudan in January the mean daily maximum is 86° and the mean daily minimum 52°, and frosts are occasionally experienced. Very high maxima are recorded in summer, exceeding 110° on the coast and 120° in the interior, while at Azizia, in Tripoli, a shade temperature of 136° has been recorded, the highest known on the earth's surface. The air over the interior is dry, less than 40% average humidity for the year, and figures of 2 or 3% have been recorded. On the coast special conditions prevail, which will be referred to later. The amount of cloud is very small, generally less than one-fifth of the sky covered, while in parts of the Egyptian desert no cloud is seen for months together. The winds are generally light and irregular over the Sahara, but dust storms, sand pillars and other local violent winds occur. In the Nile valley the prevailing wind is southerly from November to February and northerly from April to September and reaches considerable strength in the midsummer months, greatly moderating the temperature; occasional very hot, dry, dust-laden southerly winds are known as the Khamsin; these are very unpleasant, especially when accompanied by sand storms. Similar winds from the desert occur also under local names in Tripoli, Tunis and Algeria; they frequently cross the Mediterranean to southern Italy as the scirocco. A severe form is the dreaded simoom or samun, a hot blast of air (125° or more), often accompanied by heavy clouds of dust or sand. Land and sea breezes are well developed on the coast of Tripoli, Tunis and Algeria, but not of Egypt. The corresponding desert of southern Africa, the Kalahari, is of much less extent, being limited to the western half of the continent, and the heat and dryness are not so excessive as in the Sahara.

The climate of the coast of the Red Sea and Gulf of Aden is peculiar. The rainfall is exceedingly scanty, the sky almost cloudless, and the temperature very high, but this is associated with an abnormally high humidity, the moisture being derived from the warm waters of the Red Sea, which reach 90°. The highest known temperature of the wet-bulb thermometer, 100°, has occurred at Kamaran island and Berbera; this moist heat is very unpleasant. Where the Sahara and Kalahari meet the Atlantic, different conditions occur; here the presence of cold currents makes the surface of the sea very cold, while the land a few miles inland is very hot; these regions have a very small rainfall, clear skies but frequent fogs over the sea, and a moderate temperature which changes very little throughout the year. The rainfall of the South African west coast from 17 to 28° S. is less than an inch a year.

Mediterranean Climate.—Morocco, northern Algeria and northern Tunis have pleasantly mild, rather rainy winters and

long, hot, dry, almost cloudless summers. The annual rainfall averages about 30in., but is very variable. The mean temperature is between 50° and 60° in January and about 80° in July and August; the daily range is about 1j°. A similar climate is found over a small area near Cape Town, which has a temperature ranging from 55° in July to 70° in January and February, and a rainfall of 25in. falling mainly from May to September inclusive.

Eastern Africa. — Kenya Colony, Tanganyika, Uganda, Nyasaland and Portuguese East Africa have an equable climate with a temperature between 7j° and 80° near sea-level and a rainfall of 30 to 60 inches. There is generally a fairly well-marked rainy season; near the equator this occurs in April and May with a minor rainy season in November and December, but further south there is only one rainy season, falling in summer. Thus at Zanzibar the rainiest months are April, May and November, in that order, and at Nairobi, April, November and May, but at Lourenço Marques in 26° S., January and February. The dry season or seasons are not so extreme as in West Africa; months entirely without rain are rare and the relative humidity remains fairly high throughout the year. The prevailing winds are easterly. Thunderstorms are very frequent during the rainy season, recurring with great regularity almost every afternoon. The low-lying coastal areas are enervating and in places unhealthy, but large parts of the interior, including the whole of Uganda, form plateaux with an elevation of several thousand feet, and as the average temperature decreases upwards at a rate of about 3" per 1,000ft., these uplands are much cooler and more bracing than the coastal regions, while their distance from the sea makes them somewhat drier except on slopes directly exposed to the rain-bearing easterly winds. These plateaux are rather more suitable for European habitation than the coastal areas. Natal and the eastern parts of the Cape Province have warm, rainy summers, with a temperature of 70° to 75°, and moderately cool winters, relatively dry but very seldom rainless. The annual rainfall is between 30 and 40in.; the average July temperature is 63" at Durban and 59" at East London, but over the high ground of the interior frosts are sometimes experienced in winter. This is one of the finest and healthiest climates in Africa.

(C. E. P. B.)

FAUNA

Africa, together with the Deccan and West Australia as well as Brazil, forms part of the old continental mass of Gondwanaland, whatever view one may take of the process of separation of each from the others. Gondwanaland seems to have persisted through much of the Mesozoic era, during which these southern lands were separated from the northern ones by the broad sea of Tethys, along which later uprose the great fold mountain ranges that stretch from the Pyrenees to the Malay. The southern lands thus show resemblances in their forms of life that are due to these old links. Another factor of the history of life within them is the stability of their conditions as contrasted with the wide variations that have occurred in the orography and climate of the northern lands. Those wide variations have been reflected in evolutionary changes among living things and thus the northern lands have become in a large measure the homes where new forms are born, while the southern ones are largely refugees of early strays from the north, or places where certain types immigrating since connections were made have had a great career. The Sahara desert-barrier is largely a modern (post-glacial) hindrance to immigration of animals, the Rift system a partial but serious hindrance also relatively recently established.

The isolation of Africa is far less than that of Australia, and, whereas Australia retains the two lowly egg-laying mammals (*Ornithorhynchus* and *Echidna*) and is the great home of the marsupials, and of no other truly native mammals save bats, an indication of its long separation, Africa retains neither the egg-laying mammals nor the marsupials. The lowliest order of truly placental mammals, the so called Edentata, absent from Australia, occurs in South America, Africa and south-east Asia. Its great home is South America, but the aardvark (Cape ant-eater) is peculiar to Africa and *Manis* (the scaly ant-eater) has species both in Africa and in south-east Asia. It is an interesting fact that the order,

though an ancient one is absent from Madagascar. The primates offer a contrasted distribution. Among them the lemurs are ancient forms of known fossil from the northern lands but now surviving in Africa, Madagascar and south-east Asia; Africa has many more forms than south-east Asia and Madagascar many more still. From the lemurs have descended monkeys and apes; the platyrrhine monkeys are American, the catarrhine, African and Asiatic, including, among anthropoid apes, the orang-utan and the gibbon of south-east Asia and the gorilla and chimpanzee of intertropical Africa. It is generally thought that the survival of lemurs in Madagascar is a result of its separation from Africa before the great carnivores had spread thither. The absence of elephants, rhinoceros and anthropoid apes from Madagascar is noteworthy. The most important African carnivore is the lion, also found in parts of Arabia, Persia and western India and formerly more generally distributed in south-west Asia and north-east Africa until man restricted its range. The leopard (panther) and hyena are the other large carnivores. Madagascar has very primitive carnivores only, one of which was formerly said to be closely related to a West Indian form though the resemblances seem better interpreted by the fact that both are ancient types. The African elephant is a species distinct from the Indian one; the distribution of the genus was of course far wider until postglacial times. The hoofed animals of Africa are of some interest. Of even-toed forms Africa alone preserves the hippopotamus which ranged widely in northern lands until a late phase of the ice age; remains of a small hippopotamus species have been found in Madagascar which also possesses a river hog (*Potamochoeros*). It is thought that they may have swum across from Africa before the separation between continent and island became very marked. The giraffe and okapi are another family of hoofed animals found in East Africa only. The rhinoceros has east African and south-east Asiatic species. The single humped camel is now a feature of the steppes and deserts of north Africa but only as a domesticated animal introduced from Arabia. Deer are absent from Africa save for a few forms in French Africa, north of the Sahara, just as bears and wolves do not occur south of the desert. On the other hand the immense warm African grasslands are overrun by many antelopes, and the zebra and formerly the quagga. Africa thus, along with a number of old fashioned forms has several relatively new fashioned ones, but the absence of true cattle, pigs, goats, sheep and camels until man brought them is a striking fact. Of the genus *Bos*, nevertheless, South Africa possesses a representative in the Cape buffalo (*Bos capensis*). Africa has many birds peculiar to it but we need only notice the ostrich family of birds that run over grassland and desert border; extinct running birds of great size (*Aepyornis*) lived in Madagascar apparently not very long ago. Some African reptiles (*e.g. Amphisbaena*) appear closely related to South American forms, others to those of northern lands, the abundance of crocodiles is a feature and so are the chameleons, which especially abound in Madagascar. The python and puffadder are notable among African snakes. Monitor lizards, abundant in Africa and elsewhere, have not reached Madagascar. The Amphibians of Madagascar include several species also found in south-east Asia and this may be a result of an ancient land connection, and analogous arguments could be given concerning the land snails. Africa has the disastrous fate of being the one home of the tse-tse fly.

(X.)

FLORA

The character of the vegetation of Africa is largely determined by the distribution of heat and moisture coupled with the great range in altitude. Phytogeographically the continent may be primarily divided into three sections: (1) a northern extratropical region, bordering the southern shores of the Mediterranean and gradually fading into the northern Sahara desert with a very scanty flora; (2) a tropical African region, bounded approximately on the north by the Tropic of Cancer; and (3) a South African region, reaching as far north as the Limpopo, Lake Ngami and southern Angola. According to Thonner (*Fl. Pl. of Africa, 1913*), there are in Africa about 3,712 genera and over 40,000 species of flowering plants, a number constantly being added to.

The Northern Area.—The northern area contains a considerable proportion of genera and species common to the south of Europe, besides a large number of endemics in and south of the Atlas mountains and in Morocco. In the Atlas mountains the Atlantic cedar (*Cedrus atlantica*) is a characteristic tree, and is very closely related to species in Asia Minor and the western Himalayas, some authorities having considered them all to be forms of one variable species. The flora of Morocco is related to that of the Canary islands, whilst the somewhat meagre indigenous vegetation of Egypt is largely the same as that of Palestine and Persia.

The tropical African flora may be roughly divided into four regions: (1) a northern desert or semi-desert region; (2) a savannah region; (3) a high mountain region; and (4) the tropical rain forest. The first type is characterized by a very scanty rainfall, and its flora consists largely of plants which are short-lived, such as annuals, or those specially adapted to resist long periods of drought. These include the date-palm (*Phoenix dactylifera*) which grows where other vegetation is practically non-existent. The transition from the semi-desert to that of the savannah is usually gradual with an increase in annual rainfall and pronounced wet and dry seasons. In the savannah the low, thorny bushes of the desert are replaced by scattered trees and shrubs, giving the country a park-like appearance, with an undergrowth of grasses and herbaceous flowering plants, including numerous annuals and species with underground root-stocks. This vegetation is typical of the elevated plateau-region which occupies a large portion of the continent. Characteristic trees are the baobab (*Adansonia digitata*), the shea butter tree (*Butyrospermum Parkii*), *Anogeissus Schimperii*, *Azelia africana*, *Entada sudanica*, *Parkia filicoidea*, the fan-palm (*Borassus flabellifer*), etc.

In general it may be stated that the desert type is steadily encroaching on the savannah, which in turn is gradually penetrating the northern limits of the forest region, a condition resulting from a combination of desiccating winds during the prolonged dry period and of human agency (shifting cultivation and burning of the grass). In the drier parts of the savannah, for example in the eastern Sudan, large areas are covered by species of thorny acacia, including *A. arabica*, producing gum-arabic. In somewhat less arid but similar country farther south, in Rhodesia, south-east Belgian Congo and parts of Angola, another leguminous genus, *Brachystegia*, is very plentiful, and forms almost pure low forest, whilst in the drier semi-desert areas of south Angola and Damaraland a unique example of the vegetable kingdom, *Welwitschia mirabilis*, is found. In the savannah and neighbouring forest regions there are numerous plants with edible fruits and not a few poisonous plants such as species of *Dichapetalum* (Cfzailletiaceae), the arrow-poison (*Akokantlera*), *Lasiosiphon Kraussianus*, *Strophanthus*, etc.

The high mountains capping the savannah region, such as the Cameroon mountains, Mt. Elgon, Mt. Kenya, Mt. Ruwenzori, Mt. Kilimanjaro, etc., carry a flora of great interest. On one or other of these mountains it is possible to traverse almost as varied a succession of types of vegetation as might be encountered in a journey from the equator to the vicinity of either of the poles. Many of the genera found on their slopes are represented elsewhere only in the temperate regions of the northern or southern hemispheres. Some of the better known examples are berberis, cornus and anemone, whilst outliers from the Cape region occur, such as *Protea*. The weird forests of tree-groundsels (*Senecio*) and the giant species of lobelia are characteristic features of the East African mountains.

The evergreen forest occupies mainly the low-lying country with a high rainfall distributed throughout the year, and extends in an ever-widening belt from the colony of Sierra Leone to the Cameroons, whence it spreads out over a great part of the Belgian Congo and the Gabon as far as the Victoria Nyanza. This forest sometimes penetrates for a considerable distance into the savannah regions along the banks of rivers. It is particularly rich in endemic species of trees, shrubs and woody climbers, some of which are of great commercial value. The most important timber trees are the African mahoganies (*Khaya*, *Pseudocedrela*, *Entandrophragma*, etc.) and numerous trees of the families Caesalpini-

aceae, Combretaceae, Simarubaceae and Euphorbiaceae. Amongst ornamental shrubs the numerous species of *Mussaenda* (Rubiaceae), with enlarged, brightly coloured calyx-lobes, and the brilliant-flowered combretums, are conspicuous. The silk-cotton or kapok tree (*Ceiba pentandra*), with its enormous buttressed trunk, often attains gigantic proportions, whilst in West Africa especially the valuable oil-palm (*Elaeis guineensis*) is abundant. As many of the peculiar genera found in this primaeval forest, especially in the Cameroons and Gabon regions, are also found in the Guianas and Brazil on the opposite side of the Atlantic, it seems probable that it is but the remains of a once much more extensive and continuous tract of forest. Apart from Madagascar, the connection between the East African forests and those of tropical Asia is not nearly so marked.

South African Flora.—The South African flora, broadly speaking, consists of two main types: the typical Cape or south-western region occupies a narrow strip within the southern coast line. In some respects it resembles certain features of the Australian flora, the peculiar families Proteaceae and Restionaceae and certain groups of Leguminosae being common to the two areas and rare in other parts of the world. The vegetation of this coastal area is of a marked xerophilous character and bears a superficial resemblance to that of certain parts of the Mediterranean. It is of the so-called bushwood type, and here and there are tracts of grassland. Intermingled with the shrubs are numerous annuals, herbaceous perennials, succulents, etc. Farther inland, between the ranges of mountains, much of the surface is occupied by the "rhenosterbosch," *Elytropappus rhinocerotis* (Compositae). True forests occur only towards the eastern part of the region, in the districts of Knysna and Humansdorp, and the trees composing them nearly all belong to tropical genera. In the north-west a few trees of a conifer, *Callitris juniperoides*, are found, being the sole remains of a once extensive forest. The silver-tree, *Leucadendron argenteum*, is now confined to the Cape peninsula, which harbours as many as a hundred species of Erica. Other striking plants in the same district are the brilliant scarlet *Disa uniflora* and the blue *D. granzinifolia*, two beautiful ground orchids. There are also numerous species of the geranium family and many beautiful oxalis, large numbers of which are in cultivation.

Of the remainder of the South African regions perhaps the most interesting and remarkable is the Karroo, which occupies a broad belt in the hinterland of the south-western coast region. It is mainly a vast shallow basin which in former times was the bed of a large lake. Its altitude, according to Bolus, ranges from 1,800–2,500ft., the mountains on the northern margin reaching 8,000ft. altitude. The vegetation is of an intensely xerophytic type, being composed mainly of succulents of weird and diverse form, thorn-bushes and numerous plants with bulbous and tuberous root-stocks. Trees are almost entirely absent. The predominant fam-

A FAMILY OF MAKALANGA NATIVES
The Makalangas are a branch of the Bantu race of southern Africa—an agricultural people and more civilized than the tribes of the interior

ilies in this region are Compositae, Leguminosae and Ficoideae, the last-mentioned being almost entirely represented by about 70 species of the genus *Mesembryanthemum* and its segregates. In this area the exotic *Opuntia* from Central America has become a pest.

The upper and Kalahari regions distinguished by Bolus may for convenience be treated as one. Whilst the families mentioned above are still highly represented, the grass family, Gramineae, takes a very high place, much of the country being grassland (high veld). Here also there is a considerable influx of families and

genera characteristic of the tropical regions to the north. Amongst the Compositae the everlastings (*Helichrysum*) are conspicuous.

The south-eastern coast region is bounded on the south-west by the Van Stadens mountains and extends northwards east of the Drakenberg as far as the tropic into which it gradually merges. It is essentially a southerly extension of the tropical flora of East Africa, and contains a large number of such tropical families as Asclepiadaceae, Acanthaceae, Rubiaceae, etc. True rain-forest occurs in Natal. The plants so characteristic of the south-western coast region diminish rapidly northward. Some of the most striking plants in the area are a large tree-euphorbia (*E. grandidens*) and several species of *Eucephalartos* (Cycadaceae) and numerous species of aloe. Although nearly opposite the island of Madagascar, there is scarcely anything in common between the two floras.

As in the case of the tropical flora, it seems clear, judging by the history of the vegetation, that the climate of South Africa is gradually becoming drier. (J. Hu.)

GEOLOGY

Africa has a simpler geological structure than any other continent, although it has many unique features and formations. It consists essentially of a plateau of which the rocks have not been bent into steep folds by compression since primaevial times, except for a strip in Cape Colony, which was part of an ancient southern continent, and for the Atlas Mountains, which are geologically and biologically European. The continent between these remote chains of fold mountains has undergone no close folding, and most of it has remained above sea level since the time of the oldest known fossils. The margins have been repeatedly reached by the sea, which has submerged the coastal plains and occasionally extended inland up the valleys. The plateau has been fractured and cleft by earth movements which occasioned widespread volcanic eruptions; but the plateau surface has remained a land area on which plants and animals have evolved continuously, subject to the stimulus of changing climate, but never interrupted by submergence. Africa is part of an ancient continent which included most of South America, India and Australia. This southern continent, Gondwanaland, was separated from the contemporary northern land of Eurasia, except for an occasional isthmus, by a sea, the Tethys, which extended from central America through the Mediterranean and across southern Asia to the Eastern Archipelago. The range of this southern continent is best established in Carboniferous times; by the Jurassic its disruption had begun by subsidences which formed the Atlantic and Indian oceans, introduced great changes in its biological relations, and repeatedly caused widespread volcanic eruptions.

The foundation of the continent consists of a vast slab of rocks belonging to the Primaevial or Pampalaeozoic era. They are exposed over about one-third of the continent. They outcrop from Cape Town to southern Egypt, and from the Gold Coast on the west to Somaliland, the eastern horn of Africa. Most progress in the classification of these rocks has been made in South Africa, where they have great mineral wealth. They are divided into three main divisions. The lowest, the Swaziland system, consists of gneisses and coarse schists; in addition to the typical areas in South Africa, it forms most of Africa, including Nubia, the highlands along the eastern and Atlantic coasts, and the Sudan from Abyssinia to Nigeria and the Gold Coast. This division corresponds to the old gneiss of other lands, such as the Laurentian of Canada and the Lewisian of Britain.

The second division consists of sedimentary rocks, including quartzites, limestones, dolomites and slaty schists, with vast sheets of volcanic rocks. They are classified in South Africa as the Witwatersrand, Ventersdorp and Transvaal systems. Some of the rocks are so little altered that they have been expected to yield fossils; but none has been found and the *Orthoceras*, said to prove the Ordovician age of the Otavi dolomite, was based on cylindrical concretions. Some of these beds were regarded as Lower Palaeozoic; but they are probably earlier owing to the absence of fossils, and their resemblance to the pre-Cambrian rocks of other continents. The representatives of this division include important cop-

per, lead and zinc mining fields in northern Rhodesia and the Congo basin, the goldfield of Kilo in the eastern Belgian Congo, the goldfields of the Gold Coast Colony and the less important gold occurrences that have been discovered in Tanganyika Territory and Kenya Colony.

The third division includes sandstones that are so little altered that they have been persistently regarded as the inland continuation of the Devonian red sandstones of the coast at Cape Town. The chief member is the Waterberg sandstone of the northern Transvaal, which is probably represented in Uganda by part of the Karagwe series (most of which is referable to the second division), and in Angola by the Oendolongo series. These sandstones are probably the equivalent of the Torridonian of Britain and the Keweenaw of the United States and Canada.

The Palaeozoic era began with apparently the whole of Africa as part of a continent, for the only Cambrian beds known in it are in Morocco near Tetuan, though the sea came close to the eastern coast in Sinai. No certain Ordovician rocks are known, though they have been doubtfully recorded from the Atlas mountains. Many beds in Africa have been called Ordovician and Silurian on inadequate evidence, but some Silurian beds with graptolites occur in the central Sahara.

The Devonian is the oldest African system with widespread fossiliferous beds. It includes the Bokkeveld beds in Cape Colony, and has a wide extent in the Sahara, Libya and the western Sudan, and it reaches the Atlantic on the Gold Coast; marine representatives occur of the lower, middle and upper divisions. Marine Carboniferous rocks occur to the north of the Devonian beds in Cape Colony and limestones with crinoids and *Productus* show that a contemporary sea covered part of Egypt. The Lower and Middle Carboniferous are widely developed in the northern and north-western Sahara, and in south-western Tripoli; and there are small outcrops by the Gulf of Suez. The Carboniferous land deposits are extensive. The lowest part of the Karroo system of southern Africa is Upper Carboniferous and includes the glacial Dwyka Conglomerate and rich coal seams. Coal is also found in southern Rhodesia, Tanganyika Territory and Lake Nyasa. The glacial deposits of this period extend northward into the Congo basin and southern Madagascar. The later divisions of the Karroo system range from the Permian to the Lower Lias and are represented in equatorial Africa; they have yielded many remarkable fossil reptiles. The Permian beds (Lower Beaufort) are represented by shales of freshwater origin with *Palaeonodonta* on the Sabaki in Kenya Colony, and the Trias (Upper Beaufort) by the Tanga beds and part of the Buruma sandstone, of which the fossil *Dadoxylon* forest may be the equivalent of that of the Molteno beds of South Africa. In the Congo there are large areas of sandstones, the Lualaba and Lubilache series, which, judging from their sparse fossils, are Permian and Trias.

There is no established marine Trias in Africa, except for a small development in southern Tunis and along the Atlas of beds like those in Andalusia; though the sea lay a little north in the Mediterranean, most of the Triassic beds of Algeria and Tunis are of the continental type, like those of England and Germany. The breaking up of Gondwanaland had nevertheless probably begun in the Trias, and in the next period, the Jurassic, marine beds were deposited along parts of the east African coast. An arm of the sea then ran up the Mozambique channel between Madagascar and the mainland. The eastern part of Madagascar consists of the primaevial gneisses and schists, on which rest some Karroo beds; the western slope consists of marine Jurassic, Cretaceous and Kainozoic beds, with some volcanic rocks. The Jurassic beds of Madagascar and Tanganyika Territory range from the Lias to the end of the system; further north, in Kenya Colony and Somaliland, the horizons established represent from the Bathonian to the Tithonian. In Tanganyika Territory the Upper Jurassic beds (Corallian to Tithonian) in Tenduguru are famous for their fossil reptiles, of which *Gigantosaurus* is the largest known animal.

The advance of the sea during the Jurassic received in East Africa a check in the Cretaceous; for though a Neocomian gulf ran northward from Uitenhage in Cape Colony past Madagascar, the lowest Cretaceous series is barely represented in Kenya and

its occurrence in Abyssinia is probably due to a gulf from the Mediterranean. The widespread Cretaceous rock of eastern Africa is the Nubian sandstone (possibly partly Upper Jurassic), a land deposit which extends from Egypt to Abyssinia and Somaliland. In Egypt an arm of the Mediterranean sea deposited Cretaceous beds, which represent all the series from the Lower Cenomanian to the Danian.

A Cretaceous strait in the Upper Albian and Senonian extended from the Mediterranean across the Sahara, past Lake Chad and along the Benue valley as far south as Angola. The Cretaceous in Africa is best represented in Tunis, Algeria and Morocco. At the beginning of the period the sea covered a narrow strip of land from the coast to just south of Tunis and Oran; but by the Middle and Upper Cretaceous compact limestones were deposited over much of northern Algeria, and the Cenomanian lagoons lay along the front of the Sahara.

In the same region the Cretaceous sea was succeeded directly by that of the Lower Eocene, wherein were deposited the phosphatic limestones that are the most valuable mineral deposit of northern Africa. A still wider submergence in the Middle Eocene formed the Nummulitic limestone, which ranges across northern Africa from Cairo through Cyrenaica and along the Atlas Mountains to Morocco; and a gulf southward extended on to some of the lower parts of the Sahara. A strait from this gulf continued to the Niger valley and covered the district of Sokoto, and reached the Gulf of Guinea in southern Nigeria and the Cameroons. The Oligocene saw a general retreat of the sea from northern Africa, but beds with small Nummulites were deposited in bays. The freshwater lakes of the Oligocene have yielded at Fayum the fossils which revealed to C. W. Andrews the story of the origin of the elephants from the primitive *Moeritherium*.

The Miocene sea along the Atlas was restricted to a strait from Oran to central Tunis, which was one of the passages that connected the Atlantic and the western Mediterranean. A renewed uplift at the end of the Miocene of the channel reduced these straits, though that south of the Riff in Morocco was apparently still occupied by the sea. In other parts of Africa the marine Cainozoic deposits are scanty. The sea occasionally reached the tropical coasts. A full series of Eocene limestones occur in Somaliland, with also the Upper Oligocene. Eocene and Miocene deposits occur both on the coasts of Kenya Colony and in Tanganyika Territory at Lindi; Miocene limestone occurs in the island of Pemba. The marine Pliocene of the Mediterranean is represented in Algeria and Egypt, while marine Pliocene deposits allied to those of the Persian Gulf also occur, notably in Zanzibar island and at Mombasa.

Africa, therefore, has a long stable development, which was occasionally interrupted by volcanic outbreaks connected with the fractures made by the foundering of the adjacent ocean basins. The eastern half of Africa appears to have been slowly upraised during the Mesozoic into a broad, flat arch contemporary with the formation of a great sea-filled trough along the East African coast. The wider subsidence that formed the Indian Ocean led to the giving way of the eastern side of the arch, and the infall of its roof formed the Great Rift valley, which extends from Mozambique throughout eastern Africa and along the Red Sea to the Jordan valley. The fractures connected with its formation were accompanied by great volcanic eruptions, and the Kapitan phonolites of Kenya Colony are probably contemporary with the Deccan traps of north-western India. The earth movements connected with the formation of the Great Rift valley lasted from the Oligocene to the Pleistocene, and they were accompanied by repeated volcanic eruptions. They built up the two highest of African mountains—Kilima Njaro, which still has a crater upon its summit, and Kenya, which is the denuded neck of an old volcano. Subsidences around volcanic centres formed great cauldrons, such as Ngorongoro in Tanganyika and Menengai in Kenya Colony. Volcanoes along the fractures connected with the formation of the Atlantic produced the shonkinite vent at Chieuca in Angola, the volcano of the Cameroons, which is still active, while eruptions along a fracture parallel to the coast formed the islands of the Guinea Gulf, Fernando Po, San Thomé, Príncipe and

Annobon. The deepest subsidences along the Rift valley in Africa formed the lake basins of Tanganyika, Nyassa, the Albert Nyanza and Lake Rudolf.

The economic geology of Africa is connected mainly with its rich mineral fields, especially of gold and diamonds in South Africa, southern Rhodesia and the Gold Coast; of gold at Kilo; of diamonds, copper, zinc and lead in Northern Rhodesia and Katanga. Tin and platinum are found in the Transvaal, and chromium in southern Rhodesia. The most important phosphate deposits are along the Atlas Mountains. The only productive African oil-field is on the coast of the Gulf of Suez; oil-shale is known in South Africa, Nigeria and elsewhere; rich coal-fields are worked in the Transvaal, Natal and Southern Rhodesia; and coal also occurs in Tanganyika Territory, Nyassaland and Nigeria. Iron ores are widespread, as are also deposits of bauxite and manganese, which are most extensively worked on the Gold Coast. The chief African mica mines are in Tanganyika Territory.

TABLE OF FORMATIONS

CAINOZOIC	
Pleistocene.	Raised coral reefs. Alluvial river and lake plains. Moraines on Kilima Njaro, Kenya, and Ruwenzori. Elephant beds in Zululand. Lavas and tuff, of recent volcanoes. Gravels, desert sands, etc., with Neolithic and Palaeolithic implements.
Pliocene.	Marine beds in Tunis and Algeria. Sands with <i>Clypeaster</i> in Egypt. Limestones of Zanzibar, Pemba and Mombasa. Naivashan lavas in Kenya. Bone beds at Homa, Omo Valley, etc. Lavas in Atlantic islands, Aden, etc.
Miocene.	Marine limestones in Algeria and Tunis. Limestones of Pemba and Tanganyika coast. <i>Dinotherium</i> beds of Victoria Nyanza. Limestones of Egypt with oil-field of Gulf of Suez.
Oligocene.	In former bays along Mediterranean coastlands. Dubar limestone of Somaliland. Limestones N. of Mombasa and at Lindi. Lake beds of Fayum. Early faulting of Great Rift valley.
Eocene.	Nummulitic limestone of N. Africa coastlands; in Sokoto, northern Nigeria, Somaliland; Coasts of Kenya Colony, Tanganyika Territory. Sheringoma in S. Mozambique. <i>Aturia</i> beds of S.W. Africa. Widespread volcanic eruptions in Kenya.
MESOZOIC	
Cretaceous.	Neocomian to Up. Cretaceous along eastern coast of S. Africa. Neocomian-Cenomanian in Mozambique; Urgovian-Senonian in Tanganyika Territory. Cenomanian-Danian Egypt. Lower to Up. Cretaceous along the Atlas mts. Albian in Angola. Turonian, Benue valley. Kapitan Phonolites of Kenya Colony. Nubian sandstone in Nubia, Abyssinia, and Somaliland.
Jurassic.	Upper.—Meragalleh limestone in Somaliland and Kimmeridgian-Purbeckian, with giant reptiles and marine beds, in Tanganyika Territory. Ammonite beds near Mombasa. Middle.—Kenya and Tanganyika Territory. Lower.—Bathonian and Bajocian limestones in Tanganyika Territory, Kenya (Kambe limestone), Somaliland, and Madagascar.
Trias.	Lias. Tanganyika Territory and Jubaland. Rhaetic. Drakenberg lavas. Upper Tanga beds with plants. Coal series in Natal.
Trias.	Marine. Terrestrial Trias in S.S. Tunisia and Atlas Cave sandstone and Molteno beds. Mazeras sandstone with <i>Dadoxylon</i> forest in Kenya coastlands.
Upper Beaufort.	Kenya coastlands. Burghersdorp beds of S. Africa. Lubilache sandstones of Congo basin.
PALAEOZOIC	
Permian.	Lower Beaufort in S. Africa. Tanga beds. Sabaki shales with <i>Palaeonodonta</i> . Tanga beds. Upper Lualaba sandstones of Congo.
Carboniferous.	Upper Uralian. Ecce beds with coal-fields of Transvaal and glacial Dwyka conglomerate in S. Africa. Wankie coal in S. Rhodesia. Coals in Tanganyika Territory and Congo. Glacial beds in Congo and Madagascar. Middle.—Absent.
Devonian.	Lower.—Witteberg series of Cape Colony. Crinoid and <i>Productus</i> limestone in Egypt. Bokkeveld series of Cape Colony. Marine beds of Sahara, Libya, and Sudan. Table Mountain sandstone.

Silurian.	Central Sahara.
Ordovician.	Absent.
Cambrian.	N.W. Morocco and Gulf of Akaba.

PAMPALAEZOIC (PRIMAEVAL)

- Upper Division.* Waterberg sandstone of S. Africa. Oendolongo beds, Angola.
- Middle Division.* Transvaal, Ventersdorp, and Witwatersrand systems in Transvaal and S.W. Africa with representatives in Rhodesia, southern Congo. Lepi series of Angola. Kandelurgu and Karagwe quartzites of Tanganyika and Uganda. Banket series of Gold Coast.
- Lower Division.* Swaziland system with gneiss Schists of the main foundation of the African continental plateau.

ANTHROPOLOGY AND ETHNOLOGY

North Africa and Egypt.—Apart from Egypt and the Nile Valley the divisions of Africa north of the Sudan are in the main political and from the anthropological standpoint almost entirely artificial. Not only are the Egypto-Tripolitan and the Morocco-Algerian frontiers entirely conventional, but even the Libyo-Tunisian frontier lacks the ethnic significance it might possess if instead of leaving the Mediterranean in the neighbourhood of Cape Roux it ran almost due south from the Gulf of Gabes. The political divisions of the western portion of North Africa—Africa Minor—thus stand in sharp contrast to its natural unity, so well-defined between the desert and the Mediterranean that the early Arab geographers named it Geziret el Magreb, "the Western Island." It is also necessary to realize that the predominantly Arab complexion of North Africa and the general substitution of Hamitic languages by Arabic began little more than 1000 years ago, while to appreciate the vast area of country over which the spread of Arab influence has obliterated or modified the earlier Berber tongues reference should be made to some such linguistic map as that given by Meinhof in *Die moderne Sprachforschung in Afrika* (Berlin 1910).

The Berbers and Their Position in North Africa.—While Sergi (*Antropologia della Stirpe Camitica*, Turin, 1897) regards the Berbers as the northern branch of the Hamitic stock (the Eastern Hamites being typically represented by proto-Egyptians, Beja and Galla), Keane (*Man, Past and Present*, Cambridge, 1920) quotes T. A. Joyce to the effect that it is impossible to prove the connection between Eastern and Northern Hamites, and that the latter should be regarded as the African representatives of the Mediterranean race. The question is largely a matter of terminology, since we cannot doubt the close relationship of the groups commonly termed Mediterranean, proto-Egyptian, and Beja.

The term Moor, which is often applied to the townsmen of Morocco, is here purposely avoided, and with Collignon and Deniker ("Les Maures du Senegal," *L'Anthropologie*, 1896) is restricted ethnically to a group of peoples lying between the Senegal River and Morocco and extending east to the Tuareg country.

Egypt.—For Egypt alone in North Africa it is possible to construct a connected anthropological record, which, in spite of gaps, reaches back to the very dawn of history. Some forty years ago Flinders Petrie and J. E. Quibell discovered at Naqada and Ballas in Upper Egypt a series of cemeteries belonging to a people with a mode of life and habit of burial utterly different from those of the dynastic civilization previously known in Egypt. Their discovery was followed up and extended by de Morgan, who recognized that Petrie's "new race" preceded even Mena, traditionally the first ruler of a united Egypt, whose tomb he found and excavated. Unfortunately de Morgan applied the term "neolithic" to this newly discovered people, a complete misnomer—though still used in French works—since detailed archaeological examination indicates that copper occurs in the earliest graves in

these cemeteries. These early inhabitants of the Nile Valley are now known as the predynastic or proto-Egyptians, terms which respectively emphasize their position in time and their ethnic relation to the other inhabitants of the Nile Valley.

The **Pre-dynastic** Egyptians.—The proto-Egyptians have been best described by Elliot Smith, who writes of them (The People of Egypt, Address to Cairo Scientific Society, 1909) as a people slightly below the average size of mankind, with muscular development so feeble that it may be difficult to determine to which sex an isolated skull belongs. In physical character they exhibit a remarkable degree of homogeneity. Their hair was dark, and either straight or wavy, never woolly. In the men apart from a chin-tuft beard there was the scantiest development of facial hair. These proto-Egyptians had long narrow heads with a narrow forehead and prominent occiput, so that the skull when viewed from above presents a characteristic form which has been termed "coffin-shaped." The face was a moderately long and narrow ellipse, and the chin was almost always pointed. More precisely, they were longheaded, with a cranial index of 73 (Naqada) and a mean height estimated at a little under 65 inches for men and about 60 inches for women, and though there can be no direct evidence as to skin and eye colour there is no doubt that they had dark eyes and skins of a yellowish brown or pale copper colour.

The **Dynastic** Egyptians.—All this applies only to the population of Upper Egypt; knowledge is lacking of the inhabitants of the delta at this early period, as of the whole of Lower Egypt until the time of the pyramid builders. Among the skeletons of this date from the neighbourhood of the pyramids Elliot Smith found a considerable number in which the skeleton was more robust, with a bigger and especially a broader skull without the angularity and the projecting occiput of the proto-Egyptian type; there are modifications in forehead, orbits and nose, with particularly obvious differences in the jaw, in fact the type of man buried round the pyramids belonged to that well characterized group known as the dynastic Egyptian, which in antiquity is represented by the Saqqara "Scribes" and the Sheikh el Belled, and is essentially that of the peasant Egyptians, the fellahin of the present day. For a detailed account of skeletal material, and especially of crania, throughout the dynastic period see A. Thomson and D. Randall-Maciver *The Ancient Races of the Thebaid* (Oxford 1905). Elliot Smith (The Ancient Egyptians, 1923, chapter 7), arrays evidence that long before the New Empire, Egypt was permeated from end to end by this foreign element, which in his opinion carries the physical traits of the Armenoid race. There is however one difficulty in accepting this view, which does not arise from any examination of the skeletal remains but results from the large number of portrait statues which the Egyptians have left to us, namely, that although so many of these statues exhibit the broader face and heavier jaw brought in by the alien race, not one of them exhibits any approach to the typical Armenoid, so-called "Jewish," nose. If therefore the foreign element is to be termed Armenoid it can only be called by this name so long as it is realized that this does not imply the presence of one of the most characteristic features of that race as known at the present day. The difficulty is not lightened by the fact that less than 1000 years later at Beni Hassan there are excellent representations of the Aamu, a people of the eastern desert with typical Armenoid noses.

Contemporary Representations of Beja.—The proto-Egyptian type persists to the present day among the southern Beja (*q.v.*), tribes of the Anglo-Egyptian Sudan. It also occurs, though probably in less typical form, among the Ababda of the Eastern (Egyptian) Desert and the riverain settlements in the neighbourhood of the first cataract. We have direct evidence dating from about 2000 B.C. of the existence of the pure proto-Egyptian type among a people wearing their hair in the same fuzzy mop as the Beja of the present day on the eastern border of Egypt. Among the wall paintings of the 12th Dynasty in the tombs at Meir (A. M. Blackman, *The Rock Tombs of Meir*, vol. ii., Pl. xxx., London, 191j), is one that undoubtedly represents a Beja. The long thin figure and limbs, with broad chest, narrow

flanks and retracted abdomen, are no doubt conventional and exaggerated representations of the characters of the lean pastoral desert men as they appeared to the agricultural Egyptians, but there can be no criticism of the splendid naturalism of the lined face, the thin pointed nose and the mop of hair projecting over the forehead and standing out stiffly over the whole head to the nape of the neck. The beard is the usual chin tuft of the Beja tribes, and comparison with modern Beni Amer clinches the identity of the two peoples, living in the same desert area but separated by 4,000 years. Confirmatory evidence of the proto-Egyptian characters of the inhabitants of the eastern desert and of their civilization is offered by the discovery by G. W. Murray of a burial of late pre-dynastic date, with characteristic grave goods, near Ras Samadi on the Red Sea Coast, in lat. 24° 59' N. (Man 1923, 81). The skull accorded well with those of the pre-dynastic Egyptians.

The desert must indeed be regarded as a reservoir not only of early archaic physical types no longer preserved in the richer Nile lands but also of ancient ideas and appliances, *e.g.*, the camel stick of the Ma'aza of the Eastern Desert is no other than the *Uas* sceptre of ancient Egypt applied to a new use.

The **Arab Element.**—The Arab conquest, which politically altered the whole history of Egypt, had no appreciable influence on the physique of its inhabitants. While in part this may be due to a certain physical resemblance between Arabian and Egyptian the numerical inferiority of the conquerors must be held to be the determining cause. The nature of the invasion may be best illustrated by considering the history of the Juhaina (Sudanese, Guhayna, *q.v.*). The tribesmen took a prominent part in breaking the power of the Christian kingdom of Nubia; yet in spite of their importance in the past, at the present day few groups that may fairly be called Arabs exist except in association with the desert. Such are the fisher folk of Lake Menzaleh, who trace their origin to Sinai; the Harabi of the Fayum, extending into the Tripolitan desert, still pastoral nomads; the Aulad Ali of the Behera district of the Delta, no longer nomads; and the practically sedentary Howeitat of Matarieh; all dolichocephals or low brachycephals. In the Eastern Desert the only important Arab tribe is the Ma'aza, about whom very little is known, described by Chantre (*Recherches Anthropologiques en Egypte*, Lyon, 1904), as short dolichocephals.

Besides these more or less well-defined groups there is in upper Egypt a small number of people, generally mobile in their habits, living along the edge of the cultivation. These folk generally keep goats and often own a few palm trees, and formerly may have been of more importance as charcoal burners. Somewhat in the position of gypsies in England fifty years ago, they are generally unpopular with the fellahin, on whom they levy a certain amount of blackmail. Such groups as the Bili, near Baliana, and the Aleiqat, of whom there are a considerable number near Qus, do not come into this category.

In Sinai, with a total population of some 10,000, the chief tribes are the Howeitat, the Tiyaha and Terabin, in the North; in the South the Tawara (*i.e.*, the people of Tor), who include the Aleiqat, the Sawalha and Muzaina.

The **Modern Egyptian.**—Passing to the fellahin, the modern Egyptian, the most important of the numerous studies that have been made are those of C. S. Myers ("Contributions to Egyptian Anthropology," in vols. xxxv., xxxvi., and xxxviii. of the Journal of the Royal Anthropological Institute) and of J. R. Craig ("Anthropometry of Modern Egyptians," *Biometrika*, vol. viii., 1911). Omitting the province of Aswan and the town dwellers, these papers, which must be regarded as complementary, indicate that the Egyptian peasant has a stature of approximately 65½ in., showing no sharp division between Upper and Lower Egypt; he is longheaded, with a cephalic index of about 75, the cephalic index—again omitting Aswan—being about a unit higher in Lower than in Upper Egypt. There is no evidence that the natives of various provinces differ in variability, nor is it possible to resolve distribution curves, whether of measurements or indices, into components corresponding to hypothetical underlying ethnic types, though it seems that passing from Lower to Upper Egypt

eye and skin colour darken and the proportion of unusually broad noses increases as does the frequency of spiral and crisp hair, all evidences of increased though still well diluted negro blood in the population.

The position of the Copts (the Christian population of the present day, and therefore with insignificant exceptions the descendants of the Egyptians who refused to relinquish their faith at the Conquest or during the succeeding centuries) is particularly interesting. The observations available refer to Coptic peasants, not town dwellers, and so far as these go the remark commonly made by Europeans that they can distinguish at sight between Muslim and Copt is not borne out. No significant deviation from the general Muslim population is found as regards head measurements or facial characteristics, though the nose is slightly less broad and the lip slightly thinner, with eye and skin colour a trifle lighter. Thus, diagnosis at sight between Copt and Muslim, if really practicable, cannot rest on easily defined physical characteristics but must be attributed to such other factors as gait, dress, etc.

The measurements and photographs of natives of Kharga Oasis published by Hrdlicka (*The Natives of Kharga Oasis, Egypt*, Washington, 1912) show that its inhabitants are Egyptians, differing in no essentials from the inhabitants of the Nile Valley. The inhabitants of Siwa speak a Berber dialect, akin to Tuareg, with many Arabic loan words, some so profoundly modified that their origin is not immediately apparent. Jaghbub (Jarabub), in Italian territory, is believed to have been uninhabited before its occupation by the Senussi, whose capital it now is.

Disposition of the Fellahin. — Difficult as it is to sum up the temperament or disposition of a people it is probably true to say that the fellahin are in the main good natured, cheerful and excitable, genuinely religious but not generally fanatical, though certain centres such as Tanta have a bad reputation in this respect. They are liable to occasional bursts of ferocity (such as distinguished the rioting of 1919), and inter-village enmities, leading to fights with iron-shod staves, were formerly fierce and persistent. Nothing approaching an adequate account of the beliefs and customs of the fellahin has yet been written, for Lane's *Modern Egyptians*, first published in 1836 before western influence had contaminated Egyptian habits and modes of thought, though giving an invaluable account of Cairene life and manners cannot be held to apply except in somewhat general terms to the habits and beliefs of the peasants, which even preliminary inquiry will show to vary not only from those of the towns but as between Upper and Lower Egypt. Meanwhile the work of Miss Winifred Blackman (*The Fellahin of Upper Egypt*, 1927) avowedly only a preliminary account, contains much useful information.

Tattoo, etc.—Tattooing is the most obvious, common and widespread method of bodily enhancement and mutilation. Lane mentions the simpler designs—dots, lines and circles—common in women and refers to the "extremely displeasing" habit of the women of Upper Egypt of discolouring their lips with tattoo. C. S. Myers ("Contributions to Egyptian Anthropology, Tattooing," *J.R.A.Z.*, vol. xxxiii., 1903) found that of about 400 male subjects nearly 100 were tattooed, the designs falling into two main classes, namely simple, generally geometrical, designs, and pictorial representations, e.g., the façade of a mosque or the Persian lion with sword. Local examples of the type prevailing throughout North Africa form the first class while the latter are derived from eastern sources. Circumcision is universal; clitoridectomy, though far less recognized by Europeans, is customary

in cities, at least among the poorer class, and may be equally common among the Fellahin. Both long antedated Islam, circumcision being represented in a tomb of the pyramid age at Saqqara, while clitoridectomy or a similar operation is alluded to by Strabo—*Circumcidunt etiam mares et foeminas excidunt*.

Survivals from Ancient Egypt. — One of the most interesting features of present day Egypt is the persistence in popular belief of ideas traceable to ancient Egypt, especially intricate ceremonies connected with mourning, the survival of the belief in ka or double, the persistence of a ceremony in which a sacred boat takes a prominent part, and the superstitions connected with particular days in the calendar. The boat ceremonies are particularly important, since these exist widely in Asia outside the Near East (e.g., in Ceylon) and it seems probable that their distribution has been to a considerable extent brought about from Egypt by the spread of Islam. Nearly 20 years ago the writer observed a full-sized river boat suspended in a tree outside Luxor; enquiries showed that once a year this was placed in a cart, filled with children and dragged round the fields. Actually there are three boat processions every year in Luxor, the most important being observed in honour of Abu'l Heggag, the patron saint of Luxor. The substitution of Aion and his sacred barque by Abu'l Heggag and his Nile boat is suggested by the popular belief at Karnak that on certain nights the golden boat of Amon may still be seen to emerge from the waters of the sacred lake, steered, as of old, by the Pharaoh.

The calendar customs are a striking example of how beliefs attached to a particular day may last for over 3,000 years, persisting through a complete change in the mode of reckoning time, as well as the introduction of new beliefs. The Sallier papyrus, which dates from the time of Rameses II. or possibly his successor, gives an account of the lucky and unlucky days in the year, and describes in some detail the quality of the good and bad luck, with instructions for behaviour on each of these days. It may first be noted that the five epagoimeneal days of the old Egyptian year were unlucky. In modern Egypt the epagomenal days are still observed to the extent that neither sowing nor planting should be undertaken, mares and cattle should not be covered lest their offspring be misshapen, and it is even believed that children begotten during these days will show some abnormality. A still more interesting example perhaps is that afforded by a day near the end of the old Egyptian month of Choiak; the Sallier Papyrus marks the 26th of this month as most unlucky, and of this day it is written, "Do not eat fish. Those residing in the midst of Tattu turn themselves into the fish An." The mythological allusion cannot be explained, but the modern popular calendar, such as is hawked about the Bazaars, notes that on the 11th of Moharram (corresponding to the 26th day of the Coptic month Kyhak) "the eating of pigeons is liked, that of fish disliked."

The Beja Tribes of Egypt. — Of the Beja tribes of the eastern desert the Ababda (q.v.) fall wholly within Egyptian territory; the Bisharin extend some 80 miles south of the boundary and occupy a strip of territory stretching along the right bank of the Atbara. While the physical characters of both tribes have been studied by E. Chantre (*Recherches Anthropologiques en Egypte*, Lyons, 1904) and the mode of life of the Bisharin described by Linant de Bellefonds (*L'Etbaie*, 1858), two recent papers by G. W. Murray ("The Ababda," *J.R.A.I.*, vol. liii., 1923, and "The Northern Beja," vol. lvii., 1927) constitute by far the most valuable account of these people. The Ababda inhabit the eastern desert from the Sudan frontier to north of the Kena-Kuseir road, and there are isolated colonies along the edge of the cultivation from Assiut to Korosko. In the time of Bruce their southern range was limited by the 'Atawna (Arabs) who have now vanished from the desert. Earlier yet Makrisi records the Beii (Bili) a tribe of which scattered groups still exist along the edge of the cultivation—as being in possession of parts of the desert now belonging to the Ababda. The desert Ababda intermarry with the Bisharin, and those settled in the Nile Valley with the Fellahin, but they do not appear to intermarry with any Arab tribes still carrying the desert tradition. Like other Beja tribes the Ababda wear the *dirwa*, the shock head-dress of hair

BY COURTESY OF NORTHERN BAPTIST CONVENTION

A NATIVE OF BELGIAN CONGO
Of powerful physique and expert hunters, a few of the tribes in the Belgian Congo persist in cannibalism.

besmeared with mutton fat, though this custom is gradually dying out. Unlike their Beja neighbours to the south the Ababda speak Arabic, but coloured by Bedaue (To-Bedawi) words, while transposition of consonants—a Hamitic rather than a Semitic feature—often occurs.

In physique the Ababda resemble the Beni Amer, and therefore the predynastic Egyptians, *i.e.*, they are longheaded with a cephalic index of 73.6 and a stature of 1.63 metres. The Bisharin on the other hand present two types, those of the Red Sea coast with a cephalic index of 74.7, and those living inland with a cephalic index of 78.4, the latter substantially identical with the index given by Chantre, presumably derived from individuals living in or near the Nile Valley. (Murray, *op.cit.*)

Tripoli.—Westwards beyond the Egyptian frontier knowledge of the physical anthropology of Tripoli is but slight. At the extreme west of Italian territory, *i.e.*, in the area surrounding Tripoli city, the systematic observations of Bertholon and Chantre show that the population is predominantly long-headed and of rather low stature (below 1.65 $\frac{1}{2}$ m.) but there is an island of high brachycephaly in the immediate area of Bu Ajilat, though these brachycephals exhibit no marked departure from the general low stature of the area. Throughout the rest of Tripoli but few observations have been made, certainly not enough to permit of any connected anthropological history or description of the country. The observations of the late Oric Bates at Mersa Matruh, not far east of the Egyptian frontier ("Archaic Burials at Marsa Matrûh" *Ancient Egypt*, 1915, Part IV., p. 158) suggest that at a period possibly as remote as that of the pyramid builders the population of the coastal plain was not unlike that of the proto-Egyptians, and presumably a people of some such type long continued to form the basis of the population of the coastal plain. Evidence such as that afforded by the ram of Bu Hamama (in Algiers) crowned with the sun-disk and uraei, as well as the presence of the sun-disk on Carthaginian coins, indicates the very considerable cultural influence exercised by Egypt along the north African littoral in late dynastic times, but so far there is no direct evidence of Egyptian influence on the physical anthropology of the country. Nor is there any knowledge in this sense of the effect of the Roman occupation. Herodotus, however, describes the Libyans east of Lake Tritonis, *i.e.*, the inhabitants of Tripoli, as nomadic and thus differing from the settled agricultural peoples of what is now predominantly Algeria, although it is clear that many of these people were in fact no more than semi-nomadic; the Nasamones for instance with their main settlements on the Syrtic shore, left their herds in summer and went up to Aujila for the date harvest, just as some "nomad" Arab tribes of the present day sow their crop in the oases in the autumn, leading a more or less wandering life until the spring.

Apart from the littoral belt the greater portion of Tripoli is desert or poor steppe, for the most part with an annual rainfall varying from three to less than ten inches, such a country can never have been densely populated or have offered any great temptation to highly civilized folk. The position is different with regard to nomads or semi-nomads; here is a sparsely inhabited area which could scarcely fail to attract the Arab tribes that poured into north Africa after the conquest of Egypt under the Khalif Omar, and again in the eleventh century when, in 1048, the Wazir of the Fatimid Khalif Mustansir launched a number of the nomad tribes of Upper Egypt, including the Beni Halal, against his master's orthodox vassals of the northern African States. Each man was given a camel and a gold piece on condition that he would settle in Maghreb, with the result that within two years Cyrenaica had been pillaged and Kairwan captured. But the western movement of the Hilali invasion did not stop here, for while the majority of the Beni Hilal settled in Tripoli and Tunis, and the Athbej passed into what is now Algeria, as far as the Aures mountains and the river Zab, the Makil pressed westwards as far as the high plateau of Morocco-Algeria. Beneath this flood the Berber tongue largely disappeared, and except among the Beni M'zab, the Abadite schism was almost wiped out.

At the present day the population of the coastal plain may for practical purposes be regarded as Arab, and since with the excep-

tion of the towns and the oases of the far south the coastal plain—never more than 20 miles in width and generally less than this—constitutes almost the whole of the available territory suitable for agriculture, the Arab tribes of this area form the predominant factor in the population of the country. Of these tribes the Awlad Ali may be taken as the type. Extending from the outskirts of Alexandria to the neighbourhood of Tobruk they grow a considerable amount of barley, and (at any rate before World War I) possessed horses, sheep and camels, the latter constituting their main wealth. Predominantly sedentary, and horsemen rather than camel-men, they yet live in tents. Their tribal organization is into sections and divisions as among the Arabs of the Sudan, whom (*e.g.*, the Kababish) they closely resemble physically to judge from the measurements given by Chantre. But not all the folk who have been described as Tripolitan Arabs are long-headed; an examination by Mochi ("Presentazione di cranii d'indigeni di Tripoli" *Archiv. per l'Antrop. e la Etnol.*, Florence XL, 1912, p. 381) of the skulls from Tripoli in the National Museum at Florence indicates that they contain at least one hyperbrachycephalic group. Remarkable as is this fact, its significance becomes clear in the light of a series of skulls described by Giuffrida Ruggeri ("I Crani Egiziani antichi e Arabo-Egiziani dell' Università di Napoli," *Atti della Società Romana di Antropologia*, XV., 1910, pp. 112 et seq.) from an ancient Arab cemetery at Abassieh near Cairo, with an average cranial index (13) of 85.3. The significance of these skulls and their relation to definite areas of round-headedness in Tripoli has been studied by Selignan ("The Physical Character of the Arabs," *J.R.A.Z.*, vol. xlvii., 1907), who points out that their characters indicate that the Abassieh skulls belonged to natives of Southern Arabia, that brachycephaly prevails both in southern Arabia and in the Levant, and that both these areas have contributed to the population of North Africa.

Barbary (Tunis, Algeria, Morocco).—Tunis, Algeria and Morocco, are but artificial political divisions of one natural area, which from the anthropological as well as the geographical aspect might still be called by its old name of Barbary. Its inhabitants, the Berbers, are commonly regarded as aborigines, and apart from immigrant stocks this seems to be true as far back as the end of the palaeolithic period. The physical anthropology of the natives of Eastern Tripoli, Tunisia and Algeria, has been exhaustively studied by Bertholon and Chantre (*Recherches anthropologiques dans la Berberie Orientale Tripolitaine, Tunisie, Algerie*, Lyon, 1912). The following facts give a rough idea of the progressive weakening of Arab influence, passing from East to West, and the physical characteristics of the three main groups generally recognized.

In Tunis, with a total Islamic population of something over two millions, there are about half a million Berberized Arabs and less than 100,000 Berbers, forming for the most part two isolated masses, the Matmata in the far south in the neighbourhood of Jebel Nefusa, and a group mainly of the Ababdite (Kharijite) heresy in the island of Jerba. Passing westwards to Algeria there are pure Berber groups in the Kabyle hills and in the Aures mountains. Apart from these two areas the remainder of the province of Constantine may be regarded as inhabited by Arabized Berbers except for a few Arab coastal areas. Numerically some 75% of the inhabitants of the province may be regarded as Berber or Berber-speaking, the remainder Arabs or partially Berberized Arabs. In the department of Algiers Arabs mixed with Arabized Berbers preponderate, while in Oran the Arab element is frankly dominant. In Morocco on the contrary the Berbers are not only in great numerical majority but socially form by far the most important groups. Here it is calculated that not more than five per cent of the population are Arabs, with perhaps another five of Berberized Arabs, the remainder of the population being fairly equally divided into pure Berbers and Berbers with a tinge of Arab influence. Nothing would be gained by attempting to enumerate the "Berber" and "Arab" tribes of Morocco. Westermarck (*The Moorish Conception of Holiness*, Helsingfors, 1916) divides the Berbers into five groups:—(1) the Ruâfa—the Berbers of the Rif—whose country extends along the

Mediterranean coast from the neighbourhood of Tetuan to the Algerian frontier; (2) the Berāber, who inhabit the mountain regions of Central Morocco and the eastern portion of the Great Atlas; (3) the Shleuh, inhabiting the western part of this range, and to the south of it in the province of Sūs a territory with an eastern frontier running from Demnat in a south-easterly direction and a northern frontier uniting Demnat with Mogador on the Atlantic coast, following more or less closely the foot of the mountains; (4) the Dra'a, who inhabit the valley of the Wad Dra'a in the extreme south of Morocco; (5) various tribes living in the neighbourhood of Ujda, in the north-east of the country. The so-called "Arabs" are the Jebala, the mountain-dwelling tribes of Northern Morocco, with their centre in the area between the Rif and Fez and extending westwards of the latter.

Physical Characteristics of the Berbers.—Morocco, is from the standpoint of physical anthropology for the most part unexplored. Three physical types of Berber are, however, generally recognized: (1) tall men, with a stature of about 1.70m., dolichocephalic, with strongly marked supraorbital ridges, the face long, tending to oval, the cheek bones by no means prominent, nose long and narrow, chin square and rather scant beard. This type appears to form perhaps half the population of Tunisia and is widespread in Algeria. (2) The second type is short, with a stature of about 1.63m., longheaded, with a prominent occiput so that the head when viewed from above is distinctly pentagonal; the face is short and broad, the cheek bones well developed, the nose tends to be broad, the chin prominent and often well bearded, the lips full. This type is to be found in the mountains of central Tunisia, in the neighbourhood of Gabes and of Algiers, in the south of Algeria, as well as all over Morocco. It seems to be generally accepted that the skulls found in the megalithic monuments of this part of Africa belong to one or other of these types. (3) The third group is of moderate stature, 1.64m. to 1.65m., and brachycephalic. The face is broad and short, the forehead round (*bombé*), nose short and broad. This type is specially present in the Island of Jerba and in the oasis of M'zab; it is also found in the hills to the south of the Gulf of Gabes, western Tripoli, and on the Algerian littoral, as well as among the Kabyles and the inhabitants of the Aures hill. Many of the M'zab have a skin so pale that they burn wheat colour rather than brown in the sun.

While the number of the blonde Berbers certainly varies locally and their proportion has no doubt often been exaggerated (at least in Algeria), a competent anthropologist, the late Anthony Wilkin, specially studying the problem, has recorded that of the observed population of El Arbaa fully 20% were "fair men" (Among *the* Berbers of Algeria, 1900, p. 77). Good observers always lay stress on the essentially white quality of the skin of the pure Berber tribes. The origin of this blonde element has been much discussed; it is no doubt foreign—presumably Nordic, with perhaps Alpine admixture—and it existed in Libya as long ago as the New Empire, as is shown by contemporary paintings in Egyptian tombs.

Cultural Characteristics of the Berbers.—On the psychical side some of the main Berber characteristics can perhaps be best appreciated by contrasting them with those of the Arab; moreover such a comparison is particularly useful since apart from the Nile Valley it in some sense embodies an epitome of the history for some 1,200 years of the whole of North Africa.

The Berber is essentially an agriculturist, with a passionate love of the soil upon which he has been born, though a keen trader, often willing to take service abroad but always anxious to return to his village in his old age or when he has amassed a competence. He is a stern fighter, often a determined brigand and in religious matters a born sceptic, while his strong democratic tendencies are indicated by his social organization in which leadership is usually a matter of election, though raiding and war may give real authority to individual strong men which may to a limited extent pass to their descendants. In contrast, the Arab is typically a nomad pastoralist, whose attitude to agriculture is mirrored in the proverb that shame enters with the plough, a poor worker, whose real courage is less likely to be shown when raiding than on a point

of honour or as an expression of his religious faith. Moreover, Arab society is essentially aristocratic; the Arab is, and always has been, ruled by hereditary leaders, and his struggles when he does revolt are spasmodic, and directed against the individual rather than the system. With this aristocratic and religious bias there exists a strong contempt not only for the stranger but for Muslims of other sects, and here again he stands in strong contrast to the Berber. These contrasts are of course not absolute; there are nomad Berbers, and many sedentary Arabs; some Berbers become really good Mohammedans, though generally there is much truth in the epigram that the Berber is not a Mohammedan but only thinks he is. Moreover, in the West, *i.e.*, in Algiers and Morocco, there is always the difficulty of knowing whether a given people not obviously Berber or Arab should be regarded as Arabized Berbers or Berberized Arabs. Here social organization and history rather than language seem to be the best guides.

Political and Social Organization of the Berbers.—In spite of the religious and cultural influence of Islam the social organization of the Berbers differs in every essential from that of the Arabs. The following outline (see MacIver and Wilkins, *Libyan Notes*, London, 1901), in principle valid throughout Barbary, applies specifically to the Kabyle Hills. The Berbers are typically hillmen, living in isolated villages, formerly often well fortified or with a central citadel, and, while possessing flocks and herds which in particular instances may regulate their mode of life, are essentially skilled agriculturists, who have long practised irrigation and are quick to take advantage of every scrap of cultivable ground in the difficult and often sterile hills among which they live.

The unit of government is the village, each possessing complete autonomy. A number of villages form the tribe, the connection being administrative and not regulated by kinship. A union of several such tribes may be termed a Confederation; the bond is looser than in the lower federative grade and the confederation never interferes in the affairs of its tribes unless directly appealed to or when vitally necessary. In time of war a head is appointed for each of the tribes and for the confederation. The tribe has deliberative and administrative duties, such as the determination of questions of peace and war, the making of roads, and manages tribal property such as mosques, tombs of saints, and educational establishments; it is concerned with the levying of taxes necessary for these purposes, and may act as arbiter between villages. A general assembly of the tribe is almost unknown, its affairs being managed by a deputation of the chief men from each of the villages composing it.

Every village is brought into contact with its neighbours by means of its *sof*, of which there are always two, the term signifying a group whose members covenant to render mutual aid to one another in cases of necessity. In each village the two *sof* are in some sense opposed, and each *sof* will be allied with similar fraternities in neighbouring villages, the ramifications of the *sof* organization extending through entire districts. Within the village the members of each *sof* are united by the closest bonds, the obligations ranking above all personal interests and even ties of kinship. Nevertheless, though loyal to his *sof* while he is a member of it, the Kabyle thinks little of transferring his allegiance from one *sof* to another if he thinks he will gain thereby, and outside the village the members of a *sof* though willing to assist their fellows with provisions and even with money would expect to be paid for any active armed assistance they might give. The funds of the *sof* are raised by subscription from members and are administered by the heads of the organization, usually men of powerful families and of private wealth, who may disburse considerable sums on secret services without rendering account to the members.

Within the village affairs are controlled by the *jemâa*, the general assembly of the citizens, of which every adult man is a member though in practice only the old men and heads of families exercise the right to speak. Nothing which concerns the welfare of the village escapes the control of the *jemâa*—it exercises judicial authority, makes laws, levies taxes and administers the public property. Decisions are not taken by a majority of votes

NATIVES OF WEST AFRICA

- 1. An inhabitant of Diola, in Senegal, with ornaments and jewellery
- 2. Natives of Mankena, in Senegal
- 3. Fulani woman from French West Africa, with headdress and earrings
- 4. A Moorish camp on the desert
- 5. Native fishing canoes on a river in West Africa
- 6. Tuareg warriors from the neighbourhood of Tirnabuktu
- 7. Native method of canoe-manufacture in West Africa. Pieces of wood are sewn together

but unanimity is required, and if the assembly fails to arrive at an agreement the discussion may be adjourned, or reference made to an arbiter chosen from among its members or from another village. The executive head of the Assembly is the Amin, sometimes called amekkeran (chief) or *amrân* (old man), usually a member of one of the leading families, a man of wealth and able to rely absolutely on the support of his *sof*. He is put forward by the influential persons of the village, the appointment being ratified by the Assembly. His duties include public finance, but except in small matters he has no independence or initiative and cannot act without the consent of the *jemâa*, over whose meetings he presides. He has assistants who are in some sense "police," supervising the various quarters of the village and giving information of all that passes.

Although emphasis must be laid on the agriculture and even the horticulture of the Berbers—the Shawia of the Aures Mountains and the Kabyles being regarded as typical—the Berbers are also pastoralists, and in the higher mountains the seasonal change of pasture-land (cf. French *transhumance*), plays an important part in their social life. Thus in the Middle Atlas, a tract of plateaux and peaks some 7,000 feet high merging in the west into the Tadla plain and in the south into the High Atlas, there is a heavy winter snowfall as low as 3,000 feet, which determines a transhumance of the winter type (as in Europe in the Carpathians and Balkans), the flocks being driven down to the lowlands. The familiar summer type of transhumance of the Mediterranean valleys also occurs in the Middle Atlas, the animals leaving the dried sun-parched valleys for mountains; indeed in the Middle Atlas some tribes—as the Beni Mguild—practise both forms, and such tribes when the winter movement leads them far into foreign territory do in fact approach a nomadic life. The so-called nomadism of the Berbers in Morocco should not, therefore, be classed with the wanderings of such true nomads as, e.g., the Berber-speaking Tuareg.

Arts and Crafts.—The Berbers are good craftsmen. The best Kabyle silver work is probably as good as any made by Africans, many of their tribes make excellent carpets, and in studying their decorative art it is possible to make the generalization that apart from Arab influence their limiting lines are straight, not circular or even arcs of circles. This is particularly obvious in their architecture, even when advanced, as in the minarets of their finest mosques, e.g., in Marrakesh, Rabat (and even in Seville) the mosque towers are square in section, or sometimes hexagonal, contrasting notably with the rounded minarets of Egypt and the Near East generally. So too the designs woven into their carpets by the more typically Berber peoples of Morocco is geometrical, often rectangular, and always made up of straight lines. Nevertheless, Arabic influence has brought in the arc and the cupola, the latter as common in the *Qubba* (saints' tombs) of the countryside as in Egypt.

The hand made pottery of the Berbers of Algeria, and especially of the Kabyles has excited much interest; it was even suggested that it betokened a direct and somewhat close relationship between the ancient inhabitants of Algeria and the proto-Egyptians (MacIver and Wilkins, *op. cit.*, give good coloured plates of Kabyle pottery; see also papers by MacIver and by J. L. Myres in J.R.A.I., vol. xxxii., 1902). It is now generally held that the red-faced pot fabrics of Kabylia descend directly from the widespread red-ware of the Neolithic period, so that their resemblance to certain types of pottery of pre-dynastic Egypt is secondary. As regards the characteristic geometric designs, usually black on white or yellow, of the area, these too descend from the endemic geometrical art of north Africa, though affected by Mediterranean influences, especially Aegean. Further, since the Punic settlers of the early Iron Age used the wheel, the survival of hand-made fabrics in the mountains is of interest as defining the rather limited quality of outside influences to which the mountaineers have been subjected.

Medicine and Surgery.—By far the greater part of medicine proper is little more than magic, but there is evidence that, in spite of the recognized danger of the necessarily large doses, henbane (*Hyoscyamus albus*) may be used before operations

for its sedative and alleged paralytic and anaesthetic qualities, while in surgery trepanning is successfully performed for fractured skulls. The dura mater is never incised—indeed every attempt is made to avoid touching it—and the danger of the brain bulging through the wound (*hernia cerebri*) is appreciated and special means taken to prevent it. As might be expected, dead bone is freely removed when necessary, but the repair of limbs does not stop here; bone grafting is practised, grafts taken from a dog being most approved, and the cases recorded seem to indicate that the operation may be successful. Other operations include the removal of pterygium from the eye, and, it is said, occasionally lithotomy.

Berber Folklore.—The folk beliefs and customs of the Berbers are particularly well known as the subject of the classical works of Douitté (*Magie & Religion dans l'Afrique du Nord*, Alger, 1908) and, especially, Westermarck (*Marriage Ceremonies in Morocco*, 1914, *Ritual & Belief in Morocco*, 2 vols., 1926). Among outstanding examples of the successful study of the magic and superstitions (in the sense of unorthodox beliefs) of a barbaric people, may be mentioned the ceremonial use during the *ashura* ceremony (*i.e.*, the festival held on the tenth day of Moharram, the first month of the Muslim year) of two figures, male and female, called by the names Yagkussa and Yazrka, who according to local popular belief were idols of olden days. These can be none other than the pre-Islamic gods Yaghzith and *Y'a'ûq* mentioned in the Koran (sura lxxi., v. 23). The extreme rarity of the persistence of the names of pre-Islamic deities makes this of particular interest, and suggests the early date at which Arab influence began to be felt.

Sudan.—The Anglo-Egyptian Sudan, including Darfur, incorporated in 1916, has an area of over a million square miles, measuring roughly 1,300 miles from north to south (lat. 22° N.

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS
MAT WEAVING, A COMMON INDUSTRY AMONG THE TRIBES OF SOUTHERN AND CENTRAL AFRICA

to lat. 4° N.) and a its greatest breadth over 1,000 miles from east to west (long. 21° 30' E. and long. 30° E.). It is divided into fifteen Provinces and one Military District, the latter the Sobat-Pibor between the Nile and the Abyssinian frontier. Although a number of these Provinces are well characterized units from the historical or geographical standpoint, they are not generally delimited on lines of ethnic significance, and no attempt to hold to them will be made in the following account.

The population of the Anglo-Egyptian Sudan may most conveniently be considered under two headings, Northern or Mohammedan, and Southern or Pagan. The former embraces the peoples of the dry regions of the north, Islamic in religion and culture, predominantly Arab in language, and at least in part Arab in origin. The Pagans include the great mass of the negro or negro-tribes of the south, though nowhere are the two zones clearly defined by any single degree of latitude.

Even the northern area has no ethnic unity: in the east the Red Sea and Kassala provinces are in the main Hamitic, and many of the riverain Arabs of the White and Blue Niles carry at least as much negro as Arab blood, both superimposed upon older Hamitic stocks which were predominant in the land before the

introduction of Islam. In the south, although the negro has given his name to the Sudan (*Bilad el-Sudan*, the Land of the Blacks of mediaeval Arab authors) and has excited the greatest interest from mediaeval times onwards, yet adequate knowledge is lacking of the habits, customs and religion of any one tribe.

The tribes of the Northern area belong to two great families, (a) Hamite, and (b) Arab. The Hamites proper include the group of tribes known historically as the Beja (*q.v.*) inhabiting the Red Sea Province and outside the Anglo-Egyptian Sudan extending into Eritrea. Less purely Hamitic, but none the less to be classed as Hamites, are the inhabitants of Nubia, commonly called Berberines or Barabra (*q.v.*), for, in spite of much negro blood and a language which is commonly regarded as negro, history indicates that fundamentally they are of Hamitic origin, while their civilization is not and seems never to have been negro in character. (See ARABS, BARABRA, BEJA.)

The true negro undoubtedly represents one of the most primitive of the African stocks. His main physical characteristics are tall stature, a "black" skin, woolly hair and moderate dolichocephaly, a flat broad nose and thick and often everted lips, prominent cheekbones and a varying degree of prognathism. With these qualities there go certain cultural characteristics. Such true negroes are found in the far western Sudan and the Guinea Coast, but hardly in the valleys of the Nile or of its affluents where as far as many of its most characteristic groups are concerned there is evidence of old Hamitic mixture. It is indeed scarcely possible to go further than this at the present time. In a classification proposed by Westermann, based on linguistic criteria, the term Nilotic is used in a sense so wide that it seems to signify no more than related to the Nile valley, but within it three groups are constituted, "High," "Middle" and "Low" Nilotic, which in part at least may be natural.

1. The High Nilotic group, comprising Mittu, Madi, Abukaya, Abaka, Luba, Wira, Lendu and Moru.

2. The Middle Nilotic group, comprising Shilluk, Anuak, Beir, Jur, Belanda and many of the peoples of Eastern Uganda, the Acholi, Lango (*q.v.*), Aturu and Jaluo.

3. The Low Nilotic group, comprising Dinka and Nuer.

This classification, though of wider geographical scope, embraces the whole of the Anglo-Egyptian Sudan, but the Bari with their numerous constituent "sub-tribes" are not mentioned, nor are the Lotuko-speaking tribes. Westermann places the former in his Nilotic-Hamitic group, *i.e.* with the Masai, Turkana, etc. to which the Lotuko-speaking tribes may also be assigned. For descriptive purposes, the following scheme is proposed:

A. Tall "black" dolichocephals, comprising Dinka, Shilluk, Nuer, Anuak, with perhaps some others as yet unclassified. These are the typical Nilotes of most writers, and in this article the term will be confined to this group. The mesaticephalic Acholi no doubt arose within this group, which probably also gave origin to the Belanda and the (Shilluk-speaking) Jur.

B. Tall "black" mesaticephals (probably sometimes brachycephals) comprising some Nuba and probably a number of the little-known tribes of Dar-Fung, including the Barun.

C. Medium statured "black" dolichocephals, comprising the Bari (but probably not the majority of the Bari-speaking tribes of the west bank), the Lotuko-speaking tribes and perhaps some of Westermann's High Nilotic group.

D. Short mesaticephals, with skin showing a coppery tinge—the Azande—or with blacker skins as the Bongo, Mittu and probably a number of the tribes now constituting the Azande nation. Knowledge of this group is very limited.

This classification by no means includes all the tribes of the Sudan. Many of the peoples of the Bahr-el-Ghazal Province are quite unknown ethnologically, *e.g.* the Moro, the Kaliko, the Bukuru (Babuckur) and the Liggi, and even the relations of such important Bari-speaking tribes of the west bank as the Mandari, Kuku, Kakuak, Nyangwara and Fajelu, are far from clear. Nor is there any substantial knowledge of the Madi, who in the south cross the political boundary into Uganda. In the east, on the borders of Uganda and Abyssinia, are groups of unknown tribes, some of which may constitute ethnic units, *e.g.* Didinga, Longarim,

Murle, with perhaps further north and nearer the Nile the Beir (Ajiba), all said by J. H. Driberg (unpublished information) to speak dialects of one language. The position of the Dongotono is obscure, while Driberg considers the Lorwama to be a section of Lotuko-speaking Lango. (C. G. S.)

EAST AFRICA

The geographical area which is included under this designation extends roughly from the north frontier of Kenya Colony as far south as the Zambezi, and includes Kenya Colony, the Uganda Protectorate, Tanganyika Territory, Nyasaland and Portuguese East Africa.

We cannot say for certain who were the original inhabitants of this vast territory, for as yet our archaeological data are too scanty, but a number of tribes preserve in their mythology and legends recollections of what may have been a bygone autochthonous race. Thus the Akikuyu tell of cannibal dwarfs known as Maitoachiana, and both the Nandi and Masai have traditions of fantastically shaped ogres with cannibalistic instincts. Probably the nomads, who still exist under a variety of names wherever the natural conditions permit, represent the earliest inhabitants of whom we can have any knowledge. In this area they occupy a subordinate, almost a servile position, live by trapping and hunting, or by collecting roots and berries, are often shy, elusive creatures of the forest, rarely seen, and at other times are engaged in what their neighbours consider the menial task of blacksmiths, and always dreaded for their knowledge of poisons and witchcraft. Excluding these nomads, the races of East Africa fall into the following groups: (1) Bantu; (2) Nilotic; (3) Nilo-Hamitic. The Bantu are subdivided into Lacustrians and eastern Bantu. The classification is really linguistic, but happens to be sufficiently valid in this case as a cultural criterion. Thus by Bantu are meant all those peoples of Africa who use the root *ntu* or some similar word to express human being. Ba- is the plural personal prefix of which mu- or omu- is the singular. Thus we speak of *Muganda*, a Ganda person and Baganda, Ganda people. As the prefix is really redundant we shall refer to the Bantu tribes without the prefix and speak of Ganda, Nyoro, Swahili and so on.

The history of East Africa is the history of the Hamites, for the various groups are differentiated by the degree and nature of their Hamitization. The Bantu-speaking peoples are an early mixture of negroes and Hamites, and a series of later waves from the north-east, culminating in the great upheaval of the 16th century, of which the Galla expansion under Mohammed Granye and his invasion of Abyssinia in 1537 was a symptom, profoundly affected East African cultural relations. The Lacustrians were further Hamitized and a Hamitic autocracy imposed itself on many of the conquered Bantu peoples to the north and west of Lake Victoria. The Nilotics or inhabitants of the Kile valley, a parallel fusion of negroes and Hamites, with possibly a Semitic element added as well, were dispossessed of their tribal territories in what is now the south-eastern Sudan and were dispersed by invaders from the east. The bulk of them moved northwards and became the modern Shilluk, Dinka and allied tribes, but a few followed natural lines southwards, and to-day are known as the Acholi, Lango, Alur, Jopalu and Jaluo. The invaders themselves were what are often known as "Half-Hamites," a rather meaningless term to which Nilo-Hamitic is preferable, as they are in fact increasingly Hamitized Nilotics. Southern Abyssinia and regions round Lake Rudolf have during the last 400 years witnessed a perpetual ebb and flow of immigrant peoples, more and more Hamitized, who were deflected by the Nile valley and moved southwards to populate the highlands of Kenya Colony and Tanganyika, until gradually the whole area from these highlands to the Horn of Africa was filled up with mainly pastoral peoples of Hamitic ancestry. This centrifugal movement southwards was

only checked by the intervention of western Powers in whose absence the process would undoubtedly have continued despite temporary checks such as the defeat of the Masai at the hands of the Bantu Hehe. This wedge of Nilo-Hamitics thrust southwards into Bantu areas appropriated the highlands to their pastoral requirements and separated the eastern Bantu from the Lacustrians. The eastern Bantu were agriculturalists and content with the lower highlands and the coastal regions, but under the stress of isolation came very much under the influence of their Hamitic neighbours, and though linguistically they remain Bantu they have assimilated many of the characteristic features of Hamitic culture.

The coastal belt and the adjacent islands, including Zanzibar and Pemba, are inhabited by the Swahili, whose language is morphologically Bantu and who are therefore generally classed as such. Culturally, however, they are not homogeneous and have few Bantu affinities. Since Abdul Malik bin Muriani brought his Syrian builders in A.D. 659 to found his African kingdom, a succession of colonizing waves from Persia and from the Oman established a Mohammedan empire over the whole coastal region from the Lamu archipelago to the Zambezi. These immigrants brought their own culture, interbred with and assimilated the local Bantu at each of their administrative and trading centres. Thus was gradually formed the Swahili language, largely Arabic in origin, though structurally Bantu; and this was the genesis of what are now known as the Swahili people, or more properly the Swahili-speaking peoples, a heterogeneous conglomerate of localized dialects and customs, based on the original Bantu tribes who both assimilated the alien Mohammedan culture and incorporated in it no inconsiderable portion of their own. There were early Chinese voyages to the east coast of Africa, relics of which in pottery and coins, have survived on the coast from Lamu southwards. The Mongoloid eye found sporadically throughout this area, may also be a survival of Chinese infiltration, though other explanations are possible.

The Lacustrian and eastern Bantu meet in Tanganyika Territory and gradually the typical Bantu characteristics reassert themselves, though now we find a social organization with a more pronounced military bias than we encounter farther north. Typical of such tribal polities are the Hehe of Tanganyika Territory and the Yao of Nyasaland, whose organization, though much the same as that of their neighbours the Anyanja, is more closely knit and adapted to the exigencies of war. This may in part be due to the influence of the Angoni, an offshoot of the Zulu who fought their way north and penetrated as far as the southern shores of Lake Victoria. They were finally conquered by the Nyamwezi, a tribe also Zuluized and organized for military purposes, and were permitted to settle in their present homes. The Simba appeared on the lower Zambezi in 1540 and triumphing over the Portuguese and their African allies pushed north-east and succeeded in capturing Mombasa, before they were finally defeated and apparently annihilated near Malindi. The whole of this southern area has for centuries been the battle-ground of warring tribes, marching and counter-marching in almost inextricable confusion, achieving an evanescent eminence and as rapidly fading to comparative insignificance. Consequently there are fewer individual characteristics, the distinctions are less clearly cut, and their affinities are southern and western rather than northern. They belong to the southern Bantu more than to the Lacustrians despite the common characteristics which are part of the Bantu inheritance as a whole. The Thonga of Portuguese East Africa, for instance, very definitely merge into the southern complex and in Nyasaland the Anyanja extend into Rhodesia and come into contact with distinct Zambezi affinities.

In an area so complex and so full of cultural conflict it would be difficult to summarize the salient characteristics both briefly and adequately. Overlapping between the different groups is inevitable owing to the diffusion of cultural elements from one to the other and emphasizes the impossibility of a rigid classification. A fair picture, however, may be obtained of tribal cultures (social organization, mode of life and religious beliefs) by a concise examination of representative tribes in each group, with allowance for individual variation from the norm. The nomads require

separate mention, and the Ganda and Ankole represent the Lacustrians. The Nyika group represent the eastern Bantu. The Hehe and Angoni represent the fusion of the Lacustrians and the eastern Bantu with their southern influences. Lango represent the Nilotics and Masai the Nilo-Hamitics.

WEST AFRICA

West Africa was inhabited in prehistoric times, ancient stone implements being found in Senegal, the Sudan, French Guinea, the Ivory Coast, Gold Coast and Nigeria, and sites are frequently found in the Sahara in regions now barren, but which no doubt anciently enjoyed different climatic conditions. North Africa was probably peopled by men of Mediterranean race, then by Eastern Hamitic people (dark-skinned, fine features, soft hair), the modern Berber resulting from their admixture. Later came the Jews and Arabs. The Pygmies or Negrilloes, were pushed back by negroes from Central Africa, and were established in the area lying between the Sahara and the Gulf of Guinea and between the Atlantic and Lake Chad. Negrilloes and negroes at first interbred among themselves, then mixed with Berbers and peoples of Hamitic and Semitic stock, thus giving rise to higher grade peoples such as the Bornuan, Kanuri, Hausa, Mandingo, Yoruba and Ashanti.

Principal Ethnic Groups.—The following provisory classification rests on physical, cultural and institutional data:

- I. White race: Berbers, Fulani
- II. Black race: a) Senegalese-Guinea family
- b) Nigerian Senegalese "
- c) Volta "
- d) Guinea "
- e) Lower Nigerian "
- f) Hausa "

Social Organization: General.—The social unit is the family in the strict sense, and more often the extended family, a group occupying the same enclosure whose members are divided into classes consisting of parallel generations having equal rights, with labour and ownership in common. Several related family groups form a village quarter. The distinct and organized clan is rare; more easily distinguished is the identity of the tribe and sub-tribe. Matriarchy is rare. Marriage is seldom exogamous, nearly always patrilocal; the children are attributed to the father, and descent is usually traced in the paternal line. Family authority devolves upon the father or the patriarch assisted by elders. Common ownership of family goods, with individual ownership of personal property, is almost universal. Women are usually at liberty to dispose of their own property. Succession to the family possessions, of which women form part, is vested sometimes in the brother and sometimes in the son of the deceased. On the Ivory Coast, in the Upper Volta and Nigeria, a husband allows his wife to cohabit with another man, the children belonging to him. Marriage between brothers-in-law and sisters-in-law is frequent. Personal possessions are heritable in the same way as family goods, but frequently men succeed to a man's goods and women to a woman's.

Government.—Many bush peoples (Liberia, Ivory Coast, Southern Nigeria) and peoples of the French Sudanese region (Gourounsi, Bobo, Lobi, Bariba) live in small independent groups. Elsewhere kingdoms have been constituted, very often theocratic in character and ruled over by a priest-king or by a king and a priest reigning together (Nigeria, Dahomey, French Sudan, Upper Volta) and uniting the civil and magico-religious power. Ministers and councillors assist the sovereign. The Queen-Mother (Gold Coast, Nigeria) possesses authority. The heir to the throne is often chosen, by an electoral group, from certain families according to local hereditary laws.

Religion. — Islam spread, in particular, over Mauritania, Senegal, the Guineas, the Niger valley, the Hausa country, Bornu and Nigeria; elsewhere, there is general belief in a supreme deity, in a sky and an earth god, and in inferior gods. Respect is paid to ancestors. Gods and ancestors share in the life of the social group. Various methods of divination are in vogue to ascertain their will. Infraction of certain sacred inhibitions (murder, the shedding of blood) are displeasing to the gods and are regarded as sins and require compensation and expiation. Family and clan cults are found, more rarely tribal cults. Sacrifices, frequently of a seasonal character (altars, trees, stones, hills, streams), insure fertility and fecundity, there being a close association between magic and religion. The head of the family is the domestic priest, and the descendant of the first occupant of the country is the priest of the earth. Sacerdotal colleges, male and female, are frequent (Dahomey, Ashanti, Yoruba). Traces of totemism are found in French Sudan, Ashanti, Dahomey, Nigeria. Numerous tribal, clan, family, individual, occasional and professional tabus, probably of totemic origin, are recorded.

Belief in witchcraft is general, the sorcerers being supposed to be able to change themselves into animals, injuries to the animal inflicted during the metamorphosis appearing on the sorcerer's body. There are special laws and punishments for sorcery.

Initiation of members of the social group is by successive degrees in secret ceremonies to adolescents, adults and men of full experience. They seclude the grades in the forest or in sacred groves. The neophyte is considered to have died and to have been reborn with a new personality, and receives instruction (moral, religious, technical, aesthetic). His position in the group depends on initiation. There are similar but less complicated ceremonies for women.

In Nigeria the king was frequently slain after he had reigned for a certain period, or when he grew old (Yoruba, Jukun, Hausa); the same custom appears to have existed in the French Sudan (Mandingo, Dogon).

Cannibalism and head-hunting have almost disappeared, but existed on the Ivory Coast, in Liberia, Dahomey and Nigeria. In former times human sacrifices were followed almost everywhere by a feast at which the victim was eaten. (H. LAB.)

SOUTH AFRICA

The natives of Africa south of the Kunene, Okavango and Zambezi rivers fall into three main divisions, known respectively as Bushmen, Hottentots and Bantu. These divisions represent a series of successive waves of southerly migration by which the peopling of the country has been effected. The Bushmen, a race of short yellowish-brown nomad hunters, are the earliest human inhabitants of South Africa of whom there is any reliable historical record. Recent archaeological research, however, has established clearly that they were not the first to occupy the country, but are an invading people who superseded the original inhabitants of this part of South Africa. From the evidence afforded by their cultural remains it seems likely that at a very early time they occupied the hunting grounds of tropical East Africa and gradually passed southwards until, when the written history of the country begins, they were roaming all over the territory south of the Zambezi river.

By this time they were already being encroached upon by the Hottentots, who resemble them greatly in racial characters and in language, but are a pastoral people with a more complex material culture and social organization. The Hottentots seem to have sprung out of a mixture of the old Bushman population of East Africa with an early migration of Hamites from whom they obtained their cattle and certain elements of their language. They migrated south later than the Bushmen, and after crossing the upper waters of the Zambezi passed on to the west coast and down to the south coast, where they were found by the first Europeans to touch at the Cape.

The Bantu peoples are the latest of the native inhabitants to have entered South Africa. They all speak languages belonging to the characteristic Bantu language family of Africa (see AFRICAN LANGUAGES), but in racial characters they vary considerably,

though certain negro characteristics predominate. They seem to have originated as a distinct variety somewhere in the neighbourhood of the Great Lakes and to have migrated South at various times between about the 12th and 15th centuries, each of their main groups (see below, Principal Groups) representing a different series of tribal movements.

The impacts upon one another of all these different peoples, and the later advance inland from the Cape of the European settlers, resulted in a complicated series of wars, migrations and exterminations, in which the Bushmen and the Hottentots were almost completely broken up, while the original distribution and condition of the Bantu were profoundly disturbed (see SOUTH AFRICA, History).

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

A HAUSA HEADMAN

More Arab than negro, the Hausa peoples are intelligent, well developed physically and good traders

Principal Groups. — At the present time the Bushmen are confined to the Central and Northern Kalahari and neighbouring regions. They are there found chiefly in the southern portion, each speaking its own language (see BUSHMAN LANGUAGES), but as a result of intermixture with the neighbouring Bantu peoples they have to a great extent lost their purity of race. The Hottentots were formerly divided into four main sections—the Nama, Korana, Gonaqua and old Cape Hottentots—but of these the only relatively compact group to-day are the Nama, who are found chiefly in the southern half of South-west Africa. The others have either died out or completely lost their racial entity. The Bantu peoples, on the other hand, are still vigorous and powerful, and are increasing in numbers. They are divided into numerous small tribes which on the basis of cultural and linguistic differences, may be classified into the following groups:—

(a) Eastern, or Zulu-Xosa, which occupies the coastal region East of the Drakenberg mountains and South of the Sabi river. This group includes the so-called "Kafirs" of the Transkei (*i.e.*, the AmaXosa, AmaMpondo, AmaMpondomisi, and AmaTembu), the "Fingoes" of the Cape Province, who are the fugitive remnants of tribes broken up in Natal during the great intertribal wars at the beginning of last century, the Zulu peoples of Natal and Zululand, with their offshoot the Matabele (AmaNdebele) of Southern Rhodesia, the AmaSwazi of Swaziland, and the BaThonga (AmaTonga) and kindred tribes of Portuguese East Africa.

(b) Central, or Sotho-Chwana. This group occupies the greater portion of the interior plain North of the Orange river, and includes among many others the BaTauana about the Botletle river and Lake Ngami, the BaMangwato of North Bechuanaland, the degraded BaKalahari of the Kalahari desert, the BaKuenta, BaNgwaketse, BaRolong and BaTlaping of Central Bechuanaland, the BaHurutse, BaPedi, BaKgatlha and kindred tribes of West and Central Transvaal, the BaVenda of the North East Transvaal and the celebrated Basuto of Basutoland.

(c) The so-called "Mashona" peoples of South Rhodesia, including the BaNyai or BaRoswi and the AbeNanswa immediately South of the Zambezi river, the MaKaranga (MaKalanga), WaManyika and BaZezuru of Mashonaland and the VaNdau of Portuguese East Africa.

(d) South-western, comprising the OvaHerero and the OvaMbo peoples of South West Africa. They are each divided into various tribes which between them occupy the northern half of the region between the Western fringe of the Kalahari desert and the Atlantic ocean.

Another distinct, though less important, division of the natives of South Africa is constituted by the Bergdama (Haukhoin), who inhabit the coastal region of South West Africa. Their racial history is still far from clear. Physically they are a true negro people, yet they are isolated far from others of their kind; they

live an extremely primitive life, and speak the language of the Naman, to whom they have long been in subjection.

Social Organization.—Both the Bergdama and the Bushmen have very simple forms of social structure. Among the Bergdama the social units are small, independent local groups, each consisting of a patriarchal family, together with any relatives who may put themselves under the protection of its head, and sometimes including a certain number of dependent families who do not feel capable of founding a settlement of their own. The Bushmen are divided into small hunting bands, each of which owns a definite hunting territory over which it wanders and out of which it may not venture except with the permission of the neighbouring group. Within this territory members of the band are free to go where they like. The organization of the band is of the loosest kind. There is no chief, but skilled hunters and the older, more experienced, men in general have a great influence in directing social affairs. The only other structure of any importance is the family, consisting of a man and his wife, or wives, with their dependent children. Marriage within the band appears to be forbidden. A wife generally joins her husband's people, although in some of the northern tribes the young couple remain with the wife's parents until after the birth of the first child.

Of the Hottentots the only section whose social organization has been studied are the Nama, comprising several tribes, each of which has its own territory, name and chief. The tribe, however, is not a centralized body, but is made up of a rather loose aggregation of clans with the chieftainship hereditary in one of them. The authority of the chief is slight. The heads of the other clans act as his council, and he cannot do much without their co-operation. Each clan consists of a number of families claiming descent from some remote ancestor in the male line after whom they are named, and marriage within the clan is strictly forbidden. Polygamy was formerly practised, but monogamy is now the rule.

Among the Bantu peoples considerable variation exists in details of social organization, but certain general features prevail. Each tribe occupies its own territory under its own chief. His authority is generally considerable, but his actual power is somewhat modified by a council consisting of some of his relatives and the more influential heads of families. The family or household group is always of great social importance. It is normally polygamous, and generally forms a distinct local unit, except among the central tribes, where there is a tendency for different household groups to collect together in villages. Even here, however, each household is distinctly marked off from the rest. Within the household each wife has her own hut; and with her children constitutes an economic unit with well defined legal rights. Marriage is patrilocal, and is legalized by the payment of a bride-price (*lobola*), generally in the form of cattle. There exists also an organization of the people into clans, which, except in the eastern group, are associated with totemism. Clan exogamy is customary, but does not obtain among the Sotho-Chwana tribes. Membership of the clan is determined by descent through the father, except among the OvaMbo, who are matrilineal people, while the OvaHerero have a double system of clans, one set with patrilineal descent, the other with matrilineal (*see later, General Features of Note*).

Mode of Life.—Levels of culture differ considerably. All the Bushmen in their original condition are hunters and collectors. They practise neither agriculture nor pastoralism, but derive their subsistence entirely from the game they hunt and from the wild vegetable foods which the women collect. Their chief hunting weapons are the bow and small arrows with detachable poisoned points, but they also make use of throwing-sticks, pitfalls, traps and snares of all kinds, while the women have pointed digging-sticks, which are sometimes weighted with perforated stones. They are a nomadic people, confined in the dry season to places well supplied with water-holes, but, when the rainy season comes, wandering about freely within the limits of their hunting territory. Their encampments are temporary, and their dwellings crude shelters of rush or reed. The Bergdama on the whole lead a similar mode of life, although many of them also keep goats.

The Hottentots are chiefly a pastoral people, with herds of long-horned cattle and flocks of fat-tailed sheep. Sour milk forms

a staple element of their diet; and in contrast to all the Bantu except the OvaHerero, it is not the Hottentot men, but the women, who do the milking. Hunting also plays an important part in their economic life, their methods of hunting and their weapons being practically identical with those of the Bushmen. To some extent they are also nomadic, as fresh pastures for their herds are necessary from time to time. Their encampments, however, are less impermanent than those of the Bushmen. They live in beehive huts, covered with reed mats, and their settlements are arranged in circular form, leaving in the centre an open space in which the cattle are collected at night. Their material culture is on the whole superior to that of the Bushmen; in particular they smelt iron for the manufacture of their implements and weapons, while the Bushmen barter with the neighbouring Bantu peoples for whatever iron they require.

With the exception of the OvaHerero who are a purely pastoral people, all the Bantu tribes practise both hoe-culture and pastoralism. The eastern tribes are more predominantly pastoral, the others more agricultural, but all have this combined means of subsistence. Each household group has its own cattle and goats, as well as its own fields. The cattle are the concern of the men (except among the OvaHerero, where the women do the milking), the fields that of the women. The food supply is derived mainly from sour milk and from crops of millet and maize, supplemented in minor forms by pumpkins, peas, beans, etc., while for meat they rely chiefly upon the game hunted by the men. Cattle are never slaughtered for food except on ceremonial occasions. The life of the people is more or less sedentary. The eastern and south-western tribes live in beehive huts of thatch, the central and Mashona tribes in circular huts with conical roofs. The settlement is always arranged on the circular principle already noted among the Hottentots. All the industries are essentially domestic, practically everything required by the household being made within it. The one exception is in the case of iron implements and weapons, for which there are special workers, who barter their products for cattle and grain.

Religion, Special Features.—In religious beliefs there are certain fundamental features which appear to be common to both the Bushmen and the Hottentots, but there is also considerable variation in several important details. All Bushmen pray to the moon and other celestial bodies, and have an extensive series of myths and legends relating to them. They believe also in certain mythical beings, known variously to different tribes as Cagn (the mantis), Huwu, Tora, Gauna, etc., who appear to be personifications of natural forces, especially those producing the rain, and are frequently invoked. These mythical beings are credited with creative powers, and are met with in various myths of origin. From references in their myths and folk-tales it appears that the Bushmen have further a well developed system of ritual relating to animals and other sources of food, but it is not known in any detail what that ritual is or was. There seem also to be certain beliefs and practices connected with the spirits of the dead, but concerning these the information available is vague.

The religious cult of the Hottentots seems in general to consist mainly in the worship of mythical heroes derived partly from animistic beliefs and partly from the personification of the natural forces producing rain. In their general attributes these beings, chief of whom are Tsui-goab, Heitsi-Eibib and Gaunab, strongly resemble those of the Bushmen. The worship of the moon also seems to have been prevalent among the Hottentots at one time, judging from the records of prayers made to it for food and rain. There is further an extensive ritual relating to the cattle, which, as the chief source of food, are of paramount importance to the well-being of the community; while water, another extremely important factor in the economic life of the Hottentots, also plays a part in numerous ceremonial performances and taboos. One of the chief functions of the medicine-men, as among the Bushmen, is always the making of rain.

Among the Bantu, the religious cult is very largely a strongly developed form of ancestor worship. This is primarily a domestic cult, each family through its eldest male representative worshipping its ancestors in the male line. On important tribal occasions

the chief also prays to his ancestors on behalf of the tribe as a whole. The ancestors are regarded as guiding the destiny of their living descendants, and are propitiated by means of sacrifices offered on ceremonial festivals such as birth and marriage and on other special occasions. All the Bantu have also some conception, often rather vague, of a power in the universe which is not connected with the ancestors. This power is often associated with the sky, but shows itself most impressively in the phenomena of the weather, and hence rain, lightning and thunder are considered its manifestations. It is also sometimes looked upon as the creator of all things and the moulder of destiny. It is met with under various names (such as Tilo among the BaThonga, Unkulunkulu and Inkosi among the Zulu, Modimo in the central tribes and Nzame among the OvaMbo), and the beliefs and customs relating to it differ considerably from tribe to tribe. There is further an extensive ritual relating to agricultural life and to the cattle (the OvaHerero have a sacred herd of cattle), while traces of a totemic cult are found in all the tribes except the eastern. Magic and witchcraft play an extremely important part in the lives of the people, and in connection with this shamanism has developed to a high degree, so that there are many different kinds of medicine men with special functions, such as rain-making, divining, "doctoring" the crops, purifying the army, healing disease, etc.

General Features of Note.—In physical appearance there are many features which readily distinguish the Bushmen from all other inhabitants of South Africa, save the Hottentots. They are typically short in stature, but not dwarfish. Their limbs are slight and finely shaped, the hands and feet being especially small; but there is a curious curvature of the spine which gives a great prominence to the buttocks, where also a great accumulation of fat (steatopygia) sometimes occurs in the women. The skin is yellowish-brown in colour, and wrinkles very easily. The hair is woolly and sparse, commonly very short, and is scattered on the head in little tufts, or "peppercorn" fashion. The head is small and markedly low in the crown, the face broad, with prominent cheek bones, bulging forehead and convex upper lip, the nose extremely flat, the eyes narrow and often slightly oblique; frequently there is no lobe to the ear. In the more northern and eastern tribes there is a distinct tendency towards greater stature, darker colour and better muscular development, while the head and face are longer and higher. These divergent characters are the result of intermixture with the neighbouring Bantu peoples.

The culture of the Bushmen is noted for the highly artistic paintings and engravings which they executed on the walls of caves and rock-shelters. The subjects portrayed are chiefly animals, human beings, hunting, battle and dancing scenes, and the representations are remarkable for their fidelity to nature. The practice of the art seems to have died out, but it proves a most important link in the chain of evidence connecting the Bushmen of South Africa with the Palaeolithic cultures of the peoples of Europe.

Of the social customs of the Bushmen, especially those connected with birth and marriage, little is known. Initiation ceremonies at puberty are common to all Bushmen. On reaching her first menstrual period a girl is secluded in her hut and has to observe various food taboos. In the northern tribes a special religious dance, known as the "eland bull" dance, is added in her honour. Initiation ceremonies for boys seem to be restricted to the northern tribes. The special tribal marks are cut by the medicine men between the eyebrows of the boys, who are then kept in a secluded spot for about a month. During this time they are instructed in the lore of the tribe, and religious dances are held in which animal masquerades predominate. The Tati Bushmen practise circumcision as part of the initiation ceremony, but they are the only Bushmen of whom this is known, and have probably adopted the custom from the Bechuana among whom they live. At death the corpse is usually buried lying on one side with the knees drawn up against the breast. The group then removes to another site.

The Hottentots resemble the Bushmen closely in appearance, and it is only in certain characters that there are any noticeable differences. They are taller than the Bushmen, and have dis-

tinctly longer and narrower heads. Their skull is also higher and the face more prognathous. They have, however, the same prominent cheek bones, small chin, flat nose and peculiar eyes as the Bushmen, while their ears are often also lobeless. Their hair and their skin colour are the same as in the Bushmen, and steatopygia is often more marked.

An important feature in their culture is the great prominence of the communal meal in their ceremonies. It is a means of curing a sick person by aggregating him to the group of those who have had the disease and recovered; of introducing young men and women to the life of full members of the tribe; of bestowing on a young mother the solidarity of the group of mothers with strong and healthy children; of welcoming a widow, or widower, into the group of the widowed, and so giving them a new place in the society as a whole. The part water has come to have in their ceremonial life because of its extreme value in their economic life is also noteworthy. In addition to there being a great annual rain-making ceremony, water plays an essential part in many religious ceremonies, is endowed with a special protective power in some cases, and is considered extremely dangerous in others. Rain, as the source of water, is also held sacred, and the natural forces producing it are even personified and worshipped.

The Bergdama are of considerable interest, as they appear to be the most primitive negro people known, apart from the Congo pygmies. They are of medium height, strong, even coarse, build, with long rather thick skulls, prognathous faces, broad noses, very dark, even black skin, and all the features typical of the true West African negro. What their original language was is not known, for they have been so long enslaved by the Hottentots that they have completely adopted the Hottentot language. Yet in ceremonial their lives appear to have been but little influenced by the Hottentots, and among them there is found what appears to be a very important feature of many Bantu cultures, the sacred fire round which the whole life of the society centres. Each little group has a sacred fire which must never be allowed to go out, but which must be guarded day and night by the chief wife of the patriarch. Day by day, when the members of the group go out to seek for food, the head of the group and the old men sit guarding the fire, and as long as that is aglow and respected by all, the hunters and collectors will find food for the day. All game must be laid by the sacred fire, and certain portions of it must be eaten ceremonially by the elders of the group. Each kind of berry and root, as it ripens, must be brought to the sacred fire before it can be eaten. All good, all evil hangs upon the guarding of the fire from all impurities, which come from breaches in the regulations as laid down in the traditions of the tribe.

Racially the Bantu peoples present a great variety of types. They are fundamentally negro peoples, mixed with Hamitic, negrito and other types. The skin is usually less dark, stature lower, head less elongated, forehead flatter, prognathism less marked, nose generally more prominent and narrower than in the true negro. The Hamitic strain often shows itself clearly among the Zulu and allied tribes in a relatively narrow nose. The hair is uniformly of the ordinary negro type, the skin all shades from yellowish-brown to the black of the AmaSwazi, usually a reddish ground tint, dark chocolate colour being the prevalent hue. The Eastern tribes are on the whole taller and more dolichocephalic than the Central, while the South-western tribes are more typically negro than the rest.

The political organization of these peoples is well developed, and they have an elaborate system of laws regulating their social life. Among the OvaMbo blood revenge is still practised, but among the Central and Eastern tribes the tribal authority is supreme. All members of the tribe are regarded as belonging to the chief; an injury to them is, therefore, an injury to him, and compensation for death or injury must be paid to him. The AmaZulu and AmaXosa are renowned as fighting tribes, none of the rest being specially war-like; and among the former a strict disciplinary system was established by the great chief Chaka, who abolished the throwing spear, which is the typical weapon of this area, and introduced the short stabbing spear. By this reform he forced upon his warriors the necessity of coming to close quarters,

and from that time the Zulu became a dominant people and were able to found and develop a great military kingdom in South East Africa.

The initiation ceremonies at puberty of the Eastern and Central tribes are of some importance. The boys are initiated in groups, which are kept secluded in a special "lodge" for about three months, during which they are taught their tribal history, the moral and religious code of the society and its social etiquette. The ceremony itself consists in circumcision, performed by a special medicine man. These initiation "schools" are held every year in some tribes, in others at intervals of from four to five years. In each case the group of initiates is usually given a special name by which it is known throughout life. These groups play an important part in the tribal organization, and form the nucleus of the military system. The Zulu do not have initiation schools, nor do they practise circumcision, but the system of initiation groups has persisted in the formation at regular intervals of military regiments comprising boys of about the same age. Girls are also initiated in groups at the time of puberty, and are not considered marriageable till they have passed through the ceremony.

The Central tribes have remains of a tribal totemism. Each independent section of the people, which may at one time have represented a clan, has a *siboko* or laudatory name, taken from some animal or some natural phenomenon. In former times there was a definite ritual connected with the species of animal so used. Nowadays, however, the main division of the people is into patrilineal clans, and the possession of a common *siboko* is no bar to marriage. In the Eastern tribes all traces of totemism, if it was ever present, have disappeared. They are all divided into clans each with its own *isibongo* (laudatory name) which is generally the name of the ancestor from whom the clan is thought to have sprung. Marriage between people with the same *isibongo* is not permitted. Very often, however, a clan will split up, a younger branch taking some more immediate ancestor as its *isibongo*, while the older branch preserves the more ancient *isibongo*, and inter-marriage between the two branches is then permissible.

The OvaHerero clan system is a combination of the patrilineal and matrilineal systems. The people are divided in the first place into clans with matrilineal descent, called *eanda*, and then into clans with patrilineal descent, called *oruzo*. Every person belongs to the *eanda* of his mother, and the *oruzo* of his father. Both the *eanda* and the *oruzo* are totemic and exogamous. Each of these clan divisions has a different function. The *eanda* is associated with economic relationships, so that inheritance is in the female line. The religious life, on the other hand, is almost entirely connected with the *oruzo*, and is a developed form of ancestor worship, so that a man prays always to the ancestors of his father. Here again, the sacred fire is very prominent. At the chief's village the ancestors of the chief are worshipped, and represent the ancestors of the whole tribe. In addition the sacred fire is found in the kraal of each head of a family, lighted, in the first instance, from that of the chief. None of these fires must ever be allowed to go out. To this fire the women bring the milk each night and morning to have it blessed by the kraal head and the ancestors.

ARCHAEOLOGY AND ANTIQUITIES

The boundary between Negro Africa and "White" Africa, *i.e.*, Egypt and the northern and north-western portions of the continent, must be both conventional and provisional. The explorations of Reisner at Kerma in Nubia (between the third and fourth cataracts) and of Garstang at Meroe, have carried Egyptian influence so far south in the Nile valley that these sites, although inhabited by peoples of mixed culture, must from the archaeological standpoint be referred rather to Egypt than to the Sudan.

No such line of division exists in the west between the North African cultures and those of negro-land; indeed Gautier ("Études d'ethnographie saharienne," *L'Anthropologie*, 1907) has shown that there is good reason to suppose that the latter has advanced perhaps as much as 1,000 km. at the expense of the former, during the last 2,000 or 3,000 years. Moreover, Meroe itself does not accurately represent the southern limits of the mixed civilization to which it has given its name; some 12 m. south of Khartoum on the right bank of the Blue Nile are the remains of Soba, a Meroitic site, later the capital of the Christian kingdom of 'Alwa (the Alut of the hieroglyphs), while Meroitic remains have been recently discovered 200 m. south of Khartoum.

Yet Meroe, which lies in the neighbourhood of the 17th parallel of north latitude, may well stand as the main southern bastion of Egyptian influence, and the area with which this article will deal is that part of Africa lying south of 16° north, which will be divided into three provinces, eastern, western and southern.

The Nile-Congo watershed, a natural feature of geographical and ethnic importance, constitutes part of the dividing line between the eastern and western areas, which continues northwards along the broad ridge of relatively high land that roughly divides the territories of the Anglo-Egyptian Sudan from those administered by France. Thus the boundary line somewhat closely follows the western confines of Darfur, while south of the Nile-Congo watershed it coincides with the boundary between the Belgian Congo and British territories to the east, both eastern and western provinces being limited to the south by a line roughly following the 10th parallel of south latitude.

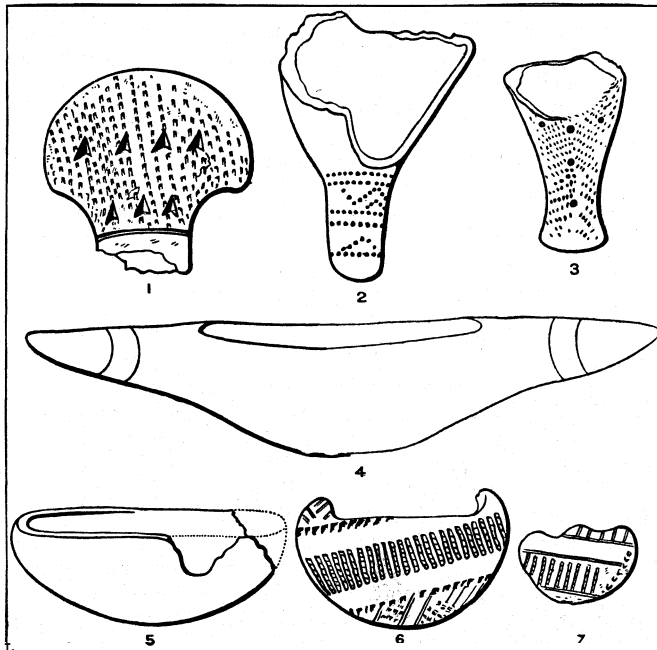

THE EASTERN PROVINCE

Palaeolithic Artifacts.—Here discoveries have so far been limited to the Sudan, Uganda, Somaliland and Kenya Colony, while surprisingly little is yet known of the early pre-history of even these territories. Except possibly in the extreme north, within a few miles of Halfa, no implement of River-drift type is known to have been found in the Sudan. This fact may be due to incomplete exploration, but is of some significance considering the abundance of specimens which have been found on the surface in Egypt and Libya, in Soinaliland (where H. W. Seton-Karr has collected countless specimens of River-drift and Mousterian types), South Africa, and recently, in deposits, by Wayland in Uganda, though the majority of the implements he discovered are perhaps to be associated with the Le Moustier *facies* rather than that of the River-drift. Be this as it may, Wayland has collected Chellean hand-axes in gravels, considered of Pleistocene date, capping quartzite hill-tops some 300 ft. above the present level of the lake, and also implements of a well-developed Mousterian type, including "points, side-scrapers, flake knives, tortoise cores and tortoise points," as well as two typical side-scrapers in a cave under some five feet of cave earth. (A. A. Smith and E. J. Wayland, *Some Primitive Stone Implements from Uganda*; Uganda Protectorate, Geological Survey Dept., 1923.)

No typical Mousterian specimens have yet been found in the Sudan, but certain specimens collected from two sites, namely, Jebel Katul in north-west Kordofan, and Jebel Gule in Dar Fung, are considered by the Abbé Breuil to belong to the Mousterian period. So far as is known no implements attributable to the latter part of the Palaeolithic age have been found anywhere in the Eastern Province, certain pygmy implements which will be mentioned later being regarded as Neolithic. (C. G. Seligman, "A Neolithic Site in the Anglo-Egyptian Sudan," *J.R.A.I.*, vol. 40, 1910.)

Neolithic Age.—Evidence concerning the Neolithic age is furnished by a number of finds made on widely scattered sites in the Sudan, Uganda and Kenya Colony, and there are hints that in parts of Negro Africa, which nowhere had a Copper or Bronze age, stone implements may have persisted to within the last few centuries and the use of iron be quite recent. The distribution of the most typical of Neolithic implements, the ground stone axe, makes it necessary to refer to the conditions prevailing north of latitude 16 degrees. Unknown in pre-dynastic Egypt polished axe heads are common in Nubia, where a number have been found in pre-dynastic and early dynastic tombs. Many examples have come from Meroe, and specimens probably occur on every site of Neolithic date in the Sudan; they have been found, *e.g.*, at Jebel Geili, 90m. east of Khartum, at Jebel Gule, and at Faragab in northern Kordofan; moreover, the grooves in the rock faces on which they were ground exist both at Jebel Gule and Jebel Geili, while stone axes of a peculiar type have been found in western Darfur by D. Newbold. These facts all support the idea put forward (Rep. Brit. Assn., Pres. Address, Section H, 1915) that the ground stone axes of the Nile valley are of negro origin, a view consistent with their occurrence in the Congo, and, in relatively enormous numbers, in the Gold Coast. Perforated discs or rings, and hollow conical and spherical stones, all ground in the usual Neolithic style, have been found at Meroe, on Jebel Haraza (Kordofan) and at Jebel Geili, where stone discs and axe heads can be definitely associated together and with Meroitic potsherds.

Besides the types already alluded to, Jebel Gule yielded a large number of pygmy implements of quartz, carnelian and hornstone (similar to those found in South Africa and attributed to Bushmen), and there is reason to believe that this industry also existed at Faragab, where these "points" were used to bore the innumerable disc heads of ostrich egg-shell which cover the ground. The British Museum has a number of beautifully worked *dos abattu*

POTTERY FROM THE MOUNDS AT FARAGAB KORDOFAN

Figures 1, 2 and 3 are fragments of vessels; figure 4 is a reconstructed vessel of a type hitherto unknown in Africa; figure 5 is a bowl; figures 6 and 7, objects of unknown use

specimens of obsidian from the neighbourhood of Njoro in Kenya Colony; typical lunates, of jasper and of carnelian respectively, have been found in Uganda (Wayland), while to pass northwards of latitude 16°, G. A. Reisner (Sudan Notes and Records, vol. 2, No. 4, 1919) has found in tombs dating to the Egyptian 25th dynasty in Upper Nubia, perfect lunates of carnelian, in such numbers that there can be no question of their inclusion in the tombs being accidental.

This may close the account of stone implements which may be assigned to the Stone age cultures, so long as it is realized that the Neolithic certainly comes down to a period vastly more recent than the Neolithic of even northern Europe, and that in the Sudan, at least, it is overlapped by the Meroitic civilization, numerous outliers of which have been found, including those of Jebel Geili, another in the neighbourhood of the Makwar dam on the Blue Nile, notable for its Greco-Roman bronze vessels, and at Abu Sofian in western Kordofan. Although there is no evidence to show that they are Meroitic it will be convenient here to refer to the discoveries made by H. S. Wellcome at Jebel Moya near the Blue Nile and by Seligman in the mounds near Faragab, a village of sedentary Arabs some 20m. east of Bara in northern Kordofan. Though made about 1910 only the most meagre descriptions of the Jebel Moya discoveries have been published, although they are of prime importance to the history of the Sudan. Besides stone implements, were found beads and amulets, a number of scarabs and small plaques bearing Ethiopian and Egyptian cartouches, ranging from about 700 B.C. or perhaps going back to an even earlier date (Brit. Assn. Reports, 1912), while a paper by Prof. D. E. Derry (Proc. 17th Internat. Congress of Medicine, Sec. 1, Pt. 2, 1913), giving anatomical details of skeletons from graves at this site indicates that the inhabitants were tall negroes resembling in height and cephalic index some of the present day negroes of the hills of southern Kordofan (C. G. Seligman, J.R.A.Z. vol. 40, 1910. Plate xxxv., figs. 8 and 9). At Faragab the mounds extend over acres and their surface and the areas between them are literally covered with disc beads of ostrich egg, fragments of bone debris and other foreign objects, including fragments of imported rocks. Two types of potsherds are of special interest, one consisting of a fabric bearing the impression of the string mat on which it was made (such mats are still used in the hills of northern Kordofan), and in this resembling the coarser wares found by Garstang in the graves of Meroe, the other oblong-oval in shape and rather shallow, often decorated with geometrical designs and produced at each end into a solid mass (handle?), its general appearance recalling that of many Melanesian wooden food bowls. This type seems to be hitherto unknown anywhere in Africa. The beads are of ivory, dolomite and scolecite; the single dolomite bead is definitely not of a type hitherto regarded as negro, while a single carnelian bead, if Egyptian, as no doubt it is, is regarded by Sir Flinders Petrie as certainly not later than 18th dynasty. (C. G. Seligman, "Prehistoric Site in Northern Kordofan," *Annals of Archaeology and Anthropology*, vol. 7, 1915.) The presence of many pieces of worked ivory is noteworthy. Of Meroitic monuments of any size, apart from those found at Soba, *e.g.*, the "lamb" now in the Palace gardens at Khartum, the rock drawings discovered by Crowfoot at Jebel Geili, representing a king wearing the uraeus crown worshipping a rayed solar divinity, which may be taken to be of late Meroitic date, is of special interest.

Rock Drawings.—The rock drawings of the Sudan are in Kordofan and Darfur. Generally they are outlined in red or blackish pigment, but examples roughly graved on masses of granite also occur in the Jebel Haraza massif. Drawings with pigmented outlines are found on Jebel Haraza and Jebel el 'Afarit, and seem to form two groups. (H. A. MacMichael, "Rock Pictures in North Kordofan," *Journ. Roy. Anthropol. Inst.* vol. xxxix., 1909, pp. 562-68.) To the first belong rough but spirited sketches of men on horseback, camels and giraffes. The workmanship of the second group is rougher and much less vigorous; it includes representations of camels, men on horseback and men marching or dancing, carrying the small round Hamitic shield. This, together with their general resemblance to the "Libyo-Berber" rock pictures of the southern Sahara, indicates a comparatively recent date. Moreover, the work is faint and indeterminate, and there is no trace of graving; in other words the Neolithic tradition has not persisted. Probably the drawings are more recent than the stone discs and hollow conical and spherical stones found on Jebel Haraza, already mentioned.

It is as yet too early to estimate the significance of the objects found by D. Newbold (Sudan Notes and Records, vol. 7, 1924) on his recent journey from Bara in Kordofan to the international

boundary (long. 24° E.) between the Sudan and French Equatorial Africa. Evidence of former occupation of the country, now desert or the poorest steppe, was abundant, including cairns, pottery (some Meroitic), a small brick pyramid at Abu Sofian (16° N., 28° E.), and five ground axes of glauconite of hitherto unknown type from the Wadi Hawa. Drawings roughly incised on boulders, e.g., at Sobat el Hammad, showed tailed and phallic men, elephants, giraffes, ostriches, oryx, cattle and several other animals which could not be identified. At Umm Tersawen there were also a number of human figures, some tailed, some armed with bows. "At Abu Sofian two groups of pictures, obviously of the same date and 'school,' were within a day's march of one another. Here the drawings were incised on rough boulders, and were very numerous. Camels are shown literally in hundreds; giraffes and ostriches still appear; but the cattle dwindle in numbers, while the elephant is not represented, and the bowmen give place to men armed with spears and carrying shields." The latter armament appears to bring these drawings into the Libyo-Berber class.

Megalithic Monuments.—Megalithic stone monuments occur in the Sudan, some of the present day, others certainly recent, a few apparently of some antiquity, though as to these our knowledge is of the slightest. In the northern Sudan the Beja tribes surround the graves of their dead with a circle of upright stones; round some of the older graves individual stones were occasionally taller than a man, and it is probably the persistence of such stones after their smaller neighbours have disappeared that has given rise to monoliths such as that some two metres high (to which the Prophet, according to the accepted tradition, tied his horse) overlooking the Khor Arab near the Sinkat-Erkowit road in the Red Sea Province.

Another monolith of much the same dimensions has been described and figured by J. W. Crowfoot from Assarema Derheib, inland from 'Aqiq (*Geog. Jour.*, May 1911), and in this instance there seems nothing to suggest its origin in a Beja grave. Farther south megalithic monuments have been reported from the Madi, while stone circles are made by the Lotuko-speaking tribes wherever stone is abundant, as squatting places for the men, though in no case could evidence be obtained of stones large enough being carried even a few miles. Again, although megalithic structures occur among the Lotuko and the Bari-speaking tribes of Mongalla Province, it is certain that some are recent erections over graves, e.g., the examples discovered by E. E. Evans-Pritchard among the Moro of the eastern Bahr el Ghazal. Although megalithic neither in structure nor form there is a type of stone monument some 80ft. long and about 4ft. high occurring in some number in the neighbourhood of Erkowit. These (*Jour. Egypt. Archaeology*, vol. 2, 1915) are constructed without any cement or mortar; the face consists of a limiting wall of more or less flat slabs of local rock, while the spaces between the containing walls are filled in. Each monument may be considered as of three main elements, viz.: (1) an oblong rectangular portion, (2) two oval masses, to each of which is attached an expansion shaped somewhat like a fish's tail and (3) the curved walls uniting the other elements. Their orientation seems to have been toward the rising sun, while each oval element is interrupted at a constant point in its circumference by the interposition of from two to four upright slabs. There is no chamber or space behind these stones, but from their constant presence and the uniformity of their position it is obvious that they must have had a perfectly definite significance to the builders, indeed they recall the false doors of Egyptian monuments. J. W. Crowfoot found human bones under the filling of the rectangular portion but no objects with them. They may provisionally be regarded as mediaeval, but as antedating the spread of Mohammedan influence which was becoming dominant towards the middle of the 15th century.

Abyssinia.—Although the monuments dating from the 4th century A.D. discovered at Aksum by Theodore Bent (*The Sacred City of the Ethiopians*, 1896) are still the most important, interest will for some time tend to centre round the many new discoveries of "prehistoric" date, including some presumably of no great age, made by the Rev. Father Azais.

Littman, the leader of the German expedition to Aksum, holds

that the carved and decorated monuments generally termed "obelisks" are in fact stelae (of huge dimensions it is true, e.g., from 15 to 33 metres) and therefore each to be regarded as part of a tomb, a point of view rendered the more probable by the presence at their base of stone slabs, often carved, which have every appearance of being altars. All this seems to imply a cult of the dead, but, apart from this, inscriptions dating from the 1st and 4th centuries record the names of the gods of the Semitic conquerors of northern Abyssinia. A Greek inscription of Adulis, no longer in existence but copied in the 6th century by Cosmos Indicopleustes, states that the king of Aksum of the 1st century, who caused this record to be cut, worshipped Zeus, Ares and Poseidon. A later document of King Aizanas (about A.D. 350) is in Greek, Sabaeen and old Ethiopic. An analysis by Littman of this inscription, together with one dating from about a century later, indicates that worship was rendered to Heaven, Sea and Earth, together with Mahren "who begat the King," the latter being identified with Ares. Other monuments include rude monoliths, some ornamented with bands, and a most spirited rock-carving of a lioness in low relief.

The recent work of Father Azais shows that Abyssinia is remarkably rich in stone monuments, of types hitherto unsuspected. The following is derived from the well illustrated, but summary, account of the rev. father's investigations given by A. Kammerer (*Essai sur l'Histoire antique d'Abyssinie*, Paris, 1926). Most of the discoveries were made in an area stretching southwards from Addis Ababa beyond Lake Zwai to the neighbourhood of Lake Margherita. Large tumuli, some surrounded by a circle of megaliths, and a number of dolmens in excellent preservation, were found about 100m. south-east of Harrar, i.e., on the edge of the Ogaden Somali country. These dolmens are said to be of the same general type as is found in western Europe. One which was systematically explored yielded, besides human remains, potsherds, a silver ring and a heavy metal bead.

Menhirs are particularly abundant in Sidamo Province, where they are generally of dressed stone, phallic in form, and may attain a height of 20 feet. A number of menhirs with anthropoid designs in low relief were found near Silte, the capital town of Guragwe. Further south, not far from Lake Margherita, statue menhirs carved in the round occur. These may show geometric designs which suggest tattoo or cicatrices, while to the west and north-west of Lake Zwai, hundreds of short stout uprights of dressed stone, "stunted menhirs," have been discovered, each bearing in relief representations varying in number from one to 13 of a short broad-bladed sword which vaguely suggests the short Roman sword. In this district, too, were found several stele bearing Arabic inscriptions in the Nasri script.

Recent Discoveries in Kenya and Tanganyika.—Important (and at the time of writing unpublished) discoveries have been made in East Africa. In 1913 a human skeleton was found by Dr. Hans Reck at Oldaway, in northern Tanganyika, on the borders of the Serengeti plain. This lay some three metres deep, in undisturbed deposits of the last Pluvial period, associated with a fauna of which more than 50% represents extinct species, including *E. antiquus* Reckii, *Hipparion* sp., and an extinct sheep (*Pelorovis oldnwayensis*). The skull from this skeleton is said to resemble that from Elmenteita, found by L. S. B. Leakey, whose important discoveries in Kenya in the neighbourhood of Lake Nakuru may provisionally be summarized as follows:—

A partial excavation of a flat-topped kopje at Eburu yielded crouched burials of a people with long slender limb bones and long narrow skulls, probably Negro-Hamitic. There was an iron toe-ring on one of the skeletons. At Nakuru a series of forcibly contracted burials was found along the side of a cliff; the skulls which are not negro—it is too early to discuss whether they are in any degree negroid—are long and massive with a long face and well developed and narrow nose. The muscular impressions are well marked, the longbones long and relatively slender. With these skeletons were found obsidian microliths, including lunates, small dos abattu blades, stone bowls and mortars, grinding-stones, pottery, simple bone tools and two beads of foreign origin which may possibly date about 2,000 B.C. At Elmenteita, near the Makalia

river, there were found bones, including skulls, probably representing burials disturbed by flood, and some of these bones are definitely fossil. Here the skulls are of more than one type, (1) strongly built, dolichocephalic, and, apart from the lower jaw, somewhat resembling the Combe Capelle skull, (2) smaller, brachycephalic, represented only by women. The associated industry consists of fair-sized flakes, lunates and end-scrapers of obsidian, ostrich-shell beads and pearl shell pendants, as well as at least three types of pottery. Besides the effects of flood this site was disturbed some ten years ago, so that the original stratification may have become confused and the associated objects be of different ages.

THE WESTERN PROVINCE

Palaeolithic Remains.— It is only recently that stone implements of River-drift type, and therefore to be regarded provisionally as of Palaeolithic age, have been discovered in West Africa. In the British Museum there is a series of massive implements of Chellean type, consisting of quartz porphyry, which on the surface have weathered to the softness of chalk. These come from the alluvial deposits of the Bauchi plateau, as do a smaller number of implements of Mousterian type of the same mineral, and one very steep end-scraper of a more homogenous stone showing no surface weathering. (These implements are described by H. J. Braunholtz in Occasional Paper No. 4 of the Geological Survey of Nigeria.) There is also in the national collection a number of short stumpy implements of Drift type of a reddish quartzite, for the most part with unworked butt, found on the golf links of Accra (Gold Coast). Similar specimens have been found in the local gravels, the actual specimens in the museum having apparently been washed up from the beach.

Neolithic Age.— Polished axe-heads of ordinary Neolithic type are by no means uncommon in West Africa and the Congo valley. They are found in Northern Nigeria, especially in the Bauchi Plateau gravels, where it is said that they overlap to some extent the Drift types. They are, however, of a different stone, for the most part of dolerite. In the Gold Coast Colony they are found in large numbers, as are perforated quartz discs, while a few bossed spheres about 2 in. in diameter, of anomalous appearance and unknown use, have been recovered. A collection of Neolithic implements from Calabar include stone axes, unusual in that they possess a definite tang for hafting.

Under the title "Tumbakultur" Oswald Menghin (*Anthropos*, 20, 1925) has described a culture characterized by series of implements, widespread in the Lower Congo area, which he tends to approximate, though with difficulty, to the Campignian of Europe. Be this as it may, Menghin finds a long series of artifacts passing insensibly from implements of coup-de-poing type, Campignian *pics*, flattened ovals of almost laurel-leaf type, to notched and roughly cruciform spear or arrowheads, some, though larger and coarser, irresistibly recalling the "freak" forms from Breonio in Italy. Apart from these, many ground stone axes have been found in the Congo area.

Megalithic Monuments.— Megalithic monuments are distributed widely in West Africa in the form of stone circles and standing stones. In Gambia both classes of monuments have been carefully described by the late Henry Parker in a paper published after his death (*Jour. Roy. Anth. Inst.*, vol. 53, 1923):—

"The circles themselves are generally found in groups or clusters comprising from two to nine, but single circles are met with. With one possible exception there are no uncompleted circles, except those formed by concentric outer pillars standing round an inner circle. . . . The groups of circles are arranged in single straight lines; in nearly parallel lines consisting of two, three or four circles; or in pairs; but never in triangles or pentagons. Many stones are prostrate and . . . almost invariably these fallen pillars . . . are at least partly buried by the soil. . . . Some have their upper face almost level with the ground, and as a rule the others are half or three-quarters covered by the earth. . . . Superficially considered this is the only indication of the age of these structures, and . . . it would be of great value if we knew the rate of elevation of the soil. Without such knowledge it is only possible to draw the conclusion from this evidence that both

the circles and the menhirs must have been erected many centuries ago.

"In addition to the concentric outer pillars, there are several instances where the outer pillars are arranged on the eastern side of the circle in a straight line, or even in two parallel lines, in a north and south direction. Such lines are invariably to the east of the circle. . . ."

The circles are considered sacred to the Earth Spirit, and ceremonies are performed in them to propitiate the latter, as also for the protection of the crops. It does not, however, appear that Parker excavated in them, and their date and purpose must be left for further exploration, though in the light of information received on the spot the contents of the circle (human remains, spearheads, copper armlets) dug by J. L. Todd and G. B. Wolbach (*Man*, No. 96, 1911) suggest that in recent times these monuments were the sites of sacrifice for success in warfare.

In some of the northern villages of the Cross River Division of Nigeria, *i.e.*, in the villages of the Akayu, Indem and Atam districts (on the left bank of the Aweyong river) there are stone circles, the stones often more or less conical and carved to represent the human body from the waist upwards. These have been described and figured by C. Partridge (*Cross River Natives*, 1905, pp. 268–599); the navel is specially prominent, and cicatrices seem to be reproduced. At Agba village the circle surrounds an old tree, and the grove of the great chief who erected the circle. The tree is sacred, and of the stones it was said by the ancestors "these stones are your forefathers, your very great chiefs; every year you must sacrifice to them" (p. 271).

Beads.— In the past, claims of high antiquity have been made on behalf of the so-called "aggry" beads that have been found in West Africa. Yet as stated by Sir Hercules Read, with the single exception of the necklace to be discussed immediately none of these beads shows features not to be found in mediaeval or later beads from the factories of Venice. The necklace, presented to the British Museum by L. P. Davies, was obtained from the grave of "a renowned chief" at Mansu, a town on the route from Elmina to Kumasi. It is described in detail in *Man* (1905, 1).

For present purposes interest centres in some 20 beads of crystalline glass, irregular-faceted, and especially one bead of crystalline glass moulded like a mulberry. Sir Hercules Read writes of these as being in a state of iridescent decay, the surfaces being in many cases deeply pitted and presenting exactly the same appearance as beads of the same kind from the Mediterranean area. He points out that the crystalline glass in this necklace is identical in appearance with those from the tombs at Kameiros in Rhodes, dating from the 6th century, and goes on to suggest, but "without insisting too strongly on this point," that here are "glass beads of classical style found for the first time in West Africa, and presenting features that in point of date may justifiably be associated with the name and time of the Carthaginian Hanno, a name often invoked when objects of indeterminate age are found on the African coast."

Though probably not of any great age, reference must be made to the soap-stone carvings of human heads or figures (occasionally animal figures) found in the ground, sometimes apparently in pits, in certain districts of Sierra Leone, where they are used as agricultural charms. These figures are for the most part roughly carved, the work being well within the scope of present-day Africans, and Joyce (*Man*, No. 57, 1905, and No. 40, 1909), points out that there is really no reason to see in them—as has been proposed—evidence of foreign, *i.e.*, Egyptian or Carthaginian influence. The objects described by Frobenius from Old Ife (The

BY COURTESY OF THE PRESBYTERIAN BOARD OF FOREIGN MISSIONS

WOMEN SERVE AS CARRIERS IN AFRICA, COVERING 35 MILES A DAY

Voice of Africa, 1913, vol. i, chap. 14; "The Archaeological Finds"; and *Das Unbekannte Africa*, Munich, 1923), the ancient capital of the Yoruba, are also probably of no great age; there do not seem to be any which the 16th century Benin civilization might not have produced.

Possibly of about the same date are a number of bronze and silver objects, now on deposit in the British Museum, from a sandy mound (no doubt a grave) at Tumuni in the Sokoto Province of Northern Nigeria. Sir Hercules Read holds that they exhibit features and analogies which are unusual in negro African metal work, pointing to artistic or commercial relationship with the culture of the Mediterranean area, doubtless at a period remote from the date of the manufacture of the relics themselves.

The most important pieces are a bucket with incurved sides and lugs, and a barrel-shaped armlet (?) for wear on the bicipital region. The lines and casting of both, and the geometrical patterns tooled on their surfaces, are good and careful work. While the find as a tomb-group may date to A.D. 1480, as suggested by H. R. Palmer, yet, as stated by Read, they are of unusual interest from the analogies they present with the early Mediterranean cultures, and we may have here a distant echo of the early art of the Bronze age. At the same time there is no reason to think that the actual objects are anything but local productions, though they may differ from those of more recent date.

THE SOUTHERN PROVINCE

Palaeolithic Implements. — Artifacts of rude Chellean type, often larger than the corresponding implements of western Europe, are found over the greater portion of South Africa, nor does there seem to be any reason why these should not be regarded as true palaeoliths perhaps of an age comparable to those of Europe. One of the most satisfactory finds of this order is constituted by a considerable number of implements of chalcedony, quartzite, etc., exactly similar to types characteristic of the River-drift Period of western Europe and Great Britain, associated with and evidently forming part of ancient terrace gravels deposited as drifts by the Zambezi (in the neighbourhood of Victoria Falls) at a remote period. The position of these terrace gravels and surface drifts in regard to the Batoka Gorge indicates their real antiquity, since they must have been deposited by the river when the latter was covering the old valley floor more than 400ft. above its present level. Here Henry Balfour excavated several implements from undisturbed gravel deposits at depths varying from 6in. to zft., some greatly water-worn and heavily patinated.

Recently A. J. H. Goodwin ("South African Archaeology," *Man*, 1927, 14, and "Capsian Affinities of S. A. later Stone age Culture," *South African Journal of Science*, vol. xxii., 1925) has summarized South African history on the following lines:—

The terms Palaeolithic and Neolithic are dropped, the two main periods being termed the Earlier Stone age and the Later Stone age, Péringuey's name for the main coup-de-poing culture of the Earlier Stone age, the Stellenbosch industry, being retained. A second culture, the Victoria West industry, centres round Victoria West in the south-central Karroo, running north into the Free State and west to Nakob on the S.-W. African border; the *coup-de-poing* occurs, but the main implement appears to be a core similar to the European Acheulean tortoise-core, but some 8in. or so in length. It is not clear whether core or flake was the desired element, but secondarily worked flakes of this industry have not been found. The last culture of the Earlier Stone age is that of Fauresmith in the Orange Free State, with a flake worked to resemble a coup-de-poing as the characteristic tool.

