Among enactments made by congress on recommendation of the administration were the repeal of the stamp taxes on matches, proprietary articles, and bank cheques; the reduction of letter postage from three cents to two cents; the enlargement of fast-mail and free delivery systems; and the establishment of special letter deliveries. In 1882 a convention was made for relocating the boundary between Mexico and the United States, and in 1883 a reciprocal commercial treaty for fostering trade with Mexico was negotiated. In connection with commercial treaties President Arthur recommended the establishment of a monetary union of American countries to secure the adoption of a uniform currency basis, and to promote the general remonetization of silver. A treaty was negotiated with Nicaragua which empowered the United States to construct a canal, railway and telegraph line across Nicaraguan territory but mas not ratified by the senate. On Feb. 21, 1885, President Arthur made an address at the dedication of the Washington monument, at the national capital, which was brought to completion during his term. One of his last official acts was the appointment of Gen. U. S. Grant as general of the army, a special bill creating this rank having been passed by congress March 3, 1885. In 1884 Arthur permitted his name to be presented for renomination at the Republican National convention, but he was easily defeated by the supporters of James G. Blaine. Although a close friend of Conkling, long an implacable political enemy of Blaine, Arthur supported the latter in the ensuing presidential campaign. At the end of his term he resumed his residence in New York city, where he died on November 18, 1886.

That Arthur should have retired from the presidency with the respect of the people of the United States is the best testimonial to the way in which he had filled the office, especially in view of his earlier record. It remains only to be said that, alike in public and private life, his bearing was always dignified without being pompous; that he was easy of approach, genial in conversation and manner, and a man of many and close friends.

For an account of his administration *see* UNITED STATES: *History.*

ARTHUR, JOSEPH CHARLES (1850–1942), American botanist, was born at Lowville, N.Y., on Jan. 11, 1850. He graduated at Iowa State college in 1872, and after various periods of graduate study he received the degree of doctor of science at Cornell university in 1886. Following three years as instructor in botany at the universities of Wisconsin and Minnesota in 1879–82 and a like period as botanist in the New York Agricultural Experiment station at Geneva in 1884–87, he was made professor of botany in Purdue university, where he served until 1915. During his professorship at Purdue he was also professor of vegetable physiology and pathology in the Indiana Agricultural Experiment station. He conducted researches on plant diseases, especially those caused by fungi, and made numerous contributions regarding the life history of rusts. From 1882 to 1900 he was an editor of the *Botanical Gazette.* He wrote numerous botanical articles, and published a *Handbook* of *Plant Dissection,* with *C.* R. Barnes and J. M. Coulter (1886), *Living Plants and Their Properties,* with *D. T.* MacDougal (1898), and *Manual* of *the Rusts in United States and Canada* (1934). He died April 30, 1942.

ARTHURIAN LEGEND. By the "Arthurian legend" or *Matière* de *Bretagne* we mean the subject matter of that important body of literature which centres round the picturesque figure of the British hero, Arthur. Did Arthur ever live? Opinion on this point has been much divided, but, while the idea of a *King* Arthur whose dominions extended beyond the confines of the British Isles is now very generally rejected, we may probably accept as a fact the existence of a chieftain of mixed Roman and British parentage (witness the Latin names in his pedigree), who had learned the art of war from the Romans and successfully led the forces of the British kings against the Saxon invaders. As Nennius phrases it, *"tunc Arthur pugnabat cum regibus Britonum, sed ipse dux erat bellorum."* He was not a king, but the general of the royal armies. If we add to this the hypothesis that he was betrayed by his wife and a near kinsman, and fell in battle, we have stated all that can be claimed as an historical nucleus for his legend. But into this shadowy historic figure other elements have entered; he is not merely a possible historic personality, but a survival of prehistoric myth, a hero of romance, and a fairy king, and all these threads are woven together in one fascinating but bewildering web. Thus it is in his *mythic* character that Arthur slays monsters, the boar Twrch Trwyth, the Giant of Mont St. Michel, the Demon Cat of Losanne. (André de Coutances tells us that Arthur was really vanquished and carried off by the cat, but that one dare not tell that tale before Britons.) He never, it should be noted, rides on purely chivalric adventures such as aiding distressed damsels, seeking the Grail, etc.; his expeditions are, as a rule, military, and the character of successful general clings to him throughout.

As a *ronzantic* hero he differs very considerably from the character familiar to us through Tennyson's *Idylls of the King.* In the earlier poems he is practically a lay figure; his court is the point of departure and return for the knights whose adventures are related in detail, but he himself is a passive spectator. In the prose romances he is a monarch, the splendour of whose court, his riches and generosity, are the admiration of all; but morally he is no whit different from the knights who surround him. He has two sons, neither of them born in wedlock, one of them, Modred, alike his son and his nephew. In certain romances, *Perlesvaus* and *Diu Crône,* he is a veritable *roi fainkant,* overcome by sloth and luxury. As a *fairy* king not only does Layamon represent three ladies as appearing at his birth, and prophesying his future greatness, while, as we all know, three queens appear at his death to bear him to the land of Avalon, but in *Huon de Bordeaux* he is heir to the kingdom of the fairy king Oberon; and in the little-known poem of *Brun de la Montagne,* preserved in a unique ms. of the Bibliothèque Nationale, we are told that all fairy-haunted places, wherever they may be, belong to Arthur—

et touz ces lieux fads
sont Artus de Bretagne.

Thus in the diverse aspects of Arthur's character we have some indication of the perplexing variations of the literature which gathered round his name.

So far as the historic element is concerned it is meagre, consisting in the bare statement by Nennius, quoted above,, and in the *Historia Regum Britanniae* of Geoffrey of Monmouth, which might perhaps be more correctly characterized as the most successful work of fiction ever composed. Between these two there is an interval of upwards of 400 years, Nennius dating from the 8th century, Geoffrey writing in the middle of the 12th. Arthurian tradition is a stream which runs underground, starting as a mere trickle, and emerging at the end of its journey as a mighty river. Literature is silent, but popular tradition must have been active. William of Malmesbury, writing just before Geoffrey, refers to Arthur as one of whom the Britons "rave wildly to-day" *("hodie delirant"),* and there were certainly many more tales current than Geoffrey found room for in his history. Close upon the appearance of Geoffrey's work followed the rhymed adaptations of Wace (French) and Layamon (early English), both of which, notably the latter, contain material lacking in the prose work. That stories of Arthur and his knights had, before this, travelled as far afield as Italy is proved by the Arthurian carvings on the north doorway of Modena cathedral (early 12th century) and the fact that Signor Rajna has discovered the names of Arthur and Gawain as witnesses to deeds belonging to the first quarter of the 12th century; it is clear from the character of the documents that the persons attesting could not have been born later than 1080, which would argue a popular knowledge of Arthurian tradition in the 11th century.

The great body of verse romances which constitutes the most interesting, and from the literary point of view, the most important, section of Arthurian romance only came into existence in the latter half of the 12th century.

Its most important monuments are the works of Chrétien de Troyes *(Erec, Yvain, Le Chevalier de la Charrette, Perceval,* or *Le Conte del Graal),* and of his translator, Hartmann von Aue *(Erec, Iwein);* and the *Parzival* of Wolfram von Eschenbach, the source of which is still a subject of debate, but which has become familiar through Wagner's *Parsifal.* To the poetical succeeded the prose versions, headed by the trilogy of Robert de Borron: *Joseph of Arimathea, Merlin* and *Perceval;* and these comparatively short texts were expanded gradually into the enormous body of cyclic romances of which numerous mss. are extant. In its final form the *Joseph* became the *Grand Saint Graal,* or *Estoire del Saint Graal,* probably the last of the romances to be composed; the *Merlin* received pseudo-historic and romantic additions; the *Perceval* was replaced by the prose *Lancelot,* with the Galahad *Queste* and *Mort Artus* as concluding sections. In the final stages the prose version of the *Tristan* story was interpolated into the already unwieldy *corpus* of romance.

(J. L. W.)

ARTICHOKE. The common, or "globe," artichoke, *Cynara scolymus,* is a plant belonging to the family Compositae, bearing some resemblance to a large thistle. It has long been esteemed as a culinary vegetable, the parts chiefly employed being the immature receptacle or floret disc, with the lower part of the surrounding leaf scales, known as artichoke bottoms. In Italy the dried receptacles of the cultivated plant, *Carciofo domestico,* and of the wild variety, *Carciofo spinoso,* are largely used in soups. Its origin has been traced to Asia, but because it grows wild in many parts of southern France it is often called the Paris or French artichoke. Commercially the globe artichoke is propagated by sprouts or suckers, usually 900 plants to the acre, 6 or 8 ft. apart, in rows 6 ft. apart. Rich, well-drained land, with plenty of water and manure, is necessary for its best growth. Extreme heat makes it inedible and it cannot stand frost. A foggy climate is necessary. Most of the plantings in the United States are confined to an area extending from San Francisco, Calif., on the north, southward halfway to Los Angeles, within a mile or two from the coast for most of the way. For its best flavour the artichoke bud should not be allowed to stay too long on the plant but should be cut before it opens. Although the small, compact sizes are the most tender, the larger sizes seem to be in greater demand commercially. Several hundred tons of artichokes are canned each year in California, one-third of the pack being exported to South America.

The first shipment sent east by express occurred in 1907 and amounted to a few thousand boxes. Between 1925 and 1940 United States production varied from about 7,500 to 10,000 ac., which yielded between 700,000 and 1,250,000 40-lb. boxes annually.

Fondness for this vegetable, which is rich in iron, mineral salts and iodine, is usually the result of an acquired taste. Although delicious when boiled, baked, fried, stuffed or used in soup, the French artichoke is best known in a salad form. Served whole, halved or quartered; hot, with mayonnaise or butter; each leaf pulled off separately, the large end dipped in the sauce and the soft part eaten off, the globe artichoke affords a salad that is unique in appearance and flavour.

The Jerusalem artichoke, *Helianthus tuberosus* or girasole, is quite unrelated to the globe artichoke. The edible portion consists of tubers, borne underground like potatoes, by large, coarse, generally much-branched plants 6 to 10 ft. tall, similar to the common sunflower. It has been called an "artichoke" probably because of some resemblance to artichoke in the taste of the tubers; the term "Jerusalem" is believed to be derived from mispronunciation of the Italian word "girasole," for sunflower. Although it is native to the United States, repeated efforts to establish the plant as a crop have failed, apparently because other crops have been more profitable for the farmer. In France it is grown extensively as feed for sheep, cattle and hogs, but in the United States it is grown only to a very limited extent (chiefly in Oregon) as stockfeed. It is grown occasionally in home gardens for use as a vegetable or in the making of pickles. The tubers stand hard freezing in the soil, but are very difficult to store successfully after harvesting.

The plant is adapted to medium or high latitudes having long summer days and moderate temperature. In the short days and high temperatures of sub-tropical or tropical regions the plant produces flowers and terminates its season's growth in a relatively short time, often reaching a height of only 3 feet or less. While it may survive hot, dry weather and poor soils over much of its natural range, it requires deep, rich soil with an ample moisture supply to make large growth and yields of tubers. The tops are killed by frost, but the tubers are so persistent in the soil in temperate climates that the plant tends to become a weed and can be eradicated from a field only by diligent and timely cultural practices.

The Jerusalem artichoke plant stores its carbohydrates chiefly as inulides, which yield levulose upon hydrolysis, instead of in the form of starch, which is hydrolyzed to dextrose. This fact led to studies of its use in the diet of diabetics. Medical opinion is divided as to its value for this purpose and its use remains limited. Some believe its apparent value is due to the non-availability of its carbohydrates to the human digestive system, thus furnishing the diabetic patient no harmful quantity of carbohydrates although it be eaten rather freely. The preparation of hard refined crystalline levulose in the laboratory, from hydrolysis of the inulides of the tubers, has stimulated interest in the plant. Although tubers of improved types may contain the equivalent of 12% to 15% of levulose, no practical commercial method has been developed (up to 1943) for making crystalline levulose from them. It has been studied both in Europe and America as a source of industrial alcohol, but has not competed successfully with molasses and other cheap sources of fermentable carbohydrates.

Under unusually favourable conditions the Jerusalem artichoke has yielded nearly 20 tons of tubers per acre, in France and in Oregon, but average yields are only about 5 tons per acre, too low for the plant to compete successfully with other crops. The tops are sometimes harvested for ensilage, before they become too coarse and woody for feed. Early removal of the tops prevents profitable production of tubers. Good yields of tubers can develop only if the tops are undisturbed until after they are too woody for feed. Until practical and profitable methods of producing and using the plant become established, it must remain largely an interesting subject of speculation and study. (V. R. B.)

ARTICLE, a term primarily for that which connects two parts together, and so transferred to the parts thus joined; it is used of the separate clauses or heads in contracts, treaties, etc., of a composition in a periodical; or of particular commodities, as in "articles of trade." It appears also in the phrase "in the article of death," *in articulo mortis.* In grammar the term is used of the adjectives which describe the number of individuals to which a name applies, the indefinite article denoting one or any of a particular class, the definite denoting a particular member of a class. For articles of war *see* WAR, ARTICLES OF.

ARTICLES OF ASSOCIATION: *see* COMPANY LAW.

ARTICULATA, an obsolete zoological name applied to insects, worms, etc., in which the body is jointed or segmented. (*See* ARTHROPODA; ANNELIDA.)

ARTICULATION, the act of joining together; in anatomy the junction of the bones (*see* JOINTS AND LIGAMENTS); in botany the point of attachment and separation of the deciduous parts of a plant, such as a leaf. The word is also used for division into distinct parts, as of human speech by words or syllables.

ARTIFICIAL RESPIRATION. When the normal respiratory function in man is arrested by disease or accident, it is frequently possible through external agencies to imitate the normal movements of the thorax and diaphragm and thus induce artificial respiration. The most common occasions for attempting resuscitation are asphyxia from smoke, gas, fumes or surgical anaesthesia, apparent drowning and electric shock. More rarely traumatism or disease may affect the nervous mechanism controlling the movements of respiration, particularly the "respiratory centre" situated in the medulla. If the normal ventilation of the lungs is approximated for some time through artificial means, the normal, rhythmic function of nerve centre and of muscles may be resumed. In many instances of impending death the heart continues to beat for some minutes after cessation of respiration. It is accordingly important that resuscitation measures be instituted with all possible promptness.

Various mechanical devices have been proposed for the purpose of inducing artificial respiration, but as most of them are almost ineffective or even dangerous they have been generally supplanted by the manual "prone pressure" method devised by E. A. Schafer of Edinburgh in 1903. This simple method provides for the compression of the thorax thus expelling poor air from the lungs and for the sudden release of the chest wall which by its elasticity expands, with the resultant intake of fresh air. Air is not forced in but is drawn in, as with natural respiration, between the intervals of compression. For further particulars of the Schäfer method *see* DROWNING AND LIFE SAVING.

FIG. 1.—FIRST MOVEMENT OF THE SCHÄFER PRONE PRESSURE METHOD
Straddle the patient. Place your palms on the small of his back with the fingers over the ribs. Bend the body slightly forward so that the weight of the shoulders can be brought into play

In cases of gas poisoning recovery may be hastened by using an air mixture rich in oxygen. If about 5% of carbon dioxide (not to be confused with carbon monoxide) is mixed with the

oxygen, a return to normal breathing may be even more rapid as carbon dioxide acts as a stimulant upon the respiratory centre in the brain. The oxygen displaces the carbon monoxide which, in poisoning due to that gas, forms a temporary union with haemoglobin in the blood.

There are now widely used various forms of inhalers through which there is supplied either pure oxygen or oxygen mixed with

which there may be administered gases which accelerate recovery. Inhalation apparatus can usually be obtained from gas companies, fire headquarters or hospitals. (See DROWNING AND LIFE SAVING.)

(W. WR.)

ARTILLERY, as constituted today (1940), is difficult to define with exactness since the point at which the large calibre machine gun merged into the small automatic cannon was an intangible one. However, if under the artillery classification are placed all firearms with a bore diameter of over 25mm. (1in.), and firing explosive projectiles, we may somewhere approach an accurate definition. But artillery also means those who transport and serve such weapons, *i.e.,* personnel, as well as the guns themselves and their appurtenances, which are designated *matériel.* For a discussion of the latter, see ORDNANCE and AMMUNITION. The flight of artillery (and other) projectiles is the subject of studies under the science of BALLISTICS (*q.v.*) while the joint employment of personnel and matkriel is discussed in the articles on FIELD ARTILLERY and TACTICS.

Artillery (*matériel*) is subject to various classifications. A simple method is to divide it into two basic groups--mobile artillery (designed for, and capable of, comparatively quick transfer from one point to another), and immobile artillery, or artillery of position, this being a relative term applied to heavy cannon which, once emplaced (as in permanent seacoast or fortress defences) are rarely moved. But upon occasion even such pieces or (more likely) the personnel serving them, may be called upon to play a part in a war of movement. And since a fortress or coast defence may include in its armament guns of every size and calibre, all effort to subclassify this becomes abortive. In the field, however, we find such specialized types as mountain artillery, tank and anti-tank, aircraft and anti-aircraft weapons, or more comprehensive groups, such as battalion and regimental guns, divisional, corps and army artillery, etc. As their names indicate, these increase steadily in calibre, range, and effectiveness from battalion up to corps, though army artillery is a composite of all types.

Yet another nomenclature in daily use, each category of which embraces both mobile and immobile pieces, classifies artillery as guns, howitzers and mortars. Briefly, for arms of like calibre, the gun is a long barrelled, long range, weapon with a relatively flat trajectory (path followed by the projectile); the howitzer has a shorter barrel, medium range, and moderately curving trajectory, while the mortar, with very short barrel, exhibits a much curtailed range and hairpin shaped trajectory because of the high angle at which it is always fired. Intermediate types also exist, possessing some of the characteristics of both mortar and howitzer, or howitzer and gun, and hence quite difficult to classify.

Prior to the invention of gunpowder, artillery, in France and England alike, signified bows and arrows. Thus the weapons of the Genoese crossbowmen at Crkcy (1346) are referred to by Froissart in his account of the battle as "leur artillerie," while Ascham in Toxophilus (1571) says that: "Artillerie nowadays is taken for two things: gunnes and bowes." Here, again, confusion results from changes in meaning undergone by certain technical words in the course of time, changes to which may be ascribed much of the uncertainty existing as to the origin and evolution of many instruments today in use. Thus the "gunnes" of Ascham meant to Chaucer no less than three different objects, as indicated by his employment of the earlier form "gonne" to designate: a throwing machine (in his translation of the *Romaunt* of the Rose); a missile (Legende of Good Women); and finally a cannon (*Hous* of Fame). Naturally the uninitiate, discovering the word "artillerie" (or "gonne") in a work of early date, would be inclined to endow it with its present meaning, and so perhaps to surmise the existence of ordnance at a period considerably antedating that of its actual introduction.

Obviously, before artillery as it is known today could take shape, some agency for propelling missiles, at once simpler and more powerful than the physical means employed in the earlier forms of projectile weapons (see ENGINES OF WAR) had to be discovered. Such an agency was gunpowder, a mixture of three ingredients, sulphur, charcoal and saltpetre, apparently first elaborated in practicable form by the English Friar (Roger) Bacon (c. 1214–1292) who described certain of its properties in a volume written some time prior to 1249. But there is nothing in that work to indicate that he possessed any idea' of its possible use as a propellant. He realized that it could and would explode, and might, as a result, be adaptable to the arts of warfare, but further he apparently failed to speculate.

So it remained (according to most authorities at least) for another ecclesiastic, one Berthold Schwarz (or Anklitzen) of Freiburg, Germany, to be credited with the invention of the cannon. The exact date is obscure, and though 1320 is the one designated by most historians, there is good evidence to indicate that 1313 is more nearly correct. Thus among the records of the city of Ghent for that year appears, after a list of municipal officers, the significant entry: "Item, in this year the use of *bussen* (*i.e.,* cannon) was discovered in Germany by a monk."

1. **Early** Artillery (14th Century).— Numerous references are found to artillery in the early 14th century, perhaps the first of which dates from 1326, in which year the authorities of the Italian republic of Florence ordered a number of "metal" cannon for the defence of the State. Hence the battle of Crécy, commonly quoted as the most remote occasion upon which gunpowder was employed by the military in projectile weapons, yields priority to several other well-authenticated instances of the use of this destructive combination. None of these, however, which suggests the existence of artillery in the Orient. or indeed anywhere else, prior to 1300, appears to withstand close scrutiny.

Many of the earliest cannon were constructed of bundles of iron (or even wooden) staves placed side by side around a cylindrical mandrel or core and welded together more or less solidly by heat and hammer into the form of a crude tube which was given added rigidity by a series of encircling iron rings, sometimes so broad and placed so close together as entirely to conceal the staves beneath. Because of the necessity for using a core, the removal of which when the cannon-tube was completed left the latter open at both ends, the matter of securely closing the breech presented quite a problem and many of the early pieces were, as a result, produced as breech-loaders, and supplied with several interchangeable breechblocks recessed to receive the powder charge. Not all artillery of this period was so constructed, however. Thus the Florentine "metal" guns referred to above were presumably of bronze, and if so, doubtless muzzle-loading and fabricated by some sort of casting process. Indeed this method of manufacture (*i.e.*, by casting) may readily have antedated all others, the oldest ordnance drawing which has been preserved, depicting a cannon as a cast, vase-like affair, broad mouthed, narrow necked, then swelling again to a bulbous breech. The projectile, naturally enough from the evolutionary standpoint, was a metal arrow or dart, its shaft doubtless wrapped with some sort of packing to lessen the escape of powder gases.

The efficiency of these crude specimens of artillery was severely limited (were any limitation necessary) by the "serpentine" powder of the day, which was truly a powder and not the grained substance now known. This required no little skill in handling, and an experienced gunner could develop the full capabilities of a piece where a tyro was likely to blow it up (and himself and crew into the bargain) or else be plagued either with a succession of "misfires" (the charge failing to burn when the match was a p plied) or a series of "overs" or "shorts" — the missile falling beyond, or on the near side of, the target. The whole secret lay in the fact that the finely divided mixture would form into a solid mass practically impermeable to flame when rammed too vigorously, or simply "fizzle out" like a weak firecracker when seated with insufficient force. Only when put in place with the delicate touch gained from long experience, which left it loose enough for a flame to spread quickly through its fine interstices, yet packed tightly enough to build up what constituted, in effect, an explosion rather than a progressive (but ballistically impotent) conflagration, did it really perform satisfactorily.

Further. it was soon discovered that such powder, when mixed beforehand and transported for any distance, tended to separate out, the heaviest component (sulphur) settling to the bottom, and the lightest (charcoal) rising to the top. Fired in this state, it was even more than ordinarily inefficient. The result was that the gunner had to mix the several ingredients on the field of battle, a precarious manbeuvre in view of the fact that the lighted matches of the musketeers were everywhere about. Thus he became a man apart, feared and shunned by all and sundry.

2. Fifteenth Century. — Dating, however, from about 1429, we find record of an achievement only less wide in its import than those accomplished by Bacon and Schwarz — the "corning" of powder. Briefly, this involved the mechanical incorporation, in fixed proportions, of the three ingredients so firmly and intimately that there was no longer any tendency for these to become dissociated on handling, plus the added feature of turning out the finished product in "grains" of various sizes according to the purpose for which intended,—*viz.*, small grains for small guns; large grains for large ones. (Large grains fired in a small piece burned so slowly that much of the charge left the muzzle unconsumed, its effect thus entirely wasted. Small grains in a large piece burned so fast as to develop dangerous pressures in the chamber, and sometimes even to burst the tube, ere the ponderous shot ahead could fairly get started.) The grains of the new product, though of about equal weight, were irregular in shape, hence could not ball up into a conglomerate mass as did the "serpentine." Instead, the interstices so necessary to the swift propagation of the flame were thus automatically provided, and the "explosion" of each successive charge was uniform — and highly effective. So effective was it indeed that though the employment of corned powder in small arms went rapidly forward, it was a full century before its adaptation to artillery had become complete. For the cannon of the period were wholly unequal to the strains set up by this improved propellant, nor was the art of gun founding able to meet the situation thus arising for many decades yet to come.

Despite the inventive genius constantly devoted to the development of firearms, artillery included, the 15th century waned and closed without these new agencies of warfare having gained sufficient recognition to receive special classification either on the basis of relative size or tactical employment. Thus Francesco di Giorgio Martini, writing a few years prior to Charles VIII's expedition against Naples (1494) describes ten different types of firearms, and adds that this by no means exhausts the list. Yet he draws no distinction between cannon and shoulder weapons. To him the bombard. 20 feet long and firing a 300lb. ball, falls in the same category with the scopietto which measured 24in.–36in. overall and discharged a missile weighing one-half to three-quarters of an ounce. All were to him, "artillery."

Nevertheless a differentiation, among the heavier pieces at least, was taking place, if insensibly, and before the 15th century ended, field artillery as distinct from the more ponderous and relatively immobile artillery of position, may be said to have been born. Prior to this time, field artillery consisted simply of such guns of its siege train as an army was able to bring into the field. But the Italian wars which Charles VIII initiated, stimulated French ingenuity to the development of means whereby guns could be endowed with a fair degree of mobility. These included the uniform mounting of ordnance on wheeled carriages (in place of the clumsy sledges theretofore prevalent) and the employment of well-trained horses, rather than the slow-footed ox, as draught animals. Thus while the Italians and Spaniards were still entrusting the transport of their artillery to that sluggish beast, and Maximilian possessed draught teams sufficient to move but half of his siege train at a time. the sturdy French horses were learning to draw heavy cannon on level roads at a pace equalling the marching speed of cavalry!

But the French were not alone in their efforts to make artillery a mobile arm. Indeed, the Italian, Bartolomeo Colleoni (d. 1475) is credited with being the first captain to develop a true field artillery tactic, locating his light guns in the rear of other elements, and firing through gaps in these which were opened at a given signal. Nevertheless, such practices were far from general, and most Italians considered Charles VIII's employment of field guns as something quite revolutionary. Fortunately for him, he so outweighed his adversaries in the quantity and quality of his artillery, not to mention pieces exceeding in calibre any yet known in Italy, all mounted on scientifically designed carriages and operated by trained gunners, that his superiority in that arm was maintained throughout all the earlier Italian campaigns, its reputation alone being in some instances, as at Fornovo, sufficient to undermine enemy morale.

It was during this century that artillery acquired a characteristic which it had theretofore lacked (to the considerable limitation of its effectiveness, withal) — namely the trunnions whereby the gun tube was affixed to its mount, about which it could be rotated when an increase or decrease in range was desired, and through which the shock of discharge was transferred in large measure to the carriage. In earlier types, the simple cylindrical tube or barrel was commonly set into a heavy wooden framework, a stout crossmember of which abutted against the breech and received from it the impulse of recoil. This crude design did not by any means yield without a struggle to the more advanced one in which trunnions figured, for the obvious reason that it was much easier to cast a plain tube than one from which two excrescences projected outwards opposite one another at right angles to the tube axis. But the advantages of the trunnions were so outstanding that the simpler but less efficient trunnionless type was finally replaced entirely by its more adaptable competitor.

3. Sixteenth Century. — Artillery continued to expand in girth and stature, — literally and figuratively. French successes stimulated others to emulate their efforts and the younger duke of Ferrara, whose father (d. 1505) had long been interested in ord-

TYPES OF EARLY ARTILLERY

1. A 14th century wrought iron 15-inch bombard, which threw a stone shot weighing about 160 pounds
2. Peterara, an early breech loader of forged iron, 1461-1463, made of bars of iron hooped together with iron rings
3. Brass culverin bastard, of the time of Henry VIII., with rose and crown in relief
4. "Mary Rose" breech-loader, a wrought iron gun recovered in 1836 from the wreck of the "Mary Rose," which sank off Spithead in 1545
5. The falconet, a wrought iron field gun of the 17th century. mounted on a swivel carriage of the period
6. French brass field gun of the time of Napoleon III., which was presented by him to Queen Victoria in 1858

FIELD AND COAST ARTILLERY

1. A 16-in. howitzer at Fort Story, Cape Henry, guarding Hampton Roads and Chesapeake bay
2. American 75-mm. pack howitzer on 75-mm. carriage
3. 105-mm. anti-aircraft gun
4. A 6-in. Stokes trench mortar, an infantry weapon used principally in trench warfare during World War I. The sandbags assisted in concealing cannon and provided protection for gun crew
5. A German heavy howitzer, 21 cm. (World War I)
6. A German heavy trench mortar, 25 cm. (World War I)
7. A 14-in. rifle at Aberdeen, Md., mounted on railway carriage, readily transportable for seacoast defense
8. Firing a U.S. 155-mm. howitzer
9. Modern American 155-mm. gun
10. Battery of 12-in. disappearing rifles. Gun in background is firing, one in foreground has been fired and has recoiled and is being sponged for reloading
11. A 16-in. coast artillery gun, mounted on a disappearing carriage

nance, and was one of the few of noble birth to engage in its production prior to 1500, turned out specimens in considerable numbers, and of increasingly high quality. In 1509 was witnessed the destruction by his artillery of the dread Venetian fleet which had proceeded up the Po to within a short distance of his capital, an event which contributed enormously to the increasing prestige of artillery in general. Only the year following, the French accomplished the reduction of Legnano chiefly through the agency of two of Ferrara's guns of tremendous size, the casting of which he had personally superintended.

As the 16th century neared midpoint, the artillery policies of all great nations of that day, which had been developing without rhyme or reason for well over 200 years, appeared ready for a complete overhaul. Calibres and varieties of guns approached infinity; standardization of any kind was unknown. To reduce this chaos to some sort of system Charles V of Spain decreed, in 1544, a total of seven models of cannon which would thenceforward be made for, and used by, the armies of his empire. These included a cannon (40-pounder), a cannon-moyen (34-pounder), two types of 12-pounder culverins, two 6-pounders, and a 3-pounder falcon. (Early pieces were often named after birds of prey.) The French were quick to follow suit, and in 1550 Henri II issued an edict restricting the number of calibres to six, the heaviest a 33-pounder weighing, with its carriage, 8,000lb., and drawn by 21 horses; the lightest a a-pounder to which two horses were assigned. Later (1584) two additional types were permitted, a 12- and 24-pounder (calibres which the Spaniards had found useful in the Low Countries).

The practice of the day involved the transport of these pieces muzzle foremost, their massive trails dragging on the ground behind, and their equine motive power stretched out in single file, so that each gun when on the march must have occupied interminable yards of road space. Nor did the passage of time simplify the picture, for the 33-pounder of 1633 (83 years later) had increased in weight by 400lb., and the horses drawing it now numbered no less than 2j, though some progress could be recorded in the fact that the weapon was now hauled trail foremost.

These gestures of Charles of Spain and Henri of France, while aimed in the right direction, left much to be accomplished. Thus, among a few of the shortcomings of contemporary artillery, may be mentioned their want of limbers; carriages which boasted but two wheels and were completely lacking in uniformity; failure to provide the artillery train with any spare parts for emergency repairs (save an occasional extra wheel), and so on. No specific powder charges were established, though practice favoured the use of a weight of the (very indifferent) propellant then current which actually equalled that of the shot. Three sizes of powder were employed—large grained for the heavier guns, small grained for the lighter, and a still finer type for priming all varieties.

During this century the art of gun-founding was introduced into England by ordnance-minded Henry VIII after he had been forced, by lack of a home industry, to reach overseas and employ the famous Fleming, Hans Poppenruyter, to supply him with close to 150 pieces of varying calibres, including the celebrated set of bombards known as the "Twelve Apostles." He likewise imported (c. 1515) foreign armourers and established schools of instruction for native artificers. Nor was he entirely satisfied with the ordinary solid shot then in use, but undertook to augment these with crude types of shell described by a contemporary as: "... hollow shot of cast yron, stuffed with fire-works or wild-fire: whereof the bigger sort for the same had screws of yron to receive a match to carry fire kindled, that the fire-work might be set on fire to break in small pieces the same hollow shot, whereof the smallest piece hitting any man would kill or spoil him." Here we see (in the type "stuffed with fire-works") the beginnings of the explosive shell and (in that containing "wild-fire") of incendiary projectiles.

In the German states, calibre simplification was not then carried as far as in France. Thus we find illustrated and described in Napoleon and Favé's work on artillery, as in use during the period 1550–1600, no less than 11 varieties of mobile cannon. from a little one-pounder to a huge piece discharging a 94lb. ball. Further, there existed among all of these save the very smallest, subclassifications which brought the total to the impressive figure of 40, the heaviest of which called for no less than 60 horses to get it into motion. But far more important than the number of cannon types employed in France, Spain or Germany at this time were the premonitory rumblings then coming out of Italy to predict the birth of a new science—ballistics. Given written expression by the famous mathematician Tartaglia in his works which appeared in 1537, 1546, and 1551, these constitute the first recorded scientific approach to the theory of gunnery as distinguished from the rule-of-thumb practice theretofore prevailing. And although in large measure incorrect, this author's ideas on the trajectory of a cannon ball (previously held to be a straight line from gun muzzle to some point in space, after which the missile fell suddenly to earth) were so far ahead of his day that he justly deserves the title of first ballistician.

4. Seventeenth Century.— By this time some artillerymen were beginning to realize that certain practices, though hoary with age, lacked foundation in logic. Thus it had, from the very beginning, been customary to make the barrels of cannon (as contrasted with mortars; howitzers came along later) outlandishly long—to afford opportunity for the complete combustion of the "serpentine" powder originally employed in them. Came the introduction, and finally the general adoption, of corned powder, which burned faster and more evenly, and accomplished as much in short barrels as its predecessor had in long. Yet long they continued to be made, no one quite knew why. Similarly, though some of the earliest cannon to be cast with trunnions had these located where they properly belonged—with their long axes in the same plane as that of the long axis of the bore—practice soon departed from this and trunnions came to be set on a level with the bottom of the bore, and remained so situated for generations. As a result there was, at each firing, an undue strain on the trail of the piece which, as the strength of powder increased, frequently gave way under the force so applied. Not until the latter half of the 18th century was this patent error generally corrected.

During the first half of this century, Gustavus Adolphus of Sweden introduced (1626) his famous "leather" guns, so named because the external casing of the barrel was of that material. The bores, however, were metal (copper) tubes. Every effort was made to curtail weight, and as a result that of the gun itself, apart from its light carriage, came to but golb., and the piece could easily be drawn by two men. Designed as the last word in mobility, it possessed that qualification in high degree but embodied at the same time a deadly disadvantage. For on repeated firing it became so hot that a new charge would often ignite spontaneously. This led to its supersession (1631) by *matériel* of more substantial, if less mobile, character, and further effort to develop a truly light artillery remained in abeyance until resumed in the century following by Frederick the Great.

During this period calibres of French cannon underwent further change by reason of the adoption of various foreign pieces. This resulted in an increase in varieties from six to seven, the largest piece now being a 48-pounder, then ranging downward through 32, 24, 16, 12 and 8-pounders to one of 4-pounds. But here all order ended. For the kingdom was divided into a number of artillery districts, each commanded by a lieutenant-general of that arm. And the cannon, and all their accessories, of one district, differed from those in the next. Each calibre of gun employed wheels of a size unlike that used by any other calibre. Spare carriages were taken into the field, but those of one district would not mount the guns from another. In but one feature was simplification of the practices of the preceding century evident: powder had become standardized in grains of a single size (and ballistically speaking, this evidenced a retrogression). But here again, specimens from the several districts were likely to exhibit marked variations in strength, though, for the most part, a charge of but two-thirds the weight of the ball now accomplished what had required weight for weight a century earlier, the quality of powder having improved to this extent over the intervening years.

5. Eighteenth Century.— This was to witness a period of marked ordnance activity on the part of all major Europesn na-

tions. Among the high lights may be noted the abolition in France (1732) by General Valière of all mobile pieces above the 24-pounder, thus making that calibre the nation's heaviest field weapon. Coincidently he decreed a uniformity in the methods of fabricating cannon never before attempted. Unfortunately, his efforts ceased at this point. There remained as many different designs of gun-carriages as there were manufacturing arsenals. Axle-trees continued to be of wood. Limbers, when used at all, were too low, and draught horses were still strung out in single file ahead of the guns to which they were hitched.

Turning to England, we find the groundwork of modern ordnance theory and practice laid by Benjamin Robins (1707–50) whose Principles of Gunnery (1742) exploded ancient superstitions upon the nature and action of gunpowder and the flight of projectiles, and formed the basis of all later scientific studies in these fields. Gunners were now for the first time able to measure with considerable exactness the muzzle velocities of projectiles delivered by their pieces—due to his invention of the ballistic pendulum, a device whereby the energy of a projectile suddenly halted in its flight could be accurately estimated and translated into terms of velocity.

By the time of Robins' death, strenuous efforts were again being made on the Continent toward developing a truly efficient mobile ordnance (field artillery). Thus the Seven Years' War found Prussia in the midst of a series of experiments with pieces weighing from 80 to 150 times as much as the balls they fired, while by 1762 the Austrians had standardized on guns all 16 calibres long (*i.e.*, with tubes 16 times their diameter in length), all 115 times the ball in weight, all firing missiles carefully cast to a true spherical form, and with so little "windage" (excess in diameter of bore over that of projectile) that they achieved excellent results with powder charges not exceeding in weight one-third that of the missile.

Other nations were not insensible to these developments, and by 1765, Jean Baptiste de Gribeauval (who became chief inspector of artillery in 1776) had commenced yet one more revamping of French *matériel*. This resulted in even further reduction in the number of different calibres employed in the field, these now totalling but three, the heaviest a 12-pounder, the others carrying 8 and 4lb. balls respectively. These were all 18 calibres long and 150 times the weight of the shot for which designed, thus continuing the now well-established trend toward reducing the length and weight of field pieces. Once again, much attention was paid to securing balls of true sphericity and correct diameter, this making possible the same reduction in powder charge as had been effected by Austria, *i.e.*, to one-third that of the ball in weight.

Another innovation was the introduction, for field use, of a light howitzer of 6in. bore. Yet another, which marked a real milestone in artillery progress, was the disposition of draught horses in double files in place of the single file theretofore employed. Six horses now sufficed to draw the 12-pounder—four for the lesser sizes, a pleasing contrast with the numbers required a century earlier. Limbers, heretofore but casually in use, became standard equipment. These were large, six-wheeled affairs, but higher and more serviceable than those of Valière. The limber box (a combination receptacle for ammunition and seat for some of the gunners), failed, however, to gain acceptance despite Gribeauval's strenuous efforts, though he did succeed in establishing interchangeability of wheels (and other parts) and in introducing iron axle-trees, elevating screws, tangent scales, and prefabricated cartridges. These (which replaced the old loose powder and shot) embodied carefully weighed powder charges sewed into cloth bags, to one end of which a shot was securely affixed, the whole being swept down the bore of the piece and seated at the breech by a vigorous movement of the rammer. They were, however, in no sense a new invention, Adolphus having used them with some success in the century preceding.

Other of Gribeauval's achievements included the tlassification of land ordnance into three well-defined groups (field, siege and coast-defence) according to the purpose for which intended. In the first category he endeavoured, unsuccessfully, to educate his countrymen to the importance of "horse artillery," an ultra-mobile element first employed by Frederick the Great (1759), designed to manoeuvre with cavalry in the manner in which field artillery operated with infantry. Not, however, until after the outbreak of the French Revolution was such a unit found in the French service, its counterpart, incidentally, appearing in England at approximately the same time. The latter years of the 18th century are marked by the invention (1784) by a British Lieutenant (later General) Henry Shrapnel of a form of "spherical case" shot later destined to bear his name and to supplant (for use against personnel) most other types of artillery ammunition for well over a century to come.

6. Nineteenth Century.— This was to record a series of advances in ordnance practice so brilliant as to render the artillery in use when the century closed, probably ten times as efficient as that which marked its opening. Contributing factors included progress in chemistry, mechanics, metallurgy, optics and associated sciences which together made possible: (1) the perfection of a workable rifled cannon, an objective long sought by ordnance engineers but never before successfully attained, and (2) the adaptation to rifled cannon of elongated projectiles which (a) because of their more streamlined form were less affected in flight by wind than were the round balls they displaced; (b) by reason of the stabilizing spin imparted them by the rifling grooves, flew much straighter, and *(c)* being decidedly heavier than a ball of like diameter, ranged much farther than the spherical form. But to propel these heavy bolts, more and better powder was required. This was made available through the researches of Captain (later General) T. J. Rodman, U.S.A., whose "mammoth" brand was produced in large hexagonal prisms, perforated to permit the flame burning from within outward as well as from outside inward. Thus the initial violent evolution of gas from the burning grains, followed at once by a progressive decrease in gas production as the surface of unburned powder exposed to the flame was steadily curtailed, gave way to a situation where, though the external surface of the grains constantly shrank, internal surfaces (provided by the perforations) were enlarging with each instant. The final effect was to stretch out materially the period of mass evolution of gas (and of high pressures on the chamber walls), and so to develop, in effect, a prolonged steady push against the base of the projectile, rather than a sudden blow, with maximum stresses much moderated. But before this achievement had been recorded, workers in other fields, attacking the problem from different angles, had succeeded in producing guns both of bronze and cast-iron (the two materials used almost exclusively in the founding of cannon for centuries past) possessing such high physical characteristics as to enable them to withstand pressures formerly unthought of. In the case of bronze, this result was attained by the admixtures of certain proportions of phosphorus to the copper-tin alloy. [The achievement came too late (1870). The day of the bronze cannon was over.]

Toward enlarging the capabilities of iron pieces, two Americans offered solutions. One, a civilian engineer, Daniel Treadwell (1791–1872) designed (1841) a built-up, muzzle-loading cannon which he evidently believed his exclusive invention, though his claims have been disputed in favour of a Frenchman (Thiery), said to have developed a similar piece in the 1830s. Treadwell's gun, in its final form, consisted of a central tube of cast-iron or steel, surrounded by a series of wrought iron or steel hoops, shrunk on after heating, and in some instances united also by screw-threaded joints. This basic method of construction was later successfully adopted in the United States by Parrott, and in England by Armstrong and Blakely, and, save for improvements in means and materials, remains accepted practice today. But Treadwell received no adequate encouragement from the military, and died disappointed and discouraged.

The other system (Rodman's), developed about 1845, was quite different. Instead of casting guns as solid cylinders of iron, later to be bored out, the ancient and honourable method. he cast them hollow about a removable core through which a stream of water was slowly passed. Cooling thus took place from within outward (the external walls were kept warm meanwhile), succeed-

ing layers of metal from bore to surface undergoing compression as those overlying slowly shrank, thus accomplishing, but by a radically different method, just what Treadwell had done. But cast-iron, like bronze, had had its day as a material for gun construction, and though Rodman's process saw active application for two or three decades, it eventually was forced to give way to others in which the piece was built up (à la Treadwell) from successive layers of steel. The advantages of this material for cannon fabrication had long been recognized, but until the mid-19th century, no methods of producing it in the quantities, and qualities required, had been evolved. As soon, however, as these were devised, steel moved rapidly to the position of ascendancy which it has since maintained.

The military world was now enjoying rifled cannon which projected heavy, elongated missiles to what were then considered stupendous ranges, this as a result of the improved powders and stronger gun tubes. Thanks to Capt. LeBoulengé of the Belgian Army it had now acquired an instrument (chronograph) which constituted a material improvement, for measuring velocities, over Robins' ballistic pendulum. But it still lacked accurate means of estimating the forces exerted by the burning powder gases against the breech of a weapon. As a result, current methods of determining the strength of the walls required to withstand these were based more on trial and error than anything else. But here again Rodman stepped into the breach by designing a gauge which permitted very accurate calculation of the pressures engendered.

But three factors were now lacking to make the gun the super-efficient engine it became with the advent of the 20th century. These were (1) a successful system of breech-loading; (2) a satisfactory smokeless powder, and (3) means to dampen the forces of recoil when the piece was fired so that it could be relaid on its target quickly and accurately. In respect of the first, breech-loading cannon of fair efficiency had been produced as recently as the 1840s by Cavalli, a Sardinian officer, and Baron Wahrendorff of Sweden. And the time was ripe for such a development, for as guns became longer and heavier, the mechanics involved in getting the charges properly inserted into their ponderous muzzles, ramming them home, then returning the pieces to their firing positions and re-laying them upon their targets became increasingly complicated, and a satisfactory system of breech-loading more urgently indicated.

During the '60s and '70s, several such methods were perfected simultaneously in France (de Bange), Germany (Krupp), Spain (Freyre) and the United States (Broadwell).

In the field of propellants, black powder, which reigned supreme, produced so much smoke as to obscure both firer and target after a heavy volley, or broadside, and left such heavy fouling in a gun bore as to require frequent cleaning if accuracy were to be maintained. In addition, it was, despite the notable achievements of Rodman and others, far from under full control in the matter of the chamber pressures it developed. A new propellant, smokeless, without residue, and capable of being harnessed over a much wider range of its activity, was urgently indicated. The answer appeared at hand when, during the 1860s, Baron General von Lenk conducted a prolonged field test of guncotton (first compounded a few years previously) in the Austrian artillery. But a lack of stability, and consequent tendency to spontaneous explosion in storage, led to its eventual rejection. So it remained for the French chemist Vieille (1884) to harness this unruly substance by gelatinizing it into colloid form with the aid of suitable solvents, and thus make available to the military world the propellant it had so long awaited.

And now the science of mechanics, which had already solved the problem of breech-loading, came again to the aid of the artilleryman, and gave him a gun mount so ingeniously designed as to permit it to absorb the tremendous recoil developed when a modern piece is fired, this without rearward movement of the carriage, or displacement of the barrel from its original position once action and reaction had had their effect. This was accomplished by suspending the gun tube proper in a cradle, and interposing between the two, compression cylinders, heavy spiral springs or other means of accumulating, as the barrel swept rearward, the energy necessary to return it to its original position, once recoil effects had been dissipated, rather than transmitting these to the carriage. (Prior to the development of such a system, the gun, and its mount, to which it was rigidly affixed, used to recoil to distances varying with the calibre of the piece and charge employed, then to be brought back "into battery" by human effort —and pointed again at its target.) With the perfection of such counter-recoil mechanisms, artillery finally acquired all the more important characteristics which it possessed at the commencement of the World War (1914–18).