There is no evidence of the Earlier Stone age developing into the Later Stone age, indeed they probably overlapped. The earliest industry of the Later Stone age is that of Still bay (near Mossel bay) covering most of the eastern part of the Union and extending into the Free State and to Okahandja in South-West Africa. This culture somewhat resembles the Solutrean of Europe, with lanceolate implements (usually small) as well as tanged forms, sometimes with serrated edges.

The Still bay culture was followed by two probably contemporaneous industries which extend into modern times, termed from

sites in the Orange Free State the Smithfield and Wilton cultures respectively. The Smithfield culture includes end-scrapers, thumb-nail and horse-shoe scrapers, trimmed points (of Chatelperron type), handpicks, bored stones, ostrich eggshell beads, ground stone rings, pottery and human remains. The human remains are of the "Bushman" type, and in a general way this culture is similar to the Capsian or the Aurignacian of Europe. The Wilton industry is very similar; the chief implements are pygmy lunates, thumbnail, and end-scrapers, as well as geometrical forms; the pottery is similar to that of Smithfield; bone arrowheads and link-shafts occur; burials are flexed, with skeletons of the same general type as the Smithfield specimens. Slate "palettes" are also found, and the culture is definitely associated with the cave paintings. Goodwin considers this culture as identical with the last phases of the Capsian of Spain and North Africa, a point of view confirmed by I. Schapera ("Some Stylistic Affinities of Bushman Art," *South African Journal of Science*, vol. xxii. Nov. 1925, pp. 504-15), who, as the result of a careful comparison of European Palaeolithic and Bushman art concludes that the Capsian art of Spain shows most affinity with that of the Bushmen.

Information supplied by Goodwin indicates the existence of a true Mousterian—the Glen Grey industry—with high-backed as well as the more usual flat points similar to those found in North Africa and Europe, while in the Later Stone age the recent discovery at Howieson's Poort of a number of true graving points (*burin*) is important, both in itself and as further suggesting contact with the north.

Pottery. — It is not clear that examples of pottery of any considerable age exist. Those figured by Péringuey (*Annals of the South African Museum*, vol. viii, 1911), provisionally assigned to Bushmen, Strandloopers and Hottentots, are of the rudest type, predominantly ovoid with conical bottoms, sometimes ornamented, the kneading and baking being very poor.

The Bushmen. — No apology seems necessary for considering the "archaeology" of the Bushmen with that of the kindred Strandloopers (no longer to be regarded as a distinct race, the name describing a mode of life and not implying a constant physical difference), for even though the former are not utterly extinct, the few survivors no longer pursue their characteristic arts of painting and graving on rock. It is generally admitted that the Bushmen stock came into South Africa from the north, and Stow was of the opinion that there were two great divisions, each with its characteristic mode of life and art, viz.: (1) cave-dwellers (painters), and (2) kopje-dwellers (sculptors), the latter producing their works by "pecking" the rock face on which they worked. This view does not seem to be generally accepted, perhaps it only emphasizes differences in technique due preponderantly to environment.

The paintings of the Bushmen, naturalistic monochrome and polychrome studies of high artistic merit, for the most part record the animals which they hunted and upon which they subsisted. But paintings of the carnivora are not absent, and cattle raids, dances and magico-religious (?) scenes are also portrayed. Belonging no doubt to the latter class are the fairly numerous examples of animal-headed human figures—representations of masked dances—not to be confused with the wearing of animal skins as a hunting ruse to admit approach to the game, as in the famous picture in the Hershel district of Cape Colony of a Bushman wearing an ostrich skin while stalking a flock of these birds.

The character of Bushman paintings has been well summed up by Henry Balfour:—

They are "remarkable not only for the realism exhibited by so many, but also for a freedom from the limitation to delineation in profile which characterizes for the most part the drawings of primitive peoples, especially where animals are concerned. Attitudes of a kind difficult to render were ventured upon without hesitation, and appreciation even of the rudiments of perspective is occasionally to be noted, though only in a crude and uncertain form. The practice of endeavouring to represent more than could be seen at one time . . . is far less noticeable in Bushman art than might have been expected from the rudimentary general culture of these peoples, and one does not see instances of both eyes

being indicated upon a profile face, or a mouth in profile on a full face. . . . The colours were usually laid on uniformly over the surface which they individually covered, but a shading off is sometimes exhibited." (Bushmen *Paintings*, 1909, p. 9.)

Dr. K. M. Barnard points out that examples similar in execution to those described by L. Péringuey (Trans. S. Afr. Philos. Soc., 16, 1906, and 18, 1909) have been discovered at various places in South-west Africa, the farthest north being in the Grootfontein district. In addition to the usual animals there are representations of the human foot, and the spoor of various bucks, while from the position in which these latter occur the explanation that they are "sign-posts" to water cannot be maintained.

Major F. J. Bagshawe (see Man, 1923, 92) has discovered in Tanganyika Territory rock-paintings of Bushmen type of so high an artistic quality that their origin can only be referred to this race, an extension northwards which goes well with the distribution of the Bushmen kwe (digging-stick weight), of which specimens, known in Tanganyika, have been discovered in Uganda (Wayland) and even among the Bari of the Southern Sudan (Seligman). The Tanganyika rock-paintings include an eland, cow, ostriches, giraffe and antelope.

Strandloopers.—The Strandloopers are a people of whom, apart from their skeletal characters, we know little, though concerning these there is a fair volume of reliable if not always consistent data. Their cultural attainments may be judged, e.g., from the remains found in the caves and rock-shelters of T'zitzikama cliffs, about 1000 m. to the west of Port Elizabeth. One of these shelters explored by F. W. Fitzsimons (described by Sir Arthur Keith, *The Antiquity of Man*, I., 1925), contained deposits some 30 ft. deep. The lower 5 ft. and the upper 6 ft. were sterile; below this latter layer was a stratum some 7 ft. thick in which numerous Strandlooper burials were encountered amidst remains of fireplaces, broken pottery, implements and ornaments in stone and bone. Then came the third stratum, over 6 ft. in thickness. While removing this stratum and working at a depth of 15 ft. below the original floor of the shelter, Fitzsimons found graves containing remains which differed from those he had met with in the stratum above. Unfortunately the bones in the lower stratum were imperfectly preserved. The graves had been partly protected by slabs of stone some of which had been rudely engraved with human figures. There were lumps of red ochre, necklaces of shell and bone and tools of stone and bone. In a still deeper stratum, also about 6 ft. in thickness, there were traces of burials and hearths, the human remains being fragmentary, but considered to belong to individuals of the Boskop type.

Mediaeval Remains in Rhodesia.—The conclusions of D. Randall-MacIver (*Mediaeval Rhodesia*, 1906) that the Zimbabwe and similar ruins in Rhodesia are negro in origin and modern in date, though not generally accepted in South Africa, have not been disproved. For though there is no inherent improbability in the early Semitic origin of these ruins, it seems unnecessary to seek a foreign colonization where the facts in no way contradict a local origin. No authentic inscriptions have been found, and no objects discovered in the Great Zimbabwe, around which the controversy has chiefly centred, need be more than a few centuries old, while those that are not foreign imports (porcelain, etc.) are of African type. Moreover, a re-examination of the evidence, including unpublished material in the library at Lisbon, has led Father Schebesta (Mitt. der *Anthrop. Ges. in Wien*, 1922-23) to the conclusion that not only is the Zimbabwe a product of the indigenous kingdom of Monomotapa described by the Portuguese, but that its builders culturally resembled the Baganda, and probably certain other of the more advanced peoples of Central Africa.

NORTH AFRICA

The archaeological documents of north Africa reflect the cultural conditions recorded in its ancient history, the imposition of successive alien civilizations by dominant Mediterranean Powers upon a receptive but resistant native population. The ancient invaders were (under their political names) Phoenicians, Greeks,

Romans, Vandals and Byzantines; the Arab invasions, which began in the 7th century A.D., belong to modern history.

Native Cultures.—The native Libyan and Berber (*q.v.*) elements, whether aboriginal or not, have persisted without visible change from the prehistoric period to the present day. Their most ancient handiwork is represented by stone implements and simple pottery found in cave-dwellings, figures of men and animals engraved on rocks, some fortress-walls and many sepulchral monuments of megalithic type, square and circular dolmens, cairns and cromlechs. This material is related on the one side to the most primitive remains of Spain and south France, on the other side to those of Egypt and Crete; but while neolithic culture in the Egyptian and European areas was superseded in the prehistoric age, the African stone implements seem to have remained in use in certain districts until very recent times. It is seldom possible to date these monuments even approximately. The Berber language was inscribed on stone, often in conjunction with Punic and Latin texts, in a local alphabet which is still current among the Tuaregs (*q.v.*) of the Sahara. Beside this backward element there was in historical times an urban population more or less civilized by contact with Greeks and Semites; but it does not appear to have developed a distinctive art. Its surviving monuments are mostly sepulchral: most notable are two pyramidal structures near Tipaza (anc. *Tipasa*) and Batna in Algeria. The former, called the Tomb of the Christian Woman (Kbor er *Roumia*), is evidently a royal tomb and perhaps that of Juba II., the philhellene king of Mauretania in the time of Augustus. The other, called the Medracen (Madghascn), is older, and may be the tomb of Massinissa, the Numidian ally of Rome in their last war with Carthage. Both are low cones of stepped masonry set on cylindrical bases which have cornices borne by engaged columns; their diameters measure about 200 feet. The form may have been derived from the native cairns, but it closely resembles the monumental tumuli of Italy and Asia. The architectural orders are Greek, with some archaisms and other peculiarities that indicate Punic influence.

Phoenician.—The Phoenician settlement, of which Carthage was ultimately the chief city, is assigned to the 12th century B.C., but its earliest known remains are not older than the 7th. At the time of its fall in 146 B.C. Carthage controlled nearly the whole of what is now Tunisia, and was in touch with the native kingdom of Numidia on the west, and through the Phoenician territory of Tripolitania with the Greek colonies of Cyrenaica on the east.

Nothing is left of the Punic city of Carthage and very little of its Roman successor, the colony which was founded as the capital of Africa after the destruction of the original Carthage. But its site is indicated by a zone of cemeteries, which lay outside the walls. It is a large semicircular area bounded on its short side by the sea; its central point, the modern St. Louis' Hill, was certainly the Punic citadel, the Byrsa, and the port was south of this, near the place where two lagoons now lie. These agree perhaps fortuitously with ancient descriptions of the commercial and war harbours, the latter having the Admiralty Island in its midst; but the coast has greatly changed even in the last century, and ancient lines of sea-walls and quays have been identified on the outer coast. The curse that Rome invoked upon the Punic site has operated on its own foundation. After the Arab sack, the city was abandoned by the conquerors, and became a quarry for Mediterranean masons of all later ages. The cathedral of Pisa is said to have been built with stones of Carthage. A few of the larger structures can be traced. On the Byrsa is a temple of Aesculapius; in the western plain, an amphitheatre; on either side of the northern hill, a theatre and an Odeum; in the eastern plain, the baths, better preserved in the Arab name of the locality (Dermesh) than in its soil. The waterworks have fared better: there are great vaulted reservoirs at Dermesh and La Malga, fed by an aqueduct from a copious source at Zaghuan, 100 miles away.

The Punic graves that have been found are not older than 700 B.C. They are mostly double chambers approached by shafts; burials were often made in stone coffins with lids carved

as recumbent human figures. There are numerous grotesque clay masks which were placed in the graves to keep evil spirits away. Personal trinkets and jewellery are the other furniture.

In a sanctuary of Baal at Dougga (Thugga) birds' bones were buried in jars. This temple, which was dedicated to Saturn under Roman rule, was enclosed in a square colonnade. A temple of Tanit-Caelestis at the same city stands in a semicircular court. A mausoleum built there in the 4th century B.C. and recently reconstructed was designed in Graeco-Phoenician style, and bore a bilingual inscription in Libyan and Punic. The art of Carthage was rapidly hellenized, probably by contact with Greek colonies in Sicily rather than with those of Africa.

Greek.—The largest Greek city in Africa was Cyrene, one of the greatest cities of the Greek world. Yet its famous and conspicuous site was almost inaccessible until the 20th century. In 1861 two young officers of the British forces at Malta, R. Murdoch Smith and E. A. Porcher, found and identified the temple of Apollo, sent to England a large series of sculptures, now in the British Museum, and excavated at other points outside and inside the city, but could not stay long enough to explore its topography more definitely. An expedition equipped by the Archaeological Institute of America made a good beginning in 1910, but met with organized hostility among the natives, and before its second season had begun the country was seized by Italy. All archaeological work in Cyrenai'ca and Tripolitania has since been directed by the Italian Government. The results at Cyrene show that the Roman city occupied the two hills that are the landmarks of the site. The western hill was the Greek acropolis and contained the agora; on the eastern hill is a Doric temple and a stadium; the residential quarters lay in the dividing valley and on the south-west slope of the eastern hill. At the north end of the valley, outside the city wall, the sanctuary of Apollo stands on a partly artificial platform below the fountain, Kyra. The low and narrow channel of this famous spring can be followed for a quarter of a mile inside the mountain; ancient inscriptions are scratched and moulded on the clay that covers its walls, and the mouth of the channel is an open chamber cut in the face of the cliff. Rows of chamber-tombs with elaborate architectural fronts are cut or built in the slopes of the plateau. It seems that the city when fully excavated will be another example of the conventional Roman splendour which is the characteristic element in north African antiquities; but the sanctuary is a new feature, preserving its original plan, and important remains of the Greek structures have been found beneath the Roman ornament. The sanctuary is a walled precinct like that of Delphi. It contains the temples of Apollo and Artemis, each with a great altar in front, and smaller shrines of lesser deities. A curious adjunct of the Artemisium is an underground Nymphaeum, apparently for purificatory rites. The Apollo temple has treasure-cists sunk in its floor. In Roman times two bath-establishments were intruded on the terrace, from one of which some 20 marble statues were recovered, including a headless Aphrodite now in the museum of the Terme at Rome. The rest of the material from Cyrene is at Bengazi. On the west side of the precinct is a Greek theatre. The Sacred Way leads from the sanctuary past the fountain to the agora, a colonnaded area of the usual Roman type containing the provincial *capitolium* and other official buildings. Among the Greek survivals here are the *heroön* and a small circular structure which was the tomb of the first Battos, founder of the city and of the dynasty which ruled it. The round tomb is apparently the base on which stood a column depicted on some Cyrenai'c coins. Curious sepulchral monuments found in the rock-tombs are sculptured busts with heads in which the face was indicated by painting, or with tapering columnar necks instead of heads. Greek art is rare: a few archaic votive statues have been found and further excavation will doubtless produce others. The archaic strata should also help to determine the origin of the so-called Laconian or Cyrenai'c pottery. (See POTTERY, Greek.) A small bronze head of a bearded man (5th century B.C.) has been found by the Italians, and a marble head of Athena (said to be 4th century) was excavated by the American expedition, but the finest work of art from Africa is a Hellenistic bronze head of 3 young Berber,

which was found by Smith and Porcher in the temple of Apollo. It is also an anthropological document of great value. There are other Hellenistic pieces among the numerous marble statues from Cyrene, but the sculpture here as in other north African cities is generally of Roman date. The other cities of Cyrenai'ca have produced Greek terra-cotta statuettes and painted vases, mostly from tombs; among the vases are several oil-jars which were prizes in the Panathenaic games. The Punic colonies must have contained examples of Greek art, and the Mauretanian capital of Juba II. at Cherchel (Caesarea) was decorated with imported statuary, some fragments of which survive. Some good examples of Hellenistic sculpture have come from the sea. They were found in a sunken ship which was located in 1907 off Mahedia near the Lesser Syrtes, and are now in the museum of the Bardo at Tunis. The most important is a bronze herm signed by Boethos of Chalcidion. There are many decorative bronzes belonging to furniture, and parts of large marble vases and candelabra in Neo-Attic style. The ship's hold was divided into three compartments, and the deck was laden with marble columns. The date of the wreck is placed in the 2nd century B.C. Two large bronze statuettes, a standing boy and a seated girl, came from the harbour of Bône (Hippo Regius) in 1912, and a bronze horseman, said to be of the 5th century B.C., was excavated at Ksar Farum (*Vulubilis*) in Morocco.

Roman.—Most of the Roman cities are comparatively late foundations. The civilization of Africa was never finished, and its imperial history is a record of continual progress southwards and westwards from the original province to the Sahara and the ocean. Even the older Greek and Carthaginian cities, such as Cyrene and Thugga, and the native capitals of Cirta and Caesarea, were converted to the metropolitan Roman model in the mature imperial age. But the ordinary African township was a mushroom growth, built to an emperor's order and peopled with colonists from the army and the countryside. As the citizens were Romanized by the gift of the Latin name, so the dignity of their city was asserted in its public buildings. Theatres and baths were erected and adorned by the munificence of wealthy Africans, to whom and to Roman landowners and their agents belonged the luxurious villas that are scattered through the country districts. But the urban population in general was meanly housed. The best example of a new city is Timgad (*Thamugadi*) in south-east Algeria (Numidia), north of Mt. Aures. It was founded by Trajan as a colony in A.D. 100, and built by military architects and labour from the Legion III. Augusta, whose discharged soldiers were the colonists. The site is laid out on the lines of a military camp, a square cut up into small blocks (*insulae*) by intersecting streets drawn parallel to the enclosing ramparts. A monumental gateway (the so-called triumphal arch of Trajan) stands in the middle of the west side. At the central crossing of the two main streets (*cardo* and *decumanus*) is the forum, occupying the space of eight *insulae*, and next to the forum is a theatre. Other public buildings now inside the ramparts are a market-place, a library and baths. The city rapidly outgrew its walls; the later *capitolium*, more baths, a larger market, another triumphal arch, pagan temples and Christian churches were built outside, and as the town grew its formal character was lost. The camp in which the legion itself was permanently quartered is Lambaesis, 20m. W. of Timgad. It was established in the first half of the 2nd century, and consists of a fortified square intersected by the two main roads and containing military offices, barracks and baths. A great part of the site is covered by a modern prison. To the south lies the town that attached itself to the legion, entered through monumental arches and equipped with the usual apparatus of capitol and lesser temples, theatres, amphitheatre and baths. Lambaesis is a unique example of a permanent camp. *Cardo* and *decumanus* are paved with stone and bordered with colonnades, and south of their intersection stands nearly to its full height the four-arched entrance to the praetorium, leading to a court with porticoes behind which are the headquarters' offices, legionary shrines and armouries.

Other municipal foundations were built on the same model as Timgad, but not always with the formal plan that can only be

achieved on an empty site. The best preserved structures are probably those of Lebda (*Leptis Magna*) in Tripolitania. This was the native city of the emperor Severus, and was magnificently adorned by him. It has been covered by wind-borne sand, which overthrew whole walls with its weight and at the same time buried and protected their ruins. But many walls and columns are still standing with cornices and entablatures intact. At the other end of the Roman dominion, in Morocco, lies Ksar Farun (Volubilis) near Meknes, a solitary outpost of classical culture in a barbarous land. A triumphal arch and the remains of a basilica were visible before its excavation. The site was largely cleared by prisoners of war in 1915. Other well-preserved or excavated cities are, in Algeria, Jemila (*Cuicul*), Khamissa (Thubursicum *Numidorum*), and Tipaza (*Tipasa*); in Tunisia, Bou Grara (Gighti), Dougga (Thugga), Henchir Kasbat (*Thurburbo Maius*), Medei'na (Althiburus), and Sbei'tla (*Sufetula*); and Sabratha in Tripolitania. In all of these the usual public places are represented, the forum with its curia, basilica, and rostra, flanked by temples and porticoes which sheltered honorific statues. Khamissa has its table of standard measures still in place; Timgad, Lembaesis, Jemila and Henchir Kasbat have markets appropriately fitted for various commodities. In the military foundations these lie just outside the gates, but Timgad has also smaller and perhaps later markets within the ramparts. There is also a library at Timgad, unique in Africa. Baths and triumphal arches (gateways) abound on these and many other sites, and each city has its theatre; those of Cherchel and Dougga are particularly well preserved. The finest amphitheatre is at El Jem (Thysdrus). The official sacred building of a provincial town was the capifolium, and was usually placed near the forum, but at Timgad it lies outside the walls. The regular tripartite plan is seen in this example. At Dougga the front columns with their pediment are still standing, and at Sbei'tla the capitol consists of three separate shrines. A temple at Tebessa (Theveste) is nearly intact, and has an elaborately carved parapet but no pediment. A notable temple is that of Aesculapius at Lembaesis, which has a thermal establishment attached and is approached through an avenue of subsidiary chapels. Many miles of aqueducts are standing between the cities and the springs from which they drew their water. The supply of Carthage came from Zaghouan, where there is an elaborate Nymphaeum. Similar water-sanctuaries exist at Hammam Derraji (*Bulla Regia*), Khamissa and elsewhere; the aqueduct at Sbei'tla is carried over the ravine on a massive bridge. Houses of Graeco-Roman design like those of Pompeii have been excavated on many sites: most famous is the House of Sertius at Timgad, but this does not belong to the original city. Bulla Regia has some underground houses, and there are catacombs at Sousse (Hadrumetum).

Large quantities of Roman sculpture have been found in these excavations, and are housed in the local museums, among them many imperial portraits and other pieces of historical value. Inscriptions also are abundant. But the peculiar artistic riches of north Africa are mosaic pavements, which have for their subjects, besides decorative patterns, seascapes and landscapes, historical and mythological scenes, and incidents of agricultural life, fishing, hunting and games. Among them are portraits of Xenophon from Sbei'tla and Virgil from Sousse. A large and varied series comes from a villa near Zliten in Tripolitania.

Vandal and Byzantine.—Mosaic decoration is a prominent feature in the remains of Early Christian churches (basilicas): there are particularly fine examples in the baptisteries of Jemila, Sbei'tla and Timgad. At the last place the church is attached to a monastery, as also at Tebessa. Some of the churches are Late Roman, others are Byzantine foundations. During the short interval of Vandal occupation (A.D. 439–533) there seems to have been no architectural activity, but some fortification and a good deal of military demolition date from this epoch. Examples of the latter are supplied by the theatres of Carthage, which were filled in with the ruins of their superstructures. The great fortress walls that dominate many sites are Byzantine. They were erected to hold the civilized country against native tribes, the same aggressors that the Roman conquerors had to face; and it is

significant that the two most imposing Byzantine strongholds, at Hai'dra and Tebessa, are on the sites of the first permanent camps that the Roman legion fortified on Mt. Aures (*Ammaedara* and Theveste). Hai'dra is the type of a military fort, Tebessa of a fortified city. The fortress-walls were made of ancient materials, and often incorporate whole buildings of preceding ages. Triumphal arches at Tebessa are worked into the circuit of the ramparts; one at Hai'dra was built up to make a tower; the capitols of Dougga and Sbei'tla were turned into forts. The ruin of classical buildings involved in these defensive works was immense, and it has been justly said that the real vandals of north Africa were the Byzantines. Arab conquests, though fatal to town-dwellers, did no great damage to the structures. Indeed their subsequent desertion and neglect have been the means of preserving so many Roman cities to an extent unequalled in any other land. (E. J. F.)

BIBLIOGRAPHY.—R. Cagnat, Carthage, *Timgad*, Tebessa et tes Villes antiques de l'Afrique du Nord (1909, a short illustrated survey). Detailed accounts of particular sites and monuments are mostly in series of monographs or periodicals published by the local Governments: S. Gsell, *Les Monuments antiques de l'Algérie* (1901, Service des Monuments Historiques); R. Cagnat and P. Gauckler, *Les Monuments historiques de la Tunisie* (1898, Direction des Antiquités et Arts); *Musées et Collections archéologiques de l'Algérie et de la Tunisie*; *Notiziario archeologico del Ministero delle Colonie and Africa Italiana* (from 1915, Cyrenaica and Tripolitania).

HISTORY

The ancient history of Africa is shrouded in mystery and the earliest records of that continent and its people are far from trustworthy. See AFRICA, ROMAN; EGYPT.

Phoenician and Greek Colonization.—The word Africa was applied originally to the country in the immediate neighbourhood of Carthage, that part of the continent first known to the Romans, and it was subsequently extended with their increasing knowledge. The Arabs still confine the name Ifrikia to the territory of Tunisia. If ancient Egypt and Ethiopia (*q.v.*) be excluded, the story of Africa is largely a record of the doings of its Asiatic and European conquerors and colonizers, Abyssinia being the only State which throughout historic times has maintained its independence. The countries bordering the Mediterranean were first exploited by the Phoenicians. Carthage, founded about 800 B.C., speedily grew into a city without rival in the Mediterranean, and the Phoenicians, subduing the Berber tribes, who then, as now, formed the bulk of the population, became masters of all the habitable region of north Africa west of the Great Syrtis. Both Egyptians and Carthaginians made attempts to reach the unknown parts of the continent by sea. The west coast was well known to the Phoenicians as far as Cape Nun, and c. 520 B.C. Hanno, a Carthaginian, explored the coast at least as far as Sierra Leone.

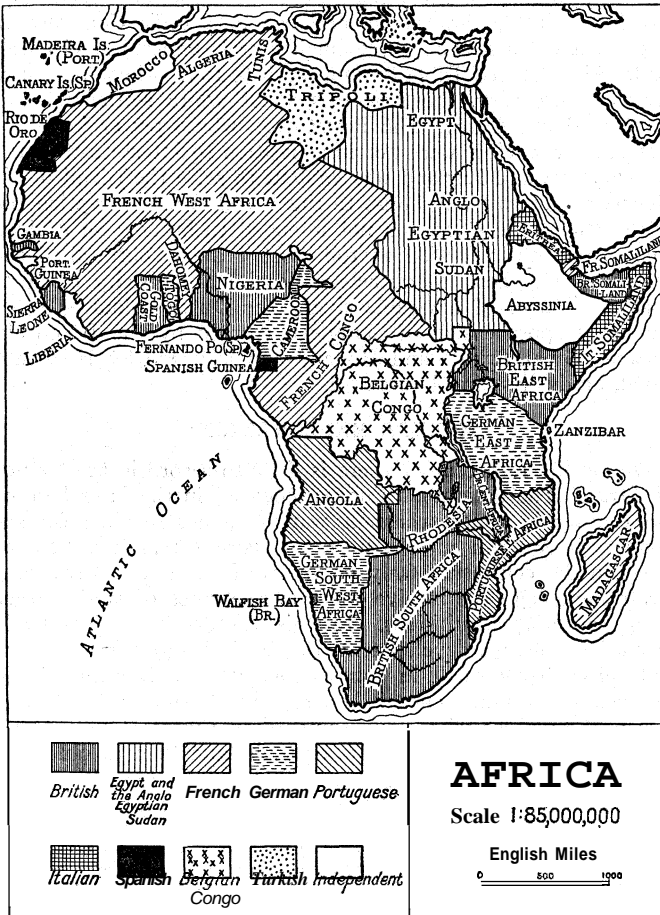

A WOMAN OF ZULULAND

Meantime the first European colonists had settled in Africa. Greeks founded the city of Cyrene (c. 631 B.C.) and exerted a powerful influence in Egypt. To Alexander the Great the city of Alexandria owes its foundation (332 B.C.), and under the Hellenistic dynasty of the Ptolemies attempts were made to penetrate southward, and in this way was obtained some knowledge of Abyssinia. Neither Cyrenaica nor Egypt was a serious rival to the Carthaginians, but all three Powers were eventually supplanted by the Romans after the fall of Carthage in 146 B.C. Under Rome the settled portions of the country were very prosperous, and a Latin strain was introduced into the land. Though Fezzan was occupied by them, the Romans elsewhere found the Sahara an impassable barrier. The utmost extent of geographical knowledge of the continent is shown in the writings of Ptolemy (2nd century A.D.), who guessed the existence of the great lake reservoirs of the Nile and had heard of the river Niger. (For the history of Africa under the empire, see ROMAN EMPIRE, LATER.)

The Arab Conquest.—In the 7th century an Arab host, following the new faith of Mohammed, conquered the whole country from the Red sea to the Atlantic and entered Spain. Throughout north Africa Christianity well-nigh disappeared, save in Egypt (where the Coptic Church was suffered to exist), and Upper Nubia and Abyssinia, which were not subdued. In the 8th, 9th and 10th centuries the Arabs in Africa were numerically weak; but in the

middle Niger regions fell under the influence of the Arabs and Berbers, but it was not until 1591 that Timbuktu—founded in the 11th century—became Muslim. That city had been reached in 1352 by the great Arab traveller Ibn Batuta, to whose journey to Mombasa and Quiloa (Kilwa) was due the first accurate knowledge of those flourishing Muslim cities on the east African sea-board. Except along this sea-board, which was colonized directly from Asia, Arab progress southward was stopped by the broad belt of dense forest which, stretching almost across the continent somewhat south of 10° N., barred their advance as effectually as had the Sahara that of their predecessors, and cut them off from knowledge of the Guinea coast and of all Africa beyond. One of the regions which came latest under Arab control was Nubia, where a Christian civilization and State existed up to the 14th century.

For a time the Muslim conquests in south Europe had virtually made of the Mediterranean an Arab lake, but in the 11th century the Norman conquest of Sicily was followed by their descent on Tunisia and Tripoli. Somewhat later a busy trade with the African coast-lands, especially Egypt, was developed by the cities of north Italy. The Italians also, in the 14th and 15th centuries, traded with the countries of the Niger bend and were conversant with the routes across the Sahara. Some Europeans even traversed the desert, while one traveller—not a merchant—the Frenchman Anselme d'Isalquier reached Gao on the Niger, in 1405.¹ Meanwhile events were impending which were to have a profound effect on north-west Africa. By the end of the 15th century Spain had completely thrown off the Muslim yoke, but even while the Moors were still in Granada, Portugal was strong enough to carry the war into Africa. In 1415 a Portuguese force captured the citadel of Ceuta on the Moorish coast. From that time Portugal repeatedly interfered in the affairs of Morocco, while Spain acquired many ports in Algeria and Tunisia. Portugal, however, suffered a crushing defeat in 1578 at al Kasr al Kebir, the Moors being led by Abd el Malek I. of the Sherifan dynasty. By that time the Spaniards had lost almost all their African possessions. The Barbary States degenerated into mere communities of pirates, and under Turkish influence civilization and commerce declined. (X.)

MODERN HISTORY

The Portuguese.—But with the battle of Ceuta, Africa had ceased to belong solely to the Mediterranean world. Among those who fought there was Prince Henry "the Navigator," son of King John I., who was fired with the ambition to acquire for Portugal the unknown parts of Africa. Under his inspiration and direction was begun that series of voyages of exploration which resulted in the circumnavigation of Africa and the establishment of Portuguese sovereignty over large areas of the coast-lands. Cape Bojador was doubled in 1434, Cape Verde in 1445, and by 1480 the whole Guinea coast was known. In 1482 Diogo Cam or Cão discovered the mouth of the Congo; the Cape of Good Hope was doubled by Bartholomew Diaz in 1488, and in 1498 Vasco da Gama, after having rounded the Cape, sailed up the east coast, touched at Sofala and Malindi, and went thence to India. Over all the countries discovered by their navigators Portugal claimed sovereign rights, but these were not exercised in the extreme south of the continent. The Guinea coast, as the first discovered and the nearest to Europe, was first exploited. Numerous forts and trading stations were established, the earliest being São Jorge da Mina (Elmina), begun in 1482. The chief commodities dealt in were slaves, gold, ivory and spices. The discovery of America (1492) was followed by a great development of the slave trade, which, before the Portuguese era, had been an overland trade almost exclusively confined to Mohammedan Africa. The lucrative nature of this trade, and the large quantities of alluvial gold obtained by the Portuguese, drew other nations to the Guinea coast. English mariners went thither as early as 1553, and they were followed by Spaniards, Dutch, French, Danish, and

POLITICAL DIVISIONS OF AFRICA IN 1910 AT THE CLOSE OF THE FINAL PHASE OF THE INTERNATIONAL "SCRAMBLE FOR TERRITORY"
Two further adjustments took place before the World War. By the 1911 agreement the Cameroon received two tongue-like extensions—one reaching to the Congo river, the other to the Ubangi. On Nov. 5, 1911, as the result of a brief war with Turkey, Italian sovereignty was extended over Tripoli

11th century there was a great Arab immigration. Even before this the Berbers had very generally adopted the speech and religion of their conquerors. Arab influence and the Mohammedan religion thus became indelibly stamped on northern Africa. Together they spread southward across the Sahara, and became firmly established along the eastern sea-board, where Arabs, Persians and Indians planted flourishing maritime and commercial colonies. Of these eastern cities and States both Europe and the Arabs of north Africa were long ignorant.

The first Arab invaders had recognized the authority of the caliphs of Baghdad. Early in the 10th century the Fatimite dynasty established itself in Egypt, where Cairo had been founded A.D. 968, and from there ruled as far west as the Atlantic. Later still arose other dynasties such as the Almoravides and Almohades. Eventually the Turks, who had seized Egypt in 1517, established the regencies of Algeria, Tunisia and Tripoli (between 1519 and 1551), Morocco remaining an independent Arabized Berber State under the Sharifan dynasty, which had its beginnings at the end of the 13th century. Under the earlier dynasties the spirit of adventure and the proselytizing zeal of the followers of Islam led to a considerable extension of the knowledge of the continent. This was rendered more easy by their use of the camel, which enabled the Arabs to traverse the desert. In this way Senegambia and the

¹D'Isalquier afterwards wrote an account (never published) of his travels, which were made known in 1927 by Charles de la Roncière in vol. iii, of *La Découverte de l'Afrique au Moyen Age*.

other adventurers. Much of Senegambia was made known as a result of quests during the 16th century for the "hills of gold" in Bambuk and the fabled wealth of Timbuktu, but the middle Niger was not reached. The supremacy along the coast passed in the 17th century from Portugal to Holland and from Holland in the 18th and 19th centuries to France and England. The whole coast from Senegal to Lagos was dotted with forts and "factories" of rival Powers, and this international patchwork persists though all the hinterland has become either French or British territory.

Southward from the mouth of the Congo' to the inhospitable region of Damaraland, the Portuguese, from 1491 onward, acquired influence over the Bantu-Negro inhabitants, and in the early part of the 16th century through their efforts Christianity was largely adopted in the native kingdom of Congo. An irruption of cannibals from the interior later in the same century broke the power of this semi-Christian state, and the Portuguese activity was transferred to a great extent farther south, São Paulo de Loanda being founded in 1576. The sovereignty of Portugal over this coast region, except for the mouth of the Congo, has been only once challenged by a European Power, and that was in 1640-48, when the Dutch held the seaports.

Neglecting the comparatively poor and thinly inhabited regions of South Africa, the Portuguese no sooner discovered than they coveted the flourishing cities held by Arabized peoples between Sofala and Cape Guardafui. By 1520 all these Muslim sultanates had been seized by Portugal, Mozambique being chosen as the chief city of her East African possessions. Nor was Portuguese activity confined to the coast-lands. The lower and middle Zambezi valley was explored (16th and 17th centuries), and here the Portuguese found semi-civilized Bantu-Negro tribes, who had been for many years in contact with the coast Arabs. Strenuous efforts were made to obtain possession of the country (modern Rhodesia) known to them as the kingdom or empire of Monomotapa, where gold had been worked by the natives from about the 12th century A.D., and whence the Arabs, whom the Portuguese dispossessed, were still obtaining supplies in the 16th century. Several expeditions were despatched inland from 1569 onward and considerable quantities of gold were obtained. Portugal's hold on the interior, never very effective, weakened during the 17th century, and in the middle of the 18th century ceased with the abandonment of the forts in the Manica district.

At the period of her greatest power Portugal exercised a strong influence in Abyssinia also. In the ruler of Abyssinia (to whose dominions a Portuguese traveller had penetrated before Vasco da Gama's memorable voyage) the Portuguese imagined they had found the legendary Christian king, Prester John, and when the complete overthrow of the native dynasty and the Christian religion was imminent by the victories of Mohammedan invaders, the exploits of a band of 400 Portuguese under Christopher da Gama during 1541-43 turned the scale in favour of Abyssinia and had thus an enduring result on the future of north-east Africa. After da Gama's time Portuguese Jesuits resorted to Abyssinia. While they failed in their efforts to convert the Abyssinians to Roman Catholicism they acquired an extensive knowledge of the country. Pedro Paez in 1615, and, ten years later, Jeronimo Lobo, both visited the sources of the Blue Nile. In 1663 the Portuguese, who had overstayed their welcome, were expelled from the Abyssinian dominions. At this time Portuguese influence on the Zanzibar coast was waning before the power of the Arabs of Muscat, and by 1730 no point on the east coast north of Cape Delgado was held by Portugal.

The English and the Dutch. — It has been seen that Portugal took no steps to acquire the southern part of the continent. To the Portuguese the Cape of Good Hope was simply a landmark on the road to India, and mariners of other nations who followed in their wake used Table Bay only as a convenient spot wherein to refit on their voyage to the East. By the beginning of the 17th century the bay was much resorted to for this purpose,

¹This river was called by the Portuguese the Zaire. They appear to have made no attempt to trace its course beyond the rapids which stop navigation from the sea.

chiefly by English and Dutch vessels. In 1620, with the object of forestalling the Dutch, two officers of the East India Company, on their own initiative, took possession of Table Bay in the name of King James, fearing otherwise that English ships would be "frustrated of watering but by licence." Their action was not approved in London, and the proclamation they issued remained without effect. The Netherlands profited by the apathy of the English. On the advice of sailors who had been shipwrecked in Table Bay the Netherlands East India Company, in 1651, sent out a fleet of three small vessels under Jan van Riebeeck which reached Table Bay on April 6, 1652, when, 164 years after its discovery, the first permanent white settlement was made in South Africa. The Portuguese, whose power in Africa was already waning, were not in a position to interfere with the Dutch plans, and England was content to seize the island of St. Helena as her half-way house to the East.' In its inception the settlement at the Cape was not intended to become an African colony, but was regarded as the most westerly outpost of the Dutch East Indies. Nevertheless, despite the paucity of ports and the absence of navigable rivers, the Dutch colonists, freed from any apprehension of European trouble by the friendship between Great Britain and Holland and leavened by Huguenot blood, gradually spread eastward.

MODERN EXPLORATION

During the 18th century there is little to record in the history of Africa. The nations of Europe, engaged in the later half of the century in almost constant warfare and struggling for supremacy in America and the East, to a large extent lost their interest in the continent. Only on the west coast was there keen rivalry, and here the motive was the securance of trade rather than territorial acquisitions. In this century the slave trade reached its highest development, the trade in gold, ivory, gum, and spices being small in comparison. In the interior of the continent—Portugal's energy being expended—no interest was shown, the nations with establishments on the coast "taking no further notice of the inhabitants or their land than to obtain at the easiest rate what they procure with as little trouble as possible, or to carry them off for slaves to their plantations in America" (*Encyclopædia Britannica*, 3rd. ed. 1797). Even the scanty knowledge acquired by the ancients and the Arabs was in the main forgotten or disbelieved. It was the period when—

Geographers, in Afric maps,
With savage pictures filled their gaps,
And o'er unhabitable downs
Placed elephants for want of towns.

(Poetry, a Rhapsody. By Jonathan Swift.)

The prevailing ignorance may be gauged by the statement in the third edition of the *Encyclopædia Britannica* that "the Gambia and Senegal rivers are only branches of the Niger." But the closing years of the 18th century, which witnessed the partial awakening of the public conscience of Europe to the iniquities of the slave trade, were also notable for the revival of interest in inner Africa. A society, the African Association,² was formed in London in 1788 for the exploration of the interior of the continent. The era of great discoveries had begun a little earlier in the famous journey (1770-72) of James Bruce through Abyssinia and Sennar, during which he determined the course of the Blue Nile. But it was through the agents of the African Association that knowledge was gained of the Niger regions. The Niger was reached by Mungo Park, who travelled by way of the Gambia, in 1795. Park, on a second journey in 1805, passed Timbuktu and descended the Niger to Bussa, where he lost his life, having just failed to solve the question as to where the river reached the ocean. (This problem was ultimately solved by Richard Lander and his brother in 1830.) The first scientific explorer of South-East Africa, Dr. Francisco de Lacerda, a Portu-

France acquired, as stations for her ships on the voyage to and from India, settlements in Madagascar and the neighbouring islands. The first settlement was made in 1642.

²The Association, in 1831, was merged in the Royal Geographical Society.

gueuse, also lost his life in that country. Lacerda travelled up the Zambezi to Tete, going thence towards Lake Mweru, near which he died in 1798. The first recorded crossing of Africa was accomplished between the years 1802 and 1811 by two half-caste Portuguese traders, Pedro Baptista and A. José, who passed from Angola eastward to the Zambezi.

Although the Napoleonic wars distracted the attention of Europe from exploratory work in Africa, those wars nevertheless exercised great influence on the future of the continent, in both Egypt and South Africa. The occupation of Egypt (1798-1803) first by France and then by Great Britain, resulted in an effort by Turkey to regain direct control over that country,¹ followed in 1811 by the establishment, under Mohammed Ali, of an almost independent state, and the extension of Egyptian rule over the eastern Sudan (from 1820 onward). In South Africa the struggle with Napoleon caused Great Britain to take possession of the Dutch settlements at the Cape, and in 1814 Cape Colony, which had been continuously occupied by British troops since 1806, was formally ceded to the British crown.

The close of the European conflicts with the battle of Waterloo was followed by vigorous efforts on the part of the British Government to become better acquainted with Africa, and to substitute colonization and legitimate trade for the slave traffic, declared illegal for British subjects in 1807 and abolished by all other European Powers by 1836. To West Africa Britain devoted much attention. The slave trade abolitionists had already, in 1788, formed a settlement at Sierra Leone, on the Guinea coast, for freed slaves, and from this establishment grew the colony of Sierra Leone,² long notorious, by reason of its deadly climate, as "The White Man's Grave." Farther east the establishments on the Gold Coast began to take a part in the politics of the interior, and the first British mission to Kumasi, despatched in 1817, led to the assumption of a protectorate over the maritime tribes heretofore governed by the Ashanti.

An expedition sent in 1816 to explore the Congo from its mouth did not succeed in getting beyond the rapids which bar the way to the interior, but in the central Sudan much better results were obtained. In 1823 three English travellers, Walter Oudney, Dixon Denham, and Hugh Clapperton, reached Lake Chad from Tripoli—the first white men to reach that lake. The partial exploration of Bornu and the Hausa states by Clapperton, which followed, revealed the existence of large and flourishing cities and a semi-civilized people in a region hitherto unknown. The discovery in 1830 of the mouth of the Niger by Clapperton's servant, Lander, already mentioned, had been preceded by the journeys of Maj. A. G. Laing (1826) and René Caillié (1827) to Timbuktu, and was followed (1832-33) by the partial ascent of the Benue affluent of the Niger by MacGregor Laird. In 1841 a disastrous attempt was made to plant a white colony on the lower Niger, an expedition (largely philanthropic and anti-slavery in its inception) which ended in utter failure. Nevertheless, from that time British traders remained on the lower Niger, their continued presence leading ultimately to the acquisition of political rights over the delta and the Hausa states by Great Britain.³ Another endeavour by the British Government to open up commercial relations with the Niger countries resulted in the addition of a vast amount of information concerning the countries between Timbuktu and Lake Chad, owing to the labours of Heinrich Barth (1850-55), originally a subordinate, but the only surviving member of the expedition sent out.

Meantime considerable changes had been made in other parts of the continent, the most notable being the occupation of Algiers by France in 1830, an end being thereby put to the piratical proceedings of the Barbary States; the continued expansion southward of Egyptian authority, with the consequent additions to the knowledge of the Nile; and the establishment of independent states (Orange Free State and the Transvaal) by Dutch

¹The Mamelukes, whom the Turks had overthrown in the 16th century, had regained practically independent power.

³The first territorial acquisition made by Great Britain in this region was in 1851, when Lagos Island was annexed.

farmers (Boers) dissatisfied with British rule in Cape Colony. Natal, so named by Vasco da Gama, had been made a British colony (1843), the attempt of the Boers to acquire it being frustrated. The city of Zanzibar, on the island of that name, founded in 1832 by Seyyid Said of Muscat, rapidly attained importance, and Arabs began to penetrate to the great lakes of East Africa,⁴ concerning which little more was known (and less believed) than in the time of Ptolemy. Accounts of a vast inland sea, and the discovery in 1848-49, by the missionaries Ludwig Krapf and J. Rebmann, of the snow-clad mountains of Kili-manjaro and Kenya, stimulated in Europe the desire for further knowledge.

Livingstone and Stanley. — At this period, the middle of the 19th century, Protestant missions were carrying on active propaganda on the Guinea coast, in South Africa, and in the Zanzibar dominions. Their work, largely beneficent, was being conducted in regions and among peoples little known, and in many instances missionaries turned explorers and became pioneers of trade and empire. One of the first to attempt to fill up the remaining blank spaces in the map was David Livingstone, who had been engaged since 1840 in missionary work north of the Orange. In 1849 Livingstone crossed the Kalahari desert from south to north and reached Lake Ngami, and between 1851 and 1856 he traversed the continent from west to east, making known the great waterways of the upper Zambezi. During these journeyings Livingstone discovered, Nov. 1855, the famous Victoria Falls, so named after the queen of Great Britain. In 1858-64 the lower Zambezi, Shiré, and Lake Nyasa were explored by Livingstone, Nyasa having been first reached by the confidential slave of Antonio da Silva Porto, a Portuguese trader established at Bihé in Angola, who crossed Africa during 1853-56 from Benguela to the mouth of the Rovuma. While Livingstone circumnavigated Nyasa, the more eortherly lake, Tanganyika, had been visited (1858) by Richard Burton and J. H. Speke, and the last named had sighted Victoria Nyanza. Returning to East Africa with J. A. Grant, Speke reached, in 1862, the river which flowed from Victoria

FROM "HOW I FOUND LIVINGSTONE," BY H. M. STANLEY, BY PERMISSION OF SAMPSON, LOW, MARSTON & CO., LTD., AND OF CHARLES SCRIBNER'S SONS

STANLEY GREET'S LIVINGSTONE WITH "DR. LIVINGSTONE, I PRESUME"
After a hazardous journey of 295 days Stanley, on Nov. 10, 1871, reached Ujiji, where he found Dr. Livingstone, sick, emaciated and depressed

Nyanza and, following it (in the main) down to Egypt, had the distinction of being the first man to read the riddle of the Nile. In 1864 another Nile explorer, Samuel Baker, discovered the Albert Nyanza, the chief western reservoir of the river. In 1866 Livingstone began his last great journey, in which he made known Lakes Mweru and Bangweulu and discovered the Lualaba (the upper part of the Congo), but died (1873) before he had been able to demonstrate its ultimate course, believing indeed that the Lualaba belonged to the Nile system. Livingstone's lonely death in the heart of Africa evoked a keener desire than ever to complete the work he left undone. H. M. Stanley, who had in 1871

⁴As early as 1848 an Arab from Zanzibar journeying across the continent had arrived at Benguela.

succeeded in finding and succouring Livingstone, started again for Zanzibar in 1874, and in the most memorable of all exploring expeditions in Africa circumnavigated Victoria Nyanza and Tanganyika, and, striking farther inland to the Lualaba, followed that river down to the Atlantic ocean—reached in Aug. 1877—and proved it to be the Congo. In South Africa, Karl Mauch in 1871 discovered the ruins of the great Zimbabwe in Mashonaland; and in the following year F. C. Selous began his journeys over South Central Africa.

Explorers were active also in other parts of the continent. Southern Morocco, the Sahara, and the Sudan were traversed in many directions between 1860 and 1875 by Gerhard Rohlfs, Georg Schweinfurth and Gustav Nachtigal. These travellers not only added considerably to geographical knowledge, but obtained invaluable information concerning the people, languages, and natural history of the countries in which they sojourned.¹ Among the discoveries of Schweinfurth was one that confirmed the Greek legends of the existence beyond Egypt of a pygmy race. But the first discoverer of the dwarf races of Central Africa was Paul du Chaillu, who found them in the Ogowé district of the west coast in 1865, five years before Schweinfurth's first meeting with the pygmies; du Chaillu having previously, as the result of journeys in the Gabun country between 1855 and 1859, made popular in Europe the knowledge of the existence of the gorilla, perhaps the gigantic ape seen by Hanno the Carthaginian, and whose existence, up to the middle of the 19th century, was thought to be as legendary as that of the pygmies of Aristotle.

Stanley's great journey down the Congo in 1875-76 initiated a new era in African exploration, and since 1875 the map has been filled with authentic topographical details. Within their respective spheres of influence each Power undertook detailed surveys, and the most solid of the latest accessions to knowledge have resulted from the labours of hard-working colonial officials toiling individually in obscurity.

In 1877 an important expedition was sent out by the Portuguese Government under Serpa Pinto, Brito Capello, and Roberto Ivens for the exploration of the interior of Angola. The first named made his way by the head-streams of the Kubango to the upper Zambezi, which he descended to the Victoria Falls, proceeding thence to Pretoria and Durban. Capello and Ivens confined their attention to the south-west Congo basin, where they disproved the existence of Lake Aquilunda, which had figured on the maps of that region since the 16th century. In a later journey (1884-85) Capello and Ivens crossed the continent from Mossamedes to the mouth of the Zambezi, adding considerably to the knowledge of the borderlands between the upper Congo and the upper Zambezi. More important results were obtained by the German travellers, Paul Pogge and Hermann von Wissmann, who (1880-82) passed through previously unknown regions beyond Muata Yanvo's kingdom, and reached the upper Congo at Nyangwe, whence Wissmann made his way to the east coast. In 1884-85 a German expedition under Wissmann solved the most important geographical problem relating to the southern Congo basin by descending the Kasai, the largest southern tributary, which contrary to expectation, proved to unite with the Kwango and other streams before joining the main river. Further additions to the knowledge of the Congo tributaries were made at the same time by the Rev. George Grenfell, a Baptist missionary, who (accompanied in 1885 by K. von François) made several voyages in the steamer "Peace," especially up the great Ubangi, ultimately proved to be the lower course of the Welle, discovered in 1870 by Schweinfurth.

East Africa.—The first new journey of importance in East Africa was made (1878-80) on behalf of the British African Exploration committee by Joseph Thomson, who after the death of his leader, Keith Johnston, made his way from the coast to the north end of Nyasa, thence to Tanganyika, on both sides of which he broke new ground, sighting the north end of Lake Rukwa on the east. In 1882-84 the French naval lieutenant, Victor Giraud, proceeded by the north of Nyasa to Lake Bang-

¹Another great traveller of this stamp was Wilhelm Junker, who spent the greater part of the period 1875-86 in the east central Sudan.

weulu, of which he made the first fairly correct map. North of the Zanzibar-Tanganyika route a large area of new ground was opened in 1883-84 by Thomson, who traversed the whole length of the Masai country to Lake Baringo and Victoria Nyanza, shedding the first clear light on the great East African rift-valley and neighbouring highlands, including Mts. Kenya and Elgon. A great advance in the region between Victoria Nyanza and Abyssinia was made in 1887-89 by the Austrians, Count Samuel Teleki and Lieut. Ludwig von Höhnel, who discovered the large Basso Norok, now known as Lake Rudolf, till then only vaguely indicated on the map as Samburu. At this time Somaliland was being opened up by English and Italian travellers. In 1883 the brothers F. L. and W. D. James penetrated from Berbera to the Webi Shebeli; in 1892 Vittorio Bottego (afterwards murdered in the Abyssinian highlands) started from Berbera and reached the upper Juba, which he explored to its source. The first person to cross from the Gulf of Aden to the Indian Ocean was an American, A. Donaldson Smith, who in 1894-95 explored the head-streams of the Webi Shebeli and also explored the Omo, the feeder of Lake Rudolf.

In the region north-west of Victoria Nyanza the greatest additions to geographical knowledge were made by H. M. Stanley in his last expedition, undertaken for the relief of Emin Pasha. The expedition set out in 1887 by way of the Congo and made its way, encountering immense difficulties, through the great equatorial forest, the character and extent of which were thus for the first time brought to light. The return was made to the east coast and resulted in the discovery of the great snowy range of Ruwenzori or Runsoro, and the confirmation of the existence of a third Nile lake discharging its waters into the Albert Nyanza by the Semliki river.

North and West Africa.—Great activity was also displayed in completing the work of earlier explorers in North and West Africa. Morocco was in 1883-84 the scene of important explorations by de Foucauld, a Frenchman who, disguised as a Jew, crossed and re-crossed the Atlas and supplied the first trustworthy information as to the orography of many parts of the chain. In 1887-89 Louis Gustave Binger, a French officer, made a great journey through the countries enclosed in the Niger bend, and in 1890-92 Col. P. F. Monteil went from St. Louis to Say, on the Niger, thence through Sokoto to Bornu and Lake Chad, whence he crossed the Sahara to Tripoli. Meantime explorers had been busy in the region between Lake Chad, the Gulf of Guinea, and the Congo. The Sanga, one of the principal northern tributaries of the Congo, was reached from the north by Lieut. Louis Mizon, a French naval officer, who drew the first line of communication between the Benue and the Congo (1890-92). In 1890 Paul Crampel, who in the previous year had explored north of the Ogowé, undertook a great expedition from the Ubangi to the Shari, but was attacked and killed, with several of his companions, on the borders of the Bagirmi. Several other expeditions followed, and in 1896 Emile Gentil reached the Shari, launched a steamer on its waters and pushed on to Lake Chad. Early in 1900 Lake Chad was also reached by F. Foureaux, a French traveller, who had already devoted 12 years to the exploration of the Sahara, and who on this occasion had crossed the desert from Algeria and had reached the lake *via* Air and Zinder.

Equatorial Africa.—The last ten years of the 19th century also witnessed many interesting expeditions in east Central Africa. In 1891 Emin Pasha, accompanied by Dr. F. Stuhlmann, made his way south of Victoria Nyanza to the western Nile lakes, visiting for the first time the southern and western shores of Albert Edward. Stuhlmann also ascended the Ruwenzori range to a height of over 13,000 feet. In the same year Dr. O. Baumann, who had already done good work in Usambara, near the coast, started on a more extended journey through the region of steppes between Kilimanjaro and Victoria Nyanza, afterwards exploring the head-streams of the Kagera, the ultimate sources of the Nile. In the steppe region referred to he discovered two new lakes, Manyara and Eiassi, occupying parts of the East African valley system. This region was again traversed in 1893-94 by Count von Götzen, who continued his route westwards to Lake

Kivu, north of Tanganyika, which, though heard of by Speke over 30 years before, had never yet been visited. He also reached for the first time the line of volcanic peaks north of Kivu, one of which he ascended, afterwards crossing the great equatorial forest by a new route to the Congo and the west coast. Valuable scientific work was done in 1893 by Dr. J. W. Gregory, who ascended Mt. Kenya to a height of 16,000 feet. In 1893-94 Scott Elliot reached Ruwenzori by way of Uganda, returning by Tanganyika and Nyasa, and in 1896 C. W. Hobley made the circuit of the great mountain Elgon, north-east of Victoria Nyanza. In 1890 Mt. Kenya was ascended to its summit by a party under H. J. Mackinder. The exploration of Mt. Kilimanjaro has been the special work of Dr. Hans Meyer, who first directed his attention to it in 1887. The region south of Abyssinia proper and north of Lake Rudolf, being largely the basin of the Sobat tributary of the Nile, was traversed by several explorers, among whom may be mentioned Capt. M. S. Wellby, who in 1898-99 explored the chain of small lakes in south-east Abyssinia, pushed on to Lake Rudolf, and thence traversed hitherto unknown country to the lower Sobat. Other valuable expeditions of exploration and surveying were conducted by Donaldson Smith (1899-1900), Maj. H. H. Austin (1899-1901), Maj. A. St. H. Gibbons (1895-96, 1898-900), Commander B. Whitehouse (1904-06), Lieut. Boyd Alexander, Sir H. H. Johnston, Maj. Powell-Cotton, and the duke of Abruzzi.

The first journey through the whole length of the continent was accomplished in the last two years of the century when a young Englishman, E. S. Grogan, starting from Cape Town, reached the Mediterranean by way of the Zambezi, the central line of lakes and the Nile. Other travellers followed in Grogan's footsteps, among the first Maj. Gibbons.

Additions to topographical knowledge were made from about 1890 onwards by the international commissions which traced the frontiers of the protectorates of the European powers. The Anglo-French commission in 1903 traced the Nigerian frontier from the Niger to Lake Chad, and in 1903-04 the Anglo-German commission fixed the Cameroon boundary between Yola, on the Benue, and Lake Chad. In 1901-02 a German Congolese commission surveyed Lake Kivu and the volcanic region north of the lake, while the Anglo-German boundary commission of 1902-04 surveyed the valley of the lower Kagera and fixed the exact position of Albert Edward Nyanza.

At the same time administrative needs forced the governments concerned to take in hand the survey of the countries under their protection. Before the close of the first decade of the 20th century tolerably accurate maps had been made of the German colonies, of a considerable part of West Africa, the Algerian Sahara, and the Anglo-Egyptian Sudan, mainly by military officers.

PARTITION AMONG EUROPEAN POWERS

In the last quarter of the 19th century the map of Africa was transformed. After the discovery of the Congo the story of exploration takes second place; the continent becomes the theatre of European expansions. Lines of partition, drawn often through trackless wildernesses, marked out the possessions of Germany, France, Great Britain, and other Powers. Railways penetrated the interior, vast areas were opened up to civilized occupation, and from ancient Egypt to the Zambezi the continent was startled into new life.

Before 1875 the only European Powers with any considerable interest in Africa were Britain, Portugal, and France.

In North Africa the Turks had (in 1835) assumed direct control of Tripoli, while Morocco had fallen into a state of decay though retaining its independence. A remarkable change had taken place in Egypt, where the Khedive Ismail had introduced a somewhat fantastic imitation of European civilization. In addition Ismail had conquered Darfur, annexed Harar and the Somali ports on the Gulf of Aden, was extending his power southward to the equatorial lakes, and even contemplated reaching the Indian ocean. The Suez canal, opened in 1869, had a great influence on the future of Africa, as it again made Egypt the highway to the East, to the detriment of the Cape route.

In 1875 other European nations—with the occasional exception of Great Britain—were indifferent to Portugal's pretensions, and her estimate of her African empire as covering over 700,000sq.m. was not challenged. But the area under effective control of Portugal at that time did not exceed 40,000 sq. miles. Great Britain then held some 250,000sq.m., France about 170,000sq.m., and Spain 1,000sq. miles. The total area of Africa ruled by Europeans did not exceed 1,271,000sq.m.; roughly one-tenth of the continent.

Egypt and the Egyptian Sudan, Tunisia, and Tripoli were subject in differing ways to the overlordship of the sultan of Turkey, and with these may be ranked, in the scale of organized governments, the three principal independent states, Morocco, Abyssinia, and Zanzibar, as also the negro republic of Liberia. There remained, apart from the Sahara, roughly one-half of Africa, lying mostly within the tropics, inhabited by a multitude of tribes and peoples living under various forms of government and subject to frequent changes in respect of political organization. In the whole of this vast region the negro and Negro-Bantu races predominated, for the most part untouched by Mohammedanism or Christian influences. The larger States and Sultanates possessed neither the means nor the inclination to extend their influence beyond their own borders. The exploitation of Africa continued to be entirely the work of alien races.

Leopold II.—The causes which led to the partition of Africa are to be found in the economic and political state of western Europe at the time. Germany, strong and united as the result of the Franco-Prussian War of 1870, was seeking new outlets for her energies—new markets for her growing industries, and with the markets, colonies. For different reasons the war of 1870 was also the starting-point for France in the building up of a new colonial empire. In her endeavour to regain the position lost in that war France had to look beyond Europe. To the two causes mentioned must be added others. Great Britain and Portugal, when they found their interests threatened, bestirred themselves, while Italy also conceived it necessary to become an African Power. The struggle was not, however, precipitated by the action of any of the great Powers but by the ambitious projects of Leopold II., king of the Belgians, who, in Sept. 1876, took what may be described as the first definite step in the modern partition of the continent. He summoned to a conference at Brussels representatives of Great Britain, Belgium, France, Germany, Austria-Hungary, Italy, and Russia, to deliberate on the best methods to be adopted for the exploration and civilization of Africa, and the opening up of the interior of the continent to commerce and industry. The conference was entirely unofficial. The delegates who attended neither represented nor pledged their respective governments. Their deliberations lasted three days and resulted in the foundation of "The International African Association," with its headquarters at Brussels. It was further resolved to establish national committees in the various countries represented, which should collect funds and appoint delegates to the International Association. The central idea appears to have been to put the exploration and development of Africa upon an international footing. But it quickly became apparent that this was an unattainable ideal. The national committees were soon working independently of the International Association, and the association itself passed through a succession of stages until it became purely Belgian in character, and at last developed into the Congo Free State, under the personal sovereignty of King Leopold.

Stanley's journey down the Congo had stirred ambition in other capitals than Brussels. France had always taken a keen interest in West Africa, and in the years 1875 to 1878 Savorgnan de Brazza had carried out a successful exploration of the Ogowe river to the south of the Gabun. In Portugal, too, the discovery of the Congo, with its magnificent unbroken waterway of more than a thousand miles into the heart of the continent, served to revive the languid energies of the Portuguese, who promptly began to furbish up claims whose age was in inverse ratio to their validity. In Jan. 1879 Stanley left Europe as the accredited agent of King Leopold and the Congo committee. De Brazza returned to Africa at the beginning of 1880, and while Stanley,

on behalf of King Leopold, was making treaties and founding stations along the southern bank of the river, de Brazza and other French agents were equally busy on the northern bank.

The Scramble for Territory.—Although the Transvaal between the years 1877 and 1881 had become and ceased to be British, in other respects British territory had been extended in South Africa. And in 1883, in order that the trade route to the interior might be kept open for British expansion northward from the Cape Colony, negotiations for the settlement of the western border of the restored republic were opened in London. The border was defined in the Convention of London (Feb. 27, 1884), and at the same time the Bechuana peoples were taken under British protection. Subsequently, March 23, 1885, the Bechuanaland Protectorate was extended northwards to 22° S. latitude, and westward to 20° E. longitude. (See SOUTH AFRICA, TRANSVAAL, etc.) Before the convention was signed measures had been taken—without British opposition—at Berlin to establish German authority on the west coast between the Orange river and the Portuguese province of Angola; and on Sept. 8, 1884, the German Government intimated to the British Government "that the west coast of Africa from 26° S. latitude to Cape Frio, excepting Walfish Bay, had been placed under the protection of the German emperor." In the same year, through the activities of Gustav Nachtigal, Togo and the Cameroon district were placed under German protection. Before either of these events had occurred Great Britain had become alive to the fact that she could no longer dally with the subject, if she desired to consolidate her possessions in West Africa. The British Government had again and again refused to accord native chiefs the protection they demanded. The Cameroon chiefs had several times asked for British protection, and always in vain. But at last it became apparent, even to the official mind, that rapid changes were being effected in Africa, and on May 16, 1884, Edward Hyde Hewett, British consul, received instructions to return to the west coast and to make arrangements for extending British protection over certain regions. He arrived too late to save either Togoland or Cameroon, in the latter case arriving five days after King Bell and the other chiefs on the river had signed treaties with Nachtigal. But the British consul was in time to secure the delta of the River Niger and the Oil rivers district, extending from Rio del Rey to the Lagos frontier, where for a long period British traders had held almost a monopoly of the trade.

Meanwhile the French Government was strenuously endeavouring to extend France's influence in West Africa, in the countries lying behind the coast-line. During the year 1884 no fewer than 42 treaties were concluded with native chiefs, an even larger number having been concluded in the previous twelve-month. In this fashion France was pushing on towards Timbuktu, in steady pursuance of the policy which resulted in surrounding all the old British possessions in West Africa with a continuous band of French territory. On the lower Niger, however, in 1877, Mr. Goldie Taubman (afterwards Sir George Taubman Goldie) conceived the idea of establishing a settled government. Through his efforts the various trading firms formed themselves in 1879 into the "United African Company," and the foundations were laid of something like settled administration. An application was made to the British Government for a charter in 1881, and the capital of the company increased to a million sterling. Henceforth the company was known as the "National African Company," and it was acknowledged that its object was not only to develop the trade of the lower Niger, but to extend its operations to the middle reaches of the river, and to open up direct relations with the great Fula empire of Sokoto and the smaller states associated with Sokoto under a somewhat loosely defined suzerainty.

In North and East Africa also events had moved since 1875. In 1881 France, with the consent of the Powers, undertook to reorganize the finances and administration of the meagre remains of the once splendid and powerful kingdom of Tunis. Two years later, with Lord Granville's circular despatch of Jan. 3, 1883, England's long and onerous tutelage of Egypt began. (See EGYPT.) In East Africa, north of the Portuguese possessions, where the sultan of Zanzibar was the most considerable native

potentate, Germany was secretly preparing the foundations of German East Africa. Italy, too, had obtained a footing on the African continent. The Rubattino Steamship Company as far back as 1870 had bought the port of Assab as a coaling station, but it was not until 1882 that it was declared an Italian colony. This was followed by the conclusion of a treaty with the sultan of Assab, chief of the Danakil, signed on March 11, 1883, and subsequently approved by the king of Shoa, whereby Italy obtained the cession of part of Ablis (Aussa) on the Red sea, Italy undertaking to protect with her fleet the Danakil littoral. One other event must be recorded. The king of the Belgians had been driven to the conclusion that, if his African enterprise was to obtain any measure of permanent success, its international status must be recognized; and negotiations for the purpose were opened with various governments.

The Berlin Conference 1884–85.—With these events there had grown up a general conviction that it would be desirable for the Powers interested in Africa to come to some agreement as to "the rules of the game," and to define their respective interests as far as practicable. A treaty between Britain and Portugal, giving undue recognition to Portuguese territorial claims, which was signed by Lord Granville on Feb. 26, 1884, but not ratified in view of the protests it had evoked, brought this sentiment to a head; and it was agreed to hold an international conference on African affairs. The conference assembled at Berlin on Nov. 15, 1884, and after protracted deliberations the "General Act of the Berlin Conference" was signed by the representatives of all the Powers attending the conference, on Feb. 26, 1885. The Powers represented were Germany, Austria-Hungary, Belgium, Denmark, Spain, the United States, France, Great Britain, Italy, Holland, Portugal, Russia, Sweden and Norway, and Turkey. Ratifications were deposited by all the signatory Powers with the exception of the United States. The General Act dealt with six specific subjects: (1) Freedom of trade in the basin of the Congo, (2) the slave trade, (3) neutrality of territories in the basin of the Congo, (4) navigation of the Congo, (5) navigation of the Niger, and (6) rules for future occupation on the coasts of the African continent. For the present purpose, however, the results effected by the Berlin Act may be summed up as follows. The signatory Powers undertook that any fresh act of taking possession on any portion of the African coast must be notified by the Power taking possession, or assuming a protectorate to the other signatory Powers. It was further provided that any such occupation to be valid must be effective. It is also noteworthy that the first reference in an international act to the obligations attaching to "spheres of influence" is contained in the Berlin Act.

Before the General Act was signed the International Association of the Congo was recognized by all the signatory Powers, with the not very important exception of Turkey. Two months later, in April 1885, King Leopold, with the sanction of the Belgian legislature, formally assumed the headship of the new state; and on Aug. 1 in the same year his Majesty notified the powers that from that date the "Independent State of the Congo" declared that "it shall be perpetually neutral" in conformity with the provisions of the Berlin Act. Thus was finally constituted the Congo Free State, under the sovereignty of King Leopold, though the boundaries claimed for it at that time were considerably modified by subsequent agreements.

Partition Treaties.—In the 11 years that remained of the 19th century the work of partition was practically completed. The international agreements which determined in the main the limits of the possessions of the various powers are:—

I. The agreement of July 1, 1890, between Great Britain and Germany defining their spheres of influence in East, West, and South-west Africa. This agreement was the most comprehensive of all the "deals" in African territory, and included in return for the recognition of a British protectorate over Zanzibar the cession of Heligoland to Germany.

II. The Anglo-French declaration of Aug. 5, 1890, which recognized a French protectorate over Madagascar, French influence in the Sahara, and British influence between the Niger and Lake Chad.

PAINTED FOR THE ENCYCLOPEDIA BRITANNICA

AFRICAN MAMMALS, BY PAUL BRANSOM

Upper panel: **Antelopes.** There are about 150 kinds of antelopes, some nine-tenths of which are found in Africa. In size they range from pygmy forms, as the dik-dik, only about a foot high, to oxlike species, as the eland, which attains a weight of 1,500 pounds. **Left to right:** Springbuck; Sable Antelope; Kudu; **Beatrix** Antelope; Eland; Dikdik

Centre panel, top row, left to right: Giraffe, the tallest of living animals, sometimes 18 ft. high measured from its head to the ground; Hartbeest; Waterbuck; Grant Zebra; Roan Antelope (between zebras); **Palla** or Impala; White-bearded Gnu; White-tailed Gnu. Of these the hartebeest, waterbuck, **palla** and the gnus are forms of antelopes. Right centre: **Cape**

Buffalo, a powerful animal allied to the ox, dangerous when wounded. **Lower row, left to right:** Lion and **lloiness**, the most powerful of African beasts of prey; Grey Jackal; Spotted Hyena

Lower panel, left to right: Hippopotamus, the largest aquatic hoofed mammal, sometimes reaching a weight of four tons; African Elephant, the largest land mammal, differing in appearance from the Asiatic elephant chiefly in its much larger ears; Pygmy Hippopotamus, about 2½ ft. high, native to Liberia; Black Rhinoceros, a fierce fighter when brought to bay; African Wart-hog, a grotesque kind of wild swine, taking its name from the presence of large warty protuberance on the face

III. The Anglo-Portuguese treaty of June 11, 1891, whereby the Portuguese possessions of the west and east coasts were separated by a broad belt of British territory, extending north to Lake Tanganyika.

IV. The Franco-German convention of March 15, 1894, by which the Central Sudan was left to France (this region by an Anglo-German agreement of Nov. 15, 1893, having been recognized as in the German sphere). By this convention France was able to effect a territorial junction of her possessions in North and West Africa with those in the Congo region.

V. Protocols of March 24 and April 15, 1891, for the demarcation of the Anglo-Italian spheres in East Africa.

VI. The Anglo-French convention of June 14, 1898, for the delimitation of the possessions of the two countries west of Lake Chad, with the supplementary declaration of March 21, 1899, whereby France recognized the upper Nile valley as in the British sphere of influence.

The Congo State.—The Congo Free State, which occupied, geographically, a central position, may serve as the starting-point for the story of the partition after the Berlin Conference. By his will, dated Aug. 2, 1889, King Leopold made Belgium formally heir to the sovereign rights of the Congo Free State. Proposals for Belgium to assume responsibility for its administration were made unsuccessfully in 1895 and 1901. Later, the agitation in Great Britain and America against the Congo system of government and the admissions of an official commission of enquiry concerning its maladministration strengthened the movement in favour of transfer, until in 1905 Leopold II. was forced to yield, and the annexation treaty was approved by the Belgian parliament. Thus the Congo state, after an existence of 24 years as an independent power, became a Belgian colony. (See CONGO, FREE STATE and BELGIAN CONGO.)

French and British Rivalry.—After the capture of Khartoum and the death of Gen. C. G. Gordon, the Sudan was abandoned to the dervishes. The Egyptian frontier was withdrawn to Wadi Halfa, and the vast provinces of Kordofan, Darfur, and the Bahrel-Ghazal were given over to dervish tyranny and misrule. It was obvious that Egypt would sooner or later seek to recover her position in the Sudan, as the command of the upper Nile was recognized as essential to her continued prosperity. But the international position of the abandoned provinces was by no means clear. The British Government, by the Anglo-German agreement of July 1890, had secured the assent of Germany to the statement that the British sphere of influence in East Africa was bounded on the west by the Congo Free State and by "the western watershed of the basin of the upper Nile"; but this claim was not recognized either by France or by the Congo Free State. From her base on the Congo, France was busily engaged pushing forward along the northern tributaries of the great river. The desire of France to secure a footing in the upper Nile valley was partly due to her anxiety to extend a French zone across Africa, but it was also to a large extent attributable to the belief, widely entertained in France, that by establishing herself on the upper Nile France could regain the position in Egyptian affairs which she had sacrificed in 1882.

In June 1896 Capt. J. Marchand left France with secret instructions to lead an expedition into the Nile valley. On July 10, 1898, he reached Fashoda, having established a chain of posts en route, and here the French flag was at once raised, and a "treaty" made with the local chief. Meanwhile, in 1896, an Anglo-Egyptian army, under the direction of Sir Herbert (afterwards Lord) Kitchener, had advanced southwards for the reconquest of the Egyptian Sudan. On Sept. 2, 1898, Khartoum was captured, and the khalifa's army dispersed. It was then that news

reached the Anglo-Egyptian commander, from native sources, that there were white men flying a strange flag at Fashoda. The sirdar at once proceeded in a steamer up Nile, and courteously but firmly requested Capt. Marchand to remove the French flag. On his refusal the Egyptian flag was raised close to the French flag, and the dispute was referred to Europe for adjustment between the British and French Governments. A critical situation ensued. Neither Government was inclined to give way, and for a time war seemed imminent. Happily Lord Salisbury was able to announce, on Nov. 4, that France was willing to recognize the British claims, and the incident was finally closed on March 21, 1899, when an Anglo-French declaration was signed, by the terms of which France withdrew from the Nile valley and accepted a boundary line which satisfied her earlier ambition by uniting the whole of her territories in North, West, and Central Africa into a homogeneous whole, while effectually preventing the realization of her dream of a transcontinental empire from west to east.

British and Portuguese Spheres Defined.—In the southern half of the continent, between the years 1885 and 1891, the Portuguese possessions on the west and east coasts were delimited, and Matabeleland and Mashonaland were occupied by the British South Africa Company. (See RHODESIA.) The relations between the British and Portuguese territories were determined by the treaty of June 11, 1891. Apart from defining the British and Portuguese spheres both south and north of the Zambezi, it contained many other provisions relating to trade and navigation, providing, *inter alia*, a maximum transit duty of 3% on imports and exports crossing Portuguese territories on the east coast to the British sphere, freedom of navigation of the Zambezi and Shirè for the ships of all nations, and stipulations as to the making of railways, roads, and telegraphs. Portugal was given both banks of the Zambezi to a point ten miles west of Zumbo—the farthest settlement of the Portuguese on the river. The boundary between the Portuguese sphere of influence on the west coast and the British sphere of influence north of the Zambezi was only vaguely indicated; but it was to be drawn in such a manner as to leave the Barotsi country within the British sphere. Before the conclusion of the treaty the British Government had made certain arrangements for the administration of the large area north of the Zambezi reserved to British influence. On Feb. 1 Sir Harry Johnston was appointed imperial commissioner in Nyasaland, and a fortnight later the British South Africa Company intimated a desire to extend its operations north of the Zambezi. Negotiations followed, and the field of operations of the Chartered Company was, on April 2, 1891, extended so as to cover (with the exception of Nyasaland) the whole of the British sphere of influence north of the Zambezi (afterwards Northern Rhodesia). On May 14 a formal protectorate was declared over Nyasaland, including the Shirè highlands and a belt of territory extending along the whole of the western shore of Lake Nyasa. The name was changed in 1893 to that of the British Central Africa Protectorate, for which designation was substituted in 1907 the more appropriate title of Nyasaland Protectorate.

British and German Rivalry.—In July 1890, the British and German Governments came to an agreement upon the limits of their respective spheres of influence in various parts of Africa, and the boundaries of German South-West Africa were fixed in the position they now hold as those of the territory mandated to the Union of South Africa. These Powers were also the two great rivals on the east coast. Germany, on Dec. 30, 1886, and Great Britain, on June 11, 1891, formally recognized the Rovuma river as the northern boundary of the Portuguese sphere of influence on that coast; but it was to the north of that river, over the vast area of east or east central Africa in which the sultan of Zanzibar claimed to exercise suzerainty, that the struggle between the two rival powers was most acute. By an exchange of notes in Oct.—Nov. 1886, to which the sultan adhered on Dec. 4, 1886, the British and German Governments determined what territories were to be assigned to the sultanate of Zanzibar and agreed to a delimitation of their respective spheres of influence in East Africa. On Sept. 3, 1888, the British East Africa Association

received a charter from the British Government and became the Imperial British East Africa Company. Shortly afterwards the German colony of East Africa was founded. (See KENYA.)

Meanwhile, in the country to the west and north of the British sphere of influence a contest for Uganda had arisen between Karl Peters and the British East Africa Company. The contest was decided in favour of the latter by the Anglo-German Agreement of July 1, 1890. The provisions relating to East Africa were these:—In return for the cession of Heligoland, Lord Salisbury obtained from Germany the recognition of a British protectorate over the dominions of the sultan of Zanzibar, including the islands of Zanzibar and Pemba, but excluding the strip leased to Germany, which was subsequently ceded absolutely to Germany. Germany further agreed to withdraw the protectorate declared over Witu and the adjoining coast up to Kisimayu in favour of Great Britain, and to recognize as within the British sphere of influence the vast area bounded, on the south, by the frontier line laid down in the agreement of 1886, which was to be extended along the first parallel of south latitude across Victoria Nyanza to the frontiers of the Congo Free State, on the west by the Congo Free State and the western watershed of the Nile, and on the north by a line commencing on the coast at the north bank of the mouth of the River Juba, then ascending that bank of the river until it reached the territory at that time regarded as reserved to the influence of Italy¹ in Gallaland and Abyssinia, when it followed the frontier of the Italian sphere to the confines of Egypt. To the south-west of the German sphere in East Africa the boundary was formed by the eastern and northern shore of Lake Nyasa, and round the western shore to the mouth of the Songwe river, from which point it crossed the Nyasa-Tanganyika plateau to the southern end of the last-named lake, leaving the Stevenson road on the British side of the boundary. The effect of this treaty was to remove all serious causes of dispute about territory between Germany and Great Britain in East Africa. It rendered quite valueless Peter's treaty with Mwanga and his promenade along the Tana; it freed Great Britain from any fear of German competition to the northwards, and recognized that her influence extended to the western limits of the Nile valley. But, on the other hand, Great Britain had to relinquish the ambition of connecting her sphere of influence in the Nile valley with her possessions in Central and South Africa. On this point Germany was quite obdurate; and an attempt subsequently made (May 1894) to secure this object by the lease of a strip of territory from the Congo Free State was frustrated by German opposition. (See UGANDA; KENYA, and TAXGAXIKA.)

On March 31 the union jack was raised, and on May 29 a fresh treaty was concluded with King Mwanga placing his country under British protection. A formal protectorate was declared over Cganda proper on June 19, 1894, which was subsequently extended so as to include the countries westwards towards the Congo Free State, eastwards to the British East Africa protectorate and Abyssinia, and northwards to the Anglo-Egyptian Sudan. The British East Africa protectorate was constituted in June 1895, when the Imperial British East Africa Company relinquished all its rights in exchange for a money payment, and the administration was assumed by the imperial authorities. On April 1, 1902, the eastern province of the Uganda protectorate was transferred to the British East Africa protectorate, which thus secured control of the whole length of the so-called Uganda railway, and at the same time were successful in obtaining access to the Victoria Nyanza.

¹At this period negotiations between Great Britain and Italy had begun but were not concluded.

Italy.—Early in the 'eighties as already seen, Italy had obtained her first formal footing on the African coast at the Bay of Xssab (Aussa) on the Red Sea. In 1885 the troubles in which Egypt found herself involved compelled the khedive and his advisers to loosen their hold on the Red Sea littoral, and, with the tacit approval of Great Britain, Italy took possession of Massawa and other ports on that coast. In May 1889 the Italians concluded with the negus Menelek the Treaty of Uccialli which, besides settling the frontiers between Abyssinia and the Italian sphere, contained the following article:—

XVII. His Majesty the King of Kings of Ethiopia consents to avail himself of the Italian Government for any negotiations which he may enter into with the other Powers or Governments.

In Italy and by other European governments this article was generally regarded as establishing an Italian protectorate over Abyssinia; but this interpretation was never accepted by the emperor Menelek, and at no time did Italy succeed in establishing any very effective control over Abyssinian affairs. By May 1894 under various agreements, the Italian and British Governments had fixed the northern limit of the Italian sphere as running from Ras Kasar on the Red Sea to the intersection of the Blue Nile with 35° E. longitude, and settled the boundary between their respective spheres on the Somali coast. But while Great Britain was thus lending her sanction to Italy's ambitious schemes the Abyssinian emperor was becoming more and more incensed at Italy's pretensions to exercise a protectorate over Ethiopia. In 1893 Menelek denounced the Treaty of Uccialli, and eventually, in a great battle, fought at Adowa on March 1, 1896, the Italians were disastrously defeated. By the subsequent Treaty of Addis Ababa, concluded on Oct. 26, 1896, the whole of the country to the south of the Mareb, Belesa, and Muna rivers was restored to Abyssinia, and Italy acknowledged the absolute independence of Abyssinia. By later negotiations with his European neighbours, the emperor Menelek secured boundaries on the south and west more favourable to Abyssinia than those assigned under the Anglo-Italian agreement. And Italian Somaliland, bordering on the south-eastern frontier of Abyssinia, became limited to a belt of territory with a depth inland from the Indian ocean of from 180 to 250 miles.

Anglo-French Rivalry in West Africa.—In West Africa the real struggle was between France and Great Britain, and France played the dominant part, the exhaustion of Portugal, the apathy of the British Government and the late appearance of Germany in the field all being elements that favoured the success of French policy. Two phases may be distinguished: the first dealing with the coast colonies, the second with the middle Niger and Lake Chad. On the coast France was wholly successful in her design of isolating all Great Britain's separate possessions in that region, and of securing for herself undisputed possession of the upper Niger and of the countries lying within the great bend of that river. At the date of the Berlin Conference the present colonies of Southern Nigeria and the Gold Coast constituted a single colony under the title of the Gold Coast colony, but on Jan. 13, 1886, the territory comprised under that title was erected into two separate colonies—Lagos and the Gold Coast (the name of the former being changed in Feb. 1906 to the colony of Southern Nigeria). In Aug. 1896, following the destruction of the Ashanti power and the deportation of King Prempeh, as a result of the second Ashanti campaign, a British protectorate was declared over the whole of the Ashanti territories and a resident was installed at Kumasi. But no northern limit had been fixed beyond the 9th parallel, and the countries to the north—Gurunsi (Grusi), Mossi and Gurma—were entered from all sides by rival British, French, and German expeditions. A few days before the meeting of the Berlin Conference Sir George Goldie had succeeded in buying up all the French interests on the lower Niger. The British company's influence had at that date been extended by treaties with the native chiefs up the main Niger stream to its junction with the Benue, and some distance along this latter river. But the great Fula states of the central Sudan were still outside European influence; and the German Government made efforts to secure a footing on the lower Niger until the fall of Prince Bis-

marck in March 1890. On the failure of the half-hearted attempt made later to establish relations with Gando from Togoland, Germany dropped out of the competition for the western Sudan and left the field to France and Great Britain. After its first great success the National African Company obtained a charter from the British Government, and on July 10, 1886, it became "The Royal Niger Company."

Notwithstanding her strenuous efforts, France, in her advance down the Niger from Senegal, did not succeed in reaching Segou on the upper Niger, a considerable distance above Timbuktu, until the winter of 1890-91, and the rapid advance of British influence up the river raised serious fears lest the Royal Niger Company should reach Timbuktu before France could forestall her. In 1892, however, after a troublesome war, France annexed some portion of Dahomey on the coast and declared a protectorate over the rest of the kingdom. Thus was removed the barrier which had up to that time prevented France pushing her way Nigerwards from her possessions on the Slave Coast, as well as from the upper Niger and the Ivory Coast. Henceforth her progress from all these directions was rapid, and in particular Timbuktu was occupied in the last days of 1893. It then appears to have been suddenly realized in France that, for the development of the vast regions which she was placing under her protection in West Africa, it was extremely desirable that she should obtain free access to the navigable portions of the Niger, if not on the left bank, from which she was excluded by the agreement of Aug. 5, 1890, then on the right bank, where the frontier had still to be fixed by international agreement. On Feb. 13, 1895, a French officer, Commander Toutée, arrived on the right bank of the Niger opposite Bajibo and built a fort. His presence there was notified to the Royal Niger Company, who protested to the British Government against this invasion of their territory; and eventually Toutée was ordered to withdraw, and the fort was occupied by the Royal Niger Company's troops. In 1897 the attempt was renewed in the most determined manner. In February of that year a French force suddenly occupied Bussa, and this act was quickly followed by the occupation of Gomba and Illo higher up the river. In Nov. 1897 Nikki was occupied. The situation on the Niger had so obviously been outgrowing the capacity of a chartered company that for some time before these occurrences the assumption of responsibility for the whole of the Niger region by the imperial authorities had been practically decided on; and early in 1898 Capt. F. D. (afterwards Lord) Lugard was sent out to the Niger with a number of imperial officers to raise a local force in preparation for the contemplated change. The advance of the French forces from the south and west was the signal for an advance of British troops from the Niger, from Lagos, and from the Gold Coast protectorate. The situation thus created was extremely serious. The British and French flags were flying in close proximity, in some cases in the same village. Meanwhile the diplomatists were busy in London and in Paris, and in the latter capital a commission sat for many months to adjust the conflicting claims. Fortunately, by the tact and forbearance of the officers on both sides, no local incident occurred to precipitate a collision, and on June 14, 1898, a convention was signed by Sir Edmund Monson and M. G. Hanotaux which practically completed the partition of this part of the continent. (See NIGERIA.)

Thus in its broad outlines the partition of Africa was begun and ended in the short space of a quarter of a century. The result was to divide the continent among the Powers as follows:—

	Square miles.
British Africa.....	2,101,411
Egyptian Africa.....	1,600,000
French Africa.....	3,866,950
German Africa.....	910,150
Italian Africa.....	200,000
Portuguese Africa.....	787,500
Spanish Africa.....	79,800
Belgian Africa.....	900,000
Turkish Africa.....	400,000
Independent Africa.....	613,000

11,458,811

Anglo-French Declaration, 1904.—There were still many finishing touches to be put to the structure, but a large contribution to the process was made by the Anglo-French declaration of April 8, 1904, when a series of agreements relating to several parts of the globe were signed in London by Lord Lansdowne, the foreign secretary, and M. Paul Cambon, the French ambassador, on behalf of their respective Governments. With regard to Egypt the French Government declared "that they [would] not obstruct the action of Great Britain in that country by asking that a limit of time be fixed for the British occupation or in any other manner." To understand the equivalent engagement taken by Britain, it must be recalled that to consolidate her position in north-west Africa France desired to make her influence supreme in Morocco. In April, 1902, it had been agreed between the French and Shereefian Governments to co-operate in establishing order in the frontier districts of Morocco and Algeria. Meanwhile in the northern districts of Morocco the unrest under the rule of the young sultan, Abd-el-Aziz IV., was attracting attention in Europe and evoking demands for its suppression. It was in these circumstances that in the declaration of April 1904 the British Government recognized "that it [appertained] to France, more particularly as a Power whose dominions [were] continuous for a great distance with those of Morocco, to preserve order in that country, and to provide assistance for the purpose of all administrative, economic, financial, and military reforms which it may require." Both parties, however, "inspired by their feeling of sincere friendship for Spain, [took] into special consideration the interests which that country [derived] from her geographical position and from her territorial possessions on the Moorish coast of the Mediterranean"; and in these interests the French Government undertook "to come to an understanding with the Spanish Government." The understanding was reached later in the same year, and thus Spain secured a sphere of interest on the Moroccan coast immediately facing the Spanish peninsula. Here it may be added that the protectorate of Spain over certain territories on the west coast of Africa, south of Morocco, had been notified to the Berlin Conference, and that by an agreement made with France in 1900 some 70,000sq m. of the western Sahara were recognized as Spanish; while at the same time France admitted the claim of Spain to the ownership of the district around the Muni river to the south of Cameroons. The action taken by France in Morocco in accordance with the policy marked out in the Anglo-French declaration aroused the resentment of Germany, but on July 8, 1905, the republic secured from the German Government formal "recognition of the situation created for France in Morocco by the contiguity of a vast extent of territory of Algeria and the Shereefian empire, and by the special relations resulting therefrom between the two adjacent countries, as well as by the special interest for France, due to this fact, that order should reign in the Shereefian empire." Finally, in Jan.—April, 1906, a conference of the Powers was held at Algeiras to devise, by invitation of the sultan, a scheme of reforms to be introduced into Morocco (*q.v.*). French capital was allotted a larger share than that of any other Power in the Moorish state bank which it was decided to institute, and French and Spanish officers were entrusted with the organization of a police force for the maintenance of order in the principal coast towns. The new régime had not been inaugurated fully, however, when a series of outrages led, in 1907, to the military occupation by France of Oudjda, a town near the Algerian frontier, and of the port of Casablanca on the Atlantic coast of Morocco.

LATER POLITICAL DEVELOPMENTS

The political map of Africa changed very considerably between 1910 and 1925. In 1910 the British self-governing colonies of the Cape, Natal, Transvaal, and Orange River were formed into the Union of South Africa, with a single government and one legislature. In 1911 a considerable area of French Equatorial Africa was transferred to German Cameroons and in return Germany acknowledged a French protectorate over the greater part of Morocco. On March 30, 1912, a protectorate treaty between France and the sultan was signed at Fez; and by a Franco-Span-

ish convention of Nov. 27 the Spanish zones in Morocco were defined. In 1912, also, Italy annexed the Turkish vilayets of Tripoli and Bengasi (Cyrenaica), to which the common name of Libya was given. In Dec. 1914 a British protectorate over Egypt was proclaimed, but by a declaration of Feb. 1922 Great Britain acknowledged the independence of Egypt. The status of the Anglo-Egyptian Sudan remained unchanged.

In June 1919, by the Treaty of Versailles. Germany renounced possession of all her oversea protectorates in favour of the principal Allied and Associated Powers. These territories, which had all been conquered by the Allies during the World War, were placed under mandatories. The Union of South Africa became mandatory for German South-West Africa; Togoland was divided between France and Great Britain; and France became mandatory for Cameroons, except for a small portion which was placed under the administration of British Nigeria. Britain became mandatory for German East Africa, renamed the Tanganyika Territory, but by subsequent Anglo-Belgian agreements Belgium became mandatory for the provinces of Ruanda and Urundi. In 1920-25 Italy gained additions to Tripoli and Cyrenaica by arrangements with France and Egypt and to Italian Somaliland by arrangement with Great Britain. In 1936, Italy annexed Abyssinia.

As a result of these changes Africa was divided among the following Powers. The territories governed under mandate are reckoned in the possession of the Power named.—

France	4,200,000	Italy	1,030,000
Great Britain	3,984,000*	Egypt	350,000
Belgium	930,000	Spain	140,000†
Portugal	788,000	Liberia	40,000

*Including Anglo-Egyptian Sudan.

†Including the Spanish zones in Morocco.

These figures give a total of 11,462,000 sqm as the area of Africa. In the absence of definite surveys of large areas of the continent this may be regarded as a close approximation to accuracy.

German Policy.—The extinction of Turkish rule in North Africa had long been foreseen and was no matter for regret. It ended a connection which had lasted five centuries and had been almost wholly evil in its effects. German sovereignty in Africa had only dated from 1884 and had been rapidly enlarged. Endeavours to extend it further had been a prominent factor in German policy for a decade before the World War. Germany desired a footing on the African coast of the Mediterranean and a port on the Atlantic coast of Morocco. These desires conflicted with Italian and French ambitions, and in 1911 the issue on both points was decided against Germany. As to Morocco, a Franco-German convention of Feb. 9, 1909, had recognized the privileged position of France in Morocco, but not a French protectorate over that country, and the sending of the German gunboat, "Panther," to Agadir, in July, 1911, was a protest against what Germany considered an unwarranted extension of French influence in Morocco, and an intimation that if German treaty rights in Morocco were to be renounced, France must make compensation. The intervention of Great Britain on the side of France put an end to a dangerous situation; Germany, by a convention concluded Nov. 4, 1911, accepted compensation in Central Africa and withdrew opposition to the establishment of a French protectorate in Morocco.

While the Franco-German negotiations were in progress Italy abruptly declared war on Turkey and invaded, and held, Cyrenaica and Tripoli. Thus Germany, who had designed to exploit those vilayets through the medium of an Austro-Hungarian chartered

company, was deprived of her last opportunity—short of war—of gaining a foothold in the Mediterranean. She turned her attention to the development of a *Mittel Afrika* policy. This policy aimed at securing Germany's supremacy, primarily economic and ultimately political, in central equatorial Africa. The aim was to reserve the Belgian Congo, Angola and Mozambique, north of the Zambezi, as a German sphere, and thus to link up Cameroons with the South-West and East Africa protectorates. German industries had need of the raw material tropical Africa produces, and, moreover, southern Angola was a good field for European settlement.

British statesmen were not unfavourable to German expansion in equatorial Africa, so long as it was confined to the economic sphere. In 1898 an agreement, signed by Mr. A. J. (afterwards Lord) Balfour and Count Hatzfeldt, had divided Angola and Mozambique into spheres in which Great Britain and Germany respectively were to give financial and economic help to the Portuguese. This was followed in 1899 by the Treaty of Windsor, the object being to reassure Portugal that the Balfour-Hatzfeldt agreement was not in derogation of her sovereign rights in Africa. Neither the agreement with Germany nor the treaty with Portugal was published.

After the settlement of the Morocco crisis, Germany reopened negotiations with Great Britain in respect of Portugal's African colonies, and Prince Lichnowsky (the German ambassador) and Sir Edward (afterwards Lord) Grey reached a new agreement, which was ready for signature in 1913. Nearly all Angola was recognized as a German economic sphere, as well as the northern part of Mozambique. The rest of Mozambique, including Delagoa Bay and the Zambezi valley, was to be a British economic sphere. Sir Edward Grey made it a condition of signing that the 1898 and 1899 documents should be published. The German foreign office raised objections, Herr von Jagow (then foreign minister) stating that the German Press would regard the terms of the Treaty of Windsor and the Lichnowsky agreement as contradictory. In July 1914, however, German consent to publication had been given, but before the new agreement could be signed the World War had broken out.

The World War.—During the progress of the campaigns in Africa the whole of the continent, except Abyssinia and the Spanish protectorates, became involved in the struggle. The conquest of the German colonies was foreseen in the negotiation which preceded Italy's entry into the war, and Article 13 of the agreement signed in London on April 26, 1915, between France, Russia, Great Britain, and Italy, laid down that:—

In the event of France and Britain increasing their colonial territories in Africa at the expense of Germany, those two Powers agree in principle that Italy may claim some equitable compensation, particularly as regards the settlement in her favour of the questions relative to the frontiers of the Italian colonies of Eritrea, Somaliland and Libya, and the neighbouring colonies belonging to France and Great Britain.

Italian Ambitions.—Italian ambitions had gone beyond the readjustment of frontiers; in particular Italy wished to acquire Jibuti, the port of French Somaliland and the starting place of a railway to Abyssinia. As Jibuti was the only French port on the Suez canal route to the East and to Madagascar, as well as the only approach to Abyssinia that France possessed, she declined to entertain proposals for its surrender.

Italy, however, obtained from France a welcome rectification of the Tripoli-Tunisia frontier, as well as valuable concessions in Tunisia.

In regard to the Cyrenaica-Egyptian frontier, the British Government, in 1919, offered Italy a readjustment of territory in the Libyan desert. The negotiations had not been concluded when Egypt was granted independence and after that time they were conducted directly between Italy and Egypt. They turned largely on the possession of the oasis of Jaghbug, a place of some strategic importance, where is also the tomb-mosque of the founder of the Senussi sect. On Dec. 6, 1925, an Italo-Egyptian agreement was signed, by which Jaghbug was included in Cyrenaica. The wells to the west of El Sollum were included in

HOW AFRICA'S 11 MILLION SQUARE MILES ARE DIVIDED AMONG THE NATIONS. THE FIGURES FOR THE THREE SEGMENTS TOO SMALL TO SHOW ARE EGYPT, 350,000 SQ. M., SPAIN, 140,000 SQ. M., AND IN THE SMALLEST SEGMENT, LIBERIA, 40,000 SQ. M.

Egyptian territory, thus giving El Sollum a needed water supply. South of Siwa the frontier was drawn along longitude 25° E. to the boundary of the Anglo-Egyptian Sudan in latitude 22° North.

Meanwhile Mussolini pressed again for a sphere of influence in Ethiopia. Notes were exchanged with England in 1925 undertaking to support the latter's request for the right to build a dam at Lake Tana in return for support for Italy's demand for a sphere in western Ethiopia. When England, seeing an opportunity to get the dam built by Egyptian and American interests, dropped the Italian cause, Mussolini turned first to France and then in 1935 to direct aggression upon Abyssinia (q v). The war of conquest by Italy stirred the entire world. It was a direct assertion of white supremacy over a native and independent sovereignty which, in Sept. 1923, had been admitted to the League of Nations. In May 1936 Abyssinia was subdued and annexed. With Eritrea and Italian Somaliland, this ancient kingdom is included in an East African dependency over which the King of Italy has been declared Emperor.

France and Spain.—In the same year (1912) that France obtained her protectorate in Morocco she concluded an arrangement with Spain whereby a Spanish protectorate was set up in the northern part of the sultanate, the port of Tangier and a small area around it being made, however, an international zone. In the French protectorate Marshal Lyautey, the resident-general, adopted a bold and conciliatory policy and won the confidence and respect of the Moors. He was succeeded in 1925 by M. Theodore Steeg, the governor-general of Algeria. In their zone the Spaniards met with determined opposition, largely owing to the uprising of a Moor, styled Abdel-Krim. In the territory known, somewhat vaguely, as Er-Rif, there seems to have been, as in the coastward portions of Algeria and Tunisia, a much more marked Iberian element in the population than there is in the south of Morocco, and this part of northern Morocco had shown a great hatred of European interference. The Spaniards suffered a severe reverse in 1921 and there was again heavy fighting in 1924 and 1925. In the last-named year the Rifs invaded the French zone, but were defeated and driven back. In the next year the insurrection was successfully quelled; and in 1927 the king and queen of Spain were cordially received. In Southern Rhodesia the growth of a vigorous white community led to that country being made, in 1923, a self-governing colony of the British Empire, and with the assumption of direct imperial control of Northern Rhodesia in 1924 chartered-company rule in British Africa came to an end. In East Africa another vigorous and vocal white community made its influence felt, namely the settlers in the British East Africa Protectorate, which protectorate was annexed to the British Crown in 1920 and renamed Kenya Colony.

A subject which raised large issues was the position of Indians in South and East Africa, but it was of less importance than the growth of race consciousness among the Bantu and the negroes. Increase of education and of Christianity, the employment of large numbers of Africans in industries, and the lessons taught by the World War were among the factors which intensified the feeling of racial unity and led to manifestations of a new anti-white movement. This movement was different from the simple objection to interference by Europeans, or Arabs, previously displayed, and had a consciousness of the need of self-development.

France in North Africa.—Apart from the awakening of the African peoples to race-consciousness, two recent developments in the European occupation of the continent are noticeable. France has shown definite progress in the task of restoring north-west Africa to the place in Mediterranean civilization which it held from the 6th century B.C. to the 7th century of the Christian era, when the Mohammedan conquest began. Under British administration the peoples of East Africa have emerged rapidly since the World War to industrial and political advancement. Since 1912, when she acquired the protectorate of Morocco, the authority of France has become increasingly effective in the fertile littoral and high plateaux of the western half of North Africa. The political and economic development of this Mediterranean area upon European lines has been assured by the expan-

sion of Algeria southward and the subsequent linking up of Saharan Algeria with the western Sudan, the French west coast colonies, and French Congo in a vast and coherent African empire. Barely a century ago the French expeditionary force landed at Sidi Ferruch on June 14, 1830. The declared purpose of the French cabinet was "to abolish slavery and piracy, to re-establish the security of navigation in the Mediterranean and open up its southern coasts anew to agriculture, civilization, commerce, and the free access of all nations." In the interval the "restricted occupation" of the coast towns has become the "total occupation" of Algeria, and the conquest of "the South"; while the incorporation of Northern Algeria into France has been followed by the protectorates of Tunis (1881) and Morocco (1912). Within these hundred years the European element in North Africa has risen from a handful of consular officials and merchants to well over a million residents, or approximately to one-tenth of the total population. Great European towns have been built. Agriculture and stock-raising have become infinitely more productive, minerals have been found and worked and new industries introduced. Order and public security have been established in regions to which Rome never sought to penetrate and over peoples that the legionaries strove in vain to subdue. The increasing throng of tourists who yearly traverse North Africa by rail and car from Algiers to the Saharan oases and from Carthage to Marrakesh, and the frequency and regularity of the steamship services which maintain intercourse between the European and African shores of the Mediterranean, are evidence of the success with which France has fulfilled her primary task of re-opening to Europe this lost province of the Graeco-Roman world.

British Development.—After the World War appreciable progress was made in the construction of development works and in production in Uganda, Kenya, and Tanganyika (formerly German East Africa); and with a view of increasing further the economic capacity of these and the neighbouring territories of Zanzibar, Nyasaland, and Northern Rhodesia, the possibility of administrative co-operation between the several governments concerned came under consideration. As the result of conferences on this subject held in 1927 the colonial office appointed the Hilton Young Commission to inquire into the question of the federation, or other union, of the British territories from Northern Rhodesia to Uganda. And, by the desire of its ministry, Southern Rhodesia (which became self-governing in 1923) was included in the scope of the commission. The project of an administrative union, of which this official enquiry into the views of the several governments and populations concerned was the first step, acquires a special interest from the character and geographical position of the colonies affected. Both the East, and the South African colonies are mixed African and European states, in which, although the mass of the inhabitants are African, the European minority is politically dominant. But while, broadly speaking, in the former the numerical predominance and economic importance of the African population are such that the interests of this population have priority in the eyes of the administration over those of the European, in the latter, with the exception of the native territories of the high commission, the European population and its economic importance are so relatively great that European interests stand first. In the East Coast colonies, however, African interests are not so predominant as they are in the (British) West Coast colonies; and in this respect these East Coast colonies hold a position midway between the frankly African West Coast colonies and the frankly European Union of South Africa and Southern Rhodesia. The federation, if effected, of a group of colonies of this intermediate type, by showing whether a central administration is a more effective medium for arriving at a due balance between African and European interests, may be expected to provide data germane to the whole subject of the European tutelage of African peoples. And in particular, as the result of the inclusion of Southern Rhodesia in the purview of the commission and the consequent possibility of Northern Rhodesia or its western portion being incorporated into Southern Rhodesia, it is probable that the question whether Northern Rhodesia, with its large area of 300,000 sq. m., is to be

administered as a "plantation" colony or to become a new centre of British population will be at length determined.

Tangier.—The status of the Tangier International Zone was regulated by the Act of Algeciras (April 7, 1906), until modified by the conference which formulated the Tangier Statute in 1923. Although certain Powers signatory of the Algeciras Act, notably Italy, withheld their adhesion, this protocol came into force on June 1, 1925. But Spain continued to maintain that the only satisfactory arrangement was the incorporation of Tangier in the Spanish Zone by which it was encircled: while France insisted that her position in Morocco required that Tangier and its communications should be under her control. The visit of a division of the Italian navy to Tangier in Oct. 1927, emphasized Italy's refusal to recognize the statute. On March 3, 1928, agreement was reached between France and Spain. At a second conference (March 20) of France, Spain, Italy and Great Britain the Franco-Spanish Agreement of March 3, was adopted, the statute was modified, and the claims of Italy to participate in the government of Tangier were satisfied (July 17).

RECENT EXPLORATION

Progress Since 1910.—The largest unknown area of Africa in 1910 was in the Sahara desert; the greatest gaps on the map were in the Libyan desert. In 1920-21 Mrs. Rosita Forbes took an expedition across the Libyan Desert to Kufra, the headquarters of the Senussi Tariq. In 1922-23 Ahmed Bey Hassanein, who had accompanied her, led an expedition through Kufra and the southern oases to Darfur. Mrs. Forbes has made further journeys through Abyssinia, the western Mauretanian desert and western Arabia. Hassanein Bey in 1923 journeyed through the Libyan desert into Darfur and Kordofan. Previous explorations by the French (1912-17) had increased knowledge of the eastern limits of the Chad basin, and had definitely proved its distinction from the western basin of the Nile. Col. Tilho's expeditions had revealed altitudes in Tibesti of 11,200ft. and the height of Mt. Tuside as 10,700ft.; lesser altitudes of 9,800ft. were determined at Jebel Marra, in Darfur, and of 4,000 to 5,000ft. on the western borders of the Sudan. The Tibesti belt of highland probably played a great part in southward spreads of fauna and flora in Miocene and Pliocene times. In the Nilotic Sudan, east of the main Nile, altitudes of 10,000ft. were discovered in 1911-12 by Col. H. D. Pearson. In 1916 Maj. Cuthbert Christy made an interesting journey along the south-western limits of the Nile basin, traversing the ironstone region where adjoining head-streams flow either southwards into the Mbomu and its affluents (Congo basin) or north-east into the Nile basin.

A ZULU WARRIOR IN FULL BATTLE ARRAY

Carefully trained in military tactics, the Zulu warrior was feared by his neighbours as a formidable enemy

French officers, notably Capt. Augiéras, have conducted (from 1904) a scientific survey of the western Sahara, from southern Morocco to the Senegal river and the northern Niger. Augiéras has shown how the intense "desert" conditions of the western Sahara with few oases except on the periphery, accompany the extreme temperatures of the low-lying dunes, which quickly lose heat. The great Juf depression remained unexplored up to 1922; but since then the Citroen expedition from the latitudes of Insalah and Ahaggar in southern Algeria has increased our knowledge of this area. Portuguese Guinea, with its large rivers, has been partly explored, and since 1921 the vast southern part of the Niger basin, and the Black and White branches of the mighty Volta river, have become better known. Northern Togoland, Dahomey, southern Nigeria and the basin of the great Benue river have been mapped in detail.

East and Central Africa.—Much intensive work has been done in East and Central Africa. I. N. Dracopoli in 1912-1913 explored part of Jubaland; he reached the Lorian swamp, which receives the waters of the Uaso Nyiro, and showed its connection with the Juba river in Italian Somaliland. In April 1912 G. F. Archer (later Sir) completed surveys connecting the triangulation of British East Africa with the Abyssinian boundary survey. A survey by Capt. E. M. Jack, in 1911, of the region between Lakes Kivu and Victoria added to the knowledge of the Mufumbiro range of active volcanoes; Karisimbi was found to be 14,780ft. high. Since that time the Mufumbiro region and western Uganda have been surveyed in considerable detail. In 1927 geologists of the Swedish Institute found three series of sloping beaches along

the Rift valley between Menengai and Longonot. and also collected much data relative to the glaciation of Mt. Elgon and Kilimanjaro, and to the glacial geology of East Africa in general.

The first survey along its whole length of the Congo-Zambezi watershed was made in 1911-14 by Anglo-Belgian and Anglo-Portuguese boundary commissions. Many rivers run for considerable distances parallel to the divide, which is largely bush-covered. Maj. Reginald Walker, one of the British commissioners, discovered that the Luapula, a main headstream of the Congo, did not issue from Lake Bangweulu, but was a continuation of the Chambezi, which passes through the great swamp south of Bangweulu.

Results of the War.—During the World War, needs of campaigning led to many additions to the knowledge of the topography of inter-tropical Africa, partly through use of aircraft for survey purposes. Thus very useful maps were made of the northern part of Portuguese East Africa. In 1920 Dr. P. Chalmers Mitchell, who flew over the Nile basin proved the value of air reconnaissance to geology by the discovery in the Bayuda desert, north of Khartoum, of the volcanic character of a range of hills. A little later the French began to use aeroplanes for survey purposes in the Sahara. (X.)

AFRICA, ROMAN, comprised the whole of the continent known to the ancients, except Egypt and Ethiopia. The official and administrative language used the word Africa in a narrow sense, as noticed below. The term was borrowed by the Romans from the language of the natives. In Latin literature it was employed for the first time by the poet Ennius, who used it of the territory of Carthage and the eastern group of the Atlas. Numerous conjectures have been made as to the etymology of the term Africa; the best is that of Charles Tissot, who sees in the word "Africa" the name of the great Berber tribe, the Aourigha (whose name would have been pronounced Afarika), the modern Aouraghen, in ancient times the principal indigenous element of the African empire of Carthage (Tissot, *Géogr. comp.* i. 389). Africa was, in the eyes of the Romans and Carthaginians alike, the country inhabited by the great tribe of Berbers or Numidians called Afarik.

At the time of the Third Punic War the Africa of the Carthaginians was but a fragment of their ancient native empire, the rest of Africa having passed into the hands of the kings of Numidia, who were allies of the Romans.

After the capture of Carthage by Scipio (146 B.C.) this territory became a Roman province, and a trench, the *fossa regia*, was dug to mark the boundary of the Roman province of Africa and the dominions of the Numidian princes. The remains of this ditch, protected by a low wall or a stone dyke, have been discovered (1907); some of the boundary stones which marked its course, and inscriptions mentioning it, have also been found. From Testur on the Mejerda the *fossa regia* can be followed by these indications for several miles along the Jebel esh-Sheid. The ditch ran northward to Tabarca and southward to Tina. The ditch which in later times divided the provinces of *Africa vetus* and *Africa nova* was at the time of the Third Punic War the boundary of Carthaginian territory. The government of the Roman province thus delimited was entrusted to a *praetor* or *propraetor*. The towns which had fought on the side of the Romans during the Third Punic War were declared *civitates liberae*, and became exceedingly prosperous, e.g., Utica, Hadrumetum and Thapsus.

After the Jugurthine war in 106 B.C. the whole of the *regio Tripolitana* on the littoral of the two Syrtes, was annexed to the Roman province. The battle of Thapsus in 46 B.C. made the Romans definitely masters of Numidia which was converted into a new province called "*Africa Nova*": the old province of Africa was known as "*Africa Vetus*."

In 31 B.C. Octavius gave up Numidia, or *Africa Nova*, to King Juba II. Five years later Augustus gave Mauretania and some Caetolian districts to Juba, and received in exchange Numidia, which thus reverted to direct Roman control, no longer forming a distinct government, but attached to the old province of Africa. From 25 B.C. the Roman province of Africa comprised

the region between the mouth of the Ampsaga (Wad Rummel, Wad el Kebir) on the west, and the two tumuli called the altars of the Philaeni, the immutable boundary between Tripolitana and Cyrenaica, on the east (Tissot ii. 261). In the partition of the government of the provinces of the Roman empire between the senate and the emperor, Africa fell to the senate, and was henceforth administered by a proconsul.

The province of Africa was the only senatorial province whose governor was originally invested with military powers. The proconsul of Africa had command of the *legio III. Augusta* and the auxiliary corps. But in A.D. 37 Caligula deprived the proconsul of his military powers and gave them to the imperial legate (*legatus Augusti pro praetore provinciae Africae*), whose special duty it was to guard the frontier zone (Tacitus, *Hist.* iv. 48; Dio Cass. lix. 20). The headquarters of the imperial legate were originally at Cirta and afterwards at Lambaesa (Lambessa). The military posts along the frontier of the desert formed an immense arc extending from Cyrenaica to Mauretania. A network of military routes, constructed and kept in repair by the soldiers, led from Lambaesa in all directions, and stretched along the frontier as far as Leptis Magna. The powers of the proconsul scarcely extended beyond the ancient *Africa Vetus* and the towns on the littoral. Septimius Severus detached from the province of Africa the greater part of Numidia to constitute a special province governed by a *procurator*, subordinate to the imperial legate and resident at Cirta (Tissot ii. 34). This province was called Numidia Cirtensis.

In Diocletian's reform, the whole of Roman Africa, with the exception of Mauretania Tingitana (which was attached to the province of Spain), constituted a single diocese subdivided into six provinces. Changes were necessitated by the wars with the Moors and the Vandals. By a treaty concluded in A.D. 476, the Emperor Zeno recognized Gaiseric as master of all Africa. Reconquered by Belisarius in 534, Africa formed, under the name of *praefectura Africae*, one of the great administrative districts of the Byzantine empire. In A.D. 647 the Arabs penetrated into *Ifrikia*, which was destined to fall for ever out of the grasp of the Romans. In A.D. 697 Carthage was taken.

The population of Roman Africa was composed of three chief elements: the indigenous Berber tribes, the ancient Carthaginians of Phoenician origin and the Roman colonists. The Berber tribes, whose racial unity is attested by their common spoken language and by the Berber inscriptions that have come down to us, bore in ancient times the generic names of Numidians, Gaetulians and Moors or Maurusiani. Besides the Afri (Aourigha) of the territory of Carthage, the principal tribes that took part in the wars against the Romans were the Lotophagi, the Garamantes, the Misulani or Musulamii, the Massyli and the Massaesyli. African epigraphy has revealed the names of some of their deities: *deus invictus Aulisva*; the god Motmanius, associated with Mercury; the god Lilleus; *Kautus pater*; the goddess Gilva, identified with Tellus (Tissot i. 486). There were also local divinities in all the principal districts. The rock bas-reliefs and other monuments showing native divinities are rare, and give only very summary representations.

During the Roman period the ancient Carthaginians of Phoenician origin and the bastard population termed by ancient authors Libyo-Phoenicians, formed the predominant populations of the towns on the littoral, and retained the Punic language until the 6th century of the Christian era. The municipal magistrates took the title of *suffetes* in place of that of *duumvirs*, and in certain towns the Christian bishops were obliged to know the *lingua Punica*, since it was the only language that the people understood. Nevertheless, the Roman functionaries, the army and the colonists from Italy soon brought the Latin element into Africa, where it flourished with such vigour that, in the 3rd century A.D., Carthage became the centre of a Romano-African civilization of extraordinary literary brilliancy, which numbered among its leaders such men as Apuleius, Tertullian, Arnobius, Cyprian and Augustine.

Carthage regained its rank of capital of Africa under Augustus, when thousands of Roman colonists flocked to the town. Utica

became a Roman colony under Hadrian, and the *civitates liberae*, *municipia*, *castella*, *pagi* and *turres* were peopled with Latins. The towns of the ancient province of Africa which received *coloniae* were very numerous.

The province of Numidia was at first colonized principally by the military settlements of the Romans. Cirta (Constantine) and Bulla Regia (Hammam Darraj), its chief towns, received *coloniae* of soldiers and veterans, as well as Theveste (Tebessa) and Thamugas (Timgad). The fine ruins which have been discovered at the last-mentioned place have earned for it the surname of the African Pompeii.

AFRICAN LANGUAGES. Language and race have not necessarily common boundaries, but in classifying a group of languages the relation between the two must not be ignored. Apart from recent European immigration, Africa has four main types of people: Pygmy-Bushman, Negro, Hamitic and Semitic. These four races correspond to four types of languages, though the Negro group was later subdivided into two different units, viz., Sudanic and Bantu.

There is a certain unanimity regarding the main divisions, and the five groups: Bushman, Sudanic, Bantu, Hamitic, Semitic, may be considered as finally settled. Problems on which no agreement has been arrived at are: the position of Bushman (and Pygmy), the unity of the Sudanic languages, the relation between Sudanic and Bantu, and the comprehension of the term Hamitic languages.

Semitic Languages.— These tongues are spoken in Abyssinia, probably as a result of colonization from southern Arabia. Ge'ez is extinct, Amharic (*q.v.*) is in part a modern representative of Ge'ez. Out of Amharic two new languages have evolved: Tigre and Tigrinya. Other dialects are those of Gurague and Harar. Of greater importance is Arabic, which is the ruling language in north Africa and in parts of eastern Sudan; through Islamic influence it has become a literary idiom in east Africa and the Sudan.

Bushman Languages.— The Bushman tribes speak a number of languages, which, however, are all allied and may be divided into three groups, southern, central and northern. Phonetically they are remarkable for the occurrence of the so-called clicks (*q.v.*). Another feature, not only in Bushman languages, but also in Hottentot, Sudanic and Bantu, is intonation.

Each syllable, and sometimes also a single-voiced consonant, has its own level of tone, which is as essential a part of a word as the sounds. Words with identical sounds, but differing in tone, have no etymological relation whatever to each other.

A number of the features of the Bushman languages are found in Sudanic languages, e.g., intonation, monosyllabism, non-distinction between verb and noun in form, position of the genitive, formation of plural by "they," but as no etymological relations have as yet been ascertained it seems premature to ally the Bushman languages with the Sudanic group.

No Pygmy language is known. The Pygmies use their neighbours' speech. There seems to be evidence that some groups use a different mode of speech—yet unrecorded—in internal life.

Sudanic Languages.— This group is found, roughly speaking, in the stretch of the continent situated between the Atlantic ocean (Senegambia-Camerouns) and the western slopes of Abyssinia. Some enclaves, as Nuba and Kunama in the north, Gaya and Nyifwa-Kavirondo in east Africa, lie beyond this region.

This large group, stretching through the whole breadth of the continent, does not form a unit in the same sense as do the Bantu languages. It is broken up into numerous subdivisions, each of which has evolved its own type, and in the case of some tongues the divergences are so great that up to the present time, their relationship with others has not been demonstrated. The Sudan has been invaded over its whole area from time immemorial by peoples and languages from north and east. Linguistic conditions to-day are the result of this constant movement and shifting, which modified or destroyed original units and created new ones. Languages, probably whole groups of languages, have perished, or scanty remains have been embodied in new formations. As the invading tongues were largely of types differing radically from the Sudanic, these changes were radical and deeply influenced the original character of the language. Thus languages like Kanuri,

Wolof and others, have been so transformed that as yet their inclusion in the Sudanic group may seem to be merely theoretical.

Common Substratum.— While it is thus necessary to emphasize the highly complicated linguistic situation in the Sudan, and the present incomplete exploration of many problems involved, yet the Sudanic group as a whole shows certain common characteristics in phonology and structure, and there are also etymological relationships. There exists a common substratum of Sudanic speech, which is strongest where the original Negro element is strongest in population. This common substratum justifies the use of the term Sudanic languages. Some illustrations may be given: (1) the prevalence of intonation. (2) Monosyllabic stems (Ewe *ku* "death," Nuba *tu* "belly"). (3) Nouns are formed from verbs by a vocalic or nasal prefix (Yoruba *ra* "to buy," o-ra "buyer," Shilluk *bugo* "to press the bellows," o-buk "bellows"). (4) Plural of nouns is formed by adding to the noun a plural noun or pronoun (Ewe *ati* "tree," *ati-wo* "trees," Nuer *chak* "tick," *ke-chak* "ticks," -*wo* and *ke-* are the pronouns of the third person plural in Ewe and Nuer). (5) Plural of nouns is formed by adding *i* or *a* (Ibo o-ru "slave," i-ru "slaves"; Nuer *bel* "artist," *bel-i* "artists"; Edo o-ya, pl. a-ya "man"; Zande *boro*, pl. a-boro "man"). (6) Distinction between inanimate things and animate beings (or persons), the latter in most cases having the affix "o" (Twi *o-niŋa* "man"; in Shilluk o designates persons as descendants of other persons: *nayo* "the mother's brother," *o-nayo* "the mother's brother's child"). There is no grammatical sex-distinction. (7) In genitive relation the possessor precedes the possessed (Twi *niŋa dua* "a man's figure," Kunama *Ila masa* "Ila's lance"). (8) There is no formal distinction of case. The dative form is circumscribed by the verb "to give" (Ewe *edi ga na fofo* "he sought money gave father": he sought money for the father. Nuba *ir iga tir onnm* "you say give him": you say to him. (9) Postpositions, *i.e.*, space-denoting nouns, are used in the place of prepositions (Ewe *ati fa* "tree's head": on the tree; Nuba *ka tu* "house's belly": in the house. (10) Verbal combinations are frequent (Ewe *tso va na* "take come give": to bring to; Nuba *atta-den* from *ed-ta-derz* "take come give": to bring to). (11) The verbal stem is not changed in conjugation; tenses and modes are expressed by adding grammatical form words which in many cases can be traced to original nouns or verbs (in Twi the future is formed by prefixing *ba* [from *bia*] "to come," in Nuba by prefixing *bi* "to come"). (12) Sounds peculiar to the majority of Sudanic languages are the labio-velar *kɸ* and *gb*. (13) A considerable number of word-stems are identical. The characteristics just mentioned are not found in each sub-group, but there is no group which does not possess a number of them.

Divisions.— The Sudanic family may be geographically divided into an eastern, a central and a western group. The largest section of the eastern group are the Niloto-Sudanic languages comprising Shilluk with its many subdivisions, Dinka, Nuer and probably also Burun between the White and Blue Niles. Nuba on the Nile, in the Nuba mountains and in Kordofan, is connected with the Nilotic group, while other languages of these mountain regions are of a distinct character, having a class division of the noun.

The central group stretches between the 30th and 10th degree east long, and is subdivided by Delafosse into (a) Nile-Congo group, which, however, contains languages that are more closely related to the eastern Sudanic group; (b) Cbangi group; (c) Shari-Wadai group; (d) Shari group; (e) Niger-Tshad group; (f) Niger-Camerouns group. Our present knowledge concerning the central Sudanic group is so insufficient that the grouping just given is only provisional.

The western Sudanic group is better known and the sub-groups are well-defined. They are the following: (1) Tlze Kwa languages, spoken on the coast of Upper Guinea between the lower courses of the Niger and St. Paul's River in Liberia. Their sub-groups are: (a) Ewe-Akan group (Gold Coast, Togo, Dahome); (b) Lagoon group in the littoral regions of the Ivory Coast; (c) Kru group, reaching from the western Ivory Coast to the mouth of St. Paul's River; (d) Yoruba group; (e) Nupe group; (f) Ibo group; (g) Edo group; (h) Ijo (d-h in Nigeria). In the Kwa

languages the majority of word-stems consists of one consonant and one vowel. Akan *ka* "to remain," *wu* "to die." They have vocalic and nasal nominal prefixes, whose function is to form nouns out of verbs, and which are only absent in Kru. The prefixes do not form class divisions of the noun, except in rudiments.

(2) *Benue Cross River languages*. They partly coincide with Delafosse's Niger-Camerouns group and with Johnston's group A in his Bantu and Semi-Bantu languages, group (b) including Johnston's groups B-G, and group (c) comprising Johnston's group H. The languages of this group have many stems which end in a consonant. Efik *wut* "to kill" against Ewe *wu* "to kill." They have the same nominal prefixes as in group (1) (Efik *fime* "to blow," *o-fime* "wind"), but some languages have a system of prefixes which forms classes. As the group lies on the borderline between Sudanic and Bantu, some of its languages represent a stage of transition between the two.

(3) *Middle Togo group*. Most of these occupy a very small area, being situated in the mountainous region between the 7th and 8th degree N. lat.; some of them are disappearing or have already disappeared, being absorbed by Ewe and Akan. Among those which continue to exist are Avatime, Likpe, Adele, Kposso, Kebu. The word-stems in this group consist mainly of one consonant and one vowel. Kposso *wu* "to kill." A class division of nouns is formed by prefixes; some languages use class-suffixes besides the prefixes. The group stands between groups (1) and (4), having distinct connections with both.

(4) *Gur (Goor) languages*, in the northern section of the Ivory and Gold Coast, of Togo and of Dahome, and in the adjacent parts of Haute Volta. They include the following sub-groups: (a) Mossi group (Mossi, Dagomba, etc.), (b) Grussi or Gurunsi group, (c) Tem group, (d) Bargu, (e) Gurma group, (f) Kilina, (g) Senufo or Siena group, (h) Songai. The latter is in fact an isolated language having its own type, but is remotely connected with the Gur languages. Stems of the form consonant plus vowel are very frequent, though perhaps not in the majority. Dyan *wu* "to kill." All have class division of nouns by suffixes; Gurma and Tem use prefixes and suffixes.

(5) *West Atlantic languages*. These are found in part of the territory between the Senegal and the Atlantic, with a number of enclaves farther east, and are sub-divided into an eastern group, comprising Temne, Bulom, Limba, Kissi, Gola and Adjukru, and a western group, represented by (a) Dyola, (b) the Bissao-Bolama cluster (Bola, Sarar, Pepel, Kanyop), (c) the Geba cluster (Biafada, Padjade), (d) Banyun, Nalu, Bulanda, (e) Konyagi, (f) Bidjogo, (g) Wolof and Serer. Neither in general type nor in phonology and etymology do the members of this group form such a close unit as those of the preceding group. Almost all have class division of nouns; some, as Bulom, Temne, Adjukru, by prefixes, Gola by prefixes and suffixes, Wolof and Serer have suffixes, but also change the beginning consonant, which perhaps points to prefixes. Stems consisting of a consonant and a vowel are frequent (Bulom *wu* "to die"), but they are in a minority.

(6) *Mandingo or Mande languages*, in the western Sudan between groups (4) and (5). They fall into two groups, named after the numeral for "ten" prevailing in each group: (a) *Mandetan*, with Bambara, Soninke, Malinke, Dyula, as main representatives, (b) *Mandefu*, comprising Susu, the Kpelle-Mende cluster, in Sierra Leone and Liberia (Mende, Kpelle, Gbande, Gbunde, Toma, Mano, Gio), Djalonka in French Guinea, and a number of small languages reaching as far east as the north-west corner of Nigeria (Boko-Busa). In the Mandingo tongues two-syllabic words prevail; many of these are compositions of two mono-syllabic stems, each consisting of a consonant and a vowel. There are no word-forming prefixes, except in rudimentary forms. The word may often have a verbal and a nominal meaning: Bambara *ti* "thatch" and "to thatch."

Bantu Languages.—These, spreading through the southern half of the continent, form a closely united family with clearly defined features. Though the most prominent of these, the class division of nouns by prefixes, also exists in Sudanic groups, it has in Bantu reached a fuller development and has become the

dominating factor in their structure. These prefixes also form the plural; thus *m-swahili* a Swahili, *wa-swahili*, Swahili people, *ki-swahili* the Swahili language. The prefix belonging to a noun is repeated (though sometimes in a changed form) before every adjective, noun or pronoun agreeing with the noun; Swahili: *ki-su ki-kali ki-moja ki-me-potea* "knife sharp one has been lost": one sharp knife has been lost; *-su* "knife" has *ki-* as its class prefix, and this is repeated before every word agreeing with *-su*. The plural prefix corresponding to *ki-* is *vi-*; thus the plural of the preceding sentence is: *vi-su vi-kali vi-nane vi-me-potea* "eight sharp knives have been lost." The main nominal classes are: (a) for "man as an independent personality"; (b) for "man in dependent position" (slave, messenger, workman), also for physical agents, spirits, diseases, parts of the human body, animals, plants; (c) for objects existing in double or divisible form, the plural also designating collectives and liquids; (d) for "customs, usages, tools"; (e) for animals; (f) for individual objects and abstract nouns; (g) for diminutives; (h) for infinitives; (i) (or rather three) for locatives. Clicks (probably borrowed from Bushman and Hottentot) and lateral sounds are peculiar to some South African Bantu languages. Intonation is in most tongues not so important as in the Sudanic family. Stress accent is more developed than in the latter, the accent lying generally on the penultimate. Two-syllabic stems are prevalent. There is no grammatical gender, sex being indicated as in Sudanic languages, and no case inflection. The genitive follows the governing noun. The verb has a large number of derivative forms, which afford a remarkable richness in expression, e.g., Swahili *vunja* "to break," *vunjika* "to be broken"; *penda* "to love," *pendana* "to love each other"; *takata* "to be clean," *takasa* "to cleanse"; from *pata* "to obtain" the following derivatives may be formed: *patana* "make an agreement," *patanisha* "unite," *patia* "obtain for somebody," *patika* "be seized," *patilia* "reach out for something," *patiliza* "make one vexed," *patilizima* "vex each other."

It is more difficult to group the Bantu languages in subdivisions than the Sudanic languages, where the evolution of independent types is evident at first sight.

According to Homburger, Bantu is divided into the following groups (of the individual languages belonging to each group only a certain number can be mentioned here): (1) Northern or Ganda group (Ganda, Nyoro, Kerewe. (2) Ruanda group (Ruanda, Rundi). (3) North-eastern or Kilimanjaro group (Kikuyu, Kamba, Djagga, Moshi, Siha). (4) Northern group of the east coast (Taveta-Taita, Chassu, Pokomo, Nika, Shambala, Bondei, Zigula, Swahili, Comore, Zaramo, Kami, Matumbi). (5) East African group (Nyamwezi, Nyaturu, Gogo, Hehe, Pogoro, Kaguru, Konde, Yao, Nyanja, Sene, Tete, Chwabo or Kilimane). (6) South-eastern group (Makua, Ronga or Thonga, Gwamba or Hlengwe, Chopi or Lenge, Venda, Sotho, Kololo, Chwana). (7) Zulu group (Kafir or Xosa, Zulu, Tebele, Ngoni). (8a) Central group (Tabwa, Bemba, Mambwa, Bisa or Wisa, Lala-Lamba, Senga, Tonga, Subiya). (8b) Western group (Herero, Ndonga, Kwanyama, Nyaneka, Mbunda, Luyi, Umbundu, Kimbundu, Lunda, Luba or Lua). (9) Congo group (Congo, Kanioka, Kutsu, Kele, Lolo, Nkundu). (10) North-western group (Bangi, Teke, Kalai or Kele, Galoa, Duma, Benga, Noho, Basa, Duala, Bube, Kwiri, Isubu). This division appears to call for a new investigation based on a careful observation of sound-shifting, for which a good start has been made by van Warmelo in his study on South African Bantu languages.

Hamitic Languages.—These represent a linguistic type which is more closely allied with the Semitic than with any other group of African languages. Their main divisions are (1) Eastern Hamitic in north-east Africa, including, among others: Bedaue, Bogos, Danakil, Somali, Galla, Agau, Kaffitsho. (2) Niloto-Hamitic: Masai, Ndorobbo, Tatoga, Nandi, Suk, Turkana, Gimirra. (3) Western Hamitic: The Berber dialects from western Morocco to the oasis of Siwa, Tuareg, and probably the extinct language or languages of the Guanches on the Canary islands. Hausa (*q.v.*), may be called a remoter member of this sub-group. Though it has adopted many elements from neighbouring Sudanic tongues,

its Hamitic affinity cannot be doubted. Hottentot in South Africa also shows certain Hamitic features, but recent investigations, especially those undertaken by Schapera, reveal such undeniable affinities between the Hottentot and Bushman languages (*q.v.*), as can hardly be explained by borrowing, but seem to point to a genetic relation between the two. Distinction of sex, always one of the prominent reasons for including Hottentot in the Hamitic family, is also found in Naron, a Bushman tongue, being in both cases expressed by a suffix. Both Nama and Naron have a dual form besides singular and plural, [*xam* and Nama have inclusive and exclusive forms of the first person plural (including or excluding the person addressed). There are other common features in grammar and a considerable number of words common to both. Schapera's conclusion is "that in spite of the many noticeable differences between them the Hottentot and Bushman tongues must be regarded as belonging to one and the same family of languages."

The characteristic features of Hamitic speech are: (1) Grammatical gender. Schilh masc. *idilli*, fem. *t-idilli-t* "black," Masai *ol dia* "male dog," *er dia* "female dog," Nama *khoib* "man," *khois* "woman," Hausa *ya* "he," *ta* "she." (2) A richness in plural formation, which may form such distinctions as distributive, collective, general and universal plurality. Bilin *dimmū-rā* "an individual of the cat family," pl. *dimmū-t*; but: *dimmū* "cat," pl. *diāmū* "cats." Chamir *ieslemci* "a Muslim," pl. *ieslem-en*, but *ieslem-en-t* "the Muslim world." In Hausa (*q.v.*), most nouns have several plural forms; *kunba* "finger-nail" has the plural forms *kumbōbī*, *kunbuna*, *kunbai*, *kunbaibai*. Here as in other Hamitic (and Sudanic) languages re-duplication is frequently used in forming the plural. (3) Inner vowel change (ablaut): Shilh *iliwi*, pl. *ilaw-an* "thorn"; *a-fulu*, pl. *i-fel-en* "string" (the changes are, however, caused by vowel-assimilation, and are thus a phenomenon found likewise in Sudanic languages); in verbs: Shilh *of-aji* "I find," *ufi-ji* "I have found." (4) As in Bantu, the genitive follows the governing noun. In Hottentot, however, as in Bushman and Sudanic (and also Bedaue), the possessor precedes the possessed.

Fulfulde.—Meinhof includes Fulfulde, the language of the Fulbe, in the Hamitic family, but calls it Proto-hamitic or Pre-hamitic. Fulfulde has the usual Hamitic genitive position, in which the governing noun precedes the genitive, but other features regarded as Hamitic are absent. Fulfulde has no grammatical gender; there is no different plural form of nouns, and there is no inner vowel change. It is decidedly a class language, *i.e.*, like Bantu and many Sudanic languages it divides nouns into classes by affixes, and this fact separates Fulfulde from the Hamitic stock and draws it near Bantu languages and the Sudanic class languages. The connection between Fulfulde and Bantu is recognized by Meinhof, his opinion being that "originally in the whole of the present Bantu region languages of a Sudanic type were spoken, until from the north tribes with a language similar to Fulfulde penetrated and made themselves lords over the old inhabitants. The result of a mixture of these two elements was Bantu." (c D. Kolonial-Eeikon i, p. 133.) The essential identity of the class-affixes as used in Fulfulde, in Sudanic class languages and in Bantu, in their etymological form as well as in their function, is evident, while in point of vocabulary Fulfulde and Bantu differ widely.

On the other hand there is an original affinity between Bantu and Sudanic languages. This refers not only to class-affixes, but also and still more to etymology. The two families have a considerable number of word-stems in common, and also certain formative elements, apart from class-affixes, are identical in both families.

The situation may be summed up as follows: The Negro population of Africa, comprising the Bantu and the Sudanic speaking peoples, has in etymology and in a number of formative elements a common linguistic substratum. The class division of nouns existing in Fulfulde, in Bantu and in certain Sudanic languages is evidently of common origin, where or from what language it may have originated we do not know.

According to Struck, the number of African languages is as

follows: Bushman 11, Sudanic 264, Bantu 182, Hamitic 47, Semitic 10. Many of these occupy a small area, and perhaps not more than 12 are spoken by more than a million people. From the practical point of view, some of the most important African languages are (Semitic): Amharic, Arabic; (Hamitic): Hausa; (Bantu): Ganda, Kikuyu, Kongo, Luba-Lulua, Mbundu, Ngala, Nyanja, Sukuma-Nyamwezi, Ruanda-Rundi, Sotho-Pedi-Chwana, Swahili, Swina-Karanga-Ndau, Zulu-Xosa; (Sudanic): Akan, Dinka-Nuer, Efik-Ibibio, Ewe-Aneho-Dahome, Ibo, Kanuri, Kpelle-Mende, Malinke-Djula-Bambara, Mossi-Dagomba, Nupe-Gbari, Temne, Wolof, Yoruba, Zande.