THE WORLD WAR, 1914-1918

7. **Situation** in 1914.—The artilleries of the main forces were organized and equipped as follows:—

(a) Great Britain.—Each divisional artillery comprised 54 18-pdrs. in three brigades of three batteries, 18 4·5in. howitzers, in one brigade of three batteries, and four 60-pdrs. There was also a siege train of six 8in. howitzer batteries.

(b) France.—Each first line divisional artillery comprised 36 75mm. guns in three "groupes" of three batteries. There were also 20 regiments of corps artillery each consisting of four "groupes" of 75mm. guns, five regiments of heavy artillery, 11 foot regiments and some mountain artillery.

(c) Germany.—Each first line divisional artillery comprised 54 77mm. guns and 18 10·5cm. howitzers in two regiments which were subdivided into three "groupes" of three batteries of guns and one "groupe" of three batteries of howitzers. In addition there was in each corps a battalion of 12 15cm. howitzers and in each army a number of 21cm. howitzers.

The types of equipment in use by the three Powers did not vary to any marked degree. All proved deficient in range, the British equipment being initially at a particular disadvantage in this respect. The French lack of a field howitzer was due to the failure of Parliament to appropriate the money for one "groupe" per division. It will be seen that there were, however, important differences in the allotment of the artillery as between divisions, corps and armies and in the aggregate proportions of the various types of equipment. The Germans had a marked advantage in the possession of a large number of howitzers capable of assisting in both field and siege operations. Both Britain and Germany had 6-gun batteries while the French batteries were of four guns. All three countries had divisional artillery commanders, but France alone had an artillery commander at corps headquarters. Viewed in the light of subsequent experience, it would seem that both the British and French tactical doctrines of 1914 unduly emphasized the importance of mobility to the detriment of fire power. The German doctrine appears to have been better balanced in this respect and the Germans also realized more fully the necessity for co-ordination of combined action of the artillery with that of the other arms. All three countries had grossly underestimated the quantities of ammunition which would be required. The British reserve was calculated upon a basis of a probable expenditure of seven rounds per 18-pdr. per day, but in the World War the expenditure per gun often rose to 500 rounds or more per day. No country had fully appreciated the effect upon

artillery power of the development of railways, motor traction, aircraft, telegraphs, telephones, wireless and survey.

8. ***Evolution of Equipment,* 1914–1918.**—The British field artillery stood the test of the war well and the minor defects which appeared were easily remedied. The proportion of medium and heavy artillery was vastly increased, the equipments adopted being 60-pdr. and 6in. guns and 6in., 8in., and 9·2in. howitzers. Super-heavy howitzers, of rain. and upwards, and guns on railway mountings of 9·2in. and upwards, were brought into use. Mortars, which had long been discarded, made their re-appearance for the war of position. The ranges of all weapons were increased, field artillery ranges rising to some 10,000yd. and even more in the case of French and German equipments; the greatest range viz., 76 miles, was attained by the German 21cm. guns used to shell Paris. The British field guns, which had started the war with shrapnel ammunition only, were supplied with high explosive shell in addition before the battle of Loos. Shrapnel was abolished for 4·5in. howitzers, and in the heavier natures high explosive was almost exclusively used. Smoke shells were introduced for the lighter natures of guns and howitzers in 1916. In July 1915, the Germans first employed gas shells, and this type of shell came into general use in steadily increasing numbers. It is noteworthy that the supply of gas ammunition never equalled the demand and that the use of gas was still in its infancy at the end of the war. An advance in the control of fire was effected by the development of observation from aircraft. Inter-communication was improved by the more extended use of the field telephone and of wireless. Survey, sound ranging and flash spotting units were provided for co-operation with artillery. The lighter natures of artillery were still generally horse-drawn in 1918 although lorries or trucks were used, especially by the French, to transport a proportion of their field artillery. The heavier natures were drawn by motor tractors of various designs ranging from the four-wheel-drive lorry to the "caterpillar."

9. ***Evolution of Organization and Command,* 1914–1918.**—A comparison of the development of artillery organization and command in the British, French and German armies shows that, notwithstanding their initial differences and the separate lines of evolution which were followed, all three arrived at similar solutions of fundamental problems. The changes introduced may be summarized as follows:—(a) Artillery command was centralized as much as was consistent with effective control. This proved the best means of co-ordinating action, of economizing force and of concentrating fire at the right time and at the right place. Centralization of control was often carried to excess, however, in the Western theatre. This change in the system of artillery command entailed an increase of artillery headquarter staffs. (b) The necessity for a strong reserve, in the hands of the higher command, of both field and heavier natures of artillery led to the creation of large numbers of artillery units outside the organization of formations. In 1914 the proportion of field artillery to infantry in an army was about six guns to 1,000 rifles. By the end of the World War the proportion of all natures was about 10 guns and howitzers per 1,000 rifles, roughly 6 field, 2 medium, 1½ heavy and ½ super-heavy. (c) The allocation of equipments to formations was based upon their ranging powers and their degrees of mobility. Thus field artillery (in the United States light artillery) was seldom allotted to formations higher than the division; medium and heavy artillery were normally allotted to corps, while super-heavy guns were directly under armies. (d) The corps was recognized as the most suitable formation for the control of counter battery work and special staffs were provided for this task. The divisional artillery of an infantry division, U.S.A., consisted of two regiments each of six batteries of four 75mm. guns, one regiment of six batteries each of four 15jmm. howitzers and one trench mortar battery.

10. ***Evolution of Tactics,* 1914–1918.**—The evolution of equipment and organization and the evolution of tactics were, of course, interdependent. It was naturally on the Western front that artillery tactics were most fully developed. During the first operations in 1914 sharp lessons were learned. It was soon evident that owing to the hitherto unrealized power of small-arms fire in defence, attacks must be well prepared by artillery. Tactical mobility had, in fact, become dependent upon fire power, but neither side had the artillery or the ammunition to provide fire power in adequate measure. At Le Cateau the British learned the disastrous results of attempting close support of infantry with guns disposed too close to the foremost troops. The early engagements also demonstrated the necessity for distributing guns in depth in defence and for concealing them if they were to avoid destruction. The need for increased quantities of medium and heavy artillery was soon apparent.

During the trench warfare of the winter of 1914–15 new developments began to take shape. Attempts were made to engage targets by night and to provide defensive barrages, and observation of fire from aircraft rapidly found favour. The employment of barbed wire entanglements introduced a new task for artillery in the preparation of infantry attacks.

The battle of Neuve Chapelle (1915) forms a landmark in the evolution of artillery tactics. The attack was prepared by an intense hurricane-bombardment of 45 minutes and it was supported by subsequent "lifts" of fire in front of the infantry. The lessons of this operation were misapplied to some extent; in the subsequent attacks at Festubert, Givenchy and Loos, surprise was thrown to the winds and lengthy preparatory bombardments of small intensity were undertaken with the object of destroying hostile defences rather than of temporarily neutralizing and paralysing the defenders. Loos marked a development towards the "rolling" barrage which became the usual accompaniment of later attacks. The French fell into the same error as the British in their disregard of surprise in their attacks in Champagne and Artois. The first effective use of the rolling barrage for a break through on a large scale was in the German break through the Russians on the Dunajec river, Galicia (1915).

The operations of 1916 and 1917 were based upon the fact that given sufficient artillery and ammunition, limited advances of two or three thousand yards at a time could be almost guaranteed. Enormous concentrations of artillery supported every attack.[1] Thousands of tons of ammunition were fired daily during an operation on a front of a few miles. Surprise continued to be sacrificed, for the artillery carried out preliminary bombardments often lasting four or five days. Rolling barrages of great depth and heavy counter battery fire were the unvarying accompaniment of the actual advances. Such were the methods of artillery action adopted in the battle of the Somme (1916), the French attack at Verdun (1916), at Arras (1917), in Nivelle's attack on the Aisne (1917), at Messines and in the third battle of Ypres. The Germans, in their attack at Verdun in 1916, had endeavoured to obtain some measure of surprise by reducing the preliminary bombardment to ten hours and, in Allenby's attack at Gaza, measures were successfully taken to deceive the Turks who might otherwise have been warned of the British plan by the five days' preliminary bombardment. But none of the commanders had as yet appreciated the paralysing effect of the brief and intense hurricane bombardment of short duration which was adopted in 1918. It became apparent, however, that a drastic change in tactical methods must be made if decisive success was to be obtained. The defender could, in great measure, counter the form of artillery support then in vogue, heavy as it was, by suitable adjustment of his infantry tactics; the ammunition expenditure entailed proved too great a strain on industrial resources; and the effect of the fire on the ground was such as to create new obstacles for the attackers. In the defence, artillery action had

[1] At the battle of the Somme—July 1, 1916—there was approximately a gun or howitzer to every 20 yards of front assaulted, the proportion of heavy or medium pieces being one in every three.

At the battle of the Scarpe—April 4, 1917—there was a gun or howitzer to every 10 yards of front, the proportion of heavy and medium pieces being rather more than one in three.

In the British attack at Amiens—Aug. 8, 19x8—the proportion was again approximately a gun or howitzer to every 10 yards, the heavy and medium artillery being in the proportion of 7 to 12.

In the German attack in April 1918, 9,500 pieces were employed on a front of 50 miles, *i.e.*, rather more than one piece to every 10 yards of front. On the decisive sectors of the front the artillery was concentrated to one gun to every five yards of front.

taken the form of "counter preparation" to break up impending attacks of neutralization of hostile artillery and of stationary barrages close to the foremost trenches to repel assaults once they were launched.

The advent of tanks had an important bearing on artillery tactics. At the battle of Cambrai it was demonstrated that tanks could carry out tasks which had previously fallen to the artillery. They had a very great demoralizing effect, they could create gaps in barbed wire and they could neutralize small-arm fire. The employment of tanks had a considerable influence in bringing about the abolition of lengthy preliminary bombardments and the consequent simplification of the problem of ammunition supply. The battle of Cambrai further proved that effective artillery support could be given, by means of survey methods, without previous registration.

The German successes on the Western front in 1918 were largely due to skilful artillery tactics, for the development of which Colonel Bruchmüller was chiefly responsible, the element of surprise being thus safeguarded. Their new tactics had first been employed, and with marked success, at the battle of Riga in Sept. 1917. Secrecy was observed in the preliminary concentration and other arrangements, each attack was preceded by a short hurricane bombardment of a few hours' duration designed to produce moral rather than material effects and containing an element of surprise in the repeated withdrawal of fire to the forward defences after it had apparently passed on, gas and smoke shell were extensively used, counter battery fire was heavy. The advances were supported in their initial stages by intense concentrations on enemy strong points and the infantry were boldly followed up by field artillery.

A counter to the German artillery tactics was eventually devised by the French in Champagne. Careful artillery counter-preparation was carried out for some time before the German attack which the enemy had not been able to keep secret. Troops were thinned out in the forward zone, in which the first shock of the attack was to be absorbed, and the main line of defence was organized in rear, the artillery fire being adjusted to correspond with these arrangements.

A "hurricane" bombardment of 15 minutes, followed by a rolling barrage, was adopted with complete success by Allenby in his final break through the Turkish lines in Sept. 1918.

During 1918 the use of concentrations of fire increased. General Charles P. Summerall (U.S.A.) in 1918 first tried out concentrating the fire of all his divisional artillery in front of one infantry brigade at a time when the infantry could go no farther with the help of the rolling barrage. Later, in the November attack in the Argonne, he gave his army corps heavier artillery support than had been seen up to that time. The system of artillery command at last admitted of centralization or decentralization according to the varying situation. A return was made to a long preliminary bombardment when the British Fourth Army attacked the Hindenburg Line in September; surprise had then ceased, however, to have great value owing to the extent of the Allied offensive and the disappearance of the enemy's reserves.

When operations ceased the art of tactics was on the threshold of a new era of development which had been ushered in by the renewal of mobility, by the introduction of tanks and by the mechanization of transport.

(J. N. K.; X.)

AFTER 1914-18

The artillery has steadily increased in importance since 1914. The war of 1914–18 saw a great increase in the proportion of guns to infantry, in the numbers of types of artillery and also a number of new projectiles and fuses. From 1914 until Germany began her rearmament the French artillery doctrine, largely a continuation and development of the 1918 doctrine, was of primary importance. The British and Americans largely followed this French doctrine.

The Germans, being disarmed, had to limit their developments to theory except in so far as from time to time they found an opportunity, through relations with Russia, to carry out some experimentation with the Russians. The Russians, from the beginning of the organization and armament of their 1940 army, showed a tendency to develop new tactical ideas and therefore to modify their artillery armament to suit these ideas. In general, their artillery doctrine differed from the French one of using large concentrations of fire primarily under one command and leaned toward the splitting up of their artillery in small groups assigned directly to infantry units. The Italians, while closely following the French theory, showed a decided tendency since the war of 1914 to put into practice German theoretical solutions of artillery problems, in so far as their financial status would permit rearmament.

The Abyssinian campaign in 1935–36 gave the Italians the opportunity to test their theories with respect to the supporting artillery for infantry in mountainous countries and the relationship between artillery and aviation and the means of transport of artillery. The Italians steadily developed the idea that the infantry commander should have immediately available the lesser calibres needed for the assault. Therefore, besides small mortars which can be carried forward by the troops by hand, they had in each infantry regiment one battery of 65mm. mountain guns carried on pack mules.

As the result of their experience in Spain they were engaged in 1940 in rearming their infantry with 75mm. mountain guns carried by pack mules.

In the Spanish Civil War, the Italians found that in many instances larger calibres could not keep up with the infantry and at other times could not be emplaced where they could reach enemy positions well up on a mountain. They therefore came more and more to use bombing by aviation as a means of supplementing their artillery fire. The Italians found that pack and horse-drawn artillery were essential because the use of mechanized and motorized artillery was greatly limited by the lack of roads and the difficulties of the terrain. A large and well-equipped road-building force enabled them to make a much greater use of mechanized and motorized artillery than would have been the case with other armies with nothing more than their customary organization and equipment for this purpose.

The Spanish Civil War gave the Italians a chance further to develop the artillery practices of the Abyssinian campaign. These developments were primarily tactical and in the use of aviation as an artillery reinforcement. This because they had no new types of artillery in Spain. In fact the corps artillery of the Italian expeditionary force was composed of pieces captured from the Austrians in the World War (1914–18) or surrendered by them as the result of the Armistice.

In general the lessons of Abyssinia were confirmed. Spain is a country with a small road net and a great variety of difficult terrain In Abyssinia the Italians were fighting a semi-savage people, poorly armed and with primitive tactical and strategical ideas and practically no air service.

In Spain, on the other hand, they had to fight an inefficient army in so far as fundamental training and the leadership of many of its officers were concerned, but a force kept well supplied from foreign sources with modern armament of all types including tanks and aviation.

The Germans by this time had largely built up their new army and aviation, armed with the latest type of weapons which their theories had evolved during the period of their disarmament. Germany sent to Spain a sufficient number of artillery officers, signal corps or communication officers, and officers from different branches of their services, to enable them to become thoroughly acquainted with the lessons learned on the battlefield by the Italians and Spanish. Germany sent anti-aircraft artillery with enough officers and men to man it, different types of aviation with enough officers and men to man them, enough officers and men of the signal corps of communication troops to test thoroughly different means of communication on the ground, in the air, and between the air and the ground. Germany sent different types of tanks and some tank officers and specialists.

The result of the German, Italian and Spanish experimentation in battle in the Spanish Civil War showed the need for increase in all types of artillery and, in general, larger calibres. The cannon

as an aviation weapon was shown to be a necessity. The cannon as the principal tank weapon was shown to be an essential for all heavy combat. In other words, just as artillery weapons have steadily increased as essential parts of the armament of infantry units so has the artillery become an essential part of aviation and tank armament. There is little doubt that the experience in Spain with a few aeroplanes armed with a cannon of around 20mm. was the reason for the large use of aeroplanes armed with cannon by the Germans in the Polish (1939) and all subsequent campaigns.

The Spanish Civil War proved conclusively the benefit accruing from the use of aviation to supplement artillery fire or in some instances to furnish a substitute.

In all assaults in Spain in 1938 and 1939 the artillery bombardment was followed by a bombardment from heavy bombers upon the same targets as those upon which the artillery had fired. The accompanying artillery fire during the infantry assault was dispensed with. There were no rolling barrages and no concentration on the first objectives of the infantry. Artillery concentrations were on the rear of this objective. The accompanying artillery fire was furnished by the aviation and by tanks armed with cannon. The aviation attacked with light bombs and machine guns by dive bombing, one plane after another from one flank of the objective to the other. It repeated this continuously until the infantry had reached the point where it became dangerous.

Tanks with cannon were distributed at intervals in the infantry assault wave. Their guns furnished fire on all critical points encountered by the infantry during their advance. Wherever the infantry was held up, a number of tanks with cannon and dive bombers would make a concentrated attack. The use of tanks with cannon of around 47mm. and up frequently resulted in the 37mm. anti-tank guns proving ineffective, this because of the longer range of the tank cannon and its bigger bursting charge. The consequence was that the 65mm. mountain gun was more and more used as an anti-tank gun. Besides its greater range and bigger bursting charge it could, because a much smaller target, be emplaced in positions which an ordinary field gun of 75mm. or 77mm. could not use. This because the latter was such a large target it would be destroyed by the enemy's fire.

The first German anti-aircraft artillery used in the Spanish Civil War was a 77mm. gun. These guns were in mechanized batteries of four pieces each. It was soon found that the range was not great enough, the trajectory not flat enough and the bursting charge not large enough. Therefore a new piece of 88mm. calibre, and more calibres in length than the 77mm., was constructed in Germany and shipped to Spain. This piece could reach any bomber with a war load. All sighting apparatus was set and corrected by remote control from a range-finding party some distance from the guns and in a position such that it had a good view of the target. These guns, instead of being emplaced in line, were emplaced at the four corners of a square probably 100 metres to a side. When not firing on targets in the air the guns were used to fire at targets on the ground. Their long range made them particularly effective not only against positions well up on mountains but also against the rear areas including ail the roads over which enemy tanks, artillery and supplies had to advance. The guns were field artillery in that they could be put in or out of battery in a relatively short period of time and could move easily over roads and also over terrain which was not too difficult.

The Italians in Spain relied primarily upon wireless for communications. The Germans used wireless but relied largely upon telephone communications. The Germans in Spain stated that in the war of 1914–18 their communications were not sufficiently developed and therefore frequently were the cause of defeat.

As the result of their experiences in Spain the Germans and Italians made a number of changes in their armament and tactics. It may be said that these changes had to do with increasing the proportion of artillery to infantry, making cannon a part of aviation armament, increasing the number of tanks with cannon, and the calibre of these cannon and improving the communications between all parts of their armed forces so that the maximum benefit could be derived from their artillery fire for both offensive and defensive purposes. By the use of cannon in aviation and in tanks it can be said that in addition to "fire and movement," that is, fire to cover movement, there is "fire in movement." "Fire in movement" was the basis of the success of the German armoured or panzer divisions in 1939 and 1940.

From such data as is available, it is indicated that defeat of the Poles, the Allies in Norway, Holland, Belgium, Flanders and France in 1939–40, was due to their failure to provide sufficient artillery of all types, that is, infantry artillery; horse-drawn, motorized and mechanized field artillery; anti-tank and anti-aircraft artillery, and artillery in aeroplanes and in tanks, to stop by its fire the German blitzkrieg (lightning war) attack. The Allies also failed to have adequate communications and adequate ammunition supplies for such artillery as they possessed. The Allied use of aviation as an independent force with missions away from the battlefield instead of using it to support troops in advance guard-work in battle and in pursuit as an accompanying artillery also contributed largely to their defeat.

The war of 1914–18 proved that the most difficult artillery problem was to give the infantry at all times the amount of accurate supporting artillery fire necessary to ensure its advance by smashing enemy machine gun nests and other strong obstacles to its advance. One of the methods used was the rolling barrage by which a line of bursting shells moved forward at a definite rate of advance determined by a rigid time-table. In addition, the infantry were given small mortars called trench mortars by the Allies and minenwerfer by the Germans; and small cannon generally of the one-pounder type. The rolling barrage did not always prove effective, because the infantry could not always keep up with it. Also, it was not always sufficiently strong to dispose of enemy strong points, with the result that these points would continue to resist after the barrage had passed by. In other words, by holding up the infantry while the barrage passed on they separated the infantry from its barrage. This meant the dislocation of the attack. The first time a full-fledged German attack was stopped during 1918 was during the Champagne battle of July 15 and 16. The same German methods which had hitherto proved so successful failed. The primary reason was that General Gouraud commanding the Fourth French army had, under instructions from Marshal Pétain, thoroughly carried out the echelonment of his defence in great depth with the result that the German infantry lost contact with its barrage. This dislocation of the German attack allowed the French and American infantry to keep down in their trenches until the barrage had passed over and then come up to meet the German infantry attack.

The consequence was that more and more the conclusion was drawn that artillery support to the infantry should be in a greater proportion of mortars and small cannons in the hands of the infantry and a supporting artillery fire consisting primarily of concentrations of fire. The invention and development of the tank came about as the result of this necessity to increase the number of weapons which could be used at close range and without any means of communication such as telephone or wireless, to fire immediately on the targets holding up the infantry advance. The war ended in 1918 without the question of adequate artillery support to the infantry having been fully solved.

The German blitzkrieg methods in 1939 and 1940 have proved that a large increase in the proportion of infantry artillery, tanks with cannon, aviation with cannon, and an increase in the proportion of light and heavy field artillery, puts the infantry in the position where its advance can only be stopped if the artillery of the defence is more powerful in all categories than is the artillery of the offence. In order to provide this increased proportion of artillery and the ammunition necessary to enable it to give its maximum fire while at the same time not robbing the infantry of its mobility, the tendency is to decrease the size of infantry combat units.

In general this is gotten at in two ways: one the German-Russian method, the other the Italian method. In the first the division is cut from four to three regiments of infantry. The artillery of the division is so organized that it can readily be split up to give each of the three infantry regiments its necessary artillery support when operating independently. In other words, the division

during an advance or in battle can be operated as three small but completely armed infantry and artillery units of march and combat. In Italy the division was first reduced from four to three regiments of infantry. In Spain divisions of two regiments of infantry, each with the artillery necessary for their habitual missions, were found mobile on the march and easily handled in combat. In consequence the Italian army was reorganized into such divisions. From three to four of these divisions make an army corps. This corps is flexible both on the march and in combat. The amount of corps artillery has been greatly increased so that the corps commander will always have available the maximum amount of artillery needed for any situation, while his division commanders will never be burdened on the march or in ordinary combat with more than they habitually need. Such information as has been received (1940) from French battlefields indicates that this technique, developed in Spain from previous peace time theories, was the technique used.

The American division for the Regular Army consists of three regiments of infantry; for the National Guard of four. The type of divisions is still being experimented with. An important point in determining the size of the division and its organization is based on the recommendations of the artillery that the proportion of artillery to infantry be increased.

Comparison of Divisional Artillery

			Total
U.S. (3 regt.)	36 75mm. guns	16 155mm. howitzers	52
(4 regt.)	48 75mm. "	24 155mm. "	72
Germany	36 105mm. howitzers 4 105mm. guns	8 150mm. howitzers	48
France	36 77mm. guns 6 75mm. anti-tank guns	24 155mm. howitzers	66
Britain	72 25pdr. 3.45in. gun-howitzers		72
Italy	12 75mm. guns	12 75mm. pack howitzers 12 100mm. howitzers	36
Russia	16 76mm. guns	40 122mm. howitzers	56
Japan	36 75mm. guns	12 105mm. howitzers	48

This table does not show the infantry-artillery of mortars from 45mm. to 81mm.; howitzers 75–150mm., mountain guns 47mm. and anti-tank guns 2j–up millimetres.

The army corps artillery, army and G.H.Q. artillery, including railway artillery, varies greatly in the different countries. See Kurt Passow, *Taschenbuch* der *Heere* (J. F. Lehmanns Verlag, München, 1939). (H. J. RE.)

TYPES OF ARTILLERY

The function of land artillery is to kill troops at a range beyond that of a hand weapon, and to destroy material, obstacles and defences. Various natures of artillery have been developed, suitable to the tasks to be fulfilled. The four main classes are:— field artillery (of which mountain, infantry-accompanying and horse-artillery are lighter varieties); heavy artillery (which is subdivided according to power of foe and of movement); anti-aircraft artillery; trench artillery or mortars.

Thus British artillery is classified, in detail, as follows:—

Light (in India, Mountain) artillery (2·75in. guns and 3·7in. howitzers).

Horse artillery (13-pdr. guns).

Field artillery (18-pdr. guns and 4·5in. howitzers).

Medium artillery (60-pdr. guns and 6in. howitzers).

Heavy artillery (6in. guns, 8in. and 9·2in. howitzers).

Super-heavy artillery (guns of 9·2in. and upwards, and howitzers of 12in. and upwards).

Anti-aircraft artillery (gin. guns).

Field Artillery.- his is capable of accompanying the advanced fighting line of an army. It consists of light guns and howitzers able to keep pace both on the road and across country with the arm it is supporting, and to come into action without previous preparation of the ground. The field gun is, in all armies a piece throwing a shell of from 15 to 18lb. to a distance of at least 10,000yd., although effective ranges are generally less, and weighing less than 30cwt. in action. Before the introduction of mechanical traction the weight was limited to 24cwt. and the range to 6,000yd.

The limit of approximately 30cwt. is due principally to the fact that this weight is as much as a gun-detachment of six men can man-handle.

All modern field guns are quick-firing; that is, the gun recoils on the carriage and returns to the firing position, while the carriage remains steady. This saves the delay due to running up and relaying the gun after each shot, and increases the rate of fire from two rounds a minute to 25. It also enables the gun-detachment to remain behind the gun-shield, instead of having to stand clear of it during the recoil of the carriage.

The field howitzer differs from the field gun in that it throws its shell high into the air, so as to descend at an angle in excess of 45°. This enables it to reach targets, such as men in deep trenches, protected from the direct fire of guns. As this high-angle fire requires less effort than direct fire, the field howitzer is able to fire a shell double the weight of that of the field gun, without exceeding the same weight of equipment. The proportion of howitzers to guns has steadily increased. In the German army (1940), the 77mm. gun in the divisional artillery has been replaced by the 105mm. howitzer.

Special natures of field artillery are:—(a) Horse artillery, which can keep pace with cavalry across country. For simplicity of ammunition supply, the gun may be the same as that of the ordinary field artillery, but in any case the weight behind the team is reduced by mounting the gunners on horses, instead of carrying them on the limbers and ammunition wagons (caissons in American usage). (b) Light or Mountain artillery, which is divided into separate loads which can be carried on pack animals or transported for short distances by hand. It is used in country impassable to wheeled carriages, and has been adapted to serve the newly found need for artillery of accompaniment (*i.e.*, the close support of infantry).

The number of small mortars carried forward by the infantry in an attack has steadily increased.

Medium Artillery.— This consists of guns and howitzers of greater range and shell-power than field artillery, yet sufficiently mobile to accompany the infantry advance. The usual types are a gun of approximately 5in. firing a shell of about 60lb to a range of 16,000yd. and a howitzer of about 6in. firing a shell of about 100lb. to a range of 12,000yd. The 60-pdr. gun is designed to fire upon distant road crossings, railway junctions and other important points which have to be engaged without delay, and before the heavy artillery can come up. The 6in. howitzer fires a powerful shell capable of demolishing buildings and of destroying entrenchments other than those of a semi-permanent nature. It is the principal weapon used in trench warfare. Both pieces are available for counter-battery work, that is, for attacking entrenched guns which have been located by aircraft or by sound-ranging.

The medium gun is an enlarged edition of the field gun. The 6in. howitzer was formerly a short, handy piece, but owing to the increased range now required of it the length of the modem type is as much as 25 calibres.

Heavy Artillery.— This term is applied to pieces heavier than medium artillery including guns up to 8in. calibre and howitzers up to 9·2in. calibre. In modern war it is necessary to attack objectives at least 10mi. behind the fighting front and accordingly road-mobile heavy artillery, which can engage targets beyond the range of medium artillery, has been introduced. The principal gun of this type is the 6in. gun, the latest pattern of which ranges 15mi. with 100lb. shell. It can be fired from the ground without the delay entailed by building a platform; wire mats or similar appliances are used to prevent the wheels from sinking. Modern 6in. guns have split-trail carriages to enable them to be traversed quickly.

A howitzer heavier than the 6in. is required for destroying bridges and semi-permanent entrenchments. The 8in. howitzer fires a 200lbw shell and ranges 18,000yd.; the British 9·2in. howitzer, kno n in the war as "Mother," fires a zgolb. shell ranging 12,700yd.; and the new American 240mm. (9·45in.) how-

itzer, a type of gun used also by the French, fires a 356-lb. shell to a range of 25,000yd. This piece is accepted as the typical modern heavy howitzer, and is about the largest piece likely to be transported by road in future warfare, as it is considered that heavier natures are better transported by rail.

Super-heavy Artillery.— As the size of a shell is increased, the effect increases in a higher ratio. Much of the destructive effect of a 1,000-lb. shell is due to the blast, not to the local destruction caused by the high-explosive charge. The effect of the blast is to bring down walls as much as joyd. from the point of burst, to cause roofs to fall in, and generally to wreck a great building such as a railway station or factory. A single hit from a 12-in. shell might destroy a bridge altogether, whereas ten hits from 6-in. shells, equal to the same weight of ammunition, would only cause easily reparable damage. A further advantage gained by the use of very heavy guns is the greatly increased range. Thus the British 9.2-in. gun throws a 380-lb. shell 14m. while the new U.S. 14-in. gun ranges 22m. with 1,560-lb. armour-piercing shell, and nearly 30m. with a somewhat lighter stream-lined shell. These considerations have led to the extensive employment of super-heavy pieces in land warfare.

Gun versus Howitzer.— Formerly a howitzer was a low velocity weapon fired at a high angle of elevation, while a gun was a high velocity piece with a flat trajectory. The howitzer conveyed the shell to the target with a much smaller propelling charge than the gun, and consequently lasted much longer than the gun before it was worn out. At present all guns are mounted so as to fire at high angles of elevation, in order to attain their extreme range, and use reduced charges as well as full charges and super-charges in order to save wear. On the other hand, the range required of howitzers is now greatly increased so that the 1914 pattern, 12 calibres long, has been superseded by howitzers of 25 calibres and over, firing much heavier charges. The distinction between gun and howitzer is therefore tending to disappear.

Super-heavy pieces are usually fired from railway mountings or at least are transported by rail. But an invader may find it necessary to bring up large howitzers, for the reduction of fortresses near the frontier, before the captured railways can be made available. The difficulty in the way of transporting these pieces by road is the limit of the weight which bridges can carry. Even on the great main roads of western Europe this weight is not more than 30 tons, and on country roads it may be as little as 5 tons. This implies a special type of howitzer, comparatively short and light, capable of throwing a heavy shell to a short range. The German 42-cm. (16.5-in.) howitzer brought up for the siege of Antwerp was only 12 calibres long, and weighed 21½ tons, or about 29 tons on its special wagon. It threw shell of 15·7cwt. to a range of 10,300yd. It was drawn by three traction engines with a fourth in reserve for hills. The recoil gear, carriage, platform (in two parts) and gear for mounting the howitzer formed separate loads, and the piece required 13 traction engines altogether.

The French have a 370-mm. (14.6-in.) howitzer, only 8 calibres long, throwing an 8cwt. shell 11,500yd. It is rendered road-mobile by being carried on two road trucks, one following the other, with an arched girder between them from which the piece is suspended. The United States has an experimental 9·45-in. howitzer on a caterpillar mounting, driven by electricity from a separate vehicle which carries the 150h.p. power unit. The total weight of the vehicle carrying the howitzer is 13 tons.

Long-range Guns.--During the World War the Germans bombarded Paris from a distance of 76m. with specially built long-range guns, throwing 265-lb. shells. This long range was obtained by using a velocity of 5,000ft.sec., and firing at an elevation of 55 degrees, so that the shell passed through the layer of dense air nearest to the earth, and reached the comparatively thin air at a height of 10m. which opposed little resistance to its flight. In this case the greatest height of the trajectory was 24m. Guns of this type cannot fire more than about 30 rounds before they are worn out. Owing to uncertain weather conditions, the accuracy is poor; while the gun is new the shells may be expected to fall within a space of 2m. long by ¾m. wide, but as the gun becomes worn these limits are soon exceeded. Aeroplanes are far more efficient than guns for this kind of bombardment.

Anti-aircraft Artillery.— The problem of hitting a target moving in three dimensions is a difficult one and the additional complication due to a curved trajectory has to be eliminated as far as possible. All A A. guns are therefore flat-trajectory weapons with high muzzle velocities. Ordinary field guns mounted on lorries or trucks, as employed in the war of 1914–18, are of little use. Mobile A.A. guns used in the fighting line, are usually on low wheeled platforms which can be drawn behind a lorry. On coming into action, the platform is lowered to the ground, and levelled by screw-jacks at each corner, so as to bring the pivot exactly vertical. Semi-mobile guns, used in sedentary warfare, are on heavier platforms which are carried in sections and put together before firing; and non-mobile guns, for the defence of fortresses and cities, are on solid concrete or caisson platforms.

The ammunition used with A.A. guns is shrapnel or high-explosive shell; a proportion of the shells are fitted with tracers. These are necessary, since an ordinary shell fired into the air disappears until it bursts, and there is nothing to show whether it has passed close to the target or otherwise. The shell is fused so as to avoid endangering one's own troops by the shell falling among them.

Fire at aeroplanes is entirely by prediction; the course and speed of the target are measured by optical instruments, and the gun is fired at the point where the aeroplane is expected to be, making due allowance for the time of flight of the shell. If the first shot or salvo misses, the plane will at once begin to dodge, and it is useless to fire at it until it has again settled down to a regular course. As the bombers with war loads fly at steadily higher altitudes it has been necessary to increase the power of anti-aircraft weapons. Therefore the 3in. 7jmm. and 77mm. are being replaced by 3·6in., 88mm. and 90mm. guns.

Trench Artillery.— When two opposing forces are entrenched, they tend to press forward till their advanced works are within 100yd. or less of each other. The same thing occurs in siege warfare, when the besieger extends his front trench till it is close to the fortress. The need then arises for a weapon capable of throwing a heavy bomb to a short distance, yet which is so small and light that it can be carried through the trenches. The original piece of this type is the Coehorn mortar used in the sieges of the 18th century. The modern type was introduced by the Germans at the beginning of the war of 1914–18. The Krupp Minenwerfer was a light gun of 2-in. calibre mounted on a short plank. The 50-lb. spherical bomb rested on the muzzle. and had a tubular steel "stick" which extended down the bore of the gun. The piece was fired at an angle of 45 to 7j degrees of elevation, and its extreme range was about 450yd. The 50-lb. bomb, with its high-explosive charge, was capable of wrecking a "dug-out" or blowing in the walls of a trench so as to block it.

As the weight of the jo-lb. bomb rendered ammunition supply in the front trenches a laborious proceeding, the British introduced the light Stokes trench mortar, firing a 10-lb. bomb. This is a weapon of a different type. It is a light steel tube of 3-in. calibre, with a spike projecting into the breech end of the bore. The cylindrical bomb has a small cartridge and percussion cap fixed to its base; it is dropped into the muzzle and slides down till the percussion cap strikes the spike, when the cartridge is ignited and the bomb blown out. The extreme range is about 1,200yd. This enables it to be used from a point well back in the trench system where it is safer and less likely to draw fire than in the advanced works. A 25-lb. Stokes mortar was afterwards introduced, and was used principally for firing smoke shell. Later on, the bombs were fitted with air-vanes to increase their accuracy. The 3-in. Stokes proved such a handy weapon that it was used in mobile warfare as an infantry gun, for the reduction of "strong points" encountered in the infantry advance. Being a high-angle weapon, it was useless against moving tanks.

Heavy Trench Mortars.— Owing to the difficulty of supplying heavy ordnance in sufficient quantities trench mortars were introduced in 1915, capable of throwing a 200-lb. shell about 1,200 yards. The principal piece of this type was the Gatignolles 240-mm. (9.45-in.) mortar. This was in two pieces screwed together,

and was fired from a mounting fixed on a bed of wooden balks. The total weight was about a ton, and it was divisible into five barrow loads. The Allies used this weapon for firing from positions towards the rear of the trench system, where it could be turned on the front trenches in case the enemy invaded them. The Germans used, for the same purpose, a rifled 1 jo-mm. (6·69-in.) trench mortar, firing a shell of 110 lb. to a range of 1,250 yards.

TRANSPORT OF ARTILLERY

At the present time the draught horse is in process of being replaced by mechanical transport for all heavier types of artillery. This change is necessarily a gradual one, and its nature and progress in different countries are partly determined by the extent to which the mechanical transport which has replaced the horse in civil life can be rendered available for military purposes.

Artillery may be mechanized in several ways. The self-propelled gun-carriage has the gun-mounting built into it, and is preferably of the "caterpillar" type. The artillery tractor pulls the gun behind it, and carries the detachment and first supply of ammunition. The artillery carrier or transporter carries the gun on a platform from which it is dismounted, by a ramp, for firing. From the tactical point of view, the self-propelled gun-carriage is not yet satisfactory, as it is too vulnerable and too large for concealment, and requires an undue amount of labour to entrench. The motor is useless while the gun is in action, when, if it were separable from the gun, it would be most useful in bringing up ammunition. Against these defects, however, may be put the asset of its power to move forward instantly if blinded by a hostile smoke cloud. Further it is better suited than other forms of artillery for the support of a rapidly moving force of armoured fighting vehicles.

Tractors and Carriers. — The artillery tractor may be a caterpillar or a vehicle of the lorry type. Both forms are open to the objection that the complicated mechanism of a Q.-F. gun is damaged by rapid travelling on the road, even if the wheels be provided with rubber tyres. This, however, can be obviated by the use of low 2-wheeled travelling platforms, as employed in the Italian artillery for road travel. The caterpillar tractor is good across country, but on roads inherently less rapid and less economical, for its power, than the wheeled vehicle. Various attempts have been made to construct tractors and carriers having both road wheels and caterpillar tracks. The American Christy tractor, now no longer in use, travelled normally on road wheels, and had a caterpillar band which was put on round the wheels for cross-country work. The French St. Chamond carrier-tractor is a complete caterpillar vehicle, with an extra pair of road wheels on extensions of the chassis at each end, which can be raised well clear of the ground, allowing the vehicle to rest on the caterpillar tracks.

Another vehicle, of a different type, is the "4-wheel-drive" lorry, in which the wheels are driven independently. This is excellent on the road, and is capable of moving over easy country. The Pavesi agricultural tractor is a small 4-wheeled vehicle with a flexible connection between the fore and hind carriages, which enables it to adjust itself to irregularities of the surface of the ground. Its four wheels are driven independently and have removable "spuds" which are put on for cross-country work. It has a 16h.p. engine burning paraffin or petrol. The road speed is about five miles an hour, and the machine is therefore unsuited for the rapid transport of reserve field artillery.

The artillery carrier saves the gun from road strains, but entails delay in lowering the gun on to the ground when it comes into action, and in hoisting it up again with a ramp and winch. Many tractors, such as those of the American caterpillar type, can be fitted with platforms and used as carriers. It is not practically possible to fire the gun from the carrier, as this would entail a considerable increase of weight and complication. Any commercial lorry or truck of sufficient capacity can be adapted to carry light artillery. Its movement, however, is generally restricted to hara-surfaced roads. As regards the difficulty of combining a road vehicle, and a cross-country vehicle, the carrier is subject to the same disadvantages as the tractor. Experiments are now being carried out in a number of countries with six-wheeled motor vehicles which may be adapted as tractors or carriers for the lighter natures of artillery. These vehicles are considerably cheaper to manufacture than most of the tractors which have previously been tried, they are good across country, and it seems likely that they will be suitable for commercial purposes in peace, especially in undeveloped countries.

Practice in Other Armies. — The French, in 1920, proposed to introduce an agricultural tractor, encouraged by a Government subsidy, which should be available for the transport of artillery. But it was found that owing to the small size of fields in France there was little demand for the tractor, and no immediate prospect of its superseding the horse. On the other hand, the use of motor lorries is extending rapidly. The French now carry the field artillery, which is required to be highly mobile, on lorries, thus accepting the principle of the carrier, not the tractor. These lorries cannot move off the road, except on favourable ground; therefore each battery carries on its lorries some draught horses or small tractors of the Klectrac or Pavesi type to take the guns into position. The French had 83 of these *batteries portées* at the end of the war.

The Italians are tending to a somewhat different solution. No draught horses are bred in Italy; they have to be imported from Germany. It is therefore proposed that the divisional field guns should be drawn by the Pavesi agricultural tractors already described. The Italian army field artillery, which is required to be highly mobile, will be carried on low platforms, which have springs and rubber-tyred wheels, pulled by fast lorries. When the guns have to leave the roa 1, they will be taken into position by the divisional Pavesi tractors.

In the United States the caterpillar tractor, generally of standard commercial type, has been adopted for tractor-drawn artillery. For rapid movement over good roads experiments are being made of truck transport of light and medium field artillery, both wholly by truck and by combined truck and trailer.

Heavier Natures **of** Artillery. — Medium guns are usually tractor-drawn, the gun being shifted to a "travelling" position in which the weight is divided between the gun wheels and limber wheels. Heavy guns are transported on special wagons, drawn by tractors, which carry the piece itself, while the empty carriage is drawn by a second tractor.

Super-heavy artillery is transported almost entirely by rail, though in 1914 the Germans brought up their siege howitzers, divided into separate loads, on special road-wagons. The railway mounting consists of a massive platform supported by bogies, on which the gun mounting is built. *(See* Pl. II-7.) In the English Elswick type the gun is fired while the mounting is "alive" on its wheels; in other types the central platform is lowered on to the rails before firing. All-round fire from the truck, without special preparation, is only possible with medium guns; for heavier natures the gun is laid for direction by running the truck up or back along a curved siding. Or, in some railway mountings, the gun track is supported laterally by heavy "outriggers" sunk in the ground.

For the heaviest natures the railway is used for transport only, and the gun is lowered on to a previously built platform. Permanent concrete platforms were used in 1914, but these were superseded by "caisson" platforms consisting of iron boxes bolted together and filled with earth, surmounted by a steel platform plate which carried the mounting. Recent American platforms dispense with the caissons, and consist of the platform plate only; this is divided into sections for transport, bolted together on the spot, and pegged down with a number of steel stakes. These platforms can be laid in a few nours, this being a great addition to the value in the field.

Railway mountings can be used for the transport of artillery on light railways, and even on trench railways. Additional narrow-gauge wheels are fitted to the gun track for this purpose. In this case a platform must be used for firing. The limit of the height and width of a railway mounting is the loading gauee of the railways on which it may have to be used; this depends principally

on the size of the tunnels. Practically there is no limit to the length or weight. (X.)

ORGANIZATION

Artillery, unlike other arms, is not fully committed once it has become engaged with the enemy, but retains, in great measure, its liberty of action. Without change of position, its fire can be concentrated or dispersed at will, at varying degrees of intensity, on widely distributed targets. It can be disengaged from the combat with greater facility than any other arm, and, being capable of manoeuvre within striking distance of the enemy, it can be brought again into action in other parts of the battle-field while the fight is still in progress. These important characteristics govern the organization and distribution of artillery in the field. The system must be elastic in order to permit of centralization or decentralization of control according to the situation; and it must allow of the main strength of the guns being collected at points where decisive blows are to be struck.

The **Battery.**—The smallest unit of artillery is the battery, the composition of which is calculated on the assumption that its guns are normally worked together. A battery of artillery comprises three elements, viz.—*matériel*—guns, carriages, ammunition and stores; *personnel*—officers, non-commissioned officers, gunners or cannoneers, drivers and artificers; and *transport*—horses or other animals, motor or other mechanical vehicles, or rail. The number of guns in a battery varies in different countries and in different types of artillery between four and eight though some railway batteries have only two guns (howitzers or mortars); in the British army horse and field batteries have six guns or howitzers in war, anti-aircraft batteries eight, and all others, except super-heavy batteries, have four. Mixed batteries of howitzers and guns no longer exist. The vehicles of a battery include carts, wagons or lorries for the transport of ammunition, stores, provisions and forage. The organization and interior economy of a battery are much the same in all artillery. In the British army the command is held by a major; the second in command is a captain. The battery is divided into sections of two guns each, each under a subaltern officer. A section consists of two sub-sections each comprising one gun with its transport and men, and at the head of each sub-section is the "No. 1" of the gun detachment, usually a sergeant. In horse-drawn artillery the drivers ride the near horses of their respective pairs, each gun and each wagon being drawn by teams of from four to eight horses. On the march the gunners are usually seated on the battery vehicles. In horse artillery, however, the gun detachments are mounted and in light or mountain artillery, drivers and gunners march on foot. In addition to the gunners and drivers there are men specially trained in signalling, range taking, etc., in all batteries, who are either mounted or provided with some form of independent mechanical transport such as motor bicycles or cars.

Higher Organization.— In Great Britain the unit next above the battery is the brigade. In the United States two or three batteries are combined in a battalion commanded by a major; two or three battalions into a regiment commanded by a colonel; and two, three or four regiments into a brigade commanded by a brigadier general. The higher units in other armies are groups or battalions of three or more batteries, two or more groups or battalions usually forming a regiment. These units are distributed to armies, corps and divisions in the same way as units of other arms. Horse artillery is the artillery which supports the cavalry; in Great Britain one brigade of three batteries is allotted to each cavalry division; in the United States one regiment of six batteries (two battalions) is allotted to a cavalry division at war strength. In Great Britain field and light artillery together form the artillery of the infantry division. The British divisional artillery consists of three field brigades, each of three gun batteries and one howitzer battery, and one light brigade of three batteries. Non-divisional field brigades, called army field brigades, are also provided to form a reserve of field artillery at the disposal of the commander-in-chief. Army field, medium, heavy, super-heavy and anti-aircraft artillery are at the disposal of the commander-in-chief. Medium and heavy artillery are normally allotted to corps, super-heavy artillery to armies. Heavy and super-heavy artillery have not usually the complete and permanent organization that distinguishes the lighter natures of artillery and are generally organized, on mobilization, from units of coast artillery. (For natures of guns and howitzers in each class of artillery, see page 469B, TYPES OF ARTILLERY.)