AFRICAN LILY (*Agapanthus Africanus*), a member of the family Liliaceae, a native of the Cape of Good Hope, whence it was introduced at the close of the 17th century. It is a handsome greenhouse plant, which is hardy in the south of England and the warmer parts of the United States. The basal, tufted leaves are long, narrow, arching, $\frac{1}{2}$ to 2 ft. long. A central flower-stalk, 2 to 3 ft. high, ends in an umbel of bright blue, funnel-shaped flowers. The plants are easy to cultivate, and are generally grown in large pots or tubs which must be protected from frost in winter. During the summer they require plenty of water, and are very effective on the margins of lakes or running streams, where they thrive admirably. It may be propagated by dividing the root-stock in early spring or autumn. Dwarf and white-flowered forms are known in cultivation.

AFRICANUS: see SCEPTIO.

AFRICANUS, SEXTUS IULIUS, a Christian traveller and historian of the 3rd century, was probably born in Libya and lived at Emmaus. He may have served under Septimius Severus against the Osroenians in A.D. 195. He wrote a history of the world (*Χρονογραφία*, in five books) from the creation to A.D. 221, calculating the period between the creation and the birth of Christ as 5,499 years, and ante-dating the latter event by three years. This method of reckoning, known as the Alexandrian era, was adopted by almost all Eastern Churches. The history, which had an apologetic aim, is no longer extant, but copious extracts from it are to be found in the *Chronicon* of Eusebius. There are also fragments in Syncellus, Cedrenus and the *Paschale Chronicon*.

Eusebius also gives a letter to Aristides, and one to Origen, impugning the authority of the book of Susanna. The ascription to Africanus of the *Κεσροί*, a work on agriculture, natural history, military science, etc., has been disputed. Neander suggests that it was written by Africanus before he had devoted himself to religious subjects. For a new fragment of this work see *Oxyrhynchus Papyri* (Grenfeli and Hunt), iii. 36 et seq.

AFRIDI, the most powerful of the Pathān tribes which hold the mountainous borderland of the N.W. Frontier Provinces, India, though less numerous than the Wazirs. They occupy the eastern spurs of the Safed Koh. Through the north of these runs the Khyber pass, and their centre is the great upland country called Tirāh, 6,000 or 7,000ft. above sea-level, of which the Orakzais hold the southern half. The Afridi borders are the Peshāwar district on the east and north, the Mohmands on the north, the Shinwāris on the west, and the Orakzai and Bangash on the south, including the valleys of Bārā and Bāzār. The origin of the Afridis is unknown. They have a curiously Jewish cast of features, but have been supposed to be the Aparytai of Herodotus, though for over 2,000 years their history is untraceable. It is, however, certain that about the 15th century they ousted the Tirāhīs, doubtless absorbing some of their elements, but their conquests were encroached upon by their neighbours, and it was not until Jahāngīr's reign that they retook half of Tirāh from the Orakzai. Under Akbar they embraced the Roshania heresy, but after its suppression they enlisted freely in the Mughal armies and were subsidized to keep open the Rhyber pass. But they failed to defend it against Nādir Shāh, and were content to levy toil on such trade as filtered through it during the Abdālī and Sikh régimes. On the British annexation their independence was respected, in spite of their appeal to the Indian government to take Tirāh, and they were subsidized to protect trading caravans travelling through the Khyber, but their internal feuds rendered it unsafe. In 1897 the Afridis enrolled in the Khyber militia made a gallant defence of Landi Kotal, but eventually surrendered. The defection of one of their most turbulent clans the Zakka Khel soon involved the whole tribe and the Orakzai as well. This necessitated a regular invasion of Tirāh under Sir William Lockhart, and after much hard fighting every part of the country was traversed and surveyed, all the disaffected sections of the tribes being punished, the Zakka Khel being the last to submit. In 1908 an expedition had again to be launched against the Jawakki Khel. The Afridis are intensely democratic, the heads of clans having little authority, so that raiders cannot be brought to book or tribal engagements enforced. Though brave and hardy the tribe is reputed cruel and untrustworthy, but it has furnished many good soldiers in the Indian army

Military Operations. — There have been several British expeditions against the separate clans:—

(1) Expedition against the Kohat Pass Afridis under Sir Colin Campbell in 1850. The British connection with the Adam Khel Afridis commenced immediately after the annexation of the Peshāwar and Kohat districts. Following the example of all previous rulers of the country, the British agreed to pay the tribe a subsidy to protect the pass. But in 1850 1,000 Afridis attacked a body of sappers engaged in making the road, killing 12 and wounding six. It was supposed that they disliked the making of a road which would lay open their fastnesses to regular troops. An expedition of 3,200 British troops was despatched, which traversed the country and punished them.

(2) Expedition against the Jowaki Afridis of the Bori villages in 1853. When the Afridis of the Kohat Pass misbehaved in 1850, the Jowaki Afridis offered the use of their route instead; but they turned out worse than the others, and in 1853 a force of 1,700 British traversed their country and destroyed their stronghold at Bori. The Jowaki Afridis are a clan of the Adam Khel, who inhabit the country lying between the Kohat Pass and the river Indus.

(3) Expedition against the Aka Khel Afridis under Colonel Craigie in 1855. In 1854 the Aka Khels, not finding themselves admitted to a share of the allowances of the Kohat Pass, commenced a series of raids on the Peshawar border and attacked a British camp. An expedition of 1,500 troops entered the country and inflicted severe punishment on the tribe, who made their submission and paid a fine.

(4) Expedition against the Jowaki Afridis under Colonel Moccatta in 1877. In that year the government proposed to reduce the Jowaki allowance for guarding the Kohat Pass, and the tribesmen resented this by cutting the telegraph wire and raiding into British territory. A force of 1,500 troops penetrated their country in three columns, and did considerable damage by way of punishment.

(5) Expedition against the Jowaki Afridis under Brig.-General Keyes in 1877-78. The punishment inflicted by the previous expedition did not prove sufficiently severe, the attitude of the Jowakis continued the same and their raids into British territory went on. A much stronger force, therefore, of 7,400 British troops, divided into three columns, destroyed their principal villages and occupied their country for some time, until the tribe submitted and accepted government terms. The Kohat Pass was afterwards practically undisturbed.

(6) Expedition against the Zakka Khel Afridis of the Bazar valley under Brig.-General Tytler in 1878. At the time of the British advance into Afghanistan, during the second Afghan War, the Zakka Khel opposed the British advance and attacked their outposts. A force of 2,500 British troops traversed their country, and the tribesmen made their submission.

(7) Expedition against the Zakka Khel Afridis of the Bazar valley under Lieut.-General Maude in 1879. After the previous expedition the Afridis of the Khyber Pass continued to give trouble during the progress of the second Afghan War, so another force of 3,750 British troops traversed their country, and after suffering some loss the tribesmen made their submission. After this both the Khyber and Kohat Passes were put on a stable footing, and no further trouble of any consequence occurred in either down to the time of the frontier risings of 1897, when the Afridis attacked the Khyber Pass, which was defended by Afridi levies.

(8) For the Tirāh campaign of 1897 see **TIRĀH CAMPAIGN**.

(9) In February of 1908 the restlessness of the Zakka Khel again made a British expedition necessary, under Sir James Willcocks; but the campaign was speedily ended, though in the following April he had again to proceed against the Mohmands, the situation being complicated by an incursion from Afghanistan.

See Paget and Mason's *Frontier Expeditions* (1884); Warburton's *Eighteen Years in the Khyber* (1900).

(C. L.)

AFRIKANDER BOND, a party, founded in Cape Colony by the Rev. S. J. du Toit in 1879, aiming at federating South Africa in one independent republic. The official optional use of

Dutch in parliament and the law courts was secured, but under the leadership of Kofmeyer and the influence of Cecil Rhodes its anti-British sentiments were greatly modified. It was always, however, essentially an organization for the promotion of the political supremacy of the Cape Dutch. (See also HOFMEYER, JAN HENDRIK; CAPE COLONY; and SOUTH AFRICA, UNION OF.)

AFTERBIRTH, a term used to include the placenta, foetal membranes and umbilical cord. They are usually expelled from the womb in a single mass 1; to 30min. after the birth of the child. The placenta is a soft, beefy red disk, about 8 to 10in. in diameter and 1 to 1½in. in thickness. It is the organ by which the mother nourishes the child and is composed largely of capillary loops from mother and child, in close contact. While the mother's blood does not pass into the blood vessels of the child, the constituents necessary for growth pass through the capillary walls into the child's circulation by a process called osmosis, while the waste products in the foetal blood pass in the other direction and are eliminated by the mother. One surface of the placenta is attached to the inside of the womb, whence it draws its maternal blood. The other surface presents the branching blood vessels of the foetus which unite into one artery and two veins. These vessels form the umbilical cord, which usually starts from the middle of the placenta and enters the body of the foetus at the navel. It is about 22in. long. Around the edge of the placenta can be found the thin torn membrane which envelops the foetus in the womb. It forms the water bag in which the foetus floats, and usually breaks shortly before the birth of the child. If, however, the child is born with the membranes intact, he is said to be born in a caul.

AFTER-DAMP, in coal-mining, a name given to the poisonous choking gas which forms after a mine explosion. It mainly consists of carbon dioxide, and is also known as choke-damp. (See CHOKE-DAMP.)

AFTERGLOW, a broad high arch of radiance or glow seen occasionally in the western sky above the highest clouds in deepening twilight, or reflected from the high snowfields in mountain regions long after sunset. It is caused by very fine particles of suspended dust in the high atmosphere exercising a scattering effect upon the components of white light. After the eruption of Krakatoa in 1883, a remarkable series of red sunsets appeared all over the world. These were consequent on the spread by atmospheric currents of huge quantities of fine volcanic dust.

AFTER-IMAGE, the immediate recurrence of a sensation, in like or opposite quality, after the removal of its stimulus. After-images are most prominent in vision. If a person gazes steadfastly at a small coloured object for half a minute and then turns his eyes away to a neutral background, he will notice a small coloured spot of complementary hue and brightness. These are called *negative* after-images. If the object was red, the after-image is bluish green; if it was emerald green, the after-image is pink; if it was dark, the after-image is light. Positive after-images resemble the stimulus in brightness and hue and usually last only a few seconds. They are favoured by intense illumination in the stimulus, occurring after the eye has been in the dark. Positive after-images occur for pressure, temperature, and the sensations of bodily movement and posture. There are no after-images from sounds or odours.

AFTER-WORK, an expression used in Italy for the organized sociological efforts to provide for the better enjoyment and employment of the leisure created by the contraction of the working day. (See DOPOLAVORO.)

AFZEEIUS, ADAM (1750-1837), Swedish botanist, was born at Larf, Vestergötland. He founded the Linnaean Institute at Uppsala in 1802, and in 1812 became professor of materia medica at the university. In addition to various botanical writings, he published the autobiography of Linnaeus in 1823.

His brother JOHAN AFZELIUS (1753-1837) known as *Arvidson*, was professor of chemistry at Uppsala; and another brother, PER AF (1760-1843), who became professor of medicine at Uppsala in 1801, was distinguished as a medical teacher and practitioner.

AFZELIUS, ARVID AUGUST (1785-1871), Swedish poet, historian and mythologist. From 1828 till his death he was

parish priest of Enköping. He collaborated with the learned historian, Erik Gustaf Geijer, in the great collection of Swedish folk-songs, *Svenska folkvisor från forntiden* (1814-16). He published also translations of the *Såmunder Edda* and Herwara-Saga and a history of Sweden to Charles XII. (of which a German translation was published in 1842), as well as original poems.

AGA or AGHA, a word, said to be of Tatar origin, signifying a dignitary or lord. Among the Turks it is applied to the chief of the janissaries, to the commanders of the artillery, cavalry and infantry, and to the eunuchs in charge of the seraglio. It is also employed generally as a term of respect in addressing wealthy men of leisure, landowners, etc.

AGADE, the capital city of "Sargon of Agade." The city is probably identical with Tal-ed-Deir, excavated by Sir E. A. Wallis Budge in 1891. The inscriptions suggest that it was near Sippar, and Langdon identifies it with Sippar-Yakhuru, admitting, however, that the identification is uncertain. At ed-Deir there is a massive city wall forming two sides of a triangle; the third side was formed either by the Euphrates or by a canal. The main gate was at the western apex of the triangle. The city appears to have been constructed all at once, primarily as a fortress. Sargon, who is said to have been a gardener of Semitic origin at Kish, overthrew the Sumerian power of Kish and for some unknown reason changed his capital to Agade.

BIBLIOGRAPHY.—E. A. Wallis Budge, *By Nile and Tigris* (1920); S. Langdon, *Excavations at Kish* (1924).

AGADIR, the best Atlantic harbour of Morocco, 10km. N. of Wadi Jus. Pop. 3,081. It was the scene of Portuguese fisheries from 1500 and became a valuable commercial centre. Agadir sprang into prominence during the Moroccan crisis of 1911, and since 1912 it has belonged to France.

AGAIAMBO or **AGAUMBU**, a race of dwarf marsh-dwellers in British Kew Guinea, now extinct. In 1904 there were six males and four females, living in huts erected on piles in the lakes and marshes. They lived almost entirely in their "dug-outs" or canoes, or actually wading in the water. Their food consisted of sago, the roots of the water-lily and fish. In features, colour and hair they closely resembled the true Papuans.

AGA KHAN I, HIS HIGHNESS THE (1800-1881), the title adopted by general consent to HASAN ALI SHAH (born in Persia, 1800), when he settled in Bombay under the protection of the British Government. He was believed to have descended in direct line from Ali by his wife Fatima, the daughter of the Prophet Mohammed. Ali's son, Hosain, having married a daughter of one of the rulers of Persia before the time of Mohammed, the Aga Khan traced his descent from the royal house of Persia from the most remote, almost prehistoric, times. His ancestors had also ruled in Egypt, as caliphs of the Beni-Fatimites for a number of years, at a period coeval with the Crusades. Before the Aga Khan emigrated from Persia, he was appointed by the emperor Fateh Ali Shah to be governor-general of the extensive and important province of Kerman. His rule was noted for firmness, moderation and high political sagacity. At last, however, he incurred the mortal displeasure of Fateh Ali Shah. He fled from Persia and sought protection in British territory, preferring to settle down eventually in India, making Bombay his headquarters. In crossing over from Persia through Afghanistan the Aga Khan found opportunities of rendering valuable services to the British army in Afghanistan and thus cast in his lot with the British. A few years later he rendered conspicuous services in the course of the Sind campaign, when his help was utilized by Napier in the process of subduing the frontier tribes, a large number of whom acknowledged the Aga's authority as their spiritual head. When he finally settled down in India, his position as the leader of the large Ismailiah section of Mohammedan British subjects was recognized by the Government, and the title of His Highness was conferred on him, with a large pension. From that time until his death in 1881 the Aga Khan continued to discharge his sacerdotal functions, not only among his followers in India, but towards the more numerous communities which acknowledge his religious sway in Afghanistan, Khurāsān, Persia, Arabia, Central Asia, and even distant Syria and Morocco. He remained throughout

unflinchingly loyal to the British *Raj*, and his vast and unquestioned influence among the frontier tribes on the northern borders of India proved of invaluable service in the several expeditions led by British arms on the north-west frontier of India. He was also able to check the fanaticism of the more turbulent Mohammedans in British India.

He was succeeded by his eldest son, AGA KHAN II. This prince continued the traditions and work of his father and was a member of the legislative council of Bombay.

AGA KHAN III. (1877-) (Aga Sultan, Sir Mohammed Shah), only son of the foregoing, succeeded him in 1885. He was born in 1877, and, under the care of his mother, a daughter of the ruling house of Persia, was given not only that religious and oriental education which his position as the religious leader of the Ismailihs made indispensable, but a sound European training. The Aga Khan headed the Muslim deputation in 1906 to the Viceroy, Lord Minto, which submitted the case for encouraging abandonment of the studied aloofness of their community from Indian political life; and he was president of the All-India Muslim League, thereupon formed, during its first constructive years. He initiated the fund, for raising the Mohammedan college at Aligarh to university status, which was effected in 1920. In the immediate pre-war years he did much to soothe Indian Muslim sentiment in respect to the Turco-Italian and two Balkan wars. He was touring amongst his followers in East Africa, when the World War broke out, and immediately cabled to the *jamats* or councils of the millions of Ismailihs within British territories and on their borders directing his followers to place themselves unreservedly at the disposal of the British authorities. When Turkey was drawn into the struggle the Aga Khan issued a stirring manifesto showing that the Allies had no overt designs on Islam, and calling upon the Muslims of the empire to remain loyal and faithful to their temporal allegiance. His immediate followers provided a solid phalanx of whole-hearted support of Britain, which had a most steadying influence in sterilizing the efforts of impatient headstrong elements. His influence was reinforced by his close and intimate contact with leading Allied statesmen and the breadth and liberality of his outlook on the problems of reconstruction. His study of Indian and Middle Eastern affairs in *India in Transition* (1918) was not without considerable effect in the final shaping of reforms under the India Act of 1919, and was consistent in broad principle with his post-war criticisms of the British Government's Mesopotamian and Arabian policy.

The Aga Khan joined in many representations, public and private, both at the Peace Conference and subsequently, as to the immense importance to Great Britain, the ruler of the greatest aggregation of Muslims in the world, of not depriving Turkey of a real independent existence. To the G.C.I.E. and the G.C.S.I. already conferred on him there was added in 1916 a salute of 11 guns and the rank and status of a first-class chief of the Bombay Presidency, the only previous instance of the grant of a salute outside the Indian territorial ruling families being that of the first Salar Jung. The Aga Khan represented India at the World Disarmament Conference at Geneva in 1932.

AGALMATOLITE, a soft variety of the mineral pyrophyllite (HAlSi_2O_6), also called *pagodite*, used by the Chinese for carving, especially into grotesque figures (whence called "figure-stone").

AGAMEDES (ăg-ă-mă-dās), in Greek legend, king of Orchomenus in Boeotia. He and his step-brother Trophonius were skilled architects and constructors of underground shrines and treasure-houses. When building a treasure-house for the Boeotian king, Hyrieus, the brothers fixed one of the stones in the wall in such a manner that they could remove it whenever they pleased and help themselves to the treasure. Hyrieus set a trap in which Agamedes was caught; Trophonius to prevent discovery cut off his brother's head and fled with it. He was pursued by Hyrieus, and swallowed up by the earth in the grove of Lebadeia. On this spot was the oracle of Trophonius in an underground cave; those who wished to consult it, first offered a ram and called upon the name of Agamedes. A similar story is told

of the treasure of Rhapsinitus by Herodotus (ii. 121). The brothers built the temple of Apollo at Delphi. When they asked for a reward, the god promised them one in seven days; on the seventh day they died.

AGAMEMNON, a Homeric hero, son of Atreus, and Aërope, grandson of Pelops, great-grandson of Tantalus and brother of Menelaus. After the murder of Atreus (q.v.), Agamemnon and Menelaus took refuge with Tyndareus, king of Sparta, whose daughters, Clytaemnestra and Helen, they respectively married. By Clytaemnestra, Agamemnon had three daughters, Iphigeneia (Iphianassa), Electra (Laodice), Chrysothemis, and a son, Orestes. Menelaus succeeded Tyndareus, and Agamemnon, with his brother's assistance, drove out Aegisthus and Thyestes, and recovered his father's kingdom. He extended his dominion

BY COURTESY OF AMERICAN WOMEN'S HOSPITALS

THE TOMB AT MYCENAE, GREECE, KNOWN FOR YEARS AS THE TREASURE HOUSE OF ATREUS, AND CALLED THE TOMB OF AGAMEMNON

by conquest, and became the most powerful prince in Greece. When Paris (Alexander), son of Priam, had carried off his brother's wife, he went round to the princes of the country and called upon them to unite in a war of revenge against the Trojans. He himself furnished 100 ships, and was chosen commander-in-chief of the combined forces. The fleet, numbering 1,200 ships, assembled at the port of Aulis in Boeotia, but was prevented from sailing by calms or contrary winds. Calchas announced that the wrath of Artemis could only be appeased by the sacrifice of Iphigeneia (q.v.). The fleet then set sail. Little is heard of Xgamemnon

until his quarrel with Achilles (q.v.). After the capture of Troy, Cassandra, the daughter of Priam, fell to his lot in the distribution of the prizes of war. On his return, after a stormy voyage, he landed in Argolis. Aegisthus, who in the interval had seduced his wife Clytaemnestra, treacherously slew him with her help, Cassandra also perishing. The murder of Agamemnon was avenged by his son Orestes (q.v.). Agamemnon is quite possibly a more or less historical character, overlord of the Mycenaean or Achaean States of the Greek mainland. In Hellenistic times, at Sparta, he was worshipped under the title of Zeus Agamemnon. His tomb was pointed out among the ruins of Mycenae and at Amyclae.

AGAÑA, the capital and largest city of the island of Guam. The city is situated on the west coast on a low sandy beach that skirts the bay of the same name, and is about 1 m. N.E. of Piti, the port of entry for all water shipments, with which it is connected by an excellent road. The population, which is more than 90% native (Chamorro), was 7,432 in 1920; 8,690 in 1930 and 10,004 in 1940. The mean annual temperature is about 81°, and is nearly constant throughout the year; the daily variation is small. It is thought that Agaña was an important village before the coming of the Spaniards, who, during their 300 years of occupation, made it the governmental and religious centre of the island. On Feb. 1, 1899, Guam formally passed to the United States and the governor's palace at Agaña became the Government house. Near the centre of the city is the Plaza de España, an open green about 100 yd. square, bordered on all sides by rows of coconut palms. About the plaza are situated the Government house, the barracks, Dorn hall, which is used as a public school during the day, the court-house and the Catholic church. Beyond the church is the naval hospital. Agaña has two elementary schools and the only high school in Guam, a modern sewage system, a good water system, an electric light plant, telephones and a cold storage plant.

AGAPE, the early Christian love-feast (Gr. ἀγάπη, "Love"). The word seems to be used in this sense in Jude 12, but cf. 2 Pet. ii. 13, where the reading is ἀπάταις ("deceits") for ἀγάπαις. The history of the *agapē* coincides, until the end of the and century, with that of the eucharist (*q.v.*), and Tertullian's detailed account (*Apology*, c. 39) of the *agapē* is not, perhaps, exclusive of an accompanying eucharist: "It is the banquet (*triclinium*) alone of the Christians that is criticized. Our supper (*coena*) shows its character by its name. It is called by a word which in Greek signifies love (*i.e.*, *agape*). Whatever it costs, it is anyhow a clear gain that it is incurred on the score of piety, seeing that we succour the poorest by such entertainments (*refrigerio*). We do not lie down at table until prayer has been offered to God, as it were a first taste. We eat only to appease our hunger, we drink only so much as it is good for temperate persons to do. If we satisfy our appetites, we do so without forgetting that throughout the night we must say our prayers to God . . . After washing our hands and lighting the lamps, each is invited to sing a hymn before all to God, either taken from holy writ or of his own composition. So we prove him, and see how well he has drunk. Prayer ends, as it began, the banquet."

This evidence is good for Africa. But in Egypt about the same time (180-210), Clement of Alexandria (*Paedagogus*, ii. 1) condemns the "little suppers which were called, not without presumption, *agape*." This word, he complains, should be used only for the eucharist, not for mere junketings, into which the love-feasts of the church had degenerated. Tertullian too in his tract on fasting (ch. xvii.) mentions grave scandals in connection with the *agape*.

Ch. xiii. of the tract *About Virginity* (printed among the spurious works of Athanasius) describes a ritual meal which like that in 1 Cor. xi. is *agape* and eucharist in one, and it is held in a private house, not in church, and the celebrants are holy women.

The historian Socrates (*Hist. Eccl.*, v. 22) records the survival (which he characterizes as singular), around Alexandria and in the Thebaid, of love-feasts combined with the eucharist. So Basil of Cappadocia (Ep. 93), c. 359, states that in Egypt the laity, as a rule, celebrated the communion in their own houses, and partook of the sacrament by themselves whenever they chose. In the old Egyptian church order, known as the *Canons of Hippolytus*, there are numerous directions for the service of the *agapē*, held on Sundays, saints' days or at commemorations of the dead. Chrysostom describes (homily 54, tom. v., p. 365) how after the eucharistic synaxis the faithful remained in church, while the rich brought out meats and drink from their houses, and invited the poor, and furnished "common tables, common banquets, common symposia in the church itself." The Council of Gangra (A.D. 343?) anathematized the over-ascetic people who despised "the *agapēs* based on faith." But the holding of *agapēs* in church was forbidden by the councils of Laodicea (363) and Carthage (under Aurelius, 388-423), and later by the council in Trullo (692). In the age of Augustine the *agape* was frequent.

In the east Syrian, Armenian and Georgian churches, respectively Nestorian, Monophysite and Greek Orthodox in their tenets, the *agape* was from the first a survival, under Christian and Jewish forms, of the old sacrificial systems of a pre-Christian age. Sheep, rams, bullocks and fowls are given sacrificial salt to lick, and then sacrificed by the priest and deacon, who has the levitical portions of the victim as his perquisite. In Armenia the Greek word *agapē* has been used ever since the 4th century to indicate these sacrificial meals, which either began or ended with a eucharistic celebration. The earlier usage of the Armenians is expressed in two rules recorded against them by a renegade Armenian prelate named Isaac, who in the 8th century went over to the Byzantine church (Combesfius, *Historia Monothelitarum*, col. 317). Older mss. of the Greek Euchologion contain numerous prayers to be offered over animals sacrificed; and in the form of *agapē* such sacrifices were common in Italy and Gaul on the *natalis dies* of a saint, and Paulinus of Nola, in his Latin poems, describes them (c. 400) in detail. Gregory the Great sent to Mellitus, bishop of London, a written rite of sacrificing bulls for use in the English Church of the early 7th century. In Augustine's

work against Faustus the Manichean (xx. 4), the latter taxes the Catholics with having turned the sacrifices of the heathen into *agapēs*, their idols into martyrs, whom they worship with similar rite. The early Christian *agapē* admitted of adaptation to the older funeral and sacrificial feasts, and was so adapted. The association in the synoptics of the earliest eucharist with the paschal sacrifice provided a model, and long after the eucharist was separated from the *agapē* on other days of the year, we still find celebrated on the evening of Maundy Thursday the sacrifice of the paschal lamb, immediately followed by an eucharist. The council of Carthage enacted that the eucharist should be received fasting, except on the anniversary of the Lord's supper. It is clear that at an earlier date the *agape* preceded the eucharist.

Pagan Analogues.—In ancient states common meals called *sussitia* (*συσσίτια*) were instituted, particularly in the Doric States; e.g., Lacedaemon and Crete. Plato advocated them, and perhaps the later Jews imitated the Spartan community. Trade and other guilds in antiquity held subscription suppers or *ἐρανοί*, similar to those of the early Corinthian Church, usually to support the needs of the poorer members. These *hetairiai* or clubs were forbidden (except in cities formally allied to Rome) by Trajan and other emperors, as being likely to be centres of disaffection; and on this ground Pliny forbade the *agape* of the Bithynian churches, Christianity not being a lawful religion licensed for such gatherings. The custom which most resembles the eucharist and *agape* was that known as *charistia* described by Valerius Maximus ii. 1. 8: a solemn feast for members of one clan, at which those who had quarrelled were at the sacrament of the table (*apud sacra mensae*) reconciled. Ovid alludes to it (*Fasti*, ii. 617).

AGAPEMONITES OF COMMUNITY OF THE SON OF MAN. A sect founded in 1846 by the Rev. Henry James Prince, a clergyman of the Church of England (1811-1899). He studied medicine, obtained his qualifications in 1832 and was appointed medical officer to the general hospital in Bath, his native city. Compelled by ill-health to abandon his profession, he entered himself in 1837 as a student at St. David's theological college, Lampeter, where he gathered about him a band of earnest religious enthusiasts, known as the Lampeter Brethren, and was eventually ordained to the curacy of Charlinch in Somerset, where he had sole charge in the illness and absence of the rector, the Rev. Samuel Starkey. His work at this period reveals an almost hypnotic power over his converts; but soon he was mastered by delusions. He persuaded himself that he had been absorbed into the personality of God and had become a visible embodiment of the Holy Spirit. During his illness Mr. Starkey read one of his curate's sermons, and was not only "cured" forthwith, but embraced his strange doctrines, and together they procured many conversions in the countryside and the neighbouring towns. Forbidden the right to officiate in the Church of England, Prince and Starkey established themselves at Weymouth. Money flowed in; and with these resources they obtained the house at Spaxton, which became the "Abode of Love."

On the death of "Brother" Prince, the Rev. T. H. Smyth-Pigott, pastor of the "Ark,"—a branch church established at Clapton, London—became the acknowledged head of the sect. He was born in 1852, of an old Somersetshire county family, and, after a varied career as university man, sailor before the mast, soldier, coffee-planter, curate in the Church of England and evangelist in the Salvation Army, was converted about 1897 to the views of Prince. For five years after this he was not heard of outside his own sect. In Sept. 1902, however, he began to make claims similar to those of his predecessor, and proclaimed himself to be Christ. By the outside world the affair was greeted with mingled ridicule and indignation, and the new Messiah had to be protected by the police from the violence of an angry mob. Scandal was soon renewed through Pigott's relations with his female followers; and in Aug. 1908, an attempt to "tar and feather" him resulted in two men being sent to prison. Later in the month proceedings were instituted against him by the bishop of Bath and Wells under the Clergy Discipline Act.

See Law Reports, Court of Chancery, June 4-8, 1860; art. "Agapemone" in Hastings' *Encyclopaedia of Religion and Ethics*.

AGAPETAE, a name given to female Christian ascetics who dwelt with men under a vow of continency. This practice essentially belongs to the history of Christian asceticism. Its beginnings can be traced in the earliest Christian times, but it was preserved in monasticism down to the early middle ages.

See Hastings, *Encyclopaedia of Religion and Ethics*, "Agapetae"; see also ASCETICISM.

AGAPETUS, the name of two popes:

AGAPETUS I., pope from 535 to 536, collaborated with Cassiodorus in founding at Rome a library of ecclesiastical authors. King Theodahad sent him on an embassy to Constantinople, where he died, after having deposed Anthimus, the Monophysite bishop of that town, and ordained Menas his successor.

AGAPETUS II., pope from 946 to 955, at the time when Alberic, son of Marozia, was governing the independent republic of Rome under the title of "prince and senator of the Romans." He did his best to restore church discipline and to regain temporal power. His appeal to Otto the Great to intervene in Rome remained without immediate effect, since Alberic's position was too strong to be attacked, but it bore fruit after his death. Agapetus died on Nov. 8, 955.

AGAPETUS, a deacon of the church of St. Sophia at Constantinople, and author of a series of exhortations on the duties of a Christian prince, addressed (c. 527) to the emperor Justinian. The work was often reprinted, and has been translated into Latin, French and English.

AGAR-AGAR, a vegetable product resembling gelatine and made from various East Indian seaweeds. In China it is used as an ingredient of "bird's nest soup," but its main employment is as a culture-medium for bacteria. It is occasionally utilized also as a laxative.

AGARDE, ARTHUR (1540-1615), English antiquary. As a member of the Society of Antiquarians, he prepared papers for its meetings on such subjects as the origin of parliament, the office and privileges of heralds, six of these essays being printed, after his death, in Thomas Hearne's collection of *Curious Discourses written by Eminent Antiquaries* (1720). Agarde was for 45 years deputy chamberlain of the Exchequer. He bequeathed to the Exchequer his collection of papers relating to that court, and to his friend, Sir Robert Cotton, his other manuscripts, most of which are now in the British Museum.

AGARDH, KARL ADOLF (1785-1859), Swedish botanist, was born on Jan. 23, 1785, at Badstad. He was educated at Lund, where in 1807 he became lecturer in mathematics, and in 1812, professor of botany and rural economy. After being ordained in 1816, he was elected to the diet where, as a leading Liberal, he worked for the promotion of education. In 1834 he became bishop of Karlstad, where he died on Jan. 28, 1859. Agardh's chief works are *Systema Algarum* (1824), *Species Algarum* (1823-28), *Icones Algarum Europaeorum* (1828-35), *Essai de réduire la physiologie végétale à des principes fondamentaux* (1828), *Lärobok i botanik*, 2 vols. (1830) and (with Ljungberg)

Försök till en statsekonomisk statistik öfver Sverige, 4 vols. (1852-63).

AGARIC, the name applied to fungi with the spores borne on gills (mushrooms), from the generic name *Agaricus*. In pharmacology, a medicinal preparation derived from the fungus *Fomes officinalis*, a polypore growing principally on larch and pine.

AGAS, RADULPH or **RALPH** (c. 1540-1621), English land surveyor, was born at Stoke-by-Nayland, Suffolk. He is best known for his maps of Oxford (1578), Cambridge (1592) and London. Copies of the first two are preserved in the Bodleian library. Of the map of London and Westminster, which was probably prepared about 1591, two copies have been preserved, one by the Corporation of London and the other in the Pepysian collection at Magdalene college, Cambridge. The map is over 6 ft. long, printed from wooden blocks.

AGASIAS. There were two Greek sculptors of this name. Agasias, son of Dositheus, signed the statue called the Borghese Warrior in the Louvre. Agasias, son of Menophilus, is the sculptor of another striking figure of a warrior in the museum of Athens. Both belonged to the school of Ephesus and lived about 100 B.C. (See Gardner, *Handbook of Greek Sculpture*, ii. p. 475.)

AGASSIZ, ALEXANDER EMANUEL (1835-1910), American man of science, son of J. L. R. Agassiz, was born in Neuchâtel, Switzerland, on Dec. 17, 1835. He came to the United States with his father in 1846; graduated at Harvard in 1855, subsequently studying engineering and chemistry, and taking the degree of bachelor of science at the Lawrence scientific school of the same institution in 1857; and in 1859 became an assistant in the U.S. coast survey. Thenceforward he became a specialist in marine ichthyology, but devoted much time to the investigation, superintendence and exploitation of mines, being superintendent of the Calumet and Hecla copper mines, Lake Superior, from 1866 to 1869, and afterwards, as a stockholder, acquiring a fortune, out of which he gave to Harvard, for the museum of comparative zoology and for furthering the study of biology at Harvard and elsewhere upwards of \$1,000,000. In 1875 he surveyed Lake Titicaca, Peru, examined the copper mines of Peru and Chile, and made a collection of Peruvian antiquities for that museum, of which he was curator from 1874 to 1885. He assisted Sir Wyville Thomson in the examination and classification of the collections of the "Challenger" exploring expedition, and wrote the *Revision of the Echini* (1872-74) in the reports. Between 1877 and 1880 he took part in the three dredging expeditions of the steamer "Blake," of the U.S. coast survey, and presented a full account of them in 1888. Of his other writings on marine zoology, most are contained in the bulletins and memoirs of the museum of comparative zoology; but he published in 186j (with Elizabeth Cary Agassiz, his stepmother) *Seaside Studies in Natural History*, a work at once exact and stimulating, and in 1871 *Marine Animals of Massachusetts Bay*. He died at sea on the "Adriatic" bound for the United States on March 27, 1910.

See G. R. Agassiz, ed., *Letters and Recollections of Alexander Agassiz: With a Sketch of his Life and Work* (Boston, 1913).

AGASSIZ, JEAN LOUIS RODOLPHE (1807-1873), Swiss-American naturalist, geologist and teacher, was born on May 20, 1807, the son of the Protestant pastor of Motier, on the shore of Lake Morat, Switzerland. His father was the last of a long line of clergymen, the first of the series having been driven from France by the revocation of the Edict of Nantes. His mother, Rose Mayor, was a gifted woman from whom especially he inherited his love of animals and plants. In boyhood he spent four years at the gymnasium in Bienne and later attended the academy at Lausanne. He then entered, successively, the universities of Zurich, Heidelberg and Munich. On completion of his academic courses, Agassiz took at Erlangen the degree of Doctor of Philosophy and at Munich that of Doctor of Medicine.

Although as a youth he gave some interested attention to the ways of the brook fish of western Switzerland, his permanent and lifelong interest in ichthyology arose from his being chosen to study the fishes of Brazil. In 1819 and 1820 two eminent naturalists of Munich, J. B. Spix and C. P. J. von Martius, had made an extensive tour in Brazil, bringing back a large collection of

fishes, mostly from the Amazon river. The classification of these species was begun by Spix; he died in 1826, however, and the whole collection was then turned over by Martius to Agassiz. The work was completed and published in 1829, as *Selecta Genera et Species Piscium*. This splendid accomplishment was a monument to youthful industry and enthusiasm, the author being at that time only 22 years old. The study of fish-forms became henceforth the prominent feature of Agassiz's scientific research. In 1830 he issued a prospectus of a *History of the Fresh Water Fishes of Central Europe*, a valuable contribution printed in parts from 1839 to 1842.

The year 1832 proved the most significant in Agassiz's early career, because it took him first to Paris, then the centre of

AFTER "RECHERCHES SUR LES POISSONS FOSSILES"

AFTER A SPECIMEN DISCOVERED DURING HIS RESEARCHES AT NEUCHÂTEL

general scientific as well as medical research, and afterwards to Neuchâtel where he spent many years of amazingly fruitful effort. While in Paris he lived the life of an impecunious student of the *quartier latin*, supporting himself, helped at times by the kindly interest of friends, such as Humboldt, who soon secured for him a professorship at Neuchâtel, and Cuvier, the most eminent ichthyologist of his time. At Paris his scientific activities largely centred in the Natural History museum of the great park now known as the Jardin des Plantes.

Already Agassiz had become interested in the rich stores of the extinct fishes of Europe, especially those of Glarus in Switzerland and of Monte Bolca near Verona, of which only a few at that time had been critically studied. As early as 1829, Agassiz planned a comprehensive and critical study of these remains. To this end he gathered material wherever possible. His epoch-making work, *Recherches sur les Poissons Fossiles*, appeared in parts from 1833 to 1844. In it the number of named fossil fishes was raised to nearly 1,000, and the ancient seas were made to live again through disclosure of their inhabitants. The great importance of this foundation work rests on the impulse given to the study of extinct life itself. Turning his attention to other extinct animals found with the fishes, Agassiz published in 1839-40 two quarto volumes on the fossil echinoderms of Switzerland, and later (1840-45) his *Études Critiques sur les Mollusques Fossiles*.

From 1832 to 1846 he served as professor of natural history in the University of Neuchâtel, where may still be found evident traces of the activity and enthusiasm of its youngest and most eager teacher. In Neuchâtel he acted for a time as his own publisher, his private residence even becoming a hive of activities. Numerous young men were co-workers with him, dividing between themselves the scanty returns from his lectures and publications. He now began his *Nomenclator Zoologicus*, a catalogue, with references, of all the names applied to genera of animals from the beginning of scientific nomenclature, a date since fixed at Jan. 1, 1758. "This," said Agassiz, "is a work of patience. It is a barrier against the Babel of confusion which threatens to overwhelm the domain of zoological synonymy." The practical value of the compilation can hardly be overestimated.

In 1836 Agassiz began a new line of studies, that of the movements and effects of the glaciers of Switzerland. Several writers had expressed the opinion that these rivers of ice had once been much more extensive, and that the erratic boulders scattered over the region and up to the summit of the Jura mountains, were carried by moving glaciers. On the ice of the Aar glacier he built a hut, the "Hôtel des Neuchâtelois," from which he and his associates traced the structure and movements of the ice. In 1840 he published his *Études sur les glaciers*, in some regards the most important of all his works. In it he was able to show that at a period geologically recent Switzerland was covered by one vast ice-sheet. His final conclusion was that "great sheets of ice, resembling those now existing in Greenland, once covered all the countries in which unstratified gravel (boulder drift) is found."

In 1846 Agassiz was led to visit the United States for the general purpose of studies in natural history and geology, but immediately to give a course of lectures in the Lowell institute in Boston. These were followed by another series in Charleston, and afterwards by lectures both popular and technical in various cities, his brilliant and engaging personality at once winning all hearts. In 1848 he accepted a professorship of zoology at Harvard university, and from that time on became more and more enthusiastically American. Indeed, half his scientific career, and that not the least important, was lived in this country. "He came in a spirit of adventure and curiosity; he stayed because he loved a land where he could think and act as he pleased; a land where nature is rich but tools and workmen are few, and traditions none."

In America his chief volumes of scientific research were the following: *Lake Superior* (1850); *Contributions to the Natural History of the United States* (1857-1863, in several quarto volumes, the most notable being on the embryology of turtles); and the *Essay on Classification*, a brilliant production, which, however, failed to grasp the trend of modern zoology. Besides these extensive contributions appeared a multitude of short papers on natural history and especially on the fishes of America. His two excursions of highest importance were, first, to Brazil in 1865, and second, to California in 1871, the latter trip involving both shores of South America. *A Journey in Brazil* by Mrs. Agassiz and himself, published in 1868, gives a very interesting account of their experiences on the earlier voyage. His most important paper on American fishes dealt with the remarkable group of viviparous surf-fishes of California.

During many years, also, Agassiz was deeply absorbed in his cherished plan of developing at Harvard university a comprehensive museum of research in zoology. This institution, which was established in 1859 and ultimately grew into the present splendid museum of comparative zoology, enjoyed his fostering care during the rest of his lifetime. In America Agassiz's industry and devotion to scientific pursuits were as strongly marked as in Europe, but two other traits here assumed a much greater importance. As a teacher of science he was extraordinarily skilful, certainly the ablest America has ever known. In addition he was personally devoted to his students, who were in the highest sense co-workers with him—"the best friend that student ever had." His warmth of feeling moreover went out equally to colleagues and neighbours. It was said that "one had less need of an overcoat in passing Agassiz's house than any other in Cambridge." Such qualities, endeared him to all, while his amazing command of lucid and picturesque English impressed every listener. He was also as much at home before an audience of labourers or farmers as with the most erudite leaders of research.

Agassiz's method as teacher was to give contact rather than information. He discouraged the use of books except in detailed research. Among his favourite expressions were "If you study nature in books, when you go out-of-doors you cannot find her." "It's not text-books we want, but students. The book of nature is always open." "Strive to interpret what really exists." The result of his instruction at Harvard was a complete revolution in natural history study in America. The purpose came to be not a category of facts taken from others, but the ability, through contact, to gather the needed facts. As a result of his activities

every notable teacher of natural history in the United States for the second half of the 19th century was at some time a pupil of Agassiz or of one of his students.

In the interests of better teaching and of scientific enthusiasm, he organized in the summer of 1873 the Anderson school at Penikese, an island in Buzzard's bay. The details of this remarkable venture, brief in actual period but having a profound effect on science teaching and the precursor of all American summer schools and establishments for marine research, cannot be given here. But "the school of all schools which has had the greatest influence on science teaching in America was held in an old barn on an uninhabited island, 18 miles from the shore; it lasted but three months; it had virtually but one teacher. It existed in the personal presence of Agassiz. When he died, it vanished." (David Starr Jordan, *Agassiz at Penikese*.)

As Agassiz was beyond question one of the ablest, wisest and best informed of the biologists of his day, it is often asked why his attitude towards Darwinism was, throughout all his lifetime, cold and unsympathetic. It seems possible that his position was determined in part by a misunderstanding, but more particularly by his philosophy of biology. He seemed to regard Darwinism as a theory of continued progress instead of one of divergence, tempered by the weeding out of unadapted individuals. He failed to recognize the importance of separation and segregation in the development of new specific forms. He once said that in his studies of fossils he "was on the verge of anticipating Darwinism," but was withheld by the discovery that "we had the higher fishes first." In a sense this was true, for the brain development of the sharks is higher, as a whole, than that of the bony fishes. But the latter are far more specialized in fitness for aquatic life. More important to Agassiz was the fact that in his philosophy each species of animal or plant was in itself "a thought of God." Their homologies or fundamental unities were "associations of ideas in the Divine Mind." He had an intensely religious mind, although he was totally out of sympathy with sects and creeds and the outer shell of Christianity.

In physical appearance Agassiz was a striking figure, nearly six feet tall, compactly built, with noble head and broad handsome face, usually illuminated by an especially charming smile. This last, however, would suddenly turn into a frown in the presence of careless or trivial work or pretence on the part of a student. He married twice. His first wife, Cecile Braun, was the sister of an eminent botanist. In 1850, after his first wife's death, Agassiz married Elizabeth Cabot Cary, of Boston, well known as a writer and as a promoter of the education of women.

Agassiz died on Dec. 12, 1873. He was buried in Mt. Auburn at Cambridge, and by his grave stands a boulder from the moraine of the Lauteraar. At his death, Theodore Lyman, one of his students, wrote, "We buried him from the chapel that stands among the college elms. The students laid a wreath of laurel on his bier and their manly voices sang a requiem. For he had been a student all his life long, and when he died he was younger than any of them."

(D. S. J.)

AGATE, a term applied, not to a distinct mineral species, but to a group of amorphous and crypto-crystalline forms of silica. According to Theophrastus the agate (*ἀχάτης*) was named from the river Achates, now the Drillo in Sicily, where the stone was originally found. Most agates occur in eruptive rocks or ancient lavas where they fill the cavities which were produced by the lib-

eration of gas during the solidification of the molten rock. These agates have a banded structure, successive layers being approximately parallel to the sides of the cavity. A number of varieties of agate are characterized by peculiarities in the shape and colour of the bands, which are seen in sections cut at right-angles to the layers. In riband-agate they are straight or slightly curved. Such an agate with cloudy bands alternating with bands of another colour, the two sets being sharply marked off from one another, is known by the general term onyx. A ring or eye agate is one in which the differently coloured bands are disposed in concentric circles. A Mexican agate, showing only a single eye has received the name of "cyclops." When the banding forms re-entrant and salient angles, its outline resembling that of the plan of a fortress, it is called fortification-agate. Certain agates also occur, to a limited extent, in veins, of which a notable example is the beautiful brecciated agate of Schlottwitz, near Wesenstein in Saxony—a stone mostly composed of angular fragments of agate cemented with amethystine quartz. A variety having included matter of a green colour, embedded in the agate and disposed in filaments and other forms suggestive of vegetable growth, is known as moss agate. Dendritic markings of black or brown colour, due to infiltration of oxides of manganese and iron, produce the variety known as Mocha stone.

It is probable that agates occurring in cavities in igneous rocks have been formed in a number of ways, and various theories of their origin have been proposed. The theory which is now generally accepted is as follows. During the solidification of the rock an accumulation of gas or steam causes a bubble to form. Long after, when the rock has solidified, water carrying silica in solution, probably as alkali silicate, penetrates into the region where the bubble is located. It then diffuses into the cavity and subsequently the solution coagulates to a silica gel. The alkali present with the silica attacks the iron-bearing rock surrounding the cavity, giving rise to iron salts. These diffuse into the silica gel and produce the regular layers of iron hydroxide after the manner of Liesegang's rings. Finally the whole mass gradually hardens with loss of water and crystallization of much of the silica as quartz or chalcedony. During the process of crystallization the coloured bands are not disturbed and hence we have the final agate as it is now found.

Agates are cut and polished chiefly in the Idar-Oberstein district situated on the Nahe, a tributary of the Rhine at Bingen. Here the industry grew up many centuries ago by reason of an abundance of agates in the amygdaloidal melaphyre of the district. The stones used now are mostly imported from Brazil (Rio Grande do Sul) and from Uruguay.

Most commercial agate is artificially stained so that stones naturally unattractive by their dull grey tints come to be valuable for ornamental purposes. The colouring matter is absorbed by the porosity of the stone, but different stones and different layers of the same stone exhibit great variation in absorptive power. To produce a dark brown or black colour, the stone is kept perhaps for two or three weeks in a saccharine solution, or in olive oil at a moderate temperature. After removal from the solution, the agate is well washed and then digested for a short time in sulphuric acid, which, entering the pores, carbonizes the absorbed sugar or oil. Certain layers of chalcedony are practically impermeable and these consequently remain uncoloured, so that an alternation of dark and white bands is obtained, giving rise to an onyx. Agate is stained red, to imitate cornelian and sardonyx, by means of ferric oxide. Other colours are obtained in other ways.

Among the uses to which agate is applied may be mentioned the formation of knife-edges of delicate balances, small mortars and pestles for chemical work, burnishers and writing styles, umbrella handles, paper knives, seals, brooches and other ornaments. Real cameos are cut from banded agates, one layer forming the medalion, the other the design in relief.

Agates are found in England in the Cheviot Hills, in the neighbourhood of Bristol and at Lichfield in Staffordshire. In Scotland they occur at Montrose in Forfarshire, in Perthshire, and at many other localities. The majority of agates are produced in countries outside Europe, notably in South America, North America and India; they are also found in South Africa and Australia.

Falz, *Die Idar-Obersteiner Schmuckstein-Industrie, unter besonderer Berücksichtigung ihrer Betriebsformen und ihrer Handelorganisation* (1926). For American agates see G. F. Kunz, *Gems and Precious Stones of North America* (1890). For Scottish agates see M. F. Heddle, *Mineralogy of Scotland* (1901).

(W. A. W.)

AGATHA, ST., the patron saint of Catania, Sicily, where her festival is celebrated on Feb. 5. The legend is that she was a native of Sicily (probably of Catania, though Palermo also claims her) of noble birth and great beauty. She repelled the advances of the Roman prefect sent by the emperor Decius to govern Sicily, and was by his orders brutally tortured and finally sent to the stake. As soon as the fire was lighted an earthquake occurred and the people insisted on her release. She died in prison on Feb. 5, 251. The rescue of Catania from fire during an eruption of Mt. Etna was later attributed to St. Agatha's veil.

AGATHANGELUS, AGATHANGE or **AKATHANKELOS**, Armenian historian, lived during the 4th century, and wrote a History of the *Reign* of Dertad, or Tiridates, and of the Preaching of St. Gregory the Illuminator. This history was translated into several languages, and Greek and Latin translations are found in the *Acta Sanctorum Bollandistarum*, tome viii. The history consists of three parts, a history of St. Gregory and his companions, the doctrine of Gregory, and the conversion of Armenia to Christianity.

See V. Langlois, *Collection des Historiens anciens et modernes de l'Arménie* (Paris, 1868).

AGATHARCHIDES or **AGATHARCHUS**, of Cnidus, Greek historian and geographer, lived in the time of Ptolemy Philometor (181–146 B.C.) and his successors. Amongst other works, he wrote treatises on Asia, *Europe* and the Red Sea. Interesting extracts from the last, of some length, are preserved in Photius (cod. 213).

BIBLIOGRAPHY.—See H. Leopoldi, *De Agatharchide Cnidio Dissertatio* (1892); C. W. Müller, *Fragmenta Historicorum Graecorum*, iii., and *Geographi Graeci Minores*, i.; E. H. Bunbury, *Hist. of Ancient Geography*, ii. (1879).

AGATHARCHUS, the name of an Athenian painter of the 5th century B.C. He is said by Vitruvius to have been the first to paint a scene for the acting of tragedies.

AGATHIAS (c. A.D. 536–582), of Myrina in Aeolis, Greek poet and historian. He studied law at Alexandria, completed his training at Constantinople and practised as an advocate (*scholasticus*) in the courts. He wrote a number of short love-poems in epic metre, called *Daphniaca*. He next put together a kind of anthology, containing epigrams by earlier and contemporary poets and himself, under the title of a Cycle of New Epigrams. About a hundred epigrams by Agathias have been preserved in the Greek Anthology. After the death of Justinian (565), some of Agathias's friends persuaded him to write the history of his own times. This work, in five books, begins where Procopius ends, and is the chief authority for the period 558–58.

Dindorf, *Historici Graeci Minores* (1871); W. S. Teuffel, "Agathias von Myrine," in *Philologus* (i. 1846); C. Krumbacher, *Geschichte der byzantinischen Literatur* (2nd ed. 1897).

AGATHO, pope from 678 to 681, was born in Sicily. He ordered St. Wilfrid to be restored to his bishopric at York in 679, and was the first pope to cease payment of the tribute hitherto paid on election to the emperor at Constantinople. Agatho died on Jan. 10, 681.

AGATHOCLES (361–289 B.C.), tyrant of Syracuse, was the son of a potter, born at Thermae Himeratae (mod. Termini Imerese) in Sicily. He removed to Syracuse and served with distinction in the army. In 333 B.C. he married the widow of his patron Damas, a distinguished and wealthy citizen. He was twice banished for attempting to overthrow the oligarchical party in Syracuse (*q.v.*); in 317 B.C. he returned with an army of exiles and Campanian mercenaries. He banished or murdered some 10,000 members of the senate and the oligarchical party, proclaiming

himself the champion of the people, and thus made himself master of Syracuse. His tyranny was confirmed by a virtually unanimous vote of the people, and, despite his continuous wars, he seems to have been generally popular. He enriched Syracuse with many public buildings, and his reign was looked back to as a period of orderliness and tranquillity. His foreign policy was inevitably part of the almost continuous 200 years' war between the Sicilian Greeks and their secular enemy, Carthage (*q.v.*). In these wars Syracuse had always taken the lead, and Agathocles only continued the policy of Dionysius the Elder, Dionysius the Younger and Timoleon (*qq.v.*).

In 310 B.C. Agathocles, defeated and besieged in Syracuse, took the desperate resolve of breaking through the blockade and attacking the enemy in Africa. He besieged Carthage, which was at the time troubled by internal dissensions, but after several victories he was at last completely defeated (306) and fled secretly to Sicily. After concluding peace with Carthage, Agathocles styled himself king of Sicily and established his rule over the Greek cities of the island more firmly than ever. Even in his old age he displayed the same energy and is said to have been meditating a fresh attack on Carthage at the time of his death, which was followed by a recrudescence of Carthaginian power in Sicily. Agathocles was something more than the typical leader of mercenaries. He was a born leader, who knew how to inspire devotion.

BIBLIOGRAPHY.—See Justin xxii., xsiii.; Diodorus Siculus xix., xxi., xxii. (follows generally Timaeus who had a special grudge against Agathocles); Polybius ix. 23; Schubert, *Geschichte des Agathokles* (1887); Grote, *History of Greece*, ch. 97; also SICILY: *History*.

AGATHODAEMON, an early map designer of Alexandria, who probably lived in the 2nd century A.D. Some manuscripts of the Geography of Ptolemy contain 27 maps, which are stated to have been drawn by Agathodaemon of Alexandria, who "delineated the whole world according to the eight books of Ptolemy's geography." About 1470, Nicolaus Doris, a Benedictine monk, produced an edition of them in which the names were inserted in Latin instead of Greek.

See Bunbury, *History of Ancient Geography*, ii.

AGATHODAEMON, an important god in Greek mythology, the "good spirit" of cornfields and vineyards, protective spirit of individuals and the State. The Greeks drank a cup of pure wine in his honour at the end of each meal (Aristophanes, *Equites*, 106). Often accompanied by Agathe *Tuchē* (good fortune), he may be compared with the Roman *Bonus Eventus* (Pliny, *Nat. Hist.*, xxxvi., 23) and *Genius* (*q.v.*). He is represented in works of art in the form of a serpent, or of a young man with a horn of plenty and a bowl in one hand, and a poppy and ears of corn in the other.

AGATHON (c. 448–400 B.C.), Athenian tragic poet, friend of Euripides and Plato. He won his first victory in 416 (at the Lenaea), and his plays seem to have been successful, despite their artificial style. He appears to have been the first to invent an original plot, and to write choral odes unconnected with the plot. His effeminacy made him a butt of Aristophanes. Before 406 he retired to the court of Archelaus, where he died.

See Aristotle, *Poetica* g. and 18; Aristophanes, *Thesmoph.* 59, 106, *Eccles.* 100; Plato, *Symp.* 198 c.; Plutarch, *Symp.* 3; Aelian, *Var. Hist.* siv. 13; Ritsch, *Opuscula*, i.; fragments in Nauck, *Tragicorum Graecorum Fragmenta*. See also Haigh, *Tragic Drama of the Greeks*.

AGATHYRSI, a people of Thracian origin, who in the earliest historical times occupied the plain of the Maris (Maros), in the region now known as Transylvania. They are described by Herodotus (iv. 104) as of luxurious habits, wearing gold ornaments (the district is still auriferous) and having wives in common. They tattooed their bodies (Virgil, *Aeneid*, iv. 136), degrees of rank being indicated by the manner in which this was done, and coloured their hair dark blue. Valerius Flaccus (*Argonautica*, vi. 135) calls them Thyrsagetæ, probably in reference to their celebration of orgiastic rites in honour of some divinity akin to the Thracian Dionysus. In later times the Agathyrsi were driven farther north, and their name was unknown to the Romans in their original home.

See Pliny, *Nat. Hist.* iv. 12 [26], 88.

AGAVE, a large botanical genus of the family Amaryllidaceae, chiefly Mexican, but occurring also in the southern and western United States and in central and tropical South America. The plants have a large rosette of thick fleshy leaves generally ending in a sharp point and with a spiny margin; the stout stem is usually short, the leaves apparently springing from the root. They grow slowly and flower but once after a number of years, when a tall stem or "mast" grows from the centre of the leaf-rosette and bears a large number of short, tubular flowers. After development of fruit the plant dies down, but suckers are frequently produced from the base of the stem which become new plants. The most familiar species is *Agave americana* (see fig.), a native of tropical America, the so-called century plant or American aloe (the Maguey of Mexico). The number of years before flowering, 5 to 60 or more, but usually about 10, depends on the vigour of the individual, the richness of the soil and the climate; during these years the plant is storing in its fleshy leaves the nourishment required for the effort of flowering. During the very rapid development of the immense peduncle, or flowering stalk, there is a rush of sap to the base of the young flower stalk; by removing this large bud just as it is ready to emerge and by scooping out a cavity in the heart of the plant, a large quantity of sweet sap is obtained; and this *aguamiel*, removed, carried in pigskin bottles to the central repository, undergoes two kinds of fermentation, and when it has become thick, milky and more or less ropy (the sugars then being changed into alcohol) it is marketed as *pulque* (*q.v.*), the national drink of Mexico; notwithstanding its objectionable odor and consistency it is by some thought a wholesome and nourishing drink, and many train-loads are brought daily to Mexico City from the vast *pulque* plantations in the surrounding region. By distillation of *pulque fuerte*, or completely fermented juice, a very strong liquor, *mescal*, is obtained.

The leaves of several species yield commercial fibres: *A. rigida elongata* or *A. fourcroydes* is the henequen, or Yucatan sisal, formerly the principal sisal hemp (*q.v.*). *A. rigida sisalana* or *A. sisalana* is the Bahama sisal, the culture of which is expanding greatly in East Africa and Haiti.

A. cantula is the Maguey, or Philippine sisal.
A. zapufo is the Mexican *Zapufo* fibre.
A. americana produces one of the *Pita* fibres, now grown in southern Europe and parts of the West Indies as well as in Mexico.

A. neglecta is the Florida sisal, one of the largest species, the flower-stalk of which may exceed 42 feet in height.

The firm white pith of the interior of the flowering stem of any of these species, when dried and cut in slices has a variety of uses—as natural razor-strops, as lining of insect-boxes, insulating material, etc. The gummy, soapy juice expressed from the leaves will lather like soap and may be used as a detergent where alkali would be injurious. The thick reddish roots of various species are reputed to have medicinal properties. The concentrated sap exuded into the scooped-out central bud cavity is also used as a medicine and is a source of agavose (C₁₂H₂₂O₁₁), one of the rare sugars. In the Madras Presidency the plant is widely used for

LONGITUDINAL SECTION FROM BAILLON.
 "HISTOIRE DES PLANTES"
 CENTURY PLANT (*A. AMERICANA*).
 SO NAMED BECAUSE IT WAS SUPPOSED TO BLOSSOM ONLY WHEN 100 YEARS OLD AND THEN DIE
 Showing long flower stem and rosette of spiny leaves; vertical section and single flower enlarged

hedges along railroads. *Agave americana* was introduced into Europe about the middle of the 16th century and is now extensively cultivated for its handsome appearance; in the variegated forms the leaf has a white or yellow marginal or central stripe from base to apex. As the leaves unfold from the centre of the rosette the impression of the marginal spines is very conspicuous on the still erect younger leaves.

AGDE, a town of south France, in the department of HCraut, 2½ m. from the mouth of the HCraut, and 32 m. S.W. of Montpellier on the Southern railway. Pop. (1936), 8,546. It lies at the foot of an extinct volcano, the Colline St. Loup, and is surnamed "La Ville Noire" from the dark volcanic basalt of which it is built. Agde is said to have been founded as a port by Phocaeans under the name of *Agathe*. It was the seat of a bishop from 400 to 1790. Overlooking the river is the old Cathedral of St. Etienne, a grim fortress-like structure of the 12th century. The machicolations of the parapet are said to be the oldest existing instance of the kind. The *Canal du Midi*, uniting the Garonne with the Mediterranean, passes under the town walls. The maritime commerce of the town has declined, because Certe is near and the HCraut shallow, but the fishing industry is still alive. The town has a tribunal of commerce.

SYNOD OF AGDE (*Concilium Agathense*).—The 47 genuine canons of the synod (Sept. 11, 506), dealt with discipline, church life, alienation of ecclesiastical property and treatment of Jews. While favouring sacerdotal celibacy the council laid rather rigid restrictions on monasticism. It commanded that the laity communicate at Christmas, Easter and Whitsuntide. The canons of Agde are based in part on earlier Gallic, African and Spanish legislation; and some of them were re-enacted by later councils.

AGE. The subject of the duration of human and animal life does not fall within the scope of this article, and the reader is referred to **LONGEVITY**. But the word "age" has been used by physiologists to express certain natural divisions in human development and decay. These are usually regarded as numbering five, viz., *infancy*, lasting to the seventh year; *childhood* to the 14th; *youth* to the 21st; *adult life* till 50; and *old age*.

The division of human life into periods for legal purposes is naturally more sharp and definite than it can be for physiological purposes. In Roman law the legal divisions were (1) *infantia* lasting till the close of the seventh year; (2) the period between *infantia* and *pubertas*, males becoming *puberes* at 14 and females at 12; (3) *adolescentia*, the period between puberty and majority; and (4) the period after the 25th year, when males become *majores*. By English law, life is divided into two main periods—*infancy*, which lasts in both sexes until the 21st year, and manhood or womanhood. The period of infancy, again, is divided into several stages, marked by the growing development both of rights and obligations. Thus at 12 years of age a male may take the oath of allegiance; at 14 both sexes are held to have arrived at years of discretion, and may therefore choose guardians, give evidence, and consent or disagree to a marriage. A female has the last privilege from the 12th year, but the marriage cannot be celebrated until the majority of the parties without the consent of parents or guardians. At 21 both males and females obtain their full legal rights and become liable to all legal obligations. Thus both sexes may enter parliament and be called to the bar, upon attaining majority. In the Church of England, however, a candidate for deacon's orders must be 23 (in the Roman Catholic Church, 22), and for priest's orders 24 years of age; and no clergyman is eligible for a bishopric under 30. In Scotland infancy is not a legal term. The time previous to majority, which, as in England, is reached by both sexes at 21, is divided into two stages: *pupilage* lasts until the attainment of puberty, which the law fixes at 14 in males and 12 in females; *minority* lasts from these ages respectively until 21. *Minority* obviously corresponds in some degree to the English *years of discretion*, but a Scottish minor has more personal rights than an English infant in the last stage of his infancy, e.g., he may dispose by will of movable property, make contracts, including that of marriage, carry on trade and become liable to be declared a bankrupt. Throughout the British Empire the age of majority is usually 21, but the

nubile age is 20 in the Channel Islands; 18 in New Brunswick and Ontario; 18 for females in the North-West Territories and 15 for native females in Fiji. In Belgium and France the age of majority is 21, and the nubile age 18 for males and 17 for females, but marriage cannot be contracted without the consent of the parents or guardians if the parties are under 25. The age of majority is in Argentina 22; in Chile, Spain and Austria 24; in China 20; in Brazil, Denmark, Holland, Germany, Greece, Italy, Mexico, Norway, Peru, the Philippines, Poland, Portugal, Rumania, Sweden, Switzerland and Tunis, 21. In Denmark the nubile age is 18 for males and 16 for females; in Germany 20 for males and 16 for females, subject to the consent of the parents or guardians, and without such consent the males must be 25 and the females 24. But a person of 18 may be declared of full age by a competent court. In Spain majority is reached at 23; the nubile age is 18 for males and 16 for females. In Greece the nubile age is 16 for males and 14 for females; in Holland 18 for males and 16 for females; in Italy 18 for males and 15 for females; in Switzerland 21 for males and 19 for females, but the canton authorities may in extraordinary cases reduce these figures to 19 and 18 respectively. Marriage by minors is subject to the consent of their parents or guardians.

By the constitution of the United States the President must be not less than 35; a senator not less than 30, and a representative not less than 25 years of age. The age of majority, as a rule, is 21 for both males and females, but in Arkansas, California, Colorado, Dakota, Idaho, Illinois, Iowa, Kansas, Maryland, Minnesota, Missouri, Nebraska, Nevada, Ohio, Oregon, Vermont and Washington females attain majority at 18. In Maryland, Oregon, and Texas a female attains majority upon marriage. In Iowa Texas and Louisiana both males and females attain majority upon marriage, and in Washington a female minor married to a male of age is regarded as herself of full age. (H. H. L. B.)

AGE-GRADES means a system of compulsory association or classification by age and sex, whereby groups of coevals are admitted by a series of initiatory rites of varying complexity, including generally the payment of a due, into a tribal association with definite functions both within the age-group itself and in relation to the tribe as a whole, promotion to higher degrees, where such exist, being at regular intervals jointly compulsory on all the individuals comprising a group.

Though superficially resembling secret societies (*q.v.*), and though the ritual of initiation and subsequent ceremonies and esoteric beliefs are secret where a knowledge of them is confined to those who have been initiated and is moreover commensurate with the degree of their initiation, age-grades are differentiated from other forms of association, including secret societies, by the following distinctive features: (1) Admission depends primarily on age and is associated with puberty rites. (2) Every member of the tribe must be affiliated to the system at the proper age. (3) There is no individual admission, but groups of coevals are jointly initiated. (4) Promotion to higher degrees of initiation is similarly compulsory and automatic with the passage of years, even when fees have to be paid or further rites have to be undergone. (5) The system is strictly unilateral, confined to males, though a corresponding institution for females may exist but, where it exists, functions independently. (6) The system is democratic.

Primitive societies are conspicuously divided vertically into families and clans and are horizontally stratified by a variety of associations: religious, occupational, political, social, and so on. Distinction by age and sex cuts across the bonds of consanguinity and creates a new orientation of social activity. Mere classification by age or sex, however, does not of itself indicate an age-grade, for a variety of other factors is involved. A physiological classification of a tribe into boys, youths, adults and old men, with their feminine counterparts, stereotyped by custom into a conventional nomenclature, often lacks the distinctive sociological features of an age-grade: just as we find puberty (*q.v.*) rites in almost all primitive societies, whereas age-grades, though associated with puberty ceremonies and retaining them as an essential element in the complex, are comparatively rare.

Many of the institutions which are reported from different

parts of the world, though analogous to age-grades, differ in one or more essential factors and are therefore to be excluded from this survey. Such institutions are found in Australia, New Guinea, in the Banks Islands, among some of the Naga tribes of Assam, and in certain American Indian societies. The *aluzhi* of the Sema Naga, for instance, are working gangs, with few sociological obligations on the members. They are bisexual, coevality is not essential, and members can be ejected from the group. When clan feeling runs high in a community the *aluzhi* groups break up, indicating that the lateral stratification of society has not the same validity as the vertical. In short, all the essentials of an age-grade are lacking. The Kimta of Bartle Bay, though it has a superficial resemblance to an age-grade, admits of individual members being degraded or promoted to lower or higher degrees, thus invalidating the paramount theory of group-solidarity. Again, though age is the theoretical basis of Banks Islands' societies it is in fact an unimportant factor, and at every stage of initiation except perhaps the lowest, increasingly prohibitive admission fees have resulted in "a commensality of varying years and vastly different social prospects." This is no less true of America and even in the military societies of the Hidatsa, which approach nearest to the definition, the bases of membership are purchase and age, and group-promotion is not automatic but depends on purchase.

Only in Africa, and within a limited area, is the true age-grade system found functioning as a sociological element in tribal life and of the utmost importance. Nowhere do we find age-grades and secret societies concurrently, for secret societies are associated with the evolution of monarchies and powerful aristocracies, which they both limit and reinforce, whereas age-grades are democratic and are incompatible with any system of centralized and individual authority. This accounts for the absence of age-grades in Bantu societies generally, with the exception of a few Bantu tribes of the eastern group, such as the Akikuyu, Akamba, Giriama and Chaga, who have been considerably influenced by neighbouring Hamites and have a culture which is no longer characteristically Bantu. Similarly, on the west coast of Africa we find a system analogous to age-grades among the Kru, where secret societies are almost negligible and are subordinate to the Sedibo class of age-grades, which comprises the tribal legislature and executive.

The age-grade is the distinctive feature of Hamitic culture and is found in all the tribes of East Africa which belong to the Hamitic or Kilo-Hamitic groups, including the Nilotic Lango. The Galla, with their very complex system, are the centre and source of this culture, and from them it has permeated all the Nilo-Hamitic tribes which cluster round them, the Masai and the Nandi, the Topotha, the Turkana and the Didinga.

There are naturally modifications and variations in the system adapted to the cultural requirements of each tribe, but the essentials are basically the same. At the puberty rites (which recur at regular intervals) a group of boys is initiated and they are thus aggregated into tribal, as opposed to family and clan, life. Henceforth they are no longer classed with the women but find themselves in a group of coevals, with a variety of life-long privileges and obligations towards each other. Hospitality within the age-group is compulsory, and at a later stage, when the members are permitted to marry, this often includes access to the wives of age-mates. The group on the formal side is distinguished by a variety of emblems, such as shield designs, bodily markings and ornaments, and a special name assumed jointly and individually at initiation by every member of the group and retained throughout life. Promotion to higher degrees of the system is automatic after a given number of years, and each degree has its own special functions, appropriate ceremonies and emblems, and often a particular diet and distinctive tabus; the warrior degree, for instance, being generally prohibited smoking, beer and marriage. The final degree usually enables the group-members to retire from the active life of the tribe to the more passive rôle of an elder.

The essence of the system is the corporate unity of the group, which moves from degree to degree as a single entity. This unity

makes the group so significant an element in tribal culture. At the puberty schools and at subsequent initiations on promotion to higher degrees the age-groups receive a systematic education which, as among the Galla, may extend over 32 years. Candidates are instructed in the duties of citizenship, in tribal history and tradition, ethics, the law, hunting, war, religion, husbandry, medicine, sex, in short, in every aspect of individual and communal life. They are disciplined by hardships and privations and trained to endure all manner of physical discomforts and dangers, in order to be the better able to perform the rôle traditionally allotted to the group at each degree in its initiation. Among the Calla the system provides for the government of the country by each group in turn during its last eight years of active existence. The Masai and the majority of kindred tribes use the system for military and governmental purposes, and the Lango, thanks to a changed environment, have endowed their age-grade system with functions which are almost exclusively religious. Finally, the system as a whole makes for greater tribal unity by cutting across the narrow limits of the family and the clan, by giving every individual an interest in tribal, rather than parochial, concerns, and by making every individual feel that with his group he is for the time the repository of tradition and the custodian of his tribe, both heir to the past and the pledge of posterity.

AGELADAS or (as the name is spelt in an inscription) HAGELAIIDAS, a great Argive sculptor who flourished in the latter part of the 6th and the early part of the 5th century B.C. Ageladas was said to have been the teacher of Myron, Pheidias, and Polykleitus; this tradition is a testimony to his wide fame, though historically doubtful.

AGEMA, the name of the bodyguard of Alexander of Macedon. It was drawn from the distinguished corps of "shield bearers" or esquires (*ὑπασπισταί*). While in Bactria, Alexander reorganized the agema and included some Persians.

AGEN, south-west France, capital of the department of Lot-et-Garonne, 84m. S.E. of Bordeaux by the Southern railway. Pop.

THE CATHEDRAL OF ST. CAPRAIS, AGEN, DATING FROM THE 12TH CENTURY, IS MODERN COMPARED WITH THE TOWN ITSELF WHICH WAS A CELTIC STRONGHOLD AND CONSIDERED OLD IN ROMAN TIMES

(1936) 25,258. It is skirted on the west by the Garonne, here crossed by a stone bridge and by a canal-bridge.

Agén (*Aginnum*) was the capital of the Nitiobroges, and extensive Roman ruins have been discovered. Later it was the capital of the Agenais. Its bishopric was founded in the 4th century. Agén frequently changed hands during the Albigensian wars, and at their close a tribunal of inquisition was established here. In the religious wars of the 16th century Agén took the Catholic side and joined the League in 1589. The cathedral of St. Caprais has an apse of the 12th century and three apse-chapels: the rest

dates from the 12th–16th centuries, the tower flanking the south façade is modern. The church of the Jacobins is a 13th century brick building. The prefecture (18th century) was once the bishop's palace. The *hôtel de ville* occupies the former *Hôtel du Presidial*, an obsolete tribunal, and contains the municipal library. Two houses of the 16th century, the *Hôtel d'Estrades* and the *Hôtel de Vours*, are used as the museum. Through its excellent water communication, Agén affords an outlet for the agricultural produce of a rich district, and forms an *entrepôt* between Bordeaux and Toulouse, dealing in poultry, prunes (*pruneaux d'Agén*), and other fruit, wine, vegetables and cattle. Flour, dried plums, *pâté de foie gras* and other delicacies, manures, drugs, woven goods and tiles are made. Agén is the seat of a bishop. It has a court of appeal and a court of assizes, tribunals of first instance and of commerce and a chamber of commerce.

AGENAIS or **AGENOIS**, a former province of France. In ancient Gaul it was the country of the Nitiobroges with *Aginnum* for its capital, and in the 4th century it was the *Civitas Agenensium*, which formed the diocese of Agén. Having in general shared the fortunes of Aquitaine during the Merovingian and Carolingian periods, Agenais next became an hereditary countship which was purchased in 1038 by the dukes of Aquitaine. The marriage of Eleanor of Aquitaine with Henry Plantagenet in 1152 brought it under the sway of England; but when Richard I. married his sister Joan to Raymond VI., count of Toulouse, in 1196, Agenais formed part of her dowry. With the other estates of the last independent count of Toulouse it lapsed to the Crown of France in 1271, but was restored to the king of England in 1279. During the Hundred Years' War, Agenais was frequently taken and retaken, the final retreat of the English in 1453 at last leaving the king of France in peaceable possession. Thenceforth Agenais was no more than an administrative term. At the end of the *ancien régime* it formed part of the "Gouvernement" of Guienne, and at the Revolution it was incorporated in the department of Lot-et-Garonne, of which it constitutes nearly the whole. The title of count of Agenais was revived by the kings of France, and in 1789 was held by the family of the dukes of Richelieu.

AGENT: see PRINCIPAL AND AGENT.

AGENT-GENERAL, the term given to the representatives in England of certain of the self-governing British colonies. They are appointed, and their expenses and salaries provided, by the governments of the colonies they represent. Their duties are to look after the political and economic interests of their colonies in London, to assist in all financial and commercial matters in which their colonies may be concerned, and to make known the products of their colonies. Those colonies which are not under responsible government are represented in London by Crown agents.

AGENTS IN BUSINESS. An agent in the most general sense is any person who transacts business for another without being a direct employee, and in the majority of cases his function is to assist a principal in the purchase, sale or distribution of goods for a remuneration which usually takes the form of a commission on the price obtained. It is a term very loosely applied. Assistance may be rendered to principals irrespective of the commercial undertakings in which they are engaged. Consignment agents and credit enquiry agents are examples of this category as compared with factors or brokers who operate continuously for principals in particular industries and with manufacturers' agents who are more particularly associated with special lines of goods. There is an intermediate class of agents not directly concerned with the sale of goods and therefore not remunerated on a commission basis but who are of vital importance to the producer and manufacturer, the two most important being (a) advertising agents, whose function is to promote the commercial activity which is the beginning and the end of every undertaking, and (b) patent agents whose services are needed in most cases before manufacture can be commenced and who are also in a position to introduce their clients to the agents best qualified to market the product.

Manufacturers' Agents.—In the early stages of a manufacturing business when problems of production absorb the energies of the proprietor he is frequently glad to be relieved of all market-

ing problems by handing over the entire output to be disposed of by one or more manufacturers' agents on the commission basis which maintains this important section of the trading community. The method usually adopted is to sell by sample, the principal making arrangements for delivery and collecting accounts. But some manufacturers' agents operate on a much larger scale, especially in the textile industry, maintaining warehouses, stock rooms and administrative departments. The intimate knowledge possessed by the manufacturers' agent of the various requirements of the public is of great value to the principal; so much is this the case that the advisory services of the agent may be vital to the success of the undertaking and his influence on the policy of the business as powerful as if he were a partner. An agent of this standing is invariably consulted before new lines are introduced and he periodically brings forward suggestions calculated to increase trade which will bring him increased commission and the principal increased turnover.

Factors.—The tendency of modern business is to shorten the chain between producer and consumer, the chief forces operating being the extension of advertising in all directions, the growth of consumer co-operation and the increase in competition which leads to producer co-operation and the formation of trusts or buying groups. The effect on the manufacturers' agent is for him to accept greater personal responsibilities and virtually to take over the functions of a factor who, whilst his remuneration is also on a commission basis, is much more independent of his principal than is the manufacturers' agent. Invariably the factor has possession of the goods of the principal; he is generally able to get a better price and sells the goods as though they were his own leaving the buyer no clue to identity. He also frequently acts as banker for his principal owing to the necessity of his carrying a large stock for disposal in anticipation of increased demand. It is in his interests to induce the manufacturer to produce on a larger scale at a lower cost than if the production were small and this is done by his relieving the manufacturer of the necessity of recouping the expenditure of production with a quick sale. The factor is a large scale operator in a number of industries, produce, textile, grain, hide, etc., and like the manufacturers' agent is continually exposed to the pressure of the forces making for a shorter chain between producer and consumer. The tendency is for him to discharge other marketing functions, to buy up manufacturing businesses and do the work of a wholesale merchant.

Brokers.—A broker is an intermediary whose function is simply to buy or sell on behalf of a client and who does not have possession of the goods dealt with. He is present at all exchanges where produce is disposed of and business arranged. He has a specialized knowledge of particular classes of goods, their sources of supply and the avenues of marketing. His duties are of a personal character, only a small establishment being required as his business is carried on by negotiation at the exchange and in the offices of clients. In the produce market brokers are indispensable—they study the crop reports, watch cargoes, take samples, collect statistics and furnish market reports. Pressure of competition and the shortening of the producer-consumer chain impels the broker to buy and sell on his own account.

Agency as a Career.—Employment as an agent in business on a commission basis is often the last resource of a person out of employment, without any connection to assist him to secure orders and foredoomed to failure or a precarious livelihood. The ambitious youth without capital should consider agency possibilities as a stepping stone to greater remuneration as soon as he has been able to accumulate a reserve. A few years of training and experience in a merchant or factor's office will give him a knowledge of the methods of production and distribution of particular articles of manufacture until presently he has an opportunity of proving his value to his employer by suggesting new openings for agency development.

A new agency offers scope for ability and ambition to an extent presented by very few occupations. Whilst it is true that modern merchandising tends more and more towards larger units and the elimination of middlemen the increase of wealth every-

where creates new wants and an increasing market for new products. There were 30,000 applications for patents filed at the London Patent Office in the year preceding the World War and 32,000 in the year following it. The inventive genius is always bringing forward possibilities of marketing for which at first the agent is the natural instrument of development. The life is attractive to an adventurous spirit, a large circle of friends and acquaintances is formed and there is an excellent prospect of meeting the desired opportunity of entering the inner circle of the fields of manufacture and commerce. (See ADVERTISING AGENT.) (A. B. C.)

AGENTS OF PRODUCTION, in economics, a term used to describe the factors which combine in the production of wealth, as land, capital, labour (*qq.v.*) and organization. (See ENTREPRENEUR; ECONOMICS; and AGRICULTURAL ECONOMICS.)

AGESANDER, a Rhodian sculptor who is mentioned by Pliny (*Nat. Hist.* xxxvi. 37) as author (with Polydorus and Athenodorus) of the group of the Laocoon. Inscriptions found at Lindus in Rhodes date Agesander and Athenodorus to the period 42–21 B.C.

AGESILAUS II., king of Sparta, of the Eurypontid family, succeeded his step-brother Agis about 401 B.C. through the influence of Lysander. In 396 he led an expedition to Asia to secure the Greek cities against a Persian attack. Before sailing, he tried to offer a sacrifice at Aulis as Agamemnon had done before the Trojan expedition, and never forgave the Thebans for preventing him. During 396, Agesilaus made a profitable raid into Phrygia; in the following year he defeated Tissaphernes near Sardis and then ravaged the satrapy of Pharnabazus. It was said that he was planning a campaign in the interior when, to his deep regret, he was recalled to Greece owing to the war between Sparta and the combined forces of Athens, Thebes, Corinth, Argos and several minor states. After a rapid march through Thrace and Macedonia he met the confederate forces at Coronea in Boeotia and in a fierce battle was technically victorious, but the success was a barren one and he had to retire to the Peloponnese.

Agesilaus took a leading part in the Corinthian War, making successful expeditions into Corinthian territory, and capturing Lechaum. But the destruction of a *mora* by Iphicrates neutralized these successes, and Agesilaus returned to Sparta. In 387 the Peace of Antalcidas (*q.v.*), which was warmly supported by Agesilaus, put an end to hostilities. When war broke out afresh with Thebes the king twice invaded Boeotia (378, 377) and it was on his advice that Cleombrotus marched against Thebes in 371. Cleombrotus was defeated at Leuctra and the Spartan supremacy overthrown. In 370 Agesilaus tried to restore Spartan prestige by invading Mantinea territory and his heroism saved Sparta when Epaminondas penetrated Laconia that same year, and again in 362 when he all but succeeded in seizing the city. Sparta stood aloof from the general peace of 362 hoping to recover her supremacy. In order to gain money for the war Agesilaus had supported the revolted satraps; in 361 he went to Egypt at the head of a mercenary force to aid Tachos against Persia, and died, at the age of 84, on his way home.

Agesilaus was a small man, somewhat lame from birth. He was a successful leader in guerilla warfare, alert and quick, yet cautious, and his bravery was unquestioned. He lived in the most frugal style and enriched the state and his friends with the spoils of his campaigns, returning himself as poor as he had set forth. He was sincerely patriotic; but the worst trait in his character was his implacable hatred of Thebes, which led to the battle of Leuctra and Sparta's fall from supremacy.

See lives of Agesilaus by Xenophon (the panegyric of a friend), Cornelius Nepos and Plutarch; Xenophon's *Hellenica* and Diodorus xv., xv. Among modern authorities, besides the general histories of Greece, J. C. F. Manso, *Sparta* (1800–05) iii. 39 ff.; G. F. Hertzberg, *Das Leben des Königs Agesilaos II. von Sparta* (1856); Buttman, *Agesilaus Sohn des Archidamus* (1872); C. Haupt, *Agesilaus in Asien* (1874); E. von Stern, *Geschichte der spartanischen und thebanischen Hegemonie* (1884).

AGGLOMERATE, in geology, the name applied to the coarse, fragmental accumulations that accompany explosive erup-

tions (see VOLCANO). The material may consist of blocks of lava, or of fragments of rock torn off from the sides of the volcanic pipe, or of both. An agglomerate differs only from a volcanic ash in the larger size of the fragments, which are usually sharply angular.

AGGLUTINATION, a term used technically in philology for the method of word-formation by which two significant words or roots are joined together in a single word to express a combination of the two meanings each of which retains its force (Lat. *ad* and *glutinare*, lit. to fasten together with glue). This juxtaposition or conjoining of roots is characteristic of languages such as the Turkish and Japanese, which are therefore known as agglutinative, as opposed to others, known generically as inflexional, in which differences of termination or combinations in which all separate identity disappears are predominant.

The term was also formerly used by associationist philosophers for those mental associations which were regarded as peculiarly close. W. Wundt applies this term to those simplest cases of apperceptive synthesis in which the simpler ideas composing the complex idea retain their independence—as, for instance, in the idea expressed by "church-steeple."

AGGRAVATION (Lat. *ad*, "increasing," *gravis*, "heavy"), the making anything graver or more serious; also used as synonymous with "irritation." In the canon law, "aggravation" was a form of ecclesiastical censure, threatening excommunication after three disregarded admonitions.

AGGREGATE, a term used in building and construction to designate the material with which cement, lime, gypsum or other adhesive material, such as bitumen, is mixed to form a concrete or mortar (*q.v.*). The most common aggregates are sand, crushed or broken stone, gravel or pebbles, broken blast-furnace slag, boiler ashes or clinker, burned shale and burned clay. The purpose of the aggregate is to provide volume, freedom from change in volume, and resistance to wear or erosion and other desired physical properties, in the finished product.

Aggregates are divided into two general classes commonly known as fine aggregate and coarse aggregate. The fine aggregate is generally sand, crushed stone or crushed slag screenings; the coarse aggregate is gravel (pebbles), fragments of broken stone, slag and the other substances above mentioned. The dividing line between fine and coarse aggregate is usually a $\frac{1}{2}$ in. screen opening, sometimes a $\frac{3}{4}$ in. opening. Aggregates are mixed with the cement or binding material in proportions varying from one part of cementing material to one part of fine aggregate for a "rich" mortar to one part of cement to nine or ten parts of mixed fine and coarse aggregates for a "lean" concrete. The theory upon which such mixtures are proportioned is that there shall be sufficient cementing material to coat all of the particles in the fine aggregate, and that there shall be sufficient mortar so produced to fill all the voids in the coarse aggregate. The ideal concrete would consist of closely packed fragments of crushed stone, slag or pebbles in which all the fragments are coated with mortar, and all the voids between the coarser fragments filled with mortar. Under actual conditions in construction work there is practically always an excess of mortar. Nearly all natural sands require washing or rinsing to remove loam, clay, organic material, etc. A gradual variation in size from about 50 mesh (50 openings per linear inch) to $\frac{1}{4}$ in. mesh is desirable for the strongest mortar or concrete. The preparation of commercial fine aggregate therefore often requires artificial grading or mixing of the various sizes. This is usually accomplished by hydraulic separation of the undesirable fine sizes, which usually are in excess. For coarse aggregate any hard, tough, durable rock may be crushed, screened and graded. The common commercial sizes vary from $\frac{1}{4}$ in. to $3\frac{1}{2}$ in. in largest dimension. The most desirable rocks for general construction purposes are basalt, commonly called trap, and fairly pure limestone. Such rocks are not only durable but fire-resisting. Specification requirements include cleanliness (maximum limits of extraneous impurities), limiting percentages of various sizes, soundness (freezing and thawing tests, for example), sometimes mineralogical composition (designed to insure soundness).

In this age of concrete construction and road building the busi-

ness of supplying aggregates for construction work has grown to large proportions. In the U.S. alone production amounts to approximately 300,000,000 tons per annum, valued roughly at \$300,000,000, requiring an investment of about \$500,000,000 in washing, screening and crushing equipment and accessory machinery for micing and conveying the raw and finished materials.

AGGREGATES, THEORY OF. An aggregate may be defined, for the moment, as a collection of elements of some kind or other which is subjected to laws of operation and, on occasion, provided with a structure in such a way as to make it capable of being used to facilitate the arguments and calculations of mathematical analysis. From the point of view of pure philosophy such collections are of considerable interest in themselves and there is an extensive subject, which may be called for purposes of reference the theory of classes, which has grown up around them. This theory involves, as might be expected, considerable difficulties of a somewhat metaphysical nature and is in parts highly controversial. It is, however, possible to isolate from the rest of the theory a part which is of much practical value and almost completely free from controversy. This is the theory of aggregates. It concerns classes considered not as entities to be subjected to logical scrutiny and philosophical analysis but simply as symbols of a certain kind which are used to facilitate mathematical calculations in much the same way that numbers are used. The progress that has been made in some branches of mathematics since the introduction in the subject of the theory of aggregates is very striking.

Preliminary Notions.—It will be assumed that there is given a set of elements of some kind or other each of which can be distinguished from all the others and so may be indicated by an appropriately attached name. This set is described as the field of operations and the individual constituents which it contains are its elements. Specified elements are conveniently denoted by letters *a*, *b*, *c*, ... and unspecified elements by letters *x*, *y*, *z*, There are, naturally, a great many fields of operations available. It is supposed that a particular one is selected and the subsequent theory is then relative to this field. The theory of classes, of course, has to take into account all possible fields of operations. The theory of aggregates is at most concerned with the realization of a single field of operations which shall satisfy the conditions which may at the time be imposed. The question of realizing the field of operations is almost the only part of the subject which is controversial.

Aggregates are, roughly speaking, collections of elements of the field of operations. This definition is, however, subject to the criticism that it is not very precise. Moreover, the idea of a collection involves certain metaphysical difficulties which, although some of them have been known for several thousands of years, have not been completely resolved. An alternative definition has therefore been adopted by some authorities. Nothing is said about the nature of aggregates but instead their use is defined. Aggregates are taken to be symbols the sentences containing which are interpreted by given conventions in such a way that the resulting formal laws are, up to a point, identical with those which would result from the application of the rough definition originally given. The requirements of mathematics are simply that the conventions used should be consistent. Experience seems to show that this is the case. The requirements of the mathematician are that the conventions should be easily applied. These are met by treating aggregates as though there were actual collections. Experience again shows that this procedure, if certain quite simple safeguards are employed, never leads to error. Specified aggregates may be denoted by letters *A*, *B*, *C*, ... and unspecified aggregates by letters *X*, *Y*, *Z*,

The Relations ϵ and ω .—Between any element *x* of the field of operations and any given aggregate *A* one or other of two mutually exclusive relations must hold. Either *x* belongs to the aggregate, in a sense that will presently be made precise, or *x* is excluded by the aggregate. In the first case $x \epsilon A$ is written and in the second $x \omega A$. The elements which belong to *A* are described as its *members* and of them *A* is said to be *composed*.

The aggregate of which the elements which do not belong to A are the members is the *complement* of A. An interchange of ϵ and ω plainly interchanges an aggregate and its complement.

Propositional Forms.—A sentence like "a is blue" expresses a property of the element a. On the other hand a form of words and symbols like " x is blue," where x denotes an unspecified element of the field of operations, expresses nothing. It may be described as a *propositional form*. When the variable x which it contains is replaced by a name it becomes a proposition. Certain forms of words and symbols which have the appearance of propositional forms can be shown to be incapable of yielding propositions when treated in the above way. What results when the name is substituted is necessarily a meaningless array of words. The convention is therefore made that only propositional forms that are significant over the field of operations are taken into consideration in the theory of aggregates associated with any given field of operations.

The Fundamental Convention.—It is assumed that to each significant propositional form there corresponds a definite aggregate. This is described as the aggregate determined by the form. If the form is denoted by $f(x)$ the corresponding aggregate is denoted by $[f(x)]$.

The main convention governing the use of aggregates is that sentences involving $[f(x)]$ are to have the same meaning as corresponding sentences involving $f(x)$. Thus, to take a rough example, if A is the aggregate [x is blue] then "A is extensive" is taken to mean "' x is blue' is often true." More precise examples are: " $a \in [f(x)]$ " means " $f(a)$ is true" and " $a \omega [f(x)]$ " means " $f(a)$ is false." It is possible to interchange the conventions involving ϵ and ω without causing any alteration in the formulae, provided that certain simple precautions are taken. In this way each formula can be made to yield two propositions. For this reason it is convenient, at any rate for mathematical purposes, to keep the notion of an aggregate distinct from that of a propositional form.

Null Aggregates.—An aggregate determined by a propositional form which never reduces to a true proposition, no matter what name is substituted for its variable, is described as *null*. A null aggregate is denoted by the symbol o . Null aggregates have formal properties closely resembling those of the number o . The complement of a null aggregate is the aggregate consisting of all the elements of the field of operations.

Arithmetical Theory.—Between any two aggregates operations similar to those of arithmetic may be defined. Thus:—

$$\begin{aligned} A+B &= [x \in A \text{ or } x \in B], \\ AB &= [x \in A \text{ and } x \in B], \\ A-B &= [x \in A \text{ and } x \omega B]. \end{aligned}$$

The addition or multiplication of any number of aggregates presents no difficulty. In this respect the theory of aggregates is considerably easier than the theory of numbers. Operations involving limits can also be defined. Calculations in the arithmetical theory are not much different from those in the arithmetic of numbers. It is often found that the results of extremely elementary calculations involving aggregates have an interpretation which sheds considerable light on comparatively difficult problems in other branches of mathematics.

Geometrical Theory.—A completely different but equally useful theory results when the aggregates considered are endowed with a structure in some way. Between any two points of a given aggregate, for instance, a distance may be defined. Any aggregate which has been given a structure is described as a *space*. A considerable variety of spaces is known and their consideration provides much information as to the nature of the more familiar spaces, such as the Euclidean spaces.

Application to the Theory of Functions.—There are many problems in the theory of functions (*q.v.*) which have been solved either wholly or in part by means of the theory of aggregates. This is in measure due to the intrinsic power of the theory and also to the concise and expressive way in which the theory allows the formulation of ideas. A notable advance is due to the fact that numerical functions can be defined by means of a table of

aggregates. In order to know a function $\phi(x)$ it is sufficient to know the aggregates $[\phi(x) > p]$ for only the rational values of p , whereas in the ordinary way it is necessary to know $\phi(x)$ for all values, irrational as well as rational, of x .

See F. Hausdorff, *Mengenlehre* (1927, bibl.); C. J. de la Vallée Poussin, *Intégrales de Lebesgue, fonctions d'ensemble, classes de Baire* (1916). Hausdorff's work provides an unusually interesting general introduction to the subject. The reader already familiar with the theory of functions of a real variable will find some valuable applications of the theory of aggregates in the tract by de la Vallée Poussin. (S. Po.)

AGGREGATION, in physics, a collective term for the forms or states in which matter exists. Three primary "states of aggregation" are recognized—gaseous, liquid and solid. Generally, if a solid be heated to a certain temperature, it melts or fuses, assuming the liquid condition (see FUSION); if the heating be continued the liquid boils, and becomes a vapour (see VAPORIZATION).

On the other hand, if a gas be sufficiently cooled and compressed, it liquefies; this transition is treated theoretically in the article LIQUEFACTION OF GASES.

AGGTEEEK, a village in northern Hungary in that portion of the county of Gomor that remained in 1918 within Hungarian rule. Although small (pop 648), it is world-renowned for its remarkable limestone grotto, the Aggtelek or Baradla cavern, one of the largest of its kind in Europe. It is composed of a labyrinth of passages and halls of various sizes, the total length, including its ramifications, exceeding 5 mi. A stream traverses the caves, which are rich in fantastic stalactite forms.

AGINCOURT (AZINCOURT), a village of northern France in the department of Pas de Calais, 14m. N.W. of St. Pol by road, famous on account of the victory, on Oct. 25, 1415, of Henry V. of England over the French. The battle was fought in the defile formed by the wood of Agincourt and that of Tramecourt, at the northern exit of which the army under d'Albret, constable of France, had placed itself so as to bar the way against the English forces which, after the capture of Harfleur, had set out to march through Picardy to Calais. Torrential rains hindered the English in crossing the Somme, and the delay allowed the French to concentrate in overwhelming numbers—d'Albret, indeed, refused to avail himself of the offer of 6,000 crossbowmen of the Paris citizen militia. Worse still, the English became so short of supplies that had the French but been content to block the path without risking an attack, hunger would have brought them the victory. The night of Oct. 24 was spent by the two armies on the ground, and the English had but little shelter from the heavy rain which fell. Early on the 25th, St. Crispin's day, Henry arrayed his little army (about 1,000 men-at-arms, 6,000 archers, and a few thousands of other foot). It is probable that the usual three "battles" were drawn up in line, each with its archers on the flanks and the dismounted men-at-arms in the centre; the archers being thrown forward in wedge-shaped salients, almost exactly as at Crécy (*q.v.*). The French, on the other hand, were drawn up in three lines, each line formed in deep masses. They were at least four times more numerous than the English, but restricted by the nature of the ground to the same narrow front 1,000 yds., they were unable to use their full weight (cf. Banockburn); further, the deep mud prevented their artillery from taking part, and the crossbowmen were as usual relegated to the rear of the knights and men-at-arms. All were dismounted save a few knights and men-at-arms on the flanks, who were intended to charge the archers of the enemy. For three hours after sunrise there was no fighting; then Henry, finding that the French would not advance, moved his army farther into the defile. The archers fixed the pointed stakes, which they carried to ward off cavalry charges, and opened the engagement with flights of arrows. The chivalry of France, undisciplined and too obtuse to have assimilated the lesson of Crécy and Poitiers, was quickly stung into action, and the French mounted men charged, but their slow-moving horses made easy targets, soon shot down or driven back in confusion. The constable himself headed the leading line of dismounted men-at-arms; weighted with their armour, and sinking deep into the mud with every step, they yet reached and

engaged the English men-at-arms; for a time the fighting was severe. The thin line of the defenders was borne back and King Henry was almost beaten to the ground. But at this moment the archers, taking their hatchets, swords or other weapons, penetrated the gaps in the now disordered French, who could not move to cope with their unarmoured assailants, and were slaughtered or taken prisoners to a man. The second line of the French came on, only to be engulfed in the *mêlée*; its leaders, like those of the first line, were killed or taken, and the commanders of the third sought and found their death in the battle, while their men rode off to safety. The closing scene of the battle was a half-hearted attack made by a body of fugitives, which led merely to the slaughter of the French prisoners, which was ordered by Henry because he had not enough men both to guard them and to meet the attack. The slaughter ceased when the assailants drew off. The total loss of the English is stated at 13 men-at-arms (including the duke of York, grandson of Edward III) and about 100 of the foot. The French lost 5,000 of noble birth killed, including the constable, three dukes, five counts and 90 barons; 1,000 more were taken prisoners, amongst them the duke of Orleans (the Charles d'Orléans of literature). The moral lesson of the battle was the incapacity of a military caste to learn from experience, and to adapt their traditions intelligently to new needs. The material lesson was that armour stultified its own purpose when it fettered mobility. The 15th-century soldier pinned his faith as obstinately on an increasing weight of armour as the 19th-century soldier on an increasing weight of numbers.

See Sir Harris Nicolas, *Battle of Agincourt*; Fortescue, *History of the British Army*, vol. i.; and H. B. George, *Battles of English History*; Oman, *History of the Art of War in the Middle Ages*, vol. ii. 379-386.

AGIO, a term used in commerce in three connections

(a) The variations from fixed pars or rates of exchange in the currencies of different countries. For example, in most of the gold-standard countries, the standard coin is kept up to a uniform point of fineness, and so bears a constant relation to coins of other countries in a similar condition. This is what is known as the mint par of exchange. The balance of trade between the various countries is the factor determining the rate of exchange. Should the balance of trade be against England, money must be remitted to France as payment for the indebtedness. But owing to the cost for the transmission of specie there will be a demand for bills as a cheaper and more expeditious method of sending money, and it therefore will be necessary to pay a premium for it, called the agio.

(b) The term is also used to denote the difference in exchange between two currencies in the same country; where silver coinage is the legal tender, agio is sometimes allowed for payment in the more convenient form of gold, or where the paper currency of a country is reduced below the bullion which it professes to represent, an agio is payable on the appreciated currency.

(c) Lastly, in some states the coinage is so debased, owing to the wear of circulation, that the real is greatly reduced below the nominal value. Supposing that this reduction amounts to 5%, then if 100 sovereigns were offered as payment of a debt in England while such sovereigns were current there at their nominal value, they would be received as just payment; but if they were offered as payment of the same amount of debt in a foreign state, they would be received only at their intrinsic value of £95, the additional £5 constituting the agio. Where the state keeps its coinage up to a standard value no agio is required. (See BALANCE OF TRADE.)

AGIRA (formerly San Filippo d'Argirò), town in the province of Enna, Sicily, with a railway station $4\frac{1}{2}$ mi. to the south; 35 mi. W. of Catania. Pop. (1901) 17 738; (1936) 14 411 (town). 15,350 (commune). *Agyrion*, an ancient Sicily city, was ruled by tyrants, one of whom, Agyris, was contemporary of Dionysius I., and with him successfully resisted the Carthaginians in 392 B.C. Agyrion was not colonized by the Greeks until Timoleon drove out the last tyrant in 339 B.C.

AGIS, the name of four Spartan kings:

(1) Son of Eurysthenes, founder of the royal house of the Agiadae (Pausanias iii. 2. 1). His genealogy was traced back to Heracles (Herodotus vii. 204), and he belongs rather to

mythology than to history. Tradition ascribed to him the capture of Helos, and the institution of the class of serfs called Helots. (*q.v.*). See Ephorus ap. Strabo, viii. p. 365.

(2) **AGIS I.**, son of Archidamus II., Eurypontid, succeeded his father, probably in 427 B.C., and from his first invasion of Attica in 422 down to the close of the Peloponnesian War was the chief leader of the Spartan operations on land. After the conclusion of the peace of Nicias (421 B.C.) he marched against the Argives in defence of Epidaurus, and after skilful manoeuvring surrounded the Argive army, and seemed to have victory within his grasp when he unaccountably concluded a four months' truce and withdrew his forces. The Spartans were indignant, and when the Argives and their allies broke the truce Agis escaped having his house razed and a fine of 100,000 drachmae imposed only by promising to atone for his error by a signal victory. This promise he fulfilled by routing the forces of the Argive confederacy at the battle of Mantinea (418). In the winter 417-416 a further expedition to Argos resulted in the destruction of the half-finished Long Walls and the capture of Hysiae. In 413, on the suggestion of Alcibiades, he fortified Decelaea in Attica, where he remained directing operations until, after the battle of Aegospotami (405), he took the leading part in the blockade of Athens, which was ended in the spring of 404 by the surrender of the city. Subsequently he invaded and ravaged Elis. He fell ill on his return from Delphi, where he had gone to dedicate a tithe of the spoils, and died at Sparta, probably in 401.

BIBLIOGRAPHY.—See Thuc. iii. 89, iv. 2. 6, v., vii. 19, 27, viii.; Xenophon, *Hellenica*, i. 1, ii. 2. 3, iii. 2. 3; Diodorus xii. 35, xiii. 72, 73, 107; Pausanias iii. 8. 3-8; Plutarch, *Lysander* ix. 14. 22. *Alcibiades* 23-25, *Lycurgus* 12, *Agesilaus* i. 3, *de Tranquill. Anim.* 6. (See PELOPONNESIAN WAR.)

(3) **AGIS II.**, son of Archidamus III., of the Eurypontid line, succeeded his father in 338 B.C., on the very day of the battle of Chaeronea. During Alexander's Asiatic campaign he revolted against Macedonia (333 B.C.) and, with the aid of Persian money and ships and a force of 8,000 Greek mercenaries, gained considerable successes in Crete. In the Peloponnese he routed a force under Corragus and, although Athens held aloof, he was joined by Elis, Achaea (except Pellene) and Arcadia, with the exception of Megalopolis, which the allies besieged. Antipater marched rapidly to its relief at the head of a large army, and the allied force was defeated after a desperate struggle (331) and Agis was slain.

BIBLIOGRAPHY.—See Pausanias iii. 10. 5; Diodorus xvii. 48, 62, 63; Justin xii. 1; Quintus Curtius iv., 1, 39, vi., 1; Arrian, *Anabasis*, ii. 13.

(4) **AGIS III.**, son of Eudamidas II., of the Eurypontid family, succeeded his father, probably in 242 B.C., in his 20th year, at a time when the unequal distribution of land and wealth and the diminution in the number of full citizens threatened to ruin Sparta. He determined to restore the traditional institutions of Lycurgus. Lysander as ephor proposed on behalf of Agis that all debts should be cancelled and that Laconia should be divided into 19,500 lots, of which 4,500 should be given to Spartiates, whose number was to be recruited from the best of the perioeci and foreigners, and the remaining 15,000 to perioeci who could bear arms. The abolition of debts was carried into effect, but the land distribution was put off on various pretexts by Agesilaus, the king's uncle, who wished to preserve his estates. At this point Aratus appealed to Sparta to help the Achaeans in repelling an expected Aetolian attack, and Agis was sent to the Isthmus at the head of an army. During his absence his enemies gained the upper hand, and on his return Agis, after a mock trial, was strangled in prison, his mother and grandmother sharing the same fate (241).

See Plutarch's biography. Pausanias' accounts (ii. 8. 5, vii. 7. 3, viii. 10. 5-8, 27. 13) of his attack on Megalopolis, his seizure of Pellene and his death at Mantinea fighting against the Arcadians, Achaeans and Sicyonians are without foundation (J. C. F. Manso, *Sparta*, iii. a. 123-127, 1800-05). See also Manso, *op. cit.* iii. l. 276-302; B. Niese, *Geschichte der griechischen und makedonischen Staaten*, ii. 299-303 (1884).

AGISTMENT. To "agist" is, in law, to take cattle to graze, for a remuneration. The word is derived through O. Fr. from Lat. *iacere*, to lie. "Agistment," in the first instance, referred

more particularly to the proceeds of pasturage in the king's forests, but now means either (a) the contract for taking in and feeding horses or other cattle on pasture-land, for the consideration of a weekly payment of money, or (b) the profit derived from such pasturing. Agistment is a contract of bailment, and the bailee is bound to take reasonable care of the animals entrusted to him; he is responsible for damages and injury which result from ordinary casualties, if it be proved that such might have been prevented by the exercise of reasonable care.

There is no lien on the cattle for the price of the agistment, unless by express agreement. Under the Agricultural Holdings Act, 1883, agisted cattle cannot be distrained on for rent if there be other sufficient distress to be found, and if such other distress be not found, and the cattle be distrained, the owner may redeem them on paying the price of their agistment.

AGITATION, THERMAL, the motion of the molecules, within a body, which they possess by virtue of their absolute temperature (*q.v.*). (See KINETIC THEORY OF MATTER; THERMODYNAMICS.)

AGITATO (Ital.), a musical term implying that the composition or passage so marked is to be played in a restless, agitated manner, a rapid *tempo* being usually indicated at the same time by the accompanying time-direction, *e.g.*, presto agitato.

AGITATORS or **ADJUTATORS**, the name given to representatives elected in 1647 by the different regiments of the English parliamentary army. Early in 1647 the Long Parliament wished either to disband many of the regiments or to send them to Ireland. The soldiers, whose pay was largely in arrear, refused

to accept either alternative, and eight of the cavalry regiments elected agitators, called at first commissioners, who laid their grievances before the three generals, and whose letter was read in the House of Commons on April 30, 1647. The other regiments followed the example of the cavalry, and after a temporary conciliation Parliament decided to disband the army on June 1. The agitators determined to resist; a mutiny occurred in one regiment and the attempt at disbandment collapsed. There followed the seizure of the king by Cornet Joyce, Cromwell's definite adherence to the policy of the army, the signing of the manifestos, a *Humble Representation* and a *Solemn Engagement*, and the establishment of the army council composed of officers and agitators. The agitators finally demanded a march towards London and the "purging" of the House of Commons. Subsequent events are part of the general history of England. Gradually the agitators ceased to exist, but many of their ideas were adopted by the Levellers (*q.v.*), who may perhaps be regarded as their successors.

See S. R. Gardiner, *History of the Great Civil War*, vols. iii. and iv. (1905).

AGNANO, LAGO DI, a crater lake, 1/2 m. W. of Naples, Italy; 4 m. in circumference, not mentioned in antiquity, probably formed in the Middle Ages, drained in 1866. It has a large modern thermal establishment with springs, natural sulphurous vapour baths and a grotto with constant exudation of warm carbonic-acid gas from the floor. There are extensive Roman remains (V. Macchioro, *Monumenti dei Lincei*, xxi, p. 225, *sqq.*, 1911). On the north side of the crater is a racecourse.

AGNATES, in Roman law, persons related through males only, as opposed to cognates. Agnation was founded on the idea of the family held together by the *patria potestas*; cognatio involves simply the modern idea of kindred.

AGNES, SAINT, a virgin martyr of the Catholic Church. The legend of St. Agnes is that she was a Roman maid, by birth a Christian, who suffered martyrdom at the age of 13, during the reign of the emperor Diocletian, on Jan. 21, 304. The prefect Sempronius wished her to marry his son, and on her refusal condemned her to be outraged before her execution, but her honour was miraculously preserved. When led out to die she was tied to a stake, but the faggots would not burn, whereupon the officer in charge of the troops drew his sword and struck off her head. St. Agnes is the patron saint of young girls, who, in rural districts, formerly indulged in all sorts of quaint country magic on St. Agnes' Eve (Jan. 20-21) with a view to discovering their future husbands. This superstition has been immortalized in

Keats's poem, "The Eve of St. Agnes." St. Agnes's bones are supposed to rest in the church of her name at Rome, originally built by Constantine and repaired by Pope Honorius in the 7th century. Here on her festival (Jan. 21) two lambs are specially blessed after pontifical high mass, and their wool is later woven into pallia.

AGNESI, MARIA GAETANA (1718-1799), Italian mathematician, linguist and philosopher, was born at Milan on May 16, 1718. She was an extremely precocious child. Her father was a professor of mathematics. Maria was only fourteen when she began to read a series of theses on philosophical questions to the learned men of Bologna who met regularly in her father's house (see Brosse, *Lettres sur l'Italie*). Her family resisted her early desire to enter a convent, but from her 20th year onward she lived in complete seclusion at home, devoting herself to the study of mathematics. When her father fell ill in 1752 Pope Benedict XIV. appointed her to his chair in the university. But on his death in 1754 she became directress of the Hospice Trivulzio of the Blue Nuns at Milan, and eventually joined the sisterhood. She died on Jan. 9, 1799. Her principal work is *Istituzioni analitiche ad uso della gioventù italiana* (2 vols., Milan 1748; French trans. of vol. i., Paris 1775; complete Eng. trans. by Tohn Colson, 1801).

Her sister, MARIA TERESA AGNESI (1724-80), composed several cantatas, two pianoforte concertos and five operas.

BIBLIOGRAPHY.—See Antonio Francesco Frisi, *Éloge historique de Mademoiselle Agnesi*, translated by Boulard (Paris, 1807); Milesi-Mojon, *Vita di M. G. Agnesi* (Milan, 1836); J. Boyer, "La Mathématicienne Agnesi," in the *Revue Catholique des revues françaises et étrangères* (Paris, 1897).

AGNES OF MERAN (d. 1201), queen of France, was the daughter of Bertold IV., duke of Meran in Tirol. She is called Marie by some of the chroniclers. In June 1196 she married Philip II., king of France, who had repudiated Ingeborg of Denmark in 1193. The pope espoused the cause of Ingeborg; but Philip did not submit until 1200, when, interdict having been added to excommunication, he consented to a separation from Agnes. She died in July of the next year.

See the notes of Robert Davidsohn in *Philipp. II. August von Frankreich und Ingeborg* (Stuttgart, 1888). A genealogical notice is furnished by the *Chronicon* of the monk Alberic (Aubry) of Trois-Fontaines (Albericus Trium Fontium) in Pertz, *Scriptores*, vol. xxiii.

AGNEW, DAVID HAYES (1818-1892), American surgeon, was born in Lancaster county, Pa., on Nov. 24, 1818. He graduated from the medical department of the University of Pennsylvania in 1838, and a few years later set up in practice at Philadelphia and became a lecturer at the Philadelphia School of Anatomy. He was appointed surgeon at the Philadelphia hospital in 1854 and was the founder of its pathological museum. For 26 years (1863-89) he was connected with the medical faculty of the University of Pennsylvania, being elected professor of operative surgery in 1870 and professor of the principles and practice of surgery in 1871. From 1865 to 1884—except for a brief interval—he was a surgeon at the Pennsylvania hospital. During the American Civil War he was consulting surgeon in the Mower Army hospital, near Philadelphia, and acquired considerable reputation for his operations in cases of gun-shot wounds. He attended as operating surgeon when President Garfield was fatally wounded by the bullet of an assassin in 1881. He was the author of several works, the most important being *The Principles and Practice of Surgery* (1878-83). He died in Philadelphia on March 22, 1892.

AGNI, the fire god of the Hindus, second only to Indra in the Vedic mythology of India. He is invoked as "priest of sacrifice" in the first verse of the Rig-Veda, and, as messenger, between gods and men, sacrifices to him are upborne to the deities. On earth his parents are the two sticks of the fire drill, and every day he is reborn an immortal, living among men and supreme director of religious rites and duties. His form is however three-fold, fire on earth, lightning and the sun, and in art he is depicted as ruddy, with two faces, beneficent and malignant, three-legged (as in the fylfot, with seven arms). Later he was identified with Rūdra (*q.v.*). In modern India he has no professed sect, but is invoked in many ceremonies: and specially

affected by Agnihotri Brahmans who perform the "fire sacrifice" (*agnilzotra*).

See A. A. Macdonell, *Vedic Mythology*, and F. Washburn Hopkins, *Epic Mythology* (1857 and 1915); J. N. Farquhar, *Outlines of the Religious Literature of India* and Mrs. Sinclair Stevenson, *Rites of the Twice-born* (1920).

AGNI, inhabitants of the Cold Coast and the French Ivory Coast between the Fanti territory and the Comoé river, south of the Abron (*q.v.*) people. They are of the same origin and have the same physical, social and linguistic characteristics as the Baule.

AGNOETAE, a minority of adherents to the Monophysite movement who (contrary to the general tendency of that form of Christology) maintained that Christ as man was ignorant of many things (Mark xiii. 32; Luke ii. 25) (Gr. *ἀγνοέω*, "be ignorant of"). The doctrine was condemned by Gregory the Great. (See **MONOPHYSITES**.)

AGNOIOLOGY (the theory of ignorance). The term was used by J. F. Ferrier (*Institutes of Metaphysics*, 1854) as a set-off to *Epistemology* (theory of knowledge). The theory was intended to counter the sceptical contention that Absolute Being may be beyond human knowledge, that the human mind may be condemned to remain ignorant of it. Ferrier's contention is that man cannot be said to be ignorant of what cannot be known; he can only be said to be ignorant when he does not know what can be known. On such lines Ferrier concludes that, since Absolute Being must either be something that we know or something that we are ignorant of, it cannot be subject only or object only but a synthesis of both.

AGNOSTICISM. Whereas scepticism, as a technical term in philosophy, denotes varying degrees of doubt as to whether some or all of the psychological processes, purporting to yield knowledge, really do so, agnosticism rather asserts that, of certain kinds of objects or facts, we possess assured knowledge, while as to certain other kinds of alleged existents we have, and can have, none. The kinds of alleged objects, knowledge as to which the agnostic believes to be impossible, are such as are the primary concern of metaphysics and theology: God, the soul and its immortality, and—more generally speaking—the ultimate realities of which phenomenal things, such as the sciences study, are appearances. Of these phenomenal things, we have ever-increasing and irrefragable knowledge; as to the things *per se*, the ontal or noumenal existents, of which the "things" of common sense and science are the knowable shadows or appearances, we can never have knowledge pure and subjectively undefiled. If we know *that* they are, we cannot know *what* they are; if we can assert their existence, we are ignorant as to their essence.

The name "agnosticism" was coined by Huxley about 1870 to distinguish this philosophical attitude from others, but the attitude had been professed before. It is, in fact, one of the issues of Kant's imposing theory of knowledge, and it had become, through the investigations of Sir W. Hamilton, Dean Mansel and Herbert Spencer, more sharply defined and more elaborately developed. Huxley, who was perhaps its most widely-known champion in the latter half of the 19th century, gave definiteness to its exposition by forcibly contrasting metaphysical and theological belief with scientific knowledge. We can now see that the controversial issue was confused, through failure at that time to realize that the word "knowledge" denotes not one sole psychological process and product, but several that are distinguishable; and also that what is called scientific knowledge is not quite so simple in its psychological structure, nor so logically "positive" in its nature, as the philosophically-inclined representatives of science in Huxley's day were wont to assume. The positivists who were led by the progress and prestige of physical science to regard science as constituted entirely by sense-data, linked together solely by relations such as could be read-off with the inevitableness and self-evidence of similarity, temporal sequence, etc., overlooked the fact, which had been clearly discerned by Hume, that we have no *logical* right to pass from our sporadic and evanescent sense-data, which yield evidence only as to here and now, to belief in a stable system of permanent things governed by law. The right is not a matter of logical neces-

sitation but of psychological inevitableness; not of logical certification but of pragmatic verification; not of logical certainty but of personal certitude or sanguine confidence. Thus science is not knowledge, in the strict sense of reading-off, supplemented by logical inference. Such knowledge, and indeed the phenomenal objects about which it claims to know, are constituted such by suppositions that, in the first instance, are read *into* the data. Thus "knowing" means, in science of the actual, something different both from the immediate "acquaintance" of sense-perception and from the "truth" that is yielded by pure sciences, such as mathematics, whose "objects" are ideas—such as the line without breadth—and not actual things. This is also the doctrine of Kant. But Kant held that the reading-in that is involved in scientific knowledge is a *priori* necessary, so that such knowledge is knowledge in the strictest sense; whereas the reading-in that is involved in metaphysics and theology is but tentative and humanly expedient. This hard line between what Kant called understanding and reason—we might say between knowledge and mere belief—is now seen to be psychologically arbitrary, not so hard as he thought, and indeed to be drawn at the wrong place. Hence the rigid separation, once wont to be alleged between science and philosophy, and, on the strength of which, metaphysics and theology were disparaged, is no longer possible. The agnostic can no longer have that certainty as to the foundations of his science, in virtue of which he asserted nescience as to the non-phenomenal. The difference between the knowledge which he asserted and the knowledge which he disclaimed is one of degree of verifiability, not of kind or of intrinsic constitution.

But agnosticism, which issues out of Kant's phenomenalism, is imbued with consequences of what may be said to be another oversight of Kant, perhaps still more significant in import. Kant tried to work with the supposition that, though facts compel us to assert the existence of things *per se*, we can know no more about them. His doctrine implies that we can only know the phenomenal. This is the teaching that was developed by Hamilton into the dogmas that we can have no knowledge of the absolute or of ultimate reality, and no absolute or pure knowledge of anything: all knowledge is but relative. As to its Kantian foundation, it seems obvious that if we must posit things *per se*, in order to account for our sense-data being forthcoming, so must relations between things *per se* be posited to account for the stable connections between sense-data, which science elaborates into laws of nature. Indeed, unless we create most of our data out of nothing or out of our subjective states, etc., there must be structure and detail in the ontal corresponding to that which we observe in the phenomenal. Appearance cannot be appearance of nothing. Hence, instead of the Kantian formula, that we only know phenomena, it is more correct to say that we know the noumenal through the phenomenal. Thus there is not absolute nescience as to the noumenal, as agnosticism would assert. The most that can be urged is that we do not see the noumenal, so to say, through plate glass, but through the irremovable spectacles of the mind, which make a difference to the noumenal object or phenomenalize it. It is at this point that Hamilton's doctrine of the relativity of knowledge applies. He would regard phenomenal knowledge of the noumenal as not knowledge at all, because, in having it, we are not identical with the objects known nor become acquainted with them as they are in themselves. Our knowledge falls short of the ideal standard, in that it is impure—which is what he chiefly means by "relative." But it may be doubted whether knowledge suffers in value on that account. There is no reason to assume that, in imaging the real, the phenomenon veils it or caricatures and misrepresents it; it may reveal it, and reveal its significance just as effectually as would seeing face to face. What matters is that phenomenal knowledge should be *relevant* to reality, not that it should mirror its naked structure. An ordnance map serves all purposes of the tourist, though it may not mirror the coloured landscape or the geological formations of the district; it is relevant, if but appearance and not a copy. There is **point-to-point** correspondence between the lines and contours on the map and the streams, roads, gradients, etc., of the country which

it represents. Our phenomenal knowledge may bear—nay, must bear—much the same sort of relation as this to the realities which manifest themselves in and through the sensible and phenomenal. It enables us to "find our way about" our world, to be on terms of understanding with it and it may minister as much to spiritual wisdom as to practical prudence; for all that it is but phenomenal. That "we see through a glass, darkly" may be our lot here; but it does not follow that we are wholly blind as to all that concerns our souls' health. Thus it would appear that agnosticism is superfluously modest. Its demurrer to the philosopher's claim that knowledge as to ultimate reality in general is inaccessible is not sustained. If it would refuse the name of knowledge to such cognition it would seem to be cherishing a conception of knowledge to which no actually forthcoming "knowing" corresponds. For science itself, wont to be taken as the paradigm of knowledge, is at bottom interpretative, constructive, ejective and partly symbolical. Its inductive method involves faith, for which there is reasonable, but not logical, justification. And knowledge as to the objects with which metaphysics and theology are concerned, is but a further extension of the same method and the same sustaining faith as science uses, applied to such facts as evince meaning or purpose and value or significance, as well as to those which yield laws as to physical structure and connections.

AGNUS DEI, the figure of a lamb bearing a cross, symbolizing the Saviour as the "Lamb of God." The name is especially given in the Roman Church to waxen discs impressed with this figure and blessed by the pope. When first mentioned (c. 820) they were made of the remnants of the preceding year's paschal candle. In modern times they are blessed on Easter Wednesday and distributed on the following Saturday, only in the first year of each pontificate and every seventh year after.

Agnus Dei is also the name for the invocation (based on John i. 29) *Agnus Dei, qui tollis peccata mundi, miserere nobis*, which appears to have been introduced into the Mass by Pope Sergius I. (687–701). It is there repeated thrice (the third time with *dona nobis pacem for miserere nobis*) between the Lord's Prayer and the communion; it is also appended to many of the litanies. The legality of its use in English, under certain conditions, in the Anglican communion service was upheld by the judgment in the Lincoln case (1890).

For the various ceremonies in the blessing of the *Agnus Dei*, see A. Vacant, *Dict. de Théologie* (cols. 605–613).

AGOBARD (c. 779–840), Carolingian prelate and reformer. became coadjutor to Leidrad, archbishop of Lyons, in 813, and on the death of the latter succeeded him in the see (816). Deposed in 835 by the council of Thionville, he made his peace with the emperor and was reinstated in 837. Agobard occupies an important place in the Carolingian renaissance. He wrote extensively not only theological works but also political pamphlets and dissertations directed against popular superstitions. He denounced the trial by ordeal of fire and water, the belief in witchcraft, and the ascription of tempests to magic, maintained the Carolingian opposition to image-worship, but carried his logic farther and opposed the adoration of the saints. In his purely theological works Agobard was strictly orthodox, except that he denied the verbal inspiration of the Scriptures. Agobard was revered as a saint in Lyons, and although his canonization is disputed his life is given by the Bollandists, *Acta Sanctorum*, Jun. ii. 748.

BIBLIOGRAPHY.—Agobard's works were lost until 1605, when a manuscript was discovered in Lyons and published by Papirius Masson, again by Baluze in 1666. For later editions see Potthast, *Bibliotheca Historica Medii Aevi*. The life of Agobard in Ebert's *Geschichte der Litteratur des Mittelalters* (1880), is still one of the best to consult. For further indications see A. Molinier, *Sources de l'histoire de France*.

AGONALIA, in ancient Rome, festivals celebrated on Jan. 9, Mar. 17, May 21 and Dec. 11 in each year in honour of various divinities (Ovid, *Fasti*, i., 319–332). The word is derived either from *agonia*, "a victim," or from *agonium*, "a festival," but there is no certainty as to the etymology of the word.

AGONOTHETES, in ancient Greece, the president or superintendent of the sacred games. At first the person who instituted the games and defrayed the expenses was the Agonothetes. But in the public games, such as the Olympic and Pythian, these superintendents represented different States, or were chosen from the people in whose country the games were celebrated; thus at the Panathenaea at Athens ten *athlothetai* were elected for four years to superintend the various contests. They were variously called "regulators," "arbitrators," "judges of contests," "stewards of the games" (at Athens), "rod-bearers" (from the rod or sceptre emblematic of their authority), but their functions were generally the same.

AGONY COLUMN, a term often applied to the column in newspapers devoted to personal advertisements, such as announcements of losses or bequests. At as early a date as 1800 the "agony column" was a medium also for matrimonial advertisements. It is sometimes known as the personal column.

See Alice Clay, *The Agony Column of the "Times" 1800–1870* (1881).

AGORA, originally an assembly of the people of one of the Greek city States, called by the king or other authority to receive a decree or to discuss a policy. At an early period the word was used to describe the places where these meetings were held and in historic times any open space for general meetings, either official or commercial, was termed an agora. The agora of the historic Greek city was thus similar to the Roman forum or the mediaeval English market place. As the agora was the centre of the city life, it was surrounded by, or adjacent to the most important civic buildings, the prytaneum or official residence of the general, the basilica where the court sat, the *bouleuterion* or council hall, the thesaurus or treasury and the prison. As the market place, it had ranges of sheds or colonnades for shops; frequently the colonnades were divided into parts, each named after the particular merchandise sold therein.

After the Persian wars the architectural treatment of the agora became much more monumental and lavish colonnades were frequently added to the older agorae, such as the Stoa of Attalus in the agora at Athens (between 159 and 138 B.C.). Of these later agorae many fine examples exist in various states of preservation. That at Ephesus was a square court over 500 ft. on the side, connected with additional courts containing a gorgeous nymphaeum and the lavish Roman library. At Priene the agora was traversed by streets but arranged so that through traffic was carried below on a detour. The substructures of the hillside agorae at Aegaea and Alinda still remain almost complete. In these cases the agora on a high terrace had large storage warehouses below. The great terrace wall at Alinda, with its striking rusticated masonry and large Roman arched openings, is especially impressive. Most important of all, however, is the agora at Assus, of which extensive remains still exist in a good state of preservation, with enough fragments to enable a complete and definitive restoration. This, like the two foregoing, is a hillside agora, supported on massive terrace walls. Its main architectural feature is the great two-storey portico.

The forum at Pompeii, in plan, dates probably from the time of the Greek colony. It therefore forms a connecting link between the Greek agora and the Roman forum. With its surrounding colonnade, its basilica, the city temple at one end and the civic offices at the other, it gives a perfect picture of what the typical Greek agora was like. (For the agora at Athens see ATHENS.)

For a general discussion, see Cornish, *Dictionary of Greek and Roman Antiquities* (1898). The typical plan given is, however, absurd through its obvious misinterpretation of a passage in Pausanias in which he refers to colonnades separated by streets. Pausanias plainly refers to streets traversing the agora and thus dividing the enclosing colonnade into separate sections. See also S. H. Bacon and Robert Koldewey, *Expedition of the Archaeological Institute of America* (investigations at Assus in 1881–83, 1902–21); Anderson and Spiers, *Architecture of Ancient Greece*, new ed. by W. B. Dinsmoor (1927).

AGORACRITUS, a Parian and Athenian sculptor of the age of Pheidias, and said to have been his favourite pupil. His most noted work was the statue at Rhamnus of Nemesis, by some

attributed to Pheidias himself. Of this statue part of the head is in the British Museum; some fragments of the reliefs which adorned the pedestal are in the museum at Athens.

AGORANOMI. Magistrates in Greece, whose duties were similar to those of the aediles of Rome. In Athens there were ten, five of whom took charge of the city and five of the Peiraeus. They maintained order in the markets, tested weights and measures, collected the harbour dues, and enforced the shipping regulations.

AGORDAT, a town of Eritrea, North-east Africa, on the route between Massawa and Kassala. It is connected by a railway, 194 miles long, with Massawa, via Asmara. At Agordat (Dec. 21, 1893) Italians under Colonel Arimondi defeated the followers of the khalifa. (See ERITREA and SUDAN; *History*.)

AGOSTINO and **AGNOLO** (or **ANGELO**) **DA SIENA**, Italian architects and sculptors in the first half of the 14th century. Della Valle and other commentators deny that they were brothers. They certainly studied together under Giovanni Pisano, and in 1317 were jointly appointed architects of their native town, for which they designed the Porta Romana, the church and convent of St. Francis, and other buildings. On the recommendation of Giotto (*q.v.*), they executed in 1330 the tomb of Bishop Guido Tarlati in the cathedral of Arezzo, which Giotto had designed. This monument was destroyed by the French under the duke of Anjou.

AGOSTINO or **AGOSTINI** (**AUGUSTINUS**), **PAOLO** (1593-1629), Italian musician, was born at Valerano, and studied under G. B. Nanini. He succeeded Ugolini as conductor of the pope's orchestra in St. Peter's. Among his compositions is an *Agnus Dei* for eight voices, once greatly admired.

AGOULT, MARIE CATHERINE SOPHIE DE FLAVIGNY, **COMTESSE D'** (1805-1876), French author, whose *nom de plume* was "Daniel Stern," was born at Frankfurt-on-Main on Dec. 31, 1805. Her father was a French officer who had served in the army of the emigrant princes, and her mother was the daughter of a Frankfurt banker. She was married in 1827 to the comte Charles d'Agoult. In Paris she gathered round her a brilliant society which included Alfred de Vigny, Sainte-Beuve, Ingres, Chopin, Meyerbeer, Heine and others. She was separated from her husband, and became the mistress of Franz Liszt. During her frequent travels in Switzerland, France and Italy she made the acquaintance of George Sand, and figures in the *Leftres d'un voyageur* as "Arabella." By Liszt she had three children—a son who died young; Blandine, who married Émile Ollivier; and Cosima, who married first Hans von Bülow and later Richard Wagner. The story of her breach with Liszt is told under a very slight disguise in her novel *Nélida* (184). On her return to Paris in 1841 she began to write for the *Presse*, and later for the *Revue des deux Mondes* and the *Revue indépendante*. Mme. d'Agoult was an ardent apostle of the ideas of '48, and from this date her *salon*, which had been literary and artistic, took on a more political tone; revolutionists of various nationalities were welcomed by her, and she had an especial friendship and sympathy for Daniele Manin. In 1857 she produced a national drama, *Jeanne D'Arc*, which was translated into Italian and presented with success at Turin. The most important section of Daniel Stern's work is her political and historical essays: *Lettres républicaines* (1848), *Esquisses morales et politiques* (1849), *Histoire de la Révolution de 1848* (1850-1853), *Histoire des commencements de la République aux Pays-Bas* (1872). Mme. d'Agoult died in Paris March 5, 1876.

See Mme. d'Agoult, *Mes Souvenirs* (1806-33), 1877; J. Mazzini, *Lettres de Joseph Mazzini à Daniel Stern* (1872); A. Pommier, *Madame la comtesse d'Agoult* (Daniel Stern), 1876; A. Cuvillier Fleury, *Portraits révolutionnaires*, vol. i. (1889); A. Ungherini, "Daniel Stern" in the *Revista repubblicana* (1880, No. 9); S. Rocheblave, *Une Amitié romanesque, George Sand et Madame d'Agoult* (1895); R. Bory, *Une Retraite romantique en Suisse; Liszt et la comtesse d'Agoult* (1923), with an appendix containing letters; Daniel Oliver, *Mémoires de la comtesse d'Agoult: 1833-54* (1926).

AGOUTI or **AGUTI** (a-gōō-tě), rodent (*Dasyprocta aguti*), of the size of a rabbit, common to Trinidad and Guiana, and classed in the family *Caviidae*. Agoutis are slender-limbed animals,

with five front and three hind toes (the first front toe very minute), and short tails. The hair is coarse and rough; the colour being rufous brown. In habits agoutis are nocturnal, dwelling in forests, where they conceal themselves during the day in hollow tree-trunks, or in burrows among roots. They take readily to water and swim well. Their food comprises leaves, roots, nuts and other fruits. They do much harm to plantations of sugar-cane and bananas.

AGRA, the headquarters of a district and division in the United Provinces, was for long periods the capital city of India. It stands on the Jumna which, though now at this point a mere

trickle in the dry season, was formerly one of the chief arteries of commerce with the rest of India and at the same time a powerful frontier defence. Of the original Agra, which apparently lay on the left bank of the river, practically no traces remain. The present city on the right bank was the creation of the Mohammedan conquerors. The earlier dynasties fluctuated between Delhi and Agra as their centre of power; but it was at Agra that Sikander Lodi (A.D. 1500) set up his court, deeming it the strategic point for holding in check his turbulent vassals to the south. In 1526 the city was captured by Baher, the Koh-i-nor diamond being part of his booty. It was here that he decided to occupy India in permanence; here also that he died. It was his grandson Akbar who began to build the present fort (still by the people called Akbarabad), ruled India from within the walls, died in it, and was buried at Sikandra a few miles beyond the city gates. Agra fell from its pride of place when Aurangzeb moved to Delhi, and was never again the seat of monarchy. In the latter half of the 18th century, it was captured successively by the Jats, the Mahrattas, the Mohammedans and Scindhia; but it was finally taken by Lord Lake in 1803. After British rule was extended to upper India, it became the capital of the North-West provinces until at the close of the Mutiny the seat of that Government was transferred to Allahabad. The city is now a busy railway and commercial centre with cotton mills, gins and presses, flour mills and an important carpet industry. There are two large colleges and several other educational institutions, including a medical school for men and women; and the establishment of a university is under contemplation. Pop. in 1931, 229,764.

Although to travellers Agra is essentially the city of the Taj, it enshrines several other magnificent specimens of Mogul architecture, each perfect of its kind. The fort, with its lofty walls of red sandstone 1½ m. in circumference, contains at least two such gems. Separated from each other by the main block of the buildings of the imperial court, stand on the north the Pearl Mosque, built by Shah Jahan, and on the south the Jahangiri Mahal or palace built by Akbar; the former unequalled for the beauty and purity of its proportions, material and constructive design in simple white marble; the latter a perfect adaptation of stately solidity and commanding symmetry of the Hindu style. If we leave the fort and cross the river, we find another gem of its kind in the tomb of Itmad-ud-Daulah, father of Jahangir's empress. Its architecture is transitional between the virile conceptions of Akbar and the poetic richness of Shah Jahan; elegant, elaborate and scholarly, it was the first triumph of marble inlaid work in direct imitation of Persian pottery decoration. Five miles from Agra is Sikandra, where Akbar was buried, though his remains were desecrated and scattered by Jat freebooters in later years. His tomb is a noble building in a noble setting, and the marble sarcophagus on its roof is strikingly impressive in its simple dignity. Far exceeding all the others in glory is the Taj, the most beautiful mausoleum in the world. It was built by Shah Jahan for his empress, who died in A.D. 1631; and from one of her titles, Taj Mahal or Crown of the Palace, it takes the name by which it is most generally known outside India. Built of pure white marble, it stands on a vast marble terrace, crowned by a great dome in the centre and smaller domes at each of its corners. From the angles of the terrace rise

four slender minarets. Subservient and supplementary to the glory of the outline is the beauty of the ornamentation. "All the spandrils of the Taj," writes Fergusson, "all the angles and more important architectural details are heightened by being inlaid with precious stones such as agates, bloodstones, jaspers and the like. These are combined in wreaths, scrolls and frets as exquisite in design as they are beautiful in colour, and relieved by the pure white marble in which they are inlaid, they form the most beautiful and precious style of ornament ever adopted in architecture."

The architect of the Taj was Ustad Isa, variously described as a Byzantine Turk, and as a Persian from Shiraz. The artificers engaged during the 17 years of its construction came from all

BY COURTESY OF CANADIAN PACIFIC STEAMSHIPS

THE TAJ MAHAL AT AGRA. ERECTED BY THE EMPEROR SHAH JAHAN AS A MAUSOLEUM FOR HIS EMPRESS WHO DIED IN A.D. 1631. THE ARCHITECT WAS USTAD ISA

parts of Asia and probably included a French goldsmith, Austin de Bordeaux.

The district of Agra has an area of 1,849 sq. miles. Its general appearance is that common to the Doab, a level plain intersected by watercourses with fringes of ravines. Its general elevation is estimated at from 650 to 700ft. above the level of the sea. The district is intersected by the Jumna, and is also watered by the Agra canal. The principal crops are millets, pulses, barley, wheat, cotton and a little indigo. The population in 1931 was 1,048,316.

The division of Agra has an area of 8,638 sq. miles. In 1931 the population was 4,498,246. It comprises the five districts of Aligarh, Muttra, Agra, Mainpuri and Etah.

AGRA CANAL, primarily an irrigation project opened in 1874, but widely used for navigation. It is supplied with water from the Jumna river and beginning at Okla, 10 m. below Delhi it passes through the districts of Delhi, Gurgaon, Muttra and Agra as well as the Bharatpur state. It finally joins the Banganga river about 20 m. below Agra.

AGRAM: see ZAGREB.

AGRABHA, the name given to certain utterances ascribed, with some degree of certainty, to Jesus, which have been preserved in documents other than the Gospels, e.g., Acts xx. 35; 1 Tim. v. 18; 1 Cor. vii. 10-12, and the Logia (*q.v.*) discovered in 1897 and 1903 at Oxyrhynchus.

BIBLIOGRAPHY.—See A. Resch, *Agapha* (Leipzig, 1889); J. H. Ropes, *Die Sprüche Jesu* (Leipzig, 1896); and the article "Sayings" in J. Hastings's *Dictionary of Christ and the Gospels*.

AGRARIAN LAWS, law dealing with the disposal of the public land (*ager publicus*) of ancient Rome. No gratuitous disposition of state property could be made without the consent of the people. Hence many of the ordinances affecting the

public land were laws (*leges*) in the strictest sense of that word. It is, however, convenient to consider in this article all the regulations that were made for the administration of the public land by the executive authorities, as well as by the people during the republic, and by the commands of the emperor, which had the force of law during the principate.

Public land was the prize of conquest and was one of the means of defraying the expenses of state administration. For this purpose land was often leased on the condition of the payment of dues. But it was made to fulfil another purpose, the satisfaction of the individual needs of poorer citizens. To this end land was assigned, and on assignment ceased to be the property of the state. But it often happened that the state was not disinterested in such acts of assignment. It gained security and territorial control by planting garrisons in conquered country, and it relieved itself of the necessity of providing for its poorer classes by state-aid. The connection between agrarian legislation and colonization can be seen at once, and also the two aspects of colonization—the military and the social. These two objects were connected throughout the whole of the earlier period of Roman agrarian assignment. After the time of the Gracchi social motives continued to be operative when military precautions had ceased to be necessary. One of the motives which prompted infant Rome to war with her neighbours was the land-hunger of her citizens. This hunger she satisfied after conquest by annexing a portion of the enemy's territory. The amount thus confiscated varied. It was usually a third, but sometimes a half or even two-thirds, and after the fall of Capua in the Second Punic War the whole territory of the state was annexed. By the close of the 3rd century B.C. one-half of the land of Italy belonged to Rome whether in private ownership or as the property of the state. Annexation was carried on in the provinces on a smaller scale; but Rome retained as domain-land much of the territory of communities which had been destroyed (e.g., Carthage and Corinth), and the estates of former kings. This peculiar property of the Roman state in the provinces must be carefully distinguished from the general overlordship which Rome was supposed to hold over all provincial soil, expressed in the statement that provincials had only possession or usufruct of land.

Methods of Handling Public Land.—Such portions of the territories of conquered cities as were not claimed by Rome were left in the possession of these cities. If the city was a federate state (*civitas foederata*) this possession was guaranteed by a treaty; if it was a free city, the guarantee was made by charter; where Rome had marked out territory for assignment to her own citizens, but where, in or near the limits of the assignment, some of the land had been left in the hands of its former proprietors, such land was noted in the state registers as *redditus veteri possessori*.

The State dealt in two ways with such land as it retained. It alienated it, in exchange for a price or gratuitously; or it kept it as a source of revenue, whether on lease or on some system of remunerative occupation. The land might be sold for the benefit of the treasury. Typical instances of this treatment are furnished by the sale of some Campanian land during the Second Punic War. The censors may have directed the sale, but it was executed by the quaestors as the regular officials of the treasury. Hence such land was described as *ager quaestorius*. The land was sold in definitely marked out plots, and when this sale had been effected the lots fell under the absolute ownership of their purchasers.

The second mode of alienation was that by assignment. Lands thus assigned were known as *agri dati adsignati*. The gift on the part of the State was gratuitous, and ownership passed wholly to the assignee. The land so given was definitely surveyed, marked out, and registered. Such an assignment might take one of two possible forms. It might be the means of establishing a new "plantation" (*colonia*), with some independent organization of its own, or it might be the means of providing allotments for individuals who remained domiciled at Rome or in some already existing municipality. The amount granted to individuals in assignments of both types varied from time to time. It was reckoned in terms of the *iugerum*, which was approximately five-eighths of an English acre. The earliest and smallest assignment was two *iugera*:

Iugera was the maximum amount granted before the time of Ti. Gracchus (133 B.C.), and it was held by representatives of the old school that seven *iugera* were as much as any frugal Roman should want. The division was carried out by commissions appointed by the people. The land which the State retained as *ager publicus* was always placed in the hands of individuals, who occupied it in some manner remunerative to the State. These individuals (*possessores*) were never regarded as owners of the land thus occupied. It remained the property of the State, was held without a contract (*precario*), and could be resumed by the State at will. But though the tenants had no claim against the State, their ownership could be defended against all other claimants; from an early date the praetor's possessory interdict was used to protect all occupiers, provided their tenure had not been acquired by force (*vi*), by seizure of land in its occupiers' absence (*clam*), or by mere permission of the previous holder to occupy (*precario alter ab altero*). Tenants of this type could transfer their land by inheritance, and the land was accepted as security by creditors. This kind of occupation, therefore, though clearly distinguished from ownership (*dominium*), was yet regarded as a perfectly secure form of tenure. All occupiers of public land paid dues to the State through a state contractor (*publicanus*). These dues varied in amount and in the method of their collection. We learn from Appian that the ordinary dues paid by occupiers of arable land in Italy were one-tenth of seed crops and one-fifth of plant produce. Owners who turned cattle or sheep on pasture land belonging to the state also paid fixed dues to the treasury. The occupiers of the Roman public land in Campania paid a large rent. The conditions of the tenure of the Roman public land in Africa are known to us from the *Lex Agraria* of 111 B.C. The *publicanus* is the middleman between the State and the *possessor* and purchases from the censor the right of collecting dues. The law places no restriction on bargaining between the censor and the *publicanus*, but enacts that no *possessor* or *pastor* shall ever be required by the *publicanus* to pay more than the amount prescribed by the censors of 115 B.C. These conditions may be regarded as typical for the occupation of public lands. When Cicero speaks of public land as let on lease (*locatus*) by the censor, he refers to the leasing of the taxes to a *publicanus* for a fixed period, and not to the letting of the land. This seems clear from a passage (*In Verr.* iii. 6. 12) where he speaks of land in Sicily which had been restored by Rome to former owners as being leased. The land itself could not be leased by Rome if it belonged not to Rome but to the Sicilian inhabitants; but the collection of the revenues due to Rome could be so leased to *publicani* (*q.v.*). The same explanation would apply to Cicero's statements that the Campanian land was let on lease by the censors. Cicero's repeated statement that the Campanian land was expressly exempted from the legislation of the Gracchi shows that there was not sufficient distinction between the Campanian tenure and that of other public land in Italy to make this definite exception by name superfluous. The Sempronian law could obviously not touch land which the State had leased to occupiers on the basis of a definite contract. It seems certain that in every case the *possessor* occupied *precario*, and that only in the bargain between the censor and the middleman was there room for contract. Thus the State was justified in the claim to resume public land which it made in many of the agrarian laws.

Survey of Agrarian Legislation.—The earliest agrarian measures of which we have any record are the distributions to poor citizens of land conquered in war, which later authorities attribute to Numa and Servius Tullius. Such assignments were a voluntary surrender on the king's part of his own portion of the spoils. The agrarian law of Spurius Cassius (436 B.C.) distributed *ager publicus* among the plebeians. Another agrarian law proposed by the tribune Lucius Icilius in 456 B.C. regulated the tenure of public land on the Aventine. In 376 B.C. the tribunes Licinius and Sextius introduced into their laws, for the promotion of the privileges of the *plebs*, a clause enacting that no more than 500 *iugera* of land should be occupied by a single cultivator; the law also enacted that only 200 cattle and 500 sheep might be turned by one owner on the public pastures. But it failed of its object because it did not provide any adequate machinery for the resumption by

the state of land held in excess of the prescribed amount, and was therefore easily evaded. The next agrarian law was a measure dealing with lands conquered from the Senones (*q.v.*) and Picentines. In 232 E.C. C. Flaminius, tribune of the *plebs*, proposed to resume these lands for the state, although they were already occupied by large landholders, and to distribute them in allotments to poor citizens. The measure met with much opposition from the richer classes, and did not gain the sanction of the senate; but C. Flaminius ignored constitutional usage and brought it direct before the council of the *plebs*, by which it was made law. In 133 B.C. the tribune Tiberius Gracchus (*q.v.*) re-enacted the earlier measure of Licinius and Sextius, with the additional provisions that each owner might occupy 250 *iugera* for each son, in addition to the original 500, and that a commission of three (*III. viri agris dandis adsignandis*) should be appointed to carry out the terms of the law. He also enacted that the land occupied in excess of the prescribed amount, and on that account resumed for the State by the land commission, should be distributed in inalienable lots to poor citizens. Subsequent modifications of those provisions which dealt with the powers of the land commission led to a re-enactment of the whole by G. Gracchus (*q.v.*), the brother of Tiberius, tribune in 123 B.C. But within 15 years from the tribunate of G. Gracchus the whole of his law had been rendered null by three further enactments. The first of these permitted the sale of land allotted under the law, which thus tended to return into the hands of its former occupiers as private property, which the State had no longer any right to resume. The second abolished the commission appointed to carry out the terms of the law, thus putting a stop to further resumption and distribution, and also transformed existing occupiers into owners of the land they occupied, paying only a small due to the treasury. The third abolished the payment. That law belonged to the year 111 B.C.

From that time forward a change came over land legislation. The ordinary public land in Italy, in the hands of occupiers, which had given rise to all the agrarian legislation between 376 and 111 B.C. had practically ceased to exist. The Campanian land still remained, but the same reasons which led to its exemption from the Gracchan legislation seem to have continued to protect its holders until 63 B.C. In the meantime several agrarian laws were passed which provided for the distribution of land placed in some other way at the disposal of the State. In 200 B.C. Appuleius Saturninus (*q.v.*) tribune, proposed the allotment of lands recently taken from the Cimbri in Gaul. This law was passed but eventually declared null by the senate, with the rest of Saturninus's laws. A more dangerous precedent was set by Sulla in his dictatorship (82–81 B.C.). He was the first to confiscate the lands of his political opponents and of communities which had resisted him and, treating them as *ager publicus*, assign them to his veterans as a prize. This example was followed by Octavian (Augustus) and Antony (M. Antonius) after their proscriptions in 43 B.C. A third method of providing land for distribution was that adopted by Servilius Rullus (*q.v.*) in 63 B.C. His bill enacted that land should be purchased in Italy with money gained by the sale of Roman territories abroad, and allotted to citizens. A commission of ten (*X. viri agris dandis adsignandis*), annually elected by nine out of the 35 tribes, was to carry out the terms of the law. Rullus also ventured to propose the distribution of the Campanian land which had hitherto been respected by all agrarian reformers. It was chiefly on this ground that Cicero in his three speeches on the Agrarian law succeeded in exciting such a general feeling against it that it was eventually withdrawn. In 60 B.C. the tribune L. Flavius brought forward a bill for the distribution of lands to Pompey's veterans. The Campanian land was certainly to be included in the distribution, and it is clear from Cicero that the bill in some way dealt violently with the rights of private owners. It also, however, enacted that land should be purchased by the State with the wealth which Pompey's conquests had brought into the treasury. The last proposal was supported by Cicero, but the bill seems to have been dropped, only to reappear in more moderate form in the following year. A consular bill, the *lex Iulia Campana*, was passed by Julius Caesar in 59 B.C., which provided for the settlement of Pompey's veterans on the Campanian land, and other lands pur-

chased by the state from private owners in Italy with the full consent of the latter. In its original form, the bill omitted all reference to the Campanian land, which seems to have been included by Caesar in the distribution only when the continued and unreasoning opposition of the senate had goaded him to extreme measures. A commission of twenty was to be appointed to carry out the law, from which Caesar himself was expressly excluded. This measure finally settled the question of the Campanian land, which now passed out of the category of *ager publicus*. The last agrarian law of the republic was that passed in 44 B.C. on the proposal of the consul M. Antonius. We have no detailed account of the measure, but it seems to have provided grants of land for veterans, and was to be administered by seven commissioners. The law was afterwards cancelled by decree of the senate.

AGRARIAN MOVEMENT: see *LAND TENURE: Economic and Agrarian Aspects*.

AGREDA, MARIA FERNANDEZ CORONEL, ABBESS OF, known in religion as Sor (Sister) Maria de Jesus (1602–1661), was born at Agreda, on the borders of Navarre and Aragon, on April 2, 1602. All her family were powerfully influenced by the ecstatic piety of Spain in that age. From childhood she experienced ecstasies and visions. When she was fifteen the whole family entered religion. Maria, her mother and sister established a Franciscan nunnery in the family house at Agreda, which, when Maria's reputation had extended, was replaced by the existing building. She began it with one hundred reals (one pound sterling) lent her by a devotee, and it was completed in fourteen years by voluntary gifts. Much against her own wish, we are told, she was appointed abbess at the age of 25. Though the rule required the abbess to be changed every three years, Maria remained the effective ruler of Agreda till her death. In the earlier part of her life, while the Franciscan, Francisco Andres de la Torre, was her confessor, she wrote an *Introduction to the History of the Most Blessed Virgin*. It was destroyed by the direction of another confessor. Later on, under the guidance of her Franciscan confessor, Andres de Fuen Mayor, she wrote *The Mystic City of God*. It is an extraordinary book, full of apocryphal history, visions, and scholasticism. In 1642 she sent to Philip IV. an account of a vision of a council of the infernal powers for the destruction of Catholicism and Spain. The king visited her when on his way to Aragon to suppress the rebellion of Catalonia. A long correspondence, which lasted till her death on March 29, 1665, was begun. The king folded a sheet of paper down the middle and wrote on the one side of the division. The answers were to be written on the other and the sheet returned. How far Maria was only the mouthpiece of the Franciscans must of course be a matter of doubt. Her correspondence was apparently suspended whenever her confessor was absent. The letters are in excellent Spanish, are curious reading, and are invaluable as illustrations for the second part of the reign of Philip IV.

The correspondence of Sor Maria with the king has been published in full by Don F. Silueta, *Cartas de la Venerable Madre Sor Maria de Agreda y del Señor Rey Don Felipe IV.* (1885). *The Mystic City of God* continued to be much in favour with supporters of the dogma of the Immaculate Conception. It appeared in Madrid in 1668, with a biographical introduction by Samaniego, has been often reprinted, and was translated into French and Italian. It was for a time reserved by the Index, both Spanish and Papal, but was taken off by the influence of the Franciscans and of Spain, the chief supporters of the Immaculate Conception. An account of Maria de Agreda will be found in the *Tracts* of Michael Geddes (1706), vol. iii., written by a competent critic and Anglican divine of the 18th century who detested "enthusiasm."

AGRÉMENTS (Ital. *abbellimenti*; Ger. *Manieren*; Eng. *ornaments*), in music, are supplementary notes, or embellishments, introduced for the purpose of enriching, elaborating or otherwise altering the effect of the phrase or melody to which they are applied. As employed in connection with the older types of music, alike vocal and instrumental, they assumed a large variety of forms (acciaccatura, appoggiatura, arpeggio, mordent, shake, turn,

and so on) which in course of time became definitely standardized and so formed an essential part of the music, although nominally left to the discretion of the performer and indicated, if at all, only by conventional signs.

AGRIANES, a warlike tribe anciently inhabiting Upper Macedonia, and part of what is now south-western Bulgaria. They provided some of the most active and dangerous of the troops of Alexander's army, distinguishing themselves at the Granicus, Issus and on the banks of the Jhelum.

AGRICOLA, GEORG (1490–1551), German scholar and man of science, known as "the father of mineralogy," was born at Glauchau in Saxony on March 24, 1490. The name Agricola is the Latinized form of the German Bauer. His early studies were in philology, but he took his degree in medicine in Italy. On his return to Germany he settled as practising physician in the Joachimstal, a centre of mining and smelting works, his object being partly "to fill in the gaps in the art of healing," partly to test what had been written about mineralogy by careful observation of ores and the methods of their treatment. *Bermannus, sive de re metallica dialogus*, the first attempt to reduce to scientific order the knowledge won by practical work, brought Agricola into notice. (This work was translated by Mr. and Mrs. Herbert Hoover.) In 1530 Prince Maurice of Saxony appointed him historiographer with an annual allowance, and he migrated to Chemnitz, the centre of the mining industry, in order to widen the range of his observations. His chief interest was in mineralogy; but he occupied himself also with medical, mathematical, theological, and historical subjects, his chief historical work being the *Dominatores Saxonici a prima origine ad hanc aetatem*, published at Freiberg. In 1544 he published the *De ortu et causis subterraneorum*, in which he laid the first foundations of a physical geology and criticized the theories of the ancients. In 1545 followed the *De natura eorum quae effluunt e terra*; in 1546 the *De veteribus et novis metallis*, a comprehensive account of the discovery and occurrence of minerals; in 1548 the *De animantibus subterraneis*; and in the two following years a number of smaller works on the metals. His most famous work, the *De re metallica, libri xii.*, was published in 1556, though apparently finished several years before, since the dedication to the elector and his brother is dated 1550. It is a complete and systematic treatise on mining and metallurgy, illustrated with many fine and interesting woodcuts and containing, in an appendix, the German equivalents for the technical terms used in the text. He died at Chemnitz on Nov. 21, 1555.

See article by Gümbel in *Allgem. Deutsche Biog.* (1875); F. A. Schmidt, *Georg Agricola's Bermannus mit Einleitung* (Freiberg, 1806).

AGRICOLA, GNAEUS IULIUS (A.D. 37–93), Roman general, father-in-law of the historian Tacitus, was born on June 13, A.D. 37 (according to others, 39) at Forum Iulii (Fréjus) in Gallia Narbonensis. His grandfathers were of equestrian rank; his father became a senator, but was put to death by Caligula. Agricola was brought up by his mother at Massilia. He entered the army and served (59) under Suetonius Paulinus in Britain. In 61 he returned to Rome, where he married Domitia Decidiana, a Roman lady of distinction. In 63 he was quaestor in Asia, in 65 tribune, in 68 praetor, and when Vespasian was proclaimed emperor, he immediately declared himself his supporter. In 70 he was appointed to the command of the 20th Legion in Britain, then stationed at Deva (Chester). On his return to Rome, at the end of three years, he was made censor, raised to the rank of patrician, and appointed governor of Aquitania (74–78). Appointed *consul suffectus* in the following year, he was admitted into the college of pontiffs and made governor of Britain. In the same year he betrothed his daughter to Tacitus.

Agricola spent at least seven years in Britain. After conquering the Ordovices in North Wales and the island of Mona (Anglesey), during the next two years he advanced to the Taüs (Tay; others read Tanaus, perhaps the north Tyne), and in his fourth campaign fortified the country between Clota and Bodotria (the firths of Clyde and Forth) as a protection against the attacks of the Caledonians. Having explored the coasts of Fife and Forfar, he gained a decisive victory over the Caledonians under Galgacus at the

Graupian hill. (See BRITAIN: *Roman*.) Between campaigns he busied himself in helping forward the Romanization of his province. But his successes had aroused the suspicion of Domitian. He was recalled to Rome, where he lived in retirement, refusing the proconsulship of Asia. He died in 93, poisoned, it was rumoured, by the emperor's orders.

See Tacitus, *Agricola*; Ulrich's *De Vita et Honoribus Agricolae* (1868); Dio Cassius, xxxix. 50, lxvi. 20; T. Mommsen, *Provinces of the Roman Empire* (Eng. trans., 1886), i. 183-184, 104.

AGRICOLA, JOHANNES (originally Schneider, then Schnitter) (1494-1566), German Protestant reformer, was born April 20, 1494 at Eisleben, whence he is sometimes called *Magister Islebius*. He studied at Wittenberg, where he met Luther. In 1519 he accompanied Luther to the great assembly of German divines at Leipzig, and acted as recording secretary. He taught and preached the Lutheran doctrine in Frankfurt, Eisleben and Wittenberg, but in 1536 an old controversy broke out more violently than ever. Agricola was the pioneer of the Antinomian heresy, which maintained that while the unregenerate were still under the Mosaic law, Christians were entirely free from it, being under the gospel alone. During the bitter controversy with Luther that followed, Agricola in 1540 left Wittenberg secretly for Berlin, where he addressed a letter to the elector of Saxony, which was generally interpreted as a recantation of his views. Luther, however, was not satisfied, and Agricola remained at Berlin, where Joachim II. of Brandenburg appointed him court preacher and general superintendent. With Julius von Pflug and Michael Helding, he prepared the Augsburg Interim of 1548. He endeavoured in vain to appease the Adiaphoristic controversy (see ADIAPHORISTS). He died during an epidemic of plague on Sept. 22, 1566.

BIBLIOGRAPHY.—See Cordes, *Joh. Agricola's Schriften möglichst verzeichnet* (Altona, 1877); Life by G. Kawerau (1881), who also wrote the notice in Hauck-Herzog, *Realencyk. für prot. Theol.*

AGRICOLA, RODOLPHUS (properly ROELOF HUYSMANN) (1443-1485), Dutch scholar, was born at Baflo near Groningen, Aug. 23 1443. He was educated at Louvain, Paris, and at Ferrara, where he attended the lectures of the celebrated Theodorus Gaza (1400-78) on the Greek language. In 1482, on the invitation of Johann von Dalberg, bishop of Worms (1445-1503), he accepted a professorship at Heidelberg, and for three years delivered lectures there and at Worms on the literature of Greece and Rome. By his personal influence much more than by his writings he did much for the renaissance of learning in Germany; and Erasmus and other critics of the generation immediately succeeding his own are full of his praises. He died at Heidelberg on Oct. 28 1485. His principal work is *De inventione dialectica, libri iii.*, in which he attacks the scholastic philosophy of the day. His collected works were edited by Alard (Cologne, 1539).

See T. F. Tresling, *Vita et Merita Rudolphi Agricolae* (Groningen, 1830); v. Bezold, *R. Agricola* (München, 1884); and Ihm, *Der Humanist R. Agricola, sein Leben und seine Schriften* (Paderb., 1893).

AGRICULTURAL ARTICLES. Agriculture is treated in these pages under various headings, an enumeration of which will help the reader to consult any part of the subject.

For a general account of agriculture, reference should be made in the first place to the article AGRICULTURE: A GENERAL SURVEY, and to the sections on agriculture appended to the articles on the different nations.

As to the operations of agriculture, see the articles CULTIVATION; SOIL; SOWING; FERTILIZERS; DRAINAGE OF LAND; PLANT BREEDING; ROTATION OF CROPS; DRY-FARMING; ARABLE; WEED DESTRUCTION; REAPING; THRASHING; AGRICULTURAL MACHINERY AND IMPLEMENTS; ELECTRICAL POWER IN AGRICULTURE; TRACTORS; etc.

The business and organization of agriculture will be found treated under AGRICULTURAL CO-OPERATION; AGRICULTURAL CREDIT; AGRICULTURAL ECONOMICS; AGRICULTURAL EDUCATION; AGRICULTURAL INSURANCE; AGRICULTURAL ORGANIZATION, and AGRICULTURAL RESEARCH. Reference should also be made to the articles on ALLOTMENTS; SMALL HOLDINGS; FARM ORGANIZATION AND EQUIPMENT; FARM MANAGEMENT, and FARM VALUATIONS.

LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS is treated under that heading, and there is an article on FARM RENTS. The various institutions connected with agriculture are treated under the headings: INTERNATIONAL INSTITUTE OF AGRICULTURE; AGRICULTURE, CHAMBERS OF; AGRICULTURAL SOCIETIES AND SHOWS; ALLOTMENTS ORGANIZATION SOCIETY. For a discussion of farm relief legislation since 1928 in the United States see FEDERAL FARM BOARD. For statistics, see AGRICULTURAL STATISTICS; AGRICULTURE, CENSUS OF, and AGRICULTURAL PRICES. As to agricultural employment, the articles AGRICULTURAL LABOURER and AGRICULTURAL WAGES should be consulted. Coming to the products of agriculture, in addition to general articles entitled CEREALS and CROPS, each main product is given special treatment under its own heading. Thus, the cereals WHEAT, BARLEY, OATS: CULTIVATION AND TRADE, MAIZE (INDIAN CORN) are the subject of special articles. GRAIN PRODUCTION AND TRADE has lengthy treatment. ROOT-CROPS are given a heading, while TURNIP, POTATO, MANGEL-WURZEL, etc., have separate articles. There are also articles on GRASS AND GRASSLAND, HAY and LUCERNE (PURPLE MEDICK, ALFALFA).

AS to animals and meat, articles may be consulted on CATTLE, SHEEP, PIG, BEEF, MUTTON, PORK, BACON and HAM, in addition to the general account under MEAT. There are articles on FEEDING STUFFS and ENSILAGE. As to dairy work, reference should be made to DAIRY FARMING (a general account), and to the articles BUTTER, CHEESE and MILK. On special subjects, articles will be found under EGGS; FRUIT FARMING; FLOWER FARMING; FLAX; HOP; HOP, CULTIVATION OF THE; BEET; BEEKEEPING; POULTRY AND POULTRY FARMING.

Finally, the exceedingly important subject of agriculture in the tropics, upon which the livelihood and daily bread of a large section of the world's population may come to depend, will be found treated under TROPICAL AGRICULTURE, while separate headings are provided for tropical and sub-tropical products such as TEA, COFFEE, COCOA: INDUSTRY AND TRADE, JUTE, RUBBER, GUTTA PERCHA, HEMP, TOBACCO, ARROWROOT, etc.

AGRICULTURAL BUSINESS METHODS: see FARM ORGANIZATION AND EQUIPMENT; FARM MANAGEMENT.

AGRICULTURAL CO-OPERATION. The development of agricultural co-operation has taken widely different courses in various countries according to their specific needs. The main difference to be observed is between countries which are primarily producers of agricultural commodities for export, and those which produce mainly for home consumption. In the former, the co-operative movement has chiefly concentrated upon the organization of marketing; in the latter—apart from the development of rural credit and insurance—mainly upon the purchase of farm requisites, or the formation of co-operative dairy, bacon or other producing societies. Although this broad distinction holds good, it is nevertheless true that practically all types of co-operation are to be found to a greater or lesser extent in the principal agricultural countries.

Co-operation in Great Britain.—Agricultural co-operation in Great Britain may be said to have begun with isolated experiments during the 19th century, but very little resulted from these early attempts. The Agricultural Organization Society in 1901 was the centre of the movement from its formation until it was wound up in 1924. During this period a great many societies were established.

The period following the war of 1914-18 brought forth a considerable intensification of the efforts to promote co-operation amongst British farmers, and the Agricultural Organization Society was assisted by grants from the State. A number of new societies were formed between 1918 and 1924. Unfortunately these efforts met with only limited success, and the creation of new societies was largely offset by a considerable number of failures. This was due to several factors—to the rapid fall in agricultural prices which took place after the spring of 1920, to the fact that a large number of the new societies were small and financially weak and were therefore unable to secure competent management, to the failure of many societies to adopt certain principles in co-operation which in other countries had proved to be essential, and

to the lack of interest shown by farmers themselves

Among agricultural co-operative societies in Great Britain the most successful have been the relatively large-scale societies concerned with the supply of farm requisites, a few dairy societies, and a certain number of others engaged in the sale of eggs, wool, fruit and vegetables, etc. Mention should be made of the formation of the Agricultural Wholesale Society in 1918, which was an attempt to provide a central wholesale organization from which the local requisite societies could obtain their supplies; its relation to the latter was similar to that between the co-operative wholesale societies and the retail consumers' co-operative societies. Such central wholesale societies had for some years been an integral part of the agricultural co-operative organization in several European countries.

Co-operation in Europe.—In western Europe, where the majority of countries were importers of food or were approximately self-supporting, the growth of co-operation was mainly in the direction of developing rural credit societies (see **AGRICULTURAL CREDIT**) or of societies for the purchase of agricultural requisites, though often combining these functions with that of the sale of produce. But even here, Denmark, conducting a considerable export trade, developed its marketing organizations on co-operative lines in addition to its highly organized system of supply societies; indeed it has been the model upon which many of the marketing organizations in the newer countries have been based. Leadership in agricultural co-operation has belonged to Germany and Denmark.

A general characteristic of the European co-operative movement is that both in its origin and subsequent development there has been a certain idealism which has given it a special vitality. Thus, in Denmark, the movement was associated with a moral educational revival accompanied with the development of the people's high schools; in Belgium the co-operative organization had a basis of religious and social culture; in Germany the birth of the co-operative credit movement was largely a question of the social regeneration of the rural population. In most of these cases it started with the clubbing together of a small number of villagers to carry out a common object, whether it was the purchase or sale of produce, or the provision of credit. But, although built up upon this small foundation, the movement gradually assumed a different character through the consolidation of the small units into large federated organizations, the gradual centralization of control, and the development of many of the features of big-scale enterprise. Indeed, federation describes in a word the modern development of the co-operative movement in most agricultural countries.

The main divisions of the co-operative movement in Europe have been supply, production, marketing, credit and insurance. Other minor, but important, branches are the co-operative use of farm machinery, cattle breeding, the supply of electric light and power, the manufacture of potato meal and potato alcohol, forestry and fishing.

Supply Societies.—These have aimed at purchasing agricultural requisites in bulk at wholesale prices and delivering them to members at cost. They have been widely developed upon "Rochdale" principles, the goods being delivered to members at certain fixed prices and the profits of the societies being distributed amongst its members as a "dividend" in proportion to the gross amount of their purchases. This principle applies in many European countries, though an exception is to be found in France, where the profits of the "syndicats" go to the formation of a reserve fund which belongs to the members equally, irrespective of the amount of their purchases. The tendency in the development of these societies is to federate the local distributive societies to central wholesale societies on the general plan of the British distributive movement.

In Germany, the pioneer society in the movement towards wholesale federation was the Haas Society at Insterburg, founded in 1871. This example was subsequently followed by the rest of Germany, membership of the provincial wholesales being usually confined to the local distributive societies. The first permanently successful federation amongst consumers' stores in Denmark

started in 1884 with the formation of the Co-operative Wholesale Society of Denmark amongst the societies on Zealand (Sjælland), for the supply of farm requisites as well as ordinary household requisites. Four years later a similar wholesale society was started in the Jutland Peninsula, and in 1896 these two were amalgamated into one organization—the Co-operative Wholesale Society of Denmark. Since then it has made remarkable growth.

In Switzerland similar progress has been made. The Verband-Ost-Schweizerischer-landwirtschaftlicher-Genossenschaften was formed as a central society. The business was divided into two departments—the agricultural, dealing with seeds, manures, cattle food, etc., and the store department, dealing with household requisites. The organization also undertook the sale of members' produce, though its supply side remains its more important function. In France, the local, and more particularly the communal, "syndicats agricoles," united in departmental unions, and these unions formed the starting point of larger organizations—the "unions regionales."

Production Societies.—Probably the most successful branch of productive co-operation is to be found in the dairy societies existing in large numbers in all countries in which agricultural co-operation is firmly established. Leadership belonged to Germany and Denmark. Switzerland, France, Holland, Belgium and some of the countries of south-eastern Europe have also made considerable progress. Ireland, too, was one of the most successful countries in developing co-operative creameries. (See **CREAMERIES**.)

Mention should be made of the bacon factories and egg and poultry societies, the former of which have been brought to a high degree of efficiency in Denmark. These are factories requiring a considerable amount of capital and provided with subsidiary plants for the disposal of by-products. They are usually financed by loans jointly and severally guaranteed by the members, and receive the pigs from members under contracts binding them to supply their whole output for a period of years. The individual bacon factories are federated in the National Federation of Danish Co-operative Bacon Factories, with head offices in Copenhagen. One of the most remarkable achievements of this co-operative organization is the improvement of breed which it has enabled producers to bring about. A close study of the requirements of the British market (the principal export market) combined with scientific pig breeding under the supervision of the Government and the National Federation of Co-operative Bacon Factories, has led during the last 40 years to an improvement in quality, without parallel in other countries.

Marketing.—To Denmark also belongs the credit of beginning co-operative marketing. The tendency was to establish strong central selling or export agencies of which local productive societies were members. The need for co-operation among the local co-operative societies gave the impulse towards the centralization of marketing, and the formation of provincial and ultimately national associations, but many difficulties were experienced before the structural development of the marketing organizations was complete. The turning point was reached when the principle of binding contracts for the supply of produce was adopted. Under this system the members of a local co-operative marketing association undertook to supply the whole of their produce to their society for a term of years. The term ranged from one to as many as 20 years. On this firm foundation it has been found possible to build up the modern organization which markets the greater part of Danish agricultural produce. The local units, having a democratic membership control, are usually federated to the central society on "commodity" lines, that is to say, the federation of local societies is usually concerned with one agricultural commodity or commodities of closely allied character. Members are paid for produce by an advance at the time of delivery followed by a distribution of the profits at certain intervals. The produce thus delivered is classified and graded at the headquarters of the association, and the initial payment is made on the basis of this classification. For the purpose of marketing, the produce is "pooled." These principles—contracts, commodity organization and pooling—form the basis upon which a great part of Danish

co-operative marketing is conducted, and have been widely copied in America, Canada, Australia and elsewhere.

The benefits which agriculture has derived from the European co-operative system are many. By the centralization of purchase and of sale, considerable economies have been effected, not merely in consequence of the elimination of the middleman and of bulk handling of the produce, but by the removal of the powers of exploitation which buyers and sellers of agricultural commodities not infrequently exercised over unorganized farmers. In organized marketing, large-scale handling has enabled scientific grading and standardization to be carried out, which in turn has led to the production of standard grades of produce and standard breeds of live stock on the farms. This again, as in the case of bacon, has led to a general improvement in the quality of farm produce, and has greatly added to the competitive strength of the central export associations in foreign markets. Their products have earned a reputation for uniformity and sustained high quality against which unorganized farmers have found it increasingly difficult to compete.

Canadian Wheat Pools.—Canada affords some remarkable examples of the development of large scale co-operative marketing enterprise, of which the wheat organization is the most significant. The Saskatchewan Co-operative Elevator Company originated in the widespread discontent which was felt by farmers at the growing powers of the elevator companies.

Alberta followed the lead of Saskatchewan by setting up the Alberta Farmers' Co-operative Elevator Company in 1913, and four years later this company was taken over by the United Grain Growers, Limited. The movement towards centralized marketing has undergone further important developments. For the purpose of selling, an organization known as the Saskatchewan Co-operative Wheat Producers, Limited, was formed, with headquarters at Regina. Members of the company, who already form a substantial proportion of the wheat growers in the province, enter into a five years' contract to sell the wheat through the company. Very similar arrangements have been made in Manitoba and Alberta, the respective organizations being the Manitoba Co-operative Wheat Producers, Ltd., with headquarters at Winnipeg, and the Alberta Co-operative Wheat Producers, Ltd., with headquarters at Calgary. To complete the system of centralization only one step remained, namely, to unite the three provincial pools into one organization. This step was taken. The Canadian Co-operative Wheat Producers, Ltd., with headquarters at Winnipeg, was formed as the central selling agency for the above three producers' pools, and operated for the first time in respect of the 1924-25 crop. The handling of milk, butter and cheese, the marketing of wool, live stock, poultry and eggs, fruit and other produce by co-operative enterprise has also made considerable advance in Canada since the World War of 1914-18.

Australian Wheat Pools.—The co-operative wheat pools of Australia are an example of a somewhat different character, since they came into being as the result of direct State action in order to meet the abnormal conditions during the War. They have brought about a fundamental change in the system of marketing wheat in that country. The original scheme was compulsory. It was entered into by the Governments of the Commonwealth, the States of New South Wales, Victoria, South Australia and Western Australia for the purpose of realizing to the best advantage the wheat harvests of the respective States, and for making advances to farmers pending the realization. The scheme was first applied to the 1915-16 crop, and it was subsequently decided to deal with the succeeding crops on the same principle. The duty of realizing the crop was placed in the hands of the Australian Wheat Board, consisting of ministerial representatives of the Governments of the Commonwealth and the respective States, and one representative of the growers from each State.

In each State a local board or commission controlled the operations of the scheme within its area, and the local board effected all local sales, including sales to millers. Under arrangements with the Australian banks made by the Commonwealth and State Governments, advances were made to farmers upon delivery of their wheat at railway stations to the appointed representatives. The proceeds of the wheat sales were applied, as realized, in re-

duction of the bank over-drafts which had been used for the payment of advances and expenses. In 1922 the compulsory pooling of wheat was abandoned, but the principle of pooling the exportable surplus was continued on a voluntary basis under the respective State Governments. Under this scheme, as in the case of the compulsory scheme, each State ultimately received, in respect of the grain actually shipped, the average net profit from the overseas realizations, which, after paying expenses, was distributed *pro rata* amongst the growers.

Mention must also be made of the rapid growth of agricultural co-operation in India, which has mainly taken place during the present century. Indian co-operation bears a much closer resemblance to European than to the American or Australian systems. As in Germany, it has been developed largely to provide credit (and insurance) facilities, and to a limited extent for the purchase of requisites and the sale of produce. (X.)

THE UNITED STATES

For more than half a century farmers of the United States have been actively interested in the co-operative way of doing business. As early as 1870 and in isolated cases even before that, farmers in this country were banding themselves together into local groups and were marketing farm products, purchasing farm supplies, and providing themselves with farm business services on a co-operative basis.

The first broad expansion in the development of co-operative organization in this country occurred under the stimulus of the Granger movement, which reached the peak of its activity during the early '70s. Later, further stimulus was given to the movement by other farm organizations such as the Farmers' Educational and Co-operative Union, the Farmers' Alliance, the American Society of Equity, and more recently, of course, by the American Farm Bureau. But, generally speaking, agricultural co-operation as it has developed in this country represents a movement separate and distinct from the general farm organizations. It is wholly an economic movement concerning itself primarily with the marketing of farm products, the purchasing of farm supplies, and the providing of farm business services on a co-operative basis.

During its early years the movement was beset by many failures of the local associations, chiefly because of the unsound business practices. Much has been done to correct these weaknesses. Sounder business practices have been adopted and operating policies have been changed from time to time to meet changing economic conditions. The co-operative principles, however, remain much the same today as they were 50 years ago. Democratic control, limited returns on capital, and distribution of savings on a patronage basis still remain the dominant features of co-operative activity in this country. Agricultural co-operation in the United States has made its greatest gain since 1915. No other period of similar length in the history of the movement has given rise to as many associations as were formed during the years 1915 to 1921. In 1921 more than 12,000 associations, scattered throughout the United States, were in operation. Since that time, the number of active associations has declined slightly, but with a definite trend toward the formation of large-scale associations operating on a State-wide or regional basis, membership and volume of business has continued to expand. In 1939, almost 11,000 associations reported an aggregate membership of 3,300,000 and a grand total business of \$2,100,000,000.

In the United States, co-operatives have developed largely along commodity lines and the status of the movement can best be described by treating it in this manner.

Dairy Products.—In volume of business and in number of members, dairy co-operatives lead all other commodity groups. Scattered throughout 45 States are more than 2,400 dairy co-operative organizations selling milk, cream, butter, cheese and other dairy products for almost 750,000 farmers. Approximately 48% of all the fluid milk, 39% of all the butter, 25% of all the cheese and lesser amounts of other dairy products pass through the control of co-operative marketing organizations at one stage or another as these products move from farm to consumer.

Livestock.—The co-operative livestock marketing associations may be divided roughly into two groups: (1) those operating primarily at terminal markets, and (2) those operating primarily at country points. The first group is composed of 43 large terminal sales associations with 12 branches operating on 42 of the larger markets in the United States. This group of associations handles about one-fifth of all the livestock sold at public stockyards. The latter group is composed chiefly of local associations engaged primarily in assembling and shipping. In 1940 there were about 850 associations of this type in operation. A few of the local associations do their own selling, but the large majority of them consign the livestock to commission associations on the terminal markets.

Grain.—Co-operative grain handling facilities, which vary from inexpensive portable elevators to million-bushel terminals, are to be found in nearly every section of the nation where grain is produced on a commercial scale. These facilities are the property of more than

2,600 grain co-operatives which in turn are owned by 360,000 farmers. The typical local elevator has a membership of 100 to 200 persons, each of whom owns one or more shares of stock in the organization. Grain is received from both members and non-members and generally the prevailing price is paid at the time of delivery. Likewise, farm supplies such as feed, fertilizer, coal, and machinery are sold at "going" prices. Any earnings or savings made by the association are later distributed as patronage dividends on the basis of the volume of business transacted. Many of the local elevators hold membership in large regional sales agencies through which much of the grain is marketed.

Fruits and Vegetables.—In all of the important commercial growing areas, producers of fruits and vegetables have developed co-operative marketing associations. More than 1,100 associations located in 45 States are now (1940) in operation. The greatest development has occurred in producing areas farthest from the large Eastern markets. California, Florida, Colorado, Oregon and Washington are the leading States. Approximately 60% of all the citrus produced in this country is marketed by co-operative organizations. More than 180 associations, scattered over 33 States, are marketing potatoes. Apples coming mainly from the Pacific Northwest, the Shenandoah valley, and the commercial areas of Michigan and New York, are handled by 78 associations. Strawberries from Louisiana, Missouri, Arkansas, Kentucky, Virginia and other commercial areas are placed on the market by 12 co-operative associations. Many other fruits and vegetables are handled in substantial volume by co-operative organizations. Some of the more important of these are grapes, prunes, peaches, pears, beans, celery, tomatoes, lettuce and asparagus.

Cotton.—Co-operation among cotton farmers in this country has developed along three distinct lines: (1) cotton marketing associations, (2) cotton gins, and (3) cotton-seed oil mills. Fifteen large-scale centralized marketing associations, most of which are operating on a State-wide or regional basis, report an aggregate membership of 280,000 cotton farmers, and during recent years have handled from 1,500,000 to 2,000,000 bales of cotton annually. The cotton gin movement has reached its greatest development in Texas and Oklahoma where 20% to 25% of the crop is ginned through farmer-owned and farmer-operated plants. The movement is gradually spreading to other cotton States and at least a few co-operative gins will be found in Mississippi, New Mexico, Arizona, California, Louisiana and Alabama. New-est of the cotton co-operative enterprises are the cotton-seed oil mills. By 1940 there were six in operation. The first of these was organized in 1922 and has operated continuously since that time. Of the other five, two were organized in 1934, two in 1937, and one in 1939.

Wool.—Approximately 50,000 farmers and ranchmen, scattered throughout the United States, are marketing wool co-operatively. The greater part of the wool marketed co-operatively is handled by 25 to 30 large-scale centralized associations which operate on a State-wide or regional basis. These co-operatives assemble, grade, warehouse and sell the wool for their members. Much of the wool handled by this group of associations is marketed through the office of the National Wool Marketing Corporation of Boston. The remainder of the associations are mostly local wool pools. Generally these organizations are small and often serve but a single county. In most cases they are informally organized and frequently are inactive except for a month or two at shearing time. The wool is assembled and sometimes is offered for sale to the highest bidder, sometimes consigned to another co-operative, and sometimes sold direct to the mills.

Poultry Products.—The principal business of some 200 associations is that of marketing eggs and poultry for 100,000 farmers. In addition to these 200 associations, approximately some 700 other co-operatives are handling poultry products as sideline enterprises. Chief among these are a number of local co-operative creameries located, for the most part, in the Middle Western States. In the Far Western States of California, Oregon, Washington, Idaho and Utah where intensive commercial poultry production has developed on a large scale, poultrymen now own and operate some of the world's largest egg, poultry and turkey marketing associations. At least eight associations located in this area transact an annual volume of business in excess of \$1,000,000 each. In the Eastern States, where producing areas lie within easy reach of large consuming centres, the auction method of selling eggs and poultry has become very popular. In this area 26 egg and poultry auctions are now in operation. All of these have been organized since 1920.

Other Farm Products.—More than 15,000 farmers located mainly in California, Oregon, Georgia and Virginia are marketing nuts co-operatively. Eleven associations with a combined membership of 70,000 are marketing tobacco. Marketing hay is the principal enterprise of eight associations and a secondary enterprise for at least 40 others. There are 25 to 30 sugar beet bargaining associations. In the Southern States there are eight or ten co-operatives manufacturing cane sugar. And one or more associations are handling each of the following products: maple sugar and maple syrup, honey, nursery stock, pulpwood, tung oil, broomcorn and fox fur.

Farm Supplies.—One of the outstanding developments in the field of agricultural co-operation since 1920 has been the rapid growth of purchasing associations. From less than 1,000 associations in 1920, the number had increased to 2,600 in 1939. Volume of business increased from \$50,000,000 to \$335,000,000 during the same period.

Membership has grown to almost 1,000,000. Many of the marketing associations handle farm supplies as a sideline activity. Some of the fruit and vegetable associations supply their members with fertilizer, spray materials and packing supplies. Some of the dairy associations handle separators, milk pails, strainers and milk cooling equipment. Grain elevators quite generally handle feed, coal, salt, twine, hardware and other supplies for the convenience of their member-patrons.

Mutual Insurance.—Farmers' mutual insurance companies, the first of which was organized more than 100 years ago, represent one of the oldest forms of co-operative activity in this country. The primary purpose of this type of rural co-operative is to provide insurance on a cost basis. The 1,900 companies now active report an aggregate membership of 3,263,224 and a total of more than \$11,000,000,000 of insurance in force.

Mutual Irrigation.—Located mainly in the Western States are approximately 2,500 mutual irrigation companies. These are voluntary associations of persons engaged in producing farm products under irrigation. These mutual companies differ from the commercial companies in that they are operating on a non-profit basis; they differ from the irrigation districts in that membership and financial support are generally voluntary.

Mutual Telephone Companies.—Farmers' mutual telephone companies are now operating in every State in the Union. Some 2,000 of these represent fairly large formally organized companies operating complete telephone systems including a switchboard. More than 30,000 others represent small informally organized groups of farm people who have pooled their efforts and constructed neighbourhood lines. In many instances, these co-operatively operated lines provide the only telephone service available in the community and if it were not for them these communities would be entirely without telephone communication.

Rural Electric Co-operatives.—Among the newer undertakings by co-operatives is that of bringing electric power to rural communities. Since the Rural Electrification Administration was created in 1935, the number of farms in the United States provided with electricity has more than doubled. Much of this has been accomplished through the co-operative form of organization.

AGRICULTURAL CREDIT. The credit needed in agriculture is of two kinds. The first is long term credit, required to facilitate land purchase or the execution of improvements; the second is short term or personal credit, required to finance the growing, harvesting or marketing of crops, etc. Systems of agricultural credit as they exist to-day in various parts of the world may be roughly distinguished according to whether they are based on a co-operative principle or not. Co-operative credit has been successfully developed in Europe (with the marked exception of Great Britain) and in India. In most of the newer countries co-operative systems have been relatively unsuccessful, and other means of financing agriculture have had to be found.

Great Britain.—There are very few British institutions specifically engaged in providing credit for agriculture, the bulk of farm credit being furnished by the joint stock banks and tradespeople, insurance companies and private mortgages. In regard to long term credit two institutions (the Farmers' Land Purchase Company and the Lands Improvement Company) have, however, sought to specialize in this business. The former has aimed at lending money on mortgage for land purchase, but its operations have been on a very restricted scale. The latter founded in 1858 and operating under special acts of parliament, has lent upwards of £13,000,000 for the purpose of carrying out certain types of land improvement. Apart from these, farmers and landowners have mainly had to rely for long term loans on bank overdrafts secured by the deposit of title deeds and private mortgages. In regard to short term credit, for several years prior to the World

War attempts were made to establish co-operative credit societies in Great Britain on the Raiffeisen model (which had had such widespread success in Germany and other continental countries). In 1910 there were 31 co-operative credit societies in Great Britain with 663 members; during and after the War there was a substantial decline in their number and membership.

In 1922 the subject of credit was considered by a committee appointed by the Minister of Agriculture, and its report was published early in 1923. Its recommendations were adopted by the Government, and the Agricultural Credits act 1923 was passed in July of that year. The objects of this measure were: (1) to enable persons who bought their holdings during the currency of the Corn Production acts (April 5, 1917 to June 27, 1921) when prices were exceptionally high, to obtain mortgage loans from the State repayable within a maximum period of 60 years; (2) to establish co-operative credit societies with powers to borrow from the State. The latter were based on limited liability, each member being entitled to hold any number of £1 shares upon which js. had been paid up, and to borrow in proportion to his share holding. The credit societies could borrow from the State £1 for each share so held.

Under the first of the above provisions, mortgage loans were granted to the gross value of £5,000,000. Very little interest was, however, taken by farmers in the formation of co-operative credit societies, only nine societies being actually registered under the act, of which four never commenced operations. In view of the small response to this measure, State advances to credit societies were discontinued in March 1927. Subsequently, the Government stated its intention of introducing a bill dealing with this subject.

Germany.—Germany may be regarded as the birth place of co-operative credit in Europe. The typical organizations have been the *Landschaften* or Credit Unions (for long term credit) and the Raiffeisen banks (for short term credit). The former originated as far back as 1770, and gradually extended not only in Germany, but to Denmark, Hungary, Russia, Poland, Norway and elsewhere. The basic principle was the issue by the *Landschaft* of bonds based on estates mortgaged in its favour—the bonds being secured upon the collective guarantee of the members of the *Landschaft*. The borrower was paid not in cash but in bonds which he could realize on the market. He had the right to repay by annuity or by special instalments, or to cancel the loan by purchasing and tendering bonds. *Landschaften* bonds were regarded as first-class securities, and during the period 1910-14 were quoted on nearly equal terms with the loan bonds of the empire. The principle of the Raiffeisen banks, which were empowered both to make loans and to take deposits, was originally that loans were secured by the collective unlimited liability of all the members. Limited liability was, at a later date, adopted by a small number of these societies. In some cases they added to their credit business that of purchasing supplies for the members, such as seeds, fertilizers, coal, etc. Under Raiffeisen's personal guidance the local credit societies were affiliated to central loan banks, which subsequently received assistance from the State. The wonderful growth of these societies into a vast banking organization, without incurring any serious losses, is perhaps without parallel in the history of finance. In 1924, out of 38,000 registered agricultural co-operative societies in Germany over 19,500 were rural banks.

The post-War inflation in Germany, involved the whole credit organization in acute difficulties, and with the collapse of the paper mark, confidence was destroyed and depositors ceased to lend their money. For these reasons German agriculture found itself faced with an extreme shortage of capital, interest rates rose to a very high figure and farm mortgages became, for a period, unobtainable. After the stabilization of the currency and the introduction of the Rentenmark, drastic reorganization of the credit machinery became necessary. A central institution of agricultural credit, the Rentenbank-Kreditanstalt, an off-shoot of the Rentenbank, was established, which operated through the previously existing credit institutions. Ultimately, with the aid of loans raised in the United States, the situation was considerably relieved and rate; of interest substantially reduced.

France.—The conspicuous feature of agricultural credit in France is the State subsidy which it carries with it. Under the Méline act of 1894 all or part of the members of one or more agricultural *syndicat* could constitute a credit society, whose capital was obtained by subscription of members. The credit society became a *filiale* of the *syndicat*. A considerable growth of these societies took place with the assistance of a voluntary organization which prepared model rules. In 1897 it was made a condition of the renewal of the charter of the Bank of France that it would place at the disposal of the State without interest 40,000,000 francs, together with an annual share in the profits of the bank, for the assistance of agricultural credit. In 1899 regional banks were created, the members of which were the local credit societies, and the above subsidy enabled the regional banks to reduce their rate of interest to the credit societies, and consequently to provide cheap credit to farmers. The number of regional banks in 1921 was 69, with nearly 5,000 credit societies affiliated to them. The extension of the system to the provision of long term credit was made under Acts of 1910 and 1920, which permit a maximum loan of 40,000 francs to individuals to facilitate the acquisition and management of rural properties.

Canada.—In Canada credit unions have been more successful, and over 150 with a membership of more than 66,000 have been organized since 1906, mainly in Quebec and neighbouring provinces. By a number of acts the provinces of Canada have also sought to extend the facilities for short term credit to farmers. These include the Livestock Encouragement act 1917 of Alberta, under which persons may form an association and jointly apply to the Livestock Commissioners for a loan; the Livestock Purchase and Sale act 1913 of Saskatchewan; the Rural Credits act 1917 of Manitoba, and a similar act in Alberta, both designed to promote co-operative credit. Mention should also be made of the Ontario Farm Loan act and the Agricultural Development act passed by the Ontario Legislature in 1921—designed both to assist land settlement and to provide short term loans. As regards long term credit, legislation has been enacted by the separate provinces. Manitoba passed Manitoba Farm Loan act, which became effective in 1917, and was subsequently amended in 1919 and 1921. The act established the Manitoba Farm Loans Association, which serves as the lending agency between the provincial government and the farmers, and is governed by a board of five members including a Commissioner of Farm Loans. Loans are secured upon first mortgages on farm lands and are repayable by annual instalments in 30 years. Saskatchewan has passed legislation on similar lines (the Saskatchewan Farm Loan act 1917), and Alberta has followed the general lines of the Farm Loan act in the United States.

Australasia.—The development of agricultural credit has received and is still receiving a considerable amount of attention in Australia and New Zealand. In most States of Australia State credit institutions, such as State savings banks, make a speciality of providing agricultural credit. A number of acts have been passed in recent years dealing with the subject of rural credit, among which mention should be made of the Commonwealth Bank (Rural Credits) act 1925 making provision for financing producers' organizations in marketing their produce. An account of these measures is to be found in the Australian Year Book 1925. In New Zealand a Royal Commission on rural credit published a report in 1926 which was followed by two acts of parliament, the Rural Advances act 1926 and the Bank of New Zealand act 1926, both designed to assist the development of long term agricultural credit.

India.—The development of agricultural credit in India has mainly followed the European model, and has made consistently steady progress. The first act legalizing co-operative credit societies was passed in 1904. This act was replaced by an Act in 1912 which closely followed the English Friendly Societies act and permitted other forms of co-operation. The number of rural credit societies under this act exceeds 40,000 and these are mainly modelled on the Raiffeisen plan.

THE UNITED STATES

The past hundred years have seen a continuously increasing need in the United States for credit to finance farm operations, including the purchase and improvement of farm land and the production and marketing of crops and livestock. The increased cost of farm land, the use of commercial fertilizer, power machinery, and many other factors have contributed to increased credit needs. As a result a large percentage of farmers use credit. Farmers frequently have to go in debt to get in the farming business, either to buy equipment or land. To become landowners, most farmers have to supplement their savings with borrowed capital. The majority of farmers do not have sufficient working capital to supply their needs at all seasons of the year.

Rural credit, during the years in which farmers' credit needs were expanding, did not keep pace with the demand. Interest rates in some sections were abnormally high. At the turn of the century farm organizations and others interested themselves in the problem. Commissions were sent to Europe to study the farm mortgage systems in operation there. Finally, the Congress of the United States passed the Federal Farm Loan Act of 1916, which provided for the establishment of a farm mortgage credit system. In 1923 provision was made for a system of Federal intermediate credit banks which are wholesale credit agencies discounting agricultural paper. Ten years later, the Farm Credit Administration was organized bringing together these and other Federally sponsored credit services under one supervising Federal agency. The Farm Credit Act of 1933 provided for a system of production credit, supervised by the Farm Credit Administration, with local associations making loans directly to farmers and obtaining loan funds through the Federal intermediate credit banks. This act also authorized the establishment of 13 banks for co-operatives under the Farm Credit Administration to make loans to farmers' marketing, purchasing, and business service associations. The Farm Security Administration, the Rural Electrification Administration, and the Commodity Credit Corporation also are sources of credit for farmers and farmers' co-operatives. Three States have operated rural credit systems but these were (1940) in liquidation. A number of States invest school and other funds in farm mortgages. The rural credit system thus includes commercial and private agencies, such as commercial and savings banks, insurance companies, and individuals, supplemented with Government-owned institutions and Government-supervised co-operative institutions.

Long-term Credit.—Farm mortgage credit for purchasing farm land and making permanent improvements is used in much larger amounts but by a smaller number of farmers than credit for short-term production needs. The mortgage indebtedness of farmers in the United States was \$3,208,000,000 in 1910. In 1928 it was \$9,468,526,000 but had declined to \$7,214,138,000 on Jan. 1, 1938. About 57% of the farm mortgage indebtedness in 1938 was carried by farmers in the 12 North Central States.

State and national banks have always been primary sources of both long- and short-term agricultural credit. In some agricultural States rural loans account for a large percentage of all bank loans. Farm mortgages held by open State and national banks stood at \$945,172,000 in 1931, fell to \$487,534,000 in 1937, but increased to \$519,276,000 by Jan. 1, 1939. Life insurance companies, an important source of farm mortgage credit for the past 60 years, increased their holdings to a peak of \$2,172,863,000 in 1928. These declined to \$936,454,000 by 1937 and \$887,336,000 on Jan. 1, 1939. Individuals, former landowners, private investors, joint stock land banks, and farm mortgage companies have all at times been important sources of farm mortgage credit.

An outstanding change in farm mortgage credit in the 10-year period, 1928-38, was the shift in sources of credit. The refinancing activities of the Federal Land Banks and Land Bank Commissioner resulted in large increases in outstanding loans of these agencies. On June 30, 1939, these two sources accounted for 37.4% of the farm mortgage debt of the country. Investment of life insurance companies in farm mortgages dropped from 22.9% of the total farm mortgage debt to 12.4% over the 10-year period, 1928-38. Joint stock land banks in 1928 holding 7% of the farm mortgage debt had liquidated their holdings to 1.1% on June 30, 1939.

The Federal Land Bank System.—Funds for farm mortgage loans were formerly brought into farming areas largely through banks. Selling farm mortgage notes in their original form became the usual practice. It was generally necessary to find a borrower who wanted a mortgage of a given amount, covering a certain period, and with definite terms. A system was needed which could standardize farm mortgages and hold them as collateral against which bonds could be marketed. The Federal Land Bank system was established by the Federal Farm Loan Act of 1916 to meet these needs. The joint stock land banks, also established by this act and in 1928 holding a peak of \$667,000,000 in farm mortgage loans, were placed in liquidation by the Emergency Farm Mortgage Act of 1933. The 12 Federal Land Banks operated under the supervision of the Federal Farm Loan Board until 1933, when the board was abolished and the banks placed under the supervision of the newly organized Farm Credit Administration. The 12 Federal Land Banks make long-term farm mortgage loans largely through national farm loan associations, local co-operatives, organized in the first instance by 10 or more farmers desiring loans totalling at least \$20,000. In 1928 there were 4,500 to 5,000 national farm loan associations in the United States. Consolidation of associations has resulted in a decrease in number to about 3,800 on June 30, 1939. Each borrower subscribes to stock in the national farm loan association equal to 5% of his loan. The association subscribes to Federal Land Bank stock. The 12 banks had a paid-in capital of \$237,407,123, June 30, 1939. Of this amount, national farm loan associations owned \$108,772,683, or 45.8%, and the U.S. Government \$124,952,320, or 52.6%. The remainder was owned by direct borrowers.

Federal Land Bank loans can be made only to farmers or prospective farmers. No land bank loan may exceed 50% of the appraised normal value of the land plus 20% of the appraised value of the permanent insured improvements on the land. The maximum amount loanable is \$50,000. The term may extend up to 30-odd years. All loans are made on an amortized basis. Prepayment privileges are allowed after 5 years. Borrowers may deposit money in good years to meet instalments in bad years. Funds for making loans are obtained by the sale of tax-exempt bonds. The 12 banks are jointly and severally liable for the payment of principal and interest on all bonds issued. The bonds are not guaranteed by the U.S. Government. The interest rate on new loans may not exceed by more than 1% the rate borne by the last bonds issued. The contract rate on loans through national farm loan associations on Sept. 1, 1939, was 4%. This rate has been in effect since 1935. From 1917 through June 30, 1939, the Federal Land Banks made loans totalling \$3,108,221,919. Federal Land Bank loans outstanding on June 30, 1939, totalled \$1,940,586,076.

Land Bank Commissioner Loans.—As a result of the collapse in farm prices, farm income, and land values, thousands of farmers from 1932-35 were faced with foreclosure. Emergency measures were necessary. The Emergency Farm Mortgage Act of May 12, 1933, authorized the Land Bank Commissioner of the Farm Credit Administration to make farm mortgage loans of a more or less emergency character. These loans may be made up to 75% of the value of the mortgaged property but cannot exceed \$7,500 to one individual. Funds for making loans are obtained through a Government-capitalized institution, the Federal Farm Mortgage Corporation, which issued Government-guaranteed bonds aggregating \$1,651,559,000 from its establishment in 1934 to June 30, 1939. Part of these funds were used to purchase Federal Land Bank bonds. As the law stands (April 1940) the authority of the Commissioner to make loans will expire on June

1, 1942. Since Aug. 23, 1933, the Federal Land Banks have acted as agents in making and handling these loans. Some 529,000 Commissioner loans, totalling \$982,489,534 had been made to June 30, 1939. Although a large percentage of loans were used for refinancing purposes, many young farmers have used these funds to supplement Federal Land Bank loans for the purchase of farms. The Farm Security Administration makes first mortgage loans to enable a limited number of competent tenants, sharecroppers, and farm labourers, unable to obtain credit elsewhere to purchase family-size farms of their own and to make needed improvements on those farms. Loans may cover 100% of the appraised value of properties acquired but may not exceed \$12,000. The rate of interest is 3%. Annual payments of interest and principal are 4.3%. To June 30, 1939, loans made aggregated \$33,340,000. The Federal Housing Administration is authorized to insure loans made to buy and improve farms or to modernize farm houses and other buildings. Fifteen per cent of the amount of a loan must be used for materials and labour for new construction or repairs.

Terms and Conditions of Farm Mortgage Loans.—Marked changes have occurred in the terms and conditions of farm mortgages since 1917 when the 12 Federal Land Banks first introduced the amortization principle into farm mortgage lending in the United States. Prior to this, loans were made ordinarily for periods from 5 to 10 years. As farmers were often unable to accumulate enough money to pay off a mortgage in that length of time the loan was usually renewed, entailing considerable expense. Following the lead of the Federal Land banks, most insurance companies and some commercial banks are making loans covering longer periods and often repayable on an amortized basis.

The trend in interest rates on farm mortgage loans was upward from 1917 to 1921, and then gradually downward since the early 1920s, except for a short period around 1930. Farmers in most sections were (1940) obtaining farm mortgage credit at the lowest rates ever available in the United States. Federal Land Banks were making loans at a contract interest rate of 4%. The interest on instalments coming due prior to July 1, 1940, was payable at 3½%. Land Bank Commissioner loans were made at 5%, with all interest instalments occurring before July 1, 1940, payable at 4%. The United States Government reimburses the banks and the Federal Farm Mortgage Corporation for the difference between the contract rate and the temporarily reduced rate. Interest rates of some commercial banks and insurance companies compare favourably with these rates in territories where they make most of their loans.

Short-term Credit.—It is estimated that from 60 to 80% of the farmers in the United States use some form of short-term credit each year. The largest source of production credit is commercial banks, which on June 30, 1939, had short-term agricultural loans outstanding totalling \$1,193,466,000. Most country banks are either directly or indirectly affiliated with the Federal Reserve Banks, which makes it possible for them to obtain short-term loans or rediscount eligible notes. Their loan rates vary from ½ to 10%. Credit advanced by merchants and dealers in farm products is usually much more expensive. Many farmers' co-operative buying and selling associations grant some credit to their members. Production credit associations with loans outstanding on June 30, 1939, totalling \$187,711,501 are an increasingly important source of production credit. Since 1933, some 530 production credit associations have made production loans to farmers and livestock men. Twelve production credit corporations, one in each Farm Credit district, helped to organize, capitalized in part, and now supervise the local associations. Funds for making loans are obtained by discounting farmers' notes with the Federal intermediate credit banks.

Each farmer-borrower owns class "B" stock in the production credit association equal to 5% of his loan. The capital stock of the production credit associations on June 30, 1939, was \$89,035,154, of which \$14,946,895, or 16.8%, represented class "B," voting, stock owned by 260,043 farmer-members of the associations and \$74,088,259, or 83.2%, was class "A," non-voting, stock held by the corporations, farmers, and other private investors.

The rate of interest charged on production credit association loans was 4½% on Sept. 1, 1939. From May 1934 to Feb. 24,

1939, the rate was 5%, but a reduction in the Federal intermediate credit bank discount rate on the latter date enabled the associations to lower their rate.

Most loans are made on a budget basis. That is, a farmer arranges for his credit for a season and the money is advanced as he needs it. He repays the loan when the crops and livestock financed are sold. Interest is charged only for the time a farmer has the money.

In making production credit association loans careful consideration is given to farming plans and the ability of a farmer to repay a loan from the sale of farm products, rather than basing the loan entirely on the value of the collateral.

Another source of agricultural credit in a few localities is credit unions.

At times many farmers are unable to qualify for loans from banks and production credit associations. To meet the needs of this group, the United States Government has provided emergency loans from appropriated funds. Emergency crop and feed loan offices supervised by the Farm Credit Administration have made loans to needy farmers for crop production and for feed for livestock. In 1934-35 additional funds were made available to the Governor of the Farm Credit Administration for loans to farmers in drought-stricken areas.

Another source of funds for low-income farmers is the Farm Security Administration's rehabilitation loans. Farm families obtaining these loans are encouraged to raise their own food supplies and livestock feed rather than depend entirely upon cash crops.

Federal Intermediate Credit System.—The 12 Federal intermediate credit banks were established in 1923 under the Agricultural Credits Act as wholesale credit institutions for agriculture, to provide production and marketing credit for periods longer than those ordinarily supplied by commercial banks. In 1933 these banks were placed under the Farm Credit Administration and form one of the permanent units in each of 12 Farm Credit districts. The Government had paid-in capital (April 1940) in the 12 banks totalling \$70,000,000, and a paid-in surplus of \$30,000,000. Funds with which to make advances are obtained largely from the sale of collateral trust debentures. These are tax exempt, but are not guaranteed either as to payment of interest or principal by the United States Government.

These banks under the law are authorized to discount paper of any production credit association, bank for co-operatives, national bank, State bank, trust company, agricultural credit corporation, incorporated livestock loan company, savings institution, co-operative bank, credit union, or farmers' co-operative. Production credit associations accounted for about 75% of the loans and discounts of the intermediate credit banks in 1939. Loans to farmers' co-operatives through the Farm Credit system are handled largely by the 12 banks for co-operatives which use the facilities of the Federal intermediate credit banks in obtaining part of their loan funds.

Farmers' Co-operatives.—The farmers' co-operative movement in the United States has shown large growth in the past 50 years. In 1937 a national survey gave the business of some 10,500 farmers' marketing and purchasing associations as exceeding \$2,000,000,000 in a year. The capital of these associations is provided by farmer-member subscriptions and retains from the net proceeds of the products handled. Additional capital is often needed to supplement the association's funds in peak operating periods or to construct plants and to buy equipment.

To supply additional capital, farmers' co-operatives have a number of sources of credit. Commercial banks furnish a considerable portion of their credit needs. Beginning in 1923 the Federal intermediate credit banks made loans to farmers' marketing and purchasing co-operatives on the security of commodities in storage. Since 1933 loans to co-operatives through the Farm Credit system have been handled largely by the banks for co-operatives which obtain part of their loan funds from the Federal intermediate credit banks. The Agricultural Marketing Act Revolving Fund, administered by the Federal Farm Board from 1929 to 1933, provided funds for effective merchandising, facility, and commodity loans to farmers' marketing associations. Loans

from this fund were curtailed when the banks for co-operatives were established in 1933.

The 13 banks for co-operatives, one in each of the 12 Farm Credit districts and a central bank in Washington, D.C., make facility, operating capital, and commodity loans to farmers' marketing and purchasing associations and to mutual companies. About 30% of the borrowings of marketing and purchasing associations outstanding at the peak period in 1936, according to the national survey, came from the banks for co-operatives.

The Commodity Credit Corporation, organized Oct. 17, 1933, by Executive Order, provides funds for producers and farmers' co-operatives to finance the carrying and orderly marketing of certain agricultural commodities recommended by the Secretary of Agriculture and approved by the President. Loans authorized at a fixed rate per unit on basic commodities, such as cotton, corn, wheat, or wool, may be obtained by producers through banks or other lending agencies on forms provided by the Commodity Credit Corporation. The corporation also makes direct loans. Loans of the corporation outstanding on April 1, 1939, excluding loans held by banks and other financing institutions, totalled \$363,376,000.

The Rural Electrification Administration provides funds for financing the construction and operation of rural electric systems.

On April 1, 1939, loans aggregating \$202,802,000 were outstanding by the Rural Electrification Administration.

AGRICULTURAL ECONOMICS. From the earliest times the art of husbandry has been not only the preoccupation of those who practise it, but also the subject of innumerable treatises explaining its principles and suggesting methods for its improvement. Within the last century the application of the results of scientific investigation to the cultivation of the soil has been expounded with ever-increasing voluminousness. But the consideration of farming as a business has been only recently recognized as a subject for systematic study. Farming in many countries is a means of subsistence, and can only be described as a business in a limited sense, but commercial agriculture is yearly becoming more widespread and more important.

Agricultural economics may be defined as the special application of the general principles of economics to the special conditions of the production and sale of agricultural products. It comprises therefore the consideration of the factors of production, the cost of production, and the disposal of the produce. It is not concerned directly with the technique of farming but it assumes that experience, skill and energy in the use of the land will not suffice for commercial success without knowledge of the economic as well as the practical details of farm management. The subject of agricultural economics includes within its scope many subjects which are, so to speak, self-contained, such as farm accounts, farm valuations, and agricultural co-operation, which are considered under their separate headings.

In the United States, the systematic study of agricultural economics forms a part of the curriculum of State universities and agricultural colleges and of the larger endowed universities. A well equipped bureau of the U.S. Department of Agriculture has done admirable work in research and in expounding and popularizing the subject. Its work covers a wide range of subjects: Land problems; agricultural finance, including credit, insurance and taxation as they affect agriculture; farm management and cost of production; statistical and historical research on a wide range of subjects; co-operative marketing; foreign competition and demand, as affecting agriculture; and other subjects. The State agricultural experiment stations, supported by State and Federal funds, conduct research on various phases of agricultural economics. In 1925 Congress passed the Purnell Act, under which

Federal support to each State for agricultural research will reach the maximum of \$60,000 a year in 1929, in addition to the \$30,000 available under earlier acts of Congress. The Purnell Act specifies that a part of the funds shall be used for research in agricultural economics, home economics and rural sociology. Among the privately supported institutions conducting research in this field are: The Institute for Research in Land and Public Utility Economics (Northwestern university) established under the direction of Dr. Richard T. Ely, and the Food Research institute of Leland Stanford university. The field of research in agricultural economics in the U.S. may be divided into three general groups of problems: (1) Problems which may be dealt with mainly by individual effort. These include farm management, embodying the organization of the factors of production on the individual farm and the adjustment of farming according to changes in costs of production and in prices of farm products. (2) Problems that may be solved by joint effort of farmers acting through co-operative organizations or other associations. In 1926 Congress created the Division of Agricultural Co-operation in the Bureau of Agricultural Economics, to conduct research and to render services to farmers on all phases of co-operation. Legislation to remove legal obstacles to co-operative organizations, notably the Capper-Volstead Act, has been passed in recent years. (3) Economic problems of agriculture that may be dealt with by governmental policy expressed through laws and public institutions. This group includes agricultural credit, land policies, public expenditures and taxation as they affect agriculture, regulation of transportation systems in their relation to agriculture, tariff problems and other phases of public policy. In addition to these groups of problems, research is also concerned with the functions of private agencies in merchandising, transporting and processing farm products.

In Great Britain the subject was taken up by the agricultural department (Board of Agriculture and Fisheries), but with very limited resources, shortly before the war, and with assistance from the Development Fund, and from the University of Oxford an institute of agricultural economics was established at Oxford. Its activities were at first mainly directed to the improvement of farm accounts, especially by the adoption of the cost accounting system, but as further resources became available its scope was widened and it has made a number of important investigations into the economic conditions of different areas. At Cambridge, also, the farm economics branch of the department of agriculture of the university has, more recently, vigorously taken up the work. Throughout the country an agricultural economist is now a recognized and important member of the staff of all institutions which are concerned in the development of agricultural education.

Factors of Production.—The primary factors of agricultural production are land, labour and capital.

The utility of land for producing crops depends on soil, climate, situation and aspect. Nearly all kinds of soil are actually or potentially fertile, although over large areas the fertility is dormant by reason of the lack of some constituent essential to plant growth. The deficient constituent is frequently water, but in many cases it is some ingredient which may be identified by chemical analysis and conceivably supplied by man. Climate is in a large degree a matter of situation. The tropics and the temperate zone comprise all land suitable for productive use, but advantages of situation depend not only on latitude but also on altitude. By aspect is meant in a hilly country the relation of the land to the sun, as, for example, whether it lies on a northern or on a southern slope.

For the purpose of agricultural use the farmer must have exclusive control of the land. If he does not acquire its ownership the form and terms of tenure will materially affect the economic possibilities of his enterprise. From an economic point of view, holdings are of three classes: viz. (1) those which are occupied by persons who do not depend on them for their livelihood; (2) those which are cultivated for subsistence by the occupier and his family without extraneous labour (sometimes termed "family farms"); and (3) those on which hired labour is regularly employed. It is with the third class "commercial farms," that the subject of agricultural economics is mainly concerned.

In considering the capital employed in agricultural production, that which is invested in the acquisition of the land may be disregarded. In many new countries free grants of land are made to settlers. In countries where agriculture has been long established, the capital value of a holding includes its equipment as a farm and the proportion which represents the bare land may be comparatively small. The capital employed in working a farm in Great Britain, where holdings are more commonly rented than owned by the occupiers, is termed "tenant's capital." It consists of the amount invested in machinery, implements and other movable equipment of the farm, in the horses and other live stock, and in the seed, fertilizers and labour for growing crops. The amount varies greatly, but on an average farm in Great Britain it probably ranges from about £10 to £12 per acre. On specialized farms, such as those devoted to fruit or vegetables, the amount may be £40 or even more per acre.

Labour as a factor of production includes not only the manual work and skill of hired labourers but also that of the farmer, whether employing labourers or not (see AGRICULTURAL LABOURER), and animal and mechanical energy applied to the processes of the farm partly in supplement of, and partly in substitution for, human energy. Oxen are the most widely used animals for farm work, but in Great Britain they have been replaced by horses during the last 200 years, although they were still in use in some districts up to the latter part of the 19th century. In those countries, such as the United States and the Dominions, where systematic agriculture has been recently established, horses were from the first generally used. Mechanical labour includes not only motive power, such as steam or other engines, but also machines and implements such as thrashers, reapers, haymakers, ploughs, etc., which either economize human energy or enable it to be more effectively applied in the operations of the farm.

Costs of production may be divided into two classes, viz., fixed charges and current expenses. The ordinary tenant farmer regards rent as ranking foremost in his costs of production, but strictly speaking only that part of it which represents interest on capital spent in equipping the farm can be so described. The interest on capital expended on equipment, whether permanent or temporary, is a fixed charge and so also are rates and (where they exist) land-tax and tithe-rent charges. Current expenses include outlay on seed, fertilizers and feeding stuffs, fuel for engines and repairs. The payment of wages is a current expense, but it might also be described as a fixed charge, though of a variable amount. Where the occupier himself cultivates his holding it is evident that the remuneration of his labour is a fixed charge without which there would be no produce from the land. Where he employs labour his "wages of management," and such other wages as are necessary for production, may similarly be regarded as a fixed charge on the land. In all farming operations the turnover is slow, as compared with other forms of productive enterprise. This "economic lag" has been investigated on the basis of the accounts of two farms by Mr. Dampier Whetham. It was found to be greatest in the case of cattle, where the average "lag" was 18 months, and least in the case of poultry and eggs, where it was three months.

Disposal of Produce.—The simplest method by which the cultivator of the soil can dispose of its products is to consume them in his own household, but even in "subsistence" or "family" farming there is usually some surplus for sale. There are three methods by which farm products may be sold: viz., (1) by direct sale to the consumer, (2) through intermediaries, (3) by co-operative association. Direct sale is usually adopted by "small scale" producers and for "minor" products, such as eggs, poultry, fruit and vegetables, but "large scale" producers may also adopt the method by opening a shop in an adjacent town or establishing a "milk round." Direct sale of fat stock by farmers to butchers was very common in Great Britain, but it is now generally replaced by the auction system. The bulk of agricultural produce is sold through intermediaries. The commercial organization of the distribution of the main products is elaborate. Where the products are the subject of international trade, as in the case, notably, of wheat and meat, the system by which they are collected, shipped and distributed is remarkably efficient. But where

the producer, as in Great Britain, sells his products in his own country, the distributive system is, from his point of view, unsatisfactory. The difference between an export and an inland trade accounts in a large degree for the difference in the machinery of distribution. For an export trade collection of bulk consignments at fixed points for shipment is imperative. The producer has no other outlet except under these conditions. In an internal trade producers usually have a choice of alternative markets, and are not compelled to adopt a uniform method of sale. The result is that imported produce, with its highly efficient distributive organization, tends more and more to dominate the wholesale trade, and the home producer finds that his natural advantages of proximity to markets, and, generally, of superior quality, are not sufficient to enable him to maintain his position. The adoption by British farmers of a system of "orderly," or organized, marketing has been vigorously advocated (see AGRICULTURAL CO-OPERATION). The term "marketing" is now commonly used as synonymous with sale, but it perpetuates the fact that in old countries the sale of commodities, and particularly of food, was permissible only in duly constituted markets. Many of these remain, but in Great Britain they have long lost the monopoly which they once possessed, although market tolls and regulations still survive in many towns. For information on various American aspects and applications of this subject see AGRICULTURE: *Agriculture* in the United States. See also AGRICULTURAL CREDIT and AGRICULTURAL INSURANCE.

Carver, *Elements of Rural Economics* (Boston, 1924); R. C. Engberg, *Industrial Prosperity and the Farmer* (1927); B. H. Hibbard, Ph.D., *Marketing Farm Products* (1921), and *A History of the Public Land Policies* (1924); C. L. King (Ed.), "The Agricultural Situation in the United States"; E. G. Nourse, Ph.D., *American Agriculture and the European Market* (1924); *Am. Acad. Pol. and Soc. Science Annals*, Vol. cxvii. (1925); H. W. Hawthorne, *The Family Living from the Home* (1925); *Farm Living and Farm Life*, a symposium (Chicago, 1927). Bulletins and other publications by the United States Department of Agriculture and by the State experiment stations cover a wide range of topics in this field. *Journal of Farm Economics*, a quarterly published by the American Farm Economics Association, carries articles on various phases of the subject and reviews of books. (R. H. R.)

AGRICULTURAL EDUCATION. Though agriculture is the oldest and greatest of industries, agricultural education in any organized form is among the recent activities of modern states. In Great Britain, or at least in England and Wales, it may be said to go back only to 1890. It would be untrue, however, to say that before then nothing was done. Chairs of agriculture and rural economy were founded at Edinburgh in 1790 and at Oxford in 1796; the Royal Agricultural college at Cirencester was established in 1840. But agricultural education provided in universities or colleges was beyond the reach of the bulk of the agricultural population. Little or nothing was offered to the children of farmers, smallholders, and labourers until nearly the end of last century. In 1890, however, the Local Taxation (Customs and Excise) Act placed at the disposal of county councils a sum of money (popularly known as the "Whiskey Money," because it was derived from an increase of the taxation on spirits which was originally destined for another purpose), amounting roughly to £750,000 a year, and authorized them to apply it to purposes of technical instruction, including instruction in agriculture. From

1890 onwards there was a considerable, if slow, increase both of the higher education provided by university departments of agriculture and agricultural colleges, and of instruction provided by county councils. By 1912 the State was granting £19,000 a year for higher education, and the English and Welsh county councils were spending £70,000 a year on the more elementary instruction. The World War stopped the development of plans already prepared for further expansion on a relatively large scale.

Post-War Development.—The present system, though it follows pre-war lines in its organization, is largely the creation of the years since 1918. It falls into two main parts; the university departments of agriculture and agricultural colleges, whose distinctive mark is that they provide a long course, two years at least, usually three, leading to a diploma or degree; and the education provided by county councils, which is essentially an education of short courses intended for the boy or girl who is already working on the land and proposes to return to it.

Higher agricultural education in England and Wales (excluding veterinary education) is provided at 14 centres, of which seven are departments or schools of universities, and the other seven are agricultural colleges, each possessing its own governing body, and not forming an integral part of a university. Eleven of these institutions (all except the Royal Agricultural college at Cirencester and the two women's colleges at Swanley, in Kent, and Studley, in Warwickshire), discharge an important function outside the actual teaching of students. Each is an "Advisory centre" for a group of counties forming its "Province"; it is provided with specialists in the more important branches of science bearing on agriculture, such as chemistry and entomology, who supplement the more general advice provided for farmers by the technical staffs of county councils, and it acts as a unifying and co-ordinating influence for the experimental and advisory work of county councils. All the 14 institutions are recognized and aided by the State. The cost to the student varies considerably between the two Welsh colleges (Aberystwyth and Bangor) at one end of the scale and Oxford or Cambridge at the other end.

Education of a less elaborate character is provided by county councils; in some counties by means of a farm institute (a simpler and smaller agricultural college, usually possessing residential accommodation and a farm attached), in practically all counties through organized classes, held at no special institution, or through discussion clubs, evening lectures, and similar less systematic methods. In 1927 there were 16 farm institutes, four in Wales (including Monmouthshire) and the remainder in England, all but one supported and governed by county councils. On the average they can accommodate 40 students each; the fees for board, lodging, and tuition vary between 17s. 6d. a week for students coming from the county which supports a particular institute to £2. 10s. od. a week for other students. The main course at a farm institute is normally a six months' winter course in practical agriculture, extending from October to March, and designed for young people, from the age of 16 upwards, who have been working on the land and are going straight back to it. During the summer months the institute is used for courses in dairying, poultry keeping, and other special subjects. The great majority of county councils, however, do not possess farm institutes, but attempt to take agricultural education to the land-worker by such means as the "Organized day course" (a continuous course of instruction held at regular times, usually one day a week, in any town or village where there is a demand for it, and extending over several weeks or perhaps months), evening classes, travelling dairy schools, courses for instruction in manual processes (ploughing, hedging, ditching, milking, and the like), and lectures or demonstrations.

In 1925-26 the cost of the education provided by county councils in England and Wales was £312,000, of which the Government provided a fraction over two-thirds and county rates the remainder. One other activity deserves mention. In 1922 the Government started a scheme of scholarships in agriculture for the sons and daughters of agricultural workmen and of other rural workers in a similar economic position. Under this scheme approximately 100 scholarships are awarded every year, of which

the great majority are short-term scholarships to farm institutes. The cost is £20,000 a year.

In Scotland, agricultural education has followed a rather different course, though it started on the same lines. The organization is not divided between universities and colleges on the one side and county councils on the other; the colleges control and direct the whole system. Apart from the small sums received as fees, the whole cost is met by grants from the State, which in 1925-26 amounted to £75,000. But in the education given, as distinct from the organization for giving it, the Scottish system resembles the English. The three colleges in alliance with their respective universities provide long courses (three winter sessions) for the university degree or college diploma; they take the place of the English farm institutes by including in their curricula short courses for farming; and through the appointment of organizers resident in the counties they conduct extension work similar to that done in England and Wales by the staffs of county councils. Two special institutions should be mentioned: the Kilmarnock dairy school and the Craibstone School of Domestic Economy for Women, the former associated with the Glasgow college and the latter with Aberdeen.

Other Systems.—Broadly speaking, and with considerable variations due to differences of national character and environment, Continental systems tend to fall into the main divisions already enumerated, of two or three years at universities or agricultural colleges; in the second place, there are short courses of a few weeks or months in the dead season, or of a year at most, at a residential institution—sometimes a college, more usually a farm institute or farm school: thirdly, miscellaneous courses, lectures, and demonstrations given by peripatetic instructors who endeavour to bring technical education to the farmer's door, or at least to his town or village. But there are one or two features of foreign systems which ought to be mentioned, if only by way of contrast to the British system.

Of these the most striking is, perhaps, the large part taken in Germany, Denmark, Sweden, and in fact nearly all over the continent of Europe, by voluntary societies and associations; in Denmark, for instance, agricultural societies own and manage many of the Folk high schools and support many "agricultural counsellors"—experts who combine teaching, lecturing, and advisory functions. But the Folk high schools of Denmark are notable not merely as an example of voluntary effort; they are a great and successful attempt to add a finish to the education of the adult land-worker by giving him or her a six to nine months' course, not entirely agricultural and sometimes not agricultural at all, at a residential institution. In Belgium, a country of small-holders, there is a highly developed system of instruction for women and girls in a combination of practical agriculture and rural domestic economy; the system centres in the national institution at Laeken. In Sweden also (besides the usual agricultural colleges, agricultural schools, and farmers' sons' schools, the last providing a three months' theoretical course for young men, usually about the age of 22) there are something like 40 schools of agricultural economy for women.

Changes in the British System.—From 1924 or thereabouts two movements affecting agricultural education have gained prominence. The first is the movement for imparting into the ordinary subjects of instruction taught at rural elementary and secondary schools what is known as a "rural bias"—e.g., arithmetic may be taught through simple farm accounts, or geography with at least some reference to the physical characteristics of the district in which the school is situated. Provided it does not degenerate into a premature attempt at vocational training, there is everything to be said in favour of such a change.

The second change is a change of emphasis in the subjects usually taught in agricultural institutions and courses. Hitherto syllabuses of instruction have tended to be dominated by science, or rather sciences—chemistry, physics, botany. A school of thought has arisen which starts from the fact that the farmer is not only a grower of crops, a producer of eggs or milk, a breeder of stock, but also a manager of labour, a buyer of goods, and a seller of products—in the ordinary phrase, a business-man. There

is consequently a steady pressure towards modifying courses of instruction, particularly the short winter courses, by giving a larger place to such subjects as accounts (the foundation of business), the management of labour, and the elements of marketing technique. There can be little doubt that this side of agricultural education has been relatively neglected; but the teaching of management is not easy.

Defects in the British System.—But though these changes may be beneficial, the British system still reveals several notable defects. First, it is far too small, not, perhaps, for the demands which are actually made on it, but for the demands which ought to be made. In the second place, the larger part of the English and Welsh system—the part organized and directed by county councils—is "patchy." There is no power to compel county councils to supply even the barest modicum of agricultural instruction, and accordingly the provision made for it in a county varies with the character and finances of the county council and its electorate. Thirdly, provision for the residential education of adults—one of the most marked and successful features of Continental systems—is noticeably absent. Lastly, provision for instruction in manual processes and in the handling of machinery, though not absent, is not so common as it should be.

Progress Being Made.—Some of these defects are being slowly remedied. In spite of financial exigencies, college and county education does progress and grow; and, best of all signs, authorities are agreed that in the last 20 or 30 years there has been a remarkable change of attitude on the part of the agricultural community. Farmers welcome the assistance of college and county staffs; and a first attempt has been made, through private enterprise, to provide at Avoncroft, near Evesham, an institution very similar to the Folk high school of Denmark for adult landworkers. If that experiment proves a success, it may be the beginning of a new era. Moreover, the education of women and girls has recently been investigated by a strong committee, who have surveyed the whole field; and the Ministry of Agriculture has put before county councils a detailed scheme for extending instruction in manual processes. In 1925–26 the number attending such instruction rose to 1,900—a number which, however small in itself, was at least an increase of 50% on the previous year.

BIBLIOGRAPHY.—Numerous papers on different aspects of the subject are scattered about in the *Journal* of the Ministry of Agriculture, the *Proceedings of the Royal Agricultural Society*, the *Proceedings of the British Association*, and similar volumes.

(1) **Reports of Committees.**—Committee on Agricultural Education in England and Wales, 1908 (Cmd. 4,206 of 1908: Stationery Office, London). Committee on Agricultural Education and Research in Scotland, 1924 (Stationery Office, Edinburgh). These two reports contain a general survey of the British and foreign systems.

(2) **Departmental Reports.**—Reports of the Intelligence department of the Ministry of Agriculture and Fisheries for the years 1919–21, 1921–24, and 1924–26. All three published by the Stationery Office, London. Annual Reports of the Board of Agriculture for Scotland (Report for 1926, Cmd. 2,854 of 1927, Stationery Office, Edinburgh). These reports give the facts and figures in detail. The first mentioned contains a statement of Government policy in agricultural education.

Leaflet No. 197 of the Ministry of Agriculture and Fisheries, *Agricultural Education in England and Wales*, gives a list of existing institutions, together with the courses provided, fees, and similar details. Board of Education Pamphlet No. 46, 1926, *Rural Life*, gives a survey of what has been done in England to adapt school courses to the needs of rural areas.

(3) **Other Papers.**—Memorandum on the Reconstruction of Agricultural Education in England and Wales, published by the Agricultural Education Association (1919). Sir A. D. Hall, "Agricultural Education 1890–1926," in the *Scottish Journal of Agriculture*, vol. x. No. 2. pp. 135–143 (Stationery Office, Edinburgh). (H. E. D.)

IN THE UNITED STATES

Agricultural education in the United States finds its beginnings in the striving of individual land-owners toward higher levels of production. This created interest and discussion in agricultural communities, induced the making of tests, trials and observations, pointed to the advantages of concerted action, and slowly but steadily laid the foundation on which present-day educational machinery was built.

Agricultural Schools.—Among the early attempts to provide agricultural instruction in schools of less than college grade

the following may be noted: In 1821 the State legislature of Maine granted to Robert Hallowell Gardiner an annual appropriation of \$1,000 for the maintenance of an institute for agricultural and mechanic arts. The Gardiner Lyceum was opened at Gardiner, Me., in 1823. It employed a professor of agriculture, maintained a farm and offered short winter courses in agriculture. An agricultural school was founded at Derby, Conn., in 1826. So-called manual labour schools were established in New York State in the period 1825–40. They laid stress, in their curricula, on vocational training in agriculture and the industries. In 1845–50 several agricultural schools were founded, through private initiative, in New York and Connecticut. After the middle of the 19th century conditions became more propitious for the teaching of agriculture in elementary and secondary schools. A period of agitation was followed by the establishment of an agricultural high school at the University of Minnesota (1888). District and county agricultural schools were created a few years later, among them the agricultural schools in the nine congressional districts of Alabama. By 1898 there had been established ten agricultural high schools. In 1909, there were 60 separate agricultural high schools. Agricultural courses were then being offered in 346 other high schools. Several States, among them Massachusetts (1911), New York (1913), Pennsylvania (1913), New Jersey (1913) and Indiana (1913) had established definite systems of vocational agricultural education. It is estimated that in 1912–13 there were about 2,300 State agricultural schools, district agricultural schools, agricultural departments of high schools and ordinary schools that maintained systematic instruction in agriculture.

The Smith-Hughes Vocational Education Act (1917) provides Federal aid for vocational training, including the teaching of agriculture and home economics in secondary schools. Since the passage of this Act many vocational agricultural schools, as well as agricultural departments of general high schools, have been established in the several States. Of the 11,561 rural high schools, 3,339 or 29% maintained vocational agricultural departments in 1927. They had an enrolment of 129,032 students. In that year there was available for the support of vocational agricultural education nearly \$7,500,000, compared with about \$740,000 in 1918. Aside from these institutions, agriculture is being taught in some of the private high schools, in normal schools, and in special schools for negroes and Indians. It may be noted, further, that many States have special laws which concern the teaching of agriculture in elementary rural schools.

Agricultural Colleges.—Simeon de Witt, surveyor-general of New York, published, in 1819, a pamphlet entitled *Considerations on the Necessity of Establishing an Agricultural College, and Having More of the Children of Wealthy Citizens Educated for the Profession of Farming*. A State agricultural college was established in New York in 1853. The oldest surviving state agricultural college is that of Michigan (1857). Similar colleges were established in Pennsylvania and Maryland (1859) and the incorporation of agricultural colleges authorized in Iowa and Minnesota (1858). The Federal Land Grant Act (also called the first Morrill Act) was passed in 1862. It created a group of State institutions of higher learning, known as the land grant colleges and universities (*q.v.*). This legislation was far-reaching in its effects on the social and economic development of the country. The second Morrill Act (1890) and the Nelson amendment of the Morrill Act (1907) provided additional funds for the State colleges.

The State colleges and universities are intimately associated with the U.S. Department of Agriculture. This had its inception in the collection and distribution of seeds and plants by the Patent Office in 1839. The service was expanded to furnish information on various agricultural topics. In 1862 the Department of Agriculture was organized as such and in 1889 its head became a member of the President's cabinet. When the Hatch Act was passed (1887) funds were made available for the establishment of experiment stations as departments of the State colleges. Prior to that, State agricultural experiment stations had been established in Connecticut (1875), California (1877), North Carolina (1877), New York (1879 and 1882), New Jersey (188c), Ohio, Tennes-

see and Massachusetts (1882), Alabama and Wisconsin (1883), Nebraska (1884), and Michigan, Indiana, Kentucky, Maine and Minnesota (1885). A private sugar-planter's experiment station was established in Louisiana in 1885, and State stations in Louisiana, Vermont and New Hampshire in 1886.

In keeping with the provisions of the Hatch Act, an office of experiment stations was organized in the Department of Agriculture for the purpose of maintaining contracts with the stations. Subsequent legislation referred to as the Adams (1906) and Purnell (1925) Acts augmented the income of the stations, established better correlation of research on a regional and national basis and encouraged co-operation among the stations themselves and with the Department of Agriculture. The stations are primarily research institutions. As such they are maintaining many hundreds of research projects of direct significance to agriculture and the farm home, and creating a vast body of knowledge from which facts and generalizations are being drawn for the benefit of resident instruction and of extension teaching.

The Smith-Lever Act was passed in 1914. It represents a national scheme of extension teaching in agriculture and home economics and is the culmination of a long series of local, State, regional and national efforts to stimulate agricultural progress by bringing technical and general information to the farm and farm home. The antecedents of the Smith-Lever Act include the almanacs, agricultural journals and newspapers, agricultural societies, boards of agriculture, farmers' institutes and demonstrations and lectures by public-spirited individuals. The Act provides for county agents, home demonstration agents, club leaders and extension specialists. It makes the Department of Agriculture responsible for co-ordinating and supervising the extension activities in the several States.

The agricultural teaching, research and extension of the land grant colleges and universities is being generously supported by the local, State and Federal Governments. In 1928, the Federal Government was appropriating about \$7,000,000 for the support of agricultural extension, while the States, counties, farm organizations and individuals were expending for the same purpose about \$13,000,000.

See A. C. True, *Education, and Research in Agriculture and Home Economics in the United States* (1922); C. B. Smith, *Co-operative Extension Work, 1924, with ten years' Review* (1926); Walter J. Greenleaf, "Land Grant Colleges," Bureau of Education *Bulletin*, No. 37 (1927). (J. G. L.)

AGRICULTURAL ENGINEERING is that specialized branch of engineering which deals with agriculture; it seeks scientifically to direct the forces and facts of nature to the advantage of the farmer.

The distinction between agricultural and the other branches of engineering may be illustrated by examples—irrigation and drainage, for instance. The agricultural engineer concedes to the civil engineer the problems incident to the extensive storage and arterial distribution of irrigation water, and to the design and construction of large community drainage outlets. The benefits of such works, however, are realized only to the extent that contact is made with individual farms. It is at this point that the agricultural engineer claims jurisdiction. In irrigation, the water made available to the farm must be economically distributed and applied with reference to the topography, the character of the soil and the crops to be irrigated. In drainage, ditches and underdrains must be planned with regard for the peculiarities of each field and of the use to be made of the land. Again, although the agricultural engineer does not ordinarily concern himself with the commercial design and the manufacture of farming implements, he does claim a share in securing not only the best use of such equipment as is at hand, but also better designed equipment.

Agricultural engineering is the outgrowth of a realization that many of the farmers' problems lie within the field of engineering and therefore should be attacked from that point of view. It is generally recognized that the marked advance in agriculture since 1850 has been due in large measure to improved engineering practice. Thus the development of farm-land from its primal state by clearing, the control of erosion by terraces, the disposal of surplus water and the acquiring and regulating of the water needed for

plant growth and for human and animal consumption, the erection of structures of all types, with their problems of light, heat, ventilation, etc., and the best use and design for the machinery and implements used in farm operations and transportation, as well as the sources of the power which operates them, are all problems for the agricultural engineer. This is common sense, and in the United States this view is generally accepted. In England and Continental Europe, however, the scope of agricultural engineering is less defined, the tendency being rather to give practical recognition to two distinct divisions of the science, dealing respectively with the mechanical phases (implements, machinery and power) and those of the soil (irrigation, drainage, erosion control, etc.).

In the United States in 1928 12 State agricultural colleges maintained courses leading to a degree in agricultural engineering, while several others, though they did not grant degrees, offered courses that constituted a virtual recognition of the science. Such German universities as are equipped to give instruction recognize agricultural engineering by offering a doctor's degree. Up to the present time agricultural engineering has been looked upon chiefly as one of the many agencies through which, by research and dissemination of information, governmental and educational institutions are striving to improve the condition of the farmer. One does not, therefore, often meet with the practising or consulting agricultural engineer. (See also articles on LAND RECLAMATION; ELECTRICAL POWER IN AGRICULTURE; DRAINAGE OF LAND; etc.)

BIBLIOGRAPHY.—The bibliography of agricultural engineering consists chiefly of the publications dealing with its various component subjects. See *Bulletins of the U.S. Department of Agriculture* and those of the State agricultural experiment stations and extension services; publications of the American Society of Agricultural Engineers (St. Joseph, Mich.); Committee on the Relation of Electricity to Agriculture (Chicago); Institute of Agricultural Engineering (Oxford university); the Royal Agricultural Society of England (London); Deutsche Kulturtechnische Gesellschaft (Breslau); Konferenz Schweizerischer beamteter Kulturtechnische (Lucerne). See also G. S. Mitchell, *Handbook of Land Drainage* (1898); J. B. Davidson and L. W. Chase, *Farm Machinery and Farm Motors* (1908); P. McConnell, *Farm Equipment, Buildings and Machinery* (1910); C. G. Elliott, *Practical Farm Drainage* (1912); Sir Hanbury Brown, *Irrigation—its Principles and Practice as a Branch of Engineering* (1912); C. G. Elliott, *Engineering for Land Drainage* (1913); R. P. Teele, *Irrigation in the United States* (1915); B. A. Etcheverry, *Use of Irrigation Water and Irrigation Practice* (1915); J. B. Davidson, *Agricultural Engineering* (St. Paul, 1917); H. C. Ramsower, *Equipment for the Farm and Farmstead* (Chicago, 1917); F. A. Wirt, *A Laboratory Manual in Farm Machinery* (1917); A. P. Davis and H. M. Wilson, *Irrigation Engineering* (1919); J. B. Bond, *Farm Implements and Machinery* (1923); F. N. G. Kranick, *Farm Equipment for Mechanical Power* (1923); John T. Stewart, *Engineering on the Farm* (Chicago, 1923); D. N. McHardy, *Modern Farm Machinery* (1924); G. W. Pickels, *Drainage and Flood Control Engineering* (1925); R. H. Smith, *Agricultural Mechanics* (1925). (H. H. B.)

AGRICULTURAL GANGS, groups of women, girls and boys organized by an independent gang-master, under whose supervision they execute agricultural piece-work for farmers in certain parts of England. The evils of this system were so great as to lead to the passing of the Agricultural Gangs Act 1867, forbidding the employment of any child under eight years old, and of any female under a male gang-master unless a female licensed to act as gang-mistress were also present. Gang-masters must be licensed by two justices, and may not hold a liquor licence. Later legislation made more stringent the regulations under which children are employed in agricultural gangs. By the Elementary Education Act 1876, repealing and re-enacting the principal provisions of the Agricultural (Children) Act of 1873, employment of all children under 11 was forbidden and restricted under 13. Now, by the Education act of 1921, it is forbidden under 12 and restricted under 14.

AGRICULTURAL INSURANCE. The risks against which farmers have to provide are those incurred in growing, harvesting and storing crops; animal diseases; condemnation of carcasses in slaughter-houses; and those risks commonly covered by ordinary life, accident and property insurance. The nature of the risks to which farming is exposed vary between one country and another according to its situation and climate. Thus losses from wind-storms are more common in North America than in many countries of Europe (it has been stated that between 1910

and 1923, 752 tornadoes occurred in the United States—an average of 94 annually); in Great Britain animal diseases, and in Scandinavia forest fires, are more important risks, while in Canada damage by hail causes heavy losses to farmers.

Insurance against these risks may be carried out either through ordinary joint-stock insurance companies, or through farmers' mutual insurance societies. Both methods are used, but the latter is held to have certain advantages. Local mutual insurance societies operating in a small area frequently cover the risk by re-insurance.

In Great Britain there is very little co-operative insurance. A number of joint-stock companies specialize in livestock insurance in addition to covering ordinary accident and fire risks. There appears, however, to be little inclination on the part of British farmers to take advantage of these facilities except in the case of pedigree cattle and other valuable stock. The number of registered mutual insurance societies has declined since 1913, but several unregistered cow and pig clubs exist for the insurance of their members' livestock. Under the Diseases of Animals Act 1894 compensation is payable by the State in case of animals slaughtered in consequence of foot and mouth disease, swine fever, and other diseases. In other countries agricultural insurance has made considerably more progress.

The insurance of crops after harvest is a relatively simple matter, and the risk (mainly a fire risk) is often covered by ordinary joint-stock insurance companies. The insurance of growing crops is a more specialized business. Under this head the most successful development is insurance against damage by hail. In the United States, 43 joint-stock fire insurance companies, 41 mutual companies and four State insurance departments-carried hail risks estimated in 1919 at \$560,000,000. Since 1919 the amount of hail insurance written in the United States has declined. Total premiums received on hail insurance, which in 1919 amounted to \$28,000,000, had dropped by 1923 to \$18,000,000. In Canada, the Hail Insurance District of Alberta was formed under the Municipal Hail Insurance act of 1918, having in 1919 67 municipal districts. Hail taxes are paid by ratepayers to the municipal districts which in turn pay to the municipal board. The total risk borne by the Hail Insurance Board for the four years 1919-22 amounted to \$72,000,000. In Saskatchewan the Municipal Hail Insurance Association carried an insurance of about \$25,000,000 in 1921 and 1922.

Hail Insurance in Europe has been developed to a less degree, but organizations to cover this risk are to be found in Germany, Austria, Denmark, Switzerland, France, Spain, Italy and elsewhere. In France 29 mutual societies existed for this purpose in 1921, and Italy had 51 societies in 1922. Some progress has been made, particularly in the United States, in the provision of frost insurance.

Farmers in aggregate have large sums invested in livestock which is liable to suffer loss by disease and other causes. Insurance against these risks through mutual insurance societies or otherwise has made greater progress in certain European countries than elsewhere, although the United States has some 30 mutual livestock insurance companies. France provides perhaps the leading example of European livestock insurance; its development has depended partly on state subsidies. Out of the 14,896 subsidised co-operative insurance and re-insurance societies in France in 1921, over 10,000 were societies for the livestock insurance, and 78 for re-insurance.

Co-operative insurance in Germany has not made progress comparable with that of other forms of agricultural co-operation. Only a small fraction of the livestock in the country is covered by insurance. In certain States, notably Baden and Bavaria, cattle insurance has received State assistance. Insurance of carcasses against condemnation by the sanitary authorities has also been adopted on a small scale.

Fire insurance is almost universally undertaken by the ordinary joint-stock companies but in some countries, notably the United States, it has also been largely developed on a co-operative basis. Indeed mutual fire insurance is one of the most successful as well as the oldest co-operative services which have grown up in

that country, where, in 1926, there were about 2,000 farmers' mutual fire insurance companies carrying risks amounting to over \$10,000,000,000. At the close of 1926 well over half of the total farm property of the United States insurable against fire was insured in farmers' mutual companies.

See *International Review of Agricultural Economics*. (R. E.)

AGRICULTURAL LABOURER. An agricultural labourer is a person, male or female, employed by an occupier of agricultural land. In America and some other countries the term "hired man" is generally used. In Scotland the term "farm-servant" is equivalent to that of "agricultural labourer" in England where the alternative term "farm worker" has recently come also into common usage. Conditions of employment vary widely. The contract of service may be by the day, the week, the month, the half-year, or the year. Remuneration for services may be wholly in cash, or partly in cash and partly in kind. In Scotland, in the greater part of Wales and in the north of England the majority of agricultural labourers live in their employer's house or in quarters specially provided for them on the farm. They receive wages in addition and in England and Wales the amount which may be reckoned in respect of board and lodging as part payment of wages is fixed. Where the engagement is on such terms the contract of service is usually for a year, or, in some cases, for a half-year. Over the greater part of England the ordinary contract of service is by the week at a fixed cash wage. (See AGRICULTURAL WAGES.)

In addition to agricultural labourers permanently employed there are large numbers of men and women who are employed only for short periods to assist in particular operations, such as corn-harvesting, fruit-picking, hop-picking, etc. In countries such as Canada where wheat and other corn-crops are grown on an extensive scale it is usual to engage additional men for the period of harvest. In England a large number of men and women are engaged in the districts where hops are grown for picking the crop, and in some of the districts where fruit and vegetables are cultivated a similar practice prevails. Persons so employed are often not agricultural labourers in the strict sense but are in many cases townfolk unskilled in farm work.

Enumeration. — Returns collected by the Ministry of Agriculture, from all occupiers of agricultural holdings in England and Wales show that there were, in June, 1926, 794,899 agricultural labourers employed, of whom 654,361 were classified as "regular workers" and 140,538 as "casual workers." The term casual worker has a wide significance. It includes not only those employed on unskilled seasonal work for short periods but also large numbers whose chief occupation is farm work but who find employment in other occupations, such as roadmending, in the winter when the demand for labour on the farm is at its lowest.

Work on the farm is necessarily dependent on the time of year and the weather. It was formerly the practice to suspend men (to "stand them off" as the phrase ran) in wet weather. As labour became more mobile and migration from the villages became common, employment on farms tended to be more stable and every farmer aimed at keeping a permanent staff all the year round, engaging casual workers only in times of greatest pressure. The practice of "standing off" in wet weather was gradually discontinued, and, in effect, finally abolished by the Agricultural Wages Board established in 1917.

The "gang" system of organizing casual and seasonal labour was general in the last century but it gradually fell into disrepute. Under this system a number of men and women were collected by a gangmaster and travelled from farm to farm for seasonal operations. The gangmaster made a contract with the farmer to do certain work for a specified amount and divided the payment among the members of the gang. The system obviously lent itself to abuse by unscrupulous gangmasters while the association of men and women for considerable periods without fixed abodes and often without decent accommodation either by day or night led to scandal and disorder.

Classes.—The popular belief that the work of the agricultural labourer is "unskilled" is not justified by the facts. Adam Smith compared agricultural and industrial labour thus: "Many inferior

branches of country labour require much more skill and experience than the greater part of mechanic trades. The man who works upon brass and iron works with instruments and materials of which the temper is always the same, or very nearly the same. But the man who ploughs the ground with a team of horses or oxen works with instruments of which the health, strength and temper are very different on different occasions. The condition of the material which he works upon too is as variable as that of the instruments he works with, and both require to be managed with much judgment and discretion." The introduction also of numerous machines and implements in farm work calls for greater versatility and resourcefulness on the part of the farm worker to-day.

Those who are regarded as specially skilled in farm work, and are usually paid a higher wage than the ordinary labourer, are those who have charge of stock. Their additional remuneration is partly in respect of longer hours but it is also paid in consideration of their knowledge and experience and of the responsibility placed on them. Shepherds are generally the most highly paid men on a farm, and where the flocks are large the responsibility placed on them is great. During the lambing season they not only have to be in constant attendance day and night but they must possess some elementary knowledge of veterinary science. It is a common practice to give shepherds a bonus, in addition to their wages, on the number of lambs successfully reared by them.

Men who have charge of cattle are termed in various districts cattlemen, stockmen or cowmen. In Norfolk there are also classes known as bullock-tenders and sheep-tenders who receive generally the same rate of wages as cowmen. Men who have charge of horses are termed carters, waggoners, horsemen or teamsmen.

On the larger farms there is usually a foreman (termed in Scotland a grieve) who is responsible for the general oversight of the men and the organisation of labour. His position and emoluments vary according to the size of the farm, the number of men under him and the extent to which the employer himself takes an active part in the management of the farm.

Organization. — The combination of workers for the advancement of their economic interests and particularly for collective bargaining with their employers has taken comparatively little permanent hold of agricultural labourers in any country. In England, apart from a few spasmodic local efforts, the first organized attempt to establish an agricultural trade union was made in 1872 under the leadership of Joseph Arch. A National Agricultural Labourers' Union was formed which in a short time enrolled about 70,000 members. In the face of strenuous and organized opposition from farmers it soon collapsed and no serious attempt to revive it was made until the beginning of the present century. In 1911 the National Agricultural Labourers' and Rural Workers' Union was started and by the end of 1913 had a membership of nearly 12,000. The establishment of the Agricultural Wages Board and its district committees, in which organization agricultural labourers were given by act of parliament equal rights and representation with farmers, gave an impetus to the organization of farm-workers. In 1919 it was reckoned that about half the agricultural labourers were enrolled, but after 1921 the membership again rapidly diminished and in 1926 not more than about 6 per cent. retained their membership.

Agricultural labourers are not included in the Unemployment Insurance act. In 1926 a departmental committee recommended, by a majority of one, the establishment of a special system of unemployment insurance for agricultural labourers in England and Wales, but the recommendation was not adopted by the Government.

(R. H. R.)

United States.—Over the United States as a whole there is less than one-half hired agricultural labourer per farm. The total number of farms is approximately 6,750,000, while the number of farm-labourers varies from about 1,500,000 in January to at least 3,000,000 in the cropping seasons. The January figure represents mainly the permanently employed—the class that makes agricultural labour its steady occupation.

The relatively small number of farm-labourers is due to the fact that the typical American farm is a family enterprise. Ord-

inarily the family is large. In some regions there is also considerable exchange of work among farmers on adjacent farms. The number of hired labourers is steadily diminishing, as the increasing knowledge of agricultural science and the perfection of agricultural machinery constantly augment the production per man. At certain times of the year much casual labour is employed, as for cotton picking, truck planting and harvesting, fruit picking, and wheat harvesting. Except in the case of wheat, the work tends to be done by families of migratory workers. There is an excess of this type of labour, wages (at piece rates) are extremely low, and living conditions are deplorable.

The extent to which labour is employed throughout the year varies with the region and the type of farming practised. Dairying and live stock husbandry, coupled with diversified cropping, make for a fairly uniform employment of labour at all seasons. New England and New York have had for generations a tradition in favour of permanent employment of farm-labour, with a strong preference for keeping the same persons year after year. The tendency has been for the farmer to assume a patriarchal attitude toward his help. The unmarried farm-labourer used to occupy a real place in all the life of the farm family. In early days the comparatively high wages and low prices for land—when an acre could be purchased with a single day's labour—attracted a fairly high type of labour to the farms. With the increased price of land, the growth of opportunities in the cities, and increasing dislike of labourers for absolutism in their employers, the type of farm-labour has doubtless declined. There is also a tendency to depart from the custom of making the hired man practically a member of the family, although the old practice still prevails to a large extent, especially in the East.

The average prevailing farm wage rate for the United States on July 1, 1939, was \$22.71 a month with board, and \$33.73 a month without board. The highest wage rates—\$43.18 and \$64.04 respectively—are found in the Pacific States, and the lowest—\$16.47 and \$23.57 respectively—in the East South Central States. A large proportion of regularly employed farm-labourers are single men.

These almost invariably receive board. Married men usually are supplied with a house or cabin and with some such perquisites as fuel, some food, use of horses and farm tools and garden space. Not infrequently a man and his wife are both employed on the farm—he at farm work, she in domestic matters. Hours of labour on the farm average considerably longer per day, at least throughout the cropping seasons, than in industrial life, although, except in harvest and similar rush times, there is freedom from the pressure characteristic of factory work.

American farm labour is prevailingly unorganized. The oldest existing organizations are probably the Sheep Shearers' Union of North America and the United Confederation of Mexican Peasants and Workers of the State of California. The Industrial Workers of the World at one time enrolled many farm labourers. The attitude of the New Deal toward labour stimulated organization of agricultural workers, chiefly migratory, and a number of local unions are recognized by the A.F. of L. or the C.I.O. The unions are strongest in Arizona, California, New Jersey, the Northwest, and the sugar-beet regions of the Great Plains. The principal aims are higher wages, better working and living conditions, and amendment of the Social Security law to include agricultural labour. Operating farmers generally are hostile to unions, and violent strikes have occurred, notably in New Jersey, Ohio and California.

(N. A. C.)

AGRICULTURAL MACHINERY AND IMPLEMENTS. At the dawn of history we find man practising the most elementary method of modifying soil conditions. He broke up the surface and prepared a seed bed, using for this purpose the most primitive of all cultivating devices, a digging implement in nature like a hoe. The seed was sown by hand and the husbandman either drove his domesticated animals over the land to cover the seed and consolidate the ground, or used a form of harrow or similar implement or a bundle of twigs for the purpose. In early times the principal crops were cereals or pulse and a fibre crop—flax. Harvesting was performed by means of a sickle, an early

example of which, found in the Fayum in Egypt, consists of a wooden rod fitted with flint blades; metal was employed later, and a bronze sickle of about 1000 B.C. is the counterpart of the modern sickle. The crops were carried to a threshing floor where the grain was trodden out by animals, crushed out by sledges or beaten out with flails. The corn was winnowed by casting it through the air with a spade or shovel and fanning or allowing the wind to separate the heavy grain from the lighter husks.

The greatest mechanical advance during these early days of agriculture was the evolution of the plough from the primitive hoe. This transition is very clearly seen in ancient Egypt. The advent of the plough enabled man to supplement his labour by animal power and is one of the great landmarks of agricultural progress. Mesopotamia furnishes evidence of the use of a primitive combined plough and drill, but it is doubtful whether the implement had any advantage over the customary methods; at all events it was lost to later civilization. By Roman times a primitive ridging plough had been evolved by the use of a device resembling the modern double mould board. When the single mould board was developed or when wheels were added to the plough is not definitely known. Pliny, the elder, who lived in the first century, mentions a wheel plough, but the use of such ploughs did not become general until much later. Pliny also reported the use in Gaul of a harvesting device, which was pushed by oxen, for heading or stripping the grain. But ancient civilizations did not make any considerable progress on the mechanical side of agriculture and such mechanical contrivances as were used disappeared with the barbarian invasions.

During the middle ages and until after the Renaissance the variety of implements at the disposal of the husbandman had advanced but little, though the roller was known but was not employed generally in agriculture. It must not, however, be supposed that there was absolute sameness or an uncritical acceptance of the implements handed down from previous generations. Fitzherbert's *Book of Husbandry*, printed in England in 1523, mentions the different types of plough used in different districts and attempts to give reasons for the differences in design. Fitzherbert appears to have realized that the design of the plough must be modified to reduce the draught in different kinds of soil. Hand tools had been perfected and often represent, even in small details, the hand tools in use to-day. By the year 1600 more elaborate implements were coming into use, and more than one book published in England about this time deals with the "new and admirable art of setting of corn." About 1730 Jethro Tull (*q.v.*), who is renowned for his horse-hoeing husbandry, developed a seed drill which was really workable, although its general adoption was hampered by Tull's advocacy of impracticable methods of cultivation.

In the eighteenth century there was a conscious and organized attempt to improve agricultural implements, and in England the Society of Arts, which had been founded in 1754, encouraged the movement by the offer of premiums. Ploughing matches were held in many parts of the country and attracted general support from farmers and their men. There were also competitions in the use of drills and horse-hoes. New methods and inventions were being applied to most farming operations, and new conditions were being created favourable for the great advance which followed.

The Steam Engine.—By the 19th century such a complexity had been introduced as to justify the use of the term "agricultural machinery." In agriculture, as in the manufacturing industry, the use first of water-power and then of steam had immensely stimulated the invention of machinery supplementing or replacing manual labour. A workable threshing machine was invented late in the 18th century and was gradually coming into use early in the 19th; it was driven by water or wind power, sometimes by horse labour, and later by steam. But it was not until the '30s of the 19th century that steam began to be applied at all extensively to agriculture. A system was then introduced whereby one or two engines were employed to draw multi-furrowed ploughs, by means of cables, backwards and forwards across the field, and after a good deal of experimentation the established system of steam-ploughing with a double-engined cable set was devised in the fif-

ties. Heavy implements such as the cultivator and mole plough were later added to the equipment of steam tackle; mechanical threshing became popular and steam-engines were also used to some extent to drive barn machinery. Nevertheless, for the most part the development of agricultural machinery upon the farm owes little directly to steam. The mowing machine and the self-binder, the tedder and swath-turner, the drill, the potato-digger, chaff-cutters and root-cutters, all have been developed in the first instance for horse or manual labour, though doubtless receiving a fresh stimulus from the general mechanization of industry applied to the farm and the still greater stimulus, in Britain as in America, arising from a shortage of cheap labour.

The Internal-combustion Engine.—In still more recent times an important practical contribution to the mechanization of the farm came from the discovery of the internal-combustion engine. Used first of all to drive stationary machinery, as chaff-cutters, root-cutters and corn-mills in the barn, in the second decade of the 20th century the internal-combustion engine also made headway as a source of power for field operations. Steam-engines, though widely used for traction on the road, suffered the disadvantage of being heavy for use on the land for the direct haulage of machinery and implements; it was not until the internal-combustion engine had been perfected that agricultural tractors made their appearance in any number.

This type of tractor has now an established position on the farm on both sides of the Atlantic; it supplies power for ploughing, cultivating and harvesting; it can both drive and haul the threshing-machine, and there can be no doubt it contains the promise of still further usefulness. The practice of mole-draining, for example, has been greatly stimulated not only in Britain but on the Continent of Europe by the invention of mole-ploughs that can be hauled by a suitable agricultural tractor. The cost of the work is substantially less than when performed by steam tackle and is far more expeditious than when performed by horses. The tractor has also rendered it easier for the farmer to undertake deep ploughing and subsoiling, which are very important for growing a crop such as sugar beet. Subsoiling had been looked on with disfavour because of the heavy strain imposed upon the teams and, when carried out at all, had been left in great measure to steam tackle. The application of the internal combustion engine has also enabled designers to produce machines of more moderate size and weight than formerly.

Another direction in which the internal-combustion engine is likely to prove its usefulness is in rotary tillage. This is a system which may ultimately replace ploughing and subsequent cultivating by a single operation. It has been advocated since the first half of the 19th century, and many attempts have been made to devise an effective machine, the best known being the Darby digger which inverted the soil by an action somewhat resembling that of the spade. The most promising machines make use of revolving tines for disintegrating the soil and the tines revolve in such a way as to assist the propulsion of the machine. The advantages and limitations of rotary tillage have still to be tried out. In a climate like that of Great Britain the combined effects of autumn or winter ploughing and frost may not be attainable by rotary tillage. Given suitable soil and climatic conditions, however, the potential advantages of preparing a seed-bed at one operation and on a considerable scale are obvious.

The internal-combustion engine thus enables operations to be efficiently performed which were beyond the resources of the ordinary farmer, or which were little more than ideas in the days of steam and horse labour. But this is not its only or perhaps its chief usefulness. It enables operations to be performed far more speedily with an equal labour force and is therefore an ally to the farmer in his struggle against adverse weather conditions. Obviously, if five or six acres can be ploughed in a day by a tractor where formerly a plough-team accounted for less than one acre, another factor than the unit cost of the ploughing, namely, that of speed or of the time conditions, has entered into the operations. Again, if 20 acres can be reaped in a day as against ten or 12 acres by two teams of horses, the same factor enters. Full advantage, however, cannot be taken of the tractor when the implements

and machines used with it are those designed and constructed for horse haulage; to obtain the full benefit implements expressly designed for tractor work must be employed.

In the cable system of ploughing and cultivating, the internal-combustion engine appears likely also to replace steam. The ease of handling oil fuel as compared with the difficulties often attending the transport of water and coal or wood must, it would seem, in the long run prove the decisive factor. The advent of the producer-gas plant for use with tractors and lorries is also likely to extend the use of the internal-combustion engine in countries where liquid fuel is scarce and suitable materials for producing gas are available. The possibilities of the production of power alcohol on a commercial scale must also be borne in mind when considering the future sources of energy for the farmer.

Electricity. — But a still newer source of power which has made its appearance upon the farm is electricity. Owing to the shortage of coal and oil fuel during the War period, a stimulus was given to the exploitation of water-power and electricity undertakings. Although employed at first principally for lighting, electricity, when it is available at low cost relatively to other forms of power, is gradually coming into use for driving stationary machinery on the farm. Its further use for cultivating the land has scarcely gone beyond the experimental stage as yet, although systems of cable ploughing in which electric motors are employed are actually in operation in several European countries. The principal difficulty is the transmission of current to every part of the farm where it may be needed, since equipment with transmission lines may involve serious expense.

Othex Mechanical Progress. — The gradual mechanisation of the farm is apparent, however, not only in those branches of agriculture and methods of operations which are of long standing. As new crops are introduced or old crops revived, mechanical means are devised to deal with them. Each crop indeed demands its appropriate machines. A crop such as sugar beet, when introduced into a country where labour is dear, requires effective mechanical means for dealing with it at all its stages, but particularly for har-

COURTESY OF 3. I. CASE THRESHING MACHINE COMPANY

A DISC-HARROW DRIVEN BY A GENERAL UTILITY TRACTOR TO WHICH A PLOUGH OR A SMALL GRAIN SEEDING DEVICE CAN ALSO BE HITTED

vesting—the most arduous of the whole cycle of operations; consequently it is necessary to devise mechanical lifters and toppers as substitutes for the hand labour employed in countries where wages are low. Similarly with the flax crop; its revival in Britain has led to concentration on the problems of harvesting and the preparation of the fibre for the spinner. Machines for pulling the crop and for scutching (or dressing) the straw have been devised, and new mechanical processes have been advocated to supersede entirely the traditional hand methods.

Classification of Machinery. — Agricultural implements and machines are now very numerous and very diversified and may be considered under five main groups, namely: (1) *prime-movers*, i.e., engines of all kinds, tractors, water-wheels, windmills, etc.; (2) *cultivating machinery*, including ploughs of all kinds, rotary tillers,

harrows, hoes, scarifiers, rollers, manure distributors, drills, mole-ploughs, etc.; (3) *harvesting machinery*, including mowers, rakes, swath-turners, tedders, reapers, self-binders, threshing machines, elevators, potato lifters, beet toppers and lifters, crop drying plants, etc.; (4) *stationary or barn machinery*, including such food-preparing machines as cake-breakers, chaff cutters, grinding and crushing mills, root-cutters, etc.; (j) *dairy machinery*, including milking machines, separators, churns, butter workers, sterilizing and bottling machines, etc. In addition, there are a number of miscellaneous machines, including sprayers, sheep-shearing and horse-clipping machines.

Economics of Machinery. — From the development of such mechanical devices it does not, however, follow that every farmer can economically use machinery for all possible purposes. With his small acreage of grass and cereals the small-holder, for example, would probably not feel justified in purchasing any harvesting machinery, except a horse rake and a combined mower and reaper, whilst the farmer with a holding of 300 acres or so of mixed arable and pasture land would find it necessary to have a complete outfit of cultivating, harvesting and stationary machinery, besides many dairy appliances if milk production were also an important part of his enterprise. In suitable circumstances he would probably also find it desirable to supplement horse labour by one or more tractors and would probably thresh his own produce. But on very large arable farms, such as extend in some parts of the world to several thousands of acres, the range of agricultural machinery would include cable sets and possibly even trenching machines for excavating and grading drains and ditches.

The economic use of machinery in agriculture is dependent on a number of factors which vary from country to country, from district to district, and from one type and size of farm to another, but there is one principle common to all cases: a machine must do sufficient work to repay its capital outlay and working costs over a reasonable period. To meet this requirement the minimum amount of work must be available before any particular machine can be employed economically. The potato crop furnishes an excellent illustration. The cheapest way to lift a small plot of potatoes is by hand forking; the lifting of an area of an acre or so will repay the cost of a simple potato plough; while a larger area will justify the purchase of a potato-lifting machine. But the use of machinery depends also on other factors besides cheapness in comparison with other methods. Speed of work and ability to take advantage of favourable weather are factors which may influence considerably the adoption of mechanical devices, although it may be difficult for any system of farm costings to take cognisance of these advantages. Emphasis must at present be laid on the paucity of accurate knowledge regarding the cost of farming operations in general, though efforts have in recent years been made in Europe and America to analyse farm costs and to stimulate the adoption by farmers of some simplified system of cost accounting. The comparative cost of individual operations or units of work is, however, not sufficient; the problem from the farmer's point of view is rather the production of food units at a minimum cost, and the marketing of them either directly or by feeding to stock in such a way as to obtain a maximum return on the capital outlay involved.

Social Effects of Machinery. — It is sometimes supposed that the introduction of machinery has led to rural depopulation and will intensify it. But even in older countries machinery has more often than not been introduced because a labour supply of a particular kind has failed; for example, the falling-off of casual and migrant labour at harvest time due to a number of social causes has encouraged the widespread adoption of the self-binder. In newer countries the introduction of machinery has had the effect of populating waste areas, for the vast tracts of new land in the United States, Australia, Canada, etc., could not be farmed in present circumstances without the aid of machinery; the alternative would be timber production or stock raising.

The use of machinery also requires skilled workers, and the more widespread the use of machinery becomes in agriculture the more highly skilled will be the farmworkers. The mechanisation of agriculture also means that a higher wage can be paid because the unit

of production is enlarged, but as a corollary it also indicates larger farms or groups of small farms worked as one economic unit. The alternative is a system of peasant holdings with primitive methods; but the Western world is steadily moving away from the social conditions which made such a system possible.

UNITED STATES

As industry has developed and has built great cities, it has called man-labour from the country. This labour has been replaced by agricultural machinery and implements. The extent to which this has happened in the United States is indicated in fig. 1. Although the total population of the United States in 1927 was a little more than five times as great as in 1850, and although the acreage of improved farm land increased about 4½ times during the same period, yet the number of agricultural workers in 1927 was a little less than three times the number in 1850. Seventy-five years ago the proportion of total population to agricultural workers was slightly over six to one. Better adaptation of crops to soils and climate, and increased yields per acre, are probably the main reasons why the acreage of improved farm land has not kept pace with the increase in total population. But had it not been for the introduction of machinery which increased the effectiveness of man-labour on the farm, an increasing number of acres to feed and help clothe a rapidly increasing population must have been accompanied by a much more nearly equal increase in agricultural workers.

FIG. 1.—GRAPH SHOWING VARIATION IN POPULATION, IN AGRICULTURAL WORKERS AND IN ACREAGE OF IMPROVED FARM LANDS IN THE UNITED STATES

Effect on Time, Man-labour and Production.— Since 1850, when the application of machinery to farming began in earnest, the average acres of improved land per agricultural worker in the United States increased steadily from 30.4 acres to 47.2 acres in 1920; and the value of agricultural implements and machinery per agricultural worker increased from \$40.77 in 1850 to over \$200 in 1925. The 13th annual report of the United States Department of Labor shows that the man-labour requirement to produce twenty bushels (one acre) of wheat by the hand methods of 1830 was 61 hours and 5 minutes, at a labour cost of \$4.00; by the machine methods of 1895, only 3 hours and 19 minutes, at a labour cost of \$1.12 were necessary to produce the same amount. By the hand methods of 1855 an acre of corn required nearly 39 hours of man-labour; in 1894 it required slightly over 15 hours with machinery. Using the estimates of the Department of Labor for nine important crops (barley, corn, cotton, hay, oats, potatoes, rice, rye, wheat) and comparing the machine methods of about 1895 with the hand methods of earlier times, H. W. Quaintance (*The Influence of Farm Machinery on Production and La-*

bour) states: "Taking the per cent of labour saved as indicating the average proportion of these crops due to the use of machinery, it appears that the quantity of products is almost five times as great, per unit of labour, as it formerly was." This suggests how machinery has freed labour from agriculture for service in industry and commerce. After an extensive study and presentation of data on 1; crops (barley, broom corn, corn, cotton, hay, oats, onions, peas, potatoes, rice, rye, sugar cane, sweet potatoes, tobacco, wheat) grown in the United States, the same author says: "Surely it will not be too much to say that during the last half of the 19th century the cost of production¹ of these crops was reduced by one half." That the influence of machinery on labour has continued since 1895 is evidenced by the fact that now it is not uncommon to hear of farmers in the United States and Canada who, by the most modern machine methods, produce wheat and corn with a man-labour requirement per acre of only two and six hours respectively.

Influence on Quality of Work and of Product.—As inferred previously, increased yields per acre, and improved quality of product, are due to a number of factors; but the importance of one of these is not to be overlooked here. The improved methods in farming made practicable by machinery have a marked influence on the quality of work done by the farmer, and on the quantity and quality of the product. By the use of better designed, better adapted and more effective soil working, grain grading, seeding and harvesting machinery, sounder seed is more evenly sown in a better seed bed; a larger yield is promised and a more uniform and cleaner product is marketed. Modern spraying equipment not only saves the fruit crop, but its use also means better quality; then modern sorting and packing machines grade the product to command the best market price. These are but a few of scores of illustrations; yet, that is not all. Up-to-date machinery in agriculture permits better utilization of products; for instance, the feed grinder, silage cutter and shredder have increased the feeding value of roughage, and the manure spreader permits better utilization of animal refuse to help maintain fertility and good tilth.

Other Effects.—Although the average acreage of improved land per farm in the United States has fluctuated somewhat since 1850, economists point out that in the north central states, in which machinery has been more widely applied to general farming than in other divisions, the improved land acreage per farm has steadily increased; likewise, the average number of crop acres per farm in these states has increased during the period for which data are available. In other sections of the country where general farming has been practised and where machinery has not been so widely adapted, not only are the tendencies just mentioned less apparent but, even at times, there is a marked tendency toward smaller farms. In Canada, the average acreage of improved land per farm has increased steadily from 59 acres in 1901 to 99 acres in 1912; during the same period agricultural implements and machinery increased approximately from six to ten per cent of the total value of all farm property. If the total investment in all farm property in the United States is considered, the increase since 1850 has been much greater in the agricultural divisions of the country in which machinery is widely used. The greatest item in the value of farm property is the value of the land itself; and land values are based somewhat upon earning capacity. Of course, the increase in value of all farm property may be due to several factors; but, the ability of machinery to cut down the cost of production and thereby increase net profit is not to be overlooked as having had and continuing to have an influence on land value.

By lessening the time necessary to perform farm work, machinery has assisted in shortening the working day. Also, it has changed the character of the work in a way that has important social bearing. In 1880 it was easier physically and more pleasant

¹Cost of production here is based on cost of labour and does not include differences in machine overhead between hand and machine methods. This discrepancy, if it seems such, is more than offset by the fact that labour by hand methods is figured at the rate of about 1850, while for machine methods it is computed on the basis of the higher wages current about 1895.

mentally to thresh grain with a threshing machine than to use the flail of 1820. Likewise, it is easier to-day to sit upon a combination harvester-thresher, guide the machine and control the power than it was to pitch bundles and straw in the days of 1880. In this sense, agricultural machinery is truly "labour saving" in that it has relieved farm work of much of the old, arduous physical exertion so often characterized as drudgery, and demanded in its place greater skill and more intelligence on the part of the operator. The modern farmer whose business demands extensive use of agricultural machinery is just as busy, if not

BY COURTESY OF H. A. STROHMEYER, JR.

MODERN THRESHING. A SPEEDIER AND EASIER OPERATION THAN IT WAS 50 YEARS AGO BEFORE ENGINE-DRIVEN MACHINES WERE KNOWN

busier, than his grandfather, but his work is more mental and less manual. Modern farming is a complex business requiring study, wise planning and careful execution. To be sure, the farmer of to-day works hard physically as well as mentally, but, by lessening the time requirement for various farm operations and by eliminating much of the old drudgery, farm machinery and household conveniences allow the farmer and his wife and children more time for reading, for thinking, for recreation and for self-improvement.

Classification.—Types, kinds and sizes of agricultural machinery and implements form a complex subject. Agricultural conditions into which machinery must fit vary widely between the one-mule farms of the cotton-belt and the great wheat ranches of Canada; the operation of a New England farm varies from that of a corn-belt farm, and the latter, in turn, is vastly different from the California fruit ranch. Differences in sizes of farms, in size of fields, in kinds of crops grown, and in the kind and size of power units most economical or practical—all cause variation in type and size of machine or implement. For a small field, one can buy a one-horse implement for a very few dollars, or, for a great plantation one may buy a special harvester which costs several thousand dollars. Because of the wide variation in soil types, the large manufacturer selling nationally finds it necessary to make over one hundred different shapes and kinds of mould-boards for ploughs in addition to the disc type of plough which is demanded in very hard, in very fluffy or in very sticky soils. Land values have some influence. Then, last but not least, the human equation enters; differences in peoples and in regional customs add complication. The farm labourer of low mental calibre and of little mechanical skill requires a smaller, simpler implement than the skilled operator who commands a 60-horsepower tractor hauling a combination of implements which performs two or three operations in one trip over the ground.

Space does not permit description of all kinds of agricultural machines and implements. Fortunately, however, the subject lends itself to classification according to the purpose of the machine. Most of the agricultural machines, implements and tools used by farmers in the United States and Canada may be classified according to purpose. The list includes only those items considered part of the business of raising or making agricultural products up to the moment those products are sold. It does not include the strictly household conveniences, devices and utilities which are becoming so widely adapted to assist the housewife

and to enable the farmer and his family to enjoy more the art of living.

Machines and Implements for the Reclamation, Maintenance or Improvement of Land: stump pullers, pilers; brush breakers, cutters, burners; open ditch, tile ditch and mole ditch machines; land drain cleaners; land levellers; terracing scrapers, graders; irrigation pumps, sprinklers water controls, ditchers; sub-soders; limestone crushers; lime and fertilizer distributors; manure loaders, spreaders; straw spreaders.