In the United States pack and light field artillery are assigned to the cavalry division; light field artillery to the infantry division; medium and heavy field artillery to the army corps; light and heavy field artillery to the G.H.Q. artillery. The field army has no organic field artillery. The approved organization of the division field artillery brigade comprises two regiments of light guns and one regiment of light howitzers.

In the French Army one regiment of 75-mm. guns and one regiment of 155-mm. howitzers is allotted to each division, two "groupes" of 105-mm. guns and two "groupes" of 155-mm. guns to each army corps, and the remainder of the artillery forms a *réserve générale d'artillerie* which is commanded by a *général de division*. The infantry organization includes 37-mm. guns and Stokes mortars for close support. In the United States army two regiments of field guns (75mm. or 18pdr.) and one regiment of 155mm. howitzers, forming together one brigade, are allotted to each infantry division of four infantry regiments. This assignment of artillery to a three-infantry regiment division continued in 1940 to be under discussion. The infantry organization includes 37-mm. guns as well as mortars for close support. The corps and higher organization is similar to that of the British and French armies. It is obvious that there is variation in the number of field pieces allotted in different countries to an infantry division. Thus 72 are provided per division in the American, 60 in the French and 72 in the British army. On the other hand the number of pieces at the disposal of corps and army commanders generally varies in inverse proportion to the strength of the divisional artilleries, so that the total numbers available per 100 rifles do not differ greatly. In each British division an artillery officer of the rank of brigadier is in executive command of the artillery of the division. There is also a brigadier in command of the artillery of each corps and under him is a commander of the corps heavy and medium artillery. The corps artillery commander commands the divisional artilleries for special deliberate operations only. He is provided with a counter-battery staff whose task is to deal with the hostile artillery. At each army headquarters there is a major-general R.A. whose duties are mainly advisory. The system of command in Continental armies is similar. In the United States each brigade is commanded by a brigadier general. In addition to the brigade commander, there is a chief of artillery both in the corps and army.

Certain auxiliary organizations are now required by artillery. In the British army artillery survey work is carried out by survey companies which are also responsible for sound-ranging and flash-spotting. Signal units are provided down to headquarters of brigades, batteries being responsible for their own signal communications. Searchlight battalions co-operate with anti-aircraft artillery. In the U.S. flash and sound ranging are functions of the field artillery, as are signal communications within the field artillery brigade. The German divisional artillery has as an integral part of its organization one sound, one meteorological, one survey and one communications platoon. The organization for the supply of ammunition is described in a separate section. In addition to the normal chain of artillery command provision is usually made for technical control of the *matériel*, and a variety of training and experimental establishments, such as schools of gunnery, are maintained in most countries.

In the British army all the personnel of the artillery arm in the field, as well as of the coast artillery, is provided by the Royal Regiment of Artillery. Officers and men are transferred from one class of artillery to another at intervals of a few years in order that their training may be comprehensive. In some armies as, for example, the army of the United States, the artillery service is divided into two branches, the field artillery being distinct from the coast artillery corps.

TECHNIQUE

Occupation of a Position. — The actual process of coming into action may be described in a few words. The guns are "unlimbered" at or near the battery position and the gun limbers and teams or tractors sent back under cover. An ammunition wagon (caisson) or lorry is then placed, as a rule, by the side or in rear of each gun, an arrangement which simplifies the supply of ammunition. According to the British practice a battery in action is thus distributed: first the "firing battery" consisting of the guns, each with its ammunition vehicle; then, under cover in rear, the "first line of wagons" comprising teams or tractors of the firing battery, the gun limbers and the remaining ammunition vehicles. The non-combatant vehicles form the "second line of wagons."

Choice of a Position. — The nature of the position to be occupied depends primarily upon the task which is to be carried out. Although "open" positions may have to be occupied on occasions, they are generally to be avoided since guns are quickly silenced in modern war if they come into action in full view of the observing posts of the hostile artillery. As a rule, therefore, artillery use positions concealed from view behind a ridge or other cover, the elevation and direction necessary to hit the target being signalled by an observer who may be either on the ground or in the air. The choice of the position varies to some extent with the nature of the equipment; for instance, an elevated position is better adapted than a low one for high velocity guns on account of their flat trajectory. Other factors which have to be considered are (a) the desirability of a field of fire immediately in front of the guns for shooting at hostile tanks; (b) concealment from air observation; (c) avoidance of ground in which pockets of gas might lie; (d) approaches for ammunition supply. It is usually possible, however, to satisfy only the more important requirements in each particular situation. Cover from hostile fire, as distinct from observation, cannot often be obtained from the configuration of the ground, because, if a gun can shoot over a covering feature, the hostile shells can also clear it. Most of the lighter types of artillery are therefore provided with shields which, with the armoured ammunition wagons (caissons), afford some measure of protection to the guns and detachments. Guns are usually brought into action about 20 to 25 yd. apart, this interval being considered sufficient to minimize the damage which may be done by hostile shell fire.

Ranging.--This process serves to determine the elevation at which a gun will hit the target, or, more correctly, the elevation at which the greatest possible number of shells will fall on the target. This elevation is not necessarily that due to the map range, as it is affectedby the temperature, height of barometer, strength of the propellant, degree of wear of the gun and other factors. When a number of shells are fired from a gun which is pointed at a given elevation, they do not fall in the same place, but are distributed over a space which, at medium ranges, may be 100 yd. or more in depth. The centre of this space is termed the "mean point of impact." The first step in ranging is to determine, by observation of the fall of the shells, two elevations, usually 300–400 yd. apart, at the higher of which shells will fall beyond the target, and at the lower of which they will fall short. These two elevations constitute the "long bracket," within the limits of which the true elevation must lie. This bracket is then "split" by firing at the two intermediate hundreds of yards, and observing the results, thus obtaining a closer approximation to the elevation required called the "short bracket." Finally, corrections of 50yd. or less are made until an equal proportion of rounds are observed to burst over and short. Ranging for line, that is, for lateral direction, is carried out in the same way, and generally simultaneously with ranging for elevation. When time shrapnel is used it is also necessary to determine by observation the length of fuze which will give bursts at the most effective height above the ground.

Ranging by Map or Survey Methods. — It is possible to open effective fire by surprise without preliminary ranging, if the range and line can be obtained by measurement from accurate large scale maps or, in the absence of such maps, by "fixing" the positions of guns and targets by survey methods. For such "predicted" shooting certain meteorological and other information is necessary to determine the corrections which must be applied to the true range and line. A special section in each army corps, known in the British Army as "Meteor." keeps the batteries informed as to atmospheric conditions. The guns must be carefully "calibrated," a process which consists in determining the error due to wear at a known range. Survey methods cannot generally be used in very mobile operations owing to the time required to carry out the necessary preliminary work.

Sound Ranging. — This is effected by observing the moment at which the sound of the burst of the shell reaches each of a chain of recording instruments. It has recently been improved so as to give very accurate results under suitable weather conditions from a set of instruments occupying as little as 2,500 yd. of front. The setting up of the instruments takes the rather lengthy time of from 24 to 48 hours, which limits the employment of this method in mobile warfare.

It is of particular value in trench warfare for locating hostile guns by means of their reports.

Laying. — "Elevation" may be defined as the vertical inclination of the gun, "direction" as the horizontal inclination to the right or left, necessary to direct the path of the projectile to the object aimed at. In order to lay the gun in the "line of sight," *i.e.*, the line joining the sights and the point aimed at, the gun has to be "traversed" right or left so as to point in the proper direction, and also adjusted in the vertical plane. The simplest form of laying is called the "direct" method, which is employed if the point aimed at is the target and can be seen by the layer. He has then merely to look over or through the sights. But the point laid on is rarely the target itself. In war, the target, even if visible, is often indistinct, but in most cases, it cannot be seen at all from the gun position. An "aiming point," a conspicuous point quite apart and distinct from the target, has then to be employed ("indirect" method). When the guns are behind cover and no natural aiming point can be seen, an artificial aiming point is often made by placing a line of "aiming posts" in the ground. An alternative to aiming posts is now provided by the "paralleloscope" which is a mirror set up a few feet from the gun. When this device is used the layer keeps the gun in the correct line of fire by laying upon the reflection of the sights in the mirror. Finding the "line" in the case of indirect laying involves the calculation of the angle at which the guns must be laid in order that, when the sights are directed upon the aiming point, the shell will strike the target When a gun is laid for elevation by the indirect method, two angles to the horizontal plane have to be allowed for, viz., that due to range and that due to the difference in level between the gun and the target. The latter is called "the angle of sight." When the target is above the level of the gun, the angle of sight has to be added to the elevation due to the range; when the target is below the level of the gun the angle of sight has to be deducted. In all cases the actual elevation of the gun to enable the shell to strike the target is a purely mechanical adjustment, the gun being moved to the required angle with the aid of an elevation indicator or a clinometer. Frequently the battery commander directs the guns from a point at some distance, communication being maintained by signallers or by field telephone. Instruments of precision and careful calculation are, of course, required to fight a battery in this manner, many allowances having to be made for the differences in height, distances and angle between the position of the battery commander and that of the guns.

Fire. — In the British service three methods of fire for effect are used within the battery. These are: —

Gun fire, in which the guns fire independently at any rate which may be ordered;

Battery fire, in which the guns fire in succession throughout the battery;

Salvo fire, in which the guns are fired simultaneously on the order of the gun position officer.

The application of fire by batteries acting in combination is dealt with in section on TACTICS.

Use of Various Natures of Ammunition. — Shrapnel, which is fired by most guns and in some cases by howitzers, is used against troops in the open, for offensive and protective covering fire and for general harassing purposes. The forward effect of the bullets makes it especially effective when fired in enfilade. High

explosive shells with instantaneous fuzes, which are usually fired in addition to shrapnel by all natures of guns as well as by howitzers, are also used against troops in the open and for covering and harassing fire. They are further employed for wire cutting, for engaging troops under light cover and against tanks. High explosive shells with graze and delay fuzes, are used against troops in trenches and for the destruction of buildings and other strong cover. High explosive shells with time fuzes are used against aircraft. Smoke shell are employed for screening effect, to mask hostile fire and to deny observation to an enemy. Star shell are sometimes used for purposes of illumination, but they are not of great value in mobile warfare. (For description of the various types of projectiles see AMMUNITION.)

Signal Communications. — The methods at present employed on the ground are line telephony, using voice or buzzer, and visual signalling. Aircraft communicate with batteries by means of wireless telegraphy and batteries with aircraft by means of wireless telegraph and panels, *i.e.,* strips of white cloth which are laid out on the ground. Radio telephony is being developed by most countries but it has not yet reached the stage of practical utility in the field.

Observation of Fire may be done by the battery commander himself, by a special "observing" party or by an observer in an aeroplane or balloon. The difficulties of observation vary considerably with the ground, etc , for instance, the light may be so bad that the target can hardly be seen, or again, if there he a hollow near the target, a shell may burst in it so far below that the smoke appears thin to a ground observer, the round then being wrongly judged "over" or "short," or lost altogether. Smoke is often used in ranging with air observation to facilitate picking up the rounds. Observations from the air are signalled to batteries by wireless, some form of code being employed by which the fall of rounds can be plotted on a chart.

SUPPLY OF AMMUNITION

In 1914 it was considered that 500 rounds per field gun should be in hand in the theatre of war at the beginning of a campaign, with a reserve of 1,000 rounds per gun in the arsenals. It was found that this allowance was absurdly inadequate even in the more mobile phases of the World War. For great attacks on entrenched positions it was necessary to employ one field gun per 10yd. on fronts of many miles, and each gun was frequently required to fire 500 rounds or even more in a day. It was therefore essential to increase the scale of manufacture and to revise the methods of supply. The solution of the problem of supply was found in the development of the use of motor transport and, for periods of trench warfare, of light railways and specially laid trench railways.

Since 1918 a new system of ammunition supply has been introduced in the British army which will allow of a more abundant and rapid supply of ammunition in mobile warfare than ever before. Maintenance companies, under corps control, carry ammunition from railheads to ammunition companies, under divisional control. These, in turn, deliver to batteries or, alternatively, to horse-drawn divisional ammunition columns. Maintenance and ammunition companies are composed of motor lorries and have respectively a radius of action of 25 m., so that guns can be served over 50 m. from railhead. The divisional ammunition column (horse-drawn) is regarded as a mobile reserve of ammunition for the divisional artillery and is used as a link in the chain of supply only when lorries of the ammunition companies cannot deliver direct to batteries, *e.g.,* when the battery positions are on difficult ground away from roads. Army field brigades and horse artillery brigades have special brigade ammunition columns whose functions are similar to those of the divisional ammunition columns.

Some ammunition vehicles, which are usually lightly armoured, are also included in the batteries themselves. The number of rounds carried by them varies from 100 to about 300 per gun in different types of artillery. The greater the amount of ammunition a battery carries with it, the more independent it is; on the other hand, every additional wagon or lorry makes the battery more cumbrous and, by lengthening columns, increases difficulties of manoeuvre and deployment. Formerly the artillery was hampered by having to carry the reserve of small arms ammunition for infantry and cavalry, but this is no longer the case. When it is anticipated that the expenditure of ammunition in an operation will be greater than can be replaced immediately, dumps are usually placed at the guns or in suitably advanced positions; and, in a retreat, ammunition should also be dumped where it can be picked up by batteries as they withdraw. This latter expedient was used successfully by the British in the retreat from Mons in 1914.

In the army of the United States the field artillery battalion has a combat train which carries reserve ammunition; the field artillery brigade has an ammunition train; and the corps and army have ammunition trains. Ammunition supply is normally from the army to divisions.

In the French Army ammunition is conveyed from railheads (gares de *ravitaillement*) to delivery centres (centres de *livraison*) or advanced depots by motor transport units of armies. It is then conveyed to batteries by lorries of the corps artillery park (*parc d'artilleries* de corps *d'armée*), transport of the corps heavy groups, horsed and motor vehicles of the divisional artillery park sections and group ammunition columns. The main feature of the French system is its flexibility, the various transport units in the forward area usually being under the control of corps for use in the way best suited to each situation. In the American army corps trains of motor transport supply ammunition to brigade ammunition columns which may be mechanized or horsed.

TACTICS

In modern war it is found that infantry, in face of opposition, are immobilized and driven to seek cover as soon as they get within the zone of the enemy's aimed rifle and machine gun fire. Attacking troops can only continue to advance — (and without advancing no decision can be gained) — by enlisting the aid of an arm which is capable of keeping down the enemy's fire while itself remaining sufficiently immune by reason of the distance from which it can operate, or by armoured protection as in the case of tanks. At present the artillery affords the principal means of dominating the enemy's fire. The advent of tanks has, however, profoundly affected the rôle of artillery in battle and the new tactics have not yet been fully evolved. Tanks are capable of relieving the artillery of various forms of support required by infantry and cavalry, but tanks themselves require artillery support if they are not to suffer heavy casualties. The capabilities of the tank have not yet been completely determined, nor can they be until design has reached a greater degree of finality and further war experience has been gained. Further, the relative position of tanks and artillery is becoming confused since some of the most modern types of armoured artillery on self-propelled carriages are themselves but tanks under a different name. The process of mechanization of artillery transport, which is still in progress, also affects the employment of artillery. Artillery tactics are, therefore, at the present day in the midst of a period of evolution. Many of the statements which this article contains will be subject to considerable modification in the near future.

Developments during and since the World War have greatly increased the range, accuracy, fire power and mobility of artillery. A further important advance has been in methods of survey. There are certain limitations to the full development of the power of artillery, the most serious of which is perhaps the difficulty of including in mobile formations sufficient artillery to break down modern defences, and of supplying it with ammunition. Another important limitation which is still engaging the attention of military authorities in all countries is the unsatisfactory nature of the means of signal inter-communication at the disposal of modern artillery. Good signal communications between artillery commanders, their guns, and the troops they are supporting are of vital importance.

Application of Fire. — The principles of surprise, concentration and economy of force (*i.e.,* economizing strength while compelling dissipation of that of the enemy) are generally held to be

of special importance in the application of artillery fire. To obtain surprise it is necessary first to conceal the concentration of the guns and the occupation of positions. In order to evade detection by hostile aircraft, large movements of artillery are now generally carried out at night. Should they be carried out by day, skilful use of cover is necessary to screen movement from observers on the ground. Once the guns are in position, care has to be taken not to disclose their position by firing prematurely and, to this end, the survey methods of working out lines of fire and ranges, already alluded to, are of particular value, as the warning which used to be given by preliminary registration can be eliminated by their adoption in certain circumstances. There is, further, considerable scope for exploiting the value of surprise after the presence of the guns has been disclosed by the opening of fire. Stereotyped systems of shooting should be avoided and damage and casualties increased by bringing fire to bear on the enemy at unexpected times and places and in unexpected ways.

Concentration of effort is as essential in the employment of artillery as in the case of any other arm. The maximum amount of fire must be directed upon the targets which are of greatest importance, and bombardments should be intense and short rather than weak and prolonged. The best means of securing concentration is to centralize command, and it is thus a general principle that control should be vested in the highest commander who can exercise it effectively in any given situation. For effective control, a commander must be in communication with the guns and in touch with the ever-changing situation of the troops he is supporting. When operations are of a deliberate character, inter-communication is comparatively easy to maintain and information is fuller. Control may then be exercised from divisional or even corps headquarters. In very mobile operations, however, artillery brigade or battery commanders will often have to act upon their own initiative, subject to broad instructions from their superior commander.

The maintenance of the principle of concentration involves a strict observance of the allied principle of economy of force. Artillery should be economically allotted to its various tasks and where possible a reserve should be formed. The various types should be employed against the targets they are designed to engage. Thus it would be wrong to use a powerful weapon for a task which could be equally well performed by a less powerful one the life of which is longer and its ammunition more easily supplied. Fire should never be opened without a definite object, and the expenditure of ammunition should be proportionate to the tactical importance of the task. Economy is further obtained by accuracy of fire, but occasions arise when some degree of accuracy may have to be sacrificed to save time and to ensure surprise.

Observation. — Whenever possible, artillery fire is directed by observation. Observation may be carried out from the ground or from the air. Ground observation is most suitable for shooting on targets on the immediate front of friendly troops, and observation posts are selected, whenever possible, so that they may overlook the foremost elements of the troops who are being supported as well as the areas in which targets are to be engaged. Observation from air-craft is largely used for counter-battery work, for fire on distant targets and for dealing with vulnerable and fleeting targets which cannot be seen from the ground. In the British army the requirements of the artillery in air observation are met by army co-operation squadrons of the Royal Air Force. These squadrons also provide photographs of the enemy's positions and rear organization which are of great value in the discovery and selection of targets. Balloons are also used for purposes of observation, but they are handicapped by their vulnerability and the distance from the enemy at which they must operate (see also under TECHNIQUE).

Co-operation with Other Arms. — As the rôle of the artillery is to support the other arms, its action is governed by their requirements. The question of co-operation with the other arms is, therefore, one of special importance. Artillery officers of all ranks have to keep themselves informed of the general situation and plans of commanders whom they are supporting. The best means of ensuring good co-operation is for headquarters of artillery and of units with whom they are co-operating to be in close proximity. Liaison officers are also used to aid in keeping touch, and artillery patrols may be sent forward to supplement personal reconnaissance and the information iurnished by artillery observers. The artillery frequently has to rely on close reconnaissance aeroplanes or on rockets or other special signals for information of the situation of the forward troops. The other arms are trained to supply constant information to the artillery as to their movements and the obstacles which they encounter; this information is essential if artillery support is to be effective. Another important aspect of co-operation lies in the co-ordination of the action of the artillery with that of the weapons of the other arms. For example, artillery fire must be directed in such a way as best to supplement the fire of machine guns and the action of tanks.

ATTACK

In the attack the object of the artillery is to assist the other arms .to maintain their mobility and offensive power. Its tasks may be summarized as follows: — (i.) artillery preparation, (ii.) covering fire, (iii.) close support, (iv.) counter-battery work, (v.) harassing fire, (vi.) co-operation in pursuit.

Approach March. — An army advances against the enemy covered by the advanced guards of its several columns. During the approach march some light, field and possibly some medium artillery will usually be allotted to the advanced guards whose duty it is to drive in the enemy's protective troops by bold and vigorous action. If the artillery allotted to the advanced guards proves insufficient to overcome the enemy's resistance it may be reinforced from the main bodies. If the enemy is in strength a stage will be reached when the advanced guards will no longer be able to advance and when the main bodies or portions of them will be deployed. A plan of attack will then be formed by the commander of the force. If the enemy has been met on the move, or found in a hastily occupied position, the situation will call for rapidity of action, as the dominant need will be to prevent him from seizing the initiative or strengthening his defences. If, on the other hand, he is in an organized position strengthened by artificial defences such as wire entanglements, trenches, field works, etc., the attack cannot be launched without deliberate and methodical arrangement and it must be supported by a strong concentration of artillery,

Dispositions. — In disposing the artillery, the governing considerations are (i.) concentration of the maximum fire to assist the decisive phases of the attack; and (ii.) ability to support the advance to as great a distance as possible without moving the guns. This last requirement entails siting the guns well forward, the most advanced field guns being as a rule no further behind the leading troops than is necessary to obtain cover and to clear the heads of the infantry.

Plan. — The artillery plan comprises the scheme of fire and the arrangements for command, control, communications and movement of artillery in support of the advance. A commander will often have to decide whether it is important or not to use the full power of his artillery in his attack. To develop its full strength the artillery may often require more time for preliminaries than the other arms, and a plan of attack may suit it which does not best suit the other arms. In such a case a commander will generally treat his artillery as the predominant arm if the enemy's defences are strong.

Artillery preparation consists of the bombardment of the enemy's defences before the attack is launched, its objects being to inflict loss and damage, to cut wire obstacles — if tanks are lacking — and to undermine *moral.* If the enemy's positions are not strong or if tanks are available, artillery preparation may be dispensed with and surprise ensured thereby. If it is undertaken it should be as short and heavy as possible.

Covering fire may take the form of a barrage (*i.e.,* a belt of fire) moving ahead of the assaulting troops; of concentrations upon successive localities; of smoke screens; or a combination of any or all of these forms of fire. A barrage has some measure of destructive and neutralizing effect on all troops on the ground over which it passes. It is the simplest method of giving support when the enemy's positions cannot be located with accuracy — and in

modern war this is the normal state of affairs, owing to the difficulty of seeing machine-gun posts, etc. Objections to the barrage are that it is wasteful of ammunition and that the guns available in modern armies permit of this form of support in very inadequate measure. A very thin barrage can be provided by one field gun to 30yd. of front, but even this diluted form of barrage cannot be provided by the divisional artillery for more than a very short time nor over more than a small fraction of the divisional front, *e.g.*, in the case of the British division it could be provided on about one-eighth to one-tenth of the frontage occupied by the deployed infantry, the remainder of the frontage being denuded meanwhile of artillery support. It is therefore obvious that, in face of strong opposition, reliance would have to be placed upon considerable reinforcements of army artillery units or upon tanks to supplement the action of the artillery. In the provision of covering fire, field guns are used as a rule to shoot nearest the assaulting troops, who are trained to move as close to the bursting shells as possible; field howitzers and medium artillery are used to give depth to the fire and to shoot on more distant targets. As a rule covering fire is arranged in its early stages according to a time-table based on the expected rate of advance of the troops, subsequent support being given by observed fire from guns advanced if necessary during the fight. The Spanish Civil War developed the use of aviation as a reinforcement, by its fire, to the artillery. From Poland, to include the Battle of France, the habitual use of this method by the Germans gave them a great advantage over their adversaries who had no such support.