Machines and Implements for Seed-Bed Preparation: mouldboard and disc ploughs; drags; spike-tooth, spring-tooth, disc and special harrows; smoothers and pulverizers; plain, corrugated and bar rollers; surface and subsurface packers; clod crushers; special tillers; sweeps; listers; ridge busters; stalk cutters, shavers; cotton stalk choppers; stubble diggers, pulverizers; markers.

Machines and Implements for Seed Preparation: fanning mills; grain, pea, bean, cotton seed, peanut, flax, onion set, rice, potato and corn cleaners, graders and sorters; seed scarifiers; seed testers; seed stringers; seed driers; butters and tippers; potato cutters.

Machines and Implements for Seeding and Planting: broadcasters; grain, beet, grass and garden seed, bean, pea, corn, onion and rice drills; corn, cotton, beet, potato, pea, bean, onion and peanut planters; transplanters; seeders; markers; lister-planters; fertilizing attachments.

Machines and Implements for Cultivating: corn, beet, cotton, potato, sugar cane, vineyard, orchard and garden cultivators; celery, potato and tobacco hillers; drags; spike-tooth, spring-tooth and disc harrows; weeders; rotary hoes; ridgers; renovators; sweeps; root blockers; cotton scrapers, choppers; thinners.

Machines and Implements for Harvesting: mowers; tedders; "flop-over," dump and side delivery rakes; "bull" and sweep rakes; hay, shock, bundle and cane loaders; stackers; bunchers; windrowers; reapers; grain and corn binders; grain and corn headers; header-binders; combination harvester-threshers; corn, cotton, potato, peanut and fruit pickers; root and plant lifters; potato and peanut diggers; root toppers; bean, pea, beet, celery, grass seed and onion harvesters; field ensilage harvesters; seed and cotton strippers; sugar cane cutters, harvesters; corn and hemp cutters; grain and corn shockers; shock compressors, movers, sweeps; huskers; milking machines; wool clippers; tree fellers.

Machines for Preparing Products for Market: grain, pea, bean, peanut and rice threshers and cleaners; alfalfa, clover, almond, bean, pea, grain and rice hullers; grain, pea, bean, cotton seed, peanut, onion set, rice, potato, corn, berry and fruit cleaners, graders and sorters; cotton gins and presses; balers; produce washers; grain polishers; corn, peanut, rice and pop-corn shellers; vegetable bunchers; cream separators; milk emulsifiers, pasteurizers, sterilizers, coolers, aerators; churns; butter workers; bottling machines; cheese and lard presses; sugar, fruit, sorghum and syrup evaporators; honey extractors; berry and fruit crushers; cider and juice mills, Dresses,

A POWER DRIVEN SPRING-TOOTH HARROW. OPERATED BY ONE MAN AND EMPLOYED IN PREPARING AND CULTIVATING THE SEED BED

extractors; bleachers; pitters; parers; sugar cane and sorghum mills; hemp breakers and cleaners; saw mills; baggers, weighers

Machines for Feed Preparation and Feeding: cutting boxes; ensilage and fodder cutters; feed mills, grinders, mealers, roughage mealers; feed mixers; shredders; root and vegetable cutters, pulpers; feed cookers; stock feeders; bone cutters; corn and cob crushers; silo packers.

Machines and Implements for Combating Crop Enemies: sprayers; dusters; field burners; stubble pulverizers; insect sweeps, catchers, traps; tobacco bed burners; seed treaters; smut cleaners; fumigators.

Machines, Implements and Conveyances for Transportation: automobiles; motor trucks; wagons; carriages; horse and hand carts; sleighs; bobs; stone boats; wheelbarrows; farm, wagon, log, lumber, header and sugar-cane gears; racks and barge boxes; hay carriers,

forks, slings; blowers; grain dumps, elevators; car loaders; feed and litter carriers.

Power, Light and Heat Generators: gas, petrol, paraffin, distillate, hot air and steam engines; steam and internal combustion tractors; boilers; windmills; turbines; water wheels; hydraulic rams; tread mills; power sweeps; electric motors, dynamos, generators; lighting plants; tank heaters.

Miscellaneous Machines, Implements and Tools: incubators and brooders; disc and knife grinders; pumps and Dump jacks; hay

knives and hooks; hand hoes, rakes, shovels, forks; corn, cane, tobacco and cabbage knives; pruning and grafting hooks, knives, shears and saws; fence stretchers; hog rubs; post hole augers; lifting jacks; animal pokes and leads; dehorners; horse and cattle clippers; grooming machines; milk and cream testers; utensil washers, sterilizers; scales; ladders; hand tools and machines for mood and iron work

Historical Sketch. — Attempting to determine whether changes in agriculture were the cause or the result of the introduction and improvement of machinery is like trying to decide which came first—the hen or the egg. Undoubtedly, a change in agriculture at times caused sharp changes in agricultural machinery; at other times, advancement in agricultural machinery permitted, if not actually caused, marked changes in agriculture. The two are so interdependent that a historical sketch should review the status of machinery and implements in each of the five great periods in the history of American agriculture, as well as point out the high spots in the history of machinery itself.

During the colonial period (1607 to 1783), farming was on a self-sufficing basis; that is, the farmer made his own shelter, he and his family made much of what they wore, and, with the exception of some wheat, tobacco, rice and indigo, the farmer raised but little more than was required for his own family. The ground was spaded or hoed up, or it was ploughed with a crude, "bull" plough which carried a wooden mouldboard sometimes stripped with iron. Farmers who were fortunate enough to own these home-made ploughs often ploughed for others. If the seedbed was harrowed at all, a "peg tooth" harrow was used; this was a wooden frame with wooden spikes for teeth. Small grain was sown broadcast by hand; sometimes it was harrowed in or was trodden in by animals. The new crop was cut with a hand sickle, scythe or cradle, threshed with hand flail or by driving animals over it on a treading floor; then the grain was winnowed by casting it against a light wind. Corn was dropped, covered, cultivated and harvested entirely by hand. Wooden-wheeled carts were used; but evidently these were not as popular as one would suppose, because there is evidence that tobacco was placed in huge barrels which were rolled to the market point. Thus, with the exception of a great number of hand tools, crude forms of the plough, harrow and wagon were the only agricultural implements of the colonial period.

With only one or two notable exceptions the same conditions held and the same old implements were used throughout the second period (1783-1830) of agricultural history. This period was characterized by the beginnings of the public land policy and of expansion west, and by the increasing importance of cotton in the South. Early in the 1790's the Whitney cotton gin appeared; this made the removal of the seed from the cotton mechanically

possible and was a great boon to the young cotton industry. The influence of the cotton gin has been so far-reaching economically, commercially and socially that it is considered one of the high lights in the history of agricultural machinery.

About 1797 Newbold demonstrated his cast-iron plough. It was similar to the cast-iron ploughs which had been demonstrated shortly before in England. Records indicate that farmers feared detrimental effects from so much iron in contact with the soil, and evidently this first American cast plough was never repaired after its mouldboard became broken. Hence wooden ploughs, some of which carried wrought-iron cutting edges, continued well throughout the period. Between 1814 and 1820, however, Wood, evidently continuing the meditations of Thomas Jefferson on the mathematics and mechanics of the mouldboard, began to give the plough bottom scientific shape for better turning, pulverizing and for lighter draft. To secure these shapes Wood had to cast his ploughs, and he introduced the important feature of having parts of the plough renewable.

During the latter part of this period a cutting box to cut up roughage for feed, a cultivator for row crops, a horse rake and the Bailey mower appeared. The mower cut by means of a large circular blade which revolved against the grass' evidently to imitate the cutting action of the old scythe blade. The cutting box, cultivator and rake ideas were perpetuated, but this device for mowing was not further developed. It is claimed that a few "chaff piler" or "ground hog" threshers were used as early as 1822; these rubbed the grain from the heads but did not separate it from the chaff or straw. These implements, although their use did not become general until later, are mentioned here to show that, as farming moved westward and larger or new tracts of land became available to the farmer, there began a real attempt to furnish machinery to supplant a growing shortage of labour.

At no time has American agriculture undergone such changes as during its third historical period (1830-1860), and at no time has agricultural machinery been so involved in a transitory period. At the beginning of this period the farmer produced first for himself and family; at the close he was raising crops chiefly to sell. As the new railroads opened up the interior, agricultural products were shipped into the East to be laid down on the

BY COURTESY OF THE J. I. CASE THRESHING MACHINE COMPANY

A LISTER WHICH THROWS UP A SLOPING RIDGE AND CUTS OFF THE SQUARE SHOULDER

seaboard in such quantities as to affect almost the entire world. The repeal of the Corn Laws in England, the rapid development of manufacturing both in England and America, the potato famine in Ireland and the settling of western lands by thousands of immigrants following the German revolution of 1848 all gave stimulus to American agriculture. Not only did breaking and cultivating the black lands of the Middle West present new problems in soil working implements, but also over the entire country farmers awoke to the pressing need of a cheaper, faster way of doing things. This led to an outstanding period of invention and to the real beginning of implement factories to supplant the country blacksmiths who, for years had been supplying local patrons with crude implements fashioned largely after their own individual ideas.

The obstinate scouring qualities of the soils in the Mississippi valley led to the use of steel instead of iron strips to face the mouldboards of ploughs. In 1833 John Lane built the first steel mouldboard, using cross-cut saws for the purpose. John Deere starting in 1837, and William Parlin beginning in 1842, were other pioneers in the steel plough business of the Middle West. Much credit is due also to James Oliver who, beginning his experiments in 1853, greatly advanced the process of chilling cast plough parts, thus securing greater durability and improving the scouring qualities of this type of plough.

Early in the '30s the Manning, the Hussey and McCormick

patents brought out the idea of cutting grass and grain by a reciprocating knife passing through fingers or guards. It is this principle upon which modern mowers, binders, headers and combination harvester-threshers still operate.

Other patents and developments of note during the early part of this period related to corn shellers, fanning mills, grain drills, and to tread-powers and power-sweeps, whereby the power of horses or oxen could be utilized to drive the rotating parts of such stationary machines as threshers. In 1834 Pitts combined a "ground-hog" thresher and a fanning mill and thus started the development of the modern grain separator which threshes, cleans, weighs and bags the grain. Although they did not become popular until years afterward, nevertheless grain strippers and headers were patented during the twenty years prior to 1850.

By 1850 several factories had been established for the manufacture and sale of what were then improved and successful ploughs, harrows, grain drills, reapers, mowers, threshers, strippers and power-sweeps. Of course much work on the farm still had to be done by hand, and much improvement and many new devices were to appear after that date. But by that time the farming public was accepting mechanical devices so rapidly that 1850 is recorded by historians as the close of the period of "hand production" and the beginning of the machine era in American agriculture. The advent of machinery and implements placed farming on a commercial or production basis on which the farmer raised products to sell rather than simply to sustain himself and family. It is interesting to note that from 1850 to 1860 the number of establishments manufacturing agricultural machinery increased from 1,333 to 2,116.

From 1850 to 1860 patents appeared and development work was carried on on each of the following: force-feed devices in grain drills, stalk cutters, baling presses, two row corn planters, disc harrows, feed grinders and "straddle row" cultivators. Improvements continued on all classes of implements, especially on mowers, threshers and reapers. One of the most interesting developments concerned mechanical binding attachments made for and used to some extent on reapers. Most of these attachments used wire instead of twine; wire was costly and objectionable in the straw, and one step—that of elevating the grain and getting it automatically into good binding position—was lacking. At the time that the wire binding attachments were being developed, the Marsh brothers, about 1856, conceived the idea that two men, standing on a special platform at one side of the reaper, could bind the grain by hand providing it was elevated from the platform of the reaper and delivered to them on a binding table which they faced. Although the Marsh harvester of 1858 was originally designed to facilitate hand binding, nevertheless it is very important historically because it so materially solved the problem of grain delivery. It supplied the step just referred to as lacking with the early wire binding attachments, and became the foundation for the later binding machines which were simply to substitute automatic binding and tying devices for the two men that stood on the first Marsh harvester.

The fourth period in the history of American agriculture extends from 1860 to 1887. It was characterized by remarkable expansion, a chief cause of which was the passage of the Homestead Acts. The disbanding of the armies of the Civil War sent men and mules back to the land, and, machinery being available, many sought the agricultural opportunities of the far west which was about to be opened up by the completion of the trans-continental railroads. The perfection of the twine binder and the introduction of the roller process for flour manufacture also stimulated agricultural expansion.

The drain of the Civil War on farm labour forced farmers to the use of more and more machinery. During the war mowers came into very general use, and early in the period there was much done to perfect horse rakes which, as an accompaniment to the mower, could displace more labour in the haying process. This was to be followed soon, in 1872, by the development of hay forks, slings and carriers by which hay could be moved from the wagon to the mow or to the stack by horse power rather than by hand. Thus the production of hay had become mechanical

save for one step—that of loading. This gap began to be closed in 1874 when the mechanical hay loader appeared; the implement was considerably improved about 1880 and came into use about 1885. Although they had been patented years previously, two-wheeled sulky and gang ploughs did not appear in good quantities until about 1870. In 1868 John Lane, Jr., patented soft-centre steel for plough bottoms. About the same time disc harrow manufacture began in earnest.

The first automatic grain binder—that is, the first harvester of the Marsh type to carry an automatic bundle forming, compressing and tying attachment—appeared in 1870, and was known as the Locke machine. At last the tedious process of binding

BY COURTESY OF THE INTERNATIONAL HARVESTER COMPANY
THE MCCORMICK TWINE BINDER OF 1881, ONE OF THE FIRST HARVESTING MACHINES FOR THE AUTOMATIC BINDING OF WHEAT

sheaves by hand was doomed, and the importance of this development in history of agriculture can hardly be overestimated. Attachments using twine as the binding material, and some using wire, followed quickly. About 1878 the famous tying device known as the Appleby knotter appeared. It has become the standard tying mechanism of nearly all modern grain, rice and corn binders. Thus, the grain binder was the result of 40 years of struggle in which some men lost fortunes while others became prosperous. The grain binder is the product of no one man; it is the culmination of many ideas, only the fittest of which could survive.

Although combination harvesters and threshers had been thought of as early as 1826, it was not until about 1875 that the "combine" came into use, and then it appeared in the vast wheat fields of the Pacific coast states. These were large machines, drawn by from 12 to 30 horses, cutting a swath of grain from 16 to 24ft. wide, and threshing, cleaning and sacking the grain in one trip over the field.

In 1875, largely through the activities of the Haworth brothers, automatic check-rows for planting corn became practical. The dropping mechanism in these machines was operated by regularly spaced buttons on a wire stretched across the field, instead of by an extra man on the planter. Thus one man, and the previous operation of marking off the field, were eliminated from the planting process. In 1876 manure spreaders of the wagon type were developed to the practical stage. About the same time ensilage cutters, or silo fillers, and disc ploughs appeared, the latter, however, did not become commercially practicable until about 1890. Although stationary steam engines, and steam engines on trucks which could be hauled from place to place, had been used previously, the self-propelled steam traction engine did not appear in agriculture until about 1880. This was the forerunner of the modern tractor. In 1884 three-wheeled sulky and gang ploughs were developed; these were of high-lift design and the prototype of the modern riding plough used so extensively in both the United States and Canada. About 1885 a combination machine for husking corn and shredding the stalk made its appearance.

The fifth period in American agriculture, 1887 to the present time, began with the practical exhaustion of those public lands in the United States which could be converted easily and cheaply into quick producing farms. Since 1887 agriculture has been settling down to more intensive cultivation accompanied by improvement in farms and the subsequent rise in land values. (The same tendency is in evidence in Canada, though there the cor-

responding periods are from ten to twenty years later.) Obviously, attempts to intensify and diversify agriculture involved machinery and implements in no small way. Increasing land values must sooner or later force a greater return per acre; this is possible by increasing the production per acre or by lessening the cost of production, either one of which involves machinery and power.

The period opened with many of the most fundamental types of agricultural machinery well established. Minor improvements continued in all classes of implements. Sled corn harvesters, corn binders, and side delivery rakes to facilitate loading hay with hay loaders, came in early in the period. These were great labour savers. Inasmuch as one man with three horses on a two-row cultivator can cultivate 90% more acreage per day than one man with a single-row machine, it was only natural that attention should be given the two-row cultivators which began to appear early in the '90s. About 1890 the Babcock device and system was developed for determining the butterfat content of milk and cream. The Babcock test helps the farmer cull the unprofitable cows from his herd. Cream separators appeared about 1890, and a great labour saver—the milking machine—came into use about 1910.

Among the early attempts to adapt the internal combustion engine to farm work no efforts stand out more prominently than those of Hart and Parr, two young men who developed very satisfactory, stationary, gasoline (petrol) engines as early as 1896. A little later they conceived the idea of mounting a gasoline engine on a truck, and gearing the two together so that the combined unit would propel itself. In 1902 these men built such a machine and proved that the gasoline engine could be used for haulage purposes. A new industry—the great modern tractor industry—was born. Manufacture began almost immediately by several companies, and within nine years a large number of tractors were ploughing, harrowing, seeding and threshing in those regions of the United States and Canada where the farms and fields were large. These early tractors were large, heavy and somewhat crude. Being able to develop 30, 40 and sometimes 50 horse power at the draw bar, they pulled six, eight, ten and twelve-bottom ploughs, or large combinations of soil preparation and seeding implements. One single ploughing outfit, consisting of three large tractors pulling a so-bottom plough, once demonstrated its ability to plough an acre of ground in 43 minutes. The advent of the large tractor called for ploughs of size not known before, but manufacturers were quick to respond with the big, multiple-bottom gang ploughs of the independent lift type in which each bottom or each pair of bottoms raised and lowered independently of those adjacent. Larger, heavier disc harrows, and wider grain drills also were developed for the new "brute."

The tractor had demonstrated its ability to get work done quickly with a minimum of human labour, and, in farming, getting work done when weather, crop or soil is right is a decided advantage. The old heavy tractors, however, required considerable outlay in cash, and they were too unwieldy for practical use except in large fields. About 1910 the power farming idea had so thoroughly gripped agriculture that suddenly a demand for small tractors developed from farmers on smaller tracts, and many of the old manufacturers, together with a great number of new tractor concerns, began bringing out smaller tractors. This tendency to cut the size, power, weight and price continued until the light tractor of 8-16 and 10-20 horse power came onto the market about 1916 and brought with it the light, two-wheeled tractor plough which was quite an innovation in plough design. The light tractor and light plough, selling at prices which made their use economical on small farms, introduced power farming onto thousands of farms in both the United States and Canada which could not have enjoyed its advantages had not smaller, cheaper units been made available. Likewise, small sizes of grain threshers, of ensilage cutters and of feed grinders became popular because the presence of the small tractor on the farm enabled the farmer to perform these respective operations himself instead of having to depend upon the custom outfit which previously had passed from farm to farm doing belt work for hire.

Another major development in the current period of agriculture

is the mechanical corn picker. Such a machine was talked of in 1851; some were built and successfully operated about 1910, but not until about 1920 did it really start to take its place in the corn belt. Likewise, rotary hoes, for rapid corn cultivation, were in 1928 just beginning to become popular, although they had been on the market for 20 years. A new machine of importance to the sugar cane industry is the mechanical harvester which cuts, strips and bunches the cane in one operation. This is a big, expensive machine, but, when finally perfected, it will be a great labour saver.

Present Position.—Inasmuch as we are now in the midst of tendencies and developments in agricultural machinery which promise far reaching effects, it is well to consider the period since 1925 separately. Thus far the farm tractor has functioned well for ploughing, harrowing, seeding small grains and for belt work. The conventional type of tractor, however, has not been so well adapted to mowing and raking hay, or to planting and cultivating row crops. In such work not so much power is required; quick guiding and short turning are necessary, and the implement elements which perform the work must be so placed that the operator can readily see their action and easily manipulate them. What agriculture needed was a light tractor, perhaps of special form, which, in addition to ploughing, harrowing and doing belt work, could serve as a base for the quick attachment and detachment of such implement elements as an eight-foot cutter bar for mowing, a rake, hoppers for planting four rows of seed at once and cultivator rigs for cultivating those rows. Since 1925, general-purpose tractors of this type have proved successful and are becoming very popular. They are bound to have considerable influence in several kinds of farming and probably will cause rather marked changes in implement design. Another tractor development of importance is the power take-off, a device and system by which the tractor can drive directly the working parts of the grain binder, corn picker or combination harvester-thresher.

To-day the farmer of 200 acres can have his 15-30 horsepower, conventional type tractor for the heavy field and belt work; then he can resort to his general-purpose tractor for the lighter field and row crop jobs. The farmer of a tract too small to support two tractors can use his general purpose tractor for all tractor jobs. Either of these farmers can have a motor truck to haul

BY COURTESY OF THE J I CASE THRESHING MACHINE COMPANY

THE MODERN TWO BOTTOM TRACTOR-PLOUGH, FOR USE ON SMALL FARMS. DEVELOPED FROM THE BULKY 8 AND 12 BOTTOM TRACTOR-PLOUGHES THAT REVOLUTIONIZED THE FARMING INDUSTRY IN 1902

his produce to market, and both are sure to have an automobile. Thus, except in the poorer agricultural regions and in extremely hilly country, the slower methods by horses have received a severe setback.

The old process of loading manure by hand may give way soon to the mechanical manure loader now being developed. Mechanical shockers are on the market; they promise relief in the back-breaking task of shocking grain after the grain binder. Another development, however, threatens the grain binder. Since 1925 it has been found that combination harvester-threshers can be used successfully for small grain and soy-beans grown in humid regions, and several of these machines have been sold in the north central states, in western Canada, and even to a few large farms in the

eastern states. The appearance of this great labour saver in the smaller wheat fields of the upper Mississippi valley has been somewhat of a sensation. There, of course, smaller machines are used, the ten and twelve foot size now being most popular. The use of the "combine" means a saving of approximately 20 cents a bushel in the cost of raising wheat. The combination harvester-thresher is introducing another machine, the windrow-harvester, as an accompaniment to the "combine" in territories where uncertain weather, uneven ripening or the presence of a heavy growth of weeds require that the cut grain lay in the windrow a few days previous to threshing. The windrow-harvester, tractor drawn and tractor driven, cuts a wide swath of grain high, and lays it in a windrow on top of the stubble. After the material has cured, the "combine" is used to pick up and thresh the windrows.

From the standpoint of cost of production, a mechanical means of picking cotton has been needed and sought for many years. Not until quite recently, however, have efforts to produce a practical device been successful enough to promise early relief. One type of cotton picker consists of a number of revolving spindles which pluck the cotton by wrapping it about them as they turn; the spindles then recede to a cleaning chamber where the cotton is removed ingeniously, and the spindles automatically return to come in contact again with the plant. The action is continuous as the machine straddles the row. Such pickers, although they are not quite to the manufacturing stage, seem very promising for territories where uneven ripening necessitates several pickings. Where killing frosts occur before picking time, as in north-western Texas, manufacturers are now marketing cotton strippers. These strip the cotton from the plant, and are much simpler and cheaper than the typical, mechanical picker. This method of harvesting has become practical only since improvements in ginning machinery have made it possible for the ginner to handle the great amount of trash and bolls which the stripper gathers. Since 1921, renewed attention has also been given to the application of electricity to agriculture. For this see ELECTRICAL POWER IN AGRICULTURE. As to the farm home, one need only liken the application of electricity there to that in the most modern city dwelling.

From this brief historical sketch we see that through the introduction of agricultural machinery and implements the muscular exertion of farm work was slowly shifted from man to beasts of burden. These in turn have been displaced by mechanical power units and by more machinery until to-day, comparatively speaking, agriculture seems well mechanized. The same is true in all industry; but the benefits of the transition in farming are especially significant because in agriculture there is more primary horsepower involved than in all manufacturing and mining combined. With the cheap fertile lands of the United States and Canada largely utilized, with fertility being depleted, with the population increasing rapidly, more intensive agriculture that will increase production per acre seems sure to come. But, again, this involves machinery in no small way if increased production is to be had without marked increase in costs. If the farmer is to maintain his standard of living, and at the same time successfully meet competition in the world's markets, he must pay increasing attention to the many phases of agricultural machinery and implements.

Manufacturing.—As indicated in the table, taken mostly from United States census reports, the value of machinery and implements on farms has increased rapidly until to-day it aggregates a large investment. It is to be noted, too, that capital used in the manufacture of agricultural machinery indicates an extensive industry.

Between 1900 and 1910, several large combinations of manufacturers were effected in order to pool interests, to secure "full lines" of merchandise, and to lessen the expense of development and sales work. This introduced a new era in the manufacture and sale of farm equipment. The manufacturer's problem to-day is not one of new developments alone. The merchandising of farm machinery and simplification of types are also vexing problems, and in these the manufacturer is handicapped by the farmer

Year	Value of machinery and implements on farms in U. S. A.	Manufacture of Farm Machinery

himself. Developing and introducing a new device calls for peculiar talent and is often a greater task than simply patenting the idea. In addition to commending the thousands of inventors who contributed to the development of agricultural machinery, much credit is due also to such men as McCormick, Deering, Osborne, Wood, Deere, Parlin, Emerson, Noyes, Brown, Adams, Steward, Oliver and a score of others, the pioneers in manufacture.

AGRICULTURAL ORGANIZATION. In most countries a growing realization of the weakness of the isolated farmer as a marketing unit and, again, of the dominance of industrial and commercial interests in modern legislation has prompted the formation of farmers' organizations, in order to secure more adequate consideration of the position and needs of agriculture. The conditions of food scarcity brought about by the World War stimulated this movement. (See AGRICULTURE.) Governments were obliged to deal collectively with the primary food producers, who on their side were forced into combinations to secure that the necessary regulations neither impeded production nor imposed an impossible burden on the farmers. Combinations for marketing are dealt with elsewhere (see AGRICULTURAL CO-OPERATION); and the organizations here to be considered aim at uniting the farming community in order to influence legislation.

Further, since it has become clear that the status of the food producer can with difficulty be determined within the nation itself, considerable effort has been given to the formation of international associations which might be able to secure common action in the interests of agriculture. It is recognized that as regards the great staple articles of food, wheat and the other cereals, meat and dairy products, a common world price tends to be set, determined by the incidence of the exportable surpluses from the countries producing more than they consume, upon the chief open markets, e.g., Great Britain. For example, the United States produces a certain excess of wheat beyond its requirements, which has to be exported chiefly to Europe. The price the American farmer will receive will be forced down by competition to the price obtainable in Europe less freight and commission. This is, to take an analogy, the pressure generated by internal competition to sell, at which the safety-valve blows off. The coincidence of other surpluses upon the European market or weakness in purchasing power there tends to lower the price; conversely the growth of a new demand, as from China and Japan, will enhance the price.

The tendency of commerce is generally to bring the run of prices of agricultural products, the output of which fluctuates from causes beyond control, continually down to the level caused by a surplus anywhere, a level which is on the average undesirably close to or even below the cost of production. Hence a general depression of the agricultural interest all over the world and an increasing tendency on the part of farmers to seek more remunerative occupation in industry or commerce. This is the justification for the attempts to create some international organization of farmers, however remote and impracticable common action may seem.

National Organization.— Examples of the type of national organization which aims at influencing legislation are the National Farmers' Union of Great Britain, the Farm Bureaus Federation and The Grange in the United States, and the Union Suisse des Paysans, but parallel organizations exist now in most countries.

The National Farmers' Union was only founded in 1908 and grew comparatively slowly until 1917, when it became necessary for agriculturists to have one organization to deal with the Government on behalf of the farmers engaged in the campaign for the increase of food production. It is organized on a basis of county branches, each of which makes an allotted contribution to the central body; only men actually engaged in farming are accepted as members. By 1927 the membership had reached 130,000, farming an area of some 12,500,000 acres. A similar Society exists in Scotland.

One of the most notable organizations in Europe from the point of view of the influence it has been able to exert is the Union Suisse des Paysans of which Dr. E. Laur is the director.

Its membership includes nearly all the farmers in Switzerland, though the only figure available, 402,000, is the sum of the members of all the affiliated societies, and the same individual may be a member of several of these simultaneously. It enjoys a subscription income of upwards of 100,000 francs a year. The oldest of the organizations in the United States is The Grange, or Patrons of Husbandry, which was founded in 1868 for educational and social purposes. Later it became active in political life and in organizing marketing agencies.

More recently the Federation of Farm Bureaus grew up among the Farm Bureaus which were initiated for educational purposes by the County Agricultural Agents. It is now a widespread and active organization, exercising considerable influence both as regards marketing and legislation.

International Organization.— The International Institute of Agriculture, the original conception of which was due to the late David Lubin, though it took shape on the initiation of the present king of Italy, began operations in 1910. Its constitution is determined by treaty between the contributing States, and it is governed by a president and a permanent committee acting as the executive authority to carry out the instructions given by an assembly representative of the constituent States, sitting every two years in Rome, where the Institute has its permanent home. The representatives at the assembly and on the permanent committee are nominated by the respective governments; thus the Institute is essentially a governmental organization, in which agricultural associations as such have no part. The work of the Institute has always been of a technical character. It prepares an annual summary of the agricultural statistics of all countries and a digest of agricultural legislation; it also issues bulletins at regular intervals which abstract the papers appearing in the technical publications of the world on economic and scientific subjects connected with agriculture. The Institute also convenes from time to time international conferences on particular questions. In order to obtain an expression of international agricultural opinion that shall be independent of governments the Institute has formed an association of representatives of agricultural associations of all countries, and the first meeting of this body was held in Nov. 1927. The associations to be invited to send representatives are, however, nominated by the governments of the respective countries. It has been urged that the international body which is to express the considered opinion of agriculturists must be independent of all governmental control or direction, especially as regards the nomination of representatives or associations to be represented.

To this end the Commission Internationale d'Agriculture, a body founded in 1891, of which the chief task was the organization of the successive International Congresses of Agriculture, has been reconstituted to consist of representatives of agricultural associations (not exceeding six for each country) and of co-opted members of distinction in agriculture, which latter may take part in the discussions but not vote. While the Commission meets twice a year in Paris, the resolutions that are to be communicated to governments are reserved for discussion at a conference to be held every second year in connection with the International Congress of Agriculture, of which conference only the elected representatives of the associations are members.

On the formation of this Commission, which held its first meeting in Rome in 1927, various other proposals for the establishment of an international association of agriculturists, e.g., that initiated by Dr. Laur of Switzerland, were dropped. Eighty associations from 22 different countries including all the European States except Great Britain and Italy, have adhered, and the Commission has entered into relations with the League of Nations and the International Institute of Agriculture at Rome. The Commission may be regarded as possessing the best title to express the considered opinion of the agriculturists of the world, and it may be hoped that it will also be accepted as the Conference of Associations working with the International Institute at Rome.

(A. D. H.)

AGRICULTURAL PRICES. In the early stages of English agriculture the mass of producers were content to satisfy

their own wants and were practically indifferent to outside trade. Later, however, the need arose for some machinery for bringing buyers and sellers into touch, and this was met by the institution of fairs and markets held at fixed places and periods. These in the first instance no doubt arose spontaneously, but it speedily became apparent that the holding of a fair or market in a town could be made a source of profit to the burgesses, or if there were no sufficiently powerful organized community, to the lord of the manor. Thus arose a system of tolls on goods exposed for sale in the market. The Crown, exercising its authority as overlord, saw at once an opportunity of revenue and claimed and exercised the right to forbid the holding of a fair or market except under royal charter, which was granted on terms. Tolls and regulations of the market would tend to raise the price level, but the effect could only have been slight.

A more serious effect on agricultural prices was caused by legislation against the practices of badgering, forestalling, engrossing and regrating, which was passed in the early part of the 16th century and did not disappear from the statute book until late in the 18th century. The purpose of this legislation in restraint of trade was to protect the consumer from trade practices which were presumed to raise artificially the price of food. A "badger" was a dealer in food who bought in one place and sold in another. He was licensed for a year and was under recognisances against forestalling, engrossing and regrating. "Forestalling" was purchasing food on the way to market with intent to sell it at a higher price; "engrossing" was attempting to control—in modern phraseology to "corner"—the market by buying up all the food for the purpose of exacting higher prices; "regrating" was the resale of food previously bought in the same market.

The State for many centuries intervened directly in the regulation of the price of wheat and bread. From the Norman conquest to the reign of Henry VI. the exportation of wheat was prohibited, although in earlier times it had been common. Importation was unchecked, although there is no record of it until the 14th century. In 1436 an act was passed authorizing the exportation of wheat whenever the price did not exceed 6s. 8d. per quarter and in 1463 the exportation of corn was forbidden until the price exceeded that at which exportation ceased. Thereafter a succession of enactments were passed some giving a bounty on exports, others imposing a duty on imports, or adopting both methods under limitations of prices. In 1774 an act was passed permitting imports at a nominal duty of 6d. per quarter when the price reached 48s. and forbidding exports unless the price was below 44s. when a bounty of 5s. per quarter was given on exports in British ships.

Up to this time legislation had for its main object the interests of consumers while attempting also to have regard to the interests of producers, and also to encourage shipping. In 1791 the first of a series of acts was passed which, with increasing stringency, aimed mainly at protecting the interests of home wheat-growers, which continued until the repeal of the Corn Laws in 1846.

In the 13th century the Assize of Bread was established, by which the duty was imposed on justices of the peace of adjusting the weight, quality and price of bread to the current prices of wheat. The system was modified in detail from time to time, but continued in force until 1822 in London and until 1836 in the provinces.

Modern Methods.—In later times the establishment of great markets in the large centres of population did much to fix prices on the basis of general and not of local supplies. Many of the markets developed from local to national importance by reason largely of their position in relation to means of communication. Covent Garden is a notable instance. It was originally a place where growers of fruit and vegetables in the vicinity of London could dispose of their produce direct to retailers and consumers. The convergence in the metropolis of the main lines of railway made it a national distributing centre, serving, through various channels, all parts of Great Britain, and "Covent Garden prices" became the standard of values throughout the country.

The organization of commercial price-fixing on a national basis had, however, scarcely been completed when a new factor was interposed which speedily changed the basis on which price-levels

of some of the principal foodstuffs rested. Imported wheat, meat, cheese, butter and other kinds of agricultural produce were sent to the British markets in ever-increasing quantities. As they increased in bulk and improved in quality their influence became so great that prices in the wholesale markets were fixed on an international rather than on a national basis.

The most prominent instance of this modern development is to be found in the wheat trade, where imported grain, forming as it does about four-fifths of the whole supply, dominates British prices and determines the value at any given time, of British wheat.

Price-fixing arrangements in the wheat trade are highly organized. World's prices are practically settled at four great markets, viz., Chicago, Winnipeg, Liverpool and London, and so well adjusted and sensitive is the mechanism that fluctuations in one are immediately reflected in the others.

The question of the effect on prices of the system under which the world's wheat trade is carried on is debatable and has been, in fact, hotly debated. It has been contended that speculation in "futures" depresses the level of prices and thus injures farmers, and, on the other hand, that it raises the level and thus injures consumers. The subject has been investigated closely, and it appears, by comparison with the price records of other commodities, that, on the whole, the organized "futures" market tends to maintain a more stable level of prices, notwithstanding occasional fluctuations caused by gambling operators.

The "stabilization" of agricultural prices is advocated in some quarters, but no intelligible scheme has been produced which does not imply State control and an acceptance by the taxpayers of the risks of State trading.

Yearly, or seasonal, fluctuations of agricultural prices are, as already indicated, occasioned mainly by variations in the weather, but there are also cyclical changes which are the result of monetary causes. Periods of low prices react not only on agricultural products but on all other commodities, and a consideration of them requires a wider outlook than that presented by one branch of production.

Price Records.—Of the price of British wheat there are consecutive and fairly comparable records for nearly 300 years.

The average prices per quarter for each decennium since 1647 are as follow:—

	s.	d.		s.	d.
1647-56	52	8	1787-96	54	4
1657-66	51	4	1797-1806	76	9
1667-76	42	4	1807-16	91	0
1677-86	42	2	1817-26	67	0
1687-96	43	2	1827-36	56	1
1697-1706	40	1	1837-46	58	7
1707-16	47	7	1847-56	55	4
1717-26	36	3	1857-66	48	6
1727-36	35	8	1867-76	54	3
1737-46	32	10	1877-86	42	3
1747-56	34	9	1887-96	29	2
1757-66	40	9	1897-1906	28	5
1767-76	49	9	1907-16	37	6
1777-86	44	5	1917-26	61	10

The highest price for any single cereal year was 126s. 6d. in 1812, and the lowest 22s. 10d. in 1894. The highest price in the last decennium was 80s. 10d. in 1920, and the lowest 42s. 2d. in 1923.

Systematic records of food prices were begun by Sauerbeck in 1846 and the series is continued in the *Statist*. Similar records have since been started by the Economist and the Board of Trade. In 1904 the British Board (now the Ministry) of Agriculture began to collect and publish weekly a market report which includes prices of all agricultural products.

By the method of index numbers these records enable the changes in the prices of agricultural products to be compared with those in the prices of commodities generally. There was a fall in prices generally between the periods 1871-75 and 1894-98 which averaged 40%. In the period from 1894-98 to 1910-14 there was an average rise in the prices of all commodities of 33%. The changes in the prices of British agricultural products in these two periods are indicated in the table given overleaf:

	1871-75 to 1894-98	1894-98 to 1910-14
	Fall per cent.	Rise per cent.
Wheat	51	22
Barley	39	13
Oats	38	19
Potatoes	39	10
Pork	23	23
Beef	29	26
Bacon	25	29
Mutton	25	20
Butter	25	25

After 1914 prices of agricultural products, as of other commodities, rose rapidly under war conditions. Taking the period 1911-13 as the base, the average percentage rise in each year is shown below, the rise in the price of feeding stuffs and fertilizers being also given:

Year	Agricultural products	Feeding	Fertilizers
1915	27	37	15
1916	60	87	56
1917	101	174	96
1918	132	187	111
1919	158	168	115
1920	192	173	159
1921	119	81	120
1922	69	46	47
1923	57	36	23
1924	61	54	19
1925	59	52	14
1926	51	25	13

(R. H. R.)

United States.—The great rise in commodity prices caused by the World War and the consequent post-war decline had grave economic consequences throughout the world. One of the distinguishing features of that international price upheaval was that during the period of rising prices, agricultural prices advanced more, whereas during the period of falling prices they declined more than did other prices. The nature of this post-war price disparity can be well illustrated with the price changes that took place in the United States, where the effect of agricultural price depression was not limited to the business depression of 1921 and 1922 but continued as a political factor for years thereafter.

According to the indexes of the U.S. Bureau of Labor Statistics, commodity prices reached a peak in 1920. In that year agricultural prices were about 121% higher and non-agricultural or industrial prices about 141% higher than the average prices of the five year period, 1910-1914.

In the great price decline of 1920-21, non-agricultural prices dropped 74, but agricultural and farm prices dropped 88 points.

The sudden deflation in the value of the farmers' products affected all sections of the agricultural industry. Land values were high, many had purchased farms at high prices, burdened themselves with heavy mortgages and expected the high prices of 1920 to continue. On practically all farm-land taxes had more than doubled, and other expenses of production, such as wages and machinery, had also risen. When in 1921 prices crumpled to half or less of those prevailing in 1920, the necessity of meeting the fixed high interest and rent charges, as well as the high production costs, left very little, if anything, of income available for living expenses. Furthermore, the higher prices of goods bought by farmers reduced the buying power of the farmer still more. The low and inadequate farm incomes of 1921 and 1922 naturally also hurt those undertakings dependent on agriculture, such as country banks, country stores, fertilizer and implement agencies. As a result of many causes, partly domestic, partly foreign, agricultural prices did not recover materially in 1922. Between 1922 and 1929, first one farm commodity, then another, usually as a result of reduced production, recovered temporarily, but in the main agricultural prices remained nearer the pre-war prices than did the non-agricultural prices, and the costs of services represented by farm taxes and debt charges, throughout the

period 1921-27. About this agricultural and non-agricultural price disparity centred much of the discussion of farm relief. The removal of that disparity by raising the level of agricultural prices to that of industrial prices, creating a greater degree of stability in agricultural prices and giving farmers a larger share of the national income have been the objects of practically all proposals for farm relief, particularly the McNary-Haugen plan which came before the U.S. Congress in several modifications for four years. It was twice passed by both Houses in 1927 and in 1928 and twice vetoed by the President.

Briefly described, the McNary-Haugen plan of farm relief provided for the establishment of a Federal Farm Board with power so to buy and sell surplus farm products of the United States as to raise the domestic prices received by producers. The cost of operating the plan and any losses sustained in the sale abroad at prices lower than in the United States would be met by a fee known as an "equalization fee" collected at the central markets from mills, packers, etc., on all units of a commodity that entered commerce. In that way all producers would contribute alike to the cost of the plan, and all would share alike in the benefits of the difference between the advance in domestic prices and the fee collected, the advantage arising from the fact that far more would be sold in the domestic markets at higher prices than would be sold at lower prices abroad.

In its early form, as voted down by Congress in 1924, the McNary-Haugen plan aimed to equalize agricultural and other prices by setting up a Federal agency to buy and sell the surplus production of crops which were held to be responsible for maintaining agricultural prices on a low level. The general level of all commodity prices, which was then approximately about 150% of the pre-war level, was to be used as a standard. This price-ratio scheme was dropped in favour of a plan to make the tariff effective, the emphasis of the latter growing out of the belief among farm leaders that the stability of non-agricultural prices was the result of protective measures enjoyed by other groups, such as existing tariffs on non-farm products, the immigration-restriction law, aiming among other things to maintain high wage standards, and the Federal Reserve System aiming toward stability in finance and commerce. The emphasis on "making the tariff effective for agriculture" was not maintained in the later forms of the McNary-Haugen plan because a tariff could not effectively protect prices of the major export products such as cotton, tobacco and wheat.

As a substitute for the McNary-Haugen Bill, the New Congress of 1929 passed the Agricultural Marketing Act, which established the Federal Farm Board. This Board was authorized among other things to carry on stabilization operations, to buy surplus farm products in order to support market prices. Its operations in cotton and wheat were conducted at a most inopportune turn of business conditions which collapsed after 1929. The Farm Board sustained very heavy losses as agricultural prices fell to record low levels in 1932, and their average purchasing power fell to about half of that of the pre-war years. Under the new administration in 1933, the Agricultural Adjustment Act was passed, creating the Agricultural Adjustment Administration with power to levy processing taxes on domestic consumption of certain basic farm products, this revenue to be paid to producers entering into contracts with the Federal Government to reduce acreage and marketings as a means of reducing accumulated surpluses. As a result of operations under this Act, devaluation of the currency, other recovery measures, general improvement in economic conditions and severe droughts, farm prices advanced from the low point of 58% of the pre-war average in June 1932 to 131% in Jan. 1937.

During the three-year interval of industrial and agricultural collapse, Dec. 1929-Dec. 1932, wholesale prices of "all commodities" fell from 136% of the 1910-14 level to 91%. Farm product prices fell from 143 to 62 or nearly 60%. Prices of non-agricultural products fell only about 20%. This unbalanced price situation was corrected in Aug. 1936 when the general average of commodity prices returned to 119% of the pre-war level, and farm products at farms returned to 124% of the pre-war level.

Wholesale prices and farm prices continued to advance until Jan. 1937, after which both farm and non-farm prices declined

with a decline in business activity and a depression in economic conditions. The most significant development since the recession of 1937 has been the stimulus given to prices at the outbreak of the European war beginning Sept. 1939. The prices of agricultural products and of some non-agricultural products advanced sharply at the outbreak of the war in 1939. (L. H. B.; X.)

AGRICULTURAL RESEARCH. In its modern aspects agricultural research began with the series of field experiments started by Jean Baptiste Joseph Dieudonne Boussingault about 1834 on his farm at Bechelbronn, in Alsace. He had already made a name as an adventurous traveller in South America, but at the age of 32 he settled down to field experiments which he carried on until Alsace passed into the hands of the Germans. Unfortunately the farm was not preserved, and in consequence this first experimental station has long ceased to exist.

The scientific foundations had already been laid by the de Saussures, Jean Senebier, and other plant physiologists of the Geneva school and elsewhere, and considerable information had been gained by Sir Humphry Davy; but these results could not be interpreted in field terms without field experiments. Boussingault used quantitative methods; he weighed and analysed the manures applied and the crops obtained and at the end of the rotation drew up a balance sheet showing how far the manures had satisfied the needs of the crops, and how far other sources of supply, air, rain, and soil, had been drawn upon. This method, patiently and carefully applied, solved the problem of the feeding of crops, and it remains the basis of all modern field work. The facts gathered by this and other methods were reduced to order by Justus von Liebig in 1840 and subsequent years in his brilliant generalizations on plant nutrition and crop production.

In 1843 J. B. Lawes and J. H. Gilbert started their experiments at Rothamsted, which are still carried on, so that Rothamsted remains the oldest agricultural station in the world. These experiments led almost immediately to the discovery of artificial fertilizers, the effects of which on the soils of Britain were so striking that similar experiments were soon made in most countries where conditions were sufficiently settled. Although the results were not always as clear and definite as in Great Britain, the experiments opened the way to new knowledge of soils, crops, and animals; in the United States, where water supply is often the limiting factor in crop production, they led to important developments in soil physics; in France, to George Villes' important contributions on the use of fertilizers; in Russia, to far-reaching studies of soil morphology.

Soil bacteriology (*q.v.*) began in France as the result of an investigation by J. T. Schloessing and C. A. Müntz; further fields were opened up by P. E. M. Berthelot. Striking advances were made by Sergei Winogradsky, who introduced new conceptions and more precise methods, raising the subject to the rank of a science. Animal nutrition was studied first by Lawes and Gilbert at Rothamsted and then considerably developed in Germany. Right up to the time of the World War there was continuous expansion; agricultural colleges and experiment stations were founded in almost every civilized country, and notable contributions to agricultural science were being made not only in the larger but in the smaller countries, Holland, Denmark, Switzerland, Sweden and others.

Since the War there have been many and striking developments. Although impoverished, the European countries have maintained and even extended their organizations for agricultural research, and in every country except one or two in south-eastern Europe there are experiment stations owned and financed by the State; frequently also others financed by agricultural societies. Indeed, the belief of the modern farmer in agricultural education and research is one of the most hopeful features of the times.

The British Empire.—For many years the great self-governing Dominions have had their own agricultural research stations which have made notable contributions to agricultural science. The Canadian workers have achieved much in the production of new varieties of wheat, the farming of dry lands, and the development of agricultural machinery

The Guelph Agricultural college had been founded in 1873 but

it grew only slowly and in 1883 it had only nine graduates. Then came the awakening of Canada to the need of agricultural research. In 1884 a select committee was appointed by the Canadian parliament to study agricultural conditions and this committee recommended the establishment of an experimental farm. In 1887 this was done, and the farm was started near Ottawa under the direction of William Saunders. It has since grown out of all recognition and has now become one of the foremost agricultural experiment stations in the world. Branch farms were established in different parts of the Dominion, some of which, such as Indian Head (Sask.) and Lethbridge (Alta.), have by reason of their special conditions been able to carry out researches which could only with difficulty have been achieved elsewhere. The present director of the Ottawa station is E. S. Archibald, who succeeded J. H. Grisdale, the second director, in 1916.

Australia has, in Farrar's wheats and many field experiments, done much for arable farming and the solving of pastoral problems; still more recently the setting up, at Adelaide, of the Waite Agricultural Research Institute in 1923 under Dr. Richardson, and of the Department of Scientific and Industrial Research under Dr. Julius, have opened up great possibilities of future development. In New Zealand the Cawthron Institute was established at Nelson in 1915; South Africa has probably the largest and best veterinary research station in the world at Onderspoort under Dr. P. J. Du Toit. In India the large experiment station at Pusa was started in 1903 by the aid of a generous gift by Mr. Phipps, an American. In other tropical regions there have been very great developments. The Imperial College of Tropical Agriculture was founded in 1924 at Trinidad to give the training which could not be provided at home. The research institute originally founded by the Germans at Amani in Tanganyika has been restarted since the World War under the directorship of Dr. Nowell. The Wellcome Tropical Research Laboratories at Khartoum are maintaining and extending their studies of soils and micro-organisms, important in tropical conditions, and each of the African territories has its own agricultural officers. Perhaps even more significant, the growers are organizing and financing their own experiment stations on broad and generous lines that augur well for the future: the Rubber Research Institute of Malaya, inaugurated in 1926; the Tea Research Institute of Ceylon, inaugurated somewhat earlier, are examples. Altogether the progress of agricultural research in the empire in the post-War period has exceeded the most sanguine expectations.

Until recently, each of the separate parts of the empire conducted its own researches independently of the rest. In Oct. 1927, however, an imperial agricultural research conference was called for the first time and the first steps were taken towards co-operation and co-ordination so far as this might be possible. It was decided to set up bureaux in Great Britain, for soil at Rothamsted, animal nutrition at the Rowett Research Institute, Aberdeen, and animal health in London; also correspondence centres for plant genetics at Cambridge and Aberystwyth, fruit at East Malling, animal genetics at Edinburgh and agricultural parasitology in London; these are in addition to the already established bureaux for entomology and mycology; while a further object that they have is to keep in touch with all agricultural research workers in the empire, provide information, and generally give any further help in their power.

Great Britain.—In 1909, parliament set up the development fund at the instance of Mr. Lloyd George and assigned a capital sum of £2,000,000 for rural development, including agricultural education and research. The commissioners adopted a novel method of organization of research which has fully justified itself. Instead of setting up one or two large stations to deal with the whole body of agricultural science they made grants to certain existing institutions, each of which was to become responsible for one or more sections of agriculture. Of these institutions the chief are:—

Soils, plant nutrition, and plant pathology.

Animal nutrition.

Rothamsted experimental station.
Cambridge university.
Rowett Research Institute,
Aberdeen.

Plant physiology.	Imperial College of Science and Technology, London.
Plant breeding.	Cambridge university. University college, Aberystwyth. Scottish plant breeding station, Edinburgh.
Fruit.	Long Ashton, Bristol. East Malling, Kent.
Glasshouse industry.	Cheshunt, Herts.
Animal breeding.	Edinburgh university.
Dairying.	Reading university.
Animal pathology.	Cambridge university. Royal Veterinary college, London.
Agricultural parasitology.	Scottish Animal Diseases Research Association. London School of Hygiene and Tropical Medicine.
Agricultural economics.	Oxford university.
Agricultural engineering.	Oxford university.

The amounts expended on agricultural research in Great Britain have increased continuously since 1909, the original development fund having been substantially increased when the Corn Production Act was repealed and the State commitments were commuted by the grant of £1,000,000 which, at the request of the farmers themselves, was devoted to agricultural research and education. In 1926 the grants amounted to £329,705, including £60,000 advisory, £9,231 rural industry, and £23,700 Scottish grants. The total research grant for England and Wales was therefore £236,774. Besides the State funds, grants are periodically made to institutions by the agricultural societies.

The United States.—Agricultural research began early in the United States. On Feb. 26, 1791, there was held at the senate chamber, New York, "a meeting of a respectable number of citizens" which established a society for "the investigation of agriculture, manufacture, and arts, with such subjects of enquiry as may tend to explain or elucidate their principles." In 1842 a successor, the New York State Agricultural Society, began the publication of a series of reports, some of which, dealing with the design of the plough, are among the best that have yet been written on the subject. Faith in agricultural education in the United States was so great that even during the anxious days of the Civil War Senator Justin S. Morrill, of Vermont, was able to persuade the legislature to adopt the Act which bears his name, and which was signed by Abraham Lincoln on July 2, 1862, this established in each State a college of agriculture and mechanical arts that often developed in conjunction with a State university. Information regarding the agricultural colleges in the United States and their work will be found in the article AGRICULTURE IN THE U.S.A.: *Experiment Stations*.

The Federal Department of Agriculture, created by an Act of Congress and signed by President Lincoln in 1862, is the most extensive agricultural research agency ever established, its work covering every field of agriculture and rural life affairs. Through its Office of Experiment Stations it has general supervision of the State Experiment Stations, with which it carries on a large number of co-operative investigations. Its great research bureaus expend over ten million dollars a year in fundamental investigations in addition to about the same amount expended by the Experiment Stations, making a total annual expenditure for research of over twenty million dollars. Recent estimates of financial returns for these expenditures published by the United States Department of Agriculture show that each dollar thus expended yields an annual return of over five hundred dollars. This explains in part the increasing support given to this type of work. There are also a certain number of private establishments. Some of these have become merged in the State institutions, such as the experiment station at Storrs, Conn., which, founded as an agricultural school, became a college and then, through the activity of one of its most distinguished members, Atwater, an important centre of research. Of the newer institutions which still retain their indi-

viduality perhaps the most notable is the Boyce-Thompson, founded in 1924.

Enormous sums of public money are expended in the United States on agricultural research. In 1925 and 1926 the amounts included:

		1926
Federal Funds	\$10,000,000.	\$10,300,000.
Hatch, Adams and <(in 1926) Purnell Acts	1,440,000.	2,400,000.
State appropriations	5,827,871.	6,000,000.
	\$17,267,871.	\$18,700,000.

In 1927 the total spent was \$21,000,000.

Some of the experiment stations are in receipt of large total incomes: in 1925 Ohio received \$736,164 and California \$665,861. But great as these sums are, they represent only six cents per acre per annum of the cultivated land in the United States and thus they are relatively not much greater than the expenditure in Great Britain, which represents four cents per acre; per \$1,000 of farm produce obtained each year the United States spends on research \$2.50 while Great Britain spends \$1.40.

France.—To France, as already described, belongs the honour of having begun the first field experiments. The college of agriculture at Grignon, founded in 1827, continues its activities. George Villes' experiments from 1848 to 1863 were made at Vincennes; Grandeau's at the Station Agronomique de l'Est founded at Nancy in 1871 and still associated with soil investigations. The experiment station at Montpellier is associated with vine investigations and with the soil studies of Delage and Lagatu. The chief organization in Paris is the Institut Agronomique; but the Institut Pasteur, although not an agricultural body, carries on researches in plant physiology and microbiology of great importance to agriculture, supplemented by the work at its sub-station at Brie-Comte Robert. It is hoped at an early date to develop a great national institute for agricultural science near Paris.

Germany.—Although the agricultural college of Hohenheim was founded as far back as 1817, there was no experiment station till 1851, when one was started at Möchern in Saxony under Emil Wolff. Others were set up later; at Munich in 1857, where much work was done on soils, and at Popplesdorf, where there had been an agricultural high school since 1847. There was a rapid expansion after the federation of the German States in 1871; in 1861 there had been only nine stations, but by 1881 there were at least 53. Most of these were attached to universities and under close Government control; they were also charged with certain responsibilities in regard to control of fertilizers, feeding stuffs, seeds, etc. Some, however, were under the agricultural societies. In 1888 the association of experiment stations was formed for the purpose of securing uniformity in methods of investigation and inspection of these various articles.

By 1914 the German experiment stations had much further increased, both in number and in size, and had attained great repute all over the world. There has, however, been some change in subject matter; much more attention is now devoted to fertilizers in consequence of the enormous strides in the output of synthetic nitrogenous compounds. Among the larger State institutions are those at Halle for animal nutrition, agricultural chemistry and microbiology; at Königsberg i. Pr., Bonn-Popplesdorf; Landsberg (Warthe) for soils, plant nutrition, animal husbandry, and plant pathology; at Bremen and Landsberg for moor culture; at Breslau, Hohenheim and Göttingen for agricultural chemistry and bacteriology; at Berlin and Leipzig (Möckern) for many branches of agricultural science. In addition to these, there are great private institutions owned respectively by the nitrogen syndicate, the potash syndicate and the superphosphate manufacturers' association.

Russia.—The Russian experiment stations have been completely reorganized since the revolution. Those best known to the outside world devote much of their time to soils; those deserving mention are:

Perrn	University biological Station
Voronezh	Agricultural institute
Gorki (White Russia)	Agricultural academy

Leningrad.	Dokuchaiev Institute of Soil Science. State Institute of Experimental Agronomy.
Moscow.	Scientific Institute of Fertilisers.
Kazan.	Forestry and Agricultural Institute.
Saratov.	Institut für Landwirtschaft und Melioration.
Ukraine.	
Kiev	Forestry and Agricultural Institute.
Odessa.	Agricultural Institute.

Holland.--Of the smaller countries Holland deserves special mention because of the admirable research work carried out in Dutch East Indies at Buitenzorg in Java, the experimental gardens and station of which are models of efficiency and activity. The results are published in *The Bulletin of the Botanical Garden*. In Holland itself there are several well-known stations, the largest of which is at Wageningen, known, among many other things, for the work of Quanjér on plant pathology, Hissink in soil, and others.

Italy.—Italy possesses agricultural stations at Rome, Pisa, Turin, Portici, and elsewhere: the scientific results are published in *Le Stazioni sperimentali agrarie Italiane*.

Denmark.—Serious agricultural research began in Denmark after the termination, in 1864, of the war with Germany. The Danes sought, in the words of one of their distinguished statesmen, "to gain within their borders what they had lost without," and they proceeded to intensify their agriculture, developing a system which has become the admiration of Europe. One of the first stations to be set up was the veterinary and agricultural high school in Copenhagen, which from 1860 onwards published a series of admirable reports on the feeding of farm animals. As it expanded it covered other subjects of agricultural importance. Since the war agricultural research has developed considerably in Denmark. The method has been to set up a number of stations, each dealing with specific subjects; at the same time to establish field experiment stations in various parts of the country, all these being directly under the State. The veterinary college remains the centre for animal husbandry, forestry, and horticulture; it is, however, primarily a teaching institution. The more important of the newer research stations, which may be regarded as offshoots from Copenhagen, are at Lyngby and Hillerød, North Seeland.

Practical Results of Research.—The chief characteristic of the work of the experiment stations in recent years has been the tendency to joint investigation. Not only have stations in the same country combined to carry out a programme of work, but even stations of different countries. In the western United States and Canada there is a combined programme of investigation on wheat rust. In Europe the chief soil investigators have co-operated with those of Great Britain in devising uniform methods of soil examination and soil mapping, under the aegis of the International Society of Soil Science. The International Institute of Agriculture at Rome has brought together the investigators concerned with fertilizers, with the view of drawing up uniform methods of studying the action of these substances on the plant and on the soil.

Much of the knowledge recently gained at the experiment stations can be appreciated only in relation to the whole subject with which it is concerned, and is therefore dealt with under the proper headings. Some of the outstanding results are, however, referred to here. In the study of soils the most important advance has been in the knowledge of the changes taking place when salts are added to the soil. In principle the changes are simple, being merely the usual exchange of bases and acids; the consequences of these changes, however, are often far-reaching and they have been found to explain many of the phenomena of acidity and alkalinity, and also the deterioration of irrigated land. These phenomena were always taken to be quite independent, but now they seem to be closely related. With fuller knowledge of the causes the possibility is opened up of designing effective methods of treatment. A better knowledge of soil biology is opening up a new chapter in the field of soil formation and fertility.

Great progress is being made in the field of soil amendments and fertilizers, especially as regards the use of concentrated fertilizers.

Another striking development has been the recognition of the Russian work, which has been slowly developing during the last 40 or 50 years. This had been published in Russian and only briefly summarized in western languages, so that it remained inaccessible to western European and American students. In 1909 Dr. Glinka expounded some of this work to the European soil investigators assembled at the soil conference in Hungary, and in 1922 Dr. Waksman, at the request of the United States department of agriculture, translated many of the Russian papers into English. Soil workers then found a great mass of knowledge in regard to classification of soils, which was new to them. The basis of the Russian classification is that the soil type is largely determined by the environmental conditions; indeed it can be predicted once these are known. The recognition of this dependence has revealed the close relationship between climatic and orographical factors with soil type, which knowledge promises greatly to simplify the work of the soil surveyor.

Great advances are being made in the study of diseases of animals and plants, especially those carried by insects and mites, such as the tick fever, discovered by Theobald Smith of the U.S. Department of Agriculture, and the mosaic or virus diseases carried by plant lice and leaf hoppers.

In plant breeding efforts have been directed largely to the production of disease resistant varieties, disease playing an increasingly important part in limiting crop production. Rust in wheat still baffles the investigators, and, worse still, new diseases brought into the different countries sometimes spread with considerable rapidity and do much damage before resistant varieties can be found. The problem of immunity has been much studied but no satisfactory explanation is yet found, while the cause of the virus diseases remains as elusive as ever. In Canada a search is continually being made for new varieties of wheat with short growing periods more suitable to the short seasons of the northern parts. There has been a steady pushing up of the northern boundary of the wheat growing area, and no one now would venture to set definite limits to it. In crop production the most striking development has been the manufacture of synthetic nitrogen fertilizers, which is now so firmly established along broad lines as finally to remove the fear of world starvation expressed in Sir W. Crook's famous address to the British Association in 1898.

In animal husbandry there have been steady developments in the prevention of animal disease, the subject now being regarded as in a great part a matter of hygiene and nutrition. The discovery of vitamins is opening up new fields of nutrition in relation to growth and health of men and animals. Great attention has been paid to the mineral nutrients, lack of which has been found responsible for serious diseases in Africa and elsewhere. Deficiency of phosphorus is one of the most serious, but deficiency of calcium and possibly of iodine is also responsible for animal disease. Fortunately, the remedy can be found as soon as the causes can be diagnosed. Considerable progress has been made in the treatment of diseases by various sera. In dairying, great strides have been made in the production of clean milk.

In every country in the civilized world the economic situation in agriculture has been profoundly altered by the great advances made in our knowledge of the effect of temperature on agricultural produce. Research laboratories have been set up particularly for studying the effects of low temperatures, and refrigeration is steadily being reduced to an exact science. In the United States, particularly in the U.S. Department of Agriculture and the State Experiment Stations, much attention is now being given to economic and sociological research in reference to agriculture and rural life.

(E. J. R.)

AGRICULTURAL REVOLUTION, THE, a term indicating that period in history which witnessed the transition of English methods of farming from mediaeval to modern conditions. During the 18th century increasing knowledge and new inventions revolutionized both agriculture and stockbreeding. At the same

time the rapid growth of enclosures vastly improved the conditions under which farming was carried on. But it increased the resources of the great landowner to the extinction of the yeoman farmer, and thus an essentially progressive movement in agriculture brought much misery in its train. The expenses incurred by the enclosure movement, the subsequent rise in the value of land, reductions in agricultural establishments, the protective system of the corn laws, and the supplementing of wages from the rates (Speenhamland system [*q.v.*] 1795) raised prices, lowered wages and depressed a large section of the agricultural population to the level of paupers. (Cf. INDUSTRIAL REVOLUTION.) See also AGRICULTURE; COMMONS; CORN LAWS.

AGRICULTURAL SOCIETIES AND SHOWS. In British agricultural history there is no parallel to the enthusiasm which spread through the country during the last quarter of the 18th century. It spread downwards from George III., "Farmer George," who himself contributed to Young's monthly publication, *Annals of Agriculture*, started in 1784. The politicians, including Fox and Burke, the great landowners, such as the duke of Bedford and "Coke of Norfolk," all shared in the zeal and were excited by farming topics and busy with farming experiments. One of the results was the founding of the Board of Agriculture by Pitt in 1793. But the board was preceded by the birth of a number of local associations in different parts of the country. Among the earliest and more important were the Bath and West of England Society, founded in 1777; the Highland Society in 1784, and the Smithfield Club in 1798; and before the end of the century very many of the counties had founded organizations of one sort or another for the promotion of the art and craft of agriculture.

The chief activity of the greater societies was the holding of an annual agricultural show; and the annals of many such shows begin in the year of the society's foundation. But in this respect the board did not at once follow the example of the societies, and its popularity waned as agriculture became depressed. It was indeed dissolved in 1822, but in the year before its temporary extinction it held, at Aldridge's repository, the first national agricultural show. It was modelled on the many local shows, of which the oldest had already a history of 44 years. But the agricultural show, such as we know it to-day, may be dated from the formation of the Royal Agricultural Society at a later date.

The Royal Agricultural Society.—This society was founded in 1838 and received its charter in 1840, the year from which most critics date the rise of modern scientific farming, as fostered by the researches of Liebig and his British successors Gilbert and Lawes. The first show under its auspices was held at Oxford under the presidency of Lord Spencer. It was various in range and of considerable extent, though small in comparison with the shows of to-day. There were six classes only for cattle, three for sheep, one for horses, and one for pigs. The section for implements was considerable, and prizes were also given for essays on agricultural subjects, for skill in ploughing, and for the best farm in Oxfordshire. Since that day the scope of this show, as that of most others, has increased; and its form has been closely imitated in the British empire overseas and in foreign countries. Few contrasts in Britain surprise foreign visitors more than the magnitude and excellence of its agricultural shows, which are celebrated in a country that is regarded as overwhelmingly industrial, and are indeed superior to any in the world.

The great additions to the scope of agricultural shows in the 20th century were made, not only with the idea of promoting agricultural science, but also to increase the spectacular attractions, and so provide funds for the proper objects of the society. The modern royal show, which continues for five days, may occupy as much as 100 acres of land, and the machinery, much of it seen "in motion," is alone a great feature. Besides classes for almost all breeds of stock and of poultry, and in addition to forestry, educational and scientific sections, it contains pavilions or tents for the display of rural crafts, and for the work of the women's institutes. A flower show, usually both large and elaborate, is housed in a series of great marquees. A working dairy is seen in action several times a day. Lectures and demonstrations of many sorts are given at intervals, and every afternoon, except on the

opening day when the bulk of the judging is done, horse jumping and harness competitions are held in a spacious ring and draw large crowds.

The royal show has always been peripatetic, except for the years 1903, 1904, 1905, when it was brought to Park Royal, on the north of London, with disastrous results to its finances. The prevailing principle in the selection of sites is to visit populous districts more or less alternately with purely agricultural centres; and except when the weather has been unfavourable, it has generally been found that the money made at the crowded centres enables the society to bear the losses sustained in more strictly agricultural areas.

Several local shows are comparable with the royal, though rather smaller and of shorter duration. But similar variety of exhibit is seen in the shows of the Highland Society, of the Bath and West of England, the Welsh national show, the "Royal Counties," the "Three Counties" and indeed many of the larger county shows, notably in Lancashire, Yorkshire, Cornwall, Oxford, and Suffolk: Many of these, as well as the royal, attract large numbers of foreign buyers, especially from South America.

The history of most of these shows and societies was a history of progress, with some oscillations, till the years of depression in agriculture following the great prosperity of 1918 and 1919. It began to appear at this time that the shows were too many, and perhaps too elaborate. Though many societies remained abundantly prosperous—and such shows as those of the Suffolk, Lincolnshire, and Cornish societies were never better than in 1927, the year of the 150th anniversary of the earliest, a movement for the amalgamation of local and county shows now began as a result of the unsatisfactory agricultural conditions and a shrinking of many farmers and landowners from the expense of exhibiting. Though some contraction may be inevitable, yet the breed societies, more in Britain than in other countries, show no sign of degeneration, and are the backbone of the agricultural show. Elsewhere two of the largest agricultural shows in the world are held annually at Buenos Aires and in Sydney, New South Wales. Both have a generic likeness to the English shows and enjoy the same popularity.

Although as already recounted, the Royal Agricultural Society of England was nearly ruined by the experiment of holding its show in London, the great fat-stock shows, held in November and December, and the dairy show, held in London in October, have flourished progressively under urban conditions. Especially since dairying took the lead over corn-growing as the chief department of British farming following the World War, the annual dairy show has become a remarkable epitome of the science of dairying as of the quality of the dairy breeds of cattle. Of the winter fat stock shows the three that attract the best fat stock are held at Norwich, Birmingham, and the Agricultural Hall at Islington in North London. The Smithfield Club, which is responsible for the London show, was founded as the Smithfield Cattle and Sheep Society as early as 1798, and has always emphasized at its shows its original object to promote the supply and breeding of the best meat. (W. B. T.)

IN THE UNITED STATES

Agricultural Societies.—Educational advancement in agriculture has been marked by undertakings common to many localities. Agricultural societies came into being in the late 18th and early 19th centuries. The New York Society for the promotion of useful arts, though not confined to agriculture, was founded in 1766. The New Jersey society for promoting agriculture, commerce and arts was in existence in 1781. The Philadelphia society for promoting agriculture was established in 1785. In the following years the number of local, county and State agricultural societies increased rapidly and played an important part in initiating systematic instruction in agriculture. In 1792 the New York society published a volume of its transactions, and the Massachusetts society issued bulletins on agricultural topics. The holding of fairs in Cambridge was suggested to the Massachusetts society in 1801. In 1807, Elkanah Watson exhibited two merino sheep in the public square of Pittsfield, Massachusetts. This may well

mark the beginning of live stock shows, enterprises of no mean educational value.

The South Carolina agricultural society, organized in 1785, bought, in that year, a tract of land on which experiments were to be conducted. In 1792 the New York agricultural society provided funds to the trustees of Columbia college for the endowment of a professorship in natural history, chemistry and agriculture. The Philadelphia society received, in 1794, recommendations from one of its committees that the legislature of the State be requested to support agricultural education in schools and colleges. A grant of \$500 was made by the Massachusetts society in 1801 for the establishment of a professorship of natural history at Harvard college.

The Columbian agricultural society was founded at Washington in 1809. It was the forerunner of the U.S. Agricultural society, organized in 1852 at a convention of delegates from 12 State agricultural societies. During 1817-25 the allotment of State funds to county and local societies encouraged their extension. In 1819, State aid was provided in New York and Massachusetts. The latter State offered \$200 annually to every society raising and investing a fund of \$1,000. For larger investments the subventions reached a maximum of \$600. In the same year the legislature of New York appropriated \$10,000 a year for four years "for the promotion of agriculture and family domestic manufactures." The climax of rural organization was reached in 1820-25. Most of the country agricultural societies disintegrated in the following 25 years, largely as a result of the withdrawal of State aid. On the other hand, the State agricultural societies continued to flourish. By means of meetings, conventions, farmers' institutes, fairs, exhibits, demonstrations, bulletins and reports they exerted a profound influence on farm practices and served as important educational agencies. Later, many of them became State boards of agriculture and, later still, State departments of agriculture. As a national group they have developed common policies that directly affect educational and regulatory activities in the several States.

(X.)

Agricultural Shows.—Fairs and exhibitions have been an integral part of American country life for more than a century and have played an important part in the progress of agriculture. In the early colonial days it was the practice of the farmers at the close of the harvest season to take their farm products and fattened live stock to the village and display them there on the commons, primarily for sale or trade; but often such exhibitions were also motivated by a sense of pride and a desire to show the neighbours what had been accomplished in the way of producing a particularly fine specimen of animal or farm product. These occasions naturally developed into gala days for the community because of the opportunity they afforded rural people from widely separated districts to meet for recreation and social contact, and because the finish of the harvest found the people in a festival mood. From post-harvest sales and gala days of early times it was a natural step to the fair as it is known to-day, with its exhibits of fruits, vegetables, grain, live stock, and culinary and domestic science products, competing for prizes and ribbons, and the horse races, ball games, fireworks, and other amusement features added to help carry the expense of the event.

The first permanent fair association in the United States grew out of a cattle show inaugurated in Pittsfield, Mass., in 1810. By 1860 the agricultural fair was an established institution, practically every State and county of agricultural importance holding an exhibition in the autumn after harvest. Then came a time, about 1900, when amusement features, such as horse racing, outweighed the agricultural exhibits in importance, and the time of holding the fairs was determined more by the convenience of the racing circuit than by the agricultural factors. Fairs as agricultural institutions suffered and many counties abandoned them. More recently, however, there has been a general revival of exhibiting agricultural products, and many county fairs are assuming their original object. The State fairs are now permanently established and in general well-managed and prosperous institutions, giving sufficient attention alike to education, recreation and entertainment features to insure a well-balanced programme

and continued success. To-day there are county fairs, district fairs, State fairs, regional fairs including two or more States and national and international expositions of world-wide fame.

The first great show of more than local importance, known as the American Fat-Stock show, was established in 1878 by the Illinois State board of agriculture and was held annually in Chicago from that time until 1897. It was the outgrowth of the desire of a number of stock breeders and feeders, as well as men interested in horses and swine, to stage a show in keeping with the progress of the purebred live stock industry. The show was patterned after the famous Smithfield Club show in England and flourished for many years until political influence and inadequate support caused its failure in 1897. Three years later, the present International Live Stock Exposition was organized. It held its first show in Dec. 1900, at the Union Stock Yards in Chicago. It was founded largely through the efforts of a group of admirers of purebred animals which included such famous leaders as Robert B. Ogilvie, Mortimer Levering, William E. Skinner, Alvin H. Sanders, John Clay and John A. Spoor. Profiting by the experience of the old Fat-Stock show, the new organization laid plans for a great educational institution free from political favoritism. Following closely the ideals of the founders, succeeding directors have made the International the leading exponent of a great movement for the improvement of live stock and crops in America. The International has been held annually in Chicago ever since its organization, except in 1914 and 1915, when it was omitted on account of the presence of foot-and-mouth disease in the United States. Staged usually during the last week in November and the first few days in December, a time when all other fairs and shows have been completed, the International draws the year's prize-winning draft horses, beef-cattle, swine, sheep, grain and hay exhibits from the United States and Canada. The organization owns its own grounds, covering 500 paved acres. Joined to the many barns and other buildings housing the show stock is the amphitheatre, seating 12,000 visitors and enclosing a tan-bark arena 238ft. long. Here the finest live stock in North and South America are paraded before the eyes of leading judges of North and South America and Great Britain. Carlots of fat stock and individual dressed carcasses are exhibited. Standards have been set by this show. Year by year this institution has expanded until all major phases of American agriculture are embraced within its scope. While the display of breeding and fat live stock is still the cornerstone of the exposition, many educational and entertainment features have been added from time to time. The evening horse shows, including ponies, hunters and jumpers, saddle and light harness horses, have won world fame for the quality of the entries. The various State colleges have long been exhibitors of some of the finest live stock in all classes and the annual live stock judging contest for agricultural college students is of far-reaching importance as an educational feature. Within the last decade 1,000 or more farm boys and girls have attended the International annually as a reward for achievement in club-work in agriculture and homemaking. Classes for baby beeves and lambs raised and fitted for show by these young farmers have formed one of the new and important attractions, and the live stock judging contest, open to champion junior judging teams from every State, is another innovation. Interest in feeding, fitting and showing live stock is encouraged by a large class of awards for herdsmen, caretakers and other helpers.

While the International is the live stock classic of the year, there are other shows of great importance to the regions in which they are held. The exhibits at such shows are often on a par with those at the International, although they draw from a much more limited territory. Such shows as the American Royal Live Stock Show held annually at Kansas City, Mo., the Pacific International Live Stock Exposition at Portland, Ore., the Southwest Exposition and Fat Stock show at Ft. Worth, Tex., and the National Western Stock show at Denver, Colo., are important shows held prior to the International. From these it draws many of the winning animals. The great show of the East is the Eastern States Exposition held annually at Springfield, Mass., since its organization in 1916. Dairy cattle are the big feature of this show, although

there are always excellent classes of all breeds of beef-cattle, sheep, swine, light horses, hunters, jumpers and ponies.

The National Dairy Show is primarily a show for the advancement of the dairy industry, although some classes are held for horses. Its live stock exhibit consists of 1,000 or more of the finest dairy cattle of all breeds in America. It is by no means limited to the live stock end of the industry. Machinery and equipment for the creamery, the distributing plant and every other phase of dairy manufacture, form a large part of the attraction and add to the educational value of the show. The show was first held in 1906 in the Chicago Coliseum. The success of this first venture resulted in the organization of the National Dairy Association and the continued success of the show ever since. It is a much travelled show, having been held in Chicago, Ill.; Columbus, O.; Springfield, Mass.; Milwaukee, Wis.; Detroit, Mich.; Indianapolis, Ind.; St. Paul, Minn., and Memphis, Tenn. Another important dairy show is the Dairy Cattle Congress held annually at Waterloo, Ia. The National Swine Show is the leading show in the world of breeding swine and is devoted exclusively to this branch of the live stock industry. While in point of numbers it is often exceeded by some of the larger State fairs, no other swine show draws so many champions of the various breeds from all parts of the continent. It was organized by the National Swine Growers' Association primarily as a breed-promotion institution, holding its first show in 1916 at Omaha, Neb. It has also travelled, having at different times been held in Cedar Rapids, Ia., and Des Moines, Ia. In 1921 it moved to Peoria, Ill., where the association now owns its buildings and grounds.

Poultry shows have been held in the United States for more than 50 years. Thousands of shows of varying sizes are held annually, small towns and communities having their local shows and many State fairs having poultry exhibits also. Large State shows are held later in the season and are followed by regional or international shows. The leading poultry show is the Madison Square Garden Poultry Show at New York city, where it has been a regular event since 1870. Thousands of birds are exhibited in individual cages designed to show them to advantage. Pigeons, bantams, and every other variety and breed of feathered domestic fowl are included. The Boston Show was the first large poultry show in the United States, having been started in 1865. It is well balanced and in some respects is better than the Madison Square Garden show. Other poultry shows of nation wide interest are held in various cities.

There is scarcely a branch of the agricultural industry that does not have some show of more or less national scope. Special shows are held by rabbit breeders and fanciers, by kennel clubs and by organizations interested in bees and in song birds. There are shows exclusively for horses of certain breeds, for fruits and vegetables and for flowers. The Society of American Florists and Ornamental Horticulturists holds the National Flower Show at a different place each year. The International Flower Show is held annually in the Grand Central Palace, New York city. The American Orchid Society holds a large show, usually every other year, at Madison Square Garden. Countless other flower societies exhibit their new products in various local and regional shows. Obviously all these exhibits are of immense value to specialists as well as amateur breeders and growers in making progress in their profession.

Canada.—Approximately 500 fairs are held annually in Canada, most of them provincial or local. The most important is the Canadian National Exhibition at Toronto, Ont. Held usually in September, this show includes exhibits from practically every branch of agriculture and allied industries and emphasizes educational features. Of the 2,368 fairs held in 1927 in North America, with a total attendance of 39,468,000, none exceeded the Canadian National with its 1,870,000 visitors. No other North American fair owns buildings and grounds of greater value; its valuation is \$13,500,000, while that of its nearest competitor, the Ohio State Fair at Columbus, O., is \$5,000,000.

Another fair of note is the Royal Agricultural Winter Fair, patterned after the Royal Agricultural Show in England. It was first held in 1922 in the new coliseum on the grounds of the

Canadian National and has since grown rapidly. It is held annually in Toronto, usually in December, and limits its exhibits to live stock, grain and hay and other farm products. It draws its entries from the best herds and flocks and fields of Canada, the United States and other countries. Dominion honours for live stock are awarded here.

Other agricultural fairs of note are the Central Canada Exhibition, held annually at Ottawa, Ont.; the Calgary Exhibition and Stampede at Calgary, Alta.; the Old Winter Fair at Guelph, Ont.; the Provincial Exhibition, New Westminster, B.C.; the Quebec Provincial Exposition, Quebec, P.Q.; the Provincial Exhibition, Regina, Sask.; and the Great Eastern Exhibition, Sherbrooke, Province of Quebec.

South America holds many local or regional fairs and expositions every autumn, but the principal one is the Argentinian *Exposición Nacional de Ganaderia*, usually called the Palermo show. This exposition ranks with the leading live stock shows of the world. It was inaugurated in 1875, with but 18 head of horned cattle by the Argentine Rural society (founded in 1866). Its early progress was irregular and in some years no shows were held because of financial and other difficulties. With the growth of the live stock industry in Argentina and other South American countries it finally became established and is now held annually in the autumn at Buenos Aires, where the society owns grounds and buildings near the fashionable Palermo suburb. The Palermo show is principally a beef-cattle show. There are often from 1,000 to 1,800 head of Shorthorn bulls in the show rings. The Shorthorn classification is perhaps the most elaborate show-ring exhibit to be found in any live stock show in the world, there being as many as 29 classes, in which the animals range from junior yearlings to 3-year-olds. The great number of classes is due to the separation of the animals into groups differing in age by from 15 to 30 days, whereas in other countries most show classes are from 4 to 8 months apart in age. Another unique feature is the compulsory auction of practically all animals exhibited, the purchaser paying a selling commission of 6%. The commission rate is doubled if the owner buys back his own exhibit. The auctioning of the grand champion bull is the outstanding attraction and has become an event in the social season. A week or ten days is often required to complete the auction after the closing of the show. Besides Shorthorns, other breeds are shown in great numbers and in good quality, as are horses of both light and draft breeds, sheep, swine, poultry and other agricultural exhibits. Dairy cattle are also an important feature of interest. The exhibition grounds are beautiful and in perfect condition and the buildings are elaborately designed and well arranged around the show rings to permit all judging to be done in the open.

Two other important live stock shows in South America, both of which are held in Uruguay, are the National Live Stock and Poultry Exposition at Montevideo, and the Live Stock and Poultry Exposition at Salto. The exposition at Montevideo is under the management of the Rural Society of Uruguay and is largely a cattle show, but there are usually good classes of sheep, swine, dairy cattle and horses. The Salto show is principally a cattle show, the Hereford breed predominating.

(L. S. R.; X.)

AGRICULTURAL STATISTICS. Agricultural statistics have a vital, basic significance in a nation's social and economic welfare. The practical use of statistics of production, supplies, and movements of the products of agriculture has been highly developed by business and Governments. The world-wide depression, and the ensuing increased activity of Governments in aiding or controlling agricultural production and marketing, have added impetus to the further development and use of agricultural statistics. War emphasizes still further the fundamental national importance of maintaining adequate sources of information on agricultural resources, potentialities, and deficiencies.

The regular systematic collection of statistics relating to agriculture began early in the 19th century. Annual estimates of agricultural production were begun in France in 1815. In the United States, agricultural census taking began in 1840, and annual estimates of production in 1866.

In England it might be claimed that the first agricultural statistics were those collected in the 11th century in Domesday Book, which included a record of the use of all land then under cultivation. Gregory King estimated the use of land and the production of England at the end of the 17th century. But it was not until the 19th century that the State undertook, as an ordinary function of administration, the annual collection of statistical information about agriculture. In the early part of the 19th century spasmodic attempts were made from time to time in different parts of the country to collect agricultural statistics. In 1855 a committee of the House of Lords reported in favour of uniform and compulsory returns and in 1864 a resolution was passed by the House of Commons demanding the immediate establishment of a national system of agricultural statistics. No legislation was passed but the Board of Trade gave effect to the wish of Parliament and established a system of annual returns from every occupier of agricultural land of the acreage of crops and number of livestock on each holding. The returns were first obtained in 1866, and in 1884 they were supplemented by the collection of estimates of the year's yield of the principal crops. The responsibility for the collection of all agricultural statistics was transferred from the Board of Trade to the Board of Agriculture soon after its establishment in 1889.

The most systematic attempt to provide agricultural statistics by private enterprise was that made by Lawes and Gilbert in their calculations of the production and consumption of wheat in the British Isles. These were started in 1852 and continued annually until official estimates of the yield of wheat and other crops were begun 32 years later.

In many countries the field of agricultural statistics has been extended to include the collection of price data, estimating cost and income, and securing data relating to the occupiers of and the conditions of living on the land.

The International Statistical Institute and the International Institute of Agriculture have been influential in extending the systematic collection of statistics relating to agriculture in many countries in recent years. About 1930 an effort was made to encourage countries which had not developed systematic census taking, to take a census which could be co-ordinated with the censuses of other countries so as to obtain a more complete world-wide coverage of agricultural production. The most significant development in agricultural statistics in recent years is the use of current and historical data relating to prices, supplies, and economic conditions affecting the demand for agricultural products, to forecast or estimate probable prices in the market or the income from the products of the year. Such analyses are being used extensively in the U.S. and to some extent in other countries as a basis for formulating programs and policies relating to agriculture.

Systems of Collection.—Most of the larger nations, and many private business groups, maintain trained organizations and well developed methods for gathering agricultural statistics. In the U.S., the Department of Agriculture issues comprehensive regular, periodic, and special reports that are accepted by business generally as authoritative. The Department's monthly forecasts and reports on crops and markets are awaited by all major lines of business and are quite a material factor in determining business activities. These statistical reports are gathered and compiled by a trained staff. In addition the Department maintains specialized services throughout the country, such as those of grain inspectors at 135 shipping points and meat inspectors at packing centres. The quinquennial census also provides comprehensive data and serves as a valuable test-check.

There are a number of private agencies that supply agricultural statistics which are accepted as authoritative. These usually relate each to a specific commodity such as cotton, wheat, sugar, etc. Outstanding among such statistical organizations is Broomhall's, Liverpool, whose forecasts and reports on grain are standard market information throughout the world. The New York Cotton Exchange, and other large commodity markets maintain permanent statistical organizations to supply information on production and distribution.

Statistics of World Agriculture.—Nearly all countries are now signatories to the International Institute of Agriculture, Rome, which supplies regular monthly and annual reports and special studies on the major crops, livestock, and livestock products of the entire world, excepting chiefly U.S.S.R. and China, for which information is fragmentary. The Institute issues a monthly *International Review of Agriculture*, which contains official reports on conditions of agricultural production in nearly all countries, forecasts of crop yields, and size of harvests. The Institute's *Yearbook of Agricultural Statistics* is an annual summary of world agricultural production and, like its monthly reports, is printed in English and French.

The average annual production (1929-38) of four principal cereal crops in major producing areas is as follows, the figures representing millions of bushels:—

	Wheat	Rye	Barley	Oats
Europe	1,548.4*	896.7*	1,040.4	2,845.7
Canada, U. S. A., Mexico	1,074.7	46.7†	311.4	1,367.8
Asia	602.0†	16.2†	73.7	89.3
Africa	116.8	...	106.1	14.8
Argentina	229.4	...	246	57.9
Australia	168.3	...	8.1	20.5

*Except U.S.S.R. †Except U.S.S.R. and China. ‡Except Mexico.

Statistics of farm livestock are less complete than those of crops and are in many countries collected infrequently at irregular intervals. The following table shows approximately the world's totals of the principal meat animals in comparison with the human populations of the six great world areas.

	Population*	Cattle†	Sheep‡	Hogs‡
Europe	394,059,603	107,300,000	122,300,000	79,800,000
North and Central America	178,320,379	96,400,000	62,500,000	66,500,000
South America	88,317,266	105,900,000	97,500,000	31,400,000
Asia	1,100,744,644	268,900,000	110,400,000	96,900,000
Africa	151,912,731	60,100,000	98,500,000	2,800,000
Oceania	10,261,154	17,300,000	140,200,000	1,800,000

*International Institute of Agriculture, 1936 figures.
†U. S. Dept. of Agriculture, "Agricultural Statistics, 1938," averages for 1931-35, except U.S.S.R.

Unfortunately no statistics of any reliability are available for China (pre-eminently an agricultural country). The annual value of pigs reared in China must be enormous and cattle and horses are everywhere in evidence; but the unsettled state of the country since the Revolution has made records difficult to obtain.

The distribution of the animals and their relative importance as indicated by their density are shown in the following table:—

Country	Number of Livestock per 1,000 Hectares*			
	Horses	Cattle	Sheep	Pigs
United States	14.0	85.8	68.4	57.4
United Kingdom	45.6	363.6	1,091.3	181.7
Canada	3.1	9.5	3.8	3.9
Germany?	73.0	435.6	99.7	506.6
France	48.9	286.8	181.4	129.2
Italy	25.5	247.3	305.3	94.8

*1 hectare = 2.47 acres. †Figures for Germany do not include Austria or the Sudeten; do include Saar. ‡The figures for livestock are for 1938.

Statistics of British Agriculture.—The continuity and in some degree the comparability of agricultural statistics for the British Isles have been affected by political and administrative changes. For many years they were collected by the Board of Agriculture for Great Britain and by the Department of Agriculture for Ireland. In 1912 the Board of Agriculture for Scotland was established and took over the collection of statistics in that country. When Ireland was divided separate agricultural departments were set up for Northern Ireland and the Irish Free State respectively, so that there are (1940) four departments responsible for the agricultural statistics of the British Isles.

The acreage and production of principal crops in the United Kingdom in 1938 were:

Crop	Acres (Millions)	Production (Million bu.)
Wheat	1.9	73.3
Barley	2.4	141.7
Oats	1.0	42.2
Potatoes	3.7	76.6

The number of farm livestock, including poultry, in the United Kingdom in 1938 were as follows: Horses and colts, 1,100,000; cattle and calves, 8,762,000; sheep and lambs, 26,301,000; pigs, 4,378,000; chickens, 69,119,300; ducks, 2,988,800; geese, 747,300; turkeys, 1,390,700.

Particulars of other crops, and statistics relating to agricultural output which are not included in the annual returns are obtained from time to time in connection with the census of production (see AGRICULTURE, CENSUS OF).

Statistics of Agriculture in the U.S.—The averages (1929-38) of the annual estimates of the area and production of some of the principal crops in the U.S. are presented as follows:

Crop	Acres (Millions)	Production (Millions)
Wheat	56.9	754.6 bu.
Corn	98.9	2,296.7‡
Barley	10.8	225.2 "
Oats	37.0	1,021.4 "
Cotton	33.2	13.5 bales
Tobacco	1.7	1,301.0 lb.
Potatoes	3.3	366.6 bu.

The crop areas seeded and harvested in the United States vary considerably from year to year. The area of wheat harvested is in many years considerably less than the area seeded because of heavy winter freezes, droughts, and diseases. The acreage losses from the seedings of the other crops are as a rule small. The estimates given above represent the areas harvested. The 10-year averages are presented as a better indication of areas and yields than the estimates of any one year which may be affected significantly by droughts or other conditions causing considerable changes in either the area harvested or the outturn of the crop.

In recent years the Department of Agriculture has extended its estimating service to include intentions to plant crops. The data are

collected in advance of seeding so that each individual farmer may have some information as to what farmers generally are planning to do for the forthcoming season. These data are useful in determining the marketing policies of both private and co-operative distributors. They are used by the Federal Government also in determining production and marketing policies. Averages of the annual estimates for the past 10 years (1929-38) of the numbers of the most important species of livestock on farms in the U.S. are: Horses and mules, 17,405,300; Dairy cattle, 24,839,000; All other cattle, 41,411,000; Sheep, 46,697,000; Hogs, 51,846,000; Chickens, 428,054,000.

The numbers of animals in the U.S. vary considerably from year to year and in cycles of years. The production of hogs in the U.S. is such an important factor in the agricultural economy of the country that an elaborate statistical service has been developed for this industry. In addition to estimating the number on farms as of January 1, the Department of Agriculture estimates in June and December of each year the number of pigs farrowed and the number of sows bred or to be bred. These estimates of breeding and farrowing are designed to provide a basis for estimating the number of hogs likely to be marketed and the pork production in the season ahead. Reports from slaughter establishments provide a basis for estimating the actual production of pork. The dairy and beef-producing industries of the U.S. are likewise important, but the changes in the numbers of cattle on farms are less variable from year to year and have longer production cycles which can be anticipated to a considerable extent from supplies of feedstuffs and the relation between prices of feedstuffs and of the animal products.

BY COURTESY OF U.S. DEPT. OF AGRICULTURE
 AGRICULTURAL PRODUCTION, CASH FARM INCOME AND FARM PRICE,
 UNITED STATES, 1924-39

Estimates of income have been developed in recent years as measures of the buying power of farmers on the one hand, and on the other hand, as indications of how economic conditions generally affect farmers. Also, the relative importance of the several agricultural enterprises of the country is best indicated by the estimates of income received from these enterprises.

The average income received from principal farm products in the last five years (1934-38) follows, in million dollars:—Dairy products, 1,362; Cattle and calves, 1,067; Cotton, 806; Hogs, 791; Chickens and eggs, 686; Wheat, 435; Tobacco, 267; Sheep, lambs, and wool, 249; Corn (maize), 215; Potatoes, 159.

The importance of corn (or maize) and other feedstuffs is, of course, not indicated by estimates of income received directly from those crops. The production of such crops comes to market mostly as livestock products. Consequently, the variations in prices of feedstuffs have little significance in the income of the country. They are an indication of the relation of supplies of feedstuffs to the demand for them and affect costs of production as between the farmer who raises the feedstuffs to sell and the farmer who buys them for feeding.

The effects of the great depression upon the agricultural economy are reflected in the annual estimates of cash income from the marketings of agricultural products. Annual estimates¹ for the years 1928-38 follow, in million dollars: 1928, 11,089; 1929, 11,221; 1930, 8,941; 1931, 6,254; 1932, 4,606; 1933, 5,248; 1934, 6,138; 1935, 6,805; 1936, 8,012; 1937, 8,621; 1938, 7,538.

The receipts from the sale of farm products are estimated currently for each month, on the basis of prices reported as received by farmers and estimates of marketings by States as well as for the country as a whole. The expenditures for production annually are also being estimated to provide a basis for determining the annual net returns to agriculture. (K. H. R.; O. C. S.)

¹These estimates do not include benefit and adjustment payments by the Agricultural Adjustment Administration, nor the value of products consumed on the farm where produced.

AGRICULTURAL WAGES. The payment of wages for agricultural labour in England began with the disappearance of serfdom. The coming of the Black Death or plague in the middle

of the 14th century hastened the growth of the wage system and stimulated a rise in wages. The Statute of Labourers was enacted in part to check this rise. The change to the wage system came much later in Eastern Europe. Even today most of the wages are paid in kind in some regions. The money wage system was carried into all of the English colonies, in many places in combination with a system of indentured servants and with slavery. When slavery was abolished in the United States, a wage system would seem logically to have followed. The Negroes, however, were not yet ready for this step and presently most of them were working under a cropper system in which they lived on plantations in cottages furnished by the owner, used equipment furnished by the owner, and received their compensation in the form of a share of the crop. Those familiar with this system still look upon it as more nearly a wage relationship than a landlord-tenant relationship. The International Labour Office is making a serious effort to assemble data on agricultural wages and no doubt in a few decades will be able to trace the current changes in them in different countries and make significant comparisons in terms of real wages. The analysis following is based largely on the data this office has already collected. A major complication is that in all countries a good part of the actual compensation of the farm worker is in the form of board and lodging, in the case of single men, and food and of fuel for the use of the family and the use of a dwelling, in the case of married workers, plus perhaps the right to use a plot of land or to keep some livestock on the employer's land. In Central Europe these allowances are known by the term *deputat*; in the United States as *perquisites*. Where wages are regulated, official valuations may be placed upon these extras; otherwise the wage-reporting agency must make a rough estimate of their value. The basis of valuation is invariably what these allowances are worth in the immediate neighbourhood. Commonly they would cost very much more if they were being purchased by an industrial worker in the city. The listing of wages is also involved by the fact that the period of hiring may be the whole year, the summer or winter half-year, a few months during the spring and early summer, or from day to day. The day labourers may be casuals hired for a few days now and then or workers hired regularly by the day for a considerable period. The most numerous in the first group are the piece-rate workers, who help especially with harvesting. The year-round rates reported are commonly for more experienced workers carrying more responsibility. Many of them are part-managers of the farm enterprise, perhaps in some such capacity as herdsman or shepherd. The "farm servant" in Great Britain and several other countries, and the "deputatist" of Germany and other countries on the continent, are typically year-round workers on a somewhat lower wage scale. From the point of view of income, only the data for the year-round workers are adequate. One has no means of knowing how much of the rest of the year the seasonal workers and day hands are without employment. Converting the earnings of these groups to an annual basis is one of the major statistical tasks confronting the International Labour Office.

Wage Differences.—The most useful body of data on wage differentials within countries and between countries is published in the *International Labour Review* for Nov. and Dec. 1934. This covers incompletely 27 countries for the period 1927-34. The comparisons following are for the relatively normal year of 1928 unless otherwise indicated. The ratio of wages of female to male workers in these data is surprisingly uniform, averaging about 70, with all but a few coming within the range of 65 to 75. The higher ratios are in such countries as Sweden, Denmark, Germany, and Canada, and the lower ratios in such countries as Italy, Latvia, Lithuania, and Finland.

In general, the wages of farm servants run from 70 to 90% of those of permanent workers such as cattlemen and ploughmen. Probably the farm servants have more security of employment. Winter wages are commonly lower than summer wages. In general, the haying and harvesting wages are higher than the wages of the planting season. Usually the day rates are higher proportionately than the year-round because the day labourers commonly do not have full year-round employment. In the United States, for example, a day labourer would need to work only 240 days to earn as much as a year-round labourer without board and lodging; in Japan, 200 days.

The wage differences between sections of any one country may be fully as large as those between whole countries. The range within France in 1928 was from 16 francs per day for regular day labourers in Dordogne to 27 francs per day in Loiret; in Italy, from 0.66 lire in Calabria to 1.59 lire in Emilia. The total wages of the deputatists (men) in 1928 were 1,619 zlotys in south Poland and 2,263 in west Poland. In the United States the range in the period 1925-29 was from around \$25 per month in the southern States (with board and lodging) to over \$50 a month in some of the western States. The comparable wage in the north central States was around \$40 a month. An analysis of these differences in the U.S. shows that they are closely correlated with such factors as natural resources and capital goods per worker, and in turn with the net farm income per worker. Thus in the east south central States of the U.S. each worker had about \$2,000 in agricultural property associated with him, and the net farm income averaged around \$500, and the monthly wage \$24. Comparable figures for the west north central States were \$11,000, \$1,360, and \$41. Associated with these circumstances are such factors as density of population, type of agriculture, alternative employment and

the like. The high wage rates reported in some of the eastern States are much affected by competition with city employments.

It is also significant that the average of the farm wage rates for the half-dozen States first admitted to the Union was around \$30 per month in 1925-29; for the half-dozen States last admitted, around \$50. Capital as well as labour is scarce in the newer States. Canada and Australia show similar effects. It may be confidently predicted that these differences will be less 100 years from now, but by no means entirely removed. Their persistence in the older countries indicates a still higher degree of immobility of labour and capital there. In general, birthrates are higher in the densely populated low-wage areas than elsewhere, and the out-movement is commonly not large enough to offset the difference in birthrates.

The sectional differences in wages within countries partly arise from different values placed on perquisites. In the U.S. the reported difference between monthly wages of workers receiving and not receiving board and lodging was \$12 in the east south central States and \$26 in New England. The purchasing power of the southern worker's dollar thus estimated is significantly higher than that of the northern worker. One of the principal reasons for this is that labour itself is directly or indirectly a major factor in the prices of goods and services bought with workers' earnings.

Almost everywhere the level of agricultural wages appears to be lower than that of industrial workers, particularly than that of skilled industrial workers. The explanation commonly offered is that the surplus population of the farms does not move to the cities rapidly enough to equalize returns. Equally important may it be that the statistics compiled do not reflect differences in real income. The purchasing power of the dollar of agricultural wages estimated by the usual methods is likely to be considerably higher than that of the industrial worker's dollar.

Wage differences between countries tend to be greater than within countries because of greater differences in the ratio of population to resources and other related factors, and they tend to persist longer because of immigration barriers and the greater disinclination of population to move to a new country and strange people. Given all the data as to budgets and purchasing power of money one would like, the 4.24 kroner received by the Swedish farm labourer for a day's work in 1928 cannot be validly compared with the 0.19 silver dollars received by the Chinese day labourer. Nevertheless, the differences between real wages in different countries are so large that the following data do have enough meaning to warrant including them in a discussion of agricultural wages. The wage taken as representative in each case is the wage without board and lodging of an adult male ordinary day labourer. The conversion to shillings and pence is in terms of the average rate of exchange for the year 1928. The prices for wheat and other products are the internal wholesale prices at a principal market in the country.

Country	wages	Wages in British money	Wages in wheat (bu.)
China	0.19 silver dollars	4d	*
Japan†	0.86 yen	1/10	0.13
Rumania‡	36 leis	1/3	0.24
Czechoslovakia	13.2 korunas	1/7	0.23

*No wheat prices available. †All figures are for 1931. ‡All figures are for 1932. §All figures are for 1929. §Figures for money wages are 1928; for wheat wages, 1932. **All figures are for 1930.

Taken at their face value, the differences appearing are very large: from 4 pence in China to 16 shillings in Australia. They are in order with what we know about relative density of population and other significant factors in the various countries; but the range is no doubt exaggerated in terms of real wages. The number of yen equal to a shilling in the foreign exchange market buys much more in the way of food, clothing, and shelter in Japan than the number of kroner equivalent to a shilling in Sweden, and even more so than the number of cents equivalent to a shilling in the American market. The comparison in terms of quantities of wheat bought by a day's wage is subject to the serious objection that the price of even as staple a commodity as wheat is subject to special influences in each country; for example, to very high tariffs in France, Italy, and Switzerland. Wheat prices in Canada, Australia, and the United States are on an export basis, which means that they are less than the world price by the amount of the cost of transportation.

History of Wages.—In terms of money, agricultural wages in England rose from 4 shillings per week in the 13th century to 46 shillings by 1775, but in terms of wheat this represented an actual decline from 126lb. to 71 pounds. This is the reason for Thorold Rogers's statement in his *Six Centuries of Work and Wages* that the 15th century was "the golden age of the English labourer." By the end of the 19th century the purchasing power of wages for wheat had returned only to the 15th century level. All through the 16th to the early 19th century, weekly wages in wheat remained around 71 to 91 pounds. The course of agricultural wages in terms of wheat in the 20th century has been a rise during the World War and postwar years, followed by some slight recession in the later years of the depression in some countries. In many cases the price of wheat declined more than the wages of agricultural labour. In Great Britain a week's work bought 6.0bu. of wheat in 1928 as compared with 4.2 in 1914. Comparable figures for Sweden are .88 and .67. It has been characteristic of recent history that real wages have not declined as much in a postwar period as they advanced in the World War years, and agricultural wages have shared in part in these gains.

Wage Regulation.—The object of the early regulation of wages in England was to keep them from rising under the impact of scarcity induced by the plague. This same object continued on through the 16th and 17th centuries, and enforcement finally became so effective that by the 18th century the agricultural labourers were thoroughly pauperized. The landed gentry thus succeeded in shifting to Poor Law relief a considerable part of the necessary cost of maintaining a supply of agricultural labour. The condition of the workers became so desperate in the early 19th century that a serious revolt arose in 1830, and in 1835 the Poor Law system was abolished and with it the whole scheme of State regulation of agricultural wages.

The agricultural wage regulation in England from the 13th to the 18th centuries was of course part of the pattern of local and State regulation of private affairs that characterized the Middle Ages and later the Mercantilistic period. Where serfdom had been abolished on the continent of Europe, agricultural wages were in the thrall of these same tendencies. The abandonment of control in 1835 in England was merely a part of the general shift toward free enterprise that followed Mercantilism in England; and the continental countries also presently, one after another, threw overboard the attempts at control of agricultural wages. By the latter half of the 19th century agricultural wages were determined nearly everywhere by individual bargaining between employer and worker.

The unionization of agricultural labourers in Europe, Australia, and elsewhere is almost altogether a development since the World War. The fixing of wages by public agencies began about the same time; for example, in England in 1917. In North America, the new Mexican constitution in 1917 provided that minimum wage rates should be fixed for all the workers. Estonia provided for fixing minimum wage rates in an act of 1921, and Hungary, Uruguay, and Argentina in acts of 1923. The present form of public wage fixing in England was provided in the Agricultural Wages Act of 1924. It can be said of the wage-fixing legislation enacted in the war and postwar years that its general purpose was to raise agricultural wages and improve the condition of agricultural workers. But much of it was induced by pressure from agricultural unions. An immediate purpose was to remove the causes of disorder and conflict between the employer and worker groups. It is proper to state that in a number of the countries agricultural wages are now adjusted mainly by collective bargaining. A large proportion of the labour may be outside the union, but the union dominates the scene. In the Netherlands, for example, collective agreements increased from 11 covering 742 farms in 1918, to 326 covering 20,700 farms in 1936. By 1937 the wage rates of 30,000 Swedish workers were covered by trade union agreements. Collective bargaining is the device used for general wage adjustments also in Denmark, France, and Norway. This system was well developed in Germany in the postwar years under the republic and in Czechoslovakia and Poland before 1938.

In Scotland the Farm Servants Union insisted upon this method of wage adjustment until July 1937. It then secured the adoption of a plan of public wage fixing similar to that prevailing in England and Wales. As a matter of fact, wage determination by collective bargaining and by public wage fixing are not as clearly distinct as the foregoing statements indicate. The two methods are frequently made to supplement each other. Thus in Italy the wages are negotiated by collective agreements, but the Charter of Labour requires that the wages so determined apply to all workers whether organized or not. In the Netherlands the employers are required to negotiate wages with the workers' organizations, and if necessary an arbitrator makes a compulsory award. In Australia and New Zealand the process of public wage fixing takes the form of calling the workers' organization and the employers' organization before an arbitration court, holding a hearing, and then establishing a rate. Even the procedure of England and Wales, which is clearly designed as minimum wage fixing, sets up local wage-fixing boards upon which the workers' organization and the employers' organization constitute all the board except for a small number of outside members appointed by the Minister of Agriculture. The Central Agricultural Wages Board has no power to influence the level of wages fixed by the local wage boards. The Irish Agricultural Wages Act of 1936, in contrast, gives to the Central

Wages Board the authority to fix the minimum wage rates, but only after consultation with the local wage committees upon which employers are represented.

The reason commonly advanced for having employer and employee organizations participate in the wage-making process is that the wages fixed are not likely to be accepted unless these groups help make them. The objection, of course, is that the unorganized employers and employees are required to abide by wage determinations made by organized groups that often are only a small minority. If, however, it is the policy of the country to encourage the unionization of agricultural labour, such an arrangement may well have the effect of bringing most of the employers and workers into it.

A development since 1930 in several countries is that minimum wage rates have been tied to arrangements for improving the prices of farm products. The sugar growers of the United States must pay certain rates to share in the benefits of the Agricultural Adjustment Act. The New Zealand butter and cheese act of 1937 has a similar stipulation. Swedish sugar factories may conclude contracts only with farmers who agree to pay the wages named in the collective agreements in force.

(I. D. Bz.)

AGRICULTURE: A GENERAL SURVEY. Agriculture is so primitive and fundamental an art, the beginnings of which so far precede any documents, that any attempt to write its earliest history becomes a matter of surmise and unverifiable conclusions from general principles. It is reasonable to suppose that prehistoric hunter man began by learning to tame the young of certain species, which proved to be fertile in captivity and could be attached to his wanderings. At probably a later stage tribes that gathered certain grains of food value began to make provision for future years by scattering a portion of the seed and effecting some rough clearance of the soil. They took the desirable grains with them in their wanderings and by sowing them they learned to become independent of return to the original centres of growth. When any remains of the early settlements emerge, they reveal evidence of animals and cultivated plants. For example, predynastic tombs in Egypt, an early Sumerian house in Mesopotamia (3500 B.C.), and lake dwellings in Switzerland and Italy associated with neolithic man, have yielded grains of wheat of a comparatively advanced type, which must have been preceded by long ages of culture. Flax and barley were also grown. It is significant, however, that no wild species can be assigned as the origin of any of our widely cultivated plants and the same complexity and uncertainty gathers round the sources of the domesticated horses, sheep, oxen and pigs. With the exception of maize and barley, the cultivated plants are polyploids, *i.e.*, the number of chromosomes in the cells is a multiple of the diploid number which characterizes the normal species. This

MEDIAEVAL METHODS OF AGRICULTURE

points to a probable hybrid source; but whatever the origin, the polyploidy provides material susceptible of the variation on which selection can work, even when it is not attended by gigantism or an excess of vigour which would naturally draw the attention of the early cultivator. Though no wild species can be fixed upon as a starting point of our cereals, Vaviloff has argued that the existing distribution of varieties points to certain centres as the original fountain of the cultivated races, these being regions which are to-day characterized by a concentration of varieties in the cultivated fields, where a host of forms occur not yet segregated into distinct races and shade off into weed forms which equally inhabit the uncultivated land. Vaviloff thus indicates the highlands of south-western Asia, particularly Afghanistan, as the probable

centre of the soft and club wheats; northern Africa as the home of *durum* wheats, while *einkorn*, a primitive wheat cultivated in prehistoric times, may have had its origin in Asia Minor. Still another race, *emmer*, perhaps the most ancient of cereals, is found in patches all over the old world and only among isolated and backward peoples.

But if we can arrive at some conclusions respecting the earliest forms of our cultivated plants and animals, the history of the growth of husbandry must ever remain a blank. When agriculture does emerge in written history in the time of the Greeks and Romans (see *GEOPONICI*), it is already a highly developed art, which had behind it long centuries of empiric progress, the fruit of observation and of trial and error. Cato, Varro, Virgil, Columella, the elder Pliny, describe an elaborate system of farming, embodying many principles, such as the value of leguminous crops as a preparation for wheat, for which modern science has only recently found an explanation. The methods of growing corn, vines and olives then prevailing had not been substantially altered down to the middle of the 19th century, and the sculptured representation of a sacrificial bull, lamb and boar on the *plutei* of Trajan in the Roman Forum bear witness to an advanced state of stock breeding. Roman agriculture is indeed the foundation of modern farming, and though over the greater part of Europe it became submerged with the irruption of the barbarians, its traditions probably never died out in the favoured regions, but shaped and were resumed in modern systems of farming.

Mediaeval Farming. — The course of farming in England that we find in early days is in many respects common to all the invading Northern peoples who drifted across Europe; it finds its parallels in all countries north of the Alps, in Russia and in India. It is not uniform, for on the western sides of the islands, in Wales and in Ireland, we find evidence of an earlier system, which is reflected to-day in the grouping of the houses into scattered hamlets instead of into the larger villages characteristic of the more purely arable districts of the Midlands and Eastern England. Whether the organization derives from an original communal ownership of the land and even of its produce is still a matter of dispute, but when records begin the system had passed out of this stage and to some extent had been shaped by feudal theory (see *ENGLISH HISTORY*).

The Manor. — The unit of land holding and cultivation was the Manor (*q.v.*), of which there might be one or more within the parish. The land was held at one or more removes from the king by the lord of the manor, from whom the tenants held in return for various services and with varying degrees of freedom. The cultivated land lay in three, or some multiple of three, open arable fields, divided into strips of one or one half acre, separated by baulks of rough grass and terminating in still wider baulks, the headlands on which the cumbrous ox team and plough could turn. On heavy land the strips were steeply ridged to throw off the water and this ridge and furrow still persists in many parts of the Midlands which have long been laid down to grass. In some places the old strips still defy cultivation, because of the labour that would be required to throw down the ridges and the infertility of the subsoil that would be bared in their crowns.

The three fields were cropped on a fixed rotation of winter corn (wheat or rye), spring corn (barley, oats, peas or beans, or mixed corn) and bare fallow. In each field the tenants held a certain number of scattered strips, the original intention being probably to give to every man a share of the good land and the bad, and mingled with them were the strips held by the lord and constituting his demesne. Each tenant farmed his own strips but was required to give a stated number of days' service to cultivate the demesne strips, services which gradually became commuted into payments in money or in kind. At a certain date after harvest the arable land was thrown open to the cattle to wander over, and this of itself prevented any growth of fodder crops. On the lower land by the river would exist an area of meadow land to be laid up for hay and again divided in proportion with the arable land. The tenure of the particular strips for the year was often balloted for, a practice which still endures in

places, as at Yarnton near Oxford. After hay harvest or Lammas the meadows were thrown open for common pasturage, hence the name of "Lammas fields" which still obtains. Besides the arable and the meadows the manor embraced a certain amount of "waste," the origin of what to-day are known as "commons" (*q.v.*). On this the tenants had right of pasturage and in suitable districts of turbarry, that is, the right to cut turf or peat for fuel. It also provided fern for litter, reeds or heather for thatching, furze and brushwood for firing, rushes for the floors and other purposes, rough timber for fencing and building, stone, gravel and sand.

Production. — The farming that prevailed under these conditions was necessarily inefficient. Some manure appears to have been made by strewing roughage, marl or clay in the folds and in the "garsons," the little enclosures by the village into which the stock were driven at night; but the crops must have mainly depended upon the inherent fertility of the soil. The sheep were folded upon the fallow by night, though tenants were often obliged to put them upon the lord's land only. In the west where the area of unoccupied land was greater, there is evidence of a practice of moving the arable fields continually, whereby some fertility would be accumulated while the land lay in rough pasture. Of extraneous fertilizers there were none; in areas on the chalk the practice of sinking pits into the chalk and spreading it on the land may have endured, for it is mentioned by Pliny in his account of Britain, and the traces of the old pits that remain in certain districts indicate a long continuance of the process of chalking and marling. The level of production was exceedingly low. Walter of Henley, who wrote early in the 13th century the standard treatise on the management of an estate, advised the sowing of two bushels of wheat per acre, which ought to yield threefold. From the context this would be a minimum, and the contemporary author of "Hosbonderie" says that barley might yield eightfold, wheat fivefold, rye sevenfold, peas and beans sixfold, and oats fourfold. From other sources we shall be justified in estimating the level of production of open field land in mediaeval times at a yield of about 10 bushels of wheat to the acre.

If the conditions of cropping were bad the live stock were in a worse state. The stock of all the tenants and of the lord herded together and were driven afield and tended by the village cowherd, shepherd and swineherd respectively. Which class of stock prevailed depended to some extent upon the class of land; in the open down and heath country sheep were a feature, the acorns and mast of the woodlands finished off the swine before the winter. Pannage (*q.v.*) for so many hogs is a common entry in Domesday as an appanage of a particular holding. But with this mixture of everybody's stock little in the nature of selective breeding could be practised. Walter of Henley insists on the value of good boars, but in general the bull and the boar were common to the manor—the result was a "haphazard union of nobody's son with everybody's daughter." Whatever disease came along ran riot through the whole herd or flock. Oxen were chiefly kept for work, and Walter of Henley considered an ox at work should consume half a sheaf of oats a day. Though the greater speed of the horse was recognized, it required more care, cost more to feed and was "carrion" instead of meat when worn out. Cows were kept for milk and the milk was mainly converted into butter and cheese. In the early summer they grazed on the "waste" and marshes or were tethered on the grass baulks; later they had the aftermath of the meadows and the stubbles. With the advent of winter the worn out oxen and the old cows were killed off and salted down:—"For Easter at Martinmas hang up the beef." During winter the cattle subsisted in the yards on hay, pea and bean haulm and straw. Rarely were cattle stall-fattened and the open field farmers sold most of their calves for slaughter. Sheep were from the earliest times an important element in English farming because of the value of their wool. The ewes were often milked, the toothless "crones" being killed for meat. During the open weather they lived on the downs or the waste by day and were folded on the fallow by night, in the depth of winter they were housed or folded and fed upon whatever roughage was available. Swine afforded the chief meat of the

community; they scavenged for a living in spring or summer and fattened upon the "pannage" of the woods. A few were specially fattened upon tail corn and the brewers' grains, for the barley that was grown was very largely turned into ale. The manor aimed at being self-supporting both for food and clothing. Rarely had even the lord any margin of corn for sale; the chief money revenue was derived from the live stock, wool, skins, and dairy produce.

Enclosures. — But the strict manorial system early began to be broken into. The lords had often retained meadows and made enclosed fields which they either farmed themselves or let. Little holdings grew up by sufferance on the waste, occupied by "tradesmen" in the villages or other cottagers who also shared in the common grazing. The rising value of wool in the late mediaeval times tempted lords to aim at enclosures of the arable, and recurring dearths and epidemics, of which the Black Death is the most notable, deprived the land of its labourers and facilitated the putting together of larger units of cultivation. From the earliest times the substantial independent farmer, represented by Chaucer's Franklyn, was a feature of English country life. Not only were the old feudal services commuted into rents, but by new intakes from the wastes or by fencing off portions of the open fields the tenants began to enjoy land in severalty. In Tudor times the process of enclosure was in full swing, though the legislature was opposed to, and public opinion was loud in denunciation of, a movement which appeared to diminish corn growing and the rural population. But the driving force was the growing commerce of the nation. Not only did both landlords and tenants want something to sell and looked upon the land as the basis of a business rather than a subsistence, but the small holders who had been barely able to exist upon their little parcels of cultivation found other and more attractive outlets in the growing commerce and industries.

The New Farming. — It was towards the close of the Tudor times and in the early seventeenth century that the new farming began. Increasing intercourse with the Continent and particularly with Flanders, where some of the old Roman tradition had persisted, brought new crops and stock and new methods into England. Sir Richard Weston (1591–1652) who farmed in Surrey in Charles I.'s time, is credited with the introduction of turnips, clover and other sown grasses, and these crops providing winter keep were the foundation of the improved system of agriculture. With them cattle could be fattened and maintained during the winter; at the same time farmyard manure was made in quantity sufficient, with the help of the clover which enriches the soil in nitrogen, to raise enormously the whole level of production. The new farming could, however, only be practised on enclosed farms; on the open fields clover and turnips would be every man's property as soon as the common stock were turned on to them.

Turnips and clover were not the only introductions from the Low Countries; most of the commoner garden vegetables, as cabbages and cauliflowers, carrots and parsnips are owing to the same source. Fruit trees too were "fetched out of Flanders." Richard Harrys, fruiterer to King Henry VIII., bought "105 good acres in Teynham which he divided into 10 parcels, and brought plants beyond the seas and furnished the ground with them," which land "hath been the chief mother of all other orchards for these kindes of fruites." Hop growing also had a similar origin.

Doubtless the same thing happened with live stock, but here the evidence is more meagre because the descriptions of the early writers are so imperfect. But it would seem probable that the large long-wooled white-faced sheep were originally of Roman origin, and the Kents or Romney Marsh, the Lincolns and Leicesters, all on the eastern side of England, may well have been derived from a very similar sheep which is still found in Flanders. The importations may, indeed, have been earlier, for the English long wool was famous in mediaeval times and was among the first of the staple articles of export, its importance being still commemorated in the "woolsack" on which the Lord Chancellor sits. The earlier long wool chiefly came from the Cotswold country, the home of the other white-faced long-wooled race of sheep, and

this possibly may be a remainder from Roman occupation. The black and white cattle which have always been about the Eastern counties were certainly of Low Country origin—the modern Frisian, Holstein or Dutch Cattle. We may even surmise that some white race of Roman origin (either directly or at second hand from the Rhine provinces) went to the making up of the Short-horn race, whose hybrid origin is betrayed by the mixed white and red in the coat colour of the roans.

Enclosure Laws.—The progress of enclosures which has been described grew apace in the 18th century. Whereas in early days it was opposed by Parliament, in the 17th century it became possible to obtain sanction for agreements from the Court of Chancery, and from the time of Anne a strictly legal procedure by private Act was made available (*see* COMMONS). Commissioners were appointed to make the award and apportion the several holdings to the tenants of the open arable fields, but a private Act remained necessary until the General Enclosure Act of 1845. Under the acts the commissioners could proceed to an award although a minority of the parties interested, one-eighth or even one-third, refused to agree. In certain counties—Suffolk, Sussex, Kent, Essex, Somerset, Devon and Cornwall, the marches of Wales, Cheshire, Lancashire and the four northern counties—enclosures were early and were but rarely effected by Act. Possibly from the nature of the land the rigorous common field arable had never been usual in them. It was in the great corn growing areas of the Midlands, Yorkshire, Lincolnshire and Norfolk, that so much enclosure by Act took place in the 18th and early 19th centuries. After 1760 the process was much accelerated by the growth of industry and population even before the Napoleonic wars created so great a call for good production. Valuable, indeed necessary, as enclosures were to the nation from the point of view of production, so great a change in the economy of the country-side could not be effected without much serious, if temporary, dislocation of labour and some permanent change for the worse in the condition of the poorer classes. Often the lord and the larger tenants took the opportunity of enclosure to put the land down to grass, so that a single shepherd would take the place of a dozen men who had formerly worked on the village land. The enclosures themselves may have been fair enough in their apportionments, though it would always have been easy for the lord and the bigger farmers to over-weigh their poorer neighbours, but many cottagers who had no arable and therefore no title in the award found their customary rights of grazing swept away with the commons. There were those who held that the commons encouraged an idle race of casual labourers and poachers, but the other side of the picture, the destruction of a thrifty peasantry, was the theme of many writers in the 17th and 18th centuries.

Arthur Young, himself an unceasing advocate of enclosure, deplored the evils that had resulted therefrom. "By nineteen Enclosure Acts out of twenty, the poor are injured, in some grossly injured. . . . The poor in these parishes may say, and with truth. *Parliament may be tender of property; all I know is that I had a cow, and an Act of Parliament has taken it from me.*"

The Agricultural Labourer.—With enclosure at any rate began the creation in rural Britain of a race of landless men, dependent for employment upon the larger holders of land; and though the darkest days of this class did not come until the close of the 18th and the first third of the 19th century, when the pauperization caused by the old Poor Law became universal, the lot of the agricultural labourer, still the worst paid and worst housed section of the community, was established. Thomas Mozley writes of his parish in Northants in 1829, "There were many farmers, several yeomen, very many small freeholders, as many tradesmen as the place could find work or customers for, and not one single labourer, in the sense of an independent workman offering his labour for wages, but a multitude of paupers." The labourer class was also recruited from those yeomen propertied who obtained small farms after enclosure but were unable to hold on to them. It requires neither fraud nor force to displace the small proprietor; the mere pressure of economic change is sufficient. A run of bad seasons, the constant temptation to mort-

gage, the inheritance by a widow, and the neighbouring proprietor who wants to add land to land finds his opportunity, especially where, as in England, land has also for so long possessed a non-economic social value. Special opportunities were also offering to active men in industries and commerce, and since many of the old yeomen farms could produce but the barest living for their occupier, they were sold and merged in larger holdings because the owner was no longer content with the income derivable from them. In other countries peasant farming has subsisted largely because there were no alternative occupations with a higher standard of living within reach and because the layout of the land on the open field system persisted and did not permit of putting together large units of farming. The open field system nevertheless persisted into the 19th century; and even in 1927 a non-enclosed parish farmed on the old English plan can be seen at Laxton in Northamptonshire, while the parishes of Epworth and Haxey in the Isle of Axholme remain in strips, though the owners crop them as they please.

The Norfolk System.—The improvement in method of farming possible on the enclosed land soon took effect. Early in the 18th century we find in operation what afterwards came to be called the "Norfolk" or four-course rotation. In consequence England became a corn exporting country during the first half of the 18th century, until the growth of population manifested itself with the development of industries. This epoch of British farming which became systematized in the early 18th century and endured until 1840, may be described as that of the conservation of the resources of the soil. The land was usually cultivated on a four course system of two corn crops, alternating with turnips and a leguminous crop—clover or beans. The leguminous crop gathered nitrogen from the air and maintained the stock of this indispensable element of fertility at a comparatively constant level, despite the wastages that were going on. The turnips and the hay and straw provided for the making of farmyard manure, whereby there was returned to the soil the greater part of the valuable materials that the crops had taken out. Nothing left the farm except the nitrogen, phosphoric acid and potash sold away in the wheat and barley, the meat, milk and wool. Strict covenants prevented such wasting of the soil capital as would occur from the sale of hay or straw or roots, or the too frequent growth of salable corn crops. Under this system the average production became more than double that of the mediaeval farms. Arthur Young speaks of 24 bushels of wheat as the average yield per acre; John Bennet Lawes, writing of Hertfordshire as he knew it when he began his experiments at Rothamsted about 1835, sets the yield at 20 bushels, and the lower estimate is probably nearer the mark for the whole country. This level of production, which we may compare with the six to ten bushels of mediaeval open field farming, could be maintained indefinitely. The limiting factor was generally the supply of nitrogen, and this depended upon the recuperative actions of the leguminous crop in the rotation and of bacteria in the soil which make use of the organic matter supplied by the roots, the stubble and the straw, as against the removals in salable produce and the wastages that occur in the making of farmyard manure and in the soil itself under particular conditions, as washing out and waterlogging. The balance that was established was sufficient to maintain the yield at the level of 20 bushels per acre of wheat.

Live-stock and Other Improvements.—Other improvements in agriculture were simultaneously in progress; great areas of waste land were being added to cultivation, especially on the heaths and light soils which before turnips and clover were introduced became immediately exhausted. Small's plough, the horse hoe, the drill, the threshing machine, were all inventions which took practical shape in the 18th century and did much to add to the effectiveness of the farming operations. Drainage and the systematic amelioration of the land which had been impracticable on the open field system were now taken up vigorously, though the wide extension of field drainage had to wait until the invention of drain tiles in the next century.

Moreover, with the prevalence of enclosed fields, the improvement of live stock could be taken up with some prospect of rapid

achievement. Robert Bakewell (*q.v.*) was the pioneer, and though he was unfortunate in selecting the Longhorn cattle to work upon, his creation of the Leicester breed of sheep persisted and led to rapid amelioration of all the long-wooled sheep. His methods were taken up by other men; Charles Colling (*q.v.*) made the Shorthorn breed, and John Ellman (1753-1832) the Southdown sheep which has been the progenitor of all the other "down" breeds. England developed a race of breeders who combined the instincts of the fancier with certain definite principles. They began by selecting their breeding stock for conformity to an ideal type in which the meat was laid on in the most valuable places; by close line-breeding, even by inbreeding, the type was fixed and the "pedigree" sires became capable of stamping their own type in a few generations upon the common country-bred stock. Early maturity, the capacity to grow rapidly on good food, proved to be equally obtainable by selection, and the result was that in the 19th century Britain was possessed of a number of definite breeds of cattle, sheep and pigs that were doubly or trebly more efficient than were the old unimproved stocks. Their value may be gauged from the way the flocks and herds of the new countries of the world have been populated with stock of British origin. Shorthorns, Herefords and Devons are the great meat producers of the Americas, Australia and New Zealand; the only non-British breeds that have achieved any worldwide extension are the Merino sheep because of their wool and adaptability to arid climates, and the Friesian cattle because of their unrivalled milk yield.

Capitalist Farming and the Great Landlords. — The new agriculture which had grown up in response to the rapid increase of population under the beginnings of industrialism and had been overstimulated by the excessive prices that prevailed during the Napoleonic wars, fell upon evil days with the break in prices and the restoration of a gold standard that followed the final peace in 1818. But it had accomplished its purpose of providing food for the nation from its own land, and it had completed the conversion of British agriculture from a system of peasant cultivation into one of capitalist business, small indeed in the main, but characterized by the employment of labour. In no other country has this development proceeded so far. Prior to the disturbances arising out of the late World War most countries in Europe other than France, Switzerland and Belgium, could show vast estates farmed as single units and owned by the territorial nobility, but there was little or nothing of a middle farming class between the domain owners and the peasants, carrying on farming as a business on land rented from the large proprietor. In Great Britain the political, social and sporting privileges attaching to the possession of land early led to the building up of great estates, but the owner found the best use of his property in letting it again to tenants, who on their side took advantage of the opportunity for employing their limited capital in the business, by which they could derive a bigger income from it than if the greater portion were locked up in ownership of the land.

Thus in England the great landowners were the leaders of agriculture along its path of progress in the 18th century, even though most of the actual improvements, especially in stock breeding, were the work of tenant farmers like Bakewell, Colling and Ellman. A few large proprietors led the way; they created the atmosphere of enterprise and confidence in the industry, and they rendered better farming possible by their expenditure on reclamations and buildings. They introduced the improved live stock to their tenants and they enforced sound methods of cropping by the covenants inserted in the conditions of tenancy. Prominent among them were the and Viscount Townshend (*q.v.*) Pope's "Turnip Townshend," who devoted himself to the improvement of his estate in Norfolk on a basis of turnip growing, with the use of the drill and the horse hoe. He is generally credited with the Norfolk four-course rotation, but it had been evolved before his time and he only gave to it a wider extension. The ideas that Townshend put into practice were chiefly derived from Jethro Tull (*q.v.*) of Berkshire, the greatest original thinker about farming processes that England had then produced. His "Horse-Hoeing Husbandry," published in 1731, was the basis of all im-

provements in the operations of cultivation during the 18th and early 19th centuries. A little later Townshend's neighbour, "Coke of Norfolk," 1st Earl of Leicester (*q.v.*) made a productive estate at Holkham of what had been little more than a rabbit warren, and became famous for his annual gatherings, the Holkham sheep shearings, where all the improving landlords and farmers of the day met and exchanged their experiences. There, too, the improved live stock of the time could be seen and judged. The duke of Bedford was equally active and held similar meetings at Woburn. A little later we may single out the earl of Egremont in Sussex, and in Scotland Hope of Rankeillor and Sir John Sinclair of Caithness, first president of the newly formed National Board of Agriculture.

Arthur Young. — But the most active promulgator of the new methods was Arthur Young (*q.v.*). The younger son of a parson with a small property, Young began by farming, but with constant ill success. He soon found his proper *métier* in writing, and from 1767 to 1795 he published those vivid accounts of the farming, the men and manners of England, Ireland and France, which have become classics of observation and shrewd judgment. In 1784 he began the publication of the "Annals of Agriculture," which embodied contributions from all the men of the time interested in agriculture, even the King himself. When a board of agriculture was established in 1793 Young became its secretary and was responsible for a series of county surveys of the state of farming in England which, if unequal and in some respects inferior to Marshall's General Survey of *the Rural Economy of England*, remains our most trustworthy source of information. Young was pre-eminently a diffuser of knowledge; he had a sound knowledge of the general trend of agriculture, witness his unceasing advocacy of enclosures, and a quick eye for improvements of method. If his zeal sometimes outran his judgment in his commendation of innovations, his lively style always exacted interest and made him for 40 years a most effective stimulus towards the reform of farming. Rarely can a farmer be instructed in the method he is to follow, but he can be excited to think out a novel adaptation to his own conditions.

Period of Scientific Progress. — We may take the accession of Victoria as the beginning of a new era in British farming. The occupiers of land had slowly adjusted themselves to the new conditions, after the shock caused by the break in prices at the end of the Napoleonic wars. Confidence in agriculture was returning and a new race of landlords was growing up imbued with the idea that the rapid development of science then in progress could be applied to the operations of the farm. In 1838 some of the leaders, among whom perhaps the most active was Philip Pusey, founded the Royal Agricultural Society (see AGRICULTURAL SOCIETIES AND SHOWS), which gave a powerful stimulus to the improvement of stock, to experiments in cultivation and manuring, and to the introduction of machinery. Another small landowner, John Bennet Lawes (*q.v.*) of Rothamsted, Herts, was beginning that fundamental series of field experiments which took formal shape in 1843 when Lawes secured the association of a young chemist, Joseph Henry Gilbert. At Rothamsted was laid the foundations of our knowledge of the use of fertilizers and the nutrition of animals. This period is indeed marked by the introduction of artificial fertilizers. Previously there had been some empiric knowledge of the fertilizing value of such waste materials as woollen rags, soot, and bones, but the supplies were limited and the employment only local. The first consignments of Peruvian guano and of nitrate of soda arrived in 1835; in 1843 Lawes began the manufacture of superphosphate, and his early experiments showed the value of the ammonia salts which could be made from the by-products of gas-making, then becoming general. Other sources of phosphates than bones were rapidly discovered and about 1860 the great deposits of potash near Stassfurt began to be exploited.

At the same time the science of agricultural chemistry was being explored and the theory of the nutrition of the plant—what it draws from the soil, the water and the air—a theory of which Justus von Liebig (*q.v.*) had given a brilliant preliminary sketch in his British Association address, provided a rational basis for

manuring. By 1850 the manufacture of artificial fertilizers was in full swing and though all too many farmers lagged behind in their application, their use, together with the employment of foreign feeding stuffs like linseed and cotton cake, the fertilizing ingredients of which found their way to the land through the farmyard manure made by their consumption, had by 1870 raised the general level of production from British land from 20 to 30 bushels of wheat per acre. As already described, up to 1840 an average of about 20 bushels per acre was all that the land could yield when the farm was strictly self-contained; it was the extraneous sources of fertility which made the higher yields possible. Fertilizers and feeding stuffs were indeed not the only factors at work, though the other improvements influence perhaps more the extension of the cultivated area than its increased yield. Field drainage was applied to great areas of heavy land under the influence of James Smith (1789-1850), of Deanston in Scotland, and of Josiah Parkes (1793-1871) whose demonstrations of the value of drainage (*q.v.*) became easy of application with Scragg's invention in 1845 of a machine for moulding cylindrical tiles. Smith drained shallow, 30 inches; Parkes put his drains in at 4ft., and much of his work has been in consequence wasted. Only since the great controversy between the two schools has it become clear that Smith's is the way to deal with ordinary heavy land which suffers because it cannot get rid of the rainfall, whereas Parkes's is the best method to cut off underground water rising from below. The improvements in cultivating machinery continued and in 1853 Croskill put an efficient reaper at the farmers' service. The steam plough was designed and ever since has had a valuable if limited field of action. Pedigree stock made rapid progress; one by one the existing breeds of cattle, sheep and pigs became differentiated; breed societies and flock and herd books grew up. Improvements in crops also followed; Shirreff, Chevalier, Le Couteur and Hallet introduced the idea of "pedigree" into cereals.

In these years from 1850 to 1874 farming was a prosperous business and money was poured into the land; British farming may then be said to have reached its high water mark of technical excellence. Of some farmers it was reported that they offered a reward to anyone who could find a weed on their cultivated land; no other country could show such yields of corn and roots; men came from all over the world to buy British live stock with which to improve their native races.

The Great Depression.—All this prosperity culminated in the high prices occasioned by the Franco-German war; in 1874 a turn in the tide was manifest. A trade depression set in which limited the purchasing power of consumers; a run of bad seasons, culminating in the disastrous wet and cold year of 1879, brought ruin to many farmers. Other major causes beyond the control of farmers were at work to reduce prices. The growth of railways and the development of steamship traffic opened up the international traffic in agricultural produce, and the wholesale settlement of the new countries, particularly of the middle west of North America, gathered way. The area of cultivated land in the world with wheat as the staple crop grew apace, faster even than the population; wheat prices fell year by year until 1894. The average *Gazette* price of English wheat was 54s. 3d. for the decade 1865-74, 46s. in the next decade, and continued to fall to 22s. 10d. in 1894. Within the 20 years 1875-1894, 124 million acres of land were added to the cultivated area of the United States alone, and the corresponding increases in Canada, S. America, Australia and New Zealand were considerable.

The other great factor was the appreciation of gold which began when Germany started to form a gold reserve after the war of 1870 and was accentuated by the falling yields from what had been the chief gold-producing centres of California and Australia. The situation was not rectified until the Transvaal became a big producer in the nineties of the last century. The prices of all commodities fell, wheat more than the rest [Sauerbeck's index, *i.e.*, all commodities fell 40%, wheat 51%], and some economists have considered that to this cause alone was due the fall in agricultural prices and the resulting depression. But the vast increase of production must have also had its effect or the demand from

the rapidly growing population would have counter-balanced it. During this period there was always a surplus of wheat and it was being grown at less than the cost of production, indeed it has been said that the only profit the pioneering American farmer made out of all the plenty lay in the eventual appreciation in value of the land he had settled.

Whatever the ultimate causes of the break in prices it had a disastrous effect upon British farming. Neither farmers nor landlords realized how continuous the fall was going to be, or how completely indifferent would the price remain to the occurrence of a short crop at home; farmers could not readjust their methods and in many cases landowners did not reduce their rents in time to avoid a crash. Much of the old perfection of British farming had

MEDIAEVAL HUSBANDRY

to go because of its expensiveness in labour, for during the whole of the period wages were tending to rise rather than to fall. Farm after farm was thrown upon the owners' hands; in Essex great areas of clay land became for a time derelict or were let to Scotsmen who would undertake to pay tithes and rates. In some cases the landowners had to farm themselves on an extensive scale, in others farmers who had acquired an art of cheap management had farm after farm thrust upon them until they were operating areas of 4,000 to 10,000 ac. These big businesses which grew up towards the close of the century are not reflected in the statistics, for the separate farms were still returned in the rate books as units. Indeed they were farmed as units, each with a bailiff but on the common system which the farmers had found to work; the buying and selling only were centralized. Though prices did turn slightly after 1895 it was not until the close of the century that the conditions began to appear at all stabilized. By that time men had learned to cheapen their methods in the purely arable districts and in others the growing demand for milk had afforded an outlet. The Essex clay lands came back into use, if not under the plough, with a new race of Scotch and Devonshire milk producers. Prices of meat and wool had fallen though not to the same extent as with cereals, and the distress in the west and north of England had never been so great as in the purely arable countries. In some districts special crops solved the farmers' difficulties; a great potato industry developed in the Fen country, where energetic men with intensive methods built up large holdings out of the bankrupt small farms: but the price of potatoes, like that of milk, was made at home, foreign competition being negligible here, while the demand was growing with a larger and more prosperous population. The growth of vegetables, fruit and flowers provided also an expanding industry, and the demand for such things increased with the rise in the standard of living.

Loss of Arable Land.—But such commodities provided the exceptions; in the main the farming community had to meet the depression by reducing expenditure, despite the resulting fall in production. The acreage only under wheat in England, 3,337,000 in 1872, had shrunk to 1,745,000 in 1900; yet there was no accompanying increase in the yield per acre such as should have attended the abandonment of the poorer land, without taking into consideration the improvements in the varieties grown and in the supply of fertilizers. The chief resort of the English farmer in order to meet the situation was to lay his land away to grass. Thereby he shifted his production towards the more remunerative live stock and at the same time reduced the labour bill, because on grassland one man may suffice for 200 or 300 ac., whereas on the arable land about four men per 100 ac. were then employed. Only when dairying on grassland is a staff required comparable with that employed on the ploughland. Between 1872 and 1900 the area of land under the plough in England was reduced by over 2½ million ac., or nearly 20% of the amount in 1872. There were some notorious examples of these changes; in one case on the Berkshire Downs some 4,000 ac. of ploughland were converted into a sheep ranch tenanted only by a few shepherds, the old farmhouses and

hamlets perishing away in desolation. In England and Wales the agricultural population diminished between 1871 and 1901 from 1,269,371 to 951,674. that is, by nearly one quarter. In Scotland the reduction in arable land was not appreciable, but a similar saving was effected by lengthening the duration of the leys in the rotation; the four-course shift became a five- or a six-course, with two or three years of temporary grass instead of one.

For all the reduction of cultivation and the lower standard of farming the period was not entirely one of retrogression. Improvements in the quality of live stock, especially in the direction of early maturity, in the production of milk, and in the special branches of potato growing, market gardening and fruit growing continued. The self-acting reaper and binder began to be imported in 1873 and proved the great labour-saving implement of the period, though at the outset it only intensified the pressure of competition, since it was worth more to the wheat grower in new countries short of labour than it was to the British farmer. This distressed state of agriculture became the subject of more than one royal commission and parliamentary enquiry, none of which, with protection ruled out as contrary to national policy, could suggest any substantial alleviation. The one legislative action of importance was the creation in 1889 as a special department of State of the Board of Agriculture whereby the importance of agriculture in the national economy was recognized, no other industry having this kind of representation in the machinery of government. The new Board took over certain existing services such as the collection of statistics, the control of scheduled animal diseases, the administration of tithes, enclosures, and university and college estates, and was also charged with one function of a constructive character, the allocation of £5,000 a year for the assistance of agricultural and dairy schools.

Agricultural Instruction.— From about 1890 onwards began the first systematic attempt at agricultural education and in its train followed some new beginnings in research. The great start made at Rothamsted had been left solitary and unaided, though other countries were copying its methods and extending them into all the fields of science which bear on agriculture. The movement was too young to have any effect on the industry before the close of the century; it had to overcome the intellectual inertia of a class which had always been indifferently educated and had no opinion of book farming, while the new scientific teachers had to learn what was good in the practical man's outfit and to recover from their own mistakes. One new fertilizer had been added to the list available for the farmer, namely, basic slag, a phosphatic by-product of the steel industry which was to do much to improve the growing area of grass land. But owing to his poverty the British farmer was not using fertilizers as much as he might have done, and the greater part of the British production of sulphate of ammonia was being exported.

The period from the beginning of the century to the outbreak of the World War was one of steady recovery and quiet progress under the favouring wind of slowly rising prices. Knowledge was growing, both from the example of successful practitioners under the new conditions, and from the technical instruction that was becoming more generally diffused. Statistically the industry continued to decline; the arable land of England diminished by a further million acres between 1900 and 1914, nor was there any compensating increase in the numbers of live stock, though the output was improving as better methods of feeding and breeding brought the animals earlier to market. All over the country examples could be found of progressive and prosperous farmers who were taking advantage of the resources science was increasingly putting at their disposal. But many were still set in old ways; mindful of the bad times that were not far off they sought the path of safety first and were distrustful of all enterprise that might cost money. In the use of lime, fertilizers and other ameliorations of the soil our farmers were falling behind their competitors in Holland, Denmark and Germany, just as in the applications of machinery they could not rival the farmers of America and Australia. Labour was still too cheap in the agricultural counties of England; farmers still clung to the traditions that had answered when wages were 7s. a week and wheat over 6s. a bushel.

Marketing.— Above all the weakness of the British farmer as an economic unit was being exposed. The rapidly growing population was to an increasing extent being fed from overseas; in the five years preceding 1914 the United Kingdom only produced 42% of the food it consumed as measured in calories, in particular it only grew 20% of the wheat it needed. Great Britain was the one open market for the agricultural surpluses of the whole world, for the one or two small countries that also persevered in a free trade policy were themselves exporters of agricultural produce. In consequence great commercial interests grew up to exploit this import trade, interests that could impose upon the aspirants for a place in the British market those conditions of uniformity of produce, standardization of output, and attractiveness of packing, which made for ready sale. Our competitors by the mere fact of dependence upon an export trade were marshalled into co-operative societies, and through this discipline the peasant farmers of other countries secured all the advantages of marketing which might have been expected to belong only to the big businesses. The typical British farmer, who in his day had been a not inefficient unit for the sale of his staple produce and could look down upon the exploitation of the peasant, was loath to forgo his individuality and slow to recognize his weakness in the world's markets. The lack of leadership and organization was all a part of the want of public confidence in an industry which had become somewhat remote from modern life. The great landowners no longer regarded agriculture as a money-making business; they maintained home farms because of the traditional association of the English gentleman with the countryside and because the exhibition of pedigree stock was a recognized form of social competition; but the lawyers, the bankers and the capitalists remembered the past and had no belief in the earning capacity of the land. No joint stock enterprise to produce food at home could hope to obtain public support, however much money might be forthcoming to exploit wheat or wool, tea or rubber or copra abroad. The farmers who were making money said little about it and trusted to obtain whatever capital was needed for their businesses, many of them extensive, from their friends or trade connections. Politically the farming interest did not count; in Parliament there could be no agrarian party, hardly even an agrarian member, because even in a purely rural constituency the more numerous labourers were not likely to vote with the farmers. Nor was there any policy upon which the agriculturists were united; although most farmers were still protectionists, such a measure was taboo to all parties so far as concerns food and even with the agricultural labourer the dread of higher prices outweighed the hope of better employment.

The one political measure of outstanding importance was the Small Holdings Act of 1908 which empowered County Councils to acquire land and equip it for small holdings and allotments (*see* ALLOTMENTS and SMALL HOLDINGS). This Act may be taken as one of the signs of a growing public interest in agriculture, of the feeling among thinking people that the urbanization of Great Britain was proceeding too fast and that some measures should be sought to check the drift of men away from the land. The triumphal march of industrialism from factory to factory had lost some of its attractiveness; statesmen no longer regarded the simple theory of Great Britain wholly given up to manufacturing, and exchanging its goods for food, as desirable or even safe. So the Small Holdings Act was an attempt to recreate the peasantry that had always been dying out in Britain, and to provide an access to the land for men whom circumstances had driven into the towns but who still felt a call to the soil. The growth of small holdings could do little towards reducing the volume of imports; the impulse was social rather than economic, but a small holding might give a jumping-off point for the energetic man who would move into larger and larger farms, and new blood was needed in the farming community. The statutory small holders rarely failed to establish themselves, but their numbers barely sufficed to keep pace with the wastage that was elsewhere going on (*see* also *post* section on *Small Holdings*).

The Development Fund.— Another measure of perhaps more far-reaching consequences was Lloyd George's Development Act of 1909, by which was set up a commission endowed with ample

funds, the function of which was to promote research and education in agriculture and to carry out other experimental work in rural industries which might help to restore prosperity to the countryside. Thanks to this fund British agriculture began to be provided with an adequate establishment for research and investigation, such as the United States, Germany and other progressive countries already enjoyed. Some results from research were already accruing. The plant breeder's improvements were quickly recognized by farmers, and Rowland Biffen of the Cambridge school of agriculture and Beaven of Warminster, working independently, had applied the principles which Mendel had been the first to bring to light, to the breeding of new varieties of cereals. Some of Biffen's wheats and Beaven's barleys were already being widely grown by farmers in the progressive districts and their success did more than anything else to convert farmers to a belief in the value of research.

One other technical advance may be noted. Towards the close of the period the tractor plough, driven by an internal combustion engine, began to appear in our fields. The new tool could be operated on a farm of ordinary British size, whereas the steam plough was only economic on an extraordinary acreage and had become an emergency implement only hired for Special work. Imperfect as the motor implement was and still is, it offers potentialities of speeding up and economizing manual labour which have not as yet been fully realized.

THE WAR PERIOD

The war struck across all these projects of quiet development, and its first effect was to sweep the agricultural colleges and research institutes of all their students and younger staff for service in the new troops. For the first two years of the war farmers were told to get on with their business as usual but that they had no special part to play or contribution to make. Prices rose steadily but not abnormally, though here and there a special shortage would declare itself. It was towards the close of 1916, when the submarine menace began to assume threatening dimensions and harvests both at home and in America were deficient, that the new government called upon the farmers to assume a share in the fight.

The Food Production Department.—The Board of Agriculture, under the presidency of Rowland Prothero (later raised to the peerage as Lord Ernle), set up early in 1917 a Food Production department directed by Sir Arthur Lee (later Lord Lee of Fareham) and county committees were constituted with certain powers of directing the crops to be grown by farmers. Little could be done to enlarge the area under crop in 1917, but rapid surveys were made of land and to each county was assigned an area of land to be put under the plough, as far as practicable in corn and potatoes. Power was also taken to enter upon land that was being inadequately cultivated; services were organized to provide and distribute steam and tractor ploughs, horses and implements; labour was recruited from every possible source, including interned persons and prisoners of war, and the women joined in large numbers and rendered devoted service, training centres being set up to make them and other unskilled labour serviceable on the land. The supply of seeds, fertilizers, feeding stuffs, and other necessities like binder twine was organized, and the necessary transport (now under control) and credits for purchases overseas were arranged. Late as came the effort it was prosecuted with great energy, and even in 1917 the area under the plough was increased by a quarter of a million acres, in addition to 720,000 ac. of arable grassland sown to crops. An increase of 60,000 ac. of wheat, 150,000 ac. of barley, 620,000 ac. of oats and 260,000 ac. of potatoes was obtained in 1917 as compared with 1916.

Another section of the Food Production department promoted the cultivation in allotments of all the spare ground that could be found round the cities and towns, and saw to the supplies of seeds and tools. This movement (see ALLOTMENTS and SMALL HOLDINGS) was of no small value in mitigating the shortages of food which set in later; it had a further result in awakening a desire among many of the urban dwellers for a plot of land to cultivate. The Allotment movement thus stimulated is still active to-day,

difficult as it is to retain land near towns from the spread of building.

The Corn Production Act.—To assure the farmers of a return for the task imposed upon them the Corn production Act (1917) was passed, which gave certain guarantees for the price of cereals for a term of six years. In effect these guarantees never were required, so rapidly did prices rise within a few months of the passing of the Act to a level then not contemplated. But other provisions of the Act touched the industry more closely. A minimum wage for agricultural labourers was fixed, and a machinery of Wages Boards was set up to determine what the minimum should be from year to year in each district. Again the stated minimum was nugatory, so rapidly did the situation develop, and the Wages Boards became organizations to fix the actual wage rate, not the minimum. Landowners were debarred from raising rents in so far as such increases could be ascribed to the guaranteed prices; indeed the whole Act was framed as a permanent policy of assisting agriculture as well as to meet the existing emergency. The farmer was to receive a certain guarantee of price that would encourage him to produce; the State assumed this burden because it was the general interest of the community to ensure production from and employment upon the land. If the farmer was thus secured the labourer in his turn must be assured of a living wage; the expenditure of the State was not to go wholly into the farmer's pocket. The landowner again was not to divert the benefit intended for the producers, as he might otherwise do on the fundamental economic basis that rent represents the difference between the earning power of that land and of land on the margin of cultivation. The Act was directed to maintain and extend the area of cultivation, and whatever its defects, defects that are inherent in all such schemes of bounties or protection (namely, that they cannot ensure a responsive effort on the part of the farmers nor avoid an unearned increment on land that was already profitable) it was the first coherent scheme that recognized the needs of all classes interested in the land.

Price Fixing.—The immediate interests of the farmers were, however, far more concerned with the course of prices. Early in 1917 definite shortages began to be manifest, attended by rapid upward rushes of price and speculation among dealers. The newly formed Ministry of Food was therefore forced to embark upon a course first of price fixing and then of rationing all the major articles of food. Such measures involved a very complete control of the whole machinery of distribution; prices had to be fixed for both consumer and producer, the middleman's allowances were determined, and the supplies had to be artificially directed to meet the requirements of each district. As far as farmers were concerned, two main difficulties had to be met by the Food Controller. He had to effect a compromise between the high prices necessary to stimulate production and the low prices required by the consumer, opposites that proved almost irreconcilable with regard to milk in the later years of Food Control. The fundamental problem of rationing was solved by leaving the consumption of bread uncontrolled and keeping its price down by a subsidy. Thus even the poorest could secure their main food supply, after which high prices might be allowed to check consumption of the supplementary articles of diet. The second difficulty lay in fixing the prices of much of the produce of the farmer on a reasonable parity, so that he would not be tempted to concentrate on the production of the most profitable. For example any cereal can be converted into milk or meat or eggs; butter or cheese might be more profitable than the raw milk. A shortage in cattle food was soon disclosed since so much of it had come from overseas while the carefully rationed ships' tonnage had to be reserved for essential human foodstuffs, soldiers and munition materials. Also the normal home production of cattle food was itself reduced because wheat was milled more deeply so as to produce 5 or 6% of poor offals instead of the 30% before the war; hence the situation had to be faced when it might be necessary to reduce greatly the animal stock. Actually the milk herd of the country was not appreciably reduced, but sheep declined by one and a half millions between 1916 and 1918, and the pig herd, nearly two and a half millions in 1914, had fallen to 1,700,000 in 1918.

It cannot be said that the numerous regulations imposed by the Food Ministry and the Board of Agriculture in the critical years 1917-19 were wholeheartedly observed. Many of them ran counter to the traditions of the farmer, who apart from any question of profit could always see his own reason for following his accustomed routine. Thus the campaign for ploughing up grassland, which was the main item in the Board of Agriculture's programme, met with much obstruction and a somewhat grudging performance. All the instincts of the farmer were against breaking up a good pasture which was producing some food when undisturbed, whereas the crop he would get from it was problematical. The argument that even a bad corn crop could do far more to feed the people than the meat or milk which could be derived from the grass, carried little weight with the farmer who was uncertain of his labour supply, who feared wireworm and weeds, who thought of the time when he would have to put the land back to grass. Few farmers again would withhold grain from stock when stock were so profitable and little or none of their accustomed feeding stuffs were to be had.

Increased Production.— During the latter part of 1917 and early 1918 the energy of the Food Production Department and its county committees found a real response, with the result that in 1918 as compared with 1916 the total arable land of the United Kingdom had been increased by 1,720,000 ac. and the land under crops by nearly three million acres, the increase in wheat being three-quarters of a million acres, in oats over one and a half million acres, and in potatoes nearly 400,000 acres. But the withdrawal of more men from the land for active service in the spring of 1918 and the disastrous harvest conditions that were unfortunately experienced, so intensified the opposition to compulsory ploughing that no further progress could be made, indeed there were nearly half a million acres less grain in 1919 than in 1918. Happily the war had come to an end in November, 1918, or the consequences of this revolt against the ploughing up of grassland might have been a food shortage of the sternest kind.

TABLE I.
CROPS AND STOCK IN ENGLAND AND WALES (000 omitted)

	1914.	1916.	1917.	1918.	1919.	1924.	1927.
	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.
Arable land . . .	10,998	11,051	11,246	12,399	12,309	10,929	10,310
Wheat	1,807	1,912	1,918	2,557	2,221	1,545	1,636
Barley	1,505	1,332	1,460	1,501	1,510	1,314	1,051
Oats	1,930	2,085	2,259	2,780	2,564	2,037	1,748
Turnips and Swedes . . .	1,045	932	969	909	981	831	716
	No.	No.	No.	No.	No.	No.	No.
Cows and heifers . . .	2,484	2,430	2,465	2,578	2,553	2,663	2,701
Other Cattle	3,394	3,786	3,762	3,623	3,041	3,231	3,484
Sheep (total)	17,260	17,951	17,170	16,475	15,124	14,843	17,070
Pigs (total)	2,481	2,168	1,919	1,697	1,798	3,228	2,687

At this stage, when the actual fighting was over but the crisis of food supplies still persisted, the temper of the farmers turned very strongly against control. They had become organized and by iteration of individual inconveniences every regulation became a general grievance. It is the evil of all price fixing that the producers are almost perforce driven to base their case upon the performance of their weakest members; hence follows either inordinate profits for the more efficient or restriction of supplies.

Effect of the War upon Farming.— The consequence of the war, which from the farmers' point of view may be regarded as persisting until near the end of 1920, for there was little relaxation in the operations of the food controller until then, was a great temporary prosperity for the farmers. Even though, checked by the regulations of the food controller, the British farmer always had to sell his wheat at less than the world price, that is, at less than foreign corn was being bought for distribution in the United Kingdom, and though the cost of labour and prices had risen to a high level and commodities rose also, rent had not varied and the balance was strongly in his favour. He had also enjoyed the benefit of the lag which affects all farming operations—that much

of the expenditure incurred in preparing a crop antedates the sale by many months; hence on a rising market some at least of the costs are incurred on a lower scale than the realization, this being particularly true of labour. While the largest sums of money were earned on farms growing potatoes and vegetables, probably the highest rate of profit was on the purely grazing farms selling sheep and wool, young stock and milk, and employing little labour. But the only men who really kept their profits were those who gave up their farms and sold their stock before the end of 1920.

The most immediate effect of these profits was a sharp rise in land values. During the period 1918-21 there were immense sales of agricultural land amounting on a conservative estimate to three million ac. in England and Wales. About one-eighth of the farming area of the country changed hands in these years at greatly enhanced values. Landowners were not able to raise rents though their disbursements for tithe, repairs and taxation had increased; farms being in demand, it was evident that they could treble or even quadruple their net incomes from land by selling it and investing the proceeds in Government Stocks. Tenants were anxious to retain their holdings but had to buy in order to do so. Consequently these years saw the creation on a fairly large scale of an owner-occupier class of farmer. Some of these men had already made money enough to pay for their farms or were able to do so while prices were high; they were comparatively safe when the crash in values came in 1921. The men who then found themselves in difficulties were those who had bought their farms on borrowed money and still carried the mortgage; still more those who had entered and stocked their farms in the period of high prices.

Considering the production of the country we have already seen that the advance in the arable and particularly in the corn area attained in 1918 was not maintained even in the years of high prices that persisted until 1921. All powers of dictating cultivation were abandoned at the close of the war. As regards live stock the size of the milk herd was maintained, though the beef herd suffered a small decline. The sheep flock of Great Britain, of England in particular, was greatly diminished; in England and Wales it stood at about seventeen and a half million at the beginning of the war, had fallen to sixteen and a half million in 1918 and reached its lowest point, 13,383,000 head in 1921, while analysis of the returns shows that the loss had fallen almost entirely upon the sheep of the arable counties. Arable sheep farming had always been a special British feature characteristic of the open country upon the chalk and the sands. There half the arable land used to be farmed with fodder crops—rye, winter barley, tares, rape, kale, turnips and swedes, which were sown so as to afford a succession of green crops upon which the sheep were closely penned in folds that were moved day by day on to fresh ground. In addition to their green food the sheep and lambs received a little hay and corn and cake to force them on for market at an early stage; the land received the benefit of the manure made from the food and the treading of the sheep. This system, the sheet anchor of the older light land farming, was unsuited to war and post-war conditions. The labour required, both for the fold and the growing of the fodder crops, was too expensive at the new rates of wage, the supplementary feeding stuffs were unobtainable, and prices tempted the farmer to sell all his flock and put the land into corn. Again fixed prices ignore quality; the arable sheep farmer could no longer realize the extra price he had been accustomed to obtain for his quickly-grown lambs. Consequently the great arable sheep areas in Hants, Wilts and similar counties lost up to 50% of their sheep and though numbers have been reviving of late years the restocking has been with grass breeds like the Cheviot-Border, Leicester half-breeds, Exmoors, Kerry Hills, etc., to the permanent loss of the Down breeds, like Hampshires, Oxford Downs and Southdowns.

The stock of pigs suffered great reductions with the shortage of feeding stuffs in 1917, 1918 and 1919. The herd which in England and Wales had remained for many years at about two million fell to 1,700,000 in 1918, but has since recovered rapidly to more than its previous level, reaching indeed three and a quarter million in

1923. The numbers of poultry followed much the same course as that of pigs and from the same causes, but the post-war development has been more marked with the rapid extension of the knowledge of skilled poultry management.

THE POST-WAR DEPRESSION

The course of agriculture after the war will be best appreciated by a study of prices. The following table shows the average prices of some of the chief items of agricultural produce for the cereal years (Sept.-Aug.) 1913-14 to 1926-27.

TABLE II.
AVERAGE PRICES FOR THE CEREAL YEARS (SEPT.-AUG.)
1914-15 TO 1926-27

	Wheat per qr. of 480 lb.	Beef (*) per cwt.	Milk (†) per gal.	Wool (**) per lb.	Potatoes‡ per ton.
	s.	s.	d.	d.	s.
1914-15	49·8	84·5	9·8	18·5	77·0
1915-16	53·0		12·8	17·0	110·0
1916-17	74·3	110·0		18·9	207·5
1917-18	72·3	114·0	15·3	20·3	139·0
1918-19	72·8	124·5	24·0	35·8	164·5
1919-20	75·6	140·0	27·5	41·0	241·0
1920-21	84·7	148·5	25·3	9·8	199·5
1921-22	50·7	96·0		13·3	174·0
1922-23	42·5	88·0	15·5	16·8	71·5
1923-24	45·0	88·0	14·9	22·4	185·5
1924-25	53·6	88·0	15·0	15·9	187·0
1925-26	52·5	84·0	14·9	14·0	108·5
1926-27	51·1	76·0	14·3	15·9	143·0

§Approximate prices.

War prices were maintained until the spring of 1921, then they dropped by about one-third by the close of the year. The prime cause was the deflation of money in Great Britain and America which was then effected; the secondary causes were the abundant harvests in the vastly expanded area of cereals in the Americas, particularly in Canada, and the lack of purchasing power among the war-ruined population of Europe. Prices in Britain continued to fall until 1923, then tended to recover a little until the long-continued coal strike of 1926 produced a new fall which specially hit the class of farmers who had so far suffered least, namely, the producers of milk and meat. The situation has been aggravated by a succession of bad seasons since 1918, which of themselves would have hurt the position of farmers even in normal times. Bad growing seasons, wet harvests, foot and mouth disease, have been serious contributory factors in the ruinous condition in which British farming now finds itself. Deflation alone wrote off nearly half the capital farmers estimated they possessed in 1921, and though this did not really alter the position of men who had been farming continuously from before the war, it fell heavily upon those who had entered farming during the years of high prices or had mortgages out from the purchase of their farms.

Post-war Legislation. — The state of agriculture has not been without consideration and legislative action during the post-war period. War experiences had persuaded both Parliament and the general public that the maintenance of a prosperous agriculture was of some moment in the national policy. Even during the war a reconstruction committee under Lord Selborne had examined the question and drawn up a series of recommendations on which the Corn Production Act of 1917 had to some extent been based. But that Act, as already seen, had immediately become nugatory as far as guarantee of prices was concerned. As the outcome of a Royal Commission which sat in 1919 an Agriculture Act was passed in 1920, which accepted the main principles of the old Act by charging the State with the payment of subsidies on the acreage of wheat and oats grown, whenever the prices fell below the assessed costs of production. The county agricultural committees became statutory bodies endowed with powers to determine ten-

ancies in case of persistent bad cultivation or neglect, and even to enter upon the land and act themselves in cases of default. Wages boards were continued and tenants were given greater security of tenure by provisions which compelled the landlord to give compensation for disturbance equivalent to a year's or even up to four years' rent, unless the county agricultural committee would certify that the notice to quit was justified by the bad cultivation of the tenant. The Agriculture Act had, however, but a brief existence. It antedated by only a few months the break in prices of 1921, and it soon became evident that under the guarantees the State would be called upon to pay a very large sum

MEDIAEVAL METHODS OF AGRICULTURE

upon the acreage of wheat and oats grown. The basal figure had in fact been set much too high for oats, a crop which is mostly consumed upon the farm and which therefore does not greatly affect the income of the farmer. But no attempt was made to remedy this defect; the public cry for economy was so insistent that the Act itself was repealed in 1921 within 10 months of its passing, in spite of all the promises set out in the Act that four years' notice would be given before the guarantees were withdrawn. The repeal coincided with the very situation the Act was designed to obviate, a wholesale break in prices brought about by causes beyond the control of the farmer, brought about indeed in this case by the deliberate deflation policy of the Government. With the guarantees the wages board disappeared and though conciliation committees were set up in most counties, the average weekly wage dropped from 42s. in September, 1921, to less than 28s. before the end of 1922. The repeal of the Agriculture Act put an end to all ideas for a national constructive policy for agriculture, the industry must henceforward sink or swim by its own powers and be guided by its own lights. The action was part of the pessimism of the time, of the war weariness that shirks any sustained effort and doubts the value of any planning for the future. Bitterly as it was resented by the farmers, who thereby lost all confidence not only in governments but in agriculture itself, it was angrily acquiesced in, because they got rid of their two greatest bugbears—the shadow of control of farming and wages boards. The resentment generated by ploughing-up orders given in 1918 and other interferences consequent upon the orders of the food controller, had been worked up to an intensity out of all proportion to the actual hardship that had been inflicted, and farmers generally were prepared to purchase freedom at any cost. A very large proportion of them indeed grew little' wheat or oats and were anxious to grow less in the difficult state of arable farming. So the farmers' representatives, while protesting, accepted the situation; they saved those sections of the Act that gave them compensation from disturbance (provisions which have injured the land-owners and are in many respects a hindrance to the improvement of farming) and they obtained as a slight recognition of the sacrifice imposed upon them the allocation of a million pounds to the extension of agricultural research and education.

Since that period the National Farmers' Union, in which is concentrated the political opinion of the farming community, has been averse to any further interference of the State with agriculture. The distressed state of the industry gave rise to a further enquiry in 1923—the Agricultural Tribunal, consisting of three economists not directly connected with agriculture, who produced an illuminating survey of the subject early in 1924. The main

recommendation of this report, a subsidy upon arable land with further assistance to the growth of wheat, received little support from the farmers' organizations and was never adopted by the government of the day. It also recommended the re-establishment of the wages boards and this was given effect to in 1924. The only other legislative measures calling for some comment were an Act in 1922 which disposed of a long-standing controversy by permitting the admission of Canadian store cattle into Great Britain, and the Agricultural Credit Act of 1923 which gave some relief in the shape of cheap mortgages to farmers who had purchased their holdings during the operation of the Corn Production and Agriculture Acts. Again the British Sugar (Subsidy) Act of 1925 provided a very ample scale of subsidies on sugar produced in Britain, for a period of 10 years, in order to encourage the establishment of a sugar beet industry in this country.

Wages and Prices.—The difficulties of agriculture at the end of 1927, enhanced by the bad harvest of the year, may be apprehended from a study of the course of prices, the cost of living and the weekly rate of wages from the beginning of the war down to the present time. The cost of living, being based on the general cost of commodities, is some index of the cost of the farmer's necessary purchases; the rate of wages measures the largest item in his expenditure, or from one-quarter to one-third of the total

TABLE III.

costs of production on arable land. The fundamental disproportion is seen—that while in October, 1927, the price of farming products only stands at 40% above the pre-war index, commodities are 67% higher and labour, the largest item of the farmer's expenditure, is 76% higher.

The low agricultural prices are not due to over-production, for as far as can be estimated the gross output from the land of the world, actually lower in some items, has not kept pace with the growth of population since 1914 (see later, section *World Agriculture*). That this shortage has not resulted in higher prices is due to the destruction of the purchasing power of so many of the countries of the world, through war and revolution and the depression in industries. The efforts that so many states are making towards a deflation of their currency is regarded by many economists as the immediately operative factor, depressing prices for all producers and destroying the confidence upon which industrial activity depends.

The other element in the equation—the relatively high cost of labour—cannot be met in England by a reduction in the wage rate, which in agriculture is already below that prevailing in other industries. Indeed, bad as is the state of trade, men are leaving farming for any other occupation that offers; many farmers are complaining of the shortage of labour, and in certain cases where profits are assured, as in sugar-beet growing, labour from Ireland is being imported. Any local call for men immediately draws agricultural labourers from their following and when any general

revival of industry takes place the land is likely to lose most of its active and able-bodied men. Thus if no other change supervenes, farming, except for those special businesses that can command a sheltered or a luxury market, will be reduced to a species of ranching with a minimum of labour. There is one alternative—a sustained effort to make labour more effective, on the one hand by better organization, by the use of machinery and the elimination of wasted effort, and on the other by careful training to increase the skill of the individual. Much of what was called "good" farming before the war was still dealing with labour on a mid-19th century basis of wages, and though operations had been cheapened after the fall of prices of the eighties and the nineties, there has been no radical reconsideration of methods such as is called for by the modern relation of wages to the prices of agricultural produce. This is the big problem before British agriculture—the revision of all its traditions of husbandry, and it requires the co-operation of the investigators, both scientific and economic, with the study by individual farmers of the conditions imposed by their own farm and particular business. The investigators may supply stimulus and guidance, but the main effort will have to be exerted by the farmers themselves, for the problem is one of management and practice, demanding a consideration of the technique of farming and the arts of leadership and management that has not been forthcoming for the last two generations. Some encouragement, some renewal of confidence may come from increasing prices, for the withdrawal of men from the land because of the superior rewards in other occupations is not confined to Britain but is common to all countries. It is affecting the peasant as well as the wage-earning labourer, it is manifest in the United States as in France. Its effect upon output must become manifest, and as the world's population still continues to grow, scarcities will be declared, and whether by compulsion or by choice, farmers will have to intensify their production from the land.

AGRICULTURAL CO-OPERATION

The obvious advantages that can be obtained by buying and selling on a wholesale scale and the great success attending co-operative effort among farmers abroad, particularly in Denmark, has for many years caused agricultural co-operation (see *CO-OPERATION*) to be pressed upon the British farmer. The work of propaganda and advice was undertaken by the Agricultural Organization Society, which was founded on the model of the successful Irish Society initiated by Sir Horace Plunkett. The A.O.S. was a voluntary organization supported by subscriptions from its affiliated societies, but it enjoyed a considerable amount of subvention from the Development Fund from 1910 to its demise in 1924. The earlier efforts at co-operation chiefly aimed at the formation of purchase societies to supply the farmers' requirements for fertilizers, feeding stuffs and other materials. Though many of these ventures had but a brief existence some have become strong trading corporations, such as the Eastern Counties Farmers' Co-operative Society at Ipswich. A wholesale society, launched during the war with the object of bulking the purchases of individual societies, came to disaster. Little progress was made with societies for the sale of farmers' produce, though a number of egg-collecting depôts were and still are flourishing. Dairy societies had a somewhat chequered existence; in some cases as soon as they attained local success they attracted the attention of one of the big dairy firms and after a period of fierce competition either succumbed or were bought out. Eventually the Agricultural Organization Society, despite all the devoted work given to it and the subventions it had enjoyed, found it necessary to dissolve. It had never received any wide measure of support from farmers, and as the National Farmers' Union had become the representative organization of the farmers of England and Wales and was prepared to take over the care of co-operative action amongst its members, the old society gave way to the National Farmers' Union. At the same time the Government under the Agricultural Credits Act made provision for loans to Agricultural Co-operative Societies on the basis of a loan of 20s. for each 20s. share taken up by members, of which

no more than 5s. need be initially called up. The history of these latter ventures has not been altogether encouraging. At the same time there was a movement for the setting up of co-operative bacon factories on Scandinavian models. Seven such societies were started, of which only four are working to-day. Two active wool-selling agencies have been established, one in the south-east and one in the northern counties, both of which are steadily progressing. In 1925 on the termination of the hop control, a wartime organization, a new voluntary organization was formed to continue the collective sale of hops and has succeeded in enlisting some 90% of the hop-growers of the country. While other examples could also be named, speaking generally, agricultural co-operation has made but little progress among the farmers of England.

The reasons are not far to seek. In the first place the larger English farmers make their purchases on a big enough scale to secure terms comparable with those offered by the co-operative society. When such men joined a purchasing society they were apt to use it merely to beat down the terms offered by their merchants. The smaller farmers followed the lead of the big men or were unable to forgo the credit they obtained from the merchants. Again the firms dealing in agricultural necessities were very firmly entrenched in Great Britain; many of them were bigger and more efficient than a newly-started co-operative society could be, and having capital behind them did not shrink from competition. They had the great advantage too of being able to offer credit, and their agents being generally drawn from the farmer class had friends-and connections among the men with whom they wanted to do business.

Societies for the sale of farmers' produce have an even more difficult task. Trade rivalry is equally strong; the customary markets are close at hand and farmers are loath to forgo their individuality or rehouse the chance of a temporary rise of prices. Co-operative selling involves working to contract and the production and regular delivery of a standardized article. The bacon factories failed largely because they could not ensure a regular supply, the farmers diverting their pigs to other channels when prices rose. Firm contracts to deliver regularly were refused by the producers or could not be enforced. Milk societies would be compelled by their members to give a price too high for successful working because a competing trader with a long view would offer prices above the economic parity. Certain ventures failed also from embarking upon a manufacturing process, like bacon curing, which requires a considerable degree of technical skill, and the inability of the society to pay a competent manager or else to find one before its resources went.

The existence of a near-by market is the great obstacle to agricultural co-operation for the sale of produce. Nearly all the examples that are so freely quoted of the success of farmers' organizations—the bacon factories of Denmark or the fruit selling associations of California—rest upon the fact that only an export trade is available and that farmers cannot engage individually in such a trade. They are driven to organize because the alternative is the control of a wholesale trader who cuts the producers' returns to the minimum that will keep them in business. For these and other reasons the true co-operative spirit has been lacking, and British farmers have not shown that loyalty to the principle of combination which would induce members to stick to their society even at the cost of some loss to themselves. When there is an old-established market at hand it is almost impossible for a co-operative business to give the farmer better returns at once. Psychologically, too, defaulters and men who stand outside a combine have a powerful disintegrating influence upon it. They share in all the benefits if the combine succeeds in raising the general level of price, they take no risks and get paid at once, while members may be waiting for a portion of their returns because the society has only succeeded in raising prices by withholding part of the crop from the market. The "outsiders" would not be human if they did not boast about their advantages, and English farmers are as yet too easy-going and too much merged in the general community to counter with a social boycott. Similar occurrences in certain of the British

Dominions have resulted in legislation to force recalcitrants into any combination which has secured the adhesion of three-quarters or four-fifths of the producers; but such procedure is quite alien to the English farmers' declared policy of "No Control." Yet the acceptance of voluntary control is the essence of co-operative organization, and by virtually compelling farmers to produce the article wanted by the market, rather than that which they fancy, exerts a powerful educational influence. On the other hand if he does not accept the voluntary control of his own organizations the British farmer is likely to drift into subjection to the much less sympathetic control of big businesses which will make of him a tied producer.

Thus the prospects of agricultural co-operation do not appear bright, though the situation is not without hope; a sense of the necessity for combination is growing. Nothing can be gained by preaching co-operation at large, but little by little particular instances are making good, especially where the association only attempts to sell and not to manufacture the raw material provided by the farmer. An alliance may be possible with the great co-operative organizations among consumers, which indeed have hitherto been spending their efforts in organizing foreign rather than home producers. But it is only by combination of some sort, from within or from without, that British farmers can hope to retain a remunerative share of the best of all agricultural markets—that of Great Britain. See AGRICULTURAL CO-OPERATION.

BRITISH FARMING SYSTEMS

British farming is characteristically an affair of small capitalist businesses employing paid labour. The following table (Table IV.) of the holdings in England and Wales shows the apportionment of such holdings with respect to their size.

TABLE IV.
NUMBER OF HOLDINGS BY SIZE, ENGLAND AND WALES, 1924
(Excluding holdings of less than 5ac.)

Area in acres.	Number of holdings.	Total acreage.	
5-20 .	111,934	1,264,217	252,252 farms, comprising 8,369,843ac. of less than 100-ac. units.
20-50 .	79,537	2,691,131	
50-100 .	60,781	4,414,495	80,272 farms, comprising 17,266,059ac., of more than 100-ac. units.
100-150 .	31,930	3,924,450	
150-300 .	35,485	7,420,533	
300 .	12,857	5,921,076	

Characteristically, too, the farms are tenancies held under yearly agreements, though the tenant is largely protected from disturbance by the Agricultural Act. The landowner provides the permanent equipment of the farm—buildings, gates and fencing, water supply, drainage. The landowner also is responsible for repairs to the fabric, but minor improvements of which he will remain possessed are generally carried out on the basis of the landowner finding materials—timber for fencing, bricks, stone, gates, drain tiles, seeds for permanent pasture, etc., and the tenant finding the labour. The landowner's capital has been estimated to amount on the average to £31 per acre, the tenants to £12-£15 per acre, and the average rent to 31s. per acre. Under such a system the entry upon and leaving of a farm, at whatever date, necessitates a considerable adjustment of account between landlord and tenant, since the farm must be left as a going concern. These adjustments were formerly regulated entirely by custom and though they are now governed by the various Agricultural Holdings Acts (consolidated in 1923), custom is recognized and still plays a large part. The basis of the Act is that the outgoing tenant is entitled to compensation from the landowner for all improvements he has effected, the amount of compensation being determined by the value of the improvement to the incoming tenant. For certain types of permanent improvement, e.g., buildings, plantations of fruit trees, the tenant is not entitled to compensation unless the consent of the landlord has previously been obtained. The purpose of this exclusion is to prevent the tenant from committing the landowner to payment for an improvement which the latter might not be able to realize. For example the

improvement effected by planting land with fruit or hops might be valued as high as £100 an acre, with embarrassment to the landowner if he had to pay out this sum on the determination of the tenancy without any assurance of being able to find a tenant willing to pay an adequate rent for it. An exception is made in the case of holdings let as market gardens. Here general legislative sanction has been given to what was known as the "Evesham custom." The tenant possesses the right of free sale of the improvements he has made, e.g., beds of asparagus, fruit plantations, etc., but must find the purchaser, the landowner being obliged to accept the tenant proposed by the outgoing tenant, who has made his own bargain for the improvement with the new tenant.

In ordinary cases the negotiations with regard to improvements proceed between the outgoing and the incoming tenant, in whose agreement with the landowner is a clause that he shall pay whatever compensation is due to the outgoer. Each tenant appoints a valuer who between them prepare an agreed valuation of the tenant right, there being provision for an arbitrator in cases of dispute. The account includes the cost of cultivations carried out before leaving the tenancy standing crops and manorial residues whether of fertilizers applied or purchased feeding stuffs consumed during the latter years of the tenancy. But as farms are vacated at different dates in different parts of the country, though most commonly at Michaelmas or Lady Day, custom still plays a large part in determining both what things are the subjects of compensation and the basis of assessment.

Tenancy. — The British tenancy system possesses many advantages. The handicap that farming is under as compared with other industries lies in the large amount of fixed capital involved in comparison with turnover and in the lag that exists between expenditure and returns. For the farmer who has to own his farm this implies a considerable degree of credit, and in foreign countries it has generally been found necessary to give some State support to landbanks or other long term credit organizations which will take the burden of the capital outlay on land and buildings. The short term credits required for the conduct of the business proper are supplied by co-operative associations or the banks. Otherwise mortgages rule and mortgages have universally proved destructive to the farmers whenever a run of bad seasons occurs. In Britain the landowner has supplied the cheap capital the industry requires for its permanent equipment, and the banking system so far pervades the community that it can furnish a not unreasonable proportion of the working capital the farmer should have. Even so the farmer would have to work upon a much smaller proportion of borrowed capital than prevails in other business, and in practice in Britain the farmer resorts to a dangerous extent to the tradespeople with whom he deals. The merchants who sell to him his requirements in manures and cakes and buy from him his corn and hay, and the auctioneers through whose hands pass the store cattle he buys and the finished cattle and sheep he has to sell, provide to a very large extent the financial backing of the industry. This custom obviously limits the power of the farmer to buy and sell in the best market, and it has been proposed by legalizing the creation of chattel mortgages to enable the banks to accord greater credit facilities. The farmer could then assign his livestock or his standing crops as security for advances.

The tenancy system undoubtedly assisted in the development of British farming in the 19th century, though it produced a certain number of cases of oppression when the power of the landowner to turn out a tenant for causes unconnected with farming remained unrestricted. The condition, however, of success in a tenancy system is the possession by the owner of a real knowledge of, and interest in, the conditions of farming. He (or, in the case of large estates or other interests, his agent) must have considerable technical knowledge, if he is to be a working element of the system, the adviser and leader of his tenants. The declining interest of landowners in agriculture and the inadequate training of so many of the agents employed by them have been a main cause of the weakness that the tenancy system has latterly displayed and its hampering effect upon enterprise and innovation among the farmers. Many people, therefore, aiming at a return

to a system of occupying ownerships plead the necessity of freedom for the cultivator and the stimulus of the "magic of property"; though it will be within the experience of those who have had occasion to survey the countryside in detail that even if some of the best, so also many of the worst, managed farms are the property of their occupiers. Further in a modern state no ownership system persists; minors, females or men with other interests inherit, and the new owners prefer to let rather than to sell. For these reasons it has been argued that the welfare of the industry demands the state ownership of all agricultural land and a stricter exercise of the continuing owner's interest in good farming.

Small Holdings. — Other observers who were impressed by the straits of wage-paying farming, even at the low rates for agricultural labour, have sought a solution in a break up of the larger holdings characteristic of British farming and a return to the peasant system of family farms which are customary in most parts of the world. Even in the worst of the depression flourishing colonies of small holders could be found in many parts of the country, and the creation of small holdings has been attended by an increase in the production from the soil. For instance in the Vale of Evesham grass farms on clay land which were indifferently grazed, and yielded but a poor return of milk and store stock, became intensively cultivated for asparagus, plums and other vegetables and fruit; where there had been perhaps one man employed per hundred acres, the small holders would make a thrifty living on fifteen acres of the new cultivation. Consideration of such cases led to the Small Holdings Act of 1908 (see *ante*, *British Farming Systems*) and to a widespread demand for a general policy of dividing up the land. It is doubtful, however, whether the admitted success of small holdings is a sufficient basis to justify their general application to British conditions. The success of small holdings depends upon two factors. The small holder, being his own master, works harder and more intelligently and for longer hours than the paid labourer; he also throws in the work of his family, often of considerable amount. Large farmers would agree that if they could get from their labourers the quality of work put in by the small holder they could pay wages even higher than the returns obtained by the small holder. Small holders, therefore, are concerned with the production of those things in which manual labour bulks largely, but also they must engage in a branch of the industry that has a rising market, and preferably one that is naturally protected. With their ears to the ground they have been quick to seize upon small things that the large farmer neglects. Milk, potatoes, vegetables, fruit and poultry, and occasionally pigs, have been the produce upon which the small holders have depended. They rarely touch the main lines of farming — corn, beef, or sheep and even with milk they often make their profit by combining retailing with production. Thus the opportunities for small holding are limited and the markets they cater for are easily overstocked although as regards milk and vegetables they have reaped the advantage of a demand that has been steadily rising for years. As a rule small holders require good land and can make little use of the great areas of the chalk and clay soils.

While it is generally agreed that small holdings are unsuited to the production of corn or cattle and sheep breeding it is argued that even these branches of agriculture could be pursued if they were organized for the co-operative use of machinery, pedigree sires, etc. But this is only equivalent to saying that small holding farming could be successful if imperfectly and by agreement it adopted the methods of large farming. Co-operative farming has not been realized and the mark of the small holder is his independence; as a rule he has only become united with co-operative selling societies when he has been under the necessity of working for an export market. Nor is there necessarily any greater production from land under small holdings; in the instance quoted above the increases are due to a change in system introduced by the small holder. But the large-scale fruit grower or market gardener or milk farmer will produce more per acre and that of better quality than the small holder working single-handed. Organization and the command of capital in the large businesses tell even against the individual attention which is the asset of the

small holder; spraying is more suitably undertaken on an extensive scale, clean milk more often comes from the large herds. The greater production per acre of the small holder is often a consequence of the more intensive farming which he is forced to adopt but which would be uneconomic if the labour had to be paid for. There are thus two cardinal difficulties attending upon a revival of a peasant system of farming in Britain, one economic, the other social. The economic drawback is the higher capital outlay involved; the creation of a colony of small holdings necessitating expenditure on buildings, roads, fencing, water supply, etc., that is much greater than would be required on a farm of equal area and engaged in the same type of farming. But it is not germane to quote the excessive cost of the small holdings set up after the war, which reached £2,000 and upwards per holding, because at that time no farm, large or small, could have been equipped on bare land so as to produce an economic rent. The old peasant holdings inherit in their buildings and equipment, the results of the gradual unpaid labour of many generations, and when the holding is sold this accumulated capital is counted cheap, because the price is based upon the farm's earning capacity, not upon what it would cost to reproduce it: hence the prime economic difficulty of building up small holdings *de novo*. The second question is whether small holdings can persist on any large scale under modern conditions. Depending on the basis of the occupier giving his labour cheaply as measured in terms of hours and wage rates, the total cash returns from a small holding are often little or no better than the wages of the agricultural labourer and still less than those of the industrial worker. A certain number of men are always prepared to give this price for their independence and for the chance of getting on, and upon this fact depends the social value, even the necessity, of small holdings. But it cannot be expected that a whole class of the community will permanently consent to lower wages and longer hours. Looking back at the history of British farming the merger of the smaller into the larger farms has always been going on. In other countries peasant farming has persisted longer because of the slower development of the industries, though even in France to-day the peasant is being attracted from the land, and in America the younger generation looks askance at continuing the family farm. It is in China, Japan and India that the sheer pressure of population maintains the one man farmer at a standard of living barely above the starvation level. Some small holdings are a necessity as a social safety valve; but a general return to small holdings would not solve the problem of increased food production. Farming is an industry like any other and a return to small holdings would be as much a retrograde step as would be a return to hand weaving. Nor is the argument valid that the State would gain by having more men employed upon the land. If extra men are employed on the land because the production has been intensified there is a gain, but if the extra labour has only to make up for an inefficient method there is loss. To prohibit machinery and return to spade labour would ensure the greatest number of men upon the land but the community would lose thereby. That community is the richer which employs the smaller proportion of persons in the production of its necessary food, leaving thereby a greater number free for the production of clothes, houses, etc., and other elements constituting wealth.

Industrialized Farming.— It is obvious that on the large farm very considerable economies of working can be effected, especially from the use of machinery. The cheapening of costs of production depends upon making manual labour more effective. Modern power cultivators are likely to be large in order to secure that speed and depth of working proper to their work; they therefore require large fields to save turning about and only broad acres defray their heavy overhead cost. Farming is no exception to other industries in that large scale working by its powers of organization and concentration of effort can obtain better work done at a lower cost. The improvement of live stock by breeding and selection is only possible with numbers upon which to work. Buying and selling is better done on a large scale, however much the small holder may be able to obviate his weakness by co-operation. Large scale enterprise can employ those methods of costing

and recording upon which good management is based. In his technical methods the small holder must work by tradition; he cannot afford to experiment and is therefore slower to accept new ideas. Furthermore the land still requires considerable capital expenditure if it is to be put to its best use; and drainage, the straightening of boundaries, and similar wholesale improvements are not practicable except on a large tract of land. It seems inevitable that as intensified production becomes imperative to provide food for a growing population it can only be obtained by large scale industrialized working. Two conditions, however, must be fulfilled before large scale farming can be attempted with confidence. First of all a new art of management must be evolved, based upon systematic cost accounting and a critical knowledge of average standard costs. Good farming has hitherto been very much a personal affair depending upon the experience, intuition and determination of the individual. Industrialized farming will always require the qualities of the old farmer—his eye and energy; but it also calls for more calculated management even though farming cannot be standardized like other industries. The other condition of success is the formation of a corps of workers trained for their job and rewarded accordingly. The old type of agricultural labourer was a highly skilled man; much of the work of farming is now being done by men who have been prevented by some defect from entering other walks of life, or by youths who have been left to learn their craft haphazard. Efficiency demands efficient men, for however much machinery may be employed a farm cannot be supervised like a factory. But if the future of agricultural production lies with industrial farming, a bigger unit will be required than the present average British holding. Successful as was the farm of 200–500ac. as a first step towards intensive production, it has become an uneconomic unit to-day; it is too small to take full advantage of machinery, is still retail in its buying and selling and demands too large a proportion of its turnover for management. With an average ratio of six labourers to one farmer on English farms, the business is insufficient adequately to pay one man solely engaged in management, and even units of 500ac. are not large enough. The proper unit is probably something of the order of 5,000ac., with some hierarchy of managers and under managers into which young men who have been trained for the work could enter in subordinate positions. But it is also one of the handicaps of the present system of British farming that its management is too rarely recruited from school or college as other businesses are. The possession of capital is more often the condition of entry and too often is regarded as dispensing with the need for any technical training; but the industry would be the gainer from a greater leaven of men who began on a more educated plane.

World Agriculture.— The depression under which agriculture is now labouring would seem, however, to offer little chance of a reorganization of the industry along industrial lines, there being nothing to tempt the large capitalists to take up food production. This depression is felt in all countries and, as the Economic Conference at Geneva in 1927 indicated, it is the outcome of the deficient purchasing power of Europe and of China due to industrial depression. It was perhaps initiated by the deflation policy of the leading States, because it is evident that the low prices are not due to overproduction in the usual sense of the word.

If we exclude from consideration Asia and tropical Africa, as being both self-contained in the matter of food, the population of the rest of the world, constituting roughly the countries inhabited by the white races of mankind, increased between 1913 and 1926 by approximately 50 millions, or 7½%. The corresponding increase in the area of cultivated land is susceptible of even less accurate estimation, but according to the best figures available is about 36 million hectares. Meantime, however, agriculture had not been intensified, rather the reverse, and on the basis of current farming one hectare of land (2½ac.) is required to produce the food and other agricultural materials consumed by one unit of population. On this showing the increased food production since 1913 has not kept pace with the growth of population. Considering again the countries making returns to the International Institute of Agriculture, the wheat

acreage has increased in the same period from 109 to 119 million hectares, the production from 1,029 to 1,139 million quintals, *i.e.*, nearly 11%. But part of this increase in wheat has been purchased at the cost of other crops. In the countries other than Asia and Africa the four chief cereals for human consumption, wheat, rye, barley and maize, taken together, have only increased in area by 4% and in production by 5%. Food animals have increased, cattle by 12%, sheep by 2%, while pigs have declined by 4%, from which an increase of 8% in the meat production may be estimated. These figures lead to the conclusion that latterly the expansion of world food production has not been keeping pace with the growth of world population, even taking account of the relative checks imposed by the war and by its consequences. The low

MEDIAEVAL HUSBANDRY
Going to the mill. From the Louterell Psalter, an illuminated ms. of the early 14th century. ("Vetusta Monumenta")

prices result from the deficient purchasing power of the larger population and from the fact that the greater part of the food production of the world is carried on by peasant farmers. This method of farming can neither alter its production in response to a lower demand nor combine to maintain prices. The men who are engaged in it accept the bad times because in the main no alternative is open to them, and by their capacity to endure hardships and yet persist in production at the low prices prevailing, they ruin the capitalist farmers who have to pay wages. But there are signs that the indifferent returns of peasant farming as compared with wage earning in the industries is beginning to tell

in the withdrawal of men from the land. It is clearly happening in the United States and in France, where may be seen in progress the movement that characterized England in the latter part of the 18th century. Peasant farming does not persist when industry and commerce come near and display their openings to the farmer. Moreover the opportunities for creating new peasant communities of farmers have become smaller; great stretches of unoccupied fertile land in temperate climates, such as were settled in the 19th century and provided food for the then unprecedented growth of population, have diminished. The demand for food and other raw materials produced from the land must soon be felt by the still growing population, and any return of industrial prosperity is likely to be followed by a sudden upward rush of prices because there is no margin of overproduction and accumulated stocks behind the present low prices. Production adequate to meet the real needs of the existing population cannot be met by extending the cultivated area but will require an intensification of farming on the land now available. Intensification will only be prompted by better prices and will then best be realized by large scale farming on industrial lines.

IN THE UNITED STATES

Canada and the United States are one agricultural unit. They produce more than one-fourth of the world's wheat supply, nearly three-fourths of the corn and more than one-third of the oats. They produce nearly one-third of the total grain supply, including rice. The United States is the most important food-producing area under one government. There are no trade barriers within the area. The population is fairly homogeneous and highly prosperous. This combination of circumstances provides the basis for a highly developed agriculture. It produces one-half of the world's cotton, two-thirds of the corn, one-fourth of the oats, one-fifth of the wheat crop and has about one-fourth of the hogs and one-tenth of the cattle.

Population.—According to estimates of the bureau of the census, over one-half of the white population of the United States came from the British Isles and seven-eighths from northwestern Europe (Table I.). It is often stated that the American population

TABLE I. *Estimated Population in the United States in 1920, by Country of Origin**

	Number
Great Britain and Northern Ireland	39,200,000
Germany	14,800,000
Irish Free State	10,400,000
Scandinavian countries	4,500,000
France	2,000,000
Netherlands	1,800,000
Czechoslovakia	1,600,000
Other western and northern European countries	3,000,000
Poland	3,600,000
Italy	3,600,000
Other southern and eastern European countries	2,500,000
All other white population	5,700,000
Total white population	94,800,000
Negro	10,500,000
Indian	200,000
Asiatic	1,200,000
Total	105,700,000

*Message from the President of the United States, 70th Congress, 1st session, Senate Document No. 65, p. 11, Feb. 27, 1928.

is a mixture of many races, but the population is as homogeneous racially as most of the countries of north-western Europe. The immigrants from southern and eastern Europe have tended to remain in cities, so that the farm population is practically all from north-western Europe, except the negroes in the cotton belt.

The white population increasingly uses power and machinery in farming. In 1880, 44.4% of the population was engaged in agri-

1910	12,659,082	25,508,254	33.2
1920	10,953,158	30,661,090	26.3

*Data for 1880-1900 were taken from the *Thirteenth Census of the United States, 1910*, vol. iv., p. 41; and for 1910 and 1920, from the *Fourteenth Census of the United States, 1920*, vol. iv., p. 34.

culture, and 40 years later, 26.3% (Table II.). The production per worker is so large that great quantities of cotton, grain and meat are available for export. In France, about 41% of the population is engaged in agriculture, but only a small quantity of agricultural products is available for export.

Settlement of the United States.—The public domain of the United States was acquired by cession, purchase and conquest. The first acquisition took place in 1781 and the last in 1853. From 1781 to 1802, the various States ceded to the United States 268,000,000 ac. (Table III.). New York State was the first to part with its lands and Georgia the last. The Louisiana purchase,

in 1803, whereby the United States obtained legal possession of 433,000,000ac. for \$27,000,000, was the greatest acquisition that the country has ever made. From this area most of the country's surplus food is produced. By the purchase of Florida in 1819, the nation obtained control of 32,000,000ac., at a cost of \$6,000,000. The annexation of Texas added 770,000,000ac. at a

For the Mexican territory of 325,000,000ac., the United States paid to Mexico \$15,000,000. In 1853, Mexico ceded to the United States 15,000,000ac. costing \$10,000,000. This was known as the Gadsden purchase.

TABLE IV. Disposition of the Public Domain*

Mineral and power reserves	48,000,000
Indian reservations	35,000,000
Remaining public domain	186,000,000
Total	1,397,000,000

*B. H. Hibbard, *A History of the Public Land Policies*, 1924, p. 570.

When the national Government was formed, it was heavily in debt and public lands were sold in order to derive necessary revenue. Later the land policy was primarily concerned with settlement. More land was disposed of through homestead and timber claims than by any other single means. Cash sales were second in importance. Large areas were given to the railroads in order to encourage the development of the country; also to public schools and other educational institutions. The area still remaining in the public domain is mostly forests or arid grazing land.

*B. H. Hibbard, *A History of the Public Land Policies*, pp. 100, 103, 106, 113-115, 1924.

The data in Table V. indicate that there were five distinct periods of settlement, the first one between 1810-19. The period of depression following the War of 1812 checked settlement.

Another wave of active settlement occurred between 1830-39. More land was settled in this decade than in any other decade. Another active period occurred between 1850-59. This carried settlement into eastern Kansas. The next period of striking activity was between 1880-89. In this period, settlement occurred over most of the remaining territory, but much of the poorer land was left in Government ownership. The land disposed of between 1900-19 was mostly arid land that previously had been considered of little value.

Number and Size of Farms. — Since the first settlement, there had been a steady increase in the number of farms until 1920. The severe agricultural depression which began in that year resulted in a decrease in the number of farms (Table VI.). The number of farms of each size is shown in Table VII. The number of

*Fourteenth Census of the United States, 1920, vol. v., p. 65.

small farms and farm homes of less than 50ac. is increasing. These farms increased from 29% in 1880 to 38% in 1925. There has been a corresponding decrease in the percentage of larger farms. While 38% of the farms were less than 50ac., these farms included only 6% of the total land in farms. Only 3.3% of the farms had 500ac. or more, but these farms included 34% of the total land. Many of these farms were in arid regions or in regions where the land is not adapted to intensive farming; therefore these large farms included only 17% of the area of improved farm-land. The average size of farms in 1925 was 145 acres. Most of the country was settled under a policy of developing family farms. The data on the size of farms indicate the success of

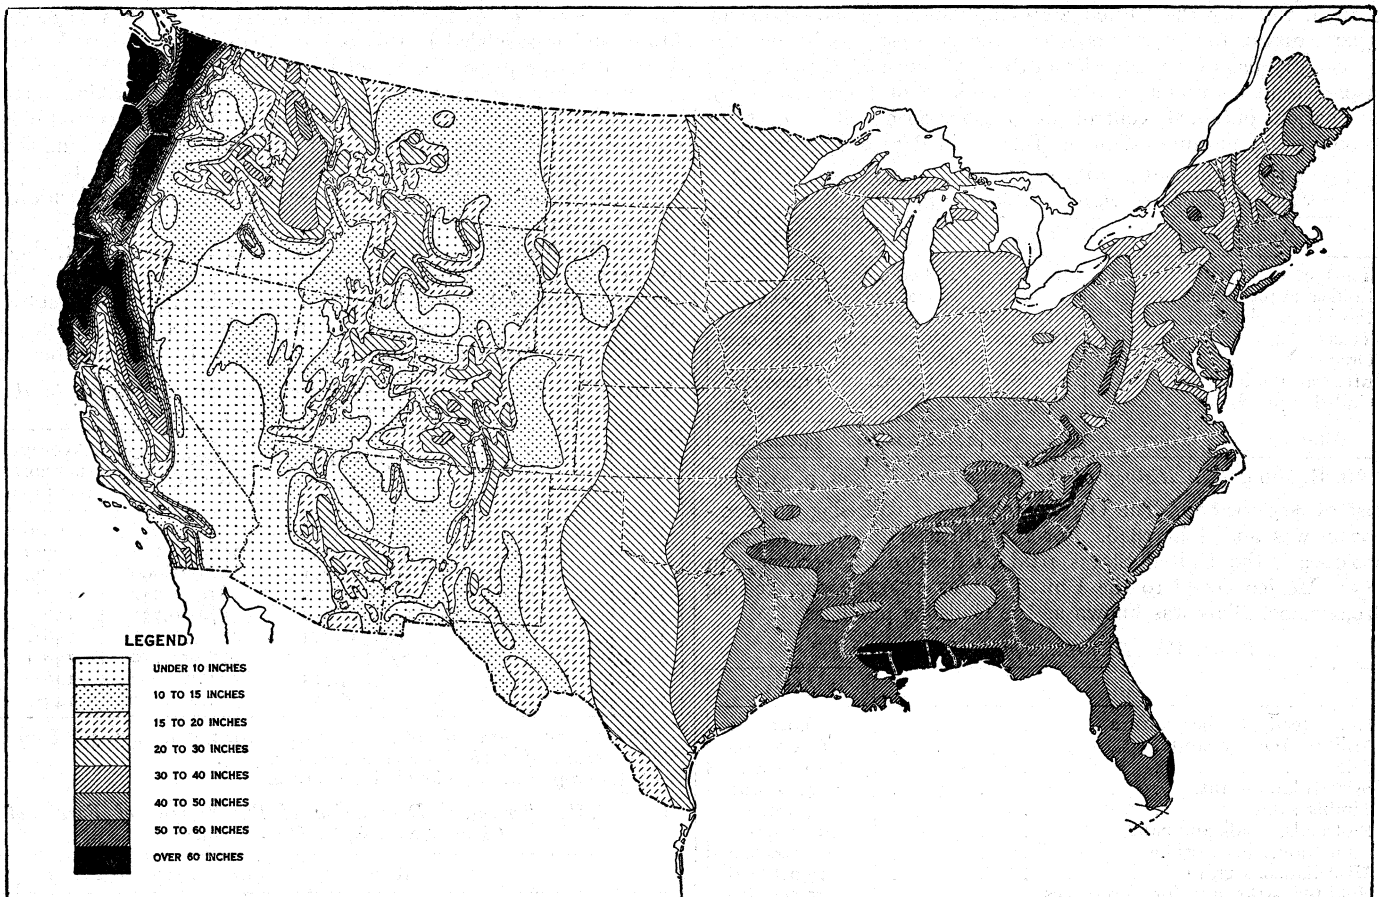

FIG. 1.—ANNUAL RAINFALL IN THE UNITED STATES. ABOUT TWO-FIFTHS OF THE COUNTRY IS SEMI ARID

this policy. There are very few farms that are too large to be handled by the farm family with a small amount of hired labour.

Uses of Land.—19% of the land area of the United States is in harvested crops; 12% in humid pasture; 12% in forests and cut-over land, a part of which is pastured; and 31% in arid pasture. The original forest area has been estimated at 822,000,000 acres. Nearly 60% of this is still in forests or cut-over land. Of the land in farms other than farm wood-lots, somewhat less than one-half was once in forests and over half was natural grass land. Additional crop land will be obtained by clearing forest lands and by use of pasture lands. The pasture land is the most available source

TABLE IX. Utilization of the Land Area of the United States, 1919*

	Acres
Crops harvested	365,000,000
Humid pasture	231,000,000
Arid pasture	587,000,000
Forest, including cut-over and burned-over land, pastured	237,000,000
Forest, including cut-over and burned-over land, not pastured	246,000,000
Farm land not in harvested crops, pasture or forest	115,000,000
Urban, desert, marsh, roads and railroads	122,000,000
Total land area	1,903,000,000

*U.S. Department of Agriculture *Yearbook*, 1923, p. 416.

of additional crop land. The largest area of readily available good crop land was the natural grass land of the Middle West, extending to about the 100th meridian. West of this there are large areas of arid and semi-arid land, much of which has now come into use, but which requires economical methods of farming and particular care in the conservation of moisture.

The period of rapid settlement following the Civil War resulted in the occupation of most of the good land as far west as the 100th meridian. This land was so easily prepared for crops that a remarkable increase in production occurred between 1880-1900.

Topography.—The topography of the United States is shown in fig. 2. There are three mountainous areas: one in the east, one in the west and the Ozark mountains in the south-central part. About one-half of the area is mountainous. Much of this is covered with forests. The primary agricultural area is the central basin. Most of it is less than 1,500ft. in elevation. Along the

FIG. 2.—TOPOGRAPHY OF THE UNITED STATES

There are three mountain areas, one on each coast and one in the South Central part. Most of the crops are grown in the level areas and in the mountain valleys

coasts and between the mountains, there are many smaller areas that are highly developed agriculturally.

Rainfall.—The rainfall of the United States is shown in fig. 1. The western mountain range causes heavy precipitation along the coast, but makes most of the western two-fifths of the country arid. The rainfall of the central basin comes largely from the Gulf of Mexico. It decreases northward from the gulf. Rainfall is carried a short distance west from the Gulf of Mexico, but decreases rapidly in that direction. The boundary line between the

humid and semi-arid areas is only a short distance west of the Gulf of Mexico. The percentage of the total area that received various amounts of rainfall is shown in Table X. Thirty-nine % of the United States receives less than zoin. of rainfall, 11% receives over 5oin.; one-half of the area receives from 20 to join.

TABLE X. Average Annual Precipitation in the United States*

Precipitation inches	Land area acres	Per cent of total
Under 10	154,000,000	8.1
10 to 20	589,000,000	30.9
20 30	314,000,000	16.5
30 40	320,000,000	16.8
40 50	325,000,000	17.1
50 60	160,000,000	8.4
60 80	29,000,000	1.5
80 100	9,000,000	0.5
Over 100	3,000,000	0.2
Total	1,903,000,000	100

*U.S. Department of Agriculture Yearbook, 1921, p. 418.

Length of Growing Season.—The average number of days between frosts is shown in fig. 3. The area with over 240 days between frosts is sub-tropical. Citrus fruits and early vegetables are produced in the most favourable parts of this area. Most of the cotton is raised in the area with a growing season of from 200 to 240 days. The only important exception is a considerable area of cotton in the portion of Texas which has a growing season of over 240 days. Most of the winter wheat is grown in regions with a growing season of from 160 to 200 days. Most of the corn is

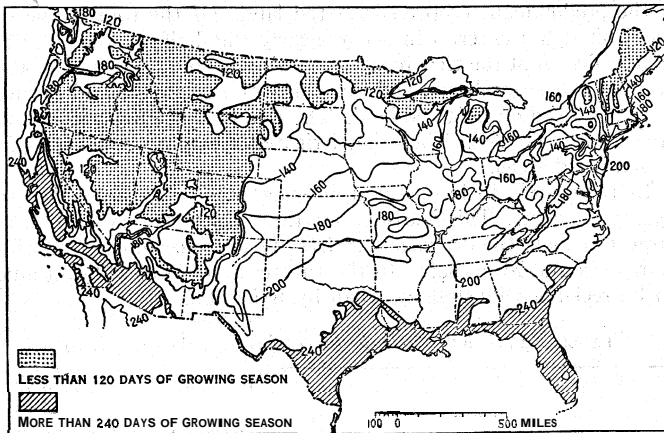

FIG 3.— LENGTH OF GROWING SEASON

Of the land area of the United States 11% has a growing season of over 240 days, while 26% has a growing season of under 120 days

grown in regions with a growing season of 140 to 180 days. Spring wheat is primarily grown in regions with less than 140 days of growing season.

TABLE XI. Normal Monthly Temperature in Berlin, Germany, and Des Moines, Iowa*

Date	Berlin	Des Moines
January	31.3	20.1
February	32.5	23.7
March	37.0	35.9
April	45.9	50.1
May	54.9	61.3
June	62.1	70.6
July	64.6	75.4
August	63.3	73.1
September	57.0	65.6
October	48.2	53.4
November	38.1	38.4
December	32.7	26.0
Average	47.3	49.5

*The normal monthly temperature at Des Moines, Ia., is based on a 30-year period. U.S. Department of Agriculture Yearbook, 1926, pp. 1,268-69; and at Berlin, Germany, is based on the 50-year period 1841-90. J. Hann, Handbuch der Klimatologie, p. 218, 1911.

Temperature.—The temperatures in Berlin, Germany, and Des Moines, Ia., are given in Table XI. The July temperature averaged 65° F in Berlin and 10° higher in Des Moines. The contrast shows the difference between a potato and a corn climate. A temperature that is high enough for the best yields of corn is too high for the best yields of potatoes. It is very easy for Germany to produce higher yields of potatoes than the United States and equally easy for the United States to produce higher yields of corn.

Value of Crops.—The value of all harvested crops in the United States is shown in fig. 4. This figure shows the combined

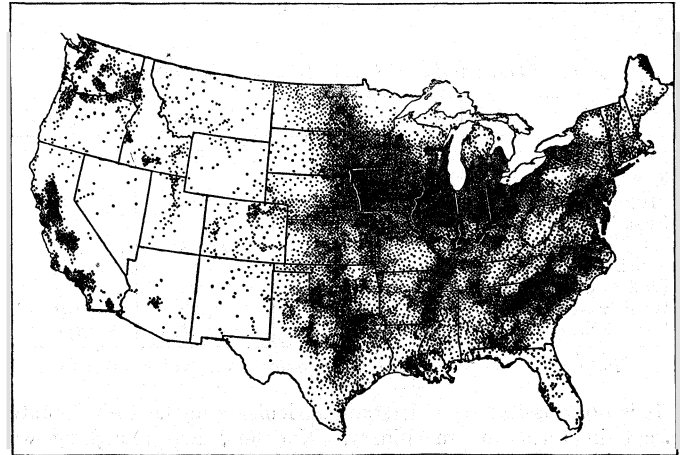

FIG. 4.— VALUE OF HARVESTED CROPS IN THE UNITED STATES, 1919
Most of the crops are grown in about one fourth of the area in regions where rainfall, soil and topography are favourable. Each dot represents \$1,000,000

effect of topography, rainfall and soil on the crop production. The areas that produce only a small amount of crops for sale are mountainous, arid or sandy. The highly productive sections of the country occupy about one-fourth of the total land area. The largest area that is highly productive is in the north-central part of the country extending from Ohio to Nebraska. There is a highly productive area south of this along the Mississippi river. A region of high crop values in Texas is caused by an area where good soils overlap on sufficient rainfall. Most of the coastal plain area from Texas to Maine and a considerable area around the Great Lakes are too sandy for most crops. Between the coastal plain area and the mountains there is a productive area extending from Alabama to Virginia. Philadelphia is in the centre of another highly productive area. Long Island, the Connecticut river valley and Aroostook county, Me., are small areas with high production. In western New York, south of Lake Ontario, is an area with level productive land. In the western half of the United States, there are many small areas of irrigated land. A number of these are indicated in fig. 4. Along the Pacific coast there are several highly productive areas.

Machinery.— This subject is also dealt with under AGRICULTURAL MACHINERY AND IMPLEMENTS.

Most of the food of the world is produced by a small number of farmers who use machinery. The millions of farmers in Asia, and other countries where machinery is not used, produce a small

TABLE XII. Value of Farm Machinery*

Year	Per acre	Per farm	Per acre of improved land
	\$	\$	\$
1850	0.52	105	1.34
1860	0.60	120	1.51
1870	0.66	102	1.43
1880	0.76	101	1.43
1890	0.79	108	1.38
1900	0.89	131	1.81
1910	1.44	199	2.64
1920	3.76	557	7.15
1925	2.01	423	5.33

*Fourteenth Census of the United States, 1920, vol. v., p. 32.

percentage of the world's food supply. In one region in China,¹ the farmers had \$8.82 worth of machinery per farm compared with \$4.23 in the United States. The value of machinery per farm increased from \$108, in 1890, to \$423, in 1925 (Table XII.). A relatively small amount of machinery is used in the southern States. The average value of machinery on farms operated by white persons in the east south central States, in 1920, was \$203, but was \$1,065 in the west north central States (Table XIII.). Coloured farmers use relatively little farm machinery regardless of the section of the country in which they are located. The average value of machinery on farms operated by coloured persons was \$109, but was \$605 on farms operated by whites (Table XIII.).

West South Central	376	101
United States	635	109

**Fourteenth Census of the United States, 1920, vol. v., p. 244.*

It is not possible to understand agriculture in the United States except in terms of machinery. Not long ago ploughing was done with a one-furrow walking-plough. To-day, the most common practice is to use a two-furrow plough drawn by horses or by tractors. A large amount of work is done with ploughs that turn three furrows or more. Harrowing, disking and other operations in fitting the soil were commonly done with two horses, but to-day four or more horses or the tractor are commonly used. About 50 years ago grain-binders and threshing machines were in common use. The harvester was later developed into the twine-binder, which dropped the bundles into piles for shocking. At that time, it was necessary to cut the bands and feed the threshing machine by hand. The grain was measured and lifted into the wagon. The straw was elevated by a carrier and several persons were needed to keep it out of the way. Horses were often used for power. If a steam-engine was used, one man and a horse were required to haul the water. To-day bundles are quite commonly pitched into a pen-rack, so that no loader is required, and then pitched into the self-feeder of the threshing machine. The grain is weighed and delivered into the wagon or truck. The straw-blower takes care of the straw. The only hand labour involved in raising a grain crop is in shocking the grain, pitching the grain onto the wagon and from the wagon to the threshing machine. For a number of years, the combined harvester and thresher has been used in the Pacific coast States. When this is used, no hand labour is involved in grain production. Recently, combines are being introduced into all the States and a large percentage of the wheat is handled in this way. The use of the tractor and the combined harvester is making it possible to farm large areas of semi-arid land on which the yields were not high enough to pay before labour-saving methods were introduced. For some time the planting of corn has been done with the corn-planter, which rows the corn in both directions, two rows at once. A considerable number of farmers are now using two-row cultivators. Most of the husking is still done by hand, but power husking machines are beginning to be used. The ears of corn were formerly shovelled from the wagon to the crib. Many farmers now have elevators to do this work. Power shellers have been in universal use for some years, but recently have been improved. The only hand labour in raising corn is husking and shovelling the ears into the sheller. Not many years ago, hay was cut with a mowing machine about 4ft. wide, and raked with a horse-rake. It was then pitched

on to the wagon, then to the mow or stack. Most of the hay produced is now loaded with a hay-loader or pushed from the field to the stack on a sweep-rake. It is elevated to the stack by horse-power. In the eastern States, hay is usually loaded with a hay-loader and unloaded with a horse-fork. In either case, the only hand labour is that of making the stack or mowing away the hay. Until recently, potatoes were planted, dug and dusted or sprayed by hand to control the potato beetle. To-day, most of the commercial crop of potatoes is planted with a potato-planter, dug with machinery and sprayed with a power sprayer. The only hand labour involved is in cutting the seed, picking up the potatoes and placing them on the wagon or truck. Under some conditions, digging machines are used to pick up the potatoes. Although the majority of cows in the United States are milked by hand, about one-half of them, in intensive dairy sections, are milked with machines. Records obtained from 422 farms in New York in 1922 showed that 46% of the farmers used milking machines.

Irrigation and Drainage.—Approximately two-fifths of the United States is too dry for crop production unless irrigated or farmed with particular reference to the conservation of moisture. A part of this area is summer-fallowed. By fallowing, enough moisture is conserved so that one crop may be grown every two years. In other regions, crops are planted every year, but with the expectation that many crop failures will occur. The total rainfall in the arid area is sufficient to irrigate only a very small percentage of it. In 1919, the area under irrigation amounted to 19,191,716 acres. The systems available at that time could have irrigated 26,000,000 acres. It is estimated that this is about one-half of the land that it is possible to irrigate. Alfalfa (lucerne) is the predominant crop on irrigated land. Of the total value of the United States crop in 1919, nearly one-half of the alfalfa, practically all of the rice, most of the lemons, over one-half of the oranges and sugar beets, and one-third of the grapes and prunes were produced on irrigated land. The rice crop is grown in humid areas, but is flooded. The other irrigated crops are grown in arid or semi-arid areas.

In 1920, the land in operated drainage enterprises amounted to 65,495,038 acres. This is over three times the irrigated land. The largest areas in the drainage districts are in Ohio, Indiana, Michigan, Iowa and Minnesota. In the future, more land will continue to be reclaimed by drainage than by irrigation.

TABLE XIV. *Relative Importance of Irrigated Crops, 1919**

Crop	Per cent of value of all irrigated crops	Per cent of value of all crops for the United States
Alfalfa	22.8	44.9
Rough rice	11.8	99.1
Oranges	7.1	53.0
Potatoes	6.2	8.0
Sugar beets	4.7	62.6
Wheat	6.4	8.9
Grapes	4.4	38.0
Cotton	3.7	1.3
Apples	3.0	10.1
Peaches	3.0	25.8
Wild hay	2.2	7.9
Lemons	2.0	87.7
Prunes	1.9	37.1
All crops		5.6

*R. P. Teele, *Economics of Land Reclamation*, p. 37, 1927.

Forests.—Originally, nearly one-half of the land in the United States was covered with forests. The estimated original quantity of timber was 5,200 billion board feet, of which about 2,200 billion board feet remain. The present cutting is about four times the annual rate of growth. The United States now uses nearly one-half of the timber and over one-half of the paper of the world. It is evident that this rate of consumption cannot continue unless provision is made for growing the crop more rapidly. The majority of the States now furnish forest trees for planting

¹J. L. Buck, "An Economic and Social Survey of 150 Farms," Yenshan county, Chihli province, China, University of Nanking, *Bul.* 13, p. 30, June 1926.

at a very small charge. Thus far, the acreage planted per year has been very small. In 1926, about 53,000ac. were planted. Farmers planted more than any other agency, followed by the Federal and State Governments. Corporations planted a relatively small percentage of the total. Farmers and other private agencies are the chief owners of forest land, but the area of national, State and municipal forests is increasing.

TABLE XV. Area of Forest Land

Ownership	Acres
National forest	89,100,000
State	8,700,000
Municipal	450,000
Farm woodlots	150,398,000
Other private forests	220,852,000
Total	469,500,000

Corn.—Corn is the most important crop in the United States. It is grown by more farmers, occupies more acres and has a greater total value than any other crop. About two-thirds of the farmers grew corn in 1925. No other crop, except hay, was grown by much more than one-third of the farmers. Less than 10% of the corn crop is used directly for human food. About 40% is fed to hogs, 15% to cattle, 20% to horses and 5% to poultry. Corn furnished over one-half of the feed, other than pasture, for live stock. While only a limited amount is used directly for food, corn is indirectly the most important single source of human food in the United States. Although a very large number of farmers grow corn, the chief centre of production is in the strip of land, zoom. wide and 800m. long, extending from Ohio to Nebraska. This region is known as the corn belt. It produces most of the corn of the world (fig. 5).

After corn is husked, cattle and horses are turned into the fields for pasture. In the dairy regions, a considerable amount of

corn is placed in the silo for winter feed. About 4% of the total crop is cut for silage and 7% is cut for fodder. About 5% of the corn is harvested by turning the hogs into the field.

Thus far, corn has been singularly free from devastating pests. The European corn-borer is now appearing in the eastern edge of the corn belt. As this spreads, it may cause serious reduction in

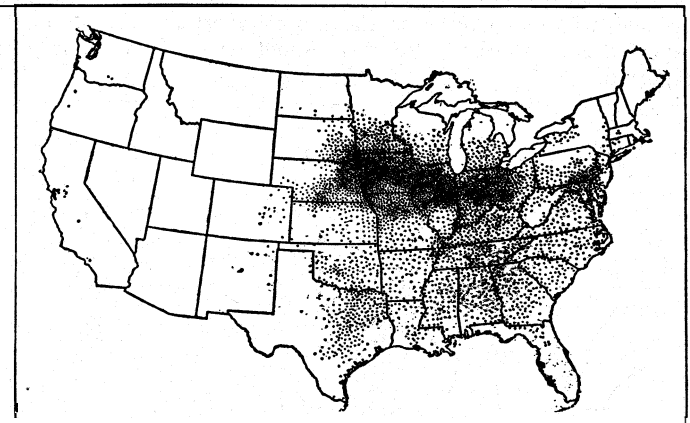

FIG. 5.— CORN PRODUCTION IN THE UNITED STATES

Corn is the most important crop in the country. Two-thirds of the farmers raise it. The region of highest production, extending from Ohio to Nebraska, is called the corn belt. Each dot represents 300,000 bushels

yields. Usually when a serious pest appears, it causes much more loss in the earlier years than later. When the natural enemies of the pest become more numerous and methods of control are better developed, the ravages are less serious.

Cotton.—Cotton is the most important cash crop grown in the United States, second only to corn in total value. Cotton is limited to the southern States. It is grown throughout the South, but there

Rye	3.6	Tobacco	1,538	Rye	63	Flaxseed	22

are three centres of intensive production. One area extends across Georgia and the Carolinas, another along the Mississippi river from the northern border of Tennessee to that of Louisiana. The third intensive area is in Texas and Oklahoma. The centres of intensive production are in the northern and western portions of the cotton belt. This is due in part to the smaller injury from the boll weevil in the regions that have light rainfall or cold winters. Cotton is the most important farm product exported from the United States. About one-half of the crop is exported.

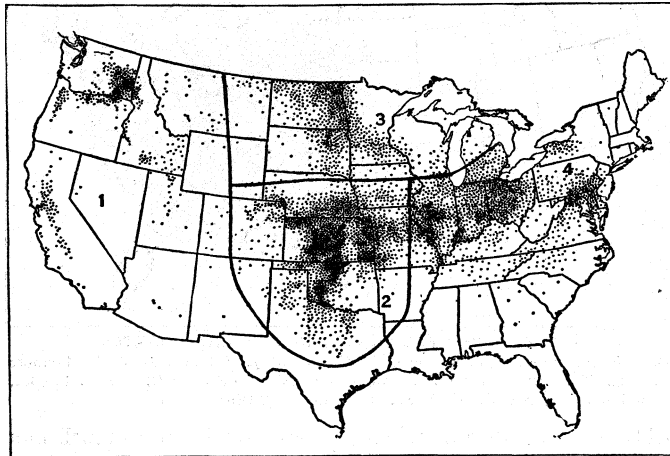

FIG. 6.— WHEAT PRODUCTION IN THE UNITED STATES
1. Soft wheat and spring wheat. 2. Hard winter wheat. 3. Hard spring wheat. 4. Soft winter wheat. Each dot represents 200,000 bushels

Wheat.—Wheat is the third crop in importance in the United States. There are four fairly distinct wheat areas. The most important one is the hard winter wheat region, of which Kansas is the centre. North of this is the hard spring wheat region. This same geographical area includes most of the wheat of Canada. East of these regions soft winter wheats are grown, although the hard wheats are encroaching on the western edge of the area. Various types of wheat are grown in the mountain and Pacific coast States, but the most important are the soft wheats grown in Oregon and Washington (fig. 6).

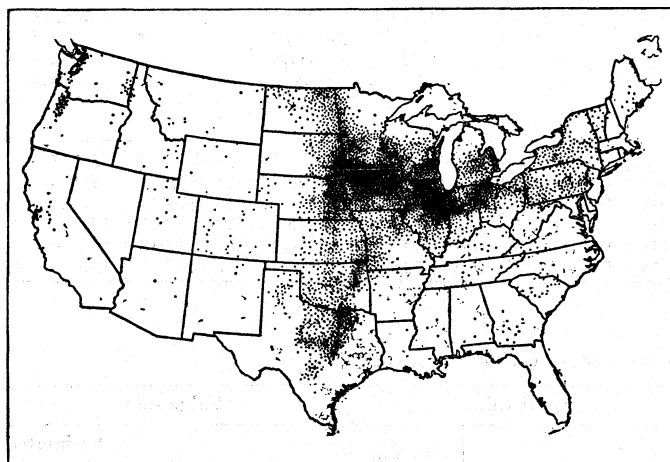

FIG. 7.— OAT ACREAGE IN THE UNITED STATES
Most of the oats are produced in the North Central parts of the country. Each dot represents 10,000 acres

Oats.—Oats are produced in many States, but the greatest production is in the corn belt. In this area they are usually grown after corn, without ploughing the ground. Oats do not give a high return per acre, but require less work (fig. 7).

Hay.—There are three more or less distinct hay areas in the United States. In the western half of the country alfalfa is the major hay crop. East of the alfalfa area and north of the cotton belt, timothy and clover are the major hay crops. South of this area, annual crops, such as cow peas, soy beans and the like, are

the primary forage crops (fig. 8). Timothy, red and alsike clover make 46% of the hay acreage. Alfalfa furnishes 14% of the hay acreage, but the yields per acre are about twice as high as the average for other hay (fig. 9).

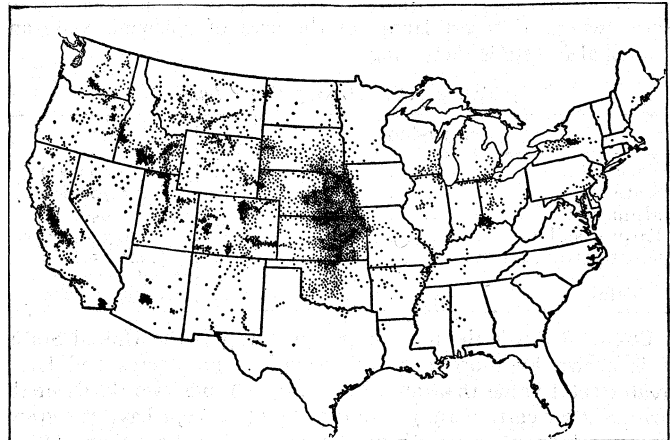

FIG. 8.— ACRES OF ALFALFA HAY IN THE UNITED STATES
Most of the alfalfa is produced in the western half of the country. Each dot represents 2,000 acres

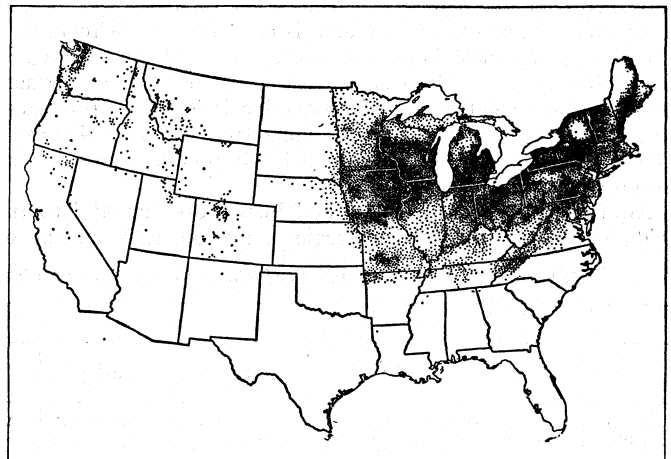

FIG. 9.— ACRES OF TIMOTHY AND CLOVER MIXED HAY IN THE UNITED STATES
Most of the clover and timothy hay is produced in the north-eastern quarter of the country. Each dot represents 2,000 acres

FIG. 10.— ACREAGE POTATOES IN THE UNITED STATES
Although potatoes are grown in most parts of the country, commercial production is limited to various areas in the Northern States and along the Atlantic coast. Each dot represents 1,000 acres

Potatoes.—Potato production is rapidly being concentrated in certain areas that have sandy soils and a cool climate. Most of the potatoes are grown in the northern tier of States or along the Atlantic coast. Formerly, potatoes were grown in small acreages

TABLE XVIII. Production of Grain in the United States* (Pounds of corn, oats, wheat, barley, rye and buckwheat?)

Year	Acres (ooo omitted)	Pounds (ooo,ooo omitted)	Pounds per acre	Pounds per capita	Year	Acres (ooo omitted)	Pounds (ooo,ooo omitted)	Pounds per acre	Pounds per capita

*G. F. Warren, "Prices of Farm Products in the United States." United States Department of Agriculture, *Bulletin* 999, p. 6, Aug. 26, 1921.

†Grain as reported by the Bureau of Crop Estimates, converted to pounds by multiplying corn and rye by '56, wheat by '60, oats by 32, barley and buckwheat by 48.

on heavier soils, but commercial production requires machinery, which works best on light soils. Fertilizers make it possible to obtain large yields of good quality on soils that were not strong enough for continued use before fertilizers were used (fig. 10).

Grain.—The total grain produced in the United States increased from 69 billion pounds in 1866 to nearly 294 billion in 1915. Since 1920, the general tendency of production has been downward. The production per capita was highest in the 20 years from 1895 to 1915. Since that time it has been declining. The yields per acre are considerably higher than formerly.

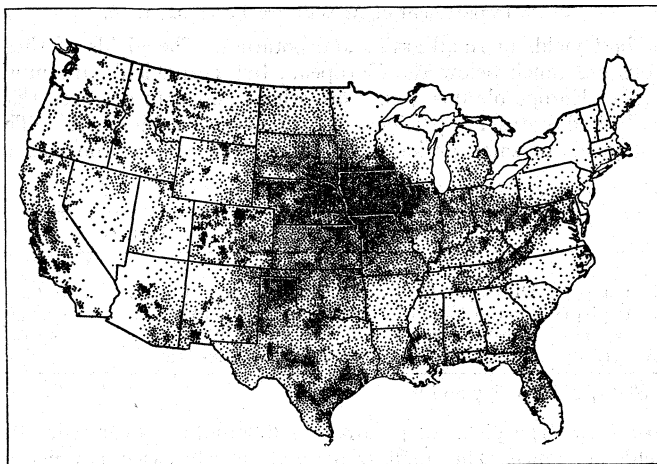

FIG. 11.— NUMBER OF BEEF CATTLE IN THE UNITED STATES
Beef cattle constitute over one half of the total number of cattle in the country. Each dot represents 2,000 head

Cattle.— The value of cattle and calves slaughtered represents 37% of the total value of all slaughtered animals. There are two major areas of cattle production: the timothy and clover areas where cattle are produced on pasture and hay, and the southern and western areas, where a greater dependence is placed

on the range. Many of the beef cattle are grown on the range and fattened in the corn belt (fig. 11).

The northern States from Minnesota to Massachusetts are the most important centres of dairy production, but dairy cows for

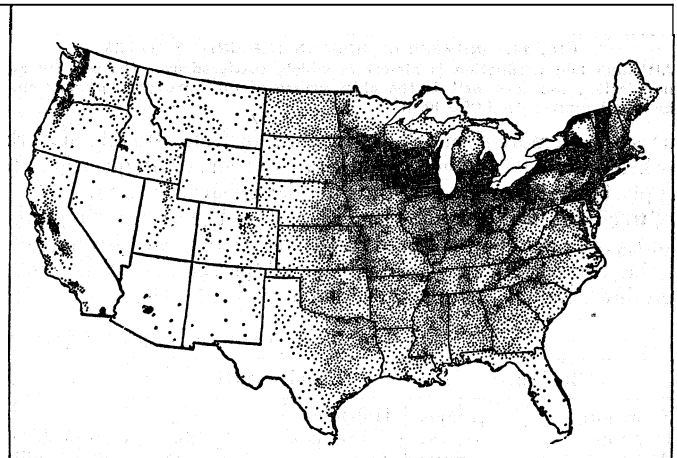

FIG. 12.— NUMBER OF DAIRY CATTLE IN THE UNITED STATES
Dairy cattle are found in all parts of the country, but most of them are raised in the north eastern quarter of the country. Each dot represents 2,000 head

milk supply are scattered wherever there are people (fig. 12). An abundance of pasture is the chief factor in economical cattle production. Some of the most favoured areas are on the Pacific coast, where good pastures are available most of the year. In most of the United States, conditions are less favourable for dairying than in England, Ireland and Holland, because the pasture season in these countries is longer. The milk production in Denmark averages about 6,300lb. per cow. The production in a number of dairy regions in the United States averages about 5,500lb. per cow. In many regions of New York State, the production aver.

ages 5,700. The dairy regions shipping milk to New York city average 6.200 pounds. Comparisons are often made between the United States and Denmark or Holland. If a significant comparison is to be made with these countries, it must be made with intensive dairy districts in the United States, because in the latter a large percentage of the cows that are milked are beef cattle.

*Fourteenth Census of the United States, 1920, p. 637 and ff.

probably indicate the relative numbers of the different breeds and the blood characteristics of the grade animals. Shorthorn and Hereford cattle are the most important beef breeds in the United States (Table XX.). Nearly all of the steers that go to market are typical Shorthorn, Hereford or Angus cattle. The majority of the dairy cattle are Holstein-Friesian or Jersey, although Guernsey are rapidly increasing. In the southern States, the majority of the cattle are of the Jersey type; in the northern States, the majority are of the Holstein-Friesian type, but the Jersey, Guernsey and Ayrshire types are quite numerous.

Pure-bred hogs in the United States are predominantly Duroc-Jersey and Poland China. The three most important breeds of hogs as well as many of the important breeds of poultry are of American origin, but the important breeds of cattle, sheep and horses are European.

In the eastern half of the United States Shropshire sheep predominate. Rambouillet are grown in all parts of the country, but are very numerous on the ranges of the West.

Percheron horses predominate, but there are considerable numbers of Belgian, Shire and Clydesdale horses.

FIG. 14.— CROP YIELDS PER ACRE EAST OF THE MISSISSIPPI RIVER, 1866-1927

Yields declined during the agricultural depression of the '80s and rose rapidly thereafter. The increase was stopped by the agricultural depression following the World War

Crop Yields.—Comparisons of yields of small grains and potatoes in Europe and the United States are often made and erroneous conclusions drawn. This is often assumed to be due to differences in methods of farming. However, they are due primarily to climate. Most parts of the United States are too hot for

TABLE XXI. Crop Yields Per Acre, in Bushels, 1921-25*

	Corn	Wheat	Rye	Oats	Barley	Potatoes
United States . . .	27.7	13.8	13.9	30.8	24.8	107
Europe . . .	19.3	18.4	20.5	35.8	23.4	169
Asia	11.8
Southern hemisphere . . .	21.4	12.3	13.7	103
Iowa . . .	39.9	19.1	17.6	36.1	28.6	86
Maine	24.4	..	38.6	29.0	262
Belgium	38.9	36.8	62.6	49.1	266
Germany	27.3	23.8	44.1	31.3	188
England and Wales	32.9	..	47.4	32.5	231
France . . .	17.8	21.5	18.5	35.3	26.6	125

*U.S. Department of Agriculture Yearbook, 1926.

the best yields of small grains and potatoes. The yields of these crops are much below the European, but corn yields are much higher. Europe obtains jbu. more wheat and oats per acre than the United States, but produces 8bu. less corn (Table XXI.). The best yields of small grains are obtained in countries too cool to

raise corn. The yields of potatoes in Belgium are over twice the yields in France. The small grains yield nearly twice as much as they do in France. France is warm enough to obtain small yields of corn, whereas Belgium raises practically none. The yields of all small grains and potatoes in France are higher than in the United States. Wheat yields are 8bu. higher, but corn yields are 10bu. less. The same comparisons are shown in different parts of the United States. The average yield of potatoes in Maine is higher than that in Germany, England or France, and nearly as high as that of Belgium (fig. 14).

The yields of small grains and potatoes in Maine are higher than those in Iowa, but Iowa yields of corn averaged nearly 40bu., while Maine raises very little of this crop. The small-grain yields in Iowa are about the same as those in France, but corn yields are twice as high. The only part of the United States that has a climate approximating that of Europe is in the State of Washington, west of the Cascade mountains. Some of the counties in this region had yields of over 40bu. of wheat per acre in 1925, and 75 to 80bu. of oats. Crop yields are exceedingly variable. The yearly variations and the long-time tendencies are shown in fig. 14. The low prices in the period of the over-expansion from 1880-90 caused yields to decline. Rising prices caused yields to increase. The rapid advance was checked by the agricultural depression following the World War.

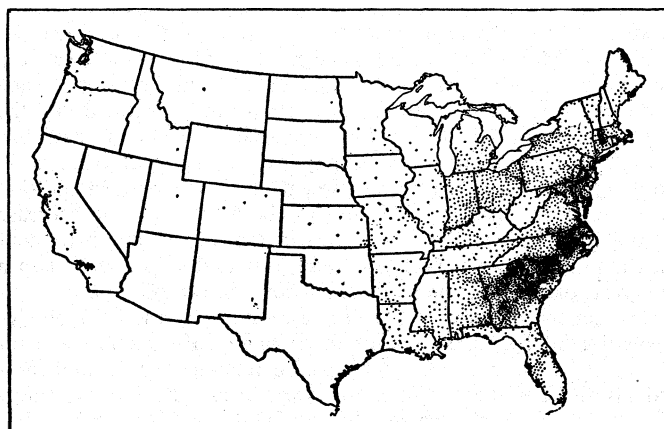

FIG. 15.—FARM EXPENDITURES FOR FERTILIZERS
Most of the fertilizer is used on the cotton, tobacco and garden crops along the Atlantic coast. Each dot represents 100,000 lbs.

Fertilizers. — A very small amount of fertilizer is used on general farm crops. Most of it is used for cotton, tobacco, potatoes and truck-crops on the sandy soils of the Atlantic coast (fig. 15). The quantity of fertilizer used is decidedly variable from year to year, depending primarily upon prices received for cotton and tobacco in the preceding year. About two-thirds of the total fertilizer is acid phosphate. Ground limestone is not listed among the fertilizer materials in Table XXII., but is one of the very important materials needed on American soils.

TABLE XXII. Relative Importance of Fertilizer Material Used in the United States*

Material	Tons
Phosphorus group:	
Acid phosphate	4,600,000
Raw ground bones	102,000
Ground steamed bones	57,000
Organic nitrogen group:	
Tankage	790,000
Cottonseed-meal.	280,000
Fish scrap	260,000
Mineral nitrogen group:	
Nitrate of soda	153,000
Sulphate of ammonia	143,000
Potassium group:	
Kainit	405,000
Muriate of potash	215,000
Manure salts	209,000
Sulphate of potash	41,000

*E. E. Vial, "Prices of Fertilizer Materials and Factors Affecting the Fertilizer Tonnage," Cornell University Agricultural Experiment Station, Memoir 119, 1928.

Most of the soils in the eastern half of the United States need limestone for the best growth of clover. In recent years, methods of grinding limestone have been so cheapened that vast quantities will be used as soon as agriculture becomes more profitable.

Cropping Systems.—In most parts of the United States certain principles of cropping are followed, but fixed rotations are not common. In regions where timothy and clover are grown, they are

usually seeded with wheat or oats. If corn, oats, wheat, timothy and clover are grown, they are commonly planted in that order. In the better parts of the corn belt, corn may be planted two or more years before it is followed by oats. From southern Pennsylvania to Kansas, there is a region which is too hot for oats. Corn can be harvested early enough to plant winter wheat. The common rotation is corn, wheat and clover. In the northern States, potatoes are commonly grown in a three-year rotation of potatoes, oats and clover. Alfalfa lives so long that it is usually left for an indefinite number of years. Corn follows alfalfa when grown in rotation with it. In the cotton belt considerable land is planted in cotton year after year, but an increasing number of farmers are using cow peas, velvet beans or other legumes in the rotation. In the arid regions, wheat is the pre-eminent crop. Since it pays so much better than most other crops, much of the land is planted to wheat for many years in succession.

Diversity.—When a self-sufficient agriculture was followed, each farmer grew many kinds of crops. This system was very wasteful of time. No region is well adapted to all crops, so that low yields were often obtained. The small acreage required a large amount of time per acre. A large production was not required, because all that was necessary was to supply the farmers' needs. With the introduction of machinery, it became necessary to have an income and sufficient acreage to use machinery effectively. There has been a steady movement to grow the major part of each crop in the region that is best adapted to it. Most farming communities specialize on one or a few products. For instance, 82% of the hens in Sonoma county, Calif., in 1924 were kept in flocks of over 600; 50% in Suffolk county, Long Island, N.Y., were kept in flocks of more than 450. One-half of the cows in New York State are in herds of 20 or more.

In some regions, several products pay about equally well. Such regions are quite diversified. In others, the second-best product yields a very poor return, compared with the best. Such regions are highly specialized. Cotton, peanuts and tobacco have been increasing so rapidly that the percentage of farms reporting them increased in the 25 years ending with 1924 (Table XXIII.) The acreage per farm also increased. For nearly all the other crops, the percentage of farmers growing the crop decreased in the 25-year period. In every case shown in Table XXIII., and for nearly all other crops, the acreage grown per farm increased.

TABLE XXIII. Per Cent of Farms Growing Each Crop and Acres Grown per Farm

	Per cent of farms reporting		Acres per farm reporting	
	1899	1924	1899	1924
Corn.	81.9	74.7	20.2	20.7
Oats	36.9	34.1	14.0	18.8
Rye	5.1	3.6	7.0	16.3
Potatoes.	49.4	36.5	1.3	1.3
Sweet potatoes	17.5	10.8	0.5	0.7
Cotton	24.7	30.3	17.1	20.3
Peanuts	2.3	3.9	3.9	4.4
Tobacco	5.4	6.2	3.6	3.9
Tomatoes	5.3	2.9	0.7	2.3
Cabbage	6.0	1.9	0.4	1.4
Beans, dry	4.3	2.4	1.0	10.9
Onions, dry	4.3	0.9	0.2	1.6

The increases are particularly striking for vegetables and other minor crops. The farmer who grew lettuce in the mountain States produced an average of 5ac. per farm, and on the Pacific coast 9 acres. In the Pacific coast States, those who grew beans raised 38ac. per farm. Those who grew sugar beets in the mountain States grew 18ac. per farm. In the west north central States those who grew corn raised an average of 45ac. Those who grew winter wheat raised an average of 65ac.

The percentage of the farmers growing hogs decreased from 68 to 57 in 15 years, and those keeping dairy cows decreased from 81 to 59%. The percentage keeping poultry decreased only slightly, but the number of chickens kept per farm increased nearly 50%. A considerable part of this is due to the establish-

ment of large commercial flocks of from several hundred to several thousand hens.

TABLE XXIV. *Number of Farms Reporting Each Kind of Live-Stock and Number of Head per Farm*

	Per cent of farms reporting		Number of head per farm	
	1910	1925	1910	1925
	Hogs	68	57	13
Dairy cows	81	81	4	6
Sheep	10	59	86	83
Chickens	88	86	50	74

Co-operation.—There has been a rapid increase in the amount of business done co-operatively. In 1924, 14% of the farmers marketed their products co-operatively and 6% did some co-operative buying. In some parts of the country co-operative fire

TABLE XXV. *Value of Farm Products Purchased and Sold Co-operatively, 1924**

Division	Amount purchased co-operatively	Amount sold co-operatively
	\$	\$
New England	5,709,116	20,745,326
Middle Atlantic	7,376,663	50,273,909
East North Central	15,688,188	145,068,000

Mountain	1,709,581	35,043,394
Pacific	9,384,978	115,871,386
United States	75,971,169	858,284,387

*U.S. Census of Agriculture, 1925, pt. 2, pp. 16-18.

insurance is practically universal. Large numbers of farmers borrow co-operatively through the Federal land banks. In 1924, the farmers purchased \$76,000,000 worth of products co-operatively, and sales amounted to \$858,000,000. In Iowa, tenants did

In Feb. 1928, there were 461,719 farmers using the system. The total loans outstanding amounted to \$1,463,918,114.

The land-bank system is under the general supervision of the Farm Loan board, which is appointed by the President of the United States. Each bank is managed by a board of directors. Three of them are appointed by the Farm Loan board, four are elected by the borrowers, but the seventh is subject to approval by the Farm Loan board. The banks obtain their funds through the sale of bonds to the investing public. They cannot charge the borrower more than 1% above the rate paid on the bonds. The Federal Land Bank bonds sell at a low rate of interest, so that these banks are usually the first to reduce interest rates. All the profits above the amount set up as reserves are returned to the borrowers as dividends on the stock held by the farmers who borrow. Each borrower is required to invest \$5 in stock for each \$100 borrowed. Most of the loans are made for 20 or 36 years. When the banks were first started, the usual method of payment was 1% on the principal the first year and an equal total payment in each successive year. The interest payments steadily declined and the payments on principal steadily increased. A form of loan now coming into general use requires payment of the total principal in 20 or 33 years by paying 5 or 3 percent of it each year, in addition to payment of interest. This makes the total payment decrease each year. It allows the farmer to pay more than one instalment on the principal when he has a good year and skip payment in a bad year, provided he had paid in advance in the good year.

The portion of the mortgage business done by the co-operative Federal land banks is rapidly increasing. Life insurance companies, private land banks, mortgage companies, banks and individuals also lend money on farm mortgages. The Federal Intermediate credit banks owned by the Federal Government, but managed by the land bank officers, lend money to marketing agencies on warehouse receipts and discount notes for banks and credit corporations. Most of the short-time credit used by farmers is furnished by banks or by dealers who sell goods on time. For tenant farms, landlords supply considerable credit. It is expensive for dealers to furnish credit; consequently farmers pay a very high rate of interest. Part is paid as interest, but a large part is covered by charging a high price. Mortgage credit is readily

almost twice as much co-operative purchasing and selling as did the owners. Grain, dairy products and live-stock were the leading products handled.

Credit.—Co-operative credit is available through the 12 Federal land banks. Although called Federal, the Federal Government owns no share in eight banks, and only 1% of the total stock of the 12 banks; all other stock is owned by the borrowers.

available on easy terms, but equally good short-time credit facilities have not been developed.

Roads.—Now that the horse has been so largely supplanted by automobiles and trucks, the road question has become of great importance to farmers. Roads are used even more as interurban thoroughfares than by farmers. Formerly all roads were considered local and practically all support came from the localities.

Now that roads have become national, farmers are often taxed to build roads for city use. On the primary highways in Pennsylvania, New York and Maine, 5% of the traffic was farm travel, in Georgia, 9%, and in Illinois, 10%. Much more than this percentage of maintenance is usually contributed by farmers. In 1925, 7.5% of the farms were on hard-surfaced roads and 15% on gravelled roads. The percentage on hard-surfaced roads was highest in the Middle Atlantic States, averaging 22%, but the percentage on either hard-surfaced or gravelled roads was highest in the east north central and Pacific States (Table XXVII.). From the standpoint of agriculture, the most important problems are the increase in the number of lateral roads and an adjustment in the methods of financing so that the local communities will pay no higher percentage of the cost of construction of these roads than their use is of the total use.

TABLE XXVII. Per Cent of Total Number of Farms on Different Kinds of Roads, 1925

Division	Concrete	Macadam	Gravel	proved lirt	U improved lirt	others
New England	1.3	12.0	24.4	22.4	38.1	1.8

United States	2.5	5.0	14.9	31.4	43.1	3.2

Tenancy.—About two-fifths of the farms in the United States are operated by tenants and the percentage is increasing. As the amount of machinery and other capital necessary to start farming increases, a longer time is required for a hired man to accumulate enough property to become an owner.

The percentage of tenancy is highest in the southern States where there are many negro tenants, and in the Middle West, where the capital per farm is high (Table XXVIII.). In New England, only 7% of the farms are operated by tenants and in the west south central States 53% are so operated (Table XXIX.). The most common form of tenancy is to share the crop for the farm. In regions where live-stock is produced in considerable quantities, the live-stock products are also shared. About one-fifth of the tenants pay cash rent. When a share of the product is given as rent, the fraction is usually one-third, two-fifths, one-half, etc. The difference between two-fifths and one-half may be very large when expressed in dollars. For this reason, a considerable number of share tenants pay some cash in order that the contract may be more closely adjusted to the value of the lease (Table XXX.).

In the cotton belt, two other forms of tenure have been adopted, primarily for negro tenants who require close supervision. One of these is called standing rent, in which the tenant pays a given quantity of cotton or other crop, regardless of the yield. All that he raises above this quantity is his own. This is intended to encourage more attention to the crop.

TABLE XXVIII. Number of Farms in the United States Classified by Tenure, 1880-1920*

Year	managers	Number of tenants	Per cent tenants
1880	2,984,306	1,024,601	28
1890	3,269,728	1,204,913	28

The cropper system is also classed as tenant farming, but is, in reality, half way between hired labour and tenancy. The owner of the farm furnishes mules and equipment, feed, fertilizer and living expenses for the worker. The worker receives a share of the crop and agrees to repay money advanced for his living. If the crop is good, payment is made; if not, the landlord may lose the money.

Farm Labour.— Before the World War, wages of farm labour were highest in the western States. Following the war, competition with nearby cities made farm wages in New York higher than in the West. Wages are lowest in the southern States, the average monthly payment in Alabama being less than one-half of those in the North (Table XXXI.).

*The quarterly wages published by the U.S. Department of Agriculture were weighted in the following manner to obtain the average yearly wage rate: April 1; July 2; October 2; and the following January 1.

Farm wages are influenced by prices of farm products and by conditions of employment and wages in cities. Near industrial centres, city wages have more effect on farm wages than do prices of farm products. For the United States as a whole, the wages of farm labour are influenced more by prices than by city wages (fig. 16). The average hours worked by farm operators per year are 3,020, but there is great variation from this average in different areas. The negroes take so many holidays that the farm labour

reported for some of the southern States amounts to only 2,034 hours. The total for Wisconsin is 3,421 hours. Since this is a dairy State, a large amount of work is done on Sundays and in all seasons. The Wisconsin farmer works about two-thirds more hours than farmers in some of the southern States and many more than farmers in China. Hard work is an important factor in the prosperity of the American farmer. He spends more years in school than does the Asiatic or negro farmer. He works more hours per year and usually is able to retire earlier. He may work fewer hours in his lifetime than the Asiatic farmer. In the regions

compared with those of Europe or Asia, they are small if measured in terms of workers. The labour force of the average farm consists of the operator, one hired man for each three farms and one member of the family assisting the operator for each three farms. The average farm, therefore, has less than two workers (Table XXXII.).

FIG. 16.— PRICES RECEIVED BY FARMERS FOR FARM PRODUCTS, FARM WAGES, CITY WAGES, 1910-1914=100 ON GRAPH
When farm prices rose, farm wages rose more rapidly than city wages. When farm prices fell, farm wages fell, but city wages remained high. Farm wages are more affected by farm prices than by city wages

Yields per acre in the United States are lower than in western Europe, but crop acres per worker are so much higher that the production per worker is about three times as much as in Europe, and six times as much as in Italy. From 1910-25, the population of the United States increased 23,000,000, but the farm population decreased over 3,000,000, in spite of which, the crop production increased about 10%. In 1925, the farm population was 28,984,221, or one-fourth of the total population.

Many more children are born on farms than are needed to do the farm work. Probably about one-half of the farm children go to cities. There is a constant movement from farms to cities and a smaller flow from cities to farms. A ten-year study of this question in New York State showed that on the average, about five persons went to cities from the farm for about every two persons that left the cities for the farm. The rate of movement from year to year was primarily dependent on conditions of city employment and profits of farming. In 1920, the net movement from New York farms to cities was 24,000. The following year, unemployment in cities was serious and the net movement was only 3,000.

that depend on crops, the amount of work during the summer is much higher than in the winter. Because of the use of machinery and the character of the population, the amount of work done per worker is very great. In China and India, there are 2ac. of crop-land per worker engaged in agriculture; in England, 6; and in Iowa, 56. When the high yield of corn per acre is considered, this large acreage indicates the very high production per worker in Iowa. The production per worker in the southern States is much lower because negroes do so much of the work. They accomplish much less per hour because so little machinery is used. There are only 10ac. of crops per person engaged in agriculture in South Carolina. While farms in the United States are large in acreage

*U.S. Department of Agriculture, *Yearbook*, 1926, pp. 1,177-80.

Exports and Imports.— The chief agricultural exports are cotton, wheat and pork. Nearly one-half of the cotton crop is exported. For a number of years before the World War, exports of food products declined, but exports of cotton increased. In the war period, there was a great increase in exports of food, but a decline in exports of cotton. After the war, food exports declined rapidly, but exports of cotton increased.

About three-fourths of the pork exported goes to Europe. Considerable pickled pork and pickled beef go to tropical countries. Most of the cotton and wheat go to Europe. Condensed milk, powdered milk, cheese and eggs are exported to tropical countries. As a whole, the major exports go to Europe and the major imports come from the tropics. The chief agricultural imports are sugar, coffee, hides, rubber and wool, all of which have constantly increased (Tables XXXIII., XXXIV., p. 416).

Taxation.— The usual method of farm taxation in the United States is a capital levy. The farms are assessed on the estimated value at market prices. In most States, machinery, live-stock and other personal property are similarly appraised. A certain percentage of this appraisal value is taken for school taxes, another for local and State taxes. A few States do not levy direct taxes for State purposes. Farmers contribute very little direct taxes to the Federal Government, as it levies no taxes on property. This system of taxation was fairly satisfactory when conditions were so uniform that the market price of a property represented its income-producing power. Such a method of taxation is unfair to industries with a slow turn-over. The most striking cases are forests and orchards, which give no returns for many years; agriculture as a whole has a very slow turn-over compared with commerce (Table XXXV.).

So much income is now derived from salaries, copyrights, patents, use of mails in advertising, etc., that real estate is no longer a good measure of ability to pay. Another difficulty is that railroads and manufacturing plants derive their revenue from large areas, but when taxed as real estate in some political unit, the tax does not go to the regions that contribute the business. With the growth in total taxes, considerable dissatisfaction with this method of taxation is developing. A few States are discontinuing direct property taxes and most States are raising an increasing percentage of their income from other sources. However, revenues for schools, roads and local government are based on property. Dissatisfaction with this system is resulting in increased aid for schools and roads from the State and nation.

The changes in taxes on a few farms in New York State indicate the increasing burden of taxation. One hundred years ago, six days of labour at farm wages were required to pay the taxes, but now about 37 days are required. The taxes could have been paid with 3bu. of wheat, but 104bu. are now necessary. In most States, taxes were from two to nearly three times as high after the World War as before. They rose almost directly in proportion to wages. The major portion of the farm taxes are spent for labour and for salaries of school teachers and other public employees. Therefore, they rise as these payments advance.

Land Values.— The average value per acre of farms in the United States nearly doubled in the 50 years ending with 1900 and doubled in the following 10 years. Prices declined from 1870-80, and from 1890-1900. They rose rapidly from 1910-20 and declined thereafter. The rise in the price of farm-land does not indicate an increase in the value of the same property. Thousands

of acres of land were drained. Many new buildings were erected and others improved. Land was cleared, fences were built, orchards were planted. There is no way of telling what portion

Acres of land that a month's labour at farm wages would buy	0.44	0.65	0.62	0.70	0.49	0.68	0.71

of the increase was due to improvements and what portion to rising prices. Prices in typical States are shown in Table XXXVI. The corn belt is the region of highest land price and has shown the greatest increase in prices.

The acres of land that could be bought with the cash paid for a month's labour in addition to board, are shown in Table XXXVI. The largest amount of land that could be bought with a month's labour was in 1925 when one-half more land could be purchased than in 1870 or 1910. Some farmers acquire land by gift or inheritance, but the majority acquire it by working as hired men or as tenants. The most common single method is to work as a hired man and later as a tenant.

Prices.—American agriculture is characterized by family farms operated with machinery on a commercial basis. When the chief purpose of the farmer was to raise his own supplies, prices were of minor concern. A large crop was an occasion for thanksgiving and was in fact the origin of Thanksgiving Day. With commercial agriculture, a large crop usually brings the American farmers less than a small crop. Formerly, a large crop meant that the farmer would live well. To-day, with commercial agriculture, it means that he lives poorly.

The relations of the size of the corn crop to prices paid to farmers in Iowa, and to prices in Chicago and Liverpool, are shown

TABLE XXXVII. Relation of the Size of United States Crops to Prices*

Crop	Crop 20% below normal	Crop 20% above normal
	Percentage that prices were above normal	Percentage that prices were below normal
Potatoes:		
Minnesota farm price (1895-1911)	50	28
Rhode Island farm price (1895-1915)	22	15
Corn:		
Iowa farm price (1877-1913)	42	25
Chicago wholesale price (1876-1913)	26	17
Liverpool wholesale price (1898-1913)	15	11
Beef cattle:		
Nebraska farm price (1890-1914)	50	28
Chicago wholesale price (1890-1914)	17	12
United States retail price (1890-1914)	15	11

*G. F. Warren and F. A. Pearson, "Inter-relationships of Supply and Price," *Cornell University Agricultural Experiment Station Bulletin 466*, Sept. 1927.

in fig. 17 and Table XXXVII. A crop 20% below normal ordinarily sells for about 42% above the normal price on Iowa farms, but brings only 15% above the normal price in Liverpool. A crop 20% above normal ordinarily sells for about 25% below normal prices in Iowa, but prices in Liverpool are depressed only about 11%. Retail prices of corn meal are only slightly affected by the size of the corn crop. A crop of potatoes 20% above normal depresses the Minnesota farm price 28%, but reduces the Rhode Island farm price only 15%. The smaller reduction in price in Rhode Island is because farmers there are so near the consumers that the farm price is more like a retail price. Most of the American farm products are so far from consumers, that prices fluctuate with extreme violence. Prices to European farmers usually fluctuate less, not only because farmers are nearer the consumers, but because so large a part of the product is consumed on the farms. Commercial production far from consumers results

FIG. 18.— PURCHASING POWER OF THE PRICE OF HEAVY HOGS AT CHICAGO, 1860-1927

The centres of the major cycles of low prices are from 5 to 8 years apart. If this cycle is of usual length, hogs may decline in purchasing power

FIG. 19.— PURCHASING POWER OF THE PRICE OF SHEEP IN THE UNITED STATES, 1880-1928

Sheep have periods of high and low prices, usually lasting about 4 or 5 years. On Jan. 1, 1928, the purchasing power of sheep was the highest ever known, 175

FIG. 20.— PURCHASING POWER OF PRICE OF BEEF CATTLE AND DAIRY COWS IN THE UNITED STATES, 1880-1928

The major centres of high and low prices of dairy cows and beef cattle occur at the same time. The periods of high prices are about 16 years apart. The last high period was in 1915

in violent price fluctuations. In agriculture, this problem is comparable with that of unemployment in cities.

For most industrial products, a year of high prices is one of high production, because it takes such a short time to produce goods. In agriculture, a much longer time is required to produce. High prices result in increased production, but it is from one to many years before the increased product appears on the market. A retail price of round steak, 20% above normal, results in receipts of cattle at Chicago 32% above normal 8 years later. When

prices are low, animals are thrown on the market and production is checked, but it is some years before the shortage occurs. The periods of high prices of hogs are 5-8 years apart; for sheep, 4-5 years; for beef cattle, about 16 years; for horses, 25 years (figs. 18, 19, 20 and 21).

Cost of Distribution.— In 1917, beef sold at retail in the United States for an average of 23.11¢ per pound. Farmers received 8.14¢ per pound for beef cattle. There was a difference of

FROM "FARM ECONOMICS"
 FIG. 21.—PURCHASING POWER OF THE PRICE OF HORSES IN THE UNITED STATES. 1880-1928
 Periods of high prices usually are about 25 years apart. Apparently the price of horses has begun to advance

FIG. 22.—COMPARISON IN COST OF DISTRIBUTING BEEF WITH EARNINGS OF NEW YORK FACTORY WORKERS
 Costs of food distribution follow wages, but because of increases in efficiency have risen less rapidly than wages

FIG. 23.—INDEXNUMBERS OF THE UNITED STATES FARM PRICE OF FOODS, COST OF DISTRIBUTION AND THE UNITED STATES RETAIL PRICE
 From 1916 to 1920, costs of distribution were low and farm prices were relatively high. Since 1920, costs of distribution have been high and farm prices low

14.97¢ between the farmer and the consumer. In 1921, beef cattle retailed at 25.59¢ per pound, but farmers received only 5.53 cents. In 1917, the retail receipts from a 1,000lb. live steer amounted to \$143.70. In 1921, they amounted to \$159.20. In 1917, it cost \$62.30 to distribute the beef and in 1921 it cost \$103.92, so that farmers received \$81.40 in the first case and \$55.30 in the second. Some persons believe that the lower farm price in 1921 was due to over-production, but retail prices were higher than in 1917.

For the five years before the World War, the average cost of distributing the beef from a 1,000lb steer was \$49. Following the World War, it was over twice as much. In each case, the farmer received the balance. The cost of distributing foods is primarily city wages (fig. 22). When financial inflation occurs, wages and the cost of distribution are low, relative to retail prices, and farm prices are very high. When financial deflation occurs, wages and the cost of distribution remain high and farm prices are low compared with retail prices (fig. 23). See UNITED STATES, *History*, 1929-35. (G. F. W.; F. A. PE.)

Agricultural Chemistry.— Agricultural chemical investigations in the United States are conducted in the various bureaux of the Federal Department of Agriculture, in the agricultural experiment stations of the States, in many universities and research institutions and in the laboratories of various industrial establishments.

The chemical control of commercial fertilizers and the study of fertilizer action upon the growth of crops engaged at first almost the exclusive attention of agricultural chemists in the United States. The study of cattle feeds for regulatory and research purposes was next taken up and finally, with the passage of State and Federal pure food laws, the diet of man began to be investigated—first for the prevention of adulteration and then for the improvement of human nutrition. The sequence of plant, animal and man, although apparently illogical as regards importance, was the natural order of research development. The passage of State and Federal laws governing the purity of insecticides made a further increase in the regulatory activities of agricultural chemists in America and the experiment stations began to find their investigational work so seriously disturbed by regulatory interferences that many of these institutions felt obliged to transfer all work of chemical control to State chemists. The policy of separating research and control work has been adopted by most of the State experiment stations. It was put into effect in the U.S. Department of Agriculture in 1927, when the execution of the Food and Drugs Act, the Insecticides Act, the Tea Inspection Act and the Naval Stores Act was transferred from the Bureau of Chemistry to the purely regulatory Office of Food, Drug and Insecticide Administration. The agricultural chemical research work of the department upon soils, fertilizers, foods, etc.,

was consolidated in a new Bureau of Chemistry and Soils. A survey of the last classified list of projects of the U.S. agricultural experiment stations shows that of a total of 6,610 projects some 1,400, or about 21%, involve various applications of chemistry to agriculture. Of these 412 relate to fertilizers and fertilizer experimentation, 188 to soils and waters, 172 to animal nutrition and 117 to human nutrition. Agricultural chemical investigations as a whole follow the numerical order of plant nutrition, animal nutrition and human nutrition. Individual State experiment stations specialize in particular types of research, lysimeter studies upon percolation in soils, for example, being given the most attention in Tennessee, soil acidity in Rhode Island, alkaline soils in California, vegetable proteins in Connecticut and animal calorimetry in Pennsylvania. The lines of investigation depend naturally upon the predominating agricultural needs of each section, chemical investigations upon dairy products being stressed by New York, Wisconsin and other large milk-producing States, those upon flour by Minnesota and the other wheat-awovina States, those upon sugar production by the cane-growing-states-of the South and the beet-producing States of the West and those upon corn by Iowa and other large corn-growing States of the Middle West. The most active subject of agricultural chemical research in America at the present time is that of vitamins, 23 of the State experiment stations conducting investigations in this field. Other investigations upon vitamins are being carried out in the research laboratories of various universities and in the bureaux of the U.S. Department of Agriculture.

In the U.S. Department of Agriculture agricultural chemical researches are conducted in the bureaux of chemistry and soils, plant industry, animal industry, dairy industry, forestry, entomology, home economics and agricultural economics. Among the more important chemical projects of these bureaux are investiga-

tions upon soils, fertilizers and nitrogen fixation; foods and food technology; human and animal nutrition; plant constituents; insecticides and fungicides; chemistry and technology of tanning materials, leather, paper, farm fabrics, sugar, starch, oils and fats; meat products, dairy products, forestry products, etc.; storage of fruits, cereals and vegetables; utilization of farm wastes; spontaneous combustion; deterioration of agricultural products; explosions of agricultural dusts; and methods of agricultural chemical analysis. Important agricultural chemical researches are also conducted in the United States in the laboratories of the large packing houses and other industries which utilize agricultural products.

The most important agricultural chemical organization in the United States is the Association of Official Agricultural Chemists (established 1884) which publishes a journal and books of methods upon agricultural chemical analysis. (C. A. B.)

EXPERIMENT STATIONS

In the United States experiments were early conducted by the agricultural colleges, but not until 1875 was the first American experiment station with State support established. This was situated at Middletown, Conn., under Dr. W. O. Atwater, and later removed to New Haven with Dr. S. W. Johnson as director. It still survives as the oldest American station. The University of California next provided funds for a station at Berkeley, under the leadership of Dr. E. W. Hilgard. Other States soon followed, so that by 1887 there were about 18 stations, some with meagre support.

The movement for a nationally supported system of experiment stations culminated in the passage of an act approved on March 2, 1887, and designated the Hatch Act, in honour of its champion, Hon. William H. Hatch. It authorized an annual appropriation of \$15,000 for an experiment station in connection with each of the agricultural colleges established under the Land Grant Act of 1862. This gave a marked impetus to the experiment stations, and States which had not previously provided them promptly took advantage of the act. In 1906 the fund was supplemented by the Adams Act, designed especially to promote original scientific investigation of agricultural problems. On its maturity in 1911 this act doubled the annual Federal support. This was again enlarged in 1925 by the Purnell Act, which authorized an increase of \$20,000 to each State the first year, with annual additions of \$10,000 until \$60,000 was reached and also extended the scope of research to include agricultural economics, home economics and rural sociology. In addition to the grants under the two previous acts, each State will thus receive \$90,000 in 1930, or an aggregate of \$4,320,000. The Federal grants are liberally supplemented by State appropriations, aggregating about three times those from the Federal Government. In Alaska, Hawaii, Porto Rico, Guam and the Virgin islands, experiment stations are maintained with special congressional appropriations under the Federal Department of Agriculture. The first was established in Alaska in 1898. Experimental work in the Philippines is under the insular Government, and receives no financial support from the United States.

The Federal Department of Agriculture aids in promoting the purposes of the stations through a central office of experiment stations, which exercise supervisory control over the Federal appropriations, maintains intimate relations with the stations in all the States, has charge of the insular stations, and issues a journal, the *Experiment Station Record*, begun in 1889, which reviews the publications on agricultural research throughout the world. The office also publishes an annual report on the progress of the stations. There has thus been developed a comprehensive and closely knit system of experiment stations, co-operating with one another and with the Department of Agriculture, and supported jointly by the States and the general Government. Total appropriations for the fiscal year 1927 aggregated \$12,733,000, including \$233,980 for the insular stations. The stations employed 2,831 persons in administration and research, some of them only part time, in addition to clerks, labourers and temporary help. Many of the States also provide branch stations or sub-stations

dealing with special enterprises, such as citrus fruits, sugar, rice, tobacco, or with the special problems of localities.

In addition to the stations receiving the benefits of the Federal Acts, a number of special stations have been provided in the States, such as the poultry and fruit stations in Missouri, the coastal plain station in Georgia, the truck station in Virginia, the institute of animal nutrition in Pennsylvania, and the stations for the sugar and pineapple industries in Hawaii. In this connection, mention should also be made of the privately supported Boyce Thompson Institute for plant research at Yonkers, N.Y., opened in 1924; the Food Research Institute at Stanford university, for studying problems connected with food supply, consumption and distribution; and the Marble Laboratory at Canton, Pa., equipped for study of fruit storage.

The State experiment stations have experimental fields and trial grounds: accommodation for experimental animals; insectariums; creameries and cheese factories; veterinary hospitals; and laboratories for chemical, botanical and bacteriological study (*see AGRICULTURE: in the United States: Agricultural Chemistry*).

All the stations publish bulletins, circulars and annual reports dealing with the results of their work, and these are sent through the mails free of postage.

Many popular articles are prepared for the Press, while the more technical features of research are published in appropriate scientific journals.

The stations are in close contact with the farming public and with extension workers.

The results of experiments are thus spread broadcast, often being applicable far beyond the boundaries of the State in which the investigations were carried on. (E. W. A.)

AGRICULTURE, CENSUS OF. The term "census" originally was restricted to a periodical enumeration of the population of a country by its Government, but its significance has widened. It is now applied to any systematic statistical enquiry, on a wide scale, into the economic or sociological conditions of the population or a section of it. Special enquiries in connection with agriculture have been made either annually or at less frequent intervals in many countries for a considerable period (*see AGRICULTURAL STATISTICS*), but they were limited in scope. Usually they were confined to statistics of the number of farms or holdings, the acreage and yield of crops and the number of live stock. An agricultural census is more comprehensive. Its object is to obtain a complete return of the production from agricultural land, and of the power—human, animal or mechanical—employed in the production.

GREAT BRITAIN

In Great Britain an agricultural census was first taken in connection with the Census of Production Act, 1906. Under this act compulsory powers were given to the Board of Trade to obtain returns of the output of all industries, but agriculture was expressly excluded, mainly on the ground that much of the information relating to that industry was already obtained annually under a long-established system of voluntary returns from all occupiers of farms. On Nov. 23, 1907, the Board of Trade addressed a communication to the Board (now the Ministry) of Agriculture stating that for the purposes of the census of production schedules issued by them would be required to be filled up by manufacturers and other industrialists, but in the case of the produce of agriculture it was proposed to leave the collection of the necessary information to the agricultural department. The Board of Agriculture acquiesced and proceeded to issue a series of enquiries designed to supplement and complete the information obtained by the annual agricultural returns.

Census of 1908.—The results of the census taken in 1908 were published under the title of "The Agricultural Output of Great Britain," described as a "Report on enquiries made by the Board of Agriculture and Fisheries in connection with the Census of Production Act, 1906, relating to the total output of agricultural land, the number of persons engaged and the motive power employed." The "output" from agricultural land is not the same as the production. It is evident that crops produced and consumed

by live stock would be reckoned twice if their total bulk were added to the beef, mutton and pig-meat produced. Such crops are of the nature of raw materials used in the process of manufacture. The object therefore was to calculate the net production or "output," being, in fact, that part of the gross production which is sold off the farms. The total value of the crops grown in 1908 was calculated (at market prices) at £125,000,000, of which £46,600,000 represented the portion actually sold. The actual value, or, as it is termed, the "consuming value" of the major portion of the crops was thus dependent on their realization in other forms.

The total sales, *i.e.*, the "output" from all the farms, were:

	£
England and Wales	127,650,000
Scotland	23,150,000
Great Britain	150,800,000

The permanent labour employed throughout the year on the farms of Great Britain, excluding the occupiers themselves but including members of their families, was 1,173,000 persons. Consequently the gross output per person employed was £129. On the total area included in the agricultural returns the gross output amounted to £3 3s. 1d. per acre but the range was very wide on different classes of land. Thus the return from woodland was only about 6s. and from rough grazings not more than 10s. or 12s. per acre. On the cultivated area, *i.e.*, the farmed land proper, the average output was £4 10s. per acre. The mechanical motive power used on farms was generated by 34,450 engines of various descriptions with a total horsepower of 213,525.

Census of 1925.—It was intended that an agricultural census should be taken, with the census of production, quinquennially, and in 1913 the Board of Agriculture again made detailed enquiries on similar lines to those made in 1908. But before the returns could be fully tabulated and analysed the outbreak of war interrupted the work and compelled the transfer of the staff engaged upon it to more urgent matters. It was not until twelve years later that it became possible to resume the enquiries under the Census of Production Act, and as on the previous occasions the agricultural census was undertaken by the agricultural departments. The establishment, in the interval, of the Board of Agriculture for Scotland left the English department responsible only for England and Wales. The result of their enquiries was published early in 1927 under the title of "The Agricultural Output of England and Wales, 1925" (Cmd. 2815), and described as a "Report on certain Statistical Enquiries made in connection with the Census of Production Act, 1906, relating to the output of all kinds of agricultural produce and to the agricultural industry generally, together with a brief survey of agricultural statistics up to 1925."

The scope of the report was wider than that relating to 1908 not only by the inclusion of serial tables for a number of years where the materials were available, but also by an endeavour to meet a desire expressed in the House of Commons during the years 1925 and 1926 for a complete survey of the agricultural conditions and possibilities of the country. An attempt was made to meet that demand on the statistical side, it being admitted that "there are necessary limitations to the information which can be supplied by agricultural statistics and also to the deductions which can safely be drawn from them."

The value of the total output from all farms in England and Wales in 1925 was £225,330,000. The following table gives the comparative figures for each of the main groups of products in 1908 and 1925 with the percentage increase in each case:

	Thousands of £.		Percentage increase.
	1908	1925	
Live stock	50,800	78,970	55
Dairy produce	25,500	57,600	126
Poultry and eggs	4,350	15,080	247
Wool	2,100	3,000	43
Farm crops and vegetables	40,200	54,450	35
Fruit, flowers, etc.	4,200	16,230	293
Annual Totals	127,150	225,330	77

The average increase of prices in 1925 over 1908 was calculated at 77%, so that it would appear that the output was practically the same in each year although the area of agricultural land had been reduced in the interval.

Of the total output in 1925 live stock and live stock produce represented 68.6%, farm crops 20.5%, and fruit, vegetables, flowers, etc., 10.9%. Sales of fat cattle, sheep and pigs—excluding transactions in store stock between one farmer and another—represented 3576, and sales of dairy produce 25.6% of the total sales. Poultry and eggs, the output of which increased since 1913 to a greater extent than that of any other kind of produce, represented 6.7%, and wool 1.3%. Corn crops accounted for no more than 10.7%, and potatoes for 5.3% of the total. Of the corn sold about one-half in value was wheat.

Strictly speaking the output of farms is meat-animals and not meat itself in its consumable form. But, following the precedent set in the 1908 report, a calculation of the quantity of meat represented by the animals sold annually off the farms was included in the 1925 report. The average number of each kind of meat-animal slaughtered annually was calculated as follows, the numbers being in thousands (000's omitted):

<i>Cattle</i>	<i>Calves</i>	<i>Sheep and lambs</i>	<i>Pigs</i>
	785	5,194	3,518

The average total quantity of meat produced (in thousands of cwt.) was:

<i>Beef</i>	<i>Veal</i>	<i>Mutton and lamb</i>	<i>Pig-meat</i>	<i>Total</i>
6,866	609	2,411	5,026	14,912

There has apparently been a substantial reduction in the production of English meat. If the estimated weight of meat of all kinds is added together the total quantity has decreased since before the war by 15%. Taking into account the increase of population the supply per head of English meat fell from 55 lb. to 44 lb., a reduction of 20%. The change in the extent of the home supply varies in each kind of meat. Beef production declined by 17% and mutton and lamb by 38%, but veal increased by 30%, and the production of pig-meat remained about the same.