Smoke shells are fired by artillery in conjunction with other types of ammunition or alone. The principal use of smoke is to furnish concealment to attacking troops in order to enable them to move unobserved for the purpose of effecting surprise. By its use an attack can get to close quarters without being seen and smoke clouds can often be so disposed as to enable the assault to be launched from an unexpected direction. Smoke screens may also be used to conceal the movement of reserves. Smoke is also of great value to reduce casualties among the assaulting troops by preventing the enemy's fire from being aimed or observed, and it should therefore be the object of the attacker to use it in such a way as to blind artillery observation posts and to mask machine gun positions, strongly defended localities, and anti-tank weapons. Smoke screens may also be put down by artillery to protect open flanks, or to prolong a front of attack and so induce the enemy to disperse his fire.

The tendency of an enemy, when a smoke cloud is put down, is to pour a heavy fire into it and this fact has to be borne in mind in evolving plans for its employment. The actual production of a smoke screen requires great skill and the wind and weather have to be carefully considered. If smoke is fired indiscriminately it may interfere seriously with observation from both ground and the air, with reconnaissance during battle, with signalling or with operations of troops on the flanks.

Close Support. — The prearranged covering fire may not be sufficient to nvercome all resistance to the advance and leading units therefore have to be accompanied by some artillery to obviate the delay which would be entailed in signalling to guns at a distance. So much is generally admitted; but the nature, command and organization of the accompanying artillery are matters on which opinions differ. Moreover, the infantry are not satisfied with guns of accompaniment, but demand a weapon of their own in the actual firing line to deal with tanks. It is impossible to go into the whole controversy in this article.

The British gun of accompaniment is at present the 3.7-in. light howitzer, but this weapon is generally considered too large and its shell is so heavy as to present serious difficulties in ammunition supply. Field artillery is also used for close support to replace or reinforce the light howitzers. The French infantry organization includes 37-mm. guns and Stokes mortars, but they also favour the employment of the 75-mm. field gun which may be provided with a special low carriage and taken into action by a small tractor. Other nations have introduced pack guns or special light guns or howitzers which can be drawn as far forward as possible by small tractors and can then be divided into loads and carried up by hand. Experiments with various kinds of equipment are being carried out in most countries. It will be difficult if not impossible, to combine in one weapon the requirements of close support, which call for a comparatively heavy shell and a curved trajectory, and those of an infantry anti-tank gun, which demand a flat trajectory, a rapid rate of fire and comparatively small calibre. It therefore seems probable that two weapons will be evolved, both mobile, and possibly carried or drawn by small armoured tractors, but one in the nature of a small howitzer for close support and the other in the nature of a heavy machine-gun capable of stopping tanks up to 1,000yd. or 1,500yd. range.

Counter-battery Work comprises the location, neutralization and, when possible, destruction of the enemy's artillery. The problem of dealing with the hostile guns is given much greater attention in all armies than was the case before the war of 1914–18. It now enters into operations of every kind and in varying degrees lies within the sphere of responsibility of every artillery commander. Special counter-battery staffs are generally provided at corps headquarters. The chief sources of information as to the enemy's artillery are (i.) observers in aircraft; and (ii.) flash-spotting and sound-ranging units on the ground. In addition, artillery and infantry observers are trained to send back information. A portion of the attacker's field and medium artillery is usually allotted the task of engaging the hostile guns before and during an action with the object of keeping down their fire and so facilitating the advance of the assaulting troops.

Harassing Fire. — The objects of harassing fire are to wear down the enemy's fighting spirit, to inflict casualties and damage upon him, to prevent movements of reinforcements and ammunition and generally hinder the conduct of the defence. Harassing fire has to be reduced to a minimum in mobile war owing to the small quantities of ammunition which are available; in deliberate operations or static warfare there is great scope for its development.

Pursuit. — During an advance artillery is pushed forward to support the infantry and to assist them in pressing the enemy, batteries usually being moved alternately within brigades so as to ensure that the covering fire will be continuous. But to obtain decisive results in a pursuit it is necessary to launch against the enemy a special pursuing force, composed of mobile troops. Mechanized artillery is of special value with such a force, and it should be handled with the greatest boldness, risks being accepted which would not be justifiable at other times.

DEFENCE

In defence the artillery assists in the protection of the other arms and co-operates with them in repelling the enemy's assaults. Its tasks may be summarized as follows: — (i.) counter preparation, (ii.) fire to repel assaults, (iii.) anti-tank defence, (iv.) counter battery work, (v.) harassing fire.

Dispositions. — In defence the artillery has to be sited in such a way that it will be able to bring the full weight of its fire to bear in front of the line of infantry defences on which the commander intends to stop the enemy. In mobile war the infantry defensive position will generally consist of a chain of defended localities, and it will usually be in front of this line that the artillery will be required to shoot in order to break up an assault. In more deliberate operations, however, time and resources may permit of the defensive position being more highly organized. It may then consist of a lightly held forward zone, intended to absorb the first shock of a heavy attack, and a strongly held main zone in which the battle is to be fought out. In this type of defence the bulk of the artillery has to be sited further back with the object of bringing the main weight of its fire to bear in front of the main zone, a small proportion only of guns being allotted to support the troops in the forward zone. This method of defence was exploited by Pétain in stopping the final German offensive of July 15, 1918, and it has found much favour in the eyes of soldiers. The bulk of the guns are not sited in such advanced positions in defence as in attack for two reasons, firstly, that they may not be easily neutralized by the attackers' artillery, and, secondly, that they may not be over-run in the first rush of an assault. A proportion of the guns must be in forward positions, however, for the purpose of

engaging the enemy's artillery and rear communications and of hindering arrangements for an attack. The fulfilment of these requirements results in the defender's artillery being distributed in depth. An important factor which must also be considered in disposing the artillery is the problem of anti-tank defence. This is discussed below. An essential requirement of defensive positions to be occupied by infantry, besides facilities for siting the guns, is suitability for artillery observation. It is always desirable that there should be some rising ground from which observation can be carried out, and such localities should be so far behind the foremost defences that they will not be captured, and the eyes of the defence blinded, by a minor penetration by the enemy.

Plan.—The artillery plan of defence comprises, besides the arrangements for dispositions, which are discussed above, the scheme of defensive fire and the policy which is to govern counter-battery action. Surprise is as important in defence as in attack and it is therefore important that the fire plan should not be disclosed prematurely. A favourite device is to keep as many as possible of the defending guns silent until an attack develops and then to engage the enemy with an unexpectedly heavy fire. In order to conceal the battle positions of the defending artillery, guns which are required to be active often shoot from temporary positions which they vacate before the enemy's attack is launched. It is important to make arrangements to concentrate as much as possible of the available artillery fire on any particular portion of the front which may be attacked by the enemy and to make all possible preparations to support counter-attacks. Smoke has to be used with caution in defence as it is liable to obscure the view of the defenders and so to hamper their fire.

Counter-preparation is the term applied to fire which is delivered with the object of breaking up an attack before it can be launched. It is directed against probable forming-up places and forward communications in order to disorganize the enemy's troops when they are suspected of being about to assault. A plan of predicted fire is usually arranged as soon as a defensive position is occupied but, if the enemy's troops can be seen and signal communications can be maintained, it is more effective to shoot with direct observation.

Repulse of Assaults.--Once an attack is launched it becomes the aim of the artillery to direct fire on the assaulting troops and reserves. It is desirable that, as in the case of counter-preparation, such fire should be controlled by observation, but this is not often practicable. Attacks may be launched under cover of smoke or in the half light of dawn, and signal communications may be cut by hostile fire; even when other conditions are favourable, observation will be rendered impossible when there is such a force of artillery that observers are unable to distinguish the shells of their own batteries. It is therefore a rule to detail targets to be engaged by all batteries with predicted fire. Such targets will generally be the most probable lines of approach for the enemy and other vulnerable portions of the front, and the fire of the guns must be carefully co-ordinated with that of the infantry weapons, especially with that of machine guns. The artillery resources of present armies will not permit of continuous belts of artillery fire being placed in front of the infantry positions as was done in the war of 1914–18, and it is not to be expected that sufficient resources will be forthcoming in the future for the resuscitation of the "standing barrage" unless periods of static warfare recur.

Anti-tank Defence.—A considerable share of the responsibility for anti-tank defence falls upon the artillery. The anti-tank weapons of the infantry are generally reinforced in the forward defences by some light or field pieces which are sited in concealed positions from which they can deliver a sudden fire at short range. A serious nbjection, however, to the employment of artillery in this task is that guns sited in forward and exposed positions are of little use for general purposes of defence. A second line of defence is formed by the main force of the artillery, all battery positions being chosen as far as possible so as to provide a field of fire against tanks. In addition, some guns have to be disposed for the protection of headquarters and other important points in rear.

Counter-battery work is generally carried out by the defenders with the object of weakening the hostile artillery before an assault can be launched. Once the attack develops, however, it may be preferable to direct the full power of the defending artillery for a time upon the assaulting troops.

Harassing Fire.--In a defensive action of a temporary nature this form of fire will not generally be developed owing to the necessity for economizing ammunition. When resources permit, however, an enemy's offensive preparations may be considerably hampered by a well devised scheme of harassing fire.

Withdrawal.—When a force is retiring in face of an enemy, mobile artillery is of particular value for covering the withdrawal of the other troops. Thus rear guards usually contain a large proportion of guns. Enemy columns should be engaged at long ranges with the object of forcing them to halt and deploy as frequently as possible. Command of the artillery will generally have to be decentralized to infantry brigades or corresponding units in this form of operation, and batteries should retire alternately in order that continuous support may be provided.

ANTI-AIRCRAFT DEFENCE

The problem of anti-aircraft defence enters into all forms of action against a well-equipped enemy, and anti-aircraft artillery is now provided in most armies. Anti-aircraft artillery may act in co-operation with fighting aircraft, when its main task will be to assist them by breaking up formations of hostile aircraft and by indicating their whereabouts by shooting at them. It may also act independently; its rôle is then to destroy hostile aeroplanes and to deny them opportunities of bombing and detailed observation. Anti-aircraft artillery will usually be employed for the protection of columns on the march and of forward areas when an army has deployed. Owing to the great radius of action of modern aircraft, anti-aircraft artillery has also to be provided for the air defence of bases, headquarters and other important points on the lines of communication of an army. Searchlights and sound detecting apparatus form part of all anti-aircraft regiments.

POSITION WARFARE

Military opinion is divided as to the likelihood of a recurrence in the future of periods of position warfare such as were experienced in the war of 1914–18. Modern armies are being trained for mobile operations, but in most countries the lessons of siege warfare which were learnt between 1914 and 1918 are recorded in military text-books. A modern entrenched position consists of an elaborate system of trenches, strong field works and barbed wire entanglements and it is arranged in successive zones in great depth so that it cannot be penetrated by a single attack. The work of the artillery in routine trench warfare is to exhaust the enemy's strength by harassing and counter-battery fire. The tactics of the attack on a fortified position are much the same as those of the attack on a position in mobile warfare. The main points of difference are: (a) the details of the defences are definitely known from aerial photographs: (b) the obstacles, such as barbed wire, are more formidable; (c) the defenders will have better cover from fire in their trenches and in deep dug-outs so that the barrage and bombardment will be less effective. The first point implies that the bombardment can he concentrated on definite points, instead of being more or less spread over the country; the second requires that field guns and, if possible, tanks, must be pushed forward to cut the wire; the third entails the employment of a strong force of field and heavy artillery.

Savage Warfare.—While the general principles outlined in the foregoing sections also govern operations in undeveloped and uncivilized countries, considerable modifications have to be made in the methods of their application. The difficult nature of the country and the absence of roads often make it impossible to use wheeled transport. In mountainous or bush country it is therefore usual for the bulk of the artillery to consist of light guns and howitzers which can be carried in pack. When field and medium guns can be employed, however, they are often of special value for the distant bombardment of villages and towers. The difficulties of ammunition supply are generally great and the artillery has therefore to be used economically. In savage warfare accurate large scale maps are seldom available and reliance has to be placed chiefly upon fire observed either from the ground or the air. In

bush country it is usually necessary to provide escorts for all artillery both on the line of march and in action.

Gas Warfare.—Though all civilized nations have condemned the employment of poison gas in warfare it is considered necessary to take measures for defence against it and to reserve the right to freedom of action in case an enemy refuses to give an undertaking not to use it. The chemical composition and effect of such gases is described under CHEMICAL WARFARE; we are here concerned with their tactical employment by artillery.

Gas shell bombardment has been, up to 1940, the most usual of the very many forms of gas attack. Bombardments in the World War (1914–18) were of various natures according to the object in view. Short concentrated bombardments with non-persistent gas were employed with the object of inflicting casualties by surprise. In such bombardments it was necessary to fire at a rapid rate from a number of batteries simultaneously, in order to produce a strong concentration of gas so quickly that casualties would be caused before respirators could be put on. Bombardments with persistent gas, such as mustard gas, were generally used if it was desired to render certain areas of ground dangerous to occupy for considerable periods of time. A third type of bombardment took the form of harassing fire in short bursts at irregular intervals. This type of fire was employed to interfere with the hostile artillery or to interrupt traffic and generally to reduce the efficiency of troops by compelling them to wear their masks for long intervals. In all types of bombardment high explosive shells were frequently used in combination with gas shells to increase disorganization as well as to conceal the presence of the gas as long as possible.

Gas shells require a special range table, as they are lighter than ordinary shell. They may be employed with any calibre of gun or howitzer and usually contain gas in liquid form. They are fired either entirely by map or after preliminary ranging with ordinary shell, as their impact cannot be observed. Hot sunshine causes volatile gas to disperse quickly, and a strong wind blows it away; gas is therefore most effective on a cloudy, still day. The shells are pitched to windward of the target so that the breeze will carry the gas in the required direction. In this respect guns are more efficient than gas cylinders, as they are not obliged to await the coming of a favourable wind. The number of gas shells required for an effective bombardment varies according tp the weather, the calibre of the piece, and the nature of the gas used, but it is always large, as the gas content of shells is small for their weight. The difficulty of supplying the ammunition in adequate quantities, therefore, considerably restricts the use of gas shells in mobile warfare. (See AMMUNITION; BALLISTICS; EXPLOSIVES; ORDNANCE; for naval guns *see* GUNNERY, NAVAL.) (J. N. K.; X.)

ARTILLERY SCHOOLS, U.S. The artillery of the United States army is divided into two separate arms, the Field Artillery and the Coast Artillery corps, and for each the War department maintains a special school. That of the coast artillery was established in 1824 at Ft. Monroe, Va. as the "Artillery School of Practice" and is the oldest of the army's special service schools. The course for regular army officers lasts nine months, that for National Guard and Reserve officers three months. There is also an advanced technical course of nine months for regular army officers and special courses in clerical training. For graduates of the regular army courses, the school offers refresher courses. In 1939 the staff of the school consisted of 25 regular army instructors and 21 enlisted instructors.

The field artillery school is located on a reservation of 51,000 acres at Ft. Sill, Okla. The main departments of instruction are animal transport, gunnery, matériel, tactics and communication, and extension courses. The courses offered annually are as follows: the regular course of nine months for army officers; two National Guard and Reserve* officers' courses which last three months each; an advanced course in horsemanship which lasts nine months; an advanced course in motors which lasts four and a half months, an advanced course in communication which lasts four and a half months, and a refresher course of one month principally for officers who have been detailed away from the field artillery. The school offers in addition several courses for enlisted men. In 1939 the school's teaching staff included 31 officer instructors and 58 enlisted instructors. The attendance at all courses except the refreshers in that year was about 450.

The strength of the Coast Artillery corps on June 30, 1939 was 10,747 officers and 32,939 enlisted men; that of the Field Artillery was 18,772 officers and 59,739 enlisted men.

ART INSTITUTE OF CHICAGO was incorporated on May 14, 1879, for the "founding and maintenance of a school of art and design, the formation and exhibition of objects of art, and the cultivation and extension of the arts of design by any appropriate means." The building, of Italian Renaissance design, faces Adams street on the lake front, and houses more than 150 galleries, schoolrooms, studios and offices, the Ryerson art library (35,969 volumes), the Burnham architectural library (8,249 volumes), Fullerton Memorial hall and the Kenneth Sawyer Goodman Memorial theatre. The 1,300 paintings include pieces from the Italian, Netherlandish, French, British, American schools, notably the Birch-Bartlett, Coburn, Eddy, Kimball, Palmer and Ryerson collections. The print department contains over 30,000 drawings, engravings, etchings, lithographs and a library of graphic arts. The Japanese print collection is the third most important in the world, numbering 3,500. The Buckingham collection of ancient Chinese bronzes and ceramics is outstanding, also unusually fine are the Cambodian and Chinese sculptures, Persian and Japanese textiles. There are also collections of sculpture, both originals and casts, classical objects, furniture, ceramics, textiles, a children's museum and a restaurant. The Art Institute school is the largest in the country, having an annual registration of 4,000, and giving instruction in all phases of art, including the theatre.

The institute has 14,700 (Jan. 1940) members, and holds 60 or 70 current exhibitions a year. Educational work is carried on

through lectures, in co-operation with the city schools; special courses by the department of museum education, extension lectures, the Florence D. Bartlett (free) and Scammon lectures. The yearly attendance averages 1,000,000. The museum is open for visitors every day in the year on payment of a small fee, free on Wednesdays, Saturdays, Sundays and public holidays.

An amended charter (1925) covers exhibitions, libraries, theatres, lectures and lecture halls, workshops, lunchrooms, entertainments, the granting of diplomas, the receiving and administration of trust property.

ARTIODACTYLA. To some of our domestic animals the term "cloven-hoofed" is commonly applied. These are the cow, the sheep, the goat and the pig. Deer are also "cloven-hoofed" animals, as are giraffes, camels, antelopes and certain other animals less well-known to us. Scientifically speaking, however, "cloven-hoofed" is not a good term; it suggests that these animals have, like a horse, a single hoof, and that this hoof is cleft down the middle. If the foot and its skeleton are examined more carefully it will be seen that each half of the so-called "cloven hoof" is really a little hoof in itself, flattened on the side which faces its fellow and belonging to a different toe. These two toes are equal in size and carry the weight of the animal, which always stands, as it were, on tip-toe, with ankle and wrist raised high off the ground, the terminal hoof-clad joint of the toe alone resting on the latter. Some "cloven-hoofed" animals have only these two toes, but some, such as the pig, have another pair of similar toes outside the central pair, while the hippopotamus has four toes of almost equal breadth, all but one of the ancestral five. In the pig each of the small lateral toes has its full complement of toe bones and a perfect little hoof at the end, but they are much shorter than the central toes and so only come into use when the animal is walking on soft swampy ground—then they help to prevent it from sinking in too far. In the cow and sheep vestiges only of these lateral toes are left, the so-called "dew claws"; in a giraffe they have quite disappeared. Intermediate conditions are found in a peccary, in a chevrotain, and in deer (see fig 1). All these forms agree, however, in having the axis of symmetry of the foot passing between the third and fourth toes of the ancestral five, these two forming an equal and symmetrical pair on either side of it. The hind foot fundamentally resembles the forefoot in construction, but the reduction of the lateral toes in the former has generally gone further, since the hind foot is of greater importance in propelling a running animal, while the forefoot is mainly concerned with supporting its weight. Fig. 2 shows the arrangement of the bones in a pig's hind foot. Of seven small ankle or *tarsal* bones the two upper ones form a joint, the "hock joint," with the-long bones of the shin, while the lower ones support a row of four metatarsals, one to each toe. The metatarsals in their turn each support three phalanges, the lowest of which are flattened and pointed and covered by the horny hoofs. The inner of the two bones at the ankle joint, the *astragalus,* is of a very characteristic shape, since it not only has a pulley-shaped surface for articulation with the shin bone or tibia, as in all mammals, but also a similarly shaped surface at the lower end, almost equally divided between the two small tarsal bones beyond it, the *navicular* and cuboid. An astragalus of this peculiar shape is found in nearly all cloven-hoofed (artiodacfyl) mammals, and appears to be a consequence of the tendency to make the two enlarged central toes do all the work of the foot. The outer bone of the shin (*fibula*) is very reduced, so that nearly all the animal's weight is transmitted through the tibia to the astragalus; half the weight then passes through the cuboid to the outer of the central toes, half through the *navicular* to the inner toe by way of the *ectocuneiform*. Stresses are transmitted from the ground upwards by the same path. In the more advanced cloven-hoofed mammals, such as the deer and sheep, the underlying plan of the hind foot remains the same, but the ankle is strengthened by fusion of *navicular* and cuboid, and the central *metatarsals* are joined to form a "cannon-bone" whose upper end is broadened out to support the whole tarsus. Fossilized *astragali* of the double-pulley shape have been found in strata of Lower Eocene age associated with teeth of the "tritubercular" pattern common to the primitive members of nearly all mammalian orders. The artiodactyl type of foot symmetry is therefore clearly of very ancient origin It may well have been evolved independently in more than one group of primitive mammals, but so far no *astragalus* has been found intermediate in shape between the double pulley and the type with a rounded lower end which appears to have been that of the original mammalian stock.

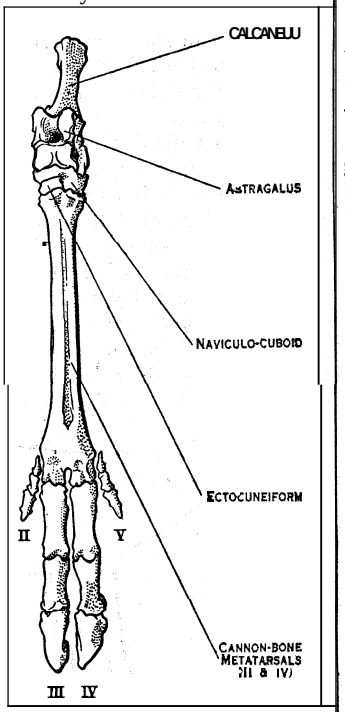

FIG. 1.—HIND FOOT OF A DEER Instead of four toes like the pig, Artiodactyla accustomed to running long distances have only two, though sometimes the others remain as useless vestiges

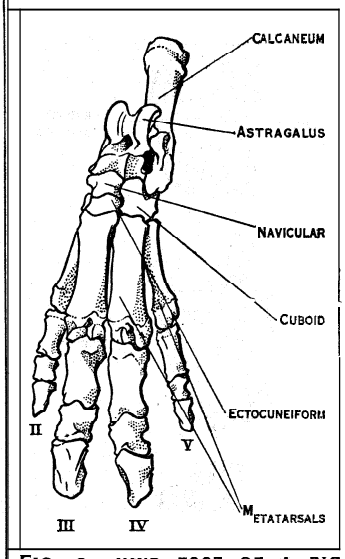

FIG. 2—HIND FOOT OF A PIG SHOWING THE TWO CENTRAL TOES WHICH MAKE IT A MEMBER OF THE ARTIODACTYLA GROUP

Classification.—The "cloven-hoofed" mammals were first grouped together as an independent order by Richard Owen in 1847, mainly on account of the structure of their feet. He termed them Artiodactyla (Gr. ἀρτιος, even, and δάκτυλος, a finger or toe) to distinguish them from those other hoofed mammals, the horses, tapirs and rhinoceroses (PERISSODACTYLA, *q.v.*) in which a single central toe does the main work of each foot, the other toes being smaller and grouped symmetrically on either side of this central one, or reduced to mere vestiges. A conservative classification of the living Artiodactyla is as follows:

I. SUINA (pig-like animals).
   1. Suidae—pigs and peccaries.
   2. *Hippopotamidae*—hippopotami.

II. RUMINANTIA (ruminant-like animals).
   1. *Tylopoda*—camels.
   2. *Tragulina*—chevrotains.
   3. Pecora (or true ruminants)—deer, giraffes, antelopes, goats, sheep, oxen, etc.