Of the total quantity of milk produced about four-fifths is consumed in its natural state as liquid milk. Of the remainder about three-fourths is made into butter and one-fourth into cheese. The production and disposal of milk and dairy produce in England and Wales in the year ending June 4, 1925, are shown in the following table:

	Sales off farms		Consumed in farm households		Total	
	Actual	Equivalent milk	Actual	Equivalent in milk	Actual	Equivalent in milk
Millions of gallons						
Liquid milk	818	818	70	70	888	888
Butter	454		115	33½	569	166½
Cheese	481	133	54	21	502	56
Cream	650		6½	..	650	6½
Total milk	..	1,011½	..	105½	..	1,117

The cream consumed in farm households is included under liquid milk. A considerable portion of liquid milk is sold by farmers to factories and creameries where much of it is converted into butter or cheese. Consequently the amount of milk actually consumed is less, and that of butter and cheese greater, than is shown in the above table.

Returns of the motive power used on farms showed a great increase in 1925, as compared with 1908, in the number of oil or petrol engines. In 1908 there were only 6,911, but in 1925 there were 56,744. On the other hand steam engines had been reduced from 8,690 to 3,731. Electric motors increased from 146 to 700. The number of motor tractors, which were not known in 1908, in use on farms in 1925 was 16,681.

Persons Employed.—An exact calculation of the amount of manual labour employed in agriculture is not possible owing to uncertainty as to the number of persons, male and female, who are engaged only on part-time or for certain seasonal occupations (see AGRICULTURAL LABOURER). The report suggests that "the total number of persons employed in the agricultural and horticultural industries in 1925 was in the neighbourhood of 800,000 which, with about 300,000 employers or persons working on their own account, gives a total of 1,100,000 engaged in the industry." On the basis of these figures it is calculated that the average output per person employed was £282, while if employers working on their own account are included the average is £205.

No official returns of the rent of agricultural land had previously been collected, but in connection with the agricultural census of 1925 estimates were obtained from the crop reporters of the average rents of holdings of various types. The average for all holdings, omitting those devoted solely to fruit, vegetables or poultry, was 31s. per acre. For arable holdings the average was 26s., for pasture holdings 36s., and for mixed holdings 29s. per acre. Classified according to size-groups, rents averaged 62s. per acre for holdings of 1 to 5 acres and 51s. for holdings of 5 to 20 acres, declining progressively to 24s. for holdings of 300 to 500 acres and 20s. for holdings of over 500 acres. The gross rental value of all farms was calculated at £43,350,000, and the gross capital value of all agricultural land at £815,000,000. The total amount of tenants' capital, including the value of live and dead stock, the tenant right valuation and other working capital was estimated at £365,000,000. (R. H. R.)

THE UNITED STATES

The first census of agriculture in the United States was taken in 1850. Beginning with this date, the farm census, covering a gradually increasing number of items, has been taken in connection with each decennial census of population up to and including 1940. Beginning in 1925, an interdecennial census of agriculture has been taken, thus providing quinquennial census data on agriculture.

The censuses taken in the middle of the decade are less extensive in scope than the decennial censuses, but serve an important purpose in furnishing more nearly current information on the basic agricultural activities, some of which are now undergoing rather rapid change.

In 1850, there were enumerated in continental United States 1,449,073 farms; in 1910, 6,361,502; in 1920, 6,448,343; in 1930, 6,288,648; and in 1940, 6,096,799. The decreases between 1920 and 1940 represent a general trend toward fewer and more productive farms. The decrease during the decade ending in 1940 was due in part to the recombination of small tracts, formerly operated as independent units by croppers or other tenants, into larger aggregates operated by hired labour, and to the effects of continued adverse weather conditions in western plains states.

The census of agriculture, like the census of population, is based upon information obtained by a large force of enumerators, who visit all the families in the United States, covering most of the territory within one month from the census date. The information for the census of agriculture was obtained, in 1940, on a four-page schedule, containing well over 300 questions—though by no means all of these questions would apply to any one farm. Nine different regional forms of the schedule were used, each calling for information in the crop section for those crops only which were actually grown in the specified region or section.

The census differs from the various estimates of crop production, live stock, etc., in that it is based upon a direct count of all the items represented, rather than upon a sample or upon calcu-

lated probabilities. The returns are carefully checked against the records of the previous censuses and are subjected to other forms of critical examination, so that ordinarily there is little opportunity for serious error in the count.

Nevertheless, the task of obtaining and tabulating reports from 6,000,000 farms is one of great magnitude on the mechanical side alone.

In order to make possible the prompt tabulation and classification of the returns, the information is taken off the schedules on punched cards, one card being used for each item or group of items. The cards may be tabulated, without sorting, on a machine which adds the punched figures representing acres, numbers of horses or cattle, dollars of property value, bushels of corn produced, etc., to obtain totals for the township or county represented by the cards; or the cards for a county may first be sorted by such items as tenure, size of farm or colour of farm operator, and then tabulated to obtain totals of the various items classified into groups on the basis of the several sorts. The machine at the same time counts the number of farms in each area or group, and possibly also the number reporting or not reporting a specified item. One tabulation, for example, might provide the number, total acreage and crop-land acreage of farms operated, respectively, by white and coloured owners, managers and tenants in each county, and another might provide similar data for farms in a dozen size groups (under 3 acres, 3 to 9, 10 to 19, 20 to 49, 50 to 99, etc.). Or again, if it is desired to know what part of the production of potatoes, for example, comes from large-scale operations, the cards may be sorted on the column showing the number of bushels of potatoes reported by individual farms (under 20, 20 to 39, 40 to 59, 60 to 79, 80 to 99, 100 to 199, etc.) and tabulated on this basis. The whole number of cards punched from the schedules in 1930 was 134,000,000 or about 21 cards per farm. Each of these cards went through the sorting and tabulating machines a number of times, so that the total amount of work of this nature amounted to the equivalent of 1,344,000,000 cards run through one of these machines one time.

The information obtained in the 1940 farm census may be grouped under seven headings:

(1) **Information with Regard to the Farmer.**—The personal questions included colour, age and date of beginning operation of present farm. The classification by tenure may be considered as relating either to the farmer or to the farm, according to the point of view.

These tenures were distinguished: Full owner, part owner, manager, cash tenant, share-cash tenant, share tenant, cropper (southern states only) and other tenant. The percentage of farms operated by tenants in 1940 was 38.7, as compared with 42.1 in 1935, 42.4 in 1930, 38.6 in 1925, 38.1 in 1920, 35.3 in 1900 and 25.6 in 1880. The increase in tenancy from 1900 to 1925 was slow, with an increase from 1925 to 1930, a decline from 1930 to 1935, and a marked decline from 1935 to 1940, resulting largely from the consolidation of tenant holdings in the south.

The classification of farmers by age and tenure shows that tenancy is most common in the younger groups, and this gives support to the theory of the "agricultural ladder," according to which the normal course of farm experience is for a young man to start as a farm hand, perhaps on his father's farm, and then to become, successively, a farm tenant, an owner subject to mortgage, and finally, the owner of an unencumbered farm. The replies to a question in the 1930 census also indicate that a large proportion of the tenants outside the south rent their farms from close relatives, the proportion running as high as 40%, and even 50% in some counties. The social significance of tenancy under these conditions is, of course, radically different from what it would be if the relation between landlord and tenant were purely a business matter.

(2) **Farms and Farm Property.**—In addition to the total acreage of land in farms, the decennial censuses up to 1920 have given the acreage of improved land, which is, in most parts of the country, a better measure of the agricultural importance of the farm. In later censuses, beginning with 1925, this item has been replaced by a more detailed classification of farm land, separating,

in particular, the different types of pasture land, and showing separately crop land idle during the preceding year, and crop failure, as well as indicating the land from which crops were harvested.

The total acreage of land in farms increased from 293,560,614 in 1850 to 986,771,016 in 1930, and from this figure to 1,060,852,374 in 1940. Of the 1940 total, 530,131,043 ac., or 50%, were designated "land available for crops," comprising all land reported as crop land, together with plowable pasture. This last figure may be considered as a rough approximation to the "improved land" of the older classification, though it is not an exact equivalent.

The relation between the acreage of agricultural land and the population is of great social significance.

The changes in this relation between 1850 and 1940 are shown in the following table:

Relation between Population and Acreage of Improved Farm Land in the United States, 1850 to 1940

Census year	Population	Improved farm land (acres)	Population per 1,000 acres of improved farm land	Acreage of improved farm land per capita
1940 .	131,669,275	*530,131,043	248	4.02
1930 .	122,775,046	*522,395,804	235	4.25
1920 .	105,710,620	503,073,007	210	4.76
1910 .	91,972,266	478,451,750	192	5.20
1900 .	75,994,575	414,498,487	183	5.45
1890 .	62,947,714	357,616,755	176	5.68
1880 .	50,155,783	284,771,042	176	5.68
1870 .	38,558,371	188,921,099	204	4.90
1860 .	31,443,321	163,110,720	193	5.19
1850 .	23,191,876	113,032,614	205	4.87

*Land available for crops.

The value of farm property shown in the census reports includes not only value of the farm real estate, with separate figures for the value of buildings, but also the value of implements and machinery and of livestock. The aggregate value, after increasing from \$20,440,000,000 in 1900 to \$77,924,000,000 in 1920, declined to \$57,018,000,000 in 1925 and showed only a slight increase in 1930; in fact, the value of land and buildings alone, which amounted to \$66,316,000,000 in 1920 and \$49,468,000,000 in 1925, showed an appreciable decline in 1930, a much greater decline, to \$32,859,000,000, in 1935, and a slight increase, to \$33,642,000,000, in 1940.

The main reason for the decline in the reported value of farm property has been, without doubt, the decline in the market value of farm land per acre, which had risen to unduly high levels in the years just prior to 1920 by reason of war demands for agricultural products.

The value of farm land and buildings in the United States in 1940, it may be noted, was very nearly the same as the value in 1910 (\$34,801,000,000).

Data on farm mortgage debt are secured only for farms operated by their owners, and the figures representing the amount of debt are shown only for what are termed full owners, that is, farmers who own all the land that they operate. The reports of the census of 1940 show the rates of interest paid on the farm mortgage debt, as well as the amount of the debt and the value of the mortgaged farms.

(3) Livestock.—The livestock inventory, as obtained at the various decennial censuses, has shown an increasing amount of detail in the classification. It has been found desirable not only to report separately the calves, lambs, colts, etc., as representing a new generation of livestock just coming into existence, but also to make other age classifications, separating, for example, horses and cattle between one and two years old from those two years old and over. Sex classifications are also required. Recent censuses have attempted to separate dairy cattle from beef cattle, though the results so far obtained have not been absolutely satisfactory, mainly because of the difficulty of classifying general-purpose cattle,

(4) Crops.—Perhaps the simplest and most fundamental item in the farm census, after the number and acreage of farms, is the acreage of the more important crops harvested in the year preceding the date of the census enumeration. The census schedules call both for the number of acres harvested and for the quantity of the product. Previous to 1920 each farmer was asked to state also the value of his product. Beginning with 1920 the average value per bushel or other unit of measure has been obtained independently for most of the crops, and the value has been computed for the total production of each county.

The cotton crop receives special attention. Its acreage and production are reported along with other crops in the returns of the decennial or quinquennial censuses. In addition, reports of production are secured every year from the ginners of cotton. These reports are received (and published) semimonthly during the major part of the ginning season, and the total production of cotton, as reported by the ginners, is available to the public shortly after the harvest is completed. The cotton-ginning reports probably represent the most accurate statistics of crop production that are available for any crop on a large scale anywhere in the world.

(5) Livestock Products.—The livestock products reported in the census comprise wool and mohair, honey, eggs and chickens and dairy products, including the total production of milk, the farm production and sales of butter and sales of milk and butterfat. Some difficulty is experienced in obtaining accurate reports from farmers as to the total production of milk, except in cases where practically the whole amount is sold.

(6) Miscellaneous Items.—Figures representing farmers' expenditures for feed, fertilizer and labour, have been obtained as a part of the farm census for several decades; in 1930 expenditures for purchased electric light and power and for farm implements and machinery were added to the list, and in 1940, expenditures for gasoline and oil and for building materials.

An increasing number of questions relating to specific types of farm equipment and home conveniences has been carried on the farm census schedule for recent censuses. These items included, in 1940, the number of automobiles, motor trucks and tractors on each farm; the number of farms having a telephone; the number of farm homes lighted by electricity from (a) a power line or (b) a home plant; proximity to an electric power line; and the kind of road adjoining the farm.

There were also questions with respect to farm labour employed on the farm during the last week in March and the last week in September and the amount of wages paid for hired labour during the year 1939; a question calling for the number of days the farm operator worked for pay off his own farm and the occupation followed in this outside work; a question on farm taxes; and a question on sales or purchases through co-operative organizations.

(7) Type of Income.—Among the new features embodied in the 1930 census of agriculture, perhaps the most important was a classification of farms by type and by value of products. The types were based primarily on source of income, the 11 main types being: general, cash-grain, cotton, crop specialty, fruit, truck, dairy, animal specialty, stock-ranch, poultry and self-sufficing (farms producing mainly for home consumption).

In combination with the classification by type, the farms returned in the year 1930 were also classified by value of products, this value including all products sold, traded or used by the farmers' families.

The report shows also, by type of farm, the acreage of different classes of farm land, the value of farm property, the number of livestock, the values of different classes of products sold, tenure and expenditures for feed, fertilizer and labour, and a classification by size of the farms of each type. Similar data are being compiled for 1940.

Census of Irrigation and Drainage.—In addition to data on irrigated crops collected from individual farmers, the decennial census of agriculture includes also statistics collected from the "enterprises" or organizations controlling the irrigation works. These statistics cover the extent of the activities of the enterprise as measured by capital investment, acreage irrigated and

length of irrigation canals; the source of the water supply (streams, gravity; streams, pumped; wells; lakes, etc.); the form of organization, as co-operative, individual or partnership, irrigation district, etc.; the equipment for pumping; and the cost of water to farmers.

The data collected from drainage enterprises cover the form of organization; the purpose of drainage (reclamation of swamp land, improvement of land already in farms, removal of alkali in irrigated lands, etc.); type of drainage works (open ditches, tile, levees, etc.); pumping equipment where used; and capital invested. (L. E. T.)

AGRICULTURE, CHAMBERS OF. The Central Chamber of Agriculture in Great Britain was founded in 1866 simultaneously with the formation of local chambers in the country. These were combined into one association, known as the Central and Associated Chambers of Agriculture. The objects of the Association are to promote the interests of agriculture, and with that view to watch over all measures affecting agriculture both in and out of parliament, and to take such action thereon as may seem desirable in its interests. The scope of the association has widened, and it now comprises not only chambers and farmers' clubs, but agricultural societies, unions, federations, dairy associations and other agricultural institutions. Its aim is to form a common centre for all the different sections and groups in the industry. The work of the chamber is governed by a council of twenty-four members chosen by the subscribing members of the central chamber, and about 70 deputies appointed annually by the various federated bodies.

AGRICULTURE, PRIMITIVE. Agriculture (cultivation or tillage of the ground for the production of plants for food) is the basis of civilization, and primitive agriculture marks the transition from the lowest cultural stage, commonly called savagery. When and where, how and why were the first steps taken? No simple answer can be given. As to the date and place, a few hints are given by archaeology, but where primitive agriculture is now established there is rarely even a tradition of its origin. "God Almighty first planted a garden" is the general belief, God being represented by Osiris in Egypt, King Kintu in Uganda, Sidi or Soidi in Torres Strait, Ofanu in Tahiti, Tupan in Brazil, and by all the other local culture-heroes who brought the good gifts to men. As to the how and the why, information must be sought in areas where beginnings are being made. There is as yet no cultivation of the soil or raising of crops in the Arctic regions, in the semi-desert regions of north and south Africa and Arabia, in the prairies of North America, the steppes of Asia, the high plateaux of Tibet and Mongolia, or the whole of central Australia. It is unknown also in certain jungle areas inhabited by groups of pygmy peoples, such as the Negrilloes of the Congo, the Andamanese, the Semang of the Malay peninsula, and there is no record of it among the extinct Tasmanians.

The first steps have been noted in various parts of the world.

In Western Australia a species of flag was cultivated to the extent of burning down the crop at the end of the season to improve the next crop. Also, when digging up yams, the natives replaced the heads in the holes. Purslane (*Portulaca*) was also encouraged if not artificially cultivated. The Besisi of the Malay peninsula used to carry fruit they were eating to fresh spots so that the seeds might spread over the country. In Arizona a company of Cocopa, Mohave or Pima women, safely guarded by a number of men, set forth to a rich and favourable spot on the side of a cañon. Each woman has a little bag of gourd seed, and she plants these, one by

AN EGYPTIAN HOE FOUND AT THEBES USED IN THE NILE VALLEY ABOUT 2,000 B.C.

one, in rich crannies or crevices where the roots can find sustenance, the sun may shine in, and the fruit may later swing down, as from a trellis. The planters go home and take no further notice of their vines until they return in the autumn to collect the gourds. In manioc areas, the natural means of procuring food is still by hunting. Cassava forms a useful alternative, and when game is scarce or hunting unsuccessful, manioc culture increases in importance, yams, beans, peas, pumpkins and maize being added to the crops, while if hunting fails altogether, the group perforce turns to agriculture. Examples are common in the Congo region. Similarly compulsion turns pastors into agriculturalists. In Africa the women have no share in cattle tending and are often mainly occupied in cultivating the crops of maize and vegetables. Should war or disease cause the herds to dwindle, or encroachments diminish the extent of the pasturage, the necessity for agriculture is increased until it absorbs the whole community. Sometimes the stimulus is given by political pressure, as in the case of the Bashkir Tatars, whose pasture lands were encroached upon by Russians to the north and west, and by the Ural Cossacks to the east, so that they could no longer support flocks and herds in sufficient numbers. Sometimes, however, although the first steps are taken, progress goes no farther, as in the wild rice districts of North America in the neighbourhood of the Great Lakes. Most of the Indians who had access to the rice fields collected the rice, ate it at every meal until it was finished, and then turned to other sources of food. There was a common belief that if any seed were sown no more would ever grow wild, and while food was plentiful and space and game were abundant, no further steps were taken.

Assartage.—In tropical or semi-tropical countries the common method of agriculture is assartage or essartage (from Lat. *cx Sartare*, to grub up trees and bushes from forest land to make it arable). For example, in South America a tract of specially productive forest land is chosen as a site for a maize field, smaller trees and undergrowth are cut down at the end of the rainy season, except those of greater size or of very hard wood, and the fallen masses, dried by sun and air for a few weeks, are then fired. On this charred surface, among half-burnt branches and blackened trunks, the maize is planted in holes a few feet apart and when it reaches the surface the Indian clears and stirs the ground with the hoe. Immediately after harvest the ground is prepared for a fresh crop, which, however, yields much less, and the clearing is then abandoned for several years. It soon becomes overgrown with weeds and undergrowth, and after a time, if no virgin land can be had, these will be burnt down and the land replanted as before; but the crops are poor, the soil is exhausted, the ashes of the undergrowth have not sufficient fertilizing value, and the clearing is finally abandoned. The burning of the felled trees enriches the land, and the same clearing can be used two, three or more times, but is less and less productive each season, so that new land is prepared and the cropped piece left fallow. The system is practised wherever space permits.

In Torres Strait each family has its patch of garden land marked out within the tribal area by definite boundaries. The limit may be marked by standing trees but more commonly the boundary is a ridge of earth, formed by the weeds and refuse thrown on the edge in the process of clearing the land. Every year a man clears a new piece of land and lets another portion lie fallow. The men cut down the larger trees, formerly with shell axes, while the women attack the undergrowth. There is no regular rotation of crops; usually the same plants (yams, bananas, sweet potatoes or sugar-cane) are planted in the same patch; only, as the crops deteriorate after one, two or three years, the land is allowed to lie fallow until the undergrowth is four or five years old, when it is cleared again. There are special names for gardens of successive ages. A newly cleared patch is *kerkar gedub* (new garden), next year it is *keas gedub*, and after two years *gazag gedub*. *Keas* and *gazag* gardens are not replanted, though sugar-cane and bananas continue to bear. (Torres Strait Reports, iv. 145-151.) Extensive agriculture (clearing a fresh patch every season) may go on as long as there is sufficient land, either virgin land still uncleared or overgrown fallow worth clearing; but where, owing to limitations of land or increase of population or

other economic influences, more crops or better crops are required and the exhausted land cannot restore itself, artificial restoration must be applied. Extensive agriculture becomes intensive.

Agriculture is everywhere associated with magic and religious ceremonies to ensure fertility, but artificial fertilization of a more practical nature is not unknown to primitive gardeners. Mariner describes it in Tonga in 1827; powdered pumice was used in the Gilbert isles; human manure was a marketable commodity in Mexico, as in China. In America artificial manuring was found from Nova Scotia to Chile. Fish was commonly planted in the mounds with the maize seed and guano was carefully collected. In Peru extensive cultivation was impossible from lack of space, and crops were restricted to the pockets (*bolson*) of rich soil, consisting of detritus washed down by the mountain torrents, enriched with mineral deposits from volcanic rocks. These natural plots were enlarged by irrigation streams which were also fertilizing. The guano beds of Peru were highly valued; they were the property of the different provinces, and the breeding places of the birds were protected by law.

Irrigation. — Leading an artificial stream on to a patch of land, to provide water for a crop varies from the hollowed tree-fern trunk which the Fijian lays down to supply his taro bed, to the imposing engineering works of the primitive agriculturalists of Peru, or the miles of aqueducts of ancient Ceylon. The sources of water may be natural rivers or lakes, artificial canals, reservoirs or underground supplies, and there are many contrivances for directing it over the land to be watered. Water from a higher level is led off in narrow mud-banked channels which can be stopped or diverted merely by blocking up or breaking down a channel wall here and there. If the water has to be raised, a man may sit by the side of a stream with a half gourd or coco-nut (nowadays often a kerosene tin) fixed to a stick, ladling out the water and pouring it on to his crop. In deep water a bucket is lowered by means of a rope and drawn up to the surface. The *shaduf*, characteristic of Egypt, and widely distributed from West Africa to the East Indies, consists of a forked pole stuck in the ground, with a long pole balancing on the fork, its heavier end on the bank, and the lighter end, with a bucket attached, over the water. The bucket is lowered into the water, and, when full, the heavy end of the pole helps to raise it. Water can thus be raised 10 or 15ft., and a succession of *shadufs* can raise it to any height required. When there is running water, a water-wheel with buckets on an endless chain is common in the Old World, or the wheel may be turned by animals or men. Where the underground supply of water is very deep, as in parts of India or in the Sahara, a pit is dug, walled in with masonry, and a skin bag lowered over a pulley by long ropes to a depth of 100 or 200ft. The ends of the ropes are attached to bullocks, mules, donkeys, camels, women or slaves, who walk down a slope equal to the depth of the wall. Neither the *shaduf*, the water-wheel or the pulley was used in the New World, but there are extensive irrigation works in the drier Pueblo region, especially Arizona, where 150 miles of ancient irrigation ditches may be traced. In Mexico and Peru extensive engineering works prove the care given to irrigation. Channels were carried round the sides of mountains arid even tunnelled through them; so that the waters of the higher valleys where the supply was abundant were made available for the cultivation of others where it was deficient; and these channels were made to irrigate not only the cultivated fields but the llama pastures on the mountain sides.

Terrace Cultivation. — In clearing the land for planting, the trees are felled, the stones are collected or undergrowth and weeds heaped up all along the edges of the space to be planted, and ridges and terraces are thus formed. The discovery of their value for preserving moisture and preventing erosion on slopes would easily lead to the artificial terracing so widely distributed throughout the Old and New Worlds. Terrace cultivation is imposed on agriculture by political, geographical, climatic or economic influences. An agricultural group is by its nature exposed to attacks which, by its nature, it is unable to resist except by retreat to a naturally fortified or easily defended position; and this is provided by the hills, where every patch must be carefully preserved and augmented. Artificial banks are therefore raised to prevent

further erosion, and, if necessary, loads of earth are retrieved from the valleys. Such is the precarious agriculture of the Man Tze, or "untameable worms," as the aboriginal inhabitants are called by their Mongol conquerors who forced them to retreat into the mountain fastnesses of the Yangtse valley, where, at a height of about 10,000ft. above sea-level, they perch their villages on the steep cliffs. The back of the house is burrowed out of the rock face; the front is supported on a platform, resting on beams; the approach is by steps made of bolts driven into the rock, and small children are tethered to the door-posts to prevent them from falling over the edge. Here in little patches between the rocks every inch of soil is carefully tilled and crops are raised though the only

A PRIMITIVE EGYPTIAN RAKE OF THE XXth DYNASTY FOUND AT LISHT

access to the terrace may be by a rope (I. B. Bishop, *The Yangtse Valley and Beyond*, 1900). Both archaeology and history show evidence of early terracing round the Mediterranean and in Britain during the Bronze Age.

In hilly and mountainous districts where the rainfall is insufficient or irregular, terrace cultivation and irrigation go hand in hand. The water from a mountain stream is easily directed down

the slope, and the embankments of the terraces preserve the moisture, so this method is universal on the drier slopes throughout the world. The Arabs in Yemen give the best example. Here the mountains are terraced from their base up to sometimes as high as 6,000ft., with terrace walls from 5ft. to 15ft. high. Reservoirs filled in the two rainy seasons supply the streams for the irrigation channels. When, in the 10th century, the Arabs reached Spain, they converted every mountain slope into a succession of green terraces. In the mountain areas of India, in Ceylon, in Tibet and in China, terrace cultivation can be seen on a large scale. The Chinese, farmers of 40 centuries, carry terracing to a fine art. In densely populated neighbourhoods every inch of soil is of value; it is collected in baskets in the valleys, carried up the barren hill slopes, and embanked, forming astonishingly productive gardens. Examples are rare in the New World, but in Peru the same necessities were met by the same device, and hundreds of terraces one above the other rose from the valleys to the utmost cultivable limit. These were extended year by year by communal labour, and produced the finest crops of potatoes and maize, eliciting the astonished admiration of Cortes: "There was not a span that was not cultivated." Increase of population and of civilized wants, with the growing importance of food-crops or drink-crops, lead to the intensive cultivation seen in the mountain zone of Europe; in Switzerland, for example, or the Moselle and Rhine valleys, in the Vosges and Black Forest, in the Suabian Jura, in Italy, up the slopes of the Apennines or the Ligurian Alps. and in the "desperate agriculture" of Teneriffe, where camels laden with earth bring soil for the gardens almost daily into the town of Santa Cruz.

Implements. — The primitive implement is everywhere the digging stick, usually merely a strong stick, with one end pointed or flattened (a rudimentary spade) and often hardened in the fire. This is used for digging up roots by people who do not cultivate the soil, such as the Australians or the Bushmen of South Africa. The Bushmen weight their digging sticks with a heavy perforated stone whorl which acts as a lever. The digging stick or *ô* in use in Tahiti nearly a century ago was originally a stick sharpened at the point and hardened by charring at the end; but when iron was obtainable, a narrow sharp piece like a chisel was fixed at the end, and as much of the ground was stony, this was found very convenient. No use was made of the foot in thrusting the spade into the soil, but the digger assumed a crouching attitude, piercing the ground and breaking up the earth by the strength of hands and arms (Ellis, *Polynesian Researches*, p. 137-138). In Fiji the grass, reeds and undergrowth were broken down by a sharp-edged club. The digging sticks (poles with one end flattened) are used by three or four men encircling a large clod which they lever up. The women, fol-

lowing on their knees, pulverize this with their hands. A hoe, made of turtle shell or an oyster valve, was used for weeding. A knife has now replaced the club, but as a spade is painful to bare feet, the digging stick holds its place, though its power is now increased by an iron blade. In New Zealand the Maori lashed on a foot-piece at right angles to the digging stick; in Peru a foot-rest is bound on with leathern thongs, and, higher up, another rest is attached in the same way; this is for the left hand, which assists the foot in applying the weight of the body to the thrust. Similar types are found from New Mexico to Chile. The caschrom, still used in the stony patches of the Shetlands and the Hebrides, is a larger and more elaborate digging stick, with its end shod in iron and a foot-rest attached. The hoe is really a pick, with the digging end flattened. The simplest form is a piece of wood, with a natural angle, usually part of the trunk and a projecting branch, or two pieces of wood fastened together. The former is illustrated in Europe in the Swedish "hack" and the latter was characteristic of ancient Egypt. In North America a bent piece of wood, the shoulder blade of elk or bison, or a piece of tortoise shell is fastened to a handle, but the hoe was rare in America except in the eastern maize area. The African hoes are of iron, often set at an acute angle to the shaft, this and the shortness of the handle necessitating a crouching position when hoeing. The size and shape of the hoes in Nigeria reflect the variation of soil, a gradation being traced from the sandy soils of the north to the heavier land of the south.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART
A STONE SICKLE OF THE TYPE USED IN EGYPT 4,000 YEARS AGO RECONSTRUCTED FROM FRAGMENTS DISCOVERED AT THEBES

There can be little doubt that women were the earliest agriculturalists. Even when the harder labour of clearing the ground is done by men, planting, sowing, tending and collecting are still women's work. "When the women plant maize," say the Indians, "the stalk produces two or three ears. Why? Because women know how to produce children. They only know how to plant corn to ensure its germinating. Then let them plant it. They know more than we do." (Payne, *History of the New World*, ii. 7.) It is therefore easy to guess that the cultivation of plants was one of women's contributions to the development of civilization; and it is quite in harmony with this conjecture that the cereal deities are usually female, both in the Old World and in the New.

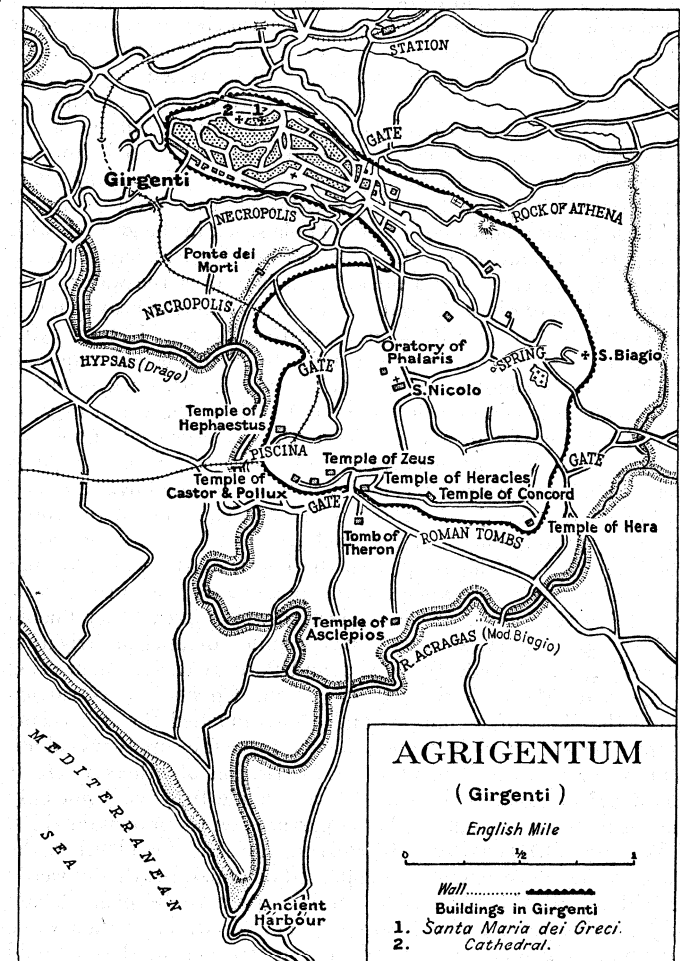

See O. T. Mason, *The Origins of Invention* (1895); E. J. Payne, *History of the New World called America* (1895); E. C. Semple, *Influence of Geographical Environment* (1911). (A. H. Q.)

AGRICULTURE, TROPICAL: see TROPICAL AGRICULTURE.

AGRI DECUMATES, "tith lands" given by the Romans to Gallic settlers, and also to Roman veterans on the payment of a rent of a tenth (decuma) of the produce, on the east of the Rhine. (See LIMES GERMANICUS.)

AGRIGENTUM (Gr. Ἀκράγας, mod. AGRIGENTO), ancient city, south coast of Sicily, 2½ m. from the sea. Founded by Greek colonists from Gela as late as 582 B.C., its favourable site for cultivation and trade with Carthage made it second only to Syracuse. Pindar calls it *καλλίστα βροτειῶν πόλιων* (fairest of mortal cities). Ruled at first by tyrants, in 472 a democracy was established. In the struggle between Syracuse and Athens (415-413) the city remained neutral. Its prosperity continued to increase (its population is given at over 200,000) until in 405 B.C. it was captured and plundered by the Carthaginians, a blow from which it never entirely recovered. It was colonized by Timoleon in 338 B.C. with settlers from Velia in Lucania, and in the time of the tyrant Phintias (289-279) it had regained some of its power. In the first Punic War, however, it was sacked by the Romans (261) and the Carthaginians (255), and finally in the

second Punic War by the Romans (210). Still in the Roman period, it exported agricultural products, textile fabrics and sulphur. In the local museum are tiles used for stamping cakes of sulphur, which show that the mines, at any rate from the 3rd century A.D., were imperial property leased to contractors. The site is unusual and beautiful with a lofty ridge with two summits to the north. On the western summit is the modern town (985 ft.), the eastern summit slightly higher, bears the name of Rock of Athena, owing to its identification by some scholars with the acropolis of Acragas as described by Polybius, who places upon it the temple of Zeus Atabyrius (said to have been erected by the half-mythical Phalaris) and that of Athena. The available space about 70 x 20 yds. on the eastern summit is, however, too small. In the modern town, on the other hand, the remains of one temple are to be seen in the church of Sta. Maria dei Greci, while the other is generally supposed to have occupied the site of the cathedral. On the north both summits are defended by cliffs; on the south the ground slopes away somewhat abruptly from the eastern summit towards the plateau on which the town stood, while the western summit is separated from this plateau by a valley traversed by a branch of the Hypsas (mod. Drago), the deep ravine of which forms the western boundary and defence of the city. On the east is the valley of the Acragas (Fiume S. Biagio). The church of S. Biagio, above it, is built into the temple of Demeter which was preceded by a sanctuary in the cliffs. The Acragas defends the approach from the east and the

deeper Hypsas that from the south-west. They unite south of the town and flow out in the small abandoned harbour. A row of important Doric temples crowns the southern slopes; they are built of the local porous stone, which is of a warm red brown colour, full of fossil shells and easily corroded when exposed to the air. Of all these temples the oldest is probably that of Heracles (eight columns of which have recently been re-erected),

*Dimensions in English feet.

while the best preserved are those wrongly attributed to Hera and Concordia, which are very similar in dimensions; the latter, indeed, lacks nothing but its roof, owing its preservation to its conversion into the cathedral in 597 by Gregory II., bishop of Girgenti. These temples are among the finest in existence. In front of the former, as in front of those of Heracles and Zeus, stood a huge altar for burnt offerings, as long as the façade of the temple itself. The cella of the temple of Heracles was modified in Roman times, and a statue of Asclepius seems to show change of cult.

In the colossal temple of Zeus the huge Atlantes (figures of Atlas), 2jft. in height, are noticeable. They seem to have stood in the inter-calumniation half-way up the outside wall and to have supported the epistyle. The collapse both of this temple and of that of Heracles must be attributed to an earthquake; many fallen blocks of the former were removed in 1756 for the construction of the harbour of Porto Empedocle. The four columns

THE TEMPLE HERE SHOWN WITH ALL ITS COLUMNS STILL IN SITU, WHICH HAS BEEN WRONGLY ATTRIBUTED TO CONCORDIA, IS THE BEST PRESERVED OF THE NUMEROUS AND SPLENDID RUINS STILL TO BE FOUND ON THE SITE OF THE CITY OF AGRIGENTUM. IT OWES ITS PRESERVATION TO GREGORY II, BISHOP OF GIRGENTI

erected on the site of the temple of Castor and Pollux are a modern (and incorrect) restoration in which portions of two buildings have been used. Of that of Hephaestus only two columns remain, while that of Asclepius, a mile to the south of the town, an anta and two pillars are preserved. Other remains are unimportant. Near the picturesque church of S. Nicolo is the so-called oratory of Phalaris, a tomb of the 1st century B.C., 27½ft. by 23½ft., and not far off on the east are two private houses of the Roman period. The fishpond (circumference said by Diodorus to be 7 stadia) is an enormous excavation south-

west of the city, with drains in its sides; the bottom is now an orange garden.

The wall line can be traced, but actual remains are small except in the valley below the temple of Demeter (S. Biagio). East and west ravines gave protection, so a massive wall was unnecessary, while near the south-east angle a breastwork was formed by the excavation of the natural rock, in later times honeycombed with tombs. Close to this temple on the west is the site of the gate known in later times as the Porta Aurea, through which the modern road passes.

Tombs of the Greek period have been found mainly on the west of the town, outside the probable line of the walls, between the Hypsas and a small tributary, the latter having been spanned by a bridge, now called Ponte dei Morti, of which one massive pier, 45ft. in width, still exists. Just inside the south wall is a Christian catacomb, and outside it a tomb in two storeys, a mixture of Doric and Ionic architecture, belonging probably to the 2nd century B.C. A village of the Byzantine period has been explored at Balatizzo, immediately to the south of the modern town. The walls of the dwellings are entirely cut out of the natural rock.

The modern town, known as Girgenti till 1928 but then reverting to the older form of Agrigento, is the capital of the province of Agrigento, and an episcopal see, 58 mi. S. by E. of Palermo direct and 84½ mi. by rail. Pop. (1936) 27,785 (town), 32,951 (commune). The cathedral occupies the highest point in the town; it was founded in the 13th century and there are other remains of architecture of this period. The museum contains fine vases, terra cottas, sculptures, etc. Porto Empedocle, pop. (1936), 13,834 (town), 14,764 (commune), 5½ mi. S. by rail, is connected with Castelvetrano, on the line from Palermo to Trapani. It is the principal port for the shipment of sulphur, the mining district beginning just north of Agrigento, and was heavily bombed by the Allies during World War II after their victory in North Africa. (T. A.; X.)

AGRIMONY, a slender perennial herb (botanical name, *Agrimonia Eupatoria*, family Rosaceae), 1½ to 3ft. high growing in hedge-banks, copses and borders of fields. The leafy stem ends in spikes of small yellow flowers. The flower-stalk becomes recurved in the fruiting stage, and the fruit bears a number of hooks which enable it to cling to rough objects, such as the coat of an animal, thus ensuring distribution of the seed. The plant is common in Britain and widely spread through the north temperate region. The underground woody stem is astringent and yields a yellow dye.

The name has been unsystematically given to several other plants; for instance: bastard, Dutch, hemp or water agrimony (*Eupatorium cannabinum*); noble or three-leaved agrimony (*Anemone Hepatica*); water agrimony (*Bidens*); and wild agrimony (*Potentilla Anserina*).

AGRIOLOGY is the science of the prehistoric human practices and ways of living, especially those pertaining to the key-factors of existence, food, shelter and clothing.

AGRIONIA, an ancient Greek festival, celebrated annually at Orchomenus in Boeotia and elsewhere, in honour of Dionysus Agrionius ("the wild") by women and priests at night. The tradition is that the daughters of Minyas, king of Orchomenus, having despised the rites of the god, were seized with frenzy and ate the flesh of one of their children. At this festival it was originally the custom for the priest of the god to pursue a woman of the Minyan family with a drawn sword and kill her. (Plutarch, *Quaest. Rom.* cii., *Quaest. Graecae*, xxxviii.)

AGRIPPA, a sceptical philosopher, whose date cannot be accurately determined. He must have lived later than Aenesidemus. To him are ascribed the five tropes (*πέντε τρόποι*) which, according to Sextus Empiricus, summarize the attitude of the later ancient sceptics. (1) Since some thinkers hold that nothing is known but the sensible; others that nothing is known but the intelligible, it follows that the only wise course is neither to affirm nor to deny. (2) The proof of one so-called fact depends on another fact which itself needs demonstration, and so on *ad infinitum*. (3) The data of sense are relative to the sentient being, those of reason to the intelligent mind; that in different conditions things themselves are seen or thought to be different. Where, then, is the absolute criterion? (4) All knowledge depends on certain hypotheses, or facts taken for granted. Such knowledge is hypothetical. (5) The fifth trope points out the impossibility of proving the sensible by the intelligible inasmuch as it remains to establish the intelligible in its turn by the sensible. Such a process is a vicious circle and has no logical validity. A comparison of these tropes with the ten tropes enumerated in the article **AENESIDEMUS** shows that scepticism has made an advance into the more abstruse questions of metaphysics. The first and the third include all the ideas expressed in the ten tropes, and the other three systematize the more profound difficulties which new thinkers had developed.

See Diogenes Laertius x. 88, and Zeller's *Greek Philosophy*. Also the articles **SEPTICISM**; **AENESIDEMUS**.

AGRIPPA, HEROD I. (c. 10 B.C.—A.D. 44), king of Judaea, the son of Aristobulus and Berenice, and grandson of Herod the Great, was born about 10 B.C. His original name was Marcus Julius Agrippa. Josephus informs us that, after the murder of his father, Herod the Great sent him to Rome to the court of Tiberius, whose son Drusus became his friend. On the death of Drusus, Agrippa, who had been recklessly extravagant, was obliged to leave Rome overwhelmed with debt. After a brief seclusion, Herod the Tetrarch, his uncle, who had married Agrippa's sister Herodias, made him *Agoranomos* (Overseer of Markets) of Tiberias, and presented him with a large sum of money; but his uncle being unwilling to continue his support, Agrippa left Judaea for Antioch and soon after returned to Rome, where he was welcomed by Tiberius and became constant companion to the emperor Gaius (Caligula), then a popular favourite. Agrippa, overheard by his freedman Eutyches to express a wish for Tiberius' death and the advancement of Gaius, was betrayed to the emperor and cast into prison. In A.D. 37 Caligula, having ascended the throne, heaped wealth and favours upon Agrippa and gave him the tetrarchy of Batanaea and Trachonitis. To this he added that held by Lysanias; and Agrippa journeyed into Judaea to take possession of his new kingdom. In A.D. 39 he returned to Rome and brought about the banishment of Herod Antipas, to whose tetrarchy he succeeded. On the assassination of Caligula (A.D. 41) Agrippa supported the emperor Claudius, who gave him the government of Judaea, while the kingdom of Chalcis in Lebanon was, at his request, given to his brother Herod. Thus Agrippa became one of the greatest princes of the east, the territory he possessed equalling in extent that held by Herod the Great. He returned to Judaea and governed it to the great satisfaction of the Jews. His zeal, private and public, for Judaism is celebrated by Josephus and the rabbis; and the narrative of Acts xii, telling of his persecution of the Apostles James and Peter, gives a typical example of it. Both the Acts of the Apostles and Josephus give an account of his sudden death after an exhibition of games at Caesarea. A

third account says that Agrippa was assassinated by the Romans, who objected to his growing power. He had shown too independent a spirit in his attempt to strengthen the walls of Jerusalem and to summon a meeting of other client princes and after his death the emperor appointed no more kings of Judaea, but ruled the province by means of procurators.

See articles Josephus, *J.A.* 18 and 19 in *Ency. Bibl.* (W. J. Woodhouse), *Jewish Ency.* (M. Brann), with further references; H. S. Libowitz, *Herod and Agrippa* (2nd ed., 1898); Gratz, *Geschichte d. Juden*, iii. 318-361.

AGRIPPA, HEROD II. (27-100), son of Agrippa, Herod I., and like him originally Marcus Julius Agrippa, was born about A.D. 27, and received from Claudius the tetrarchy of Chalcis and the oversight of the Temple on the death of his uncle, Herod, A.D. 48. In A.D. 53 he was deprived of that kingdom and given other provinces instead. He tried to prevent the Jews from rebelling, and when war broke out sent auxiliaries to help the Romans. He died in Rome in A.D. 100. He was the seventh and last king of the family of Herod the Great. It was before him and his sister Berenice (*q.v.* B.2) that St. Paul pleaded his cause at Caesarea (Acts xxvi.). He supplied Josephus with information for his history.

AGRIPPA, MARCUS VIPSANIUS (63-12 B.C.), Roman statesman and general, son-in-law and minister of the emperor Augustus, was of humble origin. He was of the same age as Octavian (as the emperor was then called), and was studying with him at Apollonia when news of Julius Caesar's assassination (44 B.C.) arrived. By his advice Octavian at once set out for Rome. Agrippa played a conspicuous part in the war against Lucius, brother of Mark Antony, which ended in the capture of Perusia (40). Two years later he put down a rising of the Aquitanians in Gaul, and crossed the Rhine to punish the aggressions of the Germans. On his return he refused a triumph but accepted the consulship (37). At this time Sextus Pompeius, with whom war was imminent, had command of the sea on the coasts of Italy. Agrippa's first care was to provide a safe harbour for his ships, which he accomplished by cutting through the strips of land which separated the Lacus Lucrinus from the sea, thus forming an outer harbour; an inner one was also made by joining the lake Avernus to the Lucrinus (Dio Cassius xlvi. 49; Pliny, *Nat. Hist.* xxxvi. 24). About this time Agrippa married Pomponia, daughter of Cicero's friend Pomponius Atticus. Having been appointed naval commander-in-chief he put his crews through a course of training, until he felt in a position to meet the fleet of Pompeius. In 36 he was victorious at Mylae and Naulochus, and received the honour of a naval crown for his services. In 33 he was chosen aedile and signalized his tenure of office by effecting great improvements in the city of Rome, restoring and building aqueducts, enlarging and cleansing the sewers, and constructing baths and porticos, and laying out gardens. He also first encouraged the public exhibition of works of art. The emperor's boast that he had found the city of brick but left it of marble ("marmoream se relinquere, quan latericium accepisset," Suet. Aug. 29), might with greater propriety have been uttered by Agrippa. He was again called away to take command of the fleet when the war with Antony broke out. The victory at Actium (31), which gave the mastery of the world to Octavian, was mainly due to Agrippa. As a token of signal regard Octavian bestowed upon him the hand of his niece Marcella (28). We must suppose that his wife Pomponia was either dead or divorced. In 27 Agrippa was consul for the third time, and in the following year the senate bestowed upon Octavian the imperial title of Augustus. Probably in commemoration of the battle of Actium, Agrippa built and dedicated the Pantheon still in existence as *La Rotonda*. The inscription on the portico states that it was erected by him during his third consulship. His friendship with Augustus seems to have been clouded by the jealousy of his brother-in-law Marcellus, which was probably fomented by the intrigues of Livia, the second wife of Augustus, who feared his influence with her husband. In 23 B.C., Agrippa went as governor to the East, ruling by means of legates, while he himself remained at Lesbos. But the death of Marcellus, which took place in the same year, obliged the emperor to look

to Agrippa as his successor. He was recalled to Rome, and to strengthen the tie between him and Augustus was made to divorce Marcella and marry the emperor's daughter Julia (21), the widow of Marcellus. In 19 he was employed in putting down a rising of the Cantabrians in Spain. In 18 B.C. he received the Tribunician power for five years, and in the following year a renewal of his command in the East, where his just and prudent administration won him the goodwill of the provincials, especially the Hebrew population. His last public service was the bloodless suppression of an insurrection in Pannonia (13). He died at Campania in March of the year following his 51st year. Augustus honoured his memory by a magnificent funeral.

Agrippa was also known as a writer, especially on geography. Under his supervision Julius Caesar's design of having a complete survey of the empire made was carried out. Amongst his writings an autobiography, now lost, is referred to. Agrippa left several children; by Pomponia, a daughter Vipsania, who became the wife of the emperor Tiberius; by Julia three sons, Gaius and Lucius Caesar (adopted by Augustus as his successors) and Agrippa Postumus, and two daughters, Agrippina the elder, afterwards the wife of Germanicus, and Julia, who married Lucius Aemilius Paullus.

Jud.* xv. 10, xvi. 2; Turnbull, *Three Dissertations*, one of the characters of Horace, Augustus and Agrippa (1740); Frandsen, *Marcus Vipsanius Agrippa* (1836); Motte, *Etude sur Marcus Agrippa* (1872); Nispi-Landi, *Marcus Agrippa e i suoi tempi* (1901); D. Detlefsen, *Ursprung, Einrichtung und Bedeutung der Erdkarte Agrippas* (1906); V. Gardthausen, *Augustus und seine Zeit*. Vol. i. 76a foll., ii. 432 foll.

AGRIPPA VON NETTESHEIM, HENRY CORNELIUS (1486-1531), German writer, soldier, physician and by common reputation a magician. Agrippa was for many years in the service of Maximilian I., the German king, who sent him in 1510 on a diplomatic mission to England, where he was the guest of Dean Colet. From 1511 to 1518 he was in Italy in the service of William VI. of Monferrato and of Charles III. of Savoy. His interest in the occult sciences had brought him into conflict with the church at Dôle in 1509 when he lectured on John Reuchlin's *De verbo mirifico*; again at Pavia in 1515 when he lectured at the university on the *Pimander* of Hermes Trismegistus; and again at Metz in 1518, where he was town orator, for his defence of a woman accused of witchcraft. He then practised medicine in Cologne, Geneva, Freiburg and Lyons for short periods until Margaret, duchess of Savoy and regent of the Netherlands, appointed him archivist and historiographer to the emperor. Margaret's death in 1530 weakened his position, but after suffering a short imprisonment for debt at Brussels he lived at Cologne and Bonn, under the protection of Hermann of Wied, archbishop of Cologne. He then went to France, where he was arrested by order of Francis I. for some disparaging words about the queen-mother; but he was soon released, and on Feb. 18 1535, died at Grenoble. He was thrice married and had a large family. Agrippa's work, *De occulta philosophia*, which brought him into antagonism with the Inquisition, was written about 1510, partly under the influence of the author's friend, John Trithemius, abbot of Wiirzburg, but its publication was delayed until 1531, when it appeared at Antwerp. It is a defence of magic, by means of which men may come to a knowledge of nature and of God, and contains Agrippa's idea of the universe with its three worlds or spheres. His other principal work, *De incertitudine et vanitate scientiarum et artium atque excellentia Verbi Dei declamatio*, was written about 1527 and published at Antwerp in 1531. In it Agrippa denounces the accretions which had grown up around the simple doctrines of Christianity, and wishes for a return to the primitive belief of the early Christian church. He also wrote *De nobilitate et praecellentia feminei sexus*, dedicated to Margaret of Burgundy, *De matrimonii sacramento* and other smaller works. An edition of his works was published at Leyden in 1550 and they have been republished several times.

See H. Morley, *Life of H. C. Agrippa* (London, 1856); A. Prost, *Les sciences et les arts occultes au XVI. siècle: Corneille Agrippa, sa vie et ses oeuvres* (Paris, 1881); A. Daguet, *Cornelius Agrippa* (Paris, 1856); J. Orsier, *H. C. Agrippa, sa Vie et son Oeuvre* (1911).

AGRIPPINA, the "elder," daughter of Marcus Vipsanius Agrippa (*q.v.*) by his third wife Julia, was the granddaughter of Augustus and the wife of Germanicus. She accompanied her husband to Germany, when the legions on the Rhine revolted after the death of Augustus (A.D. 14). Three years later she was in the East with Germanicus (*q.v.*), who died at Antioch in 19, poisoned, it was said, by order of Cn. Calpurnius Piso, governor of Syria. Eager to avenge his death, she returned to Rome and boldly accused Piso of the murder of Germanicus. To avoid public infamy Piso committed suicide. Tiberius and his favourite Sejanus feared that her ambition might lead her to attempt to secure the throne for her children, and she was banished to the island of Pandataria off the coast of Campania, where she died on Oct. 18, 33, starved to death by herself, or, according to some, by order of Tiberius. Two of her sons, Nero and Drusus, had already fallen victims to the machinations of Sejanus. Agrippina had a large family by Germanicus, several of whom died young, while only two are of importance—Agrippina the "younger" and Gaius Caesar, who succeeded Tiberius under the name of Caligula. There is a portrait of Agrippina in the Capitoline Museum at Rome and a bronze medal in the British Museum; representing the bringing back of her ashes to Rome by order of Caligula.

See Tac. *Ann.* i.-vi.; Suetonius *Tiberius*, 53; Dio Cassius lvii. 6, lviii. 22, lix. 3; Elizabeth Hamilton, *Memoirs of the Life of Agrippina* (1804); Stahr, *Römische Kaiserfrauen* (1880).

AGRIPPINA, the "younger" (A.D. 16-50), daughter of Germanicus and Agrippina the elder, sister of Caligula and mother of Nero, was born at Oppidum Ubiorum on the Rhine, afterwards named in her honour Colonia Agrippinae (mod. Cologne). By her first husband, Gnaeus Domitius Ahenobarbus, she was the mother of the emperor Nero; her second husband was Passienus Crispus, whom she was accused of poisoning, in 49. After the death of Messalina, she married the emperor Claudius, her uncle, and induced him to adopt the future Nero as heir to the throne in place of his own son (Britannicus). In 54 she poisoned Claudius and secured the throne for her son. Being alarmed at the influence of the freedwoman Acte over Nero, she threatened to support the claims of the rightful heir Britannicus. Nero thereupon murdered the young prince and decided to get rid of his mother. Pretending a reconciliation, he invited her to Baiae, where an unsuccessful attempt was made to drown her on a vessel especially constructed to founder. Eventually he had her put to death at her country house. Agrippina wrote memoirs of her times, referred to by Tacitus (*Ann.* iv. 53).

See Tac. *Ann.* xii., xiii., xiv.; Dio Cassius lix.-lxi.; Suetonius, *Nero*, 34; Stahr, *Agrippina, die Mutter Neros* (1880); Raffay, *Die Memoiren der Kaiserin Agrippina* (1884); B. W. Henderson, *The Life and Principate of the Emperor Nero* (1903); J. MacCabe, *Empresses of Rome*, ch. v. (1911); also article NERO.

AGRONOMY, the theory and practice of land management and husbandry; in the United States more specifically used of the production of farm crops and plant culture, *e.g.*, the agronomy department attached to the agricultural experiment stations.

AGROTERAS THUSIA, an annual festival held at Agrae, near Athens, in honour of Artemis Agrotera, in fulfilment of a vow made by the city, before the battle of Marathon, to offer in sacrifice a number of goats equal to that of the Persians slain in the conflict. The number being so great, it was decided to offer 500 goats yearly.

See Plutarch, *De Malignitate Herodoti*, 26; Xenophon, *Anab.* iii., 2. 12; Aelian, *Var. Hist.* ii., aj; Schol. on Aristophanes, *Equites*, 660.

AGUADILLA, the largest and most important town in the northwestern section of Puerto Rico. The population by the 1930 census of the town itself was 10,952 (1940, 13,468), while the population of the municipal district in 1940 was 34,956.

Aguadilla is situated on the west coast of Puerto Rico, on the Mona channel which connects the Atlantic ocean with the Caribbean sea. It is a seaport, but at present has little shipping. It is situated on the belt-line railroad which follows the coastal plains around the island and also has connection by well built highways with the principal cities of the island. It has several industries and its business houses are well established. Its schools are superior, and an old church is of especial interest.

According to tradition, Columbus' fleet of discovery in 1493 refilled its water casks at the fountain which still flows in the centre of the town. It is certain that Columbus' landing was near Aguadilla. A tract of land south of the town and within a short distance has been secured for a Columbus park, which will be improved and a creditable monument erected to the discoverer. There is no other place under the U.S. flag on which Columbus landed except Puerto Rico. (H. M. T.; X.)

AGUASCALIENTES, an inland state of Mexico, bounded north, east and west by the state of Zacatecas, and south by Jalisco. Pop. (1931) 132,900; (1937) 153,233. Area, 2,499 sq. miles. The state occupies a part of the plateau of central Mexico about 6,000ft. above sea level, extending from two spurs of the

CATHEDRAL AT AGUASCALIENTES
Aguascalientes, capital of the inland Mexican State of the same name, is an industrial centre for the agricultural plateau surrounding it

Sierra Madre, called the Sierra Fria and Sierra de Laurel, eastward to the rolling fertile plains of its eastern and south-eastern districts. It is well watered by numerous small streams and one large river, the Aguascalientes or Rio Grande, and has a mild healthy climate with a light rainfall. The fertile valleys of the north and west are devoted to agriculture and the plains to stock-raising. Indian corn, flour, cattle, horses, mules and hides are exported to the neighbouring States. Mining industries are still undeveloped, but considerable progress has been made in manufactures, especially of textile fabrics. The State has good railway communications and a prosperous trade. The capital, Aguascalientes, named from the medicinal hot springs near it, is a flourishing commercial and manufacturing city. Pop. (1910) 45,198, (1940) 81,124. It has cotton factories, smelting works, railway shops, potteries, tanneries, distilleries and wagon and tobacco factories. It is a station on the Mexican Central railway, 364m. N.W. of the city of Mexico, and is connected by rail with Tampico on the Gulf of Mexico. The city is well built, has many fine churches and good public buildings, street cars and electric lights. Other towns of the State are Rincón de Romos, Asientos de Ibarra and Calvillo, each having less than 5,000 inhabitants.

AGUE, the common name given to a form or stage of malarial disease; the ague fit is the cold, shivering stage, and hence the word is also loosely used for any such paroxysm. (See MALARIA.) For "brow-ague" see NEURALGIA.

AGUESSEAU, HENRI FRANCOIS D' (1668-1751), chancellor of France, was born at Limoges Nov. 27 1668, the son of Henri d'Aguesseau, who held many important posts in the Government. He studied law under Jean Domat and was one of the first masters of forensic eloquence in France. He was procurator general from 1700 to 1717, and defended the rights of the Gallican Church against Rome in the controversy which led to the promulgation of the bull *Unigenitus*.

In 1717 he was made chancellor by the Regent Orleans, but was dismissed next year because of his steady opposition to the financial projects of John Law which had been adopted by the regent. He was recalled in 1720. He then assented to the truce which Dubois made with Rome because he feared the outbreak of civil war. Popular opinion unjustly ascribed his attitude to base compliance with Dubois; but he opposed other measures of Dubois and was dismissed when the favourite became chief minister. After five years of retirement spent in study, he was recalled by Cardinal Fleury, and again became chancellor. He attempted, in vain, the codification of French law, but he executed a body of reform which placed him in the same rank with L'Hôpital and Lamoignon.

His grandson, HENRI CARDIN JEAN BAPTISTE, MARQUIS D'AGUESSEAU (1746-1826), was advocate general in the parlement of Paris and deputy in the Estates-General. Under the Consulate he became president of the court of appeal and later minister at Copenhagen. He was elected to the French Academy in 1787.

Of H. F. d'Aguesseau's works the most complete edition is that of Jean Marie Pardessus, published in 16 vol. (1818-20); his letters were edited separately by Rives (1823); a selection of his works, *Oeuvres choisies*, was issued, with a biographical notice, by E. Falconnet in 2 vol. (Paris, 1865). His works include a treatise on money; a life of his father, which is interesting from the account which it gives of his own education; and *Metaphysical Meditations*.

See Charles Butler, *Mem. of Life of H. F. d'Aguesseau*, etc. (1830); Boullée, *Histoire de la vie et des ouvrages du chancelier d'Aguesseau* (Paris, 1835); Fr. Monnier, *Le Chancelier d'Aguesseau* (Paris, 1860; 2nd ed., 1863).

AGUILAR, GRACE (1816-47), English writer, the daughter of a Jewish merchant in London, was born in June 1816. Her works consist chiefly of religious fiction, such as *The Vale of Cedars* (1850) and *Home Influence* (1847). She also wrote, in defence of her faith and its professors, *The Spirit of Judaism* (1842) and other works. She died at Frankfurt-on-Main on Sept. 16, 1847.

AGUILAR, or AGUILAR DE LA FRONTERA, a town of southern Spain, in the province of Cordova. Pop. (1930) 15,809. Aguilar "of the Frontier" was so named in the middle ages from its position on the border of the Moorish territories. Situated in the south of the fertile *Campaña* de Córdoba, its olives and white wine are celebrated; the wine is known as Amontillado, from the adjacent town of Montilla.

AGUILAS, seaport and railway terminus, south-east Spain, province of Murcia. Pop. (1930) 15,745. Águilas is built on the landward side of a small peninsula, between two bays and has a good harbour. It is the chief outlet for the Spanish trade in esparto grass, and exports also iron ore and other mineral products of the neighbourhood.

AGUINALDO, EMILIO (c. 1869-), Filipino insurrectionary leader, was born near Cavite, Luzon, of Chinese and Tagalog parentage. He was educated in his native town and in the University of St. Thomas, conducted by Dominican friars in Manila. At the outbreak of the insurrection in Aug. 1896, he was mayor of Cavite Viejo. During this uprising Aguinaldo took a prominent part, displaying marked capacity for leadership and assuming dictatorial powers. But in Jan. 1898 he left the Philippines for Hongkong, agreeing to remain permanently in exile on condition of a substantial financial reward from Spain. Immediately after the battle of Manila, May 1, 1898, he returned to the Philippines with the express purpose, it is said, of assisting the United States in the war with Spain. Obtaining the consent of the U.S. authorities, he established a native government, of which he became the head, and organized an army. On Feb. 4, 1899, he began hostilities against the United States by making an unsuccessful attack on Manila. During 1899 there were several severe engagements, but in the end the native troops became so hard pressed that Aguinaldo, after repeatedly changing his capital, was forced to take refuge in the mountains. Here the struggle was protracted until March 23, 1901, when he was captured by Gen. Frederick Funston at Palawan, Luzon. On April 19, 1901, Aguinaldo took the oath of allegiance to the United States and retired to peaceful private life.

AGUIRRE, LOPE DE (1508-1561), Spanish adventurer. In 1559 he joined Pedro de Ursua's expedition to the Upper Amazon, in search of El Dorado, and took part in the murder of Ursua and his lieutenant in 1561, after which Guzman was elected captain by the crew, with Aguirre as his master of the camp. The murderers declared themselves rebels, and sailed down the Amazon, plundering and putting to the sword whole villages of Indians. Aguirre established a reign of terror on board ship, which culminated in the murder of Guzman, and his own self-appointment to the position of captain. In July of 1561 the party reached Margarita Island, where they murdered the governor, robbed the royal treasury and proceeded to make incursions into the mainland of Venezuela. About this time Aguirre wrote and despatched an amazing letter to the king of Spain, accusing him of ingratitude toward himself, Aguirre, and his followers, and giving a full account of his own villainous exploits on the voyage.

Soon after, his men began to desert him and just when an attack was expected from Spanish troops, he was shot by his own fellow-rebels, in Oct. 1561.

See R. Southey, *Expedition of Orsua, and the Crimes of Aguirre* (1821); and P. Simon, *The Expedition of Pedro de Ursua and Lope de Aguirre in search of El Dorado and Omagua* (1861).

AGUJARI, LUCREZIA (1743-1783), an Italian operatic singer, possessed of one of the most extraordinary voices, in respect of its almost incredible compass, ever known. Mozart, who heard her at Parma in 1770, noted down some of the passages which she sang, showing her range to have extended from middle C to C in altissimo, or more than an octave above the B flat which is about the limit of the average soprano. At the same time she was a brilliant executant. Known (and advertised) as La Bastardella, on account of the circumstances of her birth, as the natural daughter of a man of rank, she paid many visits to London where she received as much as £100 a night.

AHA, of Shabha, an 8th-century Talmudist. He was author of *Quaestiones* (*Sheiltoth*), a collection of homilies (at once learned and popular) on Jewish law and ethics. This is recorded as the first work written by a Jewish scholar after the completion of the Talmud.

AHAB, son of Omri, king of Israel from c. 875 to c. 852 B.C. (I Kings xvi. 29-xxii. 40). The more important aspects of his reign, which in some respects marks the high water mark of the success of the northern kingdom, may be summarized as follows: (1) *Foreign relations*.—In the reigns of Omri and Ahab the northern kingdom for the first time took an important part in international politics. Omri left to his son an empire which comprised not only territory to the east of Jordan, in Gilead and probably Bashan, but also the land of Moab, whose king was tributary, while Judah (and probably Edom also) if not actually subject to Omri, was certainly a subordinate ally. Ahab's marriage with Jezebel, daughter of Ethbaal of Sidon, revived an alliance which had been in abeyance since the time of Solomon. But throughout the reign of Ahab a fierce border war was waged with Damascus, in which Israel, in spite of occasional victory, proved the weaker, while Mesha, king of Moab, successfully revolted and occupied the southern portions of the territory of Gad. Yet the forces of Israel retained strength enough to contribute the second largest contingent of soldiers (the largest force of chariots) to the combined armies which, under the leadership of Benhadad of Damascus, checked the westward movement of Shalmaneser III. of Assyria at Karkar in 853 B.C. After the Assyrian repulse, however, the alliance broke up, and Ahab met his death fighting the Syrians in a vain attempt to recover Ramoth Gilead. (2) *Domestic affairs*.—Contact with a wider world, and especially the alliance with Phoenicia, had far-reaching results for the kingdom of Israel itself. Jezebel attempted to introduce into religion and government elements which were common enough elsewhere in the ancient world but strange in Israel. She endeavoured to set up the worship of the Tyrian Baal in Samaria, and to maintain the familiar oriental principle of the absolute despotic power and authority of the sovereign. This roused the bitter hostility of that conservative party which clung to the sole worship of the national God, Yahweh, and at the same time held to those democratic conceptions of society which the Hebrews had brought with them from the wilderness and had consistently maintained through their history. The spirit of this party found expression in the prophet Elijah (*q.v.*), who protested alike against the establishment of the Baal priests and the judicial murder of Naboth. He and those who came after him seem to have been successful in eliminating the foreign worship, though in the end their purpose was only achieved by a bloody revolution; but they were powerless to stem the tide of social and moral deterioration. (See AMOS.) It is to the reign of Ahab that we may trace the beginning of that sapping of the national life which led to the condemnations of the 8th century prophets and to the downfall of Samaria. (T. H. R.)

AHAGGAR, general name for a large plateau region of the north centre of the Sahara, culminating about 900m. due S. of Algiers and 1,200m. due N. of the mouth of the Niger. The

highest peaks do not greatly exceed 8,000ft. above sea-level. (See also SAHARA.)

AHASUERUS, a royal Persian name occurring in Ezra iv. 6, Dan. ix. 1, and throughout the book of Esther, but its occurrence in Tobit xiv. 1j, in some Greek mss., is due to a copyist's blunder. It is the Latinized form of the Hebrew *Ahāšwērōš* (LXX. Ἀσσοῦρος). In Ezra iv. 6 Ahasuerus is mentioned as a king of Persia, to whom the enemies of the Jews sent representations opposing the rebuilding of the temple at Jerusalem. He here occupies a place in a chronological series of those Persian rulers who were directly concerned with events of Jewish history. (See EZRA AND NEHEMIAH.) Immediately preceding Artaxerxes I. Longimanus, he is evidently to be identified with Xerxes. This conclusion is supported by the resemblance of the Hebrew form of the name to the Babylonian *Ahšiyarš(u)*, the Egyptian-Aramaic transliterations, etc. The old Persian form, found in inscriptions; is *Khšayāršā*.

In the book of Esther the king, at whose court the scene is laid, bears the same Hebrew name, rendered *Assuerus* in the Latin version and Ahasuerus in the English Bible (but in LXX. "Artaxerxes" throughout). Most modern scholars are agreed that here also Xerxes is the king intended. (See ESTHER.)

In Dan. ix. 1 "Ahasuerus" (*Ahāšwērōš*) is the father of "Darius the Mede," who is said to have become king over Babylonia upon the death of Belshazzar. (See also v. 30, vi. 1, 29.) The name seems impossible here, however, and is probably due to some accident in the literary transmission (Josephus, *Ant.* x. 11, 4, has "Astyages"). It was perhaps originally a Hebrew form of *Huwahšatarā* (Cyaxares). No other name resembling Ahasuerus, nor any name like Darius, is to be found in the list of Median kings. We know, moreover, from the Cyrus cylinder, as well as from the Greek historians, that the immediate successor of Nabonidus and Belshazzar as ruler of Babylonia was Cyrus (he is represented in Dan. x. 1, xi. 1, as successor of this Darius). Comparison with the list of Persian kings in the book of Ezra (see above) seems to show that in the Jewish tradition Darius I. Hystaspis was placed before Cyrus as "Darius the Mede."

See articles "Ahasuerus" in the *Encyclopaedia Biblica*, Hastings' *Dictionary*, the *Jewish Encyclopaedia*; Driver, *Introd. to the Lit. of the Old Test.*; Torrey, *Ezra Studies*, pp. 38 seq., 135 seq., 141.

(C. C. T.)

AHAZ, king of Judah. After the death of Menahem, Pekah, king of Israel, and Rezin (rather Rasun), king of Syria, allied against Assyria and invaded Judah. At the same time the Edomites recovered Elath on the Gulf of Akabah and Judah was isolated. Notwithstanding the counsel of Isaiah, Ahaz called in the aid of Tiglath-pileser I., who, after attacking the Philistines, destroyed the power of Syria, and exacted heavy tribute from Judah. It was as a vassal that Ahaz presented himself to the Assyrian king at Damascus, and brought back religious innovations, on the nature of which see W. R. Smith, *Relig. of Semites*, pp. 485 sqq. and commentaries on II. Kings xvi. 17.

AHAZIAH, the name of two kings in the Bible. (1) Ahaziah, 8th king of Israel, was the son and successor of Ahab, and reigned for less than two years. On his accession the Moabites refused any longer to pay tribute. Ahaziah lost his life through a fall from the lattice of an upper room in his palace (2 Kings i. 2-17). (2) Ahaziah, 6th king of Judah, son of Jehoram and Ahab's daughter Athaliah, reigned one year. He, together with Joram, king of Israel, was slain by Jehu, son of Nimshi. He is variously called Jehoahaz and Azariah (2 Kings viii. 25-ix. 28).

AHENOBARBUS [Lat. "brazen-bearded"], the name of a very extensive plebeian Roman family of the gens *Domitia*. The name was derived from the red beard and hair by which many of the family were distinguished. Amongst its members the following may be mentioned:—

GNAEUS DOMITIUS AHENOBARBUS, tribune of the people 104 B.C., brought forward a law (*lex Domitia de Sacerdotiis*) by which the priests of the superior colleges were to be elected by the people in the comitia *tributa* instead of by co-optation; the law was repealed by Sulla, revived by Julius Caesar and (perhaps) again repealed by Marcus Antonius, the triumvir (Cicero *De*

Lege Agraria, ii. 7; Suetonius, Nero, 2). Ahenobarbus was elected pontifex maximus in 103, consul in 96 and censor in 92 with Lucius Licinius Crassus the orator, with whom he was frequently at variance. They took joint action, however, in suppressing the recently established Latin rhetorical schools, which they regarded as injurious to public morals (Aulus Gellius xv. 11).

LUCIUS DOMITIUS AHENOBARBUS, son of the above, and husband of Porcia the sister of Cato Uticensis. Being a convinced aristocrat he opposed Pompey and Caesar while they were united, and when their friendship cooled, attached himself to Pompey. He was consul in 54 B.C., and in 49 B.C. he was appointed by the senate to succeed Caesar as governor of Gaul. After the outbreak of the civil war he commanded the Pompeian troops at Corfinium, but was obliged to surrender. Although treated with great generosity by Caesar, he stirred up Massilia (Marseille) to an unsuccessful resistance against him. After its surrender, he joined Pompey in Greece and was slain in the flight after the battle of Pharsalus (Caesar, Bellum Civile, i., ii., iii.; Dio Cassius xxxix., xli.; Appian, B.C. ii. 82).

GNAEUS DOMITIUS AHENOBARBUS, son of the above, accompanied by his father at Corfinium and Pharsalus, and, having been pardoned by Caesar, returned to Rome in 46 B.C. After Caesar's assassination he attached himself to Brutus and Cassius, and in 43 B.C. was condemned by the lex Pedia as having been implicated in the plot. He obtained considerable naval successes in the Ionian Sea against the triumvirate, both before and after Philippi, but in 40 B.C. became reconciled to Antony, who made him governor of Bithynia. He took part in Antony's Parthian campaigns, and was consul in 32 B.C. When war broke out between Antony and Octavian, he at first supported Antony, but, disgusted with his intrigue with Cleopatra, went over to Octavian shortly before the battle of Actium (31 B.C.). He died soon afterwards (Dio Cassius xlviii.-l.; Appian, Bell. Civ., iv., v.). His son was married to Antonia, daughter of Antony, and became the grandfather of the emperor Nero.

See Drumann, Geschichte Rom., 2nd ed. by Groebe, vol. iii. pp. 14 ff.

AHITHOPHEL, one of David's most trusted advisers, whose counsel was "as though one inquired of the word of God." He took a leading part in Absalom's revolt, and his defection was a severe blow to the king, who prayed that God would bring his counsel to "foolishness." At Ahithophel's advice Absalom first took the precaution of asserting his claim to the throne by seizing his father's concubines. The immediate pursuit of David was then suggested but Hushai recommended waiting till the levies of all Israel could be called up. This advice was adopted, and David had time to escape across the Jordan. Finding that his policy was neglected, and foreseeing the disaster which actually occurred, Ahithophel went home and hanged himself. (2 Sam. xv. 31-37; xvi. 20-xvii. 14, 23.)

AHLEN, a town in the south-east of the district of Münster, in the Prussian province of Westphalia. Pop. (1939) 25,461: It produces metal-work, enamelling, die-stamping, galvanizing, etc.

AHMADABAD, a city and district of British India in the northern division of Bombay. The city was once the handsomest and most flourishing in western India, and it still ranks next to Agra and Delhi for the beauty and extent of its architectural remains. It was founded by Ahmad Shah in A.D. 1411 on a site used for earlier Hindu towns, and embellished with fine buildings of marble brought from a distance. The Portuguese Barbosa described it as "very rich and well embellished, with good streets and squares supplied with houses of stone and cement." In Sir Thomas Roe's time, A.D. 1615, "it was a goodly city as large as London." From 1411 to 1511 it grew in size and wealth; from 1512 to 1572 it declined with the decay of the dynasty of Gujarat; from 1572 to 1709 it renewed its greatness under the Moghul emperors; from 1709 to 1809 it dwindled with their decline; and from 1818 onwards it has again increased under British rule.

In consequence of these changes of dynasty, Ahmadabad became the meeting-place of Hindu, Mohammedan and Jain architecture. Ahmad Shah pulled down Hindu temples in order to build his mosques with the material. The Jama Masjid itself, with its 300 pillars fantastically carved, is a Hindu temple con-

verted into a mosque.

Many of the houses are most beautifully carved and there are numerous fine mosques, tombs, etc. One of the finest is the modern Jain temple of Hathi Singh outside the Delhi gate, which was built only in 1848. Two of the windows in Sidi Said's mosque of filigree marble work are marvels of delicacy and grace, and finer than anything of the kind to be found in Agra or Delhi.

The modern city of Ahmadabad is situated on the left bank of the river Sabarmati; Sabarmati, on the opposite bank of the river, is practically part of Ahmadabad. Its population, which has steadily increased, was (in 1931) 313,789. It has a station on the Bombay and Baroda railway, 309mi. from Bombay, whence

FROM "ARCHITECTURE OF AHMEDABAD," BY COURTESY OF JOHN MURRAY

THE TEMPLE OF HATHI SINGH AT AHMADABAD, BUILT IN 1848 AS THE LOCAL SHRINE OF JAINISM

branch lines diverge to Delhi, Khed, Brahma and Dolka, and is the largest centre for trade and manufacture in the presidency after Bombay. Its native bankers, shopkeepers and workers are all strongly organized in guilds. It has numerous cotton mills, about one-third of the population being dependent on the cotton industry, and factories for ginning and pressing cotton. Other industries include oil, flour and silk mills, manufactures of soap, matches, glass, tobacco and hosiery, carpet works and tanneries. Ahmadabad is famous for its handicrafts, including brocades and tinsel lace, copper and brass working, jewellery and wood-carving. Filtered water is obtained from wells in the river bed and the main streets are lighted by electricity. The military cantonment, 3m. N. of the native town, is the headquarters of the northern division of the Bombay command, with an arsenal.

The district of Ahmadabad lies at the head of the Gulf of Cambay, between Baroda and Kathiawar. Area 3,846 square miles. The river Sabarmati and its tributaries, flowing from north-east to south-west into the Gulf of Cambay, are the principal streams that water the district. The north-eastern portion is dotted with low hills, which gradually sink into a vast plain, subject to inundation on its western extremity. With the exception of this latter portion, the soil is very fertile, and some parts are wooded. The population in 1931 was 999,768. The principal crops are millets, cotton, wheat and pulse. The district is traversed by the Bombay and Baroda railway, and has two seaports, Dholera and Gogo, the former of which has given its name to a mark of raw cotton in the Liverpool market.

AHMAD IBN HANBAL (780-855), the founder, involuntarily and after his death, of the Hanbalite school of canon law, was born at Baghdad in A.H. 164 (A.D. 780) of parents from Merv, but of Arab stock. He studied the Koran and its traditions (*hadith, sunna*) there and on a student journey through Mesopotamia, Arabia and Syria. After his return to Baghdad he studied under ash-Shāfi'i between A.H. 195 and 198, and became, for his life, a devoted Shāfi'ite. But his position in both theology and law was more narrowly traditional than that of ash-Shāfi'i; he rejected all reasoning, whether orthodox or heretical in its conclusions, and stood for acceptance on tradition (*naql*) only from the Fathers. In consequence, when al-Ma'mūn and, after him, al-Mu'tasim and al-Wiithiq tried to force upon the people the rationalistic Mutazilite doctrine that the Koran was created, ibn Hanbal, the most prominent and popular theologian who stood for the old view, was imprisoned and scourged. In A.H. 234, under al-Motawakkil, the Koran was finally decreed un-

created, and ibn Hanbal, who had come through this trial better than any of the other theologians, enjoyed an immense popularity with the mass of the people as a saint, confessor and ascetic. He died at Baghdad in A.H. 241 (A.D. 85j) and was buried there.

BIBLIOGRAPHY.—On his great work, the *Musnad*, a collection of some 30,000 selected traditions, see Goldziher in *ZDMG*, I. 465 ff. For his life and works generally, see W. M. Patten, *Ahmed ibn Hanbal and the Mihna*; C. Brockelmann, *Geschichte der Arab. Lit.* I. 181 ff.; F. Wiistenfeld, *Schäfi'iten*, 55 ff.; M'G. de Slane's transl. of *Ibn Khalikan*, I. 44 ff.; Macdonald, *Development of Muslim Theology*, 110, 157, index.

AHMADIYYAH: see ISLAM.

AHMADNAGAR, a city and district of British India in the central division of Bombay on the left bank of the river Sina. Pop. (1931) 41,890. The town was founded in 1494 on the site of a more ancient city, Bhangar, by Ahmad Nizam Shah, who established a new monarchy, which lasted till its overthrow by Shah Jahan in 1636. In 1759 the Peshwa obtained possession of the place by bribery, and in 1797 it was ceded to the Mahratta chief, Daulat Rao Sindhia. During the war with the Mahrattas in 1803 Ahmadnagar was invested by Gen. Wellesley and captured. Restored to the Mahrattas, it again became a British possession in 1817, under the Treaty of Poona. There is a large trade in cotton and silk goods, while turbans and copper and brass pots are made. There are also factories for ginning and pressing cotton, indigo works and a tannery. Ahmadnagar is a station on the loop line of the Great Indian Peninsula railway, 218m. from Bombay, a military station of the Poona district and an important mission station.

The district of Ahmadnagar is a comparatively barren tract with a small rainfall. The area is 6,611 square miles. The population in 1931 was 988,206, showing a considerable decrease in the decade. On the north the district is watered by the Godavari and its tributaries, the Prawara and the Mula; on the north-east by the Dor, another tributary of the Godavari; on the east by the Sephani, which flows through the valley below the Balaghat range; and in the extreme south by the Bhima and its tributary the Gor. The Sina river, another tributary of the Bhima, flows through the Nagar and Karjat talukas. The principal crops are cotton, millet, pulse and wheat and dyes are produced.

AHMAD SHAH (1724–73), founder of the Durani dynasty in Afghanistan, was the son of Sammaun-Khan, hereditary chief of the Abdali tribe. While still a boy, Ahmad fell into the hands of the hostile tribe of Ghilzais, by whom he was kept prisoner at Kandahar. In March 1738 he was rescued by Nadir Shah, who soon afterwards gave him the command of a body of cavalry composed chiefly of Abdalis. On the assassination of Nadir in 1747, Ahmad, having failed in an attempt to seize the Persian treasures, retreated to Afghanistan, where he persuaded the tribes to assert their independence and accept him as their sovereign. He was crowned at Kandahar in Oct. 1747, and about the same time he changed the name of his tribe to Durani. He first crossed the Indus in 1748, when he took Lahore; and in 1751, after a feeble resistance on the part of the Mohammedan viceroy, he became master of the entire Punjab. In 1750 he took Nishapur, and in 1752 subdued Kashmir. His great expedition to Delhi was undertaken in 1756 in order to avenge himself on the Great Mogul for the recapture of Lahore. Ahmad entered Delhi with his army in triumph, and for more than a month the city was given over to pillage. The shah himself added to his wives a princess of the imperial family, and bestowed another upon his son Timur Shah, whom he made governor of the Punjab and Sirhind. As his viceroy in Delhi he left a Rohilla chief in whom he had all confidence, but scarcely had he crossed the Indus when the Mohammedan wazir drove the Afghan chief from the city, killed the Great Mogul and set another prince of the family, a tool of his own, upon the throne. The Mahratta chiefs availed themselves of these circumstances to endeavour to possess themselves of the whole country, and Ahmad was compelled more than once to cross the Indus in order to protect his territory from them and the Sikhs, who were constantly attacking his garrisons. In 1758 the Mahrattas obtained possession of the Punjab, but on Jan. 6, 1761, they were totally routed by

Ahmad in the great battle of Panipat. In a later expedition he inflicted a severe defeat upon the Sikhs, but had to hasten westwards immediately afterwards in order to quell an insurrection in Afghanistan. Meanwhile the Sikhs again rose, and Ahmad was forced to abandon all hope of retaining the command of the Punjab. He died in 1773, leaving to his son Timur the kingdom he had founded.

AHMED I. (1589–1617) sultan of Turkey was the son of Mohammed III., whom he succeeded in 1603, being the first Ottoman sultan who reached the throne before attaining his majority. He was of kindly and humane disposition, as he showed by refusing to put to death his brother Mustafa, who eventually succeeded him. In the earlier part of his reign he gave proofs of decision and vigour, which were belied by his subsequent conduct. The wars which attended his accession both in Hungary and in Persia terminated unfavourably for Turkey, and her prestige received its first check in the peace of Sitvatörök, signed in 1606, whereby the annual tribute paid by Austria was abolished. Ahmed gave himself up to pleasure during the remainder of his reign—which ended in 1617—and demoralization and corruption had become as general throughout the public service as indiscipline in the ranks of the army. The use of tobacco is said to have been introduced into Turkey during Ahmed I.'s reign.

AHMED II. (1643–95), sultan of Turkey, son of Sultan Ibrahim, succeeded his brother Suleiman II. in 1691. His chief merit was to confirm Mustafa Kuprili as grand vizier. But a few weeks after his accession Turkey sustained a crushing defeat at Slankamen (1691) from the Austrians under Prince Louis of Baden and was driven from Hungary; during the four years of his reign disaster followed on disaster, and on Feb. 6, 1695, Ahmed died, worn out by disease and sorrow.

AHMED III. (1673–1736), sultan of Turkey, son of Mohammed IV., succeeded to the throne in 1703 on the abdication of his brother Mustafa II. He cultivated good relations with England, and he afforded a refuge in Turkey to Charles XII. of Sweden, after his defeat at Poltava (1709). Forced into war with Russia, he came nearer than any Turkish sovereign before or since to breaking the power of his northern rival, whom his Grand Vizier, Baltaji Mohammed Pasha succeeded in completely surrounding near the Pruth (1711). In the treaty which Russia was compelled to sign Turkey obtained the restitution of Azov, the destruction of the forts built by Russia, and the undertaking that the tsar should abstain from future interference in the affairs of the Poles or the Cossacks. Discontent at the leniency of these terms was so strong at Constantinople that it nearly brought on a renewal of the war. In 1715 the Morea was taken from the Venetians. This led to hostilities with Austria, in which Turkey was unsuccessful, and Belgrade fell into the hands of Austria (1717). Through the mediation of England and Holland the peace of Passarowitz was concluded (1718), by which Turkey retained her conquests from the Venetians, but lost Hungary. A war with Persia terminated in disaster, leading to a revolt of the janissaries, who deposed Ahmed in Sept. 1730.

He died in captivity.

AHMED VEFIK, PASHA (1819–1891), Turkish statesman and man of letters, was born in Stambul and educated in Paris. He was appointed to a post in the *bureau de traduction* of the ministry for foreign affairs, and devoted his leisure to the translation of Molière's plays into Turkish and to the compilation of educational books (dictionaries, historical and geographical manuals, etc.) for use in Turkish schools. In 1845 he brought out the first edition of the *Salnameh*, the official annual of the Ottoman empire. Two years later he was appointed imperial commissioner in the Danubian principalities, and in 1851 ambassador to Persia. After his return he was appointed a member of the Grand Council of Justice, and was entrusted with the revision of the penal code and the code of procedure.

In 1860 he was sent as ambassador to Paris, to avert the intervention of France in the affairs of Syria. Ahmed Vefik held various important posts in the Turkish Government during the next two decades, and was twice minister of public instruction, but the position in which he rendered his most distinguished

service was as vali of Brusa (1879-82). The drainage of the pestilent marshes, the water-supply from the mountains, the numerous roads, the suppression of brigandage, the multiplication of schools, the vast development of the silk industry through the substitution of mulberry plantations for rice-fields, the opening out of the mineral springs of Chitli, the introduction of rose trees and the production of attar of roses—all these were Ahmed Vefik's work. A few days after his return he was again appointed prime minister (Dec. 1, 1882), but he made conditions which were unacceptable to the sultan, and Said Pasha was appointed in his place. For the rest of his life Ahmed Vefik, by the sultan's orders, was practically a prisoner in his own house.

Ahmed Vefik was a great linguist. He spoke and wrote French perfectly, and thoroughly understood English, German, Italian, Greek, Arabic and Persian. From all these languages he translated many books into Turkish, but wrote no original work. His splendid library of 15,000 volumes contained priceless manuscripts in many languages. In his lifetime he appreciably aided the progress of education; but, as he had no following, the effects of his labour and influence in a great measure faded away after his death.

AHOM, the branch of the Tai race settled in and giving its name to Assam (*q.v.*). This people came into Assam in the 13th century under a leader named Sukupha and gradually extended their rule westward down the Brahmaputra valley, which they dominated till its invasion by the Burmese early in the 19th century. They instituted and retained in Assam a form of government in which taxes were paid by personal service and the population was organized in *paiks* of three householders, one of whom had always to be on duty. Religion was animistic until Hinduized; society was organized in clans (*khel*), originally exogamous, but tending to become under Hinduism endogamous occupational groups. There was a written language in script derived ultimately from Devanagari, but now, like the spoken tongue, extinct, though palm-leaf books written in it are still extant. (See also SHAN.)

See Hastings' Encyclopaedia of Religion and Ethics (*s.v.*) "Ahom"; E. A. Gait, *History of Assam* (1926).

AHRENS, FRANZ HEINRICH LUDOLF (1809-81), German philologist, was born at Helmstedt, June 6, 1809, and died Sept. 25, 1881. His most important work is *De Graecae Linguae Dialectis* (1839-43, new ed. by Meister, 1882-89), which, although unfortunately incomplete, dealing only with Aeolic and Doric, and in some respects superseded by modern research, remains a standard treatise. A volume of his minor works (ed. Haeblerlin, 1891) contains a complete list of his writings.

AHRIMAN, the name of the principle of evil in the dualistic doctrine of Zoroaster (Gr. *Ἀρειμάνιος* in Aristotle, or *Ἀρειμάνης* in Agathias; in the Avesta, *Añgrō Mainyush*)—"the Destructive Spirit". In the Avesta he is called the twin-brother of the Holy Spirits, and contrasted either with the Holy Spirit of Ormazd or with Ormazd himself. He is the all-destroying Satan, the source of all evil in the world. Eventually, in the great world catastrophe, he will be defeated by Ormazd and disappear. (See ZOROASTER.)

AHRWEILER, a town in Rhenish Prussia, Germany, on the river Ahr. Pop. (1933) 7,002. The town is surrounded by mediæval walls and gates. The Gothic church dates from 1245. There is trade in the red wine of the district.

AHT, a confederacy of 22 tribes of North American Indians of the Wakashan stock. They are settled on the west coast of Vancouver, British Columbia. The chief tribes included are the Nitinaht, Tlaasaht or Makah, Tlaokiwaht or Clahoquaht, Ahansaht and Ehatishaht. In the year 1928 the confederacy numbered some 3,500.

AHTENA ("ice people"), the name of an Athapascan tribe of North American Indians, in the basin of Copper river, Alaska.

See *Handbook of American Indians*, ed. F. W. Hodge (Washington, 1907).

AHURA MAZDA, the Good Spirit in the dual system of Zoroaster, opposed to Ahriman, Angra Mainyu or Druj, the Spiritual Enemy. The name is sometimes translated as the "Wise Lord" and it is the origin of the modern Persian *Ormazd* or *Ormuzd*.

AHWAZ, a town of south-west Persia, in the province of Khuzistan, on the left bank of the River Karun, 85m. by road and 105m. by river from Mohammerah (*q.v.*), 31° 20' N., 48° 48' E. It has been identified with the Aginis of Nearchus, and occupies the site of what was once an extensive and important city, of which, however, very few vestiges remain, the present town having been built in the last 50 years from the ruins of the old. Close by are to be seen the ruins of a stone dam of great strength, constructed across the Karun for the purposes of irrigation. Dependent on it was a system of great canals on both banks which served in the 12th and 13th centuries, if not before, to irrigate an area which was estimated by Major W. R. Morton, R. E., in 1907, at approximately half a million acres. Arab historians of the 12th and 13th centuries describe Ahwaz as the centre of a great sugar, rice and silk growing area, exporting its products all over Persia and as far west as Syria. Since the opening of the Karun to foreign commerce in Oct. 1888 another settlement, called Bandar Násiri, in compliment to the Shah Násir ed Din (d. 1896), has arisen, 1m. below Ahwaz, at the point below the rapids where steamers come to anchor. Here are situated the Government post and telegraph offices, the British consulate and the Soviet consular agency. Bandar Násiri is an official port of entry under the Anglo-Persian Commercial Convention of 1903, and a custom-house is established there. The climate is dry and healthy and the town, which was well laid out between 1903 and 1925 by the Arab governor of the province, Shaikh Khazál, has a mixed Persian and Arab population of some 15,000 souls. The Anglo-Persian Oil Company's European staff at Ahwaz, where some 70,000 tons of cargo are transhipped annually and where their work-shops and stores are situated, number about 70, together with some 2,000 Persians, for most of whom special quarters have been built north of the old town. Motor routes run from Ahwaz along the right bank of the Karun and Diz to Dizful (85m.), to Shushtar (64m.), crossing the Karun at Band-i-Qir (28m.), and to Ram Hormuz (60m.) and Behbahan (126m.) (*q.v.*) and Masjid Suleiman (70 miles). An important caravan route also runs from Ahwaz to Isfahan (271m.) via Malamir.

AI (ah'è), a three-toed sloth (*Bradypus tridactylus*), a tree-dwelling mammal native to dense forests in tropical America, so called because of its plaintive cry which somewhat resembles the sound indicated by its name. For descriptive details and illustration see EDENTATA: *Pilosa*; SLOTH.

AI, in Hebrew always with the definite article, Haai, "the heap of ruins." Other forms of the name are 'Ayya (Neh. ii. 31), 'Ayyath (Isa. x. 28). Some mss. read, probably correctly, 'Ayya for Gaza in I Chron. vii. 28. It was a royal city of the Canaanites and is best known for its complete destruction by Joshua (viii. 28), from which time, indeed, the name may date. Abraham pitched his tent between Ai and Bethel (Gen. xii. 8, xiii. 3). It lay somewhere east of Bethel (Beitin) near Beth-Aven with valleys to the north and west (Josh. viii. 11, 12). Identifications have fluctuated. Et-Tell (Tell el-Hajar), Khirbet el-Qudeira, Khirbet el-Haya and Khirbet Hayyan, all of which are mounds or ruined sites in the neighbourhood, have had their advocates. The weight of authority now favours Khirbet Hayyan with visible evidence of extensive habitation in rock-hewn reservoirs and débris of stone buildings. This site is rather more than 2m. south-east of Beitin on the road leading to the Jordan valley.

Sea Pal. *Expl. Fund Quart. Statement* (1869), p. 123; (1874), p. 62-4; (1878), pp. 10, 132, 195; (1881), p. 254; E. Robinson, *Bib. Researches*, i. 143, ii. 312 ff.; Sellin, *Mitt. des Deutsch. Palastinu Vereins* (1900), p. 1 ff.; W. F. Albright, *Annual Amer. Schools of Orient. Research* (1924), appendix v. (E. Ro.)

AICARD, JEAN FRANÇOIS VICTOR (1848-1921), French poet and dramatist, was born at Toulon. He went to Paris to study law, and his first visit was to Victor Hugo, who returned the young man's admiration in kind, and is reported to have said in the Académie Française, "Je promets ce poète à la France." Aicard won the Vitet prize, and soon became known in literary circles in Paris for the charm and luminous simplicity of his verse. His poetry includes: *Les Rébellions et les apaisements* (1871); *Poèmes de Provence* (1874), and *La Chanson de l'enfant* (1876), both of which were crowned by the Academy; *Miette et Noré*

(1880), a Provencal idyll; *Le Livre d'heures de l'amour* (1887); *Jésus* (1896), etc. Of his plays the most successful was *Le Père Lebonnard* (1890), which was originally produced at the *Théâtre Libre*. Among his other works are the novels, *Le Roi de Camargue* (1890), *L'Âme d'un enfant* (1898) and *Tatas* (1901), *Benjamine* (1906) and *La Vénus de Milo* (1874), an account of the discovery of the statue from unpublished documents.

AICHINGER, GREGOR (c. 1565–1628), a distinguished composer. We was organist to the Fugger family at Augsburg in 1584. Proske, in the preface to vol. ii. of his *Musica Divina*, calls him a priest of Regensburg, and is inclined to give him the palm for the devout and ingenuous mastery of his style.

AIDAN (or AEDAN), a monk of Iona, and first bishop of Lindisfarne (A.D. 635–651). In 635 Oswald, who had succeeded to the kingdom of Bernicia in the previous year, re-united the whole of Northumbria under himself. Northumbria had been converted to Christianity by Paulinus (625–633), but had relapsed under the heathen successors of Edwin, and in 635 Oswald, who was an earnest Christian, sent for a new bishop. Paulinus had been a member of the Roman Church, but his successor was summoned from the headquarters of the Celtic church, the monastery of Iona, which Oswald had visited during his exile. The first monk sent was unsuccessful; when he reported at Iona that he could do nothing with the uncouth Northumbrians, Aidan suggested that "he had not first given them the milk of mild doctrine . . . until they were able to understand the more perfect mysteries . . . of God." Thereupon it was decided to send Aidan as bishop to Northumbria.

True to the traditions of the Celtic church, he fixed his abode on the island of Lindisfarne. Under his influence, and that of the Irish monks who joined him, churches were built, and monasteries established, and a school founded where 12 boys were trained as preachers.

Christianity spread apace through Northumbria, partly because Aidan was building on the foundations laid by Paulinus, and partly because of the active support given by Oswald. There was a close friendship between king and bishop, and Bede tells us that when Aidan was preaching, Oswald, who understood Scottish, would often act as his interpreter. But the main cause of Aidan's success was his own character; Bede, though disapproving of his observance of the Celtic Easter, gives him the highest praise for his learning, simplicity of life, and open-handed generosity. "What chiefly commended his teaching to all men was that it agreed with the life he and his followers led."

The defeat and death of Oswald at Maserfield (Aug. 5, 642) did not destroy the Northumbrian Church; though the kingdom was divided, Aidan retained his see, and legend tells that his prayers saved Bamburgh from destruction by Mercian invaders. He died at Bamburgh, Aug. 31, 651, eleven days after the murder of his friend, King Oswin of Deira.

Aidan by his energy and saintly character had established in Northumbria Christianity in its Celtic form. But the phase was not lasting; in 664, at the Synod of Whitby, Oswy adopted the Roman Easter, and, abandoning the Celtic church with its monastic ideal, brought Northumbria again into touch with the Christianity of Southern England and the Continent.

See Bede, *Hist. Eccl.* iii. 3, 5, 14–17, 25—Plummer's edition, with excursus on the Paschal Controversy; Oman, *England before the Conquest* (1921), ch. xiv.; W. Bright, *Chapters of Early English Church History* (1897) chaps iv., v. See article *EASTER*.

AIDAN (d. 606), king of the Scottish kingdom of Dalriada, was the son of Gabran, king of Dalriada, and became king after the death of his kinsman, King Conall, when he was crowned at Iona by St. Columba. He refused to allow his kingdom to remain in dependence on the Irish Dalriada, but coming into collision with his southern neighbours he led a large force against Aethelfrith, king of the Northumbrians, and was defeated at a place called Daegsanstane, probably in Liddesdale.

See Bede, *Historiæ Ecclesiasticæ gentis Anglorum*, ed. by C. Plummer (1896); Adamnan, *Vita S. Columbae*, ed. by J. T. Fowler (1894).

AIDE-DE-CAMP (Fr. for camp-assistant or, perhaps, field-assistant), an officer of the personal staff of a general, who acts

as his confidential secretary in routine matters. On Napoleon's staff such officers were frequently of high military qualifications, and acted both as his "eyes" and as the interpreters of his mind to subordinate commanders, even on occasion exercising a delegated authority. But in modern times, particularly in the British army, they have usually been of very junior rank and their duties largely social. In Great Britain the office of aide-de-camp to the king is given to senior officers as a reward or an honorary distinction. In many foreign armies the word adjutant is used for an aide-de-camp, and adjutant-general for a royal aide-de-camp. The common abbreviation for aide-de-camp in the British service is "A.D.C.," and in the United States "aid." Civil governors, such as the lord lieutenant of Ireland, have also, as a rule, officers on their staffs with the title and functions of aides-de-camp. The aide-de-camp of the governor of a State in the United States has the title of colonel.

AIDIN or **AYDIN**. (1) A vilayet in S.W. Turkey, including the lower part of the Maeander valley. (2) The principal town of the vilayet about 70 mi. E.S.E. of Smyrna. It was taken by the Seljuks, Aidin and Mentesh, late in the 13th century, and about 1390, when ruled by Isa Bey, a descendant of the first-named, acknowledged Ottoman suzerainty. In the Seljuk period it was only a secondary city under the provincial capital, Tireh. In the 17th century it came under the power of the Karasmans of Manisa and remained so till about 1820. Aidin is on the Smyrna-Dineir railway. On a neighbouring height are still to be seen the ruins of the ancient *Tralles* (*q.v.*). Aidin itself suffered severely in the Graeco-Turkish conflict of 1919–1922. Pop. 49,436.

AIDONE, a town of Sicily, in the province of Enna, about 22 mi. E.S.E. of the town of Caltanissetta. Pop. (1936), 8,178 (town), 8,694 (commune). There are ruins of an ancient city on Mte. Serra Orlando near by. Aidone has some interesting 14th-century churches. (See E. Mauceri in *L'Arte*, 1906–17.)

AIDS, a term of mediaeval finance, were part of the service due to a lord from his men, and appear to have been based upon the principle that they ought to assist him in special emergency or need. The occasions for demanding them and the amount to be demanded would thus be matters of dispute, while the loose use of the term to denote many different payments increases the difficulty of the subject.

Both in Normandy and in England in the 12th century the two recognized occasions on which, by custom, the lord could demand "aid" were (1) the knighting of his eldest son, (2) the marriage of his eldest daughter; but while in England the third occasion was, according to Glanvill, as in Normandy, his payment of "relief" on his succession, it was, according to the Great Charter (1215), the lord's ransom from captivity. By its provisions, the king covenanted to exact an "aid" from his barons on these three occasions alone—and then only a "reasonable" one—except by "the common counsel" of his realm. Enormous importance has been attached to this provision, as establishing the principle of taxation by consent, but its scope was limited to the barons and the City of London, and the word "aids" was omitted from subsequent issues of the charter. The barons, on their part, covenanted to claim from their feudal tenants only the above three customary aids. The last levy by the Crown was that of James I. on the knighting of his eldest son (1609) and the marriage of his daughter (1613).

From at least the days of Henry I. the term "aid" was also applied (1) to the special contributions of boroughs to the king's revenue, (2) to a payment in lieu of the military service due from the Crown's knights. Both these occur on the pipe roll of 1130, the military payment as *auxilium militum* (and possibly as *auxilium comitatus*). The borough "aids" were alternatively known as "gifts" (*dona*), resembling in this the "benevolences" of later days. When first met with, under Henry I., they are fixed round sums, but under Henry II., as the Dialogue on the Exchequer explains, they were either assessed on a population basis by Crown officers or were sums offered by the towns and accepted by them as sufficient. In this case the townfolk were collectively responsible for the amount.

Aids and the Great Charter.—The Great Charter, as before stated, extended specially to London the limitation on baronial "aids," but left untouched its liability to tallage, a lower and more arbitrary form of taxation, which the towns shared with the Crown's demesne manors, and which London resisted in vain. The two exactions, although distinct, have to be studied together, and when in 1296–97 Edward I. was forced to his great surrender, he was formerly supposed by historians to have pledged himself, under *De tallagio non concedendo*, to levy no tallage or aid except by common consent of his people. It is now held, however, that he limited this concession to aides, *mises* and *prises*, retaining the right to tallage. Eventually, by a statute of 1340, it was provided that the nation should not be called upon "to make any common aid or sustain charge" except by consent of parliament. The aids spoken of at this period are of yet another character, namely, the grant of a certain proportion of all "movables" (*i.e.*, personal property), a form of taxation introduced about 1188 and of rapidly increasing importance. These subsidies were conveniently classed under the vague term "aids," as were also the grants made by the clergy in convocation, the term covering both feudal and non-feudal levies from the higher clergy and proportions not only of "movables" but of ecclesiastical revenues as well.

The "knight's aid" of 1130 spoken of above is probably identical with *auxilium exercitus* mentioned in the oldest customs of Normandy, where the phrase appears to represent what was known in England as "scutage." Even in England the phrase "*quando Rex accipit auxilium de militibus*" occurs in 1166 and appears to be loosely used for scutage.

The same loose use enabled the early barons to demand "aid" from their tenants on various grounds, such as their indebtedness to the Jews, as is well seen in the Norfolk fragments of returns to the Inquest of Sheriffs (1170).

Sheriff's aid was a local payment of a fixed nature paid in early days to the sheriff for his service. It was the subject of a hot dispute between Henry II. and Becket in 1163.

AIGRETTE, the long back plumes which the egret (*q.v.*) assumes in the breeding season, the use of which as ornaments in women's headdresses has become rare, owing to the protests of humanitarians on account of the cruelty involved in slaughtering the birds and leaving their young to starve. The name is also given to any similar ornament, in gems, etc., to the insignia of rank of colonels in the French army and, in science, to feathery excrescences such as the *pappus* of the dandelion and the luminous rays seen diverging from the moon's edges in solar eclipses.

AIGUESMORTES, a town of south-east France, department of Gard, 25m. S.S.W. of Nîmes on a branch line of the P.L.M. railway. Population (1936) 3,458. It occupies an isolated position in the marshy plain at the western extremity of the Rhone delta, 2½m. from the Gulf of Lions. Louis IX. embarked from Aiguesmortes in 1248 and 1270 for the 7th and 8th crusades, and developed the town. The mediaeval fortifications which surround it are of great interest. They form a parallelogram 596yd. long by 149yd. broad and consist of crenellated walls from 25 to 36ft. in height, dominated by towers, of which the Tour de Constance (N.W.), built by Louis IX., was used as a prison for Protestants after the revocation of the Edict of Nantes. The fortifications were completed under Philip III. To further the prosperity of the town a most liberal charter was granted to it, and in addition the trade of the port was artificially fostered by a

decree requiring that every vessel navigating within sight of the lights should put in there. This ordinance remained in force till the reign of Louis XIV. The town, although steadily decreasing in population, remains important historically as an outstanding example of mediaeval city planning. Aiguesmortes is the meeting-place of several canals connecting with Beaucaire, Cette, the Lesser Rhone and the Mediterranean. Fishing and the manufacture of soda are industries, with trade in coal, fruits and wine. In the surrounding country there are important vineyards, which are preserved from disease by periodical submersion.

AIGUILLE (Fr. for needle), the sharp jagged point above the snow-line formed by a part of a mountain which has been split by frost action along joints or planes of cleavage with sides too steep for snow to rest upon them. Aiguilles are thus the forms left from the splitting up of the high ridges with "house-roof" structure into detached pinnacles. (See *ARÊTE*.)

AIGUILLON, EMMANUEL ARMAND DE WIGNEROD DU PLESSIS DE RICHELIEU, Duc D' (1720–1782), French statesman, nephew of the maréchal de Richelieu, was born on July 31, 1720. He was a member of the so-called *parti de'vot*, the faction opposed to Madame de Pompadour, to the Jansenists, and to the parlement. In 1753 he was appointed commandant (governor) of Brittany and was engaged in constant disputes with the Breton parlement, in 1768 returning to court, where he resumed his intrigue with the *parti dévot* and finally obtained the dismissal of the minister Choiseul (Dec. 24, 1770). When Louis XV., acting on the advice of Madame Dubarry, reorganized the government with a view to suppressing the resistance of the parlements, d'Aiguillon was made minister of foreign affairs, Maupeou and the Abbé Terray (1715–1778) also obtaining places in the ministry. D'Aiguillon was blamed for having provoked the *coup d'état* of Gustavus III., king of Sweden, in 1772, although the instructions of the comte de Vergennes, the French ambassador in Sweden, had been written by the minister, the duc de la Vrillière. D'Aiguillon, however, could do nothing to rehabilitate French diplomacy; he acquiesced in the first division of Poland, renewed the Family Compact, and, although a supporter of the Jesuits, sanctioned the suppression of the society. After the death of Louis XV. he quarrelled with Maupeou and with the young queen, Marie Antoinette, who demanded his dismissal from the ministry (1774). He died, forgotten, in 1782.

See *Mémoires du Ministère du duc d'Aiguillon* (3rd ed., 1792), probably written by J. L. Soulavie. On d'Aiguillon's governorship of Brittany see Carré, *La Chalotais et le duc d'Aiguillon* (1893); Marion, *La Bretagne et le duc d'Aiguillon* (1898); and Barthélemy Pocquet, *Le Duc d'Aiguillon et La Chalotais* (1901–02). The three last have full bibliographies. See also Flammermont, *Le Chancelier Maupeou et les parlements* (1883); Frédéric Masson, *Le Cardinal de Bernis* (1884).

AIGUILLON, MARIE MADELEINE DE WIGNEROD DU PONT DE COURLAY, DUCHESSE D' (1604–75), daughter of Cardinal Richelieu's sister. In 1620 she married a nephew of the Constable de Luynes, Antoine de Beauvoir du Roure, Sieur de Combalet, who died in 1622. In 1625, through her uncle's influence, she was made a lady-in-waiting (*dame d'atour*) to the queen-mother, and in 1638 was created duchess of Aiguillon. After the death of the cardinal (1642) she withdrew from the court, and devoted herself entirely to works of charity. She helped St. Vincent de Paul to establish the hospital for foundlings, and also took part in organizing the General Hospital and several others in the provinces. She died on April 17, 1675. Corneille dedicated to her his tragedy of *Le Cid*.

See E. Flécher, *Oraison funèbre de Mme. Marie de Wignerod, duchesse d'Aiguillon*; Bonneau-Avenant, *La duchesse d'Aiguillon* (1879); *Mémoires de Saint-Simon*, ed. by A. de Boislisle (1879 et seq.).

AIGUN (49° 58' N. 127° 35' E.) a treaty port on the south bank of the Amur in Northern Manchuria on the extreme north-eastern frontier of China. It lies on the opposite bank to, but about 20 miles below, the Russian city of Blagovyeshchensk, for which it serves as an entrepôt. Its trade is concerned primarily with the shipping of Mongolian cattle and meat and Manchurian grain and flour across the river to Blagovyeshchensk. But, since it was hurnt down in 1900 during the Boxer troubles, this func-

BY COURTESY OF THE CHAMBER OF COMMERCE OF THOMASVILLE, GA.

EGRETS ON A SOUTHERN RESERVE ESTABLISHED AND MAINTAINED BY THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

tion has passed to Ta-wei-ho T'an which lies immediately opposite Blagovyeshchensk. The trade of Aigun is becoming more and more local and what general traffic it once had has been diverted from the Amur to the Chinese Eastern railway which offers a more direct route between Manchuria and the better-peopled parts of Siberia. Its total trade in 1926 amounted to Hk.Tls.-2,069,279. The Treaty of Aigun (1858) was one of a series of treaties which attempted to define the boundaries between the Chinese and Russian Empires.

AIKEN, a city of South Carolina, U.S.A., 17 mi. E.N.E. of Augusta, Ga., on the highest point between Augusta and Charleston, 565 ft. above sea level; the county seat of Aiken county. It is on federal highways 1 and 78 and is served by the Southern railway. The resident population is small (4,103 in 1920, 2,286 Negroes; 1930, 6,033; 1940, 6,168 by the federal census), but it is greatly increased by visitors during the winter, spring and autumn, for Aiken is a health and pleasure resort of high repute. The climate is unusually dry and equable. There are many luxurious private estates and country clubs, besides hotels and apartments. Fox hunting, pigeon shooting, riding, polo, tennis, steeplechase racing and golf are popular sports. With its seven polo fields, Aiken is a winter training ground for this game.

Aiken was settled early in the 19th century and was incorporated in 1835. It was on the line of one of the earliest railways, and was named after the first president of that road, William Aiken (1806-87), who was governor of the State (1844-47).

AIKIN, JOHN (1747-1822), English physician and author, was born at Kibworth-Harcourt on Jan. 15, 1747, and died at Stoke Newington, London, on Dec. 7, 1822. He practised as a consulting physician in London from 1792 onwards, but gradually became absorbed in literary pursuits. Aikin and his sister, Anna Letitia Barbauld, wrote popular books which had a great vogue. Their admirable miscellany, *Evenings at Home* (1792-95) was translated into many European languages. Aikin's voluminous works include *General Biography* (1799-1811), and *Lives of John Selden and Archbishop Usher* (1812).

His daughter, **LUCY AIKIN** (1781-1864), born at Warrington on Nov. 6, 1781, wrote several books for children, including versions of classical stories written in monosyllables. She also wrote: a novel, *Lorimer* (1814); *Memoirs of the Court of Queen Elizabeth* (1818); *Memoirs of the Court of James I.* (1822); *Memoirs of the Court of Charles I.* (1833) and a *Life of Addison* (1843). Miss Aikin died at Hampstead, where she had lived for 40 years, on Jan. 29, 1864.

See a *Memoir of John Aikin, with selections of his miscellaneous pieces* (1823), by his daughter; and the *Memoirs, Miscellanies and Letters of Lucy Aikin* (1864), including her correspondence (1826-42) with William Ellery Channing, edited by P. H. Le Breton.

AILANTHUS (more correctly *ailantus*, from *ailanto*, an Amboyna word probably meaning "Tree of the Gods," or "Tree of Heaven"), a genus of trees belonging to the quassia family (Simarubaceae). The best known species, tree of heaven or Chinese sumac (*Ailanthus altissima*), is a handsome, rapidly growing tree with spreading branches and large pinnately compound leaves bearing many lance-shaped leaflets with conspicuous glandular bases. The small greenish flowers are borne in branched panicles; the staminate (male), upon opening, exhale a most disagreeable odour. The fruit is a samara with a single centrally disposed seed in the elliptical, twisted, fibrous wing. This tree, which is a native of China and Japan, was introduced into England in 1751 and is a favourite in parks and gardens. It has been planted extensively in the eastern United States and is one of a few trees capable of thriving in smoky atmospheres adjoining industrial centres. Two other species, *A. imberbiflora* and *A. punctata*, are Australian trees of secondary importance; *A. excelsa* is a common tree in India. (E. S. HR.)

AILANTHUS MOTH (*Philosamia cynflzia*), a large silk-spinning moth inhabiting China. The larvae feed on the leaves of the ailanthus tree and yield a silk more durable and cheaper than mulberry silk, but inferior to it in fineness and gloss. The moth measures about 5 in. across, and is olive-brown in colour

with a whitish spot and a white and purplish transverse bar on each wing. It was introduced with its food-tree into the eastern United States where it is now common.

AILERON, a hinged or movable portion of an aeroplane wing, the function of which is to impress a motion on the aeroplane about its longitudinal axis. Situated generally at the rear edge of the wing and at or near the wing tip, the ailerons are connected to the control column by mires or push-pull rods in such a way that a movement of it, e.g., to the right, raises the aileron on the right wing and lowers that on the left, thus causing the aeroplane to bank for a turn to the

The banking of an aeroplane in turning is brought about by two ailerons, one on the rear edge of each wing. One goes up as the other goes down

right.

Ailerons of the type shown in fig. 1 are effective in normal flight but when the aeroplane is stalled (as in the last few seconds before a normal landing) they become less effective. Great attention has therefore been devoted to aileron design in aerodynamic research laboratories throughout

The purpose of this auxiliary wing is to remove one of the most serious risks of flying. In stalling the ailerons become ineffective. By this device the "slot" opens automatically when the wing stalls and this renders the aileron effective. The illustration shows a right wing seen from below

the world. The mounting of automatic slots of the Handley-Page type (see *AEROPLANE*) along the leading edge of the wing is one of several effective methods which have been developed to retain aileron action beyond the usual stalling point. (D. SE.)

AILLY, PIERRE D' or PETRUS D'ALLIACO (1350-1420) French churchman and schoolman, was born at Compiègne and studied at the College of Navarre of the University of Paris. He became master of the college in 1384 and later obtained the highest dignity in the university, the chancellorship of Kotre Dame. John Gerson was one of Ailly's pupils and his lifelong friend. The two men played an important part in the later history of the papal schism. Pierre d'Ailly acted as spokesman of the university before the king's council (May 20, 1381) with the proposal that the best way of ending the scandal of the existence of two popes, Urban VI. at Rome and Clement VII. at Avignon, was the summoning of a general council. The suggestion was unacceptable and Ailly retired from Paris for some time. As master of the College of Navarre he was twice sent by the university on missions to Clement VII., and on the death of that pope, he was sent by the king to congratulate Clement's successor, Benedict XIII. His acceptance of that mission displeased the university, which was already beginning to demand the resignation of both popes as a preliminary to the re-unification of the church. Suspicion of his attitude was deepened by his nomination by Benedict XIII. as bishop of Le Puy (1395) and then bishop of Cambrai (1397). At the ecclesiastical council, held in Paris in 1406, Ailly, by the king's order, defended Benedict XIII., and it was not until the convocation of the general Council of Pisa (1409) that he forsook Benedict's cause and returned to the point of view of the University of Paris, of which he had been the champion before his preferment. He and Gerson urged that the unity of the church could only be restored by a general council which, in case of schism, would be supreme and legitimate even though it were not convoked by the pope. The nominee of the Council of Pisa died within a year. His successor, John

XXIII., gave Ailly the bishopric of Orange and made him a cardinal. Nevertheless Ailly was one of the most formidable adversaries of John XXIII. at the Council of Constance (Nov. 1414–April 1418). He maintained that, as the decisions of the Council of Pisa had not been accepted and there were now three "popes," it was necessary to begin *de novo* and treat the claims of all three alike, and he made serious depositions against John. The theory put forward by Ailly and Gerson that the general council had jurisdiction over the pope himself was a dangerous one, and, according to later decisions, even heretical; but both men were seeking an outlet from an impossible situation. Ailly found in the end an ingenious compromise on the rights of the Sacred College and the council and the schism was healed by the appointment of Martin V.

During the Council of Constance, Ailly had earned the hatred of the Anglo-Burgundians by trying to reduce the power of the English by contesting their right to form one of the four separate nations. He was compelled to retire to Avignon, where he died on Aug. 9 1420.

Pierre d'Ailly's written works are numerous. Many of them were published with the works of Gerson (by Ellies du Pin, Antwerp, 1706); others appeared in the 17th century, probably at Brussels; and there are many treatises and sermons still unpublished. In philosophy he was a nominalist.

(1894); N. Valois, *La France et le grand schisme d'Occident* (1896–1902); and *Bibliothèque de l'école des chartes*, vol. lxv., p. 557–574 (1904).

AILSA CRAIG, an island rock at the mouth of the Firth of Clyde, 10m. W. of Girvan, Ayrshire, Scotland. It is of conoidal form, with an irregular elliptic base, and rises abruptly to a height of 1,097ft. The only side from which the rock can be ascended is the east, the other sides being for the most part perpendicular, and generally presenting lofty columnar forms, though not so regular as those of Staffa. The island is composed of micro-granite with riebeckite, of great interest on account of the rare occurrence of this type in Britain. It is fine-grained and of a greyish colour, and may be of Tertiary age. Pebbles of this rock were carried far south (e.g. to Welsh shores) by glaciers of the Ice age. The rock is a favourite material for curling-stones. Hence curling-stones are popularly known as "Ailsas" or "Ailsa Craigs." The rock is also used for paving stones. A columnar cave exists towards the north side of the island, and on the east are remains of a tower. Two springs occur and some scanty grass affords subsistence to rabbits, and, on the higher levels, to goats. The precipices have large breeding colonies of gannets and other sea birds which spend the winter months at sea. A lighthouse on the south side flashes a light visible for 13 miles.

AIMAK, the name of nomadic or semi-nomadic Mongolian tribes inhabiting the north and north-west Afghan highlands north of Herat. *Aimak* is a Mongolian word meaning "clan" or "section of a tribe." They were originally known as "chahar (the four) eimaks," because there were four principal tribes: the Taimani, the Ferozkhoi, the Jamshidi and the Hazara. They number about 250,000, and speak a dialect akin to Kalmuck. They are Sunnite Mohammedans.

AIMARD, GUSTAVE, the pen-name of OLIVIER GLOUX (1818–83), French novelist, who was born in Paris Sept. 13, 1818, and died there June 20, 1883. He made use of the materials collected in a roving and adventurous youth and early manhood in numerous romances in the style of J. Fenimore Cooper. Among the best of them are: *Les Trappeurs de l'Arkansas* (1858); *La grande fibuste* (1860); *Nuits mexicaines* (1863); *La Forêt vierge* (1870).

AIMOIN (c. 960–c.1010), French chronicler, spent the greater part of his life in the monastery of Fleury. His chief works are: *Historia Francorum* or *Libri V. de gestis Francorum*, a history of the Franks from the earliest times to 633, which was continued by other writers and brought down to the middle of the 12th century; a life of Abbo, abbot of Fleury; and books ii. and iii. of the *Miracula S. Benedicti*,

BIBLIOGRAPHY.—The *Historia* is printed in *Monumenta Germaniae historica: Scriptores*, Band xxvi.; and the *Vita* and the *Miracula* in Mabillon, *Acta sanctorum ordinis S. Benedicti* (Paris, 1668–1701). Some fragments by another Aimoin, a monk of St. Germain-des-Prés, are printed in *Historiae Francorum Scriptores*, tome ii. (1639–49). See *Histoire littéraire de la France*, tome vii. (1865–69).

AIN, a department of eastern France, formed from Bresse, the Pays de Dombes on the lowland and the Pays de Gex, Valromey and Bugey among the high parallel scarps of the Jura reaching south to the Rhone between Geneva and Lyons. Area 2,249 sq.m. Pop. (1936) 316,710. The name is that of the river which roughly separates the two first from the other districts, running north to south at first between outer hill ranks and then along the foot of the highland to join the Rhone. The western boundary is the Saône, the southern the Rhone, the eastern Switzerland and the northern the departments of Saône-et-Loire and Jura, the boundary over against the latter being closely linked with that of old between Burgundy and Franche Comté. The Pays de Gex includes some of the highest Jura scarps (Crêt de la Neige 5,653-ft.), the Pays de Valromey flanks on the west the deep Rhone gorge below Bellegarde, the Pays de Bugey is the south-pointing triangle of the Rhone focussing on Belley. West of the hills, Bresse occupies the fertile north part of the department and is effectively drained to the Saône, thus contrasting with the Pays de Dombes, mantled in boulder clay and possessing endless pools and marshes with, still, a good deal of consequent malarial trouble. The summers are warm in the lowland but the winters, generally, are sharp, the rainfall rises well above 1 metre per annum in the highland. The farms of Bresse are famous for pigs and poultry and the latter (especially geese) are also bred, in Dombes, which also raises horses. In the Jura hill country, pastures feed sheep and cattle from which cheese is produced, while many slopes are well forested. Bresse produces considerable cereal and other crops but the rest of the department is thus concerned mainly with stock-raising or with activities connected with its forests (of fir and oak) or with extensions of the silk industry from Lyons just beyond the south-west corner of the department, thanks to the water power available from the rivers among the gorges of the limestone country. Bourg is the capital of the department; the four arrondissements of which take their names from Bourg, Belley (the seat of a bishop in the archiepiscopal province of Besançon) and Nantua. The departmental appeals are heard at the court of Lyons and the department is also under Lyons educationally. Bourg (*q.v.*) is a market town specially known in connection with the famous church of Brou, wrongly described in Arnold's well known poem as being in Savoy. Among silk towns one may mention Jujurieux, Tenay, St. Rambert, St. Bernard en Bugey; Bellegarde and St. Rambert make wood pulp; and Oyonnax, a rather larger town than several of the others, north of Nantua, makes articles in wood and horn and is specially well known for its combs. Seyssel, on the far east, yields asphalt and many parts of the department give building stones, cement or potter's clay. There is a good tourist industry for winter sports, angling, etc., and some of the gorges and ridges are very striking; near Bellegarde, at the Perte du Rhone, that great river formerly disappeared down a fissure. Though the main P.L.M. railway from Dijon to Lyons lies west of the Saône, and so outside the department, the main line from Paris to Geneva runs through Bourg and Ambérieu to Bellegarde; both the Saône and the Rhone are navigable for considerable lengths along the confines of the department.

AINGER, ALFRED (1837–1904), English divine and man of letters, was born in London on Feb. 9, 1837, the son of an architect. He was educated at King's College, London, and at Trinity College, Cambridge, and was ordained in 1860 to a curacy at Alrewas, near Rugeley. His connection with the Temple Church, in London, began in 1866, when he was appointed reader; and in 1894 he succeeded Dr. Vaughan as master. In 1887 he was presented to a canonry in Bristol cathedral, and he was chaplain-in-ordinary to Queen Victoria and King Edward VII. He died on Feb. 8, 1904. Canon Ainger's gentle wit and humour, his generosity and lovable disposition, endeared him to a wide circle. In literature his name is chiefly associated with his sympathetic appreciation of Charles Lamb and Thomas Hood.

His works include: *Charles Lamb* (1882) and *Crabbe* (1903) in the "English Men of Letters" series; editions of Lamb's *Essays of Elia* (1883) and of his *Letters* (1888; 2nd ed., 1904), of the *Poems* (1897) of Thomas Hood, with a biographical introduction; *The Life and Works of Charles Lamb* (1899-1900); articles on Tennyson and Du Maurier in the *Dictionary of National Biography*; *The Gospel and Human Life* (1904), sermons; *Lectures and Essays* (1905), edited by the Rev. H. C. Beeching.

See Edith Sichel, *The Life and Letters of Canon Ainger* (1906).

AINHARDUS: see **EINHARD**.

AINMULLER, MAXIMILIAN EMMANUEL (1807-1870), German artist and glass-painter, was born at Munich on Feb. 14, 1807. In 1828 he was appointed director of the newly-founded royal painted-glass manufactory at Munich. The method which he gradually perfected there was a development of the enamel process adopted in the Renaissance, and consisted in actually painting the design upon the glass, which was subjected, as each colour was laid on, to carefully-adjusted heating. The earliest specimens of Ainmiiller's work are to be found in the cathedral of Ratisbon. With a few exceptions, all the windows in Glasgow cathedral are from his hand. Specimens may also be seen in St. Paul's cathedral, and Peterhouse, Cambridge, and Cologne cathedral contains some of his finest productions. Ainmiiller had considerable skill as an oil-painter, especially in interiors. He died on Dec. 9, 1870.

AINSWORTH, HENRY (1571-c. 1622), English Nonconformist divine and rabbinical scholar, was born at Swanton Morley, Norfolk. He was a scholar of Caius College, Cambridge, joined the Puritan party in the church, and eventually the Separatist. Driven abroad in the persecution of 1593, he found a home in "a blind lane at Amsterdam." He acted as "porter" to a scholarly bookseller in that city, who, on discovering his skill in Hebrew, enabled him to continue his Hebrew studies. When part of the London church, of which Francis Johnson (then in prison) was pastor, reassembled in Amsterdam, Ainsworth was chosen as their doctor or teacher.

In 1596 he drew up a confession of their faith, which he reissued in Latin in 1598. Johnson joined his flock in 1597, and in 1604 he and Ainsworth composed *An Apology or Defence of such true Christians as are commonly but unjustly called Brownists*. In 1610 he was forced reluctantly to withdraw, with a large part of their church, from Johnson and his adherents on a question of church government, Ainsworth taking the more congregational view. (See **CONGREGATIONALISM**.) But in spirit he remained a man of peace. The fruit of his rabbinical learning appeared in his *Annotations — on Genesis* (1616); *Exodus* (1617); *Leviticus* (1618); *Numbers* (1619); *Deuteronomy* (1619); *Psalms* (including a metrical version, 1612); *Song of Solomon* (1623). These were collected in folio in 1627, and again in 1639. From the outset the *Annotations* took a commanding place, especially among Continental scholars.

BIBLIOGRAPHY.—John Worthington's *Diary* (Chetham Society), by Crossley, i. 263-266; works of John Robinson (1851); H. M. Dexter, *Congregationalism of the Last Three Hundred Years* (1880); W. E. A. Axon, *H. Ainsworth, the Puritan Commentator* (1889); F. J. Powicke, *Henry Barrow and the Exiled Church of Amsterdam* (1900); J. H. Shakespeare, *Baptist and Congregational Pioneers* (1906).

AINSWORTH, ROBERT (1660-1743), English schoolmaster and author, was born at Eccles, near Manchester, in Sept. 1660. Ainsworth's name is associated with his Latin-English dictionary, begun in 1714 and published in 1736 as *Thesaurus linguae Latinae compendiarius*. He died in London, April 4, 1743.

AINSWORTH, WILLIAM HARRISON (1805-1882), English novelist, was born at Manchester, Feb. 4, 1805. He was educated for the law, but at the age of 21 he married a daughter of John Ebers, the publisher, and followed his father-in-law's profession for a short time. A novel called *Sir John Chiverton*, in which he had a share, won the praise of Sir Walter Scott, and he turned to novel-writing. *Rookwood* (1834), with its description of the ride of Dick Turpin to York, had an immediate success. He published about 40 "historical" novels, of which the

best known are *Jack Sheppard* (1839), *The Tower of London* (1840), *Old St. Paul's* (1841) and *Windsor Castle* (1843). He edited *Bentley's Miscellany*, in which *Jack Sheppard* was published as a serial, and in 1842 he became proprietor of *Ainsworth's Magazine*. In 1853 it ceased to appear, and Ainsworth bought the *New Monthly Magazine*. He died at Reigate, Jan. 3, 1882.

See S. M. Ellis, *William Harrison Ainsworth and his Friends* (London, New York, 1911).

AINTAB or **GAZIANTEB** (anc. **DOLICHE**), a city of Anatolia. Turkey, just outside Syria, pop. (1940) 57,314 (two-thirds are Muslim, mainly of Turkoman origin and there are 15,000 Armenians). In ancient times (2nd Mil. B.C.) Aintab was in the Hittite area and is probably of Hittite origin. Duluk, the site of *Dolielze*, famous for the worship of Zeus Dolichenus (Baal), is marked by a mound two hours distant to the northwest. In Crusading times its strong castle (*Hamtab*) was a strategic point of importance and was captured by Saladin in 1183. It served as the last base of Ibrahim Pasha before his victory over the Turks at Nezib, 25 mi. to the northeast (1839). In the winter of 1920-21 the armed opposition of the Turkish nationalists to the French occupation of north Syria centred in Aintab, which became the "Verdun of Anatolia." After an investment lasting six months, despite determined Turkish efforts to relieve it, the city surrendered to the French troops. France returned it to Turkey under the Angora treaty of Oct. 30, 1921.

The modern city stands high (3,500 ft.) in the open, treeless valley of the Sajur, a tributary of the Euphrates, some 65 mi. N.E. of Aleppo. Important educational and medical work is carried on by the American Mission Board in their college (founded 1874) and girls' seminary. There is also a Franciscan mission. Manufactures include striped dress materials (the chief of which is a mixture of silk and cotton), black goats' hair cloth for tents, morocco leather (*sakhtiyān*) made from goats' skins (it is estimated that nearly 400,000 are tanned here annually), "Aleppo soap" made from olive oil, *Pekmez*, a sweet paste made from grapes, and the dyeing of yarns. The exports include pistachio nuts, tobacco, cotton and cereals.

AINU, who are racially closely akin to, if not identical with, the Neolithic inhabitants of Japan (see **JAPAN: History**)

AN AINU VILLAGE CHIEF

The Ainu rate down under Japanese rule. In former times their affairs were administered by hereditary chiefs, three in each village.

are now very reduced in numbers and live in Hokkaido, the northern island of Japan, in part of Saghalien, and have kinsfolk in the Ryukyu islands (*q.v.*). They are dwindling fast and are unable to compete with the advance of Japanese civilization. Physically they are probably the remains of an old Proto-Nordic population once widely spread over Northern Asia, and are certainly the relics of a very old human stock. Their culture recalls in many ways stone age man and they have preserved the very earliest stage of agriculture, when the men are still hunters but the women have developed beyond the mere collecting stage and are beginning actually to plant crops.

The Ainu religion is closely akin to the animistic religion practised by various primitive peoples of northern Asia, and they are particularly liable to that peculiar kind of religious ecstasy known as Arctic hysteria. One of their special cults is that of the bear. This animal is caught as a cub, and is carefully tended by the women who will even suckle it. At about three years old the bear is sacrificed with elaborate ceremony. In most of the Ainu villages, the special wooden cages in which the bears are kept can be seen. Prominent also in the villages are sticks which have been whittled (*inao*) and the shavings left on. The sticks are stuck in the ground and have a religious significance.

BIBLIOGRAPHY.—J. Batchelor, *The Ainu* (1901); G. Montandon, *Archiv. suisses d'anthrop. gén.* 1921. IV.; L. H. D. Buxton, *The Eastern Road* (1924), and *The Peoples of Asia* (1925). (L. H. D. B.)

AIR, the atmosphere that surrounds the earth. With the development of analytical and especially of pneumatic chemistry, the air was recognized not to be one homogeneous substance, as was long supposed, and different "airs," or gases, came to be distinguished. At the end of the 18th century oxygen gas was known as *deplzlogisticated air*, nitrogen or azote as *phlogisticated air*, hydrogen as *inflammable air*, carbonic acid gas as *fixed air*. The name is now ordinarily restricted to atmospheric air (see ATMOSPHERE). The sense of atmosphere or environment may have led to the further use of the word "air" to mean "manner" or "appearance"; and so to its employment (cf. Lat. *modus*) in music for "melody." (See ARIA.)

AIR or **ASBEN**, a country of West Africa, lying between 15° and 19° N. and 6° and 10° E. It is within the Sahara, of which it forms one of the most fertile regions. The northern portion of the country is mountainous, some of the peaks rising to a height of 5,000ft. Richly wooded hollows and extensive plains lie between the hills. The mimosa, the doum palm and the date are abundant. Some of the plains afford good pasturage for camels, asses, goats and cattle; others are desert tablelands. The country generally is of sandstone or granite formation, with occasional trachyte and basaltic ranges. There are no permanent rivers; but during the rainy season, from August to October, the water-courses in the hollows of the mountains are converted into broad and rapid streams. Numerous wells supply the people and their cattle. To the south of this region lies a desert plateau, 2,000ft. above sea-level. Still farther south is the fairly fertile district of Damerghu, of which Zinder is the chief town. There is cultivation in the neighbourhood of the villages. Millet, dates, indigo and senna are the principal products.

Air was called Asben by the native tribes until they were conquered by the Berbers. The present inhabitants combine the finer traits of the Berbers with negro characteristics. The sultan of Air is much dependent on the chiefs of the Tuareg tribes inhabiting a vast tract of the Sahara to the north-west. A large part of his revenue is derived from tribute exacted from the salt caravans. Since 1890 Air has been included in the French sphere of influence in West Africa.

Agades, the capital of the country, which has a circuit of 3½m., is built on the edge of a plateau 2,500ft. high, said to have been founded by the Berbers to serve as a secure magazine for their extensive trade with the Songhoi empire. The language of the people is a dialect of Songhoi. In former times Agades had a great trade, with a population of about 50,000. Since the beginning of the 16th century the prosperity of the town has, however, gradually declined.

AIRAY, HENRY (1560?—1616), English Puritan divine, was born at Kentmere, Westmorland, but no record remains of the date of either birth or baptism. He died on Oct. 6, 1616. His character as a man, preacher, divine, and as an important ruler in the university, will be found portrayed in the Epistle by John Potter, prefixed to his *Commentary on the Epistle to the Philippians* (1618). He must have been a fine specimen of the more cultured Puritans—possessed of a robust common sense in admirable contrast with some of his contemporaries.

AIR-BLADDER, the name given to a structure present in all bony fishes (Teleosts) and homologous with the lungs of land vertebrates. The functions of this organ, which contains gas having a high percentage of oxygen, are obscure; hydrostatic uses have been attributed to it with doubtful validity. In some fishes (especially Siluroidea), it is connected with the internal ear by a chain of bones, the Weberian ossicles, and in these forms it is possibly concerned with hearing. It usually retains a connection with the alimentary canal (except in most Acanthopterygii, *q. v.*), but is normally dorsal to it. (See FISH.)

AIRBRUSH, a machine used for applying liquid colouring powders, flock, latex, and glazes to a surface by means of compressed air. The use of compressed air for the atomization of liquids has been known for many years, but it is only in the last 35 years that the principle has been successfully applied to the application of all types of coating materials in commercial and industrial enterprises, and today there is hardly an institution

anywhere whose product requires finishing that does not employ this method of application. The early successful use of airbrushes was in the field of art for retouching, etc.

The airbrush shown in fig. 1 (p. 441) is used in drawing the most delicate hair-line work, as well as photographic retouching. It is a common implement in all large newspaper art departments. Fig. 2 illustrates the next step towards a commercial airbrush, this style being used for decorative and show-card work.

The natural evolution of the airbrush that was used by the artist brought about the present industrial type (fig. 3) which is used in practically every automobile and furniture factory, or any industry applying liquid finishes to their product. This is a universal airbrush, inasmuch as it may be used with any style of fluid supply, gravity (overhead bucket), pressure tank and cup (either syphon or gravity), thus making the airbrush applicable to all purposes. The heads for this type are made in twelve sizes, all interchangeable, thus adapting the airbrush to all consistencies of material. The production of as high as 5,000 automobiles per day could never have been reached were it not for the airbrush, which makes it possible to coat a body in less than one minute. Fig. 4 shows an industrial installation as used for the finishing of furniture, the booth and ventilating equipment being very necessary to carry off the fumes and excess spray.

Fig. 5 illustrates an automatic adhesive and flocking unit such as used by largest industrial organizations for high speed daily production. In this unit the airbrushes are operated automatically. In section to the right the automatic airbrush applies the adhesive or binder and in the second station at the left the specially designed airbrush applies the flock, the unit reclaiming all unused material. Daily production in 8 hours is 11,000 discs. Contract painters and large railroad companies also use the airbrush for general painting on buildings and bridges, effecting large savings, in addition to the fact they are able to do the work in season. Portable airpainting units for both electric and gasoline (petrol) engine operation are universally selected for outside airpainting jobs.

Airbrushes are now made to function in every capacity from that of a cement mixture to the most delicate art work.

AIR COMBAT. Combat between aircraft is a new development of war. It is one that will probably become increasingly important, since aircraft have, so far at any rate, proved in war to be the best antidote to aircraft. The most effective way in fact of preventing enemy aircraft from carrying out their object, be it reconnaissance, observation of artillery fire or bombing, is to oppose them in the air with other aircraft.

I. HISTORICAL

The term air combat covers fighting between aeroplanes and between aeroplane and airship. There has been no instance recorded of airship fighting airship.

Early History.—Prior to the outbreak of the World War, none of the belligerents had devoted much attention to air combat. Reconnaissance was regarded as the primary, indeed almost the only, duty of aircraft. There was thus little or no specialization of duties among aeroplanes; in fact it is, broadly speaking, true to say that all the belligerents began the war with one class of aeroplane—a two-seater designed solely for reconnaissance. There were a few single-seaters of high performance, but their rôle was that of fast scouts. As the war went on, specialization appeared, and a class of aeroplane designed specifically for air fighting was evolved, followed by a class of bombing aeroplanes.

Prior to the outbreak of war the British had experimented with machine-guns in aircraft, and firing tests had been carried out in the air. But on the outbreak of war no aeroplane on the Western Front was actually armed with a machine-gun. Rifles, carbines, pistols, shotguns and hand grenades were carried by pilots and observers. The tactics employed in the stray combats that did occur at this time were rudimentary. The pilot simply flew close to the enemy aeroplane, and, when within range, he or his observer blazed away with whatever weapon they happened to be carrying.

In the summer of 1915, all belligerents began to mount machine-

guns in their standard two-seater reconnaissance aircraft, the great majority of which were of the tractor type (*i.e.*, aeroplanes in which the pilot sits behind the engine). In these aeroplanes the gun was usually mounted on a swivelling bar at the back of the observer's seat. The observer could only fire the gun backwards towards the tail of the aeroplane and over the pilot's head. (At that time the observer was always seated in front of the pilot.) The arc of fire was consequently restricted; and it was necessary, owing to the fact that the gun pointed towards the aeroplane's tail, to fly *away* from the enemy aeroplane in order to bring fire to bear upon it.

It was at once apparent that, in order to attack effectively, it was essential to be able to fire *forwards* in the direction in which the aeroplane was flying. The British had already designed an aeroplane embodying this principle. This aeroplane, the Vickers Fighter, was a two-seater of the "pusher" type (*i.e.*, the pilot and observer sat in a nacelle in front of the engine). The observer, who sat in the very front of this nacelle, was armed with a Lewis gun on a swivelling mounting. Two squadrons of these aeroplanes were sent to France in the summer and autumn of 1915 respectively. The machine, however, lacked speed and climbing power, and was soon outclassed by a new type of German aeroplane—the Fokker monoplane.

The Fokker Monoplane (Autumn 1915).—This was a small, fast single-seater, of the tractor type. It was fitted with a

fixed machine-gun firing straight ahead and a synchronizing gear by which the actions of the engine and the machine-gun were so co-ordinated that the gun only fired when the propeller blade was *not* opposite the muzzle of the gun. The pilot aimed the gun by pointing his aeroplane at the enemy. This, the first effective "fighter" aeroplane, began to appear on the Western Front in the autumn of 1915, and by the end of the year had achieved such success as to be practically master of the air.

Meanwhile the Allies had not been idle. Shortly after the advent of the Fokker E.I., the French produced the "Baby" Nieuport, a single-seater tractor biplane with a Lewis gun so fixed on its top-plane as to fire straight ahead outside the arc of the propeller; while early in 1916 the British sent to France the D.H.2, and later the F.E.8. These were small single-seater fighters of the pusher type, in which the pilot operated a Lewis gun on a moveable mounting in the front of the nacelle.

By this time the need for the specialization of functions among aircraft was becoming apparent; and both the Allies and the Germans, besides producing aeroplanes designed solely for air fighting, had, by the beginning of 1916, grouped these aeroplanes into specialist fighting squadrons.

Formation Flying (Spring 1916).—The success of the Fokker monoplane had a direct and immediate effect on the tactics of air combat, and on the design of all types of aeroplanes. As regards tactics, it was responsible for the birth of formation fly-

ing. Towards the end of 1915, owing to the casualties among British and French aircraft, it became the custom to send out two or three aeroplanes to fly in close company for mutual protection, whenever their duties necessitated their penetrating more than a few miles into enemy territory. The German Fokker pilots retaliated by working together in slightly larger formations, so as to have the advantage of numbers on their side. As the war proceeded, by reason of this competition to outnumber the enemy, formations tended to increase in size, until by the end of the war formations of 50 or 60 aeroplanes, working together in close co-operation, were not uncommon.

As formations increased in size and the tactics of fighting in formation developed, individualism in air fighting tended to disappear in favour of co-operation—that is, it was found, as the war went on, to be usually of little use for one pilot to go out alone to search for and shoot down enemy aeroplanes. Not only was he liable to be attacked by a formation of enemy fighters and so outnumbered, but it was also found to be a hazardous business for one man to attack single-handed a close-knit formation of two-seater reconnaissance or bombing aeroplanes.

The System of Offensive Patrols (Summer and Autumn 1916).—By the summer of 1916 therefore the customary British method of employing fighter squadrons was to send them out in small formations of five or six aeroplanes on what were termed "offensive patrols." These formations flew out over enemy territory, often as far as the enemy aerodromes, with the object of searching for and dispersing enemy fighting patrols, and so affording indirect protection to the British reconnaissance, artillery observation and bombing aircraft. To the French must be given the credit of first employing this system on a wholesale scale. This they did at Verdun in the spring of 1916. But the system was brought to full flower by the British during the battle of the Somme, where its success was so great as to transfer for a time to the Allies the mastery of the air that had been previously won for the Germans by the Fokker monoplane.

Modifications in Design of Two-Seaters (Summer 1916).—In 1916, as a result of the increasing importance of air combat, all belligerents began to devote far more attention not only (as already described) to the development of fighting aircraft and their methods of employment, but also to the design of the two-seater reconnaissance and bombing aeroplanes, and to the tactics by which they could best defend themselves against the attacks of fighting aircraft. Thus there gradually came into vogue a more or less standard "lay-out" for the two-seater reconnaissance and bombing types—a lay-out that has not so far been materially modified. The design that was found to be most effective was a tractor biplane, in which the pilot was seated in front of the observer or gunner. The pilot had a fixed machine-gun, firing straight ahead, and a synchronizing gear—an armament in fact similar to that of the fighter pilot. The observer was seated facing backwards, behind the pilot, with a light machine-gun on a swivelling mounting with which he was able to cover an arc of rather more than 180 degrees towards the aeroplane's tail. Since—for reasons that will be explained later—the usual method of attack in the air is to take the enemy in the rear, the main defence of a two-seater was found to be in the fire of the observer from this rearward gun, supplemented of course, by such tactical manoeuvring as the pilot thought fit to carry out. The first two-seater aeroplane of this type to be used on the Western Front was a British machine, the Sopwith "1½ Strutter," the first squadron of which was sent to France in the early summer of 1916. Later aeroplanes with a similar lay-out and armament were the British R.E.8, D.H.4, Bristol Fighter and D.H.9; the French Breguet; and many types of German two-seaters, of which the L.V.C. was perhaps the most common.

ACCURACY OF FIRE ALONG THE LINE OF FLIGHT

When firing along AB the line of flight, no allowance need be made for the speed of the aeroplane, but when firing any other direction, as CD, this factor has to be taken into account

Germany's Second Period of Mastery (Spring 1917).—

Early in 1917 the Germans made a determined effort to regain the mastery of the air, which they had lost the previous summer on the Somme. They produced two new types of single-seater fighters—the Albatros D.III. and the Halberstadt—which for some months outclassed the fighters of the Allies at that time on the Western Front. Their success was due partly to their superior performance, and partly to the fact that they were armed with two machine-guns, fixed to fire through the propeller, instead of one as heretofore. The Allies, caught short of effective fighters, quickly lost the superiority in the air that they had won the previous year at Verdun and on the Somme. By February 1917 German superiority was clearly marked.

Second Period of Franco-British Superiority.—Once more, however, the pendulum swung. In the spring of 1917 the British brought to the Western Front a new type of single-seater fighter, the S.E.5, followed in the early summer by another fighter, the Sopwith Camel and by two two-seaters of exceptional performance, the D.H.4 and the Bristol Fighter. The French moreover produced an improved Spad. With the machines now at their disposal, the British and French fighting pilots gradually won back for the Allies a measure of superiority in the air that was not lost before the Armistice was signed.

In the last year of the war the tactics of fighting in formation crystallized, and tactical systems were evolved adapted to the peculiarities of the various types of aeroplanes. In the summer of 1918 on the Western Front it was rarely that either fighter or bombing squadrons operated in formations of less than squadron strength; and, as already stated, it was not uncommon for three or four squadrons to work together in one large, but rather loose formation. The tactics customarily employed in the formation fighting of this period have not materially changed and will be described in a later section.

Development between 1918 and 1940.—After the Armistice of 1918 there was a lull in the development of pursuit aircraft. The victors had great quantities of aeroplanes for which they had no need, and the vanquished were forbidden to possess any. However, when Germany began to rearm, interest was again focussed on the development of fighters. The single-seat fighter of 1940 is a low-wing, all-metal monoplane, carrying one of the following combinations of weapons: eight rifle-calibre machine-guns, all mounted in the wings; one 23mm. cannon mounted on the engine, and four rifle-calibre machine-guns, two mounted on the fuselage and two in the wings; or four .50 calibre machine-guns, mounted in the fuselage and in the wings. It has self-sealing gas tanks and the high speed of 360mi. per hour.

II. THE TACTICS OF AIR COMBAT

Types of Aircraft.—From the point of view of air fighting, aeroplanes fall into two categories—first, aeroplanes designed

FIG. 2.— SHOWING THE EASIEST TARGET IN AIR COMBAT

In direct line pursuit the pilot of the pursuing machine A is aiming at the equivalent of a stationary target

solely for air fighting, and, secondly, aeroplanes designed primarily for some other duty, such as reconnaissance or bombing.

Aeroplanes in the first category are called "fighters" (U.S. "pursuit planes"; Fr. "avions de chasse"); they are usually single-seaters of great speed and climbing power, carrying maximum fire power and some light armour.

Among aeroplanes not designed solely for air fighting there is a

wide variety in design and lay-out. Broadly speaking, however, they fall into two main classes—single-engine and multi-engine aeroplanes. The modern single-engine machine is usually a tractor monoplane of medium size carrying a crew of two, or less frequently three, men. The pilot is seated in front of the gunner, and is armed in the same way as the pilot of a fighter aeroplane with one or two fixed machine-guns firing straight ahead. The gunner or observer sits behind the pilot, facing backwards, and is armed with one or two light machine-guns on a swivelling mounting.

In the case of multi-engine aeroplanes several gunners are carried; one sits in the very front of the aeroplane's fuselage and covers the forward arc; the others sit behind the pilot and cover the rearward arc.

The Manoeuvres Preliminary to an Air Combat.—When two hostile aeroplanes meet, the higher of the two has the advantage. The reason for this is that an aeroplane can descend more quickly than it can ascend. The higher of the two aeroplanes can dive down to its opponent's level in a few seconds; whereas the lower will take several minutes to climb up to the other's height.

This is why in air fighting a pilot is constantly striving to outclimb his opponent, since superior height gives him the power to attack at once or to avoid combat altogether, just as he wishes. This also explains why speed and climbing power are such vital factors in "fighter" aircraft, since, if they lack these characteristics, their natural prey, the enemy's bombers and reconnaissance aircraft, will, by coming over high up, be able to avoid combat.

The Tactics of Attack.—A fighter pilot therefore, when on patrol, will always try to get above his opponent. He will then dive to close quarters and attack. His method of attack now requires explanation.

Referring to fig. 1, the first fact to be grasped is that it is easier for the pilot of the aeroplane depicted to hit a target with a gun firing along the line A-B (either forwards or backwards) than with one firing along any other line (e.g., the line C-D). The reason for this is that, when firing along the line A-B, he does not have to take into account the speed of his own aeroplane or the direction in which it is moving with reference to the target.

This is an important consideration in view of the high speed of aeroplanes. Generally speaking, therefore, the most effective way to attack a hostile aeroplane is for the pilot to fly towards it and shoot at it with a gun fixed so as to fire straight ahead parallel to the path of his own aeroplane, since by doing so he has to make no allowance for the speed and direction of flight of his own aeroplane.

Now if the enemy aeroplane was a stationary object that could not shoot back the problem of attack would be simple. The attacking pilot would simply fly straight at his target, aiming his gun at it by steering his aeroplane. But the target is not stationary; it is moving in three dimensions at a speed of anything up to 320m.p.h., and can moreover shoot back. The attacking pilot has therefore two objects—first to attack in such a way that the enemy aeroplane presents a reasonably easy target, and secondly to attack in such a way that the enemy cannot shoot back effectively.

A glance at fig. 2 will show that the easiest target for the pilot of the attacking aeroplane (marked A in the diagram) is an aeroplane flying directly ahead of him and in precisely the same

direction as himself.

It will be seen that when the attacking pilot is flying directly behind, and in the same direction as the aeroplane he is attacking, and is shooting at it with a fixed gun firing straight ahead, not only does he have to make no allowance for the speed and direction of flight of his own aeroplane, but he also has to make no allowance for the speed and direction of flight of the enemy aeroplane. In fact he gets a straight shot at the enemy over open sights. It is true that he himself is exposed to a straight shot over open sights from the enemy gunner, firing to the rear. But this can usually be avoided by the attacking pilot placing his aeroplane in such a position (slightly below and to the rear of the enemy aeroplane) that he is concealed from the view of the enemy gunner by the tail-plane of the enemy aeroplane.

While therefore a pilot may attack from any direction—from the front, flank or rear—to confuse an opponent or to break up an enemy formation, he will generally, when he wishes to fire for effect or deliver the *coup de grâce*, fly directly behind the enemy aeroplane, and shoot at it over open sights.

Tactics of Defence.—How will a pilot attacked in this way defend himself? He will rely of course to a certain extent on the accuracy of the gun-fire of his gunner behind him. But over and above this he will have two objects in view at the moment of attack: first to get out of the enemy's line of fire as quickly as possible; and secondly (if he is flying a pursuit aeroplane) to try to turn the tables and himself become the attacker.

There are various alternative manoeuvres by which these two objects may be attained. But it is usually accepted that the most effective manoeuvre is to do a steep, climbing turn. The turn carries the pilot attacked out of the enemy pilot's line of fire in a lateral direction; by climbing on the turn he gains that all important factor—height; and, with the help of the height so gained, he stands a good chance, by means of a second turn and a dive, of turning the tables and himself becoming the attacker.

Fighting in Formation.—One of the most convenient formations for air fighting is the wedge or "vee" (see figs. 3 and 4).

The reasons why the "vee" is the most suitable shape for a formation of aircraft are first, that all pilots can see the leader in front and so conform readily to his movements; secondly, that each pilot can fire in a forward direction without hitting one of his fellow-pilots, while in the case of two-seaters the gunners can obtain a good concentration of fire in a rearward direction; and lastly that no aeroplane is flying in another's propeller wash.

A formation is usually "stepped" upwards in height from front to rear, i.e., the leader's aeroplane is the lowest; the pilots on either side of him fly slightly higher; while the rear rank of the formation flies higher still.

A formation must not be so small as to be easily overwhelmed by superior numbers, or so large as to be unwieldy. Fifteen aeroplanes are about the maximum number that can be handled in one formation. When greater numbers than this are required for an operation, it is usual to form two or more separate formations which work together in close co-operation.

The first essential of fighting in formation is that the formation should hang together, and not be split up. Once the formation becomes disintegrated, each aeroplane is liable to be set upon separately by superior numbers and defeat in detail results. Further, the concentration of gun-fire that an organized formation of aeroplanes can bring to bear is far more likely to achieve results than the spasmodic gun-fire

FIG. 3.—FLIGHT OF 5 AEROPLANES FLYING IN FORMATION. The leading aeroplane flies at the lowest elevation, while the second and third lines fly at heights that enable them to keep their leader in full view and catch up easily if they drop behind.

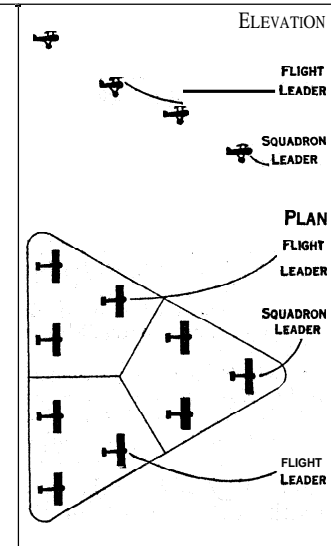

FIG. 4.—FLIGHT OF 9 AEROPLANES IN SQUADRON FORMATION. The formation is spear-headed and is composed of 3 flights of 3 aeroplanes each.

of the same number of single aeroplanes working independently of each other.

A consequence of this is that when one formation of aeroplanes meets another (e.g., a formation of fighters meets a formation of bombers), the first object of the attacking formation (the fighters) is to break up the bombers' formation. Once the bombers' formation is broken, each bomber can be dealt with separately by a superior concentration of fighters. Conversely, the bombers' object is to avoid having their formation broken. For this they will rely primarily not on manoeuvre, but on the concentration

FIG. 5.—CURTISS HAWK 75A PURSUIT SHIP. AN ALL-METAL SINGLE SEATER. IN A TEST FLIGHT THIS U.S. PLANE DIVED AT A SPEED EXCEEDING 575 M.P.H.

of fire that their gunners can bring to bear on the fighting formation, as it dives in to attack.

In other respects the principles of fighting in formation are similar to those already alluded to in the case of combat between individual aeroplanes.

Night Fighting.—Aeroplanes can fight at night. The tactics employed are the same as by day, except that aeroplanes do not usually fly in formation at night.

It is moreover far more difficult at night for a fighting pilot to

FIG. 6.—LINE OF ATTACK ON TWO-SEATER FROM THE "BLIND SPOT" By approaching along the line indicated the attacking pilot is immune from the fire of the enemy and is himself well-placed to get in a burst of fire at close range

locate an enemy aeroplane; in fact he will not usually be able to do so without the assistance of a ground organization of sound locators and searchlights.

These two books are the personal reminiscences of two of the most successful fighting pilots of the war 1914-18, one an Englishman, the other a German.

They contain accounts of air combats which give a good general impression of air combat in the World War, 1914-18. See also Major Oliver Stewart, M.C., A.F.C., "*The Strategy and Tactics of Air Fighting*" (1925), a technical treatise on the tactics of air combat. (W. S. D ; X.)

AIR CONDITIONING. The term is derived from the word "conditioning" which was applied to the determination of the moisture content of textiles, and covers the treating of air in an enclosure to regulate its moisture content, temperature, purity and usually its circulation. For increasing human comfort and for the manufacturing or processing of certain materials, an accurate control of the moisture content of the air is most important. It is

sometimes roughly effected by adding water vapour or mist directly to the enclosed air, but more precisely by using an air-conditioning apparatus by which the air is purified and its temperature and moisture definitely controlled before it is introduced into the space to be conditioned.

Originally only places where equable and moist climatic conditions prevail, such as Lancashire, England, and the Fall River district in Massachusetts, could be chosen for the building of cotton mills. Then moisture was added to the air by evaporating water in steam pots. This method sufficed for small mills, but was inadequate in the larger mills on account of the heat generated by the great concentration of machinery. In the latter half of the 19th century the direct introduction into the room of an atomized spray of water both cooled and moistened the air, thus making it practicable to spin fine cotton yarns in all climates. At about the same time moist air was supplied to malting floors by passing the air through coke filters over which water trickled, or through a large series of wetted baffle plates. In 1897 Joseph McCreary of Toledo O. patented an air washer intended primarily for purifying the air, but incidentally it cooled it and increased the moisture content. In 1906 Stuart W. Cramer of Charlotte, N.C., and Willis H. Carrier of Buffalo, N.Y., working independently, made two important contributions to the art. Cramer automatically controlled humidity by a system which depended upon the relation between the wet and dry bulb temperatures. This was applied to the humidifying spray heads located in the room. Carrier devised the "dew point control," an improved form of air washer which not only brought the air to saturation, but also controlled automatically the temperature of such saturation, thus determining the moisture content of the air supplied.

Types of Apparatus.—Of the two main types of humidifiers, the "direct spray" type, which provides for the atomization of the water and its introduction directly into the room, is made in relatively small sizes. The nozzles or distributors are placed just below the ceiling, and provide for humidifying only. The "saturated air" type, on the other hand, introduces larger volumes of saturated air at the required temperature

In the conditioning chamber it is brought into intimate contact with water finely divided by spraying through special nozzles under moderate pressure. All of the free particles of water are then removed by an "eliminator," which usually consists of a series of specially formed baffle plates on which all free particles of moisture are caught, leaving the air saturated but free of all suspended water particles.

The spray water may be heated or cooled, and the temperature of the saturated air may be modified before passing it into the room at the theoretic dew point.

Under certain conditions it is desirable to remove dust and soot from air with dry filters. Two general types of air filters are employed. Closely woven cloth or paper fabric is mounted in frames, accessible for frequent cleaning, through which the air to be filtered is passed. In the viscous type filters, the medium used is fibrous metal, fibrous glass or paper having the surfaces dipped in an oil. The dust or soot particles carried by the air are removed by adhering to the viscous surfaces. In such cases either "cloth filters" or "viscous filters" are employed. The cloth filters are large areas of closely woven cotton cloth held in frames, provision being made for frequent cleaning. The viscous filters are either intricate metal baffles or cells filled with masses of fibre-like metal. These are dipped in a viscous oil which causes the particles of dust or soot to adhere to the metal surfaces.

Usually temperature is automatically controlled by thermostats governing the admission of steam to the air heaters, or regulating the supply of cold dehumidified air. Another form controls the sprays, but is mostly used in the direct spray type humidifiers.

Since the air conditioning of small shops, restaurants and other places has become general, air conditioning units completely assembled at the factory have been developed. These units are arranged in sections enclosing the fans, heaters, cooling coils, humidifier and air filters. In conjunction with these, refrigerating units of comparable sizes, embodying safety and simplicity of

operation, have been developed. The use of new and safe refrigerants has been an important factor. Self-contained air conditioning units, complete with refrigeration equipment and all other elements built into one enclosure, are (1940) widely used for offices, stores, restaurants, etc.

The quantity of moisture which may remain in the vapour state in a unit volume of space is dependent only upon its temperature. The saturation pressure of water vapour is approximately doubled for each 20°F rise in temperature, *i.e.*, the maximum vapour pressure increases approximately in a geometric ratio for equal increments of temperature. The relation of the weight of water vapour in the atmosphere to the weight of air varies approximately in accordance with Dalton's law of partial pressures (*see* DALTON, JOHN). When water is brought into contact with unsaturated air it evaporates. If the air is the sole source of heat necessary to produce evaporation, an eventual equilibrium saturation temperature is established depending on the initial air temperature and its initial degree of saturation. The reduction in the *sensible heat* of the

BY COURTESY OF COOLING AND AIR CONDITIONING CORPORATION
DESIGN OF AIR CONDITIONING APPARATUS FOR LARGE BUILDING

atmosphere is equalled by the *latent heat* of the acquired water vapour; the *total heat* remains constant. The equilibrium temperature of evaporation is observed with practical accuracy by a wet-bulb thermometer. The general formula based upon this heat balance is found in "Rational Psychrometric Formulae," W. H. Carrier, *Trans. A.S.M.E.*, vol. xxxiii.

When unsaturated air is passed through an air washer and brought to saturation without changing the temperature of the spray water, it will be cooled to the temperature of evaporation (substantially, to the wet-bulb temperature of the entering air). For example, when the outside air is at 95°, the average wet-bulb temperature will be approximately 75°, and the air passing through a spray humidifier will be cooled to substantially 75°. This method of cooling is especially valuable in textile mills and tobacco factories where the increased humidity as well as the lower temperature is desirable.

The temperature of evaporation is independent of the actual rate of evaporation. The rate of evaporation of water into air is dependent upon the air velocity over the water surface and upon the difference in vapour pressure existing between the water and the air. The determinations of these relationships have important applications in the drying of materials in air.

Regain.—The ratio of moisture content to the weight of dry material is technically termed *regain*. The maximum regain for various materials varies widely, the amount depending principally upon the relative humidity of the air and to a slight extent upon the temperature. There is, however, no exact constant ratio between change of regain and change of relative humidity. Materials such as natural and artificial silk, wool, cotton, yarn and tobacco are sold on the basis of a standard percentage of regain, so in the drying and manufacturing of these materials it is necessary to control the relative humidity.

Comfort.—The relation of moisture, heat and air motion to human comfort and physiological efficiency has been the subject of much research, which has determined the points of equivalent comfort. Curves based on experimental results have been drawn to show the relation between temperature and humidity which will give the same sensation of comfort or temperature. Such a curve is termed an "effective temperature" line. Temperature by itself, even when automatically controlled, does not determine comfort.

Humidity is equally important. The proper relation between temperature and humidity can be maintained only by complete conditioning.

Some instrument of measurement besides the dry-bulb thermometer has yet to be devised as an indicator of comfort. One instrument attempting to accomplish this, devised by Sir Leonard Hill in England, was known as the "kata-thermometer." Under conditions of high humidity this is a reliable indicator but it does not follow with precision the experimental effective temperature lines under varying humidities.

AIR CO-OPERATION. A result of the growth of aerial navigation in the first quarter of the 20th century has been to accent the importance of co-operation between the air forces and the armies and navies of the countries of the world. The problems to be solved in the military and naval spheres though in some ways alike are in others so different as to make separate treatment desirable. (X.)

CO-OPERATION WITH AN ARMY

To gain information about one's enemy has always been one of the first preoccupations of a military commander, for, until he has accurate knowledge concerning the strength and dispositions of his opponent, it is difficult for him to evolve an effective plan to bring about the defeat of his enemy.

HISTORICAL

It did not need a very great stretch of imagination in 1903, when Orville and Wilbur Wright made the first successful flight in an aeroplane, to realize that it would be possible to obtain a great deal of the essential information concerning an enemy by flying over his positions. The practical realization, however, was slow, owing both to conservatism and technical difficulties. By the time the World War broke out in 1914, the French, Germans and British all had military aeroplanes; the latter were able to send out four squadrons of twelve aeroplanes each, with the original Expeditionary Force. The stage reached in technical progress was that aeroplanes and engines were sufficiently reliable to enable flights of 50 miles into the enemy's country to be undertaken. Although all the pilots and observers of these aeroplanes were Army officers, and many of them had passed the Staff college, it is fair to say that British military leaders were still rather sceptical as to the value of the information which could be obtained by this means. The one idea underlying the employment of the aeroplane at that time was that they should obtain information. The aeroplanes did not carry any armament, and only two had been fitted with wireless for experimental purposes.

As a result of the first few weeks of the War several new ideas emerged:—

(a) Several combats in the air took place during those weeks, revolvers and rifles being taken into the air for the purpose; and in some cases enemy aeroplanes were actually forced to land in Allied lines. In consequence it was realized that aeroplanes should be equipped with machine guns for the sole purpose of fighting

is organized into squadrons, groups, wings and even divisions. If a Task Force is organized for operations in a military theatre, pursuit aviation may be assigned to such a Task Force. However, pursuit units are not normally assigned to lower echelons, such as armies, corps and divisions.

Bombardment Aviation.— The primary function of bombardment aviation is to destroy objectives on the surface of the earth. When used in co-operation with armies, the objectives selected are those whose destruction will contribute most to the tactical success of the ground forces. Bombardment aeroplanes are divided into three classes: light (weighing about 12,000lb. loaded); medium (weighing about 16–18,000lb.); and heavy (weighing more than 18,000lb.). Light bombers are those normally used for close co-operation with ground troops, but all types can be so employed. In general, the typical bombers of the great powers are multi-engined, low- or mid-wing monoplanes, with high speeds as high as 320mi. per hour. The range and bomb loads vary with the size of the bombers.

Bombardment aeroplanes are organized into squadrons, groups and wings. Large pursuit units and bombardment units are not normally assigned to armies. They may be assigned to Task Forces in certain military theatres.

Reconnaissance.— Before a military commander can formulate a definite plan for the defeat of his enemy, he must have ample information concerning him. He must know where the enemy has his main force, the line along which he is intending to develop his attack, the location of his reserve troops, and whether or not the enemy has troops working round his flanks. A military commander has several sources of information—from spies, from captured prisoners, reports coming through neutrals, and possibly captured orders. All these will give him a portion of the information he wants, but even when he has pieced together all the evidence available from these sources, the real movements of the enemy will, in all probability, be a matter of conjecture, arrived at by drawing deductions from the incomplete information available. The enemy is likely to secure the movements of his force by a screen of mobile troops. The reconnaissance aeroplane provides a means of penetrating such screens and observing the enemy's activities many miles behind his lines.

It must not, however, be supposed that these reconnaissance aeroplanes can be sent great distances at a height from which it would be easy to see with the eye what was happening on the ground. They will carry out this duty singly, flying at about twenty thousand feet, and by far the greater proportion of their information will be obtained by taking photographs of the important points over which they pass. Consequently, the success of the reconnaissance will, to a great extent, depend on the accuracy with which the military commander has chosen the places to be reconnoitred. By means of this long-distance reconnaissance, a military commander will be able to obtain his strategical information; his subordinate commanders, however, will require much tactical information concerning the enemy's movements within 50m. of their own troops. Thus, a corps commander will want to know if the enemy is increasing the number of troops in his area, or if there are any signs of a withdrawal; early information of the presence of tanks is particularly important. Again, a divisional commander will require the fullest details of what is happening on his immediate front. He will want to know where the enemy has his reserves, where he is digging trenches, and details of his disposition.

This reconnaissance for corps and divisions will be carried out by the army co-operation squadrons. These squadrons are usually allotted to a corps on the basis of one per division in the corps. The squadrons in each corps are administered by a group headquarters, which will be situated at corps headquarters, the group commander acting as air adviser to the corps commander.

Artillery Co-operation.— An important part of the work of the army co-operation squadron is co-operation with the artillery. The undulations of the ground often make it impossible for artillery commanders either to find suitable targets to aim at, or to be able to range their guns on to important points, such as bridges and crossroads, which they may want to shell. Consequently,

aeroplanes are employed to "spot" the positions of enemy batteries. This is usually done by seeing the flash of the enemy guns when they fire, and then sending down their position by wireless. These reports are usually confirmed by photographs, which show clearly where the enemy batteries are. Other targets, such as bodies of troops or transport, are also reported to the artillery. If the artillery commander wishes it, a pilot having "spotted" a target can range a battery on to it. This is effected by means of a simple code, the target being taken as the centre of a clock, twelve o'clock always being the north point. Imaginary circles radiate outwards from the centre of the clock at distances of 10, 25, 50, 100, 200yd. etc. These circles are lettered, the corrections to the guns being sent down by sending the letter of the distance circle followed by the hour of the clock. "A" is the letter for the 100yd. circle. Thus, if the shell burst 100yd. due east of the target, the correction would be A.3. (*i.e.*, 100yd. at 3 o'clock). By this means our aeroplanes are able to tell the battery commander exactly where his shells are falling, it being his province to work out the actual corrections for the guns. To receive these messages, artillery brigades and batteries are equipped with wireless telegraphy receiving sets (*see* fig., p. 446).

Offensive Action.— Observations on the European war which began in 1939 have emphasized certain military facts: a nation with a pronounced superiority in the air thereby accords a tremendous advantage to its ground forces; while one possessing a powerful ground force but lacking air superiority finds itself nearly helpless in the face of strong enemy air concentrations. Germany, with a markedly superior air force, was able to conduct whirlwind campaigns which were literally "lightning wars" against the strong Polish army, and later against that ground force generally conceded to be the world's best—the French army. The British Expeditionary Force escaped annihilation at Dunkirk, but was compelled to abandon literally all of its field equipment.

Certain typically successful operations of the German air force in support of their field armies may be illustrated as follows:

First, the air arm in support of the ground troops attacked the hostile air forces, in order to ensure continued air superiority and safeguard the action of the army from hostile air attack. This was accomplished by continuous and heavy bombings of the air bases and landing fields of the enemy.

Then, in the case of Poland, the air force attacked the main lines of communications—the railroads. These were so completely paralyzed as to render them useless. The Polish armies lost both their means of locomotion, and their arteries of supply. As a result they never succeeded in completing their concentrations.

In the case of France, the French armies were already concentrated, but the German air force disrupted their lines of communications by air attacks against railroads and highways.

In the offensive on the western front, dive bombers were used to assist in the breakthrough of the fortified line. Thereafter light bombers were used in mass to obliterate all organized opposition to the advance of the mechanized forces. They co-operated directly by bombing forts, centres of resistance, anti-tank guns, troops on the roads, and headquarters and command posts.

The medium and heavy bombers co-operated by attacking aircraft factories, munitions plants, docks and harbour facilities, and ships bringing supplies and reinforcements.

Generally speaking, bombardment units employed in co-operation with ground forces: (1) attack the enemy air bases in order to neutralize his air force; (2) attack lines of communication in order to isolate enemy troops from their sources of supply and replacement; (3) attack the sources of munitions; (4) co-operate directly in the penetration of ground defences.

Protection.— For a commander to obtain the full value of his reconnaissance and offensive action, he must be protected against similar enemy action. He will, in other words, wish to attain and maintain, air-superiority. To enable him to achieve this, he will have fighter aircraft whose main function is to fight enemy aircraft, and enable the reconnaissance and bombing aircraft to carry out their work without undue interference. Experience in the past has shown that air-superiority is apt to fluctuate. One side will suddenly bring several new squadrons into the field, or

re-equip all its fighter squadrons with a new type of aeroplane more efficient than the fighters of the other side. Consequently a continuous progressive effort is required, and even then, it is difficult to ensure the continuous maintenance of air superiority.

The Future.— To look into the future at a transitory stage like the present, is difficult. Most of the great Powers are thinking about mechanization. The mechanization of armies, however, will not alter the principles underlying the conduct of a land campaign, and, consequently the requirements of mechanized armies will probably be much the same as those of others not equipped with armoured combat vehicles. The air units working with mechanized forces will obviously have to be highly mobile. There is, however, a possible development which may take place, in which the attainment of the ultimate object (the subjugation of the will of the enemy people) will be achieved by the air rather than the land forces. In such a case, the function of these highly mobile land forces would be to secure suitable bases from which great bombing formations could strike at the vitals of the enemy nation.

(T. L. L.-M.; H. S. HA.)

CO-OPERATION WITH A NAVY

The object of aircraft co-operation is to assist a navy in the destruction or neutralization of a hostile battle fleet, and in the control of sea communications. Aircraft can afford indirect assistance in battle by providing information of enemy naval forces obtained from long-distance or close reconnaissance, and can give direct assistance by offensive action against enemy surface and submarine craft with torpedo, bomb, and machine-gun. It is also their duty to afford protection to a fleet from enemy aircraft by attacking them in the air, on the sea, or at shore bases, and thus deny the enemy the use of his aircraft. In the control of sea communications, aircraft can be employed on reconnaissance, anti-submarine patrol, convoy escort, and for torpedo and bomb attacks on enemy forces which dispute control. Aircraft for naval co-operation operate from aircraft-carriers and from shore bases within flying range of the fleet. Aircraft borne in carriers are specially designed for launching from and alighting on their carriers, and are called ship-planes. They may be landplanes, float-planes (aircraft provided with floats for alighting on the water), or amphibians (aeroplanes which can alight on or rise from both land and water). Shore-based aircraft may be landplanes, seaplanes (floatplanes and flying-boats), amphibians, or lighter-than-air craft.

HISTORICAL

Prior to the War 1914-18, there were few instances of aircraft co-operation with a fleet, although seaplanes took part in the British naval manoeuvres of 1912-13-14. At the outbreak of war in 1914 none of the Powers had many naval aircraft, and the development of naval aviation was slow; in fact throughout the whole war the development of aircraft for naval purposes was not as rapid as that of aircraft for work with land forces. Perhaps the hardest problem was to provide aircraft to work with a fleet operating beyond the limited range of aircraft based on shore. Seaplane carriers were hastily improvised from fast merchant steamers, but the inability of the seaplanes of that time to rise from a rough sea, and the risk from submarine attack when stopping to hoist the seaplanes in and out, militated against their use. However about a dozen ships were so equipped by the Allies, and their aircraft were able to carry out observation and bombing flights.

To cope with the Zeppelins used by the Germans on long-distance reconnaissance, experiments were begun in Nov. 1917 in flying small fighting landplanes from British cruisers and seaplane carriers. These were successful, and in Aug. 1917 a Zeppelin was shot down by an aeroplane from the British cruiser "Yarmouth." The practice of carrying landplanes in fighting ships was extended in 1918 to all British battleships, battle-cruisers, and cruisers; the two former types carrying in addition to a fighter a two-seater aeroplane for observation duties. Flights were thus possible in weather which precluded the use of seaplanes. Such aircraft were, however, unable to return to their

ships, and were forced to fly to the nearest land or alight on the water.

In the meantime experiments in landing aircraft on the decks of specially designed ships had been progressing. In Aug. 1917 an aeroplane alighted on the deck of a ship for the first time, and in Oct. 1918 the British aircraft carrier "Argus," constructed for aircraft to fly both on and off, was commissioned for service in the Grand Fleet.

As regards employment, naval aircraft played a small part in close co-operation with the fleets in the War 1914-18. Seaplanes, kite-balloons, and airships carried out limited reconnaissance for the Grand Fleet, one British seaplane being present at the battle of Jutland. This aircraft sighted the German light cruisers, but low visibility prevented further observation, and only one flight was made. Seaplanes and kite-balloons were also used to observe the fire of the monitors off the Belgian coast, and of the bombarding ships in the Dardanelles. In the German fleet, Zeppelins provided valuable reconnaissance by reporting the approach of British surface craft, and by keeping down British submarines in the Heligoland Bight. The value of aircraft observation was greatly enhanced by developments in wireless telegraphy from the air.

Except for a few German attacks on British shipping in 1916 and 1917 and the attack on the Turkish battle-cruiser "Goeben" aground in the Dardanelles in 1918, there were very few instances of bombing attacks on surface craft at sea. Many naval objectives on shore, however, were bombed; as examples, Cuxhaven in 1914, the airship sheds at Dusseldorf and Friedrichshafen in 1914, the Zeppelin sheds at Tondern in 1918, and the intensive bombing of submarine bases in Flanders throughout the war.

Although as early as 1913 a Sopwith seaplane had carried a torpedo, the first torpedo attack by aircraft was carried out on Aug. 12, 1915, when for the first time in history a seaplane from the British seaplane carrier "Ben-my-chree" sank a steamer off Gallipoli. This form of attack was, however, slow to develop, and although in Oct. 1916 the British Admiralty decided to build large numbers of torpedo aircraft, it was not until three weeks before the Armistice that a squadron of torpedo-carrying aircraft was ready for service in the Grand Fleet.

By far the largest parts played by naval aircraft were those of anti-submarine patrol and convoy escort. Airships, kite-balloons, seaplanes, and, in 1918—when the supply of aircraft for the western front exceeded the demand—landplanes, were all used on these duties. From the first days of the war, when the British Expeditionary Force was crossing to France, until the Armistice, areas round the British Isles, off the Belgian coast, and in the Mediterranean—small at first, but increasing rapidly in size as the supply of aircraft became more plentiful—were systematically patrolled by aircraft: as the result, submarine activity was greatly reduced. Only 10 of the 178 German submarines sunk by anti-submarine measures were actually sunk by aircraft, although another 21 were probably seriously damaged, but the value of aircraft thus employed lay in their power to harass the submarine commander, to force him to dive to escape detection, to prevent him from taking up a suitable position for attack, and to locate submarines for their subsequent destruction by surface craft. In 1917, when the convoy system was introduced for the protection of merchant shipping, air escort was provided and a fair measure of security was afforded to convoys. For example, from April 1917 to Nov. 1918, neglecting ocean convoys, a total of 312 ships were torpedoed in convoy, but only two of these attacks occurred when vessels of the convoy were under air escort.

MODERN DEVELOPMENTS

Since the War 1914-18, rapid developments have been made, and aircraft now form an integral part of a modern fleet. Their employment may conveniently be discussed under the headings of carrier-borne aircraft and shore-based aircraft.

Carrier-borne Aircraft.— Aircraft carriers provide the aircraft for close co-operation with the battle-fleet. Their duties are reconnaissance prior to and during action, observation of gunfire, attacks on enemy ships with torpedo and bomb, and air fight-

SIDE ELEVATION AND FLIGHT-DECK PLAN OF EARLY U.S. AIRCRAFT CARRIER

The landing net will be seen just before the recessed stern portion of the flight deck; it is about 100 ft. long. Before it is a large T-shaped elevator for moving aircraft from the flight to the hangar deck. There is another and similar T-shaped elevator abeam of the cage mast. Before the mast, disposed as one to port, one to starboard, are two aircraft catapults, worked by compressed air and capable of launching the heaviest aircraft

ing. Early and accurate information of the enemy is of paramount importance to a naval commander to enable him to dispose his fleet. To obtain this information aircraft patrol ahead of and on the flanks of the fleet, and, when action is joined, they observe and report the movements of individual units of the enemy fleet, and control the effect of gun-fire. Only second in importance to the work of reconnaissance is the observation of gun-fire. By reporting the range, course, and speed of the enemy and observing the fall of shot, aircraft enable a fleet to engage a target which, owing to low visibility, smoke-screens, or the long range of modern guns, may be unseen.

Another function of aircraft in carriers is to fire torpedoes and to drop bombs. This is done by torpedo-bombers, aircraft which carry a torpedo or the equivalent weight of bombs. Torpedo-carrying aircraft can be employed against ships at sea or at anchor. Although, at the present state of development, to release their torpedoes the aircraft must fly close to the water and may thus offer a target for gun-fire, nevertheless their high speed, and the possibility of sun, haze, low clouds, or smoke, may enable them to approach undetected, and so provide an invaluable tactical weapon. If bombs are carried, the objective may be ships at sea, ships in harbour, or shore targets. The effect of bombs against modern armoured ships has continued to be conjectural. Trials in peace time and the experience gained in the first year of the European war which began in 1939, have not (1940) conclusively changed the picture. With the development of armour-piercing bombs, however, this form of attack offers great possibilities.

A third duty of carrier-borne aircraft is air fighting. In order to provide freedom of movement in the air for aircraft employed on observation or other duties, it is essential to neutralize the action of enemy aircraft. Obviously the most satisfactory way of achieving this is to destroy the sources of enemy aircraft which, in a fleet at sea beyond flying range from shore bases, are the aircraft carriers. Since low visibility and the large area involved may render the discovery of enemy carriers impossible, resort is had to single-seater fighters—small, fast, highly manoeuvrable aircraft—to seek out hostile aircraft in the air and to provide protection for friendly observation aircraft. These fighters may also be employed to attack lightly-armoured ships with machine-guns and small bombs.

Shore-based Aircraft.—These, if within range of a naval battle, will be called upon to carry out any of the duties performed by carrier-borne aircraft, but they will more often be employed to co-operate with a fleet in its function of controlling sea communications, and their work will then consist in reconnaissance, anti-submarine patrol, convoy escort, and torpedo and bombing attacks. Reconnaissance may take the form of independent long-distance reconnaissance of enemy forces and bases, trade routes, and focal areas, or of close reconnaissance in co-operation with surface craft. Reliable information of enemy movements or defences, confirmed if possible by photographs, will

be most valuable. Anti-submarine patrol is perhaps the most important duty falling to the lot of shore-based aircraft. Shipping of all kinds requires protection from enemy submarines: areas round the coasts and on the trade routes—particularly in areas where shipping routes converge and in narrow waters—require constant patrolling. Such patrols may be carried out by aeroplanes operating independently of ships, but the experience of the War of 1914-18 taught that it is not by one weapon alone that submarines are destroyed but by the cumulative efforts of air, surface, and submarine craft working in close co-operation. Further, convoys of merchant ships lightly escorted by surface craft are very vulnerable to attack by hostile surface, submarine, and aircraft, and will be escorted whenever practicable by aircraft in order that they may give warning of the approach of enemy forces, attack submarines, and warn the convoy of the presence of mines. Attack by shore-based aircraft with torpedo or bomb against ships at sea or in harbour will not differ from that on similar targets by carrier-borne aircraft, though it may be necessary to operate from advanced bases to be within flying range. Shore-based aircraft will afford a valuable coast defence weapon.

FUTURE DEVELOPMENT

Experience gained in the War of 1914-18 and since, under active service conditions, is limited. Thus the functions of aircraft in naval warfare are largely conjectural. They would appear, however, to depend on two factors, namely: the degree in ease of operation of carrier-borne aircraft, and the development in endurance and seaworthiness of the flying-boat type of aircraft.

(D. G. D.; X.)

AIRCRAFT CARRIER. The potential value of aviation in naval warfare was realized soon after the invention of the aeroplane. The first and greatest need of fleet commanders since fighting ships have gone to sea has been for information of the enemy. The aeroplane offered a means of extending the range of visibility of the surface ships and, accordingly, experiments leading toward the objective of carrying scouting aircraft aboard surface craft were started along two lines. One was, of course, the catapult which had first been used by the Wright Brothers in a rather primitive form and second was Ely's successful landing and take-off of an aeroplane on the U.S.S. "Pennsylvania" in 1911, while the cruiser lay at anchor in San Francisco harbour.

It is of the greatest historical interest to note that in these experiments aboard the "Pennsylvania" the means used of arresting the plane consisted of ropes stretched across the deck, which for the experiments consisted of a long level superstructure of timber temporarily constructed over the turrets and other obstructions on the stern. These ropes were suspended a small distance above the deck so that they could easily be picked up by the aeroplane and were weighted at each end by sand bags which afforded a means of slowing down and stopping the plane within the small space of the deck. In a more elaborate form this was the same

SIDE ELEVATION AND FLIGHT-DECK PLAN OF A MODERN U.S. AIRCRAFT CARRIER

Principal design characteristics of the newest aircraft carriers are typified by the above line drawings of the U.S.S. "Yorktown" and "Enterprise." The large clear area available on the flight deck is clearly shown. The large hangar space available for parking and working on planer is also clearly shown. This space can be opened or closed at will by means of sliding side doors in conformity with the weather

system adopted by the U. S. Navy when it came to build aircraft carriers and after many more years this same lead was followed by the British and other navies having carriers.

Although catapult experiments looking toward carrying aircraft aboard combatant vessels were successfully carried out in the U.S. Navy in 1912, it was not until 1916 that a catapult was actually fitted to a man-of-war and used under service conditions. This was done upon the U.S.S. "North Carolina." These experiments in the U.S. Navy were all predicated upon the use of a catapult for launching the aeroplane into the air and a vessel so equipped was technically an aircraft carrier, in that it carried aircraft. The aircraft carrier as it is known, however, did not come into being until the "Argus" was completed in Sept. 1918, for the royal navy. Between 1914 and 1918 under the impetus of war, several ships were converted by the royal navy for use as seaplane carriers and one of these, the "Engadine," was present at the battle of Jutland. The term "aircraft carrier" has in the years since the World War of 1914-18 come to signify a vessel which flies aircraft on and off its deck in which case the aircraft must be landplane types. This is in distinction to a "seaplane carrier" or tender, which may or may not launch its planes by catapults or on wheel trolleys but must in any case stop to hoist its planes on board since the latter, being seaplanes, can only land on the water.

The U.S.S. "Langley," commissioned in March 1922, by the U.S. Navy, was the first really successful aircraft carrier in that she was equipped with arresting gear permitting aircraft to land aboard her, even under quite severe weather conditions.

Although catapults had been installed aboard most of the battleships in the United States Navy by the time the "Langley" started operating with the fleet the inadequacy of complete dependence upon this type of aviation for service to the fleet was quickly demonstrated in comparison with the flexibility of operations from the "Langley." Valuable though battleship or cruiser carried aircraft proved to be for scouting and spotting the fall of shot for their parent ships, there are three major deficiencies connected with ship-based and catapult-launched aircraft which the aircraft carrier overcomes in excellent fashion. These are as follows:

1. Very many planes cannot be carried aboard battleships or cruisers.
2. Since these planes must land upon the water and be hoisted aboard they are likely to be lost or seriously damaged when an attempt is made to operate them under rough sea conditions.
3. The parent vessel must stop to recover her aircraft, thus becoming an excellent target for submarine attack.

In addition to the above, landplane types such as those carried by aircraft carriers are of much higher performance than it is possible to give to the seaplanes provided for catapult operation on battleships or cruisers. In case any further reason were re-

quired for the impetus given to building aircraft carriers it is only necessary to point out that only in the carrier type landplane has it been possible technically to provide together with the increased performance, the offensive qualities of heavy bomb carrying, torpedo carrying, and the strength for dive bombing. It was largely through a desire to take the dive bomber to sea with the fleet that the U.S. Navy, which had developed and brought to a high pitch of perfection this means of attack, concentrated upon the development of the aircraft carrier.

How Aircraft Carriers Operate.— Since aircraft carriers are built to carry aircraft to sea it is important that they carry as many planes as possible and operate the planes that are carried as expeditiously as possible. In order to carry as many planes as possible, the large, flat, flight deck is provided and supplemented by a large, roomy, open deck or decks below called the hangar deck. Planes can be transported between the flight and hangar decks on large, swiftly moving elevators which, when in the "up" position, are flush with and form part of the flight deck.

In all navies except the American it has long been the practice to clear the deck after each plane lands by sending it below on the elevator. This afforded each pilot an opportunity to land on a clear unobstructed deck with the additional option of applying the throttle and again taking off if for any reason he was dissatisfied with his landing. In this case the landing run of the plane on deck was slowed and stopped by the use of wheel brakes on the plane operated from the cockpit by the pilot or by the efforts of deck crews who seized the wing tips of the plane as it landed. It should be explained in this connection that before launching or landing planes a carrier always heads directly into the wind or nearly so and also increases speed if necessary in order to cause an apparent wind of approximately 30 knots over the flight deck. Thus, planes landing aboard at a speed of 60 knots will still only touch the carrier's deck at a resultant speed of 30 knots. The procedure used in the U.S. Navy, however, since the first tests with the "Langley," has been to use arresting gear on deck and simply to park on the forward part of the deck planes which have landed previously. Combined with this system there is sometimes used a safety curtain or net across the deck to prevent planes which might overrun the arresting area from crashing into those which have already landed and are parked on deck. This procedure leaves the elevators and hangar deck free to care for damaged aeroplanes or repairs and to provide, in addition, greater operating flexibility. The greatest advantage, of course, is the great saving in time since each plane need not be taken below and the elevator returned to the flight deck before the next plane is landed. This permits greater use of the planes which are carried and likewise the efficient operation of more planes than are customarily carried in other navies and explains, to a large degree, why the capabilities of U.S. Naval Avia-

tion have been so well developed and co-ordinated with the rest of that fleet. In about 1939 the same sort of gear and procedure were adopted by the British and, it is believed, the French navies.

Types of Aircraft Carriers.—The most important outward difference between aircraft carriers in their evolution up to 1940 has been the arrangement for handling the smoke from the boilers and the length and arrangement of the flight deck. Early in their development efforts were made to leave the flight deck clear and unencumbered by lowering the bridge and ship-control stations to positions flush with or under the deck and making other than the customary dispositions of the stacks. The latter efforts consisted in some or all of the following: arranging the funnels so they could be lowered mechanically; bringing them out the side horizontally and also curving them downward; and running the smoke pipes to the stern where the gases were discharged by fans; none of these were completely satisfactory however, and it was found that an elevated bridge and ship control station was necessary so that the present island type has been evolved and will probably remain the standard since it appears to be the most satisfactory compromise possible. In modern carriers of all navies therefore, the elevated bridge, smoke pipe(s), ship and fire control stations and a large part of the defensive gun armament are grouped in as compact an "island" as possible on the starboard side of the flight deck. This unit is streamlined when possible in order to cut down air disturbance aft. All carriers, built or building since the U.S.S. "Ranger," are so far as known, of this type. Even the "Ranger" has the island for ship and fire control, but her six funnels, aft, can be lowered to facilitate aircraft operations. (A. B. V.)

AIRD, SIR JOHN, 1ST BART. (1833-1911), British engineer, was born in London Dec. 3, 1833, the only child of John Aird, contractor for gas and water plants. He joined his father's business at 18, and was entrusted with the removal of the Crystal Palace buildings from Hyde Park and their re-erection at Sydenham. He took part in many enterprises, such as the Hampton and Staines reservoirs, the waterworks of Amsterdam, Copenhagen, Moscow, Bahia, Pará, Calcutta, Simla and Berlin, and later (in the joint firm of Lucas and Aird, afterwards John Aird and Co.) St. John's Wood railway, Hull and Barnsley railway and docks, the W. Highland railway and the great Aswan dam across the Nile. He represented N. Paddington in Parliament as a Unionist from 1887 to 1905, and was its first mayor in 1900. In 1901 he was created a baronet. He made a fine collection of pictures by British painters, the illustrated catalogue to which was printed in 1884. He died at Beaconsfield, Bucks., Jan. 6, 1911.

AIRD, THOMAS (1802-76), Scottish poet, and journalist, was born at Bowden, Roxburghshire, on Aug. 28, 1802, and died at Dumfries on April 25, 1876. In 1848 he published a collected edition of his poems, which met with much favour. Carlyle said that he found in them "a healthy breath as of mountain breezes." Among Aird's friends, besides Carlyle, were De Quincey, Lockhart, Stanley (afterwards dean of Westminster) and Motherwell.

See a *Life* by J. Wallace prefixed to the 5th edition (1848) of his *Poems*.

AIRDRIE, burgh of barony, municipal and police burgh, Lanarkshire, Scotland. Pop. (1931) 25,954. It is 11 mi. E. of Glasgow by the L.N.E. railway, and connects with Glasgow by the Monkland Canal, as well as by the L.M.S. railway via Coatbridge and Whifflet. The canal (constructed 1761-90) connects with the Forth and Clyde Canal near Maryhill. Airdrie was a market town in 1695, but owes its prosperity to coal and iron beds. Other industries are iron and brass foundries, engineering and cotton manufactures. The burgh was the first town in Scotland to adopt the Free Library Act. Airdrie unites with Coatbridge in sending one member to parliament. The parish of New Monkland, in which Airdrie lies, was formed (with Old Monkland) in 1640 out of the barony of Monkland, land granted by Malcolm IV to the monks of Newbattle.

AIRE, a town of north France, on the Lys, in the department of Pas-de-Calais, 12 mi. S S E. of St. Omer by rail. Pop. (1936)

5,046. The town lies in a low and marshy situation at the junction of three canals. In the middle ages Aire belonged to the counts of Flanders, and a charter (1188) is still extant. It was given to France by the Peace of Utrecht (1713). The church of St. Pierre (15th and 16th centuries) shows three stages of Gothic architecture. The hotel-de-ville is 18th century. Aire has considerable trade in agricultural produce. In the War of 1914-18 it was one of the headquarters of the British Army (1917-18).

AIRE, a town of south-west France, in the department of Landes, on the Adour, 22 mi. S.E. of Mont-de-Marsan on the railway between Morcenx and Tarbes. Pop. (1936) 2,552. Aire (*Atura, Vicus Julii*) was the residence of the kings of the Yisigoths, and there Alaric II (*q.v.*), drew up his famous code. It is the seat of a bishopric (6th century) and has a cathedral (12th century) and an episcopal palace (11th, 17th and 18th centuries). Both have been restored. The church of St. Quiterrie in Mas d'Aire, a suburb, is a building of the 13th and 14th centuries, with a choir in the Romanesque style, and a fine western portal now much disfigured. The crypt contains several Gallo-Roman tombs and the sarcophagus (5th century) of St. Quiterrie.

AIR-ENGINE. The practical drawbacks to employing air as the working substance of a heat-engine are so great that its use has been very limited. Such attempts as have been made to design air-engines on a large scale have been practical failures, and are now interesting only as steps in the historical development of applied thermodynamics. In the form of domestic motors, air-engines had some application, prior to the development of the internal combustion engine and the extended use of electricity. The type survives in a few motors of very small power. One of the chief practical objections to air-engines is the great bulk of the working substance in relation to the amount of heat that is utilized in the working of the engine. Another is the difficulty of getting heat into the working air through the walls of the containing vessel. Air takes up heat from such a surface with much less readiness than does water. The waste of heat in the chimney gases is accordingly greater; and further, the metallic shell is liable to be quickly burned away as a result of its contact at a high temperature with free oxygen. The temperature of the shell is much higher than that of a steam boiler, for in order to secure that the working air will take up a fair amount of heat, the upper limit to which its temperature is raised greatly exceeds that of even high-pressure steam.

A form of air-engine invented in 1827 by the Rev. R. Stirling is of special interest as embodying the earliest application of what is known as the "regenerative" principle, namely, the principle that heat may be deposited by a substance at one stage of its action and taken up again at another stage with but little loss, and with a great resulting change in the temperature of the substance at each of the two stages in the operation. The principle has since found wide application in metallurgical and other operations. In any heat-engine it is essential that the working substance should be at a high temperature while it is taking in heat, and at a relatively low temperature while it is rejecting heat.

An attempt to develop a powerful air-engine was made in America about 1833 by John Ericsson, who applied it to marine propulsion in the ship "Caloric," but without permanent success. Like Stirling, Ericsson used a regenerator, but with this difference, that the pressure instead of the volume of the air remained constant while it passed in each direction through the regenerator. (J. A. E.)

FIG. 1.—STIRLING'S AIR-ENGINE
The working parts shown are:
A. Externally fired heating vessel
B. Working cylinder
C. Cooling pipes
D. Displacer
E. Regenerator
F. Connecting flange to another heating vessel

FIG. 2.—ROBINSON'S FORM OF STIRLING'S AIR-ENGINE

In this domestic motor, the displacer and regenerator are combined thus simplifying the machine. A gas burner takes the place of the furnace

AIREY, RICHARD AIREY, BARON (1803-1881), British general, served in the Crimean War as quartermaster-general to Lord Raglan. He was recognized in the army as one of the best men on the staff, but public opinion held him responsible for the failures of the commissariat. Airey demanded an inquiry in which he completely cleared himself. He was governor of Gibraltar (1865-70), was promoted full general in 1871, received a peerage in 1876, and in 1878-80 presided over the commission on army reform.

AIR FORCES. The development of the aeroplane introduced a basic change in the means of waging war, the fundamental nature of which was not at once recognized by fighting men. The aeroplane was first looked upon as a means of extending the vision of the surface forces. Hence its development was fostered by the military along lines which would increase its usefulness to soldiers and sailors in their operations on the surface of the earth.

Later, they discovered the value of the aeroplane as an active participant in battles fought between armies on the land and navies on the seas. Aeroplanes were used to carry bombs and machine guns, to attack men and munitions in the battle zone. In this rôle, the aeroplane was still an auxiliary to the armies and navies—employed directly to help those forces in their tactical operations.

It was not until the latter part of the World War of 1914-18 that the full value of the aeroplane as a means of waging war was recognized. Then it became apparent that this agency was capable of striking far behind the lines of surface battle, and attacking the sources of military strength. With the recognition of this possibility came the realization that aeroplanes could be organized into forces which could deliver blows against enemy armies or navies, or attack munitions industries and lines of communication which sustain those surface forces. The development of these air forces has been rapid. They are composed of all the elements necessary to attack surface objectives in the face of opposition.

Two Theories of Control.—Two different schools of thought exist in regard to the general principle that should govern the organization, administration and development of air forces. One school regards flying as a science that can best be applied to war uses by entrusting armies and navies with its adaptation to their own respective needs. Aviation is, accordingly, constituted a component of these services, and its application in war is gov-

erned by naval and military considerations. Although this system has certain advantages, in that it grafts a novel instrument of war upon an existing stem and so avoids the disadvantage of setting up an entirely new organization, there is no doubt that it exerts a limiting influence. The soldier and the sailor naturally approach aviation from the angle of their own profession.

Such advances as are made are likely to follow divergent courses. An apparently inevitable spirit of competition between armies and navies also leads to duplication and tends to deprive effort of its full measure of results. The other school considers that the air merits a profession of its own, and that untrammelled devotion to the science and art of flying is necessary to do full justice to possibilities, not only in relation to war but as a factor in modern life. It accordingly seeks to concentrate all aeronautical effort into one main channel, with branches to the various departments which flying can serve.

Unity of Air Control.—Great Britain was the first to gather together the threads of aeronautical activity and place them in the hands of a central authority; and at the beginning of 1918 the air branches of the Admiralty and War Office departments were amalgamated into the Air Ministry. In April 1918, the flying branches of the navy and army were merged into the Royal Air Force. The idea was not a new one, and, although the impulse of war made obstacles easier to overcome, it was not in war that the conception had its origin. The sub-committee of the Committee of Imperial Defence, charged in 1911 with the study of aviation in its relation to defence, mentioned in its report that such a step might be desirable when flying was more advanced. The germ of the idea is also to be found in the constitution of the Royal Flying Corps, formed in 1912, with its naval and military wings. In this instance, however, the measure was too far in advance of the time to survive inter-service jealousies, and shortly before the outbreak of the World War of 1914-18 the Royal Naval Air Service was formed, the Royal Flying Corps becoming part of the army.

As air warfare grew in volume and importance, the defects of the dual system under war conditions became more and more apparent. Full use of the nation's resources was prejudiced, and civilian ministers were not only denied unanimous advice on air matters, but were sometimes forced to choose between discordant views and to settle vital differences of opinion. The drawbacks of this competitive system were particularly glaring in the matter of technical supply. Improvement was sought in the principle of joint naval and military Air Boards to co-ordinate supply for the two air services. These boards had, however, no executive control over policy, and achieved but little. Finally the Air Ministry was brought into being as the only apparent alternative to the existing evils.

Although a war measure, the Air Ministry survived the peace, and administers not only the Air Force but controls civil aviation as well. It was, however, not allowed to continue its existence as a department of State without considerable hostility and adverse criticism. Its chief opponents were the navy and army. With their establishments reduced to a minimum, and their budget grants diminishing every year, the older fighting services viewed with misgiving the allotment of funds to the newcomer. They argued that the main use of aircraft in war is to assist directly or indirectly the army and the navy, and that accordingly these services should have entire control of their respective air arms. The reply to this objection is that the conquest of the air has disclosed possibilities which transcend the scope of land and sea warfare; that to narrow the viewpoint to naval or military problems is to bring their possibilities into a false perspective; and although that aerial assistance to the forces that fight upon the sea and on land is necessary, this need by no means marks the limit that should be set to aerial operations. Moreover, to regard the air merely as an auxiliary to the sea and the land is a dangerous doctrine, since circumstances may render naval and military operations secondary to those carried out by air forces. Another criticism was that a separate air force is extravagant, since it involves additional overhead expenditure. The reply is that this is offset by the economy achieved in having

a single authority dealing with air matters.

One result of recognizing aviation as a profession in its own right has been a breakaway from traditional practice in policing the British mandates in the East. Security in these territories is the responsibility of the Royal Air Force; aeroplanes are recognized as the chief instruments for the support of law and order, and military forces are used as auxiliaries. The measure has been justified by the great economy achieved. The development of this conception and its successful application would not have been possible without an Air Staff. Another result is a reversal of principle governing the air *vis-à-vis* the land and sea forces in the defence of Great Britain against air attack. Instead of dividing the air into two portions, one above the land and the other above the sea, and making the army and navy responsible for their respective spheres, the air is regarded for purposes of national defence as a single field of activity. The Air Force is accordingly responsible for guarding against air attack, and such ancillary ground forces as may be necessary conform to air defence measures.

Italy (*q.v.*) was the first of the Great Powers to follow the lead of Great Britain in establishing a separate Air Force. This step was taken in 1923 as a result of Signor Mussolini's assumption of power. The decayed state into which the air services had fallen helped to facilitate a complete reconstruction on new foundations, and under the impulse of Signor Mussolini's keen interest in air questions, Italy has rapidly risen to be one of the most efficient and active air Powers.

In 1928, under pressure of public opinion following repeated accidents, and in particular the death of the minister M. de Bokanowski in an accident, France followed the example of Great Britain and Italy in unifying the control of her air activities under a separate ministry.

When Germany repudiated the arms limitations placed upon her by the Versailles Treaty, she concentrated upon the creation of a powerful air force. By 1940 she had created such a force, larger than that of any other world power.

Germany chose to control all air matters through a single Air Ministry, which held equal status with the Ministries of War and Navy. To ensure smooth team-work and unity of effort, a co-ordinating agency was provided in the form of the Defence Office, a bureau superior to all the ministries of the armed forces. This system worked remarkably well in the German Air Force, gave unusually good support to the army and navy and also showed itself capable of carrying out independent air operations in a most efficient manner.

Aviation in Peace and War.—Since it is sometimes claimed that a true appreciation of a nation's air strength cannot be reached without taking into consideration the civil aspect of flying, it is desirable to note the relationship existing between the peace and war sides of aviation. Air strength is represented by air forces maintained in peace, ready to function the moment war breaks out. Heavy losses in life and equipment are, however, to be expected in air warfare, especially if the belligerents are at all equally matched. Air power will, therefore, depend ultimately upon the means available for rapidly making good these losses—that is to say, upon a reserve of flying personnel and on a healthy aircraft industry. It is in respect of these two important factors that civil aviation must make its contribution to a nation's air strength.

Details of the various air forces or air arms and the system of control and organization in the different countries, are given under the heading of each country, as part of the section on Defence.

(A. W. H. E. W.; X.)

UNITED STATES

When in April 1917 the United States entered the World War, but little had been done by the country toward the creation of an air component for either the army or the navy. The aviation personnel consisted of 65 officers and 1,120 men in the army, 35 officers and 163 men in the navy. There were on hand no planes but those used for training, and of these only about 300, some of which were of inferior types. Aviation in the army was then a function of the Signal Corps, whose prime mission was to

provide means of communication, telephone and telegraph systems in the theatre of military operations. In the navy there was no well defined agency charged with the development of aviation. During the war the aviation section of the Signal Corps was abolished and instead there was created in the United States under the War Department, the division of military aeronautics, while in France the air component of the army was organized as the Air Service, with an officer, chief of the Air Service, in charge. In the navy, in March 1918 aviation was placed under the chief of naval operations, and was administered by an officer called the director of naval aviation.

At the Armistice in Nov. 1918 the army aviation personnel consisted of 20,000 officers, 600 cadets and 164,000 men; that of the navy, 6,716 officers and 30,692 men. There had been delivered in the United States about 8,500 training planes; there had been built for the army some 3,300 service type observation planes, the so-called De Havilland 4's, for the navy 1,600 anti-submarine flying boats, while 15,700 motors for training planes and 13,396 Liberty motors had been produced. The Liberty motor development was one of the most strikingly successful projects undertaken during the war. Service type aircraft, that is, those actually used in military operations, were frequently and greatly changed, modified and improved during the war. This was especially true of the smaller, single-seater pursuit or fighting planes. Acting upon the best advice obtainable, the production efforts of the United States were concentrated upon planes of the larger types mentioned above which were not likely to be superseded so quickly, and upon the production of motors.

Post-War Problems.—The close of the war found the United States with large numbers of these war-built planes and motors on hand, but military aviation had developed so that planes of other types, pursuit, bombing, attack, were absolutely necessary with which to equip the properly organized and constituted air components of its military forces. The possibilities and the importance of commercial aviation were also forcing recognition, and this from both the economic and the national defence stand-points. Planes for all these purposes had to be designed, tested and then built in larger and larger numbers. The designs of both planes and motors were constantly being improved, and there was the danger that if quantity production were undertaken too quickly, those thus turned out would be too soon rendered obsolete. It was decided, and no doubt correctly, to make use of the planes and motors on hand while devoting the major effort and the larger part of the funds, as they became available, to the progressive development and perfecting of planes and motors built according to new and better designs. The result of this policy was that at the end of June 1928 planes and motors designed and built in the United States were at least as good as any produced elsewhere, and furthermore they could be manufactured in quantities in relatively short periods of time.

In addition to aeroplanes, lighter-than-air craft, dirigibles or airships, are employed in both military and commercial operations. These are in use in both the army and the navy, though their development has been carried on more extensively by the latter service. Congress in 1928 authorized the navy to contract for two airships, each of about 5,000,000 cu.ft. capacity, at a cost of about \$8,000,000.

The best way in which the air effort of the United States should be organized and administered has been much discussed. There were those who advocated the creation of a department of aeronautics, under a cabinet officer, charged with the conduct of all aviation activities, military and civil. Others urged the setting up of a department of national defence, with a cabinet officer at the head, and under him three assistants in charge respectively of the land, the sea and the air forces. Still another view advanced was that the air components of the army and navy should remain separate, each under the control of the corresponding department head, and up to 1941 this view prevailed. Naval aviation, under the secretary of the Navy, is administered by the bureau of aeronautics, created in 1922, with a navy officer as its chief. Army aviation was made a separate combat arm, called the Air Service, by act of Congress in June 1920. This organization

is under the secretary of War, an army officer its chief. In 1926 the name was changed to the Air Corps. In that year, 1926, Congress created in the Department of Commerce an aeronautical section charged with all matters concerning civil or commercial aviation, with an assistant secretary of Commerce at its head, and also provided additional assistant secretaries of War and of the Navy, each to have charge of aviation, under the secretary, in his own department.

During the session which ended July 2, 1926, Congress adopted a definite continuing program to govern the development of army and navy aviation during the following five-year period. Various subsequent efforts have been made to provide an adequate air force for the army. In 1933 the Baker Board Report was accepted as a basis for the development of the Air Corps. This report recommended the creation of a General Headquarters Air Force, which would include all the combat air units in the Air Corps stationed in the United States. In 1939 Congress authorized an increase in the Army Air Corps to 5,500 aeroplanes by 1941. This number included training planes and those in reserve. In May 1940 Congress authorized an expansion of naval aviation to 10,000 aeroplanes, and removed all limitation on the total number of army aeroplanes. During 1940 Congress authorized purchase of over 18,000 planes for the army. However, the air resources available to the United States remained divided between the two services, each controlling its own air-fleet, as contrasted with those nations which placed their air arm in the category of a separate and independent service. (M. M. P.; X.)

STRENGTH OF AIR FORCES AT OUTBREAK OF WAR, 1939

Estimates of the strength of belligerent air forces at the beginning of and during the war that broke out in 1939 are necessarily provisional because of the strict military censorship imposed by all nations concerned. Table I, however, presents a reasonably accurate enumeration of the forces of the belligerents in Sept. 1939.

TABLE I.—Forces of the Belligerents, Sept. 1939

Nation	Pursuit & Fighting	Bombers	Observat'n	Training	Transport; Service	Total, all Types	Monthly Production
Germany	3,300	6,000	2,000	3,500	2,000	16,800	1,500
Britain	1,101	1,867	574	400	75	4,017	600
France	1,100	1,250	330	500	25	3,205	250
Poland	110	465	80	90	55	800	30

Many of France's planes were obsolete at the start of the war and her rate of production did not increase sharply—both factors which undoubtedly contributed to her defeat in 1940. Great Britain had stepped up plane production to approximately 800 by Jan. 1, 1940, and the Royal Air Force was augmented by purchases of American planes (as was the air force of France). Poland's air force was *hors de combat* within 48 hours after the German invasion on September 1, and all planes except a few that fled to adjacent neutral countries were destroyed.

TABLE II.—Air Forces of Principal European Powers, Dec. 1939

	Germany	Great Britain	U.S.S.R.	Italy	France
Number of planes	10	6	8	5	3
Quality	10	9	5	6	5
Production rate	10	7	4	4	2
Production capacity	10	8	6	4	4
Personnel	10	7	10	5	6
Morale	10	8	6	7	6
Total points	60	45	39	31	26
Average score, Dec. 31, 1939	10	7.5	6.5	5.2	4.3
Average score, Dec. 31, 1938	10	5.0	7.6	6.3	2.5

Intangible Factors of Strength.—In measuring the relative strength of air forces, conditions other than those of numerical power must be considered. Accordingly the American publication *Aviation* devised a table based on six factors: number of planes, quality of planes, production rate, production capacity, personnel and morale. The air force of Germany, which undoubtedly was pre-eminent at the start of the war, was used as the index figure for measuring the strengths of the five principal European air forces at the end of 1939, as shown in Table II. In computing the average scores for each nation in Table II, the total number of points was divided by six.

AIR-GAS: see GASOLINE PRESSURE APPLIANCES.

AIR-GUN, a gun in which the force employed to propel the bullet is the elasticity of compressed atmospheric air. It has attached to it, or constructed in it, a reservoir of compressed air, a portion of which, liberated into the space behind the bullet when the trigger is pulled, propels the bullet from the barrel by its expansion. The common forms of air-gun, which are merely toys, are charged by compressing a spiral spring, one end of which forms a piston working in a cylinder; when released by a pull on the trigger, this spring expands, and the air forces out the bullet.

AIR-HOIST. In factories and other places where a supply of compressed air is available, its use for operating lifting tackle is much favoured, because of the cleanliness, absence of noise, and ease of connection with flexible hose. The direct hoist, raising a load 4 or 5ft., and dealing with from 100 to 7,000lb. in different sizes, is the simplest. It comprises a cylinder, a piston, a rod attached thereto and carrying the lifting hook at the bottom, and an operating valve, controlled by pendant chains. An eyebolt at the top affords means of suspension to a fixed beam, or a swinging jib, or to a trolley running on a girder, either stationary or forming part of a jib or travelling crane.

The hoist shown in the diagram is controlled by balanced pressure. The full air pressure of 100 lb. per sq. in. is maintained at the underside of the piston throughout all the operations of lifting, lowering and remaining stationary. For lifting, the attendant manipulates the valve so that air leaks off the top piston.

Another way of applying air power is to use a special pulley block to which is attached a small pneumatic motor, the cylinders of which actuate connecting-rods and so drive a crankshaft, this being geared to the rope drum in order to gain power. Loads up to 10 tons can be lifted in this way.

For colliery service, another class of air-hoist is built, a winch or haulage engine, the rope drum being driven through gears from a pneumatic motor. This is essential in circumstances where compressed air is the power supply in use. Some of the engines can be run either with air or steam.

AIR-LIFT, a system of lifting liquids by compressed air without a pump. For artesian-wells the method consists in carrying down a smaller air-pipe either within the water delivery pipe or alongside it, and connecting up an air-compressor. The compressed air forms with the water a mixture of lower specific gravity than the surrounding water in the well or bore-hole, with the result that the mixture of air and water in the tube is forced by the weight of the surrounding water to the point of discharge (see this page). When the supply flowing into a well is not enough to give constant delivery, waste of energy may be avoided by a governor. Some air-lifts yield as many as 285,000 gals. per hour per well.

The Shone ejector, another form of air-lift, is utilized for raising sewage and other liquids automatically from one or any number of points, and forcing to any spot desired. The difference between this and the well lift just described is that the liquid gravitates into a bell-shaped casting through an inlet pipe and rises until the vessel is nearly full. Then the air trapped up at the top becomes slightly compressed, and acts on a metal cup that lifts a valve and admits a supply of compressed air into the vessel. This drives the sewage out through an outlet pipe to reach a higher level or any distance away; a fresh supply enters through the inlet pipe, which has been automatically closed during the discharge, and the cycle commences again.

AIR-LOCK, a steel-plated chamber provided in a tunnelling shield or a caisson (*q.v.*), to prevent the escape of compressed air during the passage of workers. The pressure in the caisson

may be 25 to 30 lb. per sq.in., though higher pressures have been used. A steel door at each exit of the lock provides for the

safe passage of men or material, one being opened while the other is shut. There will be several locks in a tunnel shield and in some big caissons. The diagram indicates the shape of a caisson, sunk to make the foundation for a bridge pier, two shafts for material and one for men being fitted. The shaft down which concrete is shot has its air-lock placed lower than those of the other shafts, because the concrete-mixer happens to be located on the lower platform.

Air-lock also means the trapping of air in a bend; *e.g.*, of a water or gasoline supply, stopping the flow.

AIR LOG or **AIR DISTANCE RECORDER**, an instrument which measures the distance flown by an aeroplane relative to the air. It consists of two units: a transmitter which is installed on a wing strut or in some other position on the aircraft where it receives undisturbed air, and an indicator which is mounted on the instrument board. The transmission may be either pneumatic or electric.

The transmitter comprises an impellor or wind-mill, which revolves as the aircraft moves through the air, the number of revolutions being proportional to the air distance travelled. The motion of the impellor is reduced by gearing to actuate a valve

WORKING PARTS OF AN AIR HOIST
The hoist is suspended from the eye at the top and the load is slung on the hook. The piston is shown at the top of the chamber, it having been forced upwards to the full length of its stroke by the pressure of the air from below

THE OPERATION OF AN AIR-LIFT
The diagram shows water being forced up from a well by compressed air. Although chiefly supplied to wells and for lifting sewage, the method can be also used for moving acids, sludges, slimes and heavier liquids

THE USE OF AIR-LOCKS IN CONNECTION WITH A BRIDGE CAISSON
The usual air pressure in caissons is 25 to 30 lb. per sq.in. and steel locks are provided for each shaft. Excavated material is raised by power and, at great depths, cages are used to bring workers to the surface. Under the high pressure work becomes laborious and every effort is made to minimize the worker's fatigue

or contact at a predetermined unit of distance, the resulting impulse of air or electric current operating a ratchet in the indicator. The latter unit is simply a counter. By properly relating the pitch of the impellor blades and the gearing, the instrument will record any unit of distance, such as geographic miles, nautical miles or kilometres. The instrument is rendered inoperative below a predetermined minimum speed, in the pneumatic type by relating the air pressure to the speed in such a way that operating pressure is not available below the minimum speed, and in the electric

type by using a centrifugally controlled switch. This protection is necessary to prevent the operation of the air log by the wind, while the aircraft is on the ground. (C. H. C.)

AIRPORT: see AERODROME.

AIR-PUMP. This appliance was introduced by James Watt in 1765, when he invented the separate condenser for steam engines, in order to extract a mixture of air, water and vapour from the condenser, so providing the maximum practical vacuum. The air-pump may be built with the engine and its piston moved to and fro by a rocking lever, or sometimes by an extension of the engine piston-rod through the back head of the cylinder. A separate drive by engine or motor makes the air-pump an independent unit. An arrangement of valves allows the inrush of air and vapour on the suction stroke, and expulsion through other valves on the return stroke.

A simplified pump has a conical-shaped piston or bucket (fig. 1) which dashes at high speed down on to the water collected below which it drives upwards into the pump barrel above the bucket, which has just uncovered the ring of ports. The water, vapour and air shoot up the barrel and out through the top valve.

Modern pumps move the air independently of the water. The ejector type of air-pump is the most popular. A steam jet extracts the air and vapour from the condenser, which it discharges to the second jet, which finally ejects the air against atmospheric pressure. The ejector may incorporate a small condenser, an arrangement seen in the drawing (fig. 2), consisting of a series of small tubes through which water from the condenser (termed the "condensate") is pumped. The primary steam jet sucks in air in the direction of the arrow at A, and discharges it along with the operating steam into the first condensing compartment. The secondary jet withdraws the aerated vapour from the first compartment and sends it with its operating steam into the second condensing compartment. The heat remaining in the steam after it has done its work is thus transferred to the condensate, so acting as a feed-water heater to the latter on its way to the boiler.

FIG. 1.—THE WORKING PRINCIPLES OF EDWARD'S AIR-PUMP

The function of the pump is to extract the water and air from a condenser. As the piston descends at high speed the water collected below it is driven with force up the curved walls and through the ports. On the rise of the piston the air is forced out through the delivery-valve with a portion of the water

The tire pump is a familiar example of simple reciprocating class, though strictly it should be termed an air-compressor. (See also VACUUM-PUMP)

AIR RAIDS. Air raids are efforts to destroy objectives on the surface of the earth by means of missiles released from air-

FIG. 2.—DIAGRAM SHOWING OPERATION OF AN EJECTOR AIR-PUMP

The type shown is operated by steam jets. The primary steam jet withdraws air and vapour from the main condenser and discharges to the secondary jet which finally ejects the aerated vapour at about atmospheric pressure. The tubes constitute a small condenser which helps to warm the condensate ready to go back into the boilers

craft in flight. They are the means of expressing the "offensive" in air warfare. As their name implies, they were initially looked upon as a means of harassing an enemy, and no great or decisive effect was expected from them. However, as the capacity of bombing aircraft increased, so also has the destructive potentiality of the air raid increased, until it has become possible to lay waste and cripple such great cities as Warsaw, Rotterdam and Coventry.

In the World War of 1914-18, London was the principal objective of the German air raids. The allied air forces repeatedly attacked the industrial centres of the Rhine.

In the European war of Sept. 1939, the air offensives followed several patterns, depending upon the objective of each campaign. On the morning of Sept. 1, 1939, when the German campaign against Poland was launched, the German air force struck heavily at the Polish air force.

In less than three days the air raids directed against Polish airdromes caused the complete destruction of Polish air Dower as an effective means of resistance. Then the German air raids were directed against railroad bridges, locomotives and rolling stock, to break up the lines of communication of the Polish armies. As Polish resistance crumbled, the air raids were directed against columns of moving men and vehicles on the roads, and, finally, they were centred on Warsaw, the last seat of resistance. The city suffered heavy damage.

On the western front, the first year of the war saw few large scale air raids by either side. Extensive reconnaissance flights were made and data collected for the real struggle to come. In the spring of 1940 it came with tremendous power.

In the attack on France and the Low Countries, the air raids

were designed to assist the German ground forces. In Holland parachute troops and air infantry were used with unprecedented success. Just as Holland capitulated, a three-hour air raid was directed against Rotterdam, beginning at about two o'clock in the afternoon. A tremendous degree of damage resulted, and the heart of the city was wrecked.

In France and Flanders the German air raids were directed against key fortresses in the great systems of French and Belgian ground defences. The concentration of power was so intense that the German ground forces had little difficulty in breaking through. Air raids were also directed against the French air force and the French railway system.

Under the cloak of this overpowering air attack the German ground forces drove relentlessly forward to trap the British expeditionary forces at Dunkirk. There the royal air force established a local fighter defence that largely nullified the strength of the German air attack, and the Germans were unable to carry out successful air raids on the forces being evacuated across the channel.

After the fall of France there was a lull in air activity for about two months. Then, in the latter part of August, the Germans launched an air offensive against England. Most of the air raids were centred on London, and their course throughout the remainder of the year 1940 may be divided into three phases.

First, there was an effort to crash through the British defences, using unescorted bomber formations in great numbers.

The air defences of London were the best in the world, and far superior to any the Germans had encountered. The losses to the Germans were very heavy, culminating in a loss of more than 180 planes in the vicinity of London in a single day.

The Germans then turned to daylight air raids, in which the bombers were escorted by fighters. However, these, also, were too expensive, and the Germans turned to the third phase—night air raids.

Initially, the night air raids were directed against many places, with the majority of the effort directed against London. Later the Germans began massing their forces on a single city for each air raid.

Coventry was the first victim of this system. The centre of the city was almost completely demolished.

The system of targets selected by the Germans in these air raids is difficult to determine. Either they were unable to bomb accurately at night, or else they sought to break the morale of the people by bombing populated areas. In any event, there were few profitable targets, such as electric power plants, factories or railroad stations, which were damaged as a result.

The royal air force was obliged to conduct the majority of its air raids at night, because of the larger German air force. However, extensive air raids were carried out, principally against German industry and oil refineries, and against the "invasion ports" of France.

One of the most spectacular and decisive air raids of the war took place at the Italian naval base at Taranto on the night of Nov. 11–12, 1940, when British torpedo planes entered the harbour and attacked the Italian fleet. Although there were conflicting claims of damage done, it is certain that at least three Italian capital ships were seriously damaged. This one air raid very nearly broke the back of Italian sea power.

A typical air raid of the 1939 period, from the raider's viewpoint, might follow the following pattern: An objective, a railroad terminal, having been selected, it is determined that it may be successfully bombed as an area target rather than as a precision target. Being on a bend in a large river its location may be found at night. One squadron of medium bombers may be adequate for the mission. The raider's aerodrome, however, may be flown out of at night, but may require daylight landings. Thus, the time of attack is set. Bombs of the 100 lb. size are adequate to tear up rails and demolish loading platforms and rolling stock in the yards. The yards, it has been determined, are probably defended by small calibre anti-aircraft machine guns. This would set the altitude of attack at about 5,000 to 8,000 feet. However, there is no adequate anti-aircraft warning service as the yards

are close to the sea; so the squadron commander decides to rely on the element of surprise and to take advantage of the better bombing precision which is directly proportionate to altitude. Accordingly the squadron raids the yards at 1,000 ft., an hour before daylight, almost completing the attack before most of the defending gunners, unwarned by a warning service, have had time to bring their machine guns to bear on the invading aeroplanes. The bombs were dropped in salvo. Shorts and overs damaged nearby residences, with some civilian casualties. The raiding squadron suffered three casualties; one plane crashing on the night take-off, another shot down by a coastal anti-aircraft machine gun battery, and another returning after daylight with bomber and pilot slightly wounded by fire from the rail terminal defenders. There was no pursuit aviation opposition encountered.

No longer important from a military viewpoint although quite important from an historical viewpoint, were the principal raids into the British Isles and France in 1914–18.

Raids in 1914–15.—In Dec. 1914 a couple of bombs were dropped in the sea off Dover, and three days later, on Dec. 24, the first German air projectile hit English soil. A few half-hearted attacks by military and naval planes, made during 1915, were ineffective, and it was left to the lighter-than-air machines to cause the first serious damage. In the evening of Jan. 19, 1915, two naval airships approached the coast between Yarmouth and Cromer. They separated and dropped bombs on both towns. Four people were killed.

On April 14, Mathy, boldest of all German air commanders, commanding L9, made a considerable tour over the northern counties. On this occasion he was not particularly successful, most of the bombs falling harmlessly in open country, but the following night Lg caused some damage in Suffolk. The next four raids were similar. Capt. Linnarz, very active about this time in command of one of the military airships, succeeded in bringing his ship over London on the night of May 31, 1915. There was on this night only one raider, armed with an inefficient type of bomb, but there were 41 fires while five people were killed and 14 injured.

Further raids in Yorkshire and Kent on June 4 had little result, but two nights later Mathy again attacked the north. He bombed Hull, and killed 24 people, besides wrecking some 40 houses. Another airship, LZ37, that attempted to raid on the same night, was destroyed by Lieut. R. A. J. Warneford, R.N., while returning home near Ghent. The first serious military damage in England was done by a single ship that raided the north on June 15.

A series of nine raids took place in the latter part of 1915. It opened inauspiciously for the Germans, a Zeppelin engaged in bombing Dover being hit by a 3-in. gun that had just been mounted there. She struggled across the Channel and was finished off by bombardment planes.

London was reached on four nights during this period. On Sept. 8 Mathy bombed the city deliberately; the damage done amounted to more than £500,000. Mathy also took part in the raid of Oct. 13, when his ship bombed Woolwich. On this occasion the casualties were 33 killed and 77 wounded. Two buildings were destroyed, 20 seriously damaged, and there were 13 fires, the total damage being estimated at £50,250.

Raids of 1916.—The defences could do no better in the early raids of 1916. Nine Zeppelins hovered over the midland counties on the last night of January, one getting nearly to Shrewsbury, and 59 people were killed. Out of 16 British planes that went up in pursuit, 8 crashed on landing. A month later two airships were able to hover over Hull and bomb it from a low height, without any interference. From this time, however, the defences improved. L15, one of the five ships that attacked on March 31, 1916, was hit by the gun at Purfleet, and attacked in the air by Lieut. A. de B. Brandon, of the Royal Flying Corps, eventually crashing into the sea off the coast of Essex. Fifteen hostile airship flights were made over England and Scotland during this April. The British losses were 84 killed.

Further air raids at the end of April were organized in conjunction with the naval bombardment of Lowestoft and Yarmouth. A large number of airships took part but the result was

small. London was saved from bombing by its defences on April 25. One Zeppelin was eventually destroyed on the coast of Norway.

An abortive raid on Harwich was followed on Aug. 24 by an attack on London by Mathy. A determined attempt on the city was carried out by 14 ships on Sept. 2. The metropolis was undoubtedly saved by Lieut. W. L. Robinson of the R.F.C., who attacked the military airship SL11. She fell in flames near Cuffley, Middlesex.

On Sept. 23, 1916, 11 airships left Germany for England where the main attack was directed on London by three of the newest super-Zeppelins. Having crossed the Essex coast shortly before 11 P.M., L33 was over east London ten minutes after midnight, and dropped 20 bombs. London, however, was no longer helpless. The searchlights continually lit up the hull of the airship; she was riddled by the guns, one of her engines was damaged and she began to lose gas and fly clumsily. To add to her miseries, Lieut. Brandon flew his ship close up to her. For 20 minutes he stuck to her, pumping bullets into the fabric. As she laboured back toward the North sea, the crew threw out everything they could spare. Her commander crossed the coast at Mersea island flying due east. That his ship would fall into the sea became a certainty and he flew back toward England and landed near Colchester.

Mathy meanwhile brought his ship L31, in company with L32, up the English channel and, turning in over the Kent coast, flew straight over the centre of London. South London and the extreme north of the metropolis suffered severely; but, for some reason, Mathy threw no bombs in the central districts. The handling of the companion ship, L32, was not of nearly so bold a character. Her commander spent an hour circling about Romney marshes. As he crossed the Thames near Dartford he was picked up by lights and attacked by guns. Lieut. Frederick Sowrey succeeded in setting the ship on fire in several places; she fell at Billericay. The British casualties on this night were 40 killed.

On the night of Sept. 25, seven ships raided the north. Mathy, on this occasion, took his ship on an entirely new line, as he flew up the channel as far as the Isle of Wight, where he turned north and scouted Portsmouth. He dropped no bombs on the fortress or dockyard.

Yet another serious attempt to bomb London was made on the night of Oct. 1. Eleven ships started from Germany. Mathy, in L31, came in over Lowestoft about 8 P.M. and as usual steered an excellent course on London. Soon after passing Chelmsford, however, he found that the outer defences on that side of the capital were ready for him. He therefore turned northeast. Turning again, he flew southwest, in order to get into position for his favourite dash down wind over the city. After drifting a few moments toward Ware, he started his motors and flew toward

north London at full speed. Suddenly a heavy gunfire was opened and he decided to abandon his attempt. Second Lieut. W. J. Tempest flew up to 12,700 ft. and attacked, bringing the L31 down in flames at Potter's Bar. During the whole of this great raid the only British loss was one man killed. The defence of London had now definitely got the better of the lighter-than-air attack; after this period no German airship ever flew intentionally over the metropolis. The Germans found it impractical to bomb England at heights necessary for so vulnerable a vessel as an airship.

Deterred by the victory of the London defences, the Germans turned their attention to the north for the final effort of 1916, but with no better success. Of the ten ships that left Germany in the course of Nov. 27, eight came over land. One was destroyed on the coast near Hartlepool before midnight by Capt. J. V. Pyott of the R.F.C. Another raider, L21, after a remarkable journey right across England to Cheshire, was caught in the early morning, when she was leaving the coast at Yarmouth. She fell into the sea from 8,000 ft. and sank at once. During 1916, 18 raids were made on England by German military and naval aircraft.

The first air attack on London itself was made Nov. 28, 1916, by a single aeroplane; the only result was the fall of six small bombs between Brompton road and Victoria station.

Raids of 1917.—Before the end of 1916 it had become evident to the German command that, if effective bombing was to be kept up on targets that were worth attacking, it would be necessary to try new methods. Early in 1917, therefore, they began equipping a squadron with aircraft with which to bomb England systematically.

The first attack came on May 25, 1917. The 3rd bombing squadron, 16 machines strong, left Belgium early in the afternoon and made the coast about 5 P.M. There were thick banks of cloud over Essex. The task of navigating to London was found too difficult and the leader had to give up the attempt. He therefore turned south. Bombs were dropped on the Canadian camp at Shorncliffe, where there were 100 casualties. The worst effect was produced in Folkestone itself. One bomb fell in a crowded street and killed 33 people, mostly women. The second unsuccessful attempt was made on June 5; 18 machines bombed Sheerness with some effect. The guns at Sheerness succeeded in hitting one of the raiders, which fell into the river off Banton's Point.

London Seriously Damaged.—The third attempt on London was more successful. The whole of the German 3rd squadron started in the morning of June 13; London was reached a little before noon. A few bombs were dropped in the East End and near the Royal Albert docks; then, at a signal from the leader, the formation dropped 72 bombs over a small area having Liver-

pool street station as its centre. The station itself was hit by three bombs. The casualties were severe, 104 killed and 423 injured.

The next raid on London on July 7 was also successful. Twenty-four machines started. The main body of 22 planes flew to London, dropping 76 bombs, one of them starting a fire in the general post office; 46 persons were killed and 123 injured; 22 buildings were destroyed, and 87 seriously damaged, the total damage being estimated at over £200,000. The anti-aircraft guns were without effect.

The failure of the defensive arrangements caused considerable agitation, and the British government ordered a complete reorganization. The London air defences were formed as a separate command to include all the means of defence, both from the ground and in the air. Gen. E. B. Ashmore was brought from France to take charge of the reorganization.

The new arrangements were soon tested; on Aug. 12 a party of nine Gothas reached the coast near Harwich, which they followed to the Blackwater, then turned inland for London. The communication system of the defence control worked well, and the squadrons immediately defending London were at the required height in time to meet the enemy formation. The German commander reformed his squadron before reaching the outer line of guns. A number of bombs were unloaded on Southend as the enemy made off, and 32 people were killed. An attempt by the Germans on Aug. 18 was frustrated by bad weather.

An abortive attack on the midlands by eight airships on the night of Aug. 21 was followed by the last day attack on England on Aug. 22, when Capt. Kleine, commander of the 3rd squadron, started out with 13 Gothas to bomb Sheerness and Dover. A number of British seaplanes turned the Sheerness bombers from their objective, and the German formation, harassed by the British pilots, flew south by Ramsgate. Here the anti-aircraft guns, working with great accuracy, brought down two of the raiders. A third was shot down off Dover.

Night Attacks Begin.—The first group of night attacks came in the beginning of Sept. 1917 and one of these reached London itself. On the night of Sept. 3-4, about 1030, hostile aircraft were reported near the North Foreland, and warnings were sent out by the central control a few minutes later when it was clear that the invaders were flying up the Thames. Unfortunately there was serious telephone delay in getting the warning out at Chatham, and before cover could be taken a bomb had fallen on a drill hall in which a large number of naval ratings were asleep. No fewer than 107 were killed and 86 wounded.

Although on this night the defence was ineffective certain points gave hope for the future. Three pilots went up in fast scout planes, and found that it was by no means impossible to handle them at night. The idea also was evolved of barrage fire, a curtain of bursting shell put up in the path of the raiders.

The last raid of this moon period, on Sept. 4, reached London. The barrage fire, organized since the previous night, turned back some of the pilots, but ten raiders reached the metropolitan area. However, even with ten planes, the damage caused was small, and the total casualties for the night included only 14 killed and 48 injured.

Favourable weather produced a sustained series of raids, opening on the night of Sept. 24, with an attack on London by German planes jointly operating with an airship raid on Hull and the north. Nine pilots attempted to attack London itself, but considerable improvement had by this time been effected in putting up barrage fire, which was successful in turning back all but three of the attackers. Although 27 British machines went up they failed to find any of the enemy; the gunfire brought down one of the Gothas, which fell in the river near Sheerness.

The attack on the north was carried out by ten airships under Capt. Peter Strasser. Although Hull was bombed, the raid had very little success. On the following night, Sept. 25, ten planes attacked, and nine people were killed. The attacks were continued on the 28th, when some 20 aircraft flew over; the night was cloudy and only a few approached London, being kept off by the barrage.

The barrage was again effective on the following night, Sept.

29. Out of the 18 or 19 machines that reached England only four penetrated far enough to bomb London. The Dover guns did well, bringing one of the enemy down in flames. On the next night, Sept. 30, five German pilots reached London and bombed places as far apart as Highgate, Edmonton and Woolwich; 14 people were injured and two killed. The last raid of the series, on Oct. 1, was made by about 18 machines.

During these raids a large proportion of the attackers had been turned before reaching their target, but the defences were still far from complete. The barrage fire was expensive in ammunition and there was a doubt if the supply could be kept up. The defending squadrons had not reached the necessary efficiency in pilots or materiel.

The "aprons," a new defence devised after the raid of Sept. 5, were only beginning to be installed. The central control as organized in Sept. 1917 could give no information to pilots when once they had been sent on their patrols, as aircraft radio was not then invented, but schemes to rectify this had already been initiated.

The airship raid of the night Oct. 19-20, 1917, which became known in London as the "silent raid," has points of special interest. Eleven airships met on the evening of the 19th off the Yorkshire coast for an attack on the industrial centres of the midlands. While over England, the ships flew well over 16,000 ft. At this altitude the efficiency of the crews was much impaired by altitude (lack of oxygen) sickness and the intense cold. Another and fatal condition was produced by the weather. Near the ground the air was misty and there was very little wind, but at the height of the airships a strong gale was blowing from the north, and in this the Zeppelins drifted blindly south. One airship passed over London without recognizing it and dropped a few explosive bombs; one of 50 kg. fell in Piccadilly near the circus and caused some casualties.

Realizing that, on account of the ground mists, searchlights would have no chance of lighting up a high Zeppelin, the defence ordered them to remain covered unless an airship could be heard. London was saved from a combined attack and the raid ended in disaster to the attackers. Only one airship returned to Germany in the usual way; six got back after flying over Holland or across the Allied lines. The remaining four were destroyed during the following day on French territory.

Air raiding was resumed during the moon period at the end of October. An attempt on the 31st was carried out by a squadron of 24 planes. Considering that a good many of them reached London, the effect of the bombs was small, eight persons being killed and 21 injured.

The weather in Dec. 1917 was unfavourable and only three air attacks were made on London. The defences showed steady improvement. Two Gothas were brought down by anti-aircraft during a raid in the early morning of Dec. 6. On the night of the 18th one Gotha was so damaged that it fell into the sea off Folkestone and was destroyed. On this night the new giant plane dropped one 300 kg. bomb near Eaton square, making a large crater but doing little serious damage. The whole raid, however, cost London more than £225,000, 42 buildings being seriously damaged and nine destroyed, while there were 13 fires. On Dec. 22 the last raid of the year was frustrated by unfavourable weather; one Gotha was forced by engine trouble to descend near Margate, where it was destroyed by the crew.

Raids of 1918.—In the five plane raids of the first quarter of 1918 there was a tendency to replace the smaller Gotha machines by the new giants. A Gotha was destroyed by a defending plane on Jan. 28. During this raid a bomb dropped by a giant fell on a building in Long Acre that was being used as an air-raid shelter, and 41 people were killed. Three giants attacked on Feb. 16; the only one that penetrated to London demolished a house in Chelsea hospital with a 300 kg. bomb. The raid of March 7, 1918, was remarkable as being the only occasion on which planes attacked London in the absence of any moonlight. Warrington crescent was terribly wrecked.

To turn to the airships, raiding was not resumed until the nights of March 12 and 13, 1918. Both these raids were made

at an immense height, and the damage did not amount to much. Five airships of the newest and largest type attacked the midlands on the night of April 12. The end of the airship raiding came on Aug. 6, 1918. Five ships came up to the coast of Norfolk, no bombs were dropped on land, but L70, the latest word in airship construction, was destroyed.

In the great aircraft raid of May 19, 1918, the Germans made their maximum effort in this form of attack; between 30 and 40 Gothas of the 3rd bombing squadron took part, with at least two giant bombers. Thirteen of the raiders managed to get over London. The casualties included 34 killed and 98 injured and £130,000 worth of damage was done in the London area alone. But the defence had by now made very real progress. The Germans lost seven machines, three shot down in air combat, three destroyed by gunfire, and one from engine failure. This success of the defence was final, and the London area was saved from further bombing.

In addition to casualties (1,413 killed, 3,407 injured) and damage, the German raids on England produced actual results by no means negligible when effect on production is considered.

AIR ROUTES. In late Aug. 1919, when a British company established the first regular trans-channel air service, there were hardly more than 200 mi. of air route in operation anywhere else in the world. Exactly 20 years later, as the imminence of war in Europe began the disruption of traffic and travel over half the surface of the earth, there were approximately 499,300 mi. of air route in operation. Of this total, 112,000 mi. lay in Europe (excluding Russia). European Russia and Asia together had 127,000 mi. of air route in operation; Africa had 50,000 mi.; Latin America, 98,500 mi.; Australia and New Zealand, 25,000 miles. Approximately 66,300 mi. of air route were being operated in North America north of the Rio Grande river and an additional 20,500 mi. of air route were being flown on schedule across the world's major oceans. Thus, in a mere two decades, air routes had spread over every continent, bridged almost every ocean and, in fact, girdled the earth itself. In the modern history of transportation only the growth of the world's mileage of improved highways caused by the development of the automobile can be compared to this achievement.

Types of Air Route.—Air routes can most conveniently be discussed when classified into three broad divisions. It must, however, be borne in mind throughout subsequent discussions that individual air routes frequently possess characteristics common to two or even three such classifications. Like most other industries, air transportation is importantly affected by the character of its competition. The competition offered by surface means of transportation to air carriers is of three different types: (1) That offered by highly-developed systems of railway and highway transportation; (2) that offered by less well developed means of travelling from one point to another within the confines of a single land mass such as limited railway or highway service, river steamer or even more primitive means of travel; (3) that offered by ocean steamer on oceanic routes. Air routes as they have developed in various parts of the world may be instructively classified according to which of these types of competition has been met.

Air Routes Facing Severe Surface Competition.—Highly-developed railway and highway transportation exists over areas large enough to be important to air transportation throughout the continental United States and southern Canada and throughout many parts of Europe. But even in Europe, the competition offered by surface transportation to air carriers is less severe than in the United States and southern Canada. For one thing, such natural barriers as the English channel, the North sea and the mountain ranges of southern Europe penalize the surface carrier more heavily than the airline. For another, political barriers, such as international frontiers, generally offer greater delays to surface traffic than to air traffic. As a result, examples of air transporta-

tion facing the severest type of competition, from land transportation may well be drawn from the United States.

Air transportation had scarcely begun in the United States before it was realized that real public acceptance of its services would only be forthcoming if the airlines could operate as much by night as by day and with a high degree of freedom from delays and cancellations caused by unfavourable weather. Passenger, mail and express traffic in the United States is very largely commercial in character. A large percentage of all people travelling between American cities consists of executive, technical or sales representatives of one sort or another. Mail and express shipments, likewise, in large measure consist of consignments from one commercial or industrial concern to another. As a result, time in transit is measured not so much in terms of absolute hours as in business hours. Air transportation limited solely to daylight hours could offer little or no advantage during its early stages of development even on such comparatively long routes as that between New York and Chicago. Passengers, mail and express can entrain in New York late one afternoon and reach Chicago the following morning in time for mail normally to be delivered some time that afternoon. Letters dispatched at the same time from New York by air mail would, if held for such carriage, remain in New York until the following morning, spend most of the following day in transit to Chicago and then, in all probability, not be distributed until some time on the second morning after mailing.

In the first few years of American development, attempts were made to overcome this difficulty by forwarding mail by a combination of air and railway facilities. Transcontinental air mail might be dispatched from New York aboard a train one evening, be transferred to a mail plane the following morning at Cleveland, then once more consigned to a railroad at some point west of Chicago reached at the end of the following day. But a more direct attack on the problem was also launched. As early as 1923, the post office mail service established an experimental lighted airway on the transcontinental route between Chicago and Cheyenne. Regular night mail service begun on July 1, 1924, was extended to New York the following year. and before the end of 1926 the air way from New York to San Francisco was completely equipped for night operations. As one result, air mail letters could be put in the mail at the very end of the business day and would be ready for distribution in Chicago by an early postal delivery, the next morning, and air mail volume began a steady climb.

Even after the proof that night operations were practical for the carriage of air mail, it was believed by transportation experts that the development of passenger carrying at night would be a comparatively slow process. Following this idea, one transcontinental air route was actually organized as late as 1929 in co-operation with railway carriers so that passengers flew by day, then were transferred to sleeping cars during the hours of darkness. Two nights aboard sleeping cars, two days aboard aeroplanes were required for the transcontinental run. The travelling public, however, surprised everyone. Within a few years after the domestic airlines of the United States had established really nationwide passenger services, as much passenger travelling was being done by night as by day.

Another requirement of air transportation, facing stiff ground competition, was the ability to keep to a minimum delays and cancellations caused by unfavourable weather. Both in Europe and the United States one of the first steps taken toward this end was to establish the closest possible liaison between airline systems and weather bureaus. Almost immediately, it became apparent that weather reporting and weather forecasting that had previously been designed to meet the requirements principally of agriculture, would not be adequate for the new demands of the air carriers. In the United States, many new weather observing stations were established, mostly at or near airports used by the air carriers. At these stations hourly weather reports were gathered and, after facilities were worked out and installed, distributed along airways at not more than hourly intervals. Later, the operating departments of the airlines were to play a

large part in developing and bringing about the adoption of new methods of weather analysis and forecasting, better fitted to airway needs than the older and comparatively more statistical methods used by the United States weather bureau since its organization.

Forewarning of unfavourable weather was, however, only part of the problem. There still remained many frequent occasions when planes were called upon to make their way through extensive cloud formations or wide areas in which some form of precipitation was occurring. To undertake such tasks, it was necessary for pilots to have (1) instruments which would give them infallible indications of the altitude, speed and attitude of their aircraft, even when all outside visual reference points were blotted from view, and (2) some means of determining their position above the ground under such circumstances. By 1930, instruments of various kinds, many of them depending upon the action of gyroscopes, were in use in all airline aircraft and were reliably fulfilling the first requirement. By that time, the second requirement was being fulfilled through the establishment and use throughout the country of radio "range stations." These range stations depend basically upon directional phenomena connected with the propagation of radio waves from certain types of antenna.

While the process of refinement has gone steadily forward since the installation of the first of these beam stations in 1927, the basic principle has remained unchanged. Two automatic transmitters simultaneously broadcast signals from a single station. The field of maximum signal intensity for each one of these transmitters forms a horizontal pattern shaped like a figure-of-eight with the central point of the figure corresponding with the antenna of the transmitting station. By arranging the antennae for the two stations in the proper relationship, the two figure-of-eight patterns are so orientated that their axes lie approximately at right angles to each other. One transmitter is caused to emit a series of code signals corresponding to the letter "N" in the international Morse code, that is, a dash signal followed by a dot signal. The other transmitter is set to transmit a series of signals corresponding to the letter "A," that is, a dot signal followed by a dash signal. In the regions where the signals emitted from the "N" transmitter overlap regions of signals from the "A" transmitter, these two types of signals blend together to form a single long dash signal. As applied to airway practice, these narrow areas of overlap are so arranged that a pilot flying from one station to the next can follow a "beam" of such steady dashes which is carefully directed along the airway. He can further determine whether he is to the right or left of any given beam by the nature of the signal received, whether "A" or "N."

From the outset, the federal government of the United States undertook the responsibility and the burden of establishing and maintaining aerial aids to navigation along the nation's domestic air routes. As of June 30, 1939, a total length of 24,249 mi. of air route was completely equipped for day and night operations. Along this "federal airway system" there was a total of 273 federally developed and maintained intermediate fields ready for emergency use. Of these fields, 265 were lighted with boundary markers for night landings. A total of 1,803 rotating beacons served to mark out the airways during clear hours of darkness, and more than 200 fixed beacons served similar purposes. No less than 237 radio range stations projected radio signal courses to mark the airways through all kinds of weather. By that date, 34,334 mi. of teletypewriter circuits were being operated to bring hourly weather reports to 381 airway stations, and such reports were being broadcast to planes in the air from a large number of radio beam and communication stations. In addition to all these services, the federal government was also maintaining airway traffic control centres at 12 principal air terminals scattered throughout the country, and from these centres was maintaining contact with and governing the movements of almost every city-to-city plane movement over more than half of the established airways. All in all, some 2,552 technically trained employees of the Civil Aeronautics authority were employed on that date on the construction, maintenance and operation of this airway sys-

tem. Funds appropriated for the purpose during the fiscal year of 1939 amounted to \$11,550,654.

Airline traffic is not developed entirely at the expense of surface transportation. Beyond question, many journeys are made by air and much correspondence is dispatched which would not have been considered if air transportation facilities had not existed. But the majority of air travel does represent a diversion from traffic which would otherwise have been handled by surface agencies. In a region where railroad and highway networks are already highly developed, the geographical distribution of airways will closely follow the distribution of principal land transportation routes. For the United States and southern Canada, for example, there are very strong basic resemblances between a map of the airways, a map of the principal railways and even a map of principal inter-city highways.

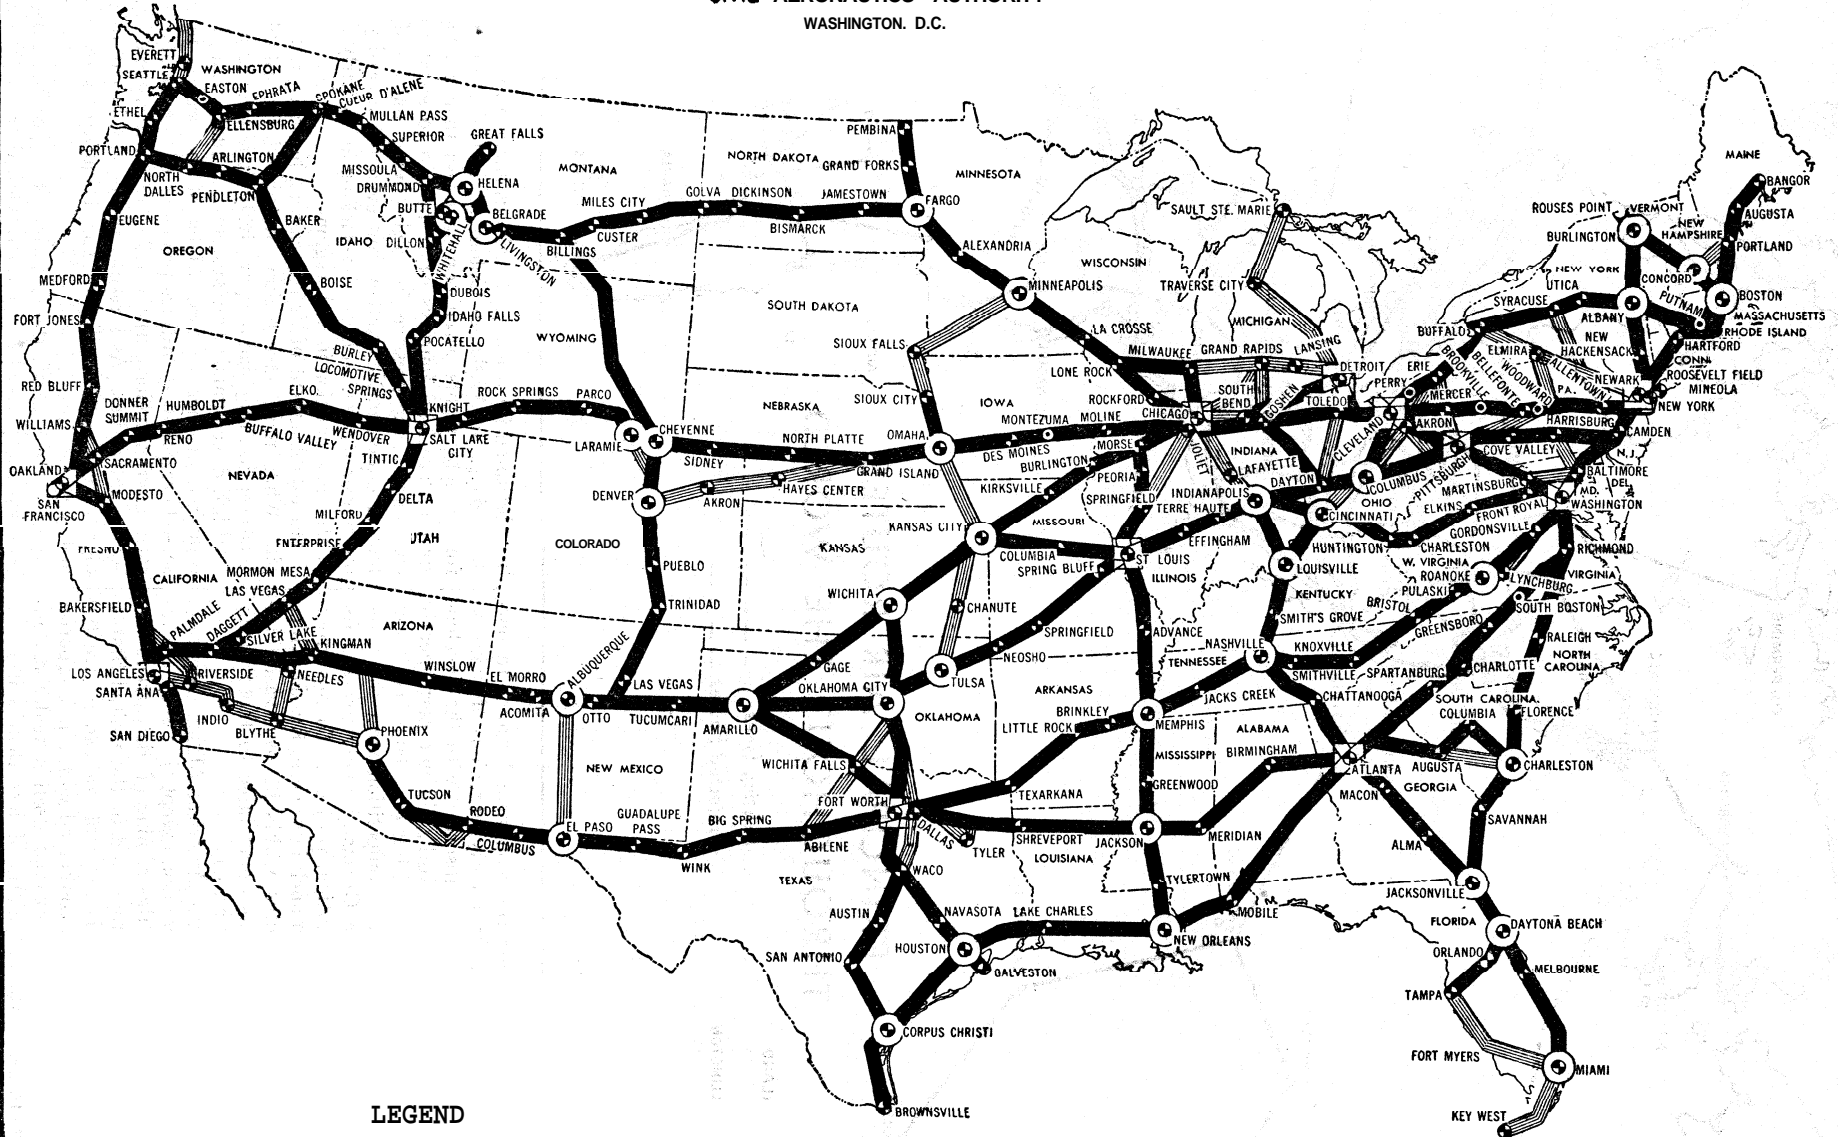

The first transcontinental air route to be established in the United States closely parallels the route of the first transcontinental railway connections between New York and San Francisco. By 1939, the map was so completely covered with air routes that it was difficult to differentiate between transcontinental routes and others, but from the Mississippi river westward four different routes were clearly discernible between east and west: (1) From the twin cities, Minneapolis and St. Paul through the northwest and approximately paralleling the Canadian border to Seattle, (2) a Chicago-San Francisco route via Cheyenne or Denver and Salt Lake City, (3) a southwestern diagonal route from Kansas City to Los Angeles and (4) a southernmost route approximately paralleling the Mexican border between Dallas, Texas, and Los Angeles. Early north and south routes connected Los Angeles, San Francisco and Seattle on the west coast; Boston, New York, Washington, Atlanta and Miami on the east coast; and established service between Chicago and Dallas, Texas. By 1940, the entire eastern section of the United States, especially throughout the midwest north of the Ohio river and throughout the eastern seaboard states north of Washington, D.C., was crisscrossed with a spider web of operating airlines. As of June 30 of that year, 18 different companies were operating 39,200 mi. of services. In Canada, where the development of a transcontinental system was long delayed, an extremely well organized service very closely patterned upon U.S. practices was finally opened in 1938. Its route, which crosses the continent at no point more than 200 mi. north of the U.S. boundary, very closely parallels the transcontinental routes followed by Canadian railways.

In Europe, airlines were first established largely between the various national capitals, although Germany was early in the development of a system of comparatively short domestic lines between its principal cities, and France from the outset maintained routes to its closest possessions in northern Africa. As previously mentioned, surface transportation has never offered as severe competition with air transportation as in the United States. In addition, the fact that few important airlines could be established in Europe within the confines of a single nation, made impossible any continent-wide program of airway lighting or of uniform aids to aerial navigation. As a consequence, few air routes in Europe were flown at night until a very short time before the opening of hostilities in 1939, and even at that time the large majority of European airline operations were still on a daytime basis.

Air Routes Facing Secondary Surface Competition.--Our second division of air routes, namely those in competition with comparatively undeveloped forms of surface transportation, accounts for by far the largest proportion of route miles mentioned in the opening paragraph of this article although the actual volume of aeroplane operations thereon is comparatively small (see AVIATION, CIVIL).

In the years immediately following the War of 1914-18, Great Britain, France, Germany and the Netherlands sensed the tremendous potential value of air transportation as an aid to international and imperial commerce and prestige. Germany was prevented by the treaty of Versailles from developing routes which it undoubtedly would otherwise have established, but the other three countries, almost from the outset, shaped their air route

ties in the United States and Europe, although there have always been striking exceptions. Such emergency fields as were absolutely necessary have generally been built by the airlines themselves. As a rule, lack of established communications and weather networks has been remedied largely by the airlines' organizing their own communications via radio and training their ground station personnel as weather observers. Frequently such measures have resulted in the substantial improvement of weather reporting and study by local or national agencies. Except in a very few localities, night flying facilities were still in 1940 non-existent or comparatively undeveloped.

Radio aids to aerial navigation outside the United States and southern Canada (and now Alaska) have never followed the radio range technique used on the United States federal airway system. Even Pan American Airways, when it began in 1927 to thrust its first route southward from Miami, Fla., was forced to discard not only this technique, but also the use of the radio telephone as contrasted with radio code signals. The static conditions of tropical climates would severely have limited the range for the reception of both beam and telephone signals. Instead, Pan Amer-

ican adopted the code radio as its basic method of communication between ground and plane and followed the lead of Europe and other international airlines in using a directional radio technique completely different from the beam pattern.

This technique is also based upon the directional phenomena of radio wave propagation, but in this case the ground station is so equipped as to measure the direction of signals transmitted from the aeroplane. The simplest equipment is merely an antenna built in the shape of a loop that can be swung about a vertical axis in the receiving station. When this antenna is at right angles to the incoming waves, the signals received will reach a maximum intensity. The direction of the plane from the station is thus determined as the bearing of a line at right angles to the plane of the loop when turned to give such maximum signals. This bearing is then very quickly transmitted back to the aeroplane. Bearings taken simultaneously from two different ground stations give the navigator of the aeroplane an absolute fix of his position at the time the signals are transmitted. Even a single station can, by giving a series of bearings to the plane, fix the plane's path and approximate its position.

As distribution of air routes enumerated in the beginning of this article would indicate, every continent in the world was well developed from the air transportation viewpoint by the summer of 1939. Of basic importance on the Eurasian land mass were the long international routes operated by Imperial Airways of Great Britain, by the Royal Dutch airlines of the Netherlands and by Air France between western Europe and southern Asia. From time to time each of these routes has shifted its course. In fact, it was the Royal Dutch airline practice to operate one route during the summer across central Europe to the eastern end of the Mediterranean and another via Marseilles, thence westward across Italy during the winter, but the average course of these three airlines can be described as beginning near the English channel, across France to Marseilles, thence crossing southern Italy to Athens. From Athens the routes diverged somewhat in the next stage as the British line swung down to Cairo but drew close again to follow the Persian gulf to Karachi in India and thence proceeded practically together to Bangkok in Thailand. Thence, the French route struck east to Indo-China. The Netherlands route struck southeastward to the Dutch East Indies (it was later extended into Australia). The British route, after reaching the Malay peninsula, branched southeastward to Australia and northeastward to complete a route to Hongkong. Just before the opening of hostilities in western Europe in 1939, the Germans stood ready to open a service via Istanbul and Afghanistan on an "interior route" to China.

In Africa, the British were successful as early as 1931 in setting up a route southward from Cairo down through British territory to Cape Town. After many years of experiment, the French, working to some degree in co-operation with the Belgian airline "Sabena," established a route southward across the Sahara to the Belgian Congo, then southeastward to Madagascar. Much earlier, the French had established coastal service in northwest Africa as far as Dakar and later had extended this coastal service to the Belgian Congo. Russia early found air transport an ideal method for speeding up its vast internal lines of communication from its westernmost boundaries to easternmost Siberia and from the Arctic sea to as far south as Kabul.

In Latin America, credit for pioneering must go to a German-financed firm SCADTA which revolutionized transportation in Colombia with a service that was inaugurated as early as 1919. By 1928, when the Pan American Airways had finally secured sufficient encouragement from the United States government to make a real bid for a leading position in South America, French and German lines were already established in Brazil, Uruguay and the Argentine, and were operating services from Natal, south and southwestward along the coast to Buenos Aires. From this point, the French were already operating a trans-Andean service to Santiago, Chile.

Within a few years, however, Pan American Airways had succeeded in establishing itself on three routes between the United States and the northern coast of South America: One from Brownsville, Texas, south and through Mexico and Central America; one directly south from Miami, Fla., via Jamaica to Venezuela; the third via Cuba and the Antilles to Trinidad. In South America itself, it had by 1933 established a complete service along the north, east and west coasts with a service at the south between Buenos Aires and Santiago, and by 1940 it had established lines into the interior to the headwaters of the Amazon and to Paraguay and had inaugurated a special express service between the United States and Rio de Janeiro which cut across a long stretch of the interior of Brazil.

In China, Pan American Airways, in partnership with the Chinese government, and a German-backed firm, Eurasia, both established extensive networks of airlines which still functioned to some extent in 1940 although the Chinese-Japanese hostilities severely limited operations and had forced the financial withdrawal of Pan American Airways. The Japanese opened up air routes into Manchoukuo and other parts of occupied China.

In Alaska, active pioneering by non-scheduled aerial operators led to the formation of an airline company which was taken over by Pan American in 1931. By 1940, this service was operating

several routes in subarctic Alaska and could offer the aerial traveller continuous transportation from Nome to Seattle via Fairbanks and Juneau.

Air Routes Above Ocean Lanes.—Transoceanic air routes, which comprise the third division, are perhaps the most dramatic of all.

With the length of non-stop stages far beyond anything in comparable air transport over land, the aeroplane engaged in transport above an ocean route has every opportunity to demonstrate its great speed to the fullest advantage. Surface competition moves at speeds rarely in excess of 20 m.p.h.

While credit for pioneering the earliest overwater routes must go to those nations which established early services across the English channel and the Mediterranean, it is customary to date the real beginnings of transoceanic air transport in the period between 1929 and 1932 when Air France and the German "Luft-hansa" were testing routes across the south Atlantic between Africa and Brazil, and Pan American Airways was developing its trans-Caribbean route between Miami and Venezuela via Jamaica. This latter route was especially productive as a laboratory for testing equipment and flight techniques which were later to result in the establishment of airlines across the Pacific and Atlantic.

By 1935, when Pan American Airways undertook the establishment of the transpacific airway, it had already developed in this "Caribbean workshop" big four-engine Sikorsky flying boats, one of which was actually used in the first survey crossings in the Pacific. Other elements of the technique which was to prove successful in the Atlantic and Pacific, which received their first testing in the Caribbean, were the use of from four to eight airmen in each flight crew, the development of accurate celestial navigation and the extension of the range of radio direction finders.

For modern-day adventuring, few incidents can rival the actual establishment of the transpacific air route. Early in March 1935, a chartered steamer was dispatched from San Francisco loaded with all sorts of supplies necessary for the erection of the complete airway, enough fuel to serve for several months of actual flight operations and construction and operating crews for the various bases. When it returned to the United States in midsummer, radio stations, landing facilities, fuel supplies and, on three islands, brand new "villages" and hotels, awaited the establishment of regular scheduled services at Honolulu, Midway island, Wake island, Guam and Manila. Previous to this expedition, Midway island was occupied only by a small colony of cable company employees and Wake island was entirely uninhabited and had previously been visited by few explorers. The route was opened for mail in Nov. 1935 and passenger service was inaugurated 12 months later.

In May 1939, on the twelfth anniversary of Lindbergh's dramatic crossing from New York to Paris, Pan American Airways opened scheduled service between the United States and Europe across the north Atlantic. The routes first flown, which offered through service to Southampton in England and Marseilles in France, had to be abandoned after the outbreak of hostilities. But this transatlantic service, thereafter maintained between New York and Lisbon, soon became of tremendous importance as one of the surest and safest means of transportation left open to transatlantic travellers. In June 1940, Pan American Airways opened up its third great transoceanic route by establishing schedules between the Hawaiian islands and Auckland, New Zealand, via New Caledonia. (D. Se.)

AIRSCREW, the designation of all those devices which, when rotated, tend to screw their way forward, sucking the air from in front and throwing it away behind, or which, when placed in a moving stream of air, are themselves rotated. The term covers (1) fans of a certain type, (2) screw propellers working in air, (3) helicopters, (4) windmills, (5) gyroplanes.

(1) If the airscrew is rotated but restrained from forward movement, air is drawn in from the front and thrown back behind, and the airscrew acts purely as a fan.

(2) If the airscrew is not so restrained, the thrust caused by moving the air backwards drives forward the airscrew and the aircraft, or body, to which it is attached. The airscrew is then acting as a propeller. The thrust exerted, and the volume of air moved, have their maximum value when the airscrew is acting purely as a fan. As the airscrew moves forward, the volume of air delivered and the thrust exerted decrease, and at a certain speed become nothing. At this forward speed the distance moved in one complete revolution is known as the "experimental pitch" of

FROM WATTS, "SCREW PROPELLERS FOR AIRCRAFT," BY PERMISSION OF LONGMANS GREEN & CO., LTD.

FIG. 1.— PLAN, ELEVATION AND CROSS-SECTIONS OF A TWO-BLADED PROPELLER. THE CROSS-SECTIONS IN LOWER HALF OF ILLUSTRATION WERE MADE AT THE POINTS A, B, C, D, E, F, ON THE TOP FIGURE: THEY SHOW THE TWISTED SHAPE OF THE AIRSCREW BLADE

the airscrew. The thrust acts approximately in a horizontal direction.

(3) If, however, the airscrew is placed so that it exerts its thrust upwards in an approximately vertical direction, it is then acting as a helicopter.

(4) In the above conditions the airscrew is driven by some engine or motor, but if it is placed freely on a shaft in a wind, or if it is moved forward through the air, it will rotate and some of the energy in the moving air will be transformed into useful work, and transmitted to whatever mechanism is attached to the airscrew. The airscrew is then acting as a windmill. The wind blows approximately in the direction of the airscrew shaft; *i.e.*, at right angles to the plane of rotation.

(5) If the wind blows at a small angle to the plane of rotation, the airscrew will not only be caused to rotate, but in doing so will exert a thrust. It is then acting as a gyroplane. The best known example of this use of the airscrew is the autogiro, invented in Spain by Señor Don Juan de la Cierva. In this case the plane of rotation is approximately horizontal and the thrust approximately vertical.

General Description.—An airscrew consists of a boss or hub with spokes radiating therefrom—like a wheel without a rim. The number of spokes or blades, as they are technically termed, is usually two or three, though four are sometimes used, particularly on the larger British transport craft. They have seen little use in the United States, however.

In fig. 1 is shown the plan and elevation of a two-bladed airscrew intended for use as an aircraft propeller. Below them are shown the sections which would appear if the blade were cut through at points A, B, C, etc. The terms used in connection with airscrews are also shown. Note the term "diameter," the distance from the tip of one to the tip of the opposite blade. For aircraft propellers the diameter varies from as little as four to as much as 16 feet. Note also the characteristic shape of the cross sections of the blade. Sections of this shape are called aerofoil sections; their properties will be found described in any standard work on aero-dynamics. The shape of these cross sections has an important influence on the efficiency of the airscrew. It will be noticed that the blades are twisted; the angle is greater at the root than at the tip. This twist is necessitated by the fact that in order to work most efficiently, an aerofoil section must move at a small angle to the relative air flow.

Now any point in the blade has two simple motions: (1) In the direction of rotation, (2) The forward motion at right angles to (1). In fig. 2 these two simple motions are illustrated to scale as

AB and AC for a point near the tip of the blade, and in fig. 3 for a point near the root of the blade; AD is the resultant direction and speed of movement. The speed AC of the forward movement is the same for both points, but the speed AB in the direction of rotation is proportional to the distance of the point from the centre. Its value is zero at the centre and a maximum at the tip.

Thus as will be seen from figs. 2 and 3, the resultant direction of movement of the point near the tip is at a smaller angle to the plane of rotation than that of the point near the centre. Since the aerofoil section must be placed at a small angle to its direction of movement, the blade has a smaller angle at the tip than near the centre. The distance travelled in one complete revolution, when the direction of the resultant motion is along the line joining the leading and trailing edge of the section (*see* fig. 1, section DD), is the geometrical pitch. It has approximately the same value for all parts of the blade, and is usually referred to by the word "pitch."

Problems of Design.—The main difference between various airscrews is in the diameter and pitch, and it is the designer's object to choose these for the attainment of certain specified results. He has three aims: (1) To ensure that the airscrew runs at a certain rate of rotation when driven by a certain power, when the aircraft to which it is attached is travelling at a certain speed at a certain height above sea level. (2) To ensure that under these conditions the airscrew will give its maximum efficiency. The efficiency is the ratio of the useful work done by the airscrew to the work done by the engine in turning it. Efficiencies of from 75 to 87% are commonly attained. (3) To ensure that the airscrew is reliable and safe. Airscrews rotate at a high speed. Their tips travel at speeds varying from 700 to as much as 1,100 ft. per second—a velocity exceeding that of sound. This sets up a centrifugal pull in the blade of as much as from 10 to 2½ tons, in addition to which the blade must withstand the bending caused by its own thrust.

To satisfy these various requirements, the designer will specify an airscrew of a certain diameter and pitch, with blades of a certain width and thickness. If any one of these conditions alters—the rate of rotation, the power or the aircraft speed—a different airscrew will be required. Hence the infinite number of designs involved.

Controllable Pitch Airscrews.—From the very start of aircraft development it has been plain to engineers and inventors that it would be very desirable to alter the pitch angles of the propeller blades during flight. If the blades are set at the proper angle for level flight at relatively high forward speed, the angles are too high at the time of take-off and climb when the forward

speed of the aeroplane is low, so that the propeller is operating inefficiently under these conditions. When the internal combustion engine was adopted universally as an aircraft power plant, there was an additional need for a variable or controllable pitch airscrew, since a propeller which was set for the proper engine rotation at level flight would not allow the engine to turn at its full rated speed at the time of take-off, so that there was a material loss in engine power under these conditions.

FIGS. 2 AND 3.—DIAGRAMS SHOWING THE MOVEMENT OF A POINT NEAR THE TIP OF THE BLADE AND NEAR THE BOSS OF THE AIRSCREW
AB=Velocity of rotation. AC=Velocity of forward motion. AD=Resultant velocity

The effect of the controllable pitch propeller on the engine is analogous to that of the gear shift for the automobile, and the controllable pitch propeller has sometimes been referred to as the "gear shift of the air."

A large part of the early pioneering development on the controllable pitch propeller was carried out at the aeronautical laboratory of the U.S. Army at McCook Field, Dayton, Ohio. These experiments led up to the adoption of the detachable aluminium alloy blades for the propellers. While the pitch of these early propellers could not be changed in flight, the development of the aluminium alloy blade paved the way to a large degree for the later development of the controllable pitch propeller.

A large number of types of controllable pitch propellers were built experimentally. The Hamilton Standard is one of the leading successful controllable pitch propellers, and may be taken to indicate the development of this adjunct to flying. The original of this type was built in late 1929, and improvement was rapid after that time. During 1933, the Hamilton Standard came into universal use on the air transport lines of the United States, and the propeller was awarded the Collier trophy for the greatest advancement in aviation during that year.

This propeller is made with semi-hollow aluminium alloy blades journaled at the end on plain bearings. Centrifugal load on the blades is taken up by means of roller bearings encircling the inner ends of the blades. The actual operation of changing the pitch is carried out by means of an oil cylinder which forces the blades into the low pitch position when oil pressure is applied. When the oil pressure is released, the propeller is forced into high pitch by means of counterweights which are acted on by centrifugal force.

The device is very simple in design and in operation. In the initial form, it utilized two pitch settings, one being suitable for take-off and climb, and the other for level flight and cruising. The latest development of the device incorporates an automatic governor which serves to change the pitch automatically so as to maintain the engine operation at any constant r.p.m. which may be selected by the pilot in flight. This device is known as the "constant speed" propeller.

Materials of Construction.—At first airscrews were invariably constructed of hardwoods, such as walnut or mahogany. The airscrew is built up of a number of superimposed planks or laminae about one inch thick, suitably cut to shape. In Fig. 1 the cut planks for a two-bladed airscrew are illustrated. The planks are glued together to form the rough block from which the airscrew is shaped. This and the finished airscrew are also shown.

Wooden airscrews are affected by the humidity and temperature of the atmosphere, and have been found unsuitable for tropical climates. Hence there has arisen a need for metal airscrews. Of such there are two distinct types: airscrews with hollow blades,

and those with solid blades. The former are constructed of steel and the latter of a light metal, usually an aluminium or magnesium alloy. Both types have met with a considerable degree of success, but both are heavier and more costly than the wooden airscrew. Despite the added expense, however, metal propellers have come into very common use, particularly on engines of higher horsepower. In large sizes the weight of the solid type appears likely to be excessive, while that of the hollow steel type approaches very closely to that of a wooden airscrew.