The Ruminantia are a well defined group united by characters of the skull, dentition and stomach, as well as by the structure of their feet. The *Suina,* on the other hand, except for their foot structure, have almost no important characters In common with the Ruminantia, nor are the Suidae very closely related to the *Hippopotamidae*. Indeed. before Owen established the order *Artiodactyla* the Suina were kept apart from the Ruminantia, which constituted an order in themselves. The *Suina* shared Cuvier's old order Paclzydermata ("thick-skinned" animals) with the rhinoceroses, tapirs and elephants, on no better grounds than that all were thick-skinned, massively built, hoofed mammals, with a number of toes to each foot and of an omnivorous diet. Owen was not a believer in evolution, at any rate in the Darwinian sense, but his rearrangement of the *Pachydermata* fitted in well with the new way in which people began to look at the problems of classification when once the idea of evolution had taken root in their minds.

That one animal had four toes and another only two now seemed no longer a sound reason for putting them in different orders, for

it was realised that every two-toed animal must once have passed through a four-toed stage and it appeared of much greater importance that in one group of animals there was a tendency to make one central toe do all the work of the foot, while in another group the tendency was to utilize two equally developed central toes.

From 1850 onwards discoveries of fossil mammals became more and more numerous. Among these were many new types of *Artiodactyla* which would not fit into the old subdivisions of that order, some being intermediate while others were entirely novel. The parts of fossil animals most commonly preserved in good condition are the teeth, owing to their hard protective coat of enamel, and so it came about that the many new attempts to subdivide the order were largely based on characters of the teeth alone, especially of the molar teeth.

One such classification (see Schlosser in Zittel's *"Grundzüge"*) is based on the shape of the cusps of the molar teeth, whether they be all crescentic (selenodont) as in the ruminants, all conical (*bunodont*) as in the pigs, or a mixture of the two types (*bunoselenodont*) as in some extinct animals (see fig. 3). Another classification, that of Dr. H. G. Stehlin, is based on the number and position of the molar cusps (see Abel's Die *vorzeitlichen* Saugetlziere).

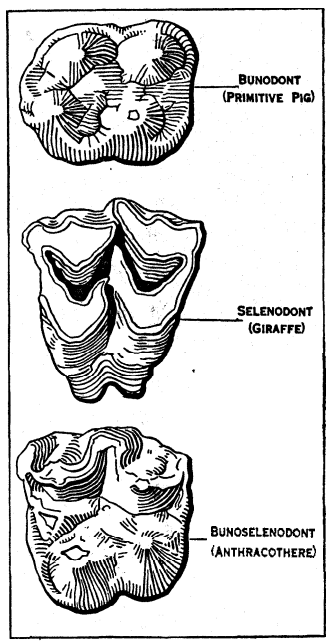

FIG. 3.— GRINDING TEETH OF ARTIODACTYL ANIMALS
The shape and pattern of the grinding teeth vary according to the animal's diet. Some extinct Artiodactyla had teeth of intermediate pattern between those of the pigs and ruminants

Each of these classifications produces an entirely different grouping of the *Artiodactyla,* indicating that the use of molar characters alone is not sufficient to express the inter-relationships of living and extinct animals. The grouping into Suina and Ruminantia given in the present article follows the old division of the living families. In allotting the extinct families to one or the other group attention has been paid to the structure of the skull as well as to the characters of the dentition. The name *Ruminantia,* suggesting a capacity to ruminate ("chew the cud"), suffers from the defect that we know nothing about the digestive processes of the extinct forms.

SUINA.—The relationship of the pigs and peccaries to the hippopotamus is very remote and no known fossil forms bridge the gulf. The two families appear to be all that has survived of a once much larger assemblage. We know practically nothing of the origin of the group, but find it richly represented in beds of Upper Eocene and Oligocene age by several not very closely related families, each of which had evidently already passed through a long period of evolution along its own particular lines. Most *Suina* have well developed incisor teeth, powerful *canine* tusks, a strong mandible articulating far back on the skull, and no mastoid exposure of the ear bone.

I. *Suidae.*—The pigs of the Old World (Suinae) and the peccaries of the New World (*Tayassuinae,* or an older name, *Dicotylinae*) resemble one another in general appearance. Both have fleshy discs on the end of their snouts which they use for rooting in the ground. Peccaries are smaller than most species of pig, have shorter snouts and short downwardly directed tusks in the upper jaw, forming efficient biting organs; the tips of their lower tusks project outwards from the mouth and can be used for ripping an enemy with a quick, upward jerk of the snout. In a pig the upper tusks as well as the lower curl outwards from the mouth; both are much longer than in a peccary and very effective ripping organs. Associated with this difference in the upper tusks are a whole series of small differences in the superficially very similar skulls. Further, the grinding teeth of peccaries are smaller, squarer and simpler in pattern than those of pigs, while in the feet the lateral toes are much reduced and the metatarsals partially fused into a "cannon-bone." The stomach of a peccary is incompletely divided into three compartments by folds of which there are only vestiges in a pig. Peccaries usually associate in very large herds, pigs in smaller groups termed "sounders."

The first true pigs are known as fossils in the Oligocene of Europe, the first true peccaries contemporaneous with them in both Europe and North America. At that period they were so alike that it is only just possible to recognize in each the characters that so clearly separate their descendants to-day. In the later Tertiaries of Europe we find only one form that possibly is allied to the peccaries, whereas there is a rich variety of pigs, of all sizes up to veritable giants, whose true relationships are very difficult to trace. Of living *Suinae* there are only five genera: Sus, represented by a number of ill-defined species widely spread over Europe, northern Africa, Asia and the East Indies; Porcula, a pigmy form in the forests at the foot of the Eastern Himalayas; *Potamochoerus,* the African river hog, hardly more than another species of *Sus; Phacochoerus,* Africa wart-hog; Hylochoerus, in the forests of Equatorial Africa; and Babirussa of the Celebes Islands (see SWINE, RIVER-HOG, WART-HOG, BABIRUSSA). From the later Tertiaries of North America there are so far known only one or two rather curious genera of peccaries which do not form good intermediate links between the modern genera and the ancestral peccaries of the Oligocene. To-day there are no peccaries in North America, but two genera, each represented by a number of ill-defined species roam in the forests of Central and South America (see PECCARY).

II. *Hippopotamidae.*—Now found only in Africa, this family during the later Tertiary had a far wider range to the north. Of its early evolution we know nothing; the hippopotami of the Indian and European Pliocene were not very different from the modern species. In marked contrast to the pigs, the hippopotamus has a very broad muzzle in which the enlarged, rootless incisor teeth and canines form deadly lacerating weapons. The crowns of its cheek teeth have a distinctive trefoil pattern when partially worn. To help it in swimming, and to support its clumsy form on the soft ground along the borders of the rivers in which it spends much of its time, four broad toes are retained in each foot. *Choeropsis,* the pigmy hippopotamus of Liberia, lacks the trefoil pattern on the molar teeth and is allied to a small fossil hippopotamus from the pleistocene of Cyprus.

III. *Cebochoeridae.*—These small animals from the Middle and Upper Eocene of Europe have been regarded as primitive Suidae because their *bunodont* molar teeth would make so good an ancestral stage in the evolution of those of a pig. The structure of their skull, however, suggests a nearer relationship to the hippopotamus or *anthracotheres.*

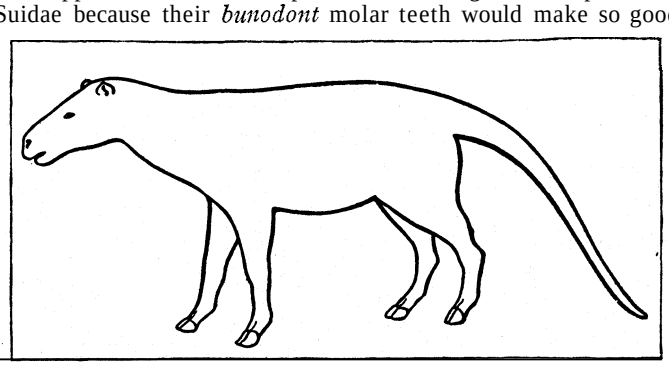

FIG. 4.— THE EXTINCT ARTIODACTYL ANOPLOTHERIUM AS RECONSTRUCTED BY CUVIER WHO BELIEVED THAT IT RESEMBLED AN OTTER

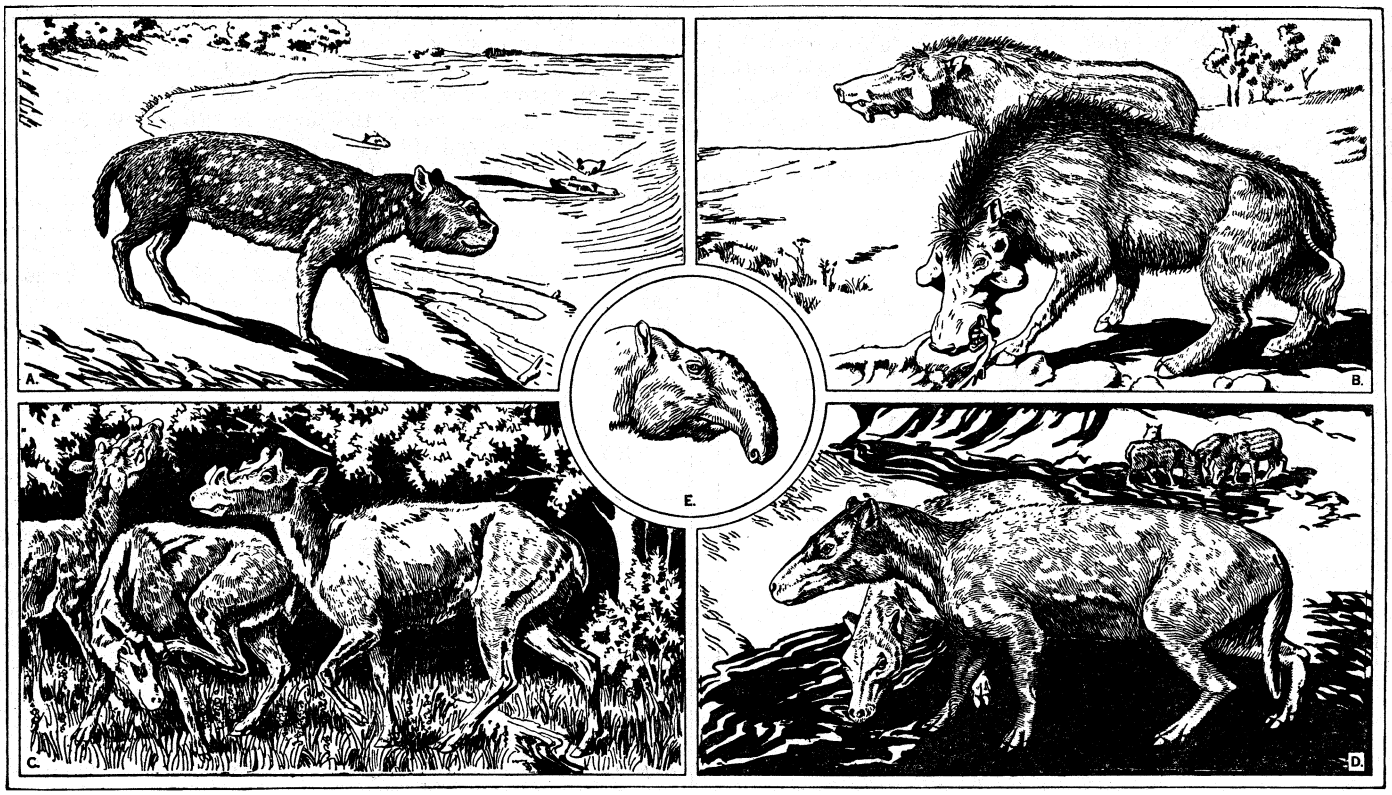
IV. *Anthracotheriidae.*—A very widespread and important family in the early Tertiary, branching out into a number of different lines of evolution adapted (if one can judge by their dentition) to very different kinds of diet. Some became gigantic and retained heavy, crushing, bunodont cheek teeth; others remained of a lighter build but developed a long slender snout and selenodont cheek teeth; apparently chewing their food with a sideways movement like a ruminant. Some retained five toes in the fore foot, four in the hind foot; in others the number was reduced.



FROM SCOTT, "HISTORY OF LAND MAMMALS," (MACMILLAN)

FIG. 5.—RESTORATIONS BASED ON THE FOSSIL REMAINS OF FIVE EXTINCT ARTIODACTYLA

A. "Leptauchenia," a short-faced Oreodont, the position of whose eyes and ears suggests amphibious habits like those of the hippopotamus
B. "Entelodon," appears to have resembled a pig in its feeding habits
C. "Protoceras," a primitive ruminant, had horn-like projections on the nose as well as above the eyes
D. "Ancodon," an Anthracothere, had five toes in its forefeet—the primitive number
E. "Pronomotherium," another Oreodont, may perhaps have had a proboscis

V. *Entelodontidae* (or *Elotheriidae*).—These giant, pig-like animals from the Oligocene of Europe and America were not really at all closely related to the true pigs. Their heavy *molar* teeth with rounded cusps must have been very efficient grinding organs, while the grooves which are sometimes worn at the base of their powerful *incisors* and *canines* suggest a habit of digging up gritty roots, A large flange projecting downwards and outwards from the cheek bone gives a very curious look to the skull. Owing to the very long limbs the animal had a stilted appearance, enhanced by the feet having only two toes apiece.

VI. Distinct from any of these families, but perhaps most nearly related to the *anthracotheres,* is the Upper Eocene genus *Choeropotamus,* famous from Cuvier's first descriptions in the *Ossements fossiles.* Like the *Cebochoeridae,* it has often wrongly been regarded as a primitive pig because of the pattern of its molar teeth.

Ruminantia.—Most living *Ruminantia* are members of one of the numerous families of the sub-order *Pecora.* These are the dominant hooved mammals of the day *(see* PECORA). The suborder *Tylopoda* is nowadays represented solely by the camels of the Old World, mostly domesticated, and by the llamas, alpacas, etc., of South America *(see* TYLOPODA, CAMEL, LLAMA). In the third suborder, *Tragulina,* are placed the two genera of Chevrotains, *Tragulus* of South-east Asia and *Hyomosuchus* of equatorial Africa *(see* CHEVROTAIN); although these have usually been regarded as belonging to a single family (*Tragulidae*) it is nevertheless very doubtful whether there is really so close a relationship between them. From the beginning of the Miocene onwards both *Pecora* and *Tylopoda* are represented by numerous fossil forms easily recognisable as belonging to one or the other sub-order. Previous to this, during Oligocene times, lived a number of small *artiodactyl* animals which were clearly primitive *Ruminantia* but cannot usually be hailed with certainty as the ancestors of this or that particular family. It is therefore convenient to unite them into a family of their own, the *Hypertragulidae,* which can then be regarded as the primitive group from which all modern *Ruminantia* are derived. They were small animals of delicate build, with slender muzzles, four crescents on the crowns of their *molar* teeth, and usually four toes in the fore foot and two in the hind. Still more primitive *Ruminantia* have been found in strata of Eocene age, and together with them a rich variety of small *Artiodactyla* with a very similar type of skull but without the four crescents on the *molar* teeth. Besides the similarity in their skulls—which were of delicate build with slender cheek bone and mandible—these small *artiodactyls* agreed with the contemporary *Ruminantia* in possessing the primitive number of forty-four teeth, no gaps between these teeth, short *canines* looking rather like the *incisors,* compressed elongated *premolar$* and central *metapodials* not fused to form "cannon-bones," although in some cases the toes were reduced to two in each foot as in modern ruminants.

The camels on the one hand and the ruminants on the other had each an independent origin from small *artiodactyla* of this primitive type. Each then developed quite independently a number of strikingly similar characters, including high-crowned *molar* teeth. a tendency for the upper *incisors* to disappear, only two functional toes in each foot, cannon-bones formed by the fusion of the third and fourth *metapodials,* a reduction of the outer bone in both forearm and lower leg, and a complex, many-chambered stomach connected with the habit of rumination. They thus afford an excellent example of "parallel evolution" in response to similar environmental conditions. The *Tragulina* show many of the same tendencies but usually not so fully developed; they too may have evolved them independently or they may be a primitive off shoot of the *pecoran* stock.

Two rather isolated families of *Ruminantia* have still to be mentioned: the *Oreodontidae* and the *Anoplotheriidae. (a)* The *Oreodonts* (*q.v.*) were a very characteristic North American family, branching out during the Oligocene and Miocene into several phyla, some of which lasted on until the Lower Pliocene. They were animals with short necks, long bodies and tails, short limbs and

feet. They retained at least four toes in each foot and many other primitive characters, but their skulls, which to start with were very like those of contemporary *Ruminantia,* underwent some curious changes. In one phylum the animals seem to have developed a short proboscis like a tapir, and to have lived in the water like a hippopotamus. One form, Agriochoerus (sometimes placed in a distinct family) differed from the typical oreodonts in having limbs

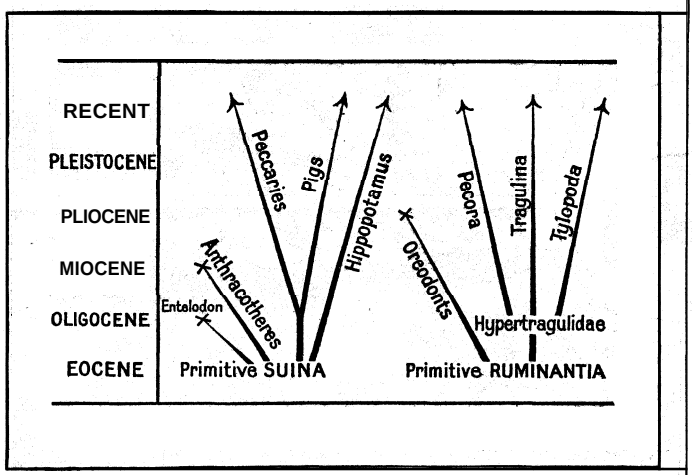


FIG. 6.—GENEALOGY OF THE DIFFERENT GROUPS OF ARTIODACTYLA
To the left are the names of the several geological periods of the Age of Mammals. Those groups marked with crosses became extinct during the period indicated. Arrows indicate that a group has continued its evolution up to the present day

and vertebrae proportioned like those of cats, as if it were an agile leaper; the feet, otherwise like those of oreodonts, were armed with sharp claws instead of narrow hoofs. The animal can hardly have been a carnivore, since its molar teeth had the four crescents characteristic of herbivores and the upper *incisor* teeth were shed in the adult. The known *Anoplotheres* were exclusively European. They were specially characteristic of the Upper Eocene and were the largest Artiodactyla of that period. Their broad feet and the very long thick tail caused Cuvier to attribute to these animals swimming habits like those of an otter.

ARTISAN or **ARTIZAN, a** mechanic, a handicraftsman in contradistinction to an artist. The English word at one time meant "artist," but has been restricted to signify the operative workman only.

ARTOIS, an ancient province of France, corresponding to the present department of Pas de Calais, less the arrondissements of Boulogne and Montreuil, which belonged to Picardy. Its capital was Arras, and other important places were Saint-Omer, Béthune, Aire, Hesdin, Bapaume, Lens, Lillers, Saint-Pol and Saint-Venant. The names Artois and Arras are derived from the Atrebates, who possessed the district in the time of Caesar. From the 9th to the 12th century Artois belonged to the counts of Flanders. It was bestowed in 1180 on Philip Augustus of France by Philip of Alsace, as the dowry of his niece Isabella of Hainaut, and in 1237 was conferred as an appanage by Saint Louis on his brother Robert, who died in 1250. His son, Robert II., was killed at the battle of Courtrai in 1302. After his death, his son Philip having predeceased him (1298), Artois was adjudged to his daughter Mahaut as against her nephew Robert, son of Philip, who attempted to support his claim to the countship by forged titles. Banished from France (1322), Robert of Artois took refuge in England, where he became earl of Riehmond, and incited Edward III. to make war upon Philip of Valois. His descendants, the counts of Eu (*q.v.*), continued to style themselves counts of Artois. By the marriage of Mahaut (d.1329) with Otto IV., Artois passed to the house of Burgundy, in whose possession it remained till the marriage of Mary, the daughter of Charles the Bold, to the archduke Maximilian, brought it to the house of Austria. Louis XI., however, occupied portions of Artois, and the claims of Austria were contested by France until the treaty of Senlis (1493). At the end of the Thirty Years' War Artois was again conquered by the French, and the conquest was ratified in the treaty of the Pyrenees (1659) by Spain, to whom the province had fallen in 1634. The treaties of Nijmwegen (1678) and Utrecht (1713) confirmed the sovereignty of France. The title of count of Artois was borne by Charles X. of France before his accession to the throne. This new creation became extinct on the death of the comte de Chambord in 1883.

ART SALES. The practice of selling objects of art by auction in England dates from the latter part of the 17th century. Towards the latter part of the first half of the 19th century an entirely new race of collectors gradually came into existence; they were for the most part men who had made, or were making, large fortunes in the various industries of the midlands and north of England, and other centres. They were untrammelled by "collecting" traditions. and their patronage was almost exclusively extended to the artists of the day. The dispersals of these collections began in 1863 with the Bicknell gallery, and continued at irregular intervals for many years, *e.g.,* Gillott (1872), Mendel (1875), Wynn Ellis and Albert Levy (1876), Albert Grant (1877) and Munro of Novar (1878). These patrons purchased at munificent prices, either direct from the easel or from the exhibitions, not only pictures in oils but also water-colour drawings. As a matter of investment their purchases frequently realized far more than the original outlay; sometimes, however, the reverse happened, as, for instance, in the case of Landseer's "Otter Hunt," for which Baron Grant is said to have paid £10,000 and which realized shortly afterwards only 5,650 guineas. One of the features of the sales of the 'seventies was the high appreciation of water-colour drawings. At the Gillott sale (1873) 160 examples realized £27,423, Turner's "Barnborough Castle" fetching 3,150gns.; at the Quilter sale (1875) David Cox's "Hayfield," for which a dealer had paid him 50gns. in 1850, brought 2,810 guineas. The following are the most remarkable prices of later years. In 1895 Cox's "Welsh Funeral" (which cost about £20) sold for 2,400 gns., and Burne-Jones's "Hesperides" for 2,460gns. In 1908, 13 Turner drawings fetched £12,415 (Acland-Hood sale) and seven brought £11,077 (Holland sale), the "Heidelberg" reaching 4,200 guineas. For Fred Walker's "Harbour of Refuge" 2,580gns. were paid (Tatham sale) and 2,700gns. for his "Marlow Ferry" (Holland), The demand for pictures by modern artists, whose works sold at almost fabulous prices in the 70's, has somewhat declined; but during all its *furore* there was still a small band of collectors to whom the works of the old masters more especially appealed. The dispersal of such collections as the Bredel (1875), Watts Russell (1875), Foster of Clewer manor (1876), the Hamilton Palace (17 days, £397,562), Bale (1882), Leigh court (1884), and Dudley (1892) resulted, as did the sale of many minor collections each season, in many very fine works of the old masters finding eager purchasers at high prices. A striking example of the high prices given was the £24,250 realized by the pair of Vandyck portraits of a Genoese senator and his wife in the Peel safe, 1900.

Since the last quarter of the 19th century the chief feature in art sales has been the demand for works, particularly female portraits, by Reynolds, his contemporaries and successors. This may be traced to the South Kensington exhibitions of 1867 and 1868 and the annual winter exhibitions at Burlington house, which revealed an unsuspected wealth and charm in the works of many English artists who had almost fallen into oblivion. A few of the most remarkable prices for such pictures may be quoted: Reynolds's "Lady Betty Delmé" (1894), 11,000gns.; Romney's "The Ladies Spencer" (1896), 10,500gns.; Gainsborough's "Duchess of Devonshire" (1876), 10,100gns. (For the history of

its disappearance see GAINSBOROUGH, THOMAS); "Maria Walpole," 12,100gns. (Duke of Cambridge's sale, 1904); Constable's "Stratford Mill" (1895), 8,500 gns.; Hoppner's "Lady Waldegrave" (1906), 6,000gns.; Lawrence's "Childhood's Innocence" (1907), 8,000gns.; Raeburn's "Lady Raeburn" (1905), 8,500gns. Here may also be mentioned the 12,600gns. paid for Turner's "Mortlake Terrace" in 1908 (Holland sale). But during the last few years all these prices, sensational in their day, have been entirely eclipsed.

The "appreciation" of the modern continental schools, particularly the French, has been marked since 1880; of high prices paid may be mentioned Corot's "Danse des Amours" (1898), £7,200; Rosa Bonheur's "Denizens of the Highlands" (1888), 5,5jogns.; Jules Breton's "First Communion," £9,100 in New York (1886); Meissonier's "Napoleon I. in the Campaign of Paris," 12¼in. by 9¼in. (1882) 5,800gns., and "The Sign Painter" (1891), 6,450 gns. High prices are also fetched for pictures by Daubigny, Fortuny, Gallait, Gérôme, Troyon and Israels. The most marked feature of late has been the demand for the 18th century painters Watteau, Boucher, Fragonard, Pater and Lancret; thus "La Ronde Champêtre" of the last named brought £11,200 at the Say sale in 1908, and Fragonard's "Le Reveil de Vénus" £5,520 at the Sedelmeyer sale, 1907.

"Specialism" is the one important development in art collecting which has manifested itself since the middle of the 19th century. This accounts for and explains the high average quality of the Wellesley (1866), the Buccleuch (1888) and the Holford (1893), collections of drawings by the old masters; for the Sibson Wedgwood (1877), the Duc de Forli Dresden (1877), the Shuldham blue and white porcelain (1880), the Benson collection of antique coins (1909), and for the objects of art at the Massey-Mainwaring and Lewis-Hill sales of 1907. Very many other illustrations in nearly every department of art collecting might be quoted—the superb series of Marlborough gems (1875 and 1899) might be included in this category but for the fact that it was formed chiefly in the 18th century. The appreciation—commercially at all events—of mezzotint portraits and of portraits printed in colours, after masters of the early English school, was one of the most remarkable features in art sales during the last years of the 19th century. The shillings of 50 years before were then represented by pounds. The Fraser collection (December 4 to 6, 1900) realized about ten times the original outlay, the mezzotint of the "Sisters Frankland," after Hoppner, by W. Ward, selling for 290gns. as against 10gns. paid for it about 30 years previously. The H. A. Blyth sale (Mar. 11 to 13, 1901, 346 lots, £21,717 10s.) of mezzotint portraits was even more remarkable, and as a collection it was the choicest sold within recent times, the engravings being mostly in the first state. The record prices were numerous, and, in many cases, far surpassed the prices which Sir Joshua Reynolds received for the original pictures; *e.g.*, the exceptionally fine example of the first state of the "Duchess of Rutland," after Reynolds, by V. Green, realized 1,000 gns., whereas the artist received only £150 for the painting itself. Even this unprecedented price for a mezzotint portrait was exceeded on April 30, 1901, when an example of the first published state of "Mrs. Carnac," after Reynolds, by J. R. Smith, sold for 1,160 guineas. At the Louis Huth sale (1905) 83 lots brought nearly £10,000, Reynolds's "Lady Bampfylde" by T. Watson, first state before letters, unpublished, fetching 1,200 guineas. Such prices as these and many others which might be quoted are exceptional, but they were paid for objects of exceptional rarity or quality.

It is not necessary to pursue the chronicle of recent sales, which have become a feature of every season. It is worth mentioning, however, that the Holland sale, in June 1908, realized £138,118 (432 lots), a record sum for a collection of pictures mainly by modern artists; and that for the Rodolphe Kann collection (Paris) of pictures and objects of art, including 11 magnificent Rembrandts, Messrs. Duveen paid £1,000,000 in 1907. In every direction there has been a tendency to increase prices for really great artistic pieces, even to a sensational extent. The competition has become acute, chiefly owing to the unprecedented growth of private and public collections in the Gnited States. The demand for the finest works of art of all descriptions is much greater than the supply. As an illustration of the magnitude of the art sale business it may be mentioned that the "turnover" of one firm in London alone has frequently exceeded £1,000,000 annually.

The public and private art sales in Great Britain from 1911 show an extraordinary revision in values. Many of the finest works of art formerly in Britain have gone to America, and the exodus is bound to continue. There are still collectors of taste and judgment in the country, but transatlantic competition makes it impossible for most of them to purchase early works of the highest importance.

The Sargent sale in 1925 may be mentioned, although the prices paid were the result of sentiment rather than artistic appreciation. Works which he himself may have regarded merely as studio "property" fetched extravagant sums: for example, a copy by him of "Prince Batasar Carlos" by Velasquez, measuring 21½in. by 17¾in. realized £6,300, a small water-colour made £4,830, an oil painting of "San Vigilio" £7,350, and the total for 163 lots on the first day reached £145.984. Rembrandt etchings also grow in favour. In 1924 the Rudge collection, which was unknown to the experts, established a new maximum in realizing £34,000, and the £3,780 given for a first state of "Dr. Arnoldus Tholinx" broke all records for any etching or engraving, the nearest to that figure being the £3,045 paid two years earlier for Valentine Green's mezzotint translation of "The Ladies Waldegrave" by Reynolds.

As already said, many famous pictures have passed from Britain to America in the period under review, but the greatest excitement was caused by the private sale of the duke of Westminster's pictures, "The Blue Boy," by Gainsborough, and "Mrs. Siddons as the Tragic Muse," by Reynolds, for £200,000 in 1921. Previously, it will be recalled, the Reynolds was withdrawn at Christie's at £52,500 and it was said that £150,000 had been refused for "The Blue Boy" which, as Farington records, was purchased by John Hoppner for 65gns. in 1803, after having been sold for 35gns. in 1796. Up to 1919 the highest auction price for a Gainsborough was the £20,160 realized for "The Market Cart"; but this was eclipsed at the Michelham sale in Nov. 1926, when this artist's portraits of Miss Tatton and Master Heathcote each brought £46,200; while the Reynolds maximum stood at £15,520 in 1919 for the portrait of "Mrs. Freeman," it was exceeded in July 1927 by his portrait of Lady Ann Fitzpatrick as "Sylvia" which brought £19,425 at the James Ross sale. The year 1919 was memorable in the annals of art sales. For the first time in history each of 100 pictures realized not less than 1,400gns. in British auction rooms; but during the season 1926–27, 173 pictures sold for £1,000 and upwards, their total amounting to £1,016,441. The Hamilton palace sale on Nov. 6, 1919, fetched 2168,957, the highest sum ever obtained in one day at Christie's, beating the £150,000 record for a two days' dispersal, amassed earlier in the year by the Drunimond collection. Three other records were made in that sale: the £6,500 for Turner's drawing of "Zurich," a similar sum for Guardi's "Fête on the Grand Canal," which cost Sir George Drummond £800, and £26,775 for a portrait of "Joseph Coymans" by Franz Hals which, however, was exceeded by the £27,400 paid in America for the same artist's "Old Lady" that figured in the Yerkes collection.

Nor were these the only records for 1919. In the Hamilton palace sale the £54,600 paid for Romney's group of "The Beckford Children" was the highest price given in the public market for any picture. The artist received £105 for the painting of the two girls. A picture of "St. Eustace" ascribed to Carpaccio brought £33,600 in the Vernon-Wentworth sale, "The Spendthrift" by Jan Steen, £17,010; while the former record was the £3,412 10s. for "The Sick Lady" in 1910, and Ruysdael's "Landscape," £12,600. James Ward's portrait of "Miss Georgiana Musgrave" made £7,140 against £1,680 in 1905, which was then the maximum for this artist's works. The remarkable events of 1919 may be compared with the auction doings in 1913, when, by middle of June. the turnover at Christie's alone reached more than £1,000,000. Romney's "Anne, Lady de la Pole" fetched £41,370; Gainsborough's "Market Cart" £20,160, as against 24,750 10s. in

1894; Hobbema's "Woody Landscape" £15,750 as against £3,460 in 1890; a Hals "Portrait of a Gentleman" £9,000 as against a price of £5 5s. with a still-life subject into the bargain in 1884.

The two abundant years before the World War had filled the warehouses of the dealers with stock, and that fact, combined with financial depression, brought about the result that when on Friday, July 24, 1914, Christie's season ended, there were few notable things to report. Only 38 pictures, compared with 85 in 1913, realized 1,400gns. or over. Two of these works were "A Man with a Red Cap," attributed to Titian, which made £13,650 and Peter de Hooch's "Interior with Figures," which was sold for £8,610 at Robinson and Fisher's, four days before war was declared.

The War Period.—The years between that date and 1919 were memorable for the sales conducted free of charge by Messrs. Christie on behalf of the Red Cross fund. The great success of these charitable sales helped to restore confidence in the art markets, which also were affected by the Duveen purchase of portions of the Pierpont Morgan collections costing £1,000,000. One of the tragedies of the World War was the loss of Sir Hugh Lane in the "Lusitania." In 1916 Christie's celebrated the 150th anniversary of the firm's existence. Instead of opening their season in Oct. or Nov. 1914, both Christie and Sotheby closed down until well in 1915, owing to the extreme tension caused by the war. The Sydney sale (by Knight, Frank and Rutley) was held in April, a Vigée le Brun portrait selling for 6,600gns.; the Sir Walter Gilbey sale (by Christie) at Elsenham hall, Essex, in June, £18,234, and the C. T. D. Crews sale at Christie's rooms, £20,400. These sales proved that, war or no war, and whichever side won, good pictures were bringing big prices. For instance, Raeburn's "The McNab" fetched £25,410 (1917). Gainsborough's charming sketch of his daughters, which fetched £3,045 (1923), went to the National Gallery, London, and Hoppner's fine "Portrait of William Pitt" was purchased for a British peer at £7,350. It came from the Baroness Burdett-Coutts's collection (1922), as did Raeburn's "Portrait of Sir Walter Scott," which made £9,660 and went to America.

In the following year the Brownlow Van Dyck "Portrait of Anton Triest" fetched £29,400. Mention should be made of the futile auction of Sir John Robinson's pictures on July 7, 1923. The nominal total for the 114 works by famed old masters was £205,741 10s., but in most cases the large reserves were not reached, so that in no previous sale in England had such a large percentage of lots been brought in, in spite of the fact that most of those actually sold showed a profit, and that many of the withdrawn pictures were knocked down at larger prices than those originally given for them by Sir John. In the autumn of 1923 it became known that ten of the finest pictures in Lord Glenconner's collection of British masterpieces had been acquired by Messrs. Knoedler, and shipped to the United States; whilst a surprise of a much more pleasant character was provided in the autumn of 1927 when it was announced that the late Lord Iveagh had bequeathed the whole of his collection to the nation, with his residence at Kenwood, Hampstead, as a permanent home for it.

The sales from 1924 to the end of 1927 may be briefly summarized. Those of John S. Sargent and J. E. Rudge have already been mentioned. The Darnley pictures from Cobham hall, May 1, 1925, 92 lots, totalled £70,758, Hoppner's portrait of Lady Elizabeth Bligh selling for 10,200gns. and 16 others reached four figures; whilst on July 17 a companion pair of whole lengths by G. Romney, Sir Everard and Lady Every (for which the artist received 140gns. in 1780) together brought £16,230, and Lord Lathom's group by the same artist of the Bootle children £8,925. The several interesting sales of the season 1925–26 (the "season" by the way, extends from October to July) included 71 pictures which passed a £1,000 limit, at the head of all coming Romney's superb portrait of Mrs. Davenport, 1782, which (July 28) reached £60,900. Other properties included a pair of fancy subjects by F. H. Drouais, "The House of Cards" and "Blowing Bubbles," £13,650; Sir Antonio Mor's portrait of Elizabeth de Valois Queen of Spain, £11,025, and Nattier's portrait of a nobleman said to be the Duc de Senthieve, £12,075; Romney's Lady Lushington £8,715, and one of the same artist's many portraits of Lady Hamilton, £13,650. There were not many collections important as such, the most notable being that of the Bischoffsheim pictures (May 7) bringing £97,794; and the J. B. Gaskell modern pictures and drawings (April 30 and May 2), £39,150. Two or three other out of many features of the season may be mentioned—the high prices paid for the very sketchy water-colour drawings by H. H. Brabazon, a two days' sale (March 18 and 19, 1926) realizing £11,576; the increasingly high prices for sporting pictures which a quarter of a century ago had very little market value, and Sir James Dunn's long series of portraits by Sir William Orpen (July 16) of which that of President Woodrow Wilson brought £2,730.

The season 1926–27 practically began with a sensation in the Michelham sale at 20 Arlington street, London, by Hampton and Son (Nov. 23–24) with a nominal total of about £589,000 for pictures and objects of art, but it was obvious to those present that some of the reserves had not been reached. Sir Thomas Lawrence's whole length of Miss Mary M. Barrett, known from the colour of her eyes as "Pinkie," was sold at 74,000gns. to Duveens, the record auction price for a picture; the whole-length Romney, Anne Lady de la Sole, went to Agnews at 44,000 gns. (the artist's price was 80gns. in 1786), and another Romney, Elizabeth Lady Forbes, 24,000gns. and two Gainsboroughs, Miss Tatton and Master Heathcote each 44,000 guineas. The chief picture sales of 1927 included Sir James Murray's collection, £69,888, the hon. Mrs. Yorke £41,581, the Italian old masters of the late Sir George Holford, £155,951, and the Empress Eugénie £20,315, and James Ross of Montreal, £138,031, which, with other properties brought the day's total to £192,451, the year finishing (Dec. 22) with the late Marquess Curzon's small but choice collection, which with other properties totalled £38,944.

Reference has been made solely to the disposal of pictures, but numerous other works of art have been sold privately and in the open market at prices not less sensational than those obtained for paintings, notably for etchings by Sir D. Y. Cameron, J. McBey, A. Zorn and others. On the continent of Europe, too, competition has been acute, with the result that prices were abnormally high in 1911, 1912 and 1913, as they were in Great Britain. In Paris, in 1911 the Maurice Kann collection, consisting of 85 lots, realized £108,850, to which must be added the tax of 10% paid then by purchasers. With a few exceptions the profits were enormous. So, too, with the collection of his brother Rodolphe Kann, which cost him about £200,000 and fetched about £1,200,000. Rembrandts, which were bought by him for £1,600 and £2,000, brought £20,000 to £30,000 and a Vermeer of Delft, for which he gave £48, sold for £2,000.

Paris and New York Sales.—In 1912 there were five great Paris sales, the Roussel, Dollfus, Carcano, Doucet and Rouart, which together realized over £1,250,000. A few individual prices may be given. In the Doucet sale a pastel portrait of "Duval de l'Epinoy" by Quentin de la Tour made £26,400, which was eight times the previous maximum for a pastel; John Russell's "Mrs. Elizabeth Curie" sold in Paris for £3,200; H. Regnault's "Salomé," £19,000; "The Countess of Wilton" by Sir Thomas Lawrence, £19,104; "Les Danseuses & la Barre" by Degas, £19,400 (the artist sold it for £20); Chardin's "Les Bulles de Savon," £12,000, and in the following year (1913), Rembrandt's "Bathsheba," £44,000. The Degas sales in 1918 totalled 8,649,000fr., and since then the million franc totals have included such sales as the Hazard, Prince Orloff, S. Bardar, Alphonse Kann, Engel Gros, Gaston le Breton and Marquise de Ganay.

Mantegna's "Madonna and Child" in the Weber sale, Berlin (1912), fetched £31,000 against £4,000 paid for it in 1902. In Amsterdam 32 Rembrandt drawings from the J. P. Heseltine collection totalled over £25,000, the highest individual price being £2,508 paid for "The Farm." In the same city (Nov. 1925) the Castiglione collection realized £150,000. Of that sum, a signed and dated (1635) Rembrandt "Portrait of a Syndic of Amsterdam" brought £17,833, Nicholas Froment's "Resurrection of Lazarus," £12,833 and Correggio's "Mystic Marriage of Saint Catharine," £10,666.

The greatest American sales were the Yerkes, 1910, which, at $2,707,866, established a New York record, the William Salomon, 1923, which realized $1,288,705 and the Elbert H. Gary, 1928, which brought $2,297,763 of which $1,154,650 was for 39 paintings. Before the Salomon sale, Sir Joseph Duveen purchased privately 15 of the more important pictures at an estimated cost of $1,000,000. The remainder of this collection was sold by Mrs. Salomon, Jan. 1928, for $675,571. In the Yerkes sale, Franz Hals's "Portrait of a Woman" fetched $137,000; in the Gary, Gainsborough's "The Harvest Wagon" brought $270,000. Another New York sale was the C. C. Stillman in 1927 when 37 pictures totalled $716,950, $270,000 being paid for Rembrandt's portrait of his son Titus.

Lord Leverhulme's art collections, after being catalogued and advertised for sale at Hampstead, was suddenly transferred to New York and sold there in Feb. 1926, the grand total amounting to $1,274,000.

BIBLIOGRAPHY.—The chief compilations dealing with art sales in Great Britain are: W. Buchanan, *Memoirs of Paznting* (1824); *Year's Art* (1880–1928); G. Redford, *Art Sales* (1888); *W*. Roberts, *Memorials of Christie's* (1897); *Art Prices Current* (1907–08) *et seq.*; *A*. Graves, *Art Sales from Early in the 18th century to 1910* (1918–21); *H*. C. Marillier, *Christie's* (1926). In France: H. Mireur, *Dictionnaire des Ventes* (1901–02); *L*. Soullié, *Les Ventes de Tableaux* (1896).

(W. ROB.)

ARTS AND CRAFTS, a comprehensive title for the arts of decorative design and handicraft — all those which, in association with the mother-craft of building (or architecture), go to the making of the house beautiful. Accounts of these will be found under separate headings. "Arts and crafts" are also associated with the movement generally understood as the English revival of decorative art, which began about 1875. The title itself only came into general use when the Arts and Crafts Exhibition Society was founded, and held its first exhibition at the New Gallery, London, in the autumn of 1888. The idea of forming a society for the purpose of showing contemporary work in design and handicraft really arose out of a movement of revolt or protest against the exclusive view of art encouraged by the Royal Academy exhibitions, in which oil paintings in gilt frames claimed almost exclusive attention — sculpture, architecture and the arts of decorative design being relegated to what then amounted to quite subordinate positions. In 1886, out of a feeling of discontent among artists as to the inadequacy of the Royal Academy exhibitions, considered as representing the art of Great Britain, a demand arose for a national exhibition to include all the arts of design. One of the points of this demand was for the annual election of the hanging committee by the whole body of artists. After many meetings the group representing the arts and crafts (who belonged to a larger body of artists and craftsmen called the Art-Workers' Guild, founded in 1884), perceiving that the painters, especially the leading group of a school not hitherto well represented in the Academy exhibitions, only cherished the hope of forcing certain reforms on the Academy, and were by no means prepared to lose their chances of admission to its privileges, still less to run any risk in the establishment of a really comprehensive national exhibition of art, decided to organize an exhibition themselves in which artists and craftsmen might show their productions, so that contemporary work in decorative art should be displayed to the public with the same advantages as had hitherto been monopolized by pictorial art. For many years previously there had been great activity in the study and revival in the practice of many of the decorative handicrafts neglected in England and America, though on the Continent and throughout the East these were carried on without a break. The machine production of an industrial century had laid its iron hands upon what had formerly been the exclusive province of the handicraftsman, who in England only lingered on in a few obscure trades and in forgotten corners. The ideal of mechanical perfection dominated workmen, and the factory system, first by extreme division of labour, and then by the further specialization of the workman under machine production, left no room for individual artistic feeling among craftsmen trained and working under such conditions. The demand of the world-market ruled the character and quality of production, and to the few who would seek some humanity, simplicity of construction or artistic feeling in their domestic decorations and furniture, the only choice was that of the tradesmad or salesman, or a plunge into costly and doubtful experiments in original design. From the 'forties onward there had been much research and study of mediaeval art in England; there had been many able designers, architects and antiquaries, such as the Pugins and Henry Shaw (1800–1873) and later William Burges (1827–1881), William Butterfield (1814–1900) and G. E. Street and others. The school of pre-Raphaelite painters, by their careful and thorough methods, and their sympathy with mediaeval design, were among the first to turn attention to beauty of design, colour and significance in the accessories of daily life, and artists like D. G. Rossetti, themselves designed and painted furniture. The most successful and most practical effort indeed towards the revival of sounder ideas of construction and workmanship may be said to have arisen out of the work of this group of artists, and may be traced to the workshop of William Morris and his associates. William Morris, whose name covers so large a field of artistic as well as literary and social work, came well equipped to his task of raising the arts of design and handicraft, of changing the taste of his countrymen from the corrupt and vulgar ostentation of the Second Empire, and its cheap imitations, which prevailed in the 'fifties and 'sixties, and of winning them back, for a time at least, to the massive simplicity of plain oak furniture, or the delicate beauty of inlays of choice woods, or the charm of painted work, the richness and frank colour of formal floral and heraldic pattern in silk textiles and wall-hangings and carpets, the gaiety and freshness of printed cotton, or the romantic splendour of arras tapestry. Both William Morris and his artistic comrade and life-long friend, Edward Burne-Jones, were no doubt much influenced at the outset by the imaginative insight, the passionate artistic feeling, and the love of mediaeval romance and colour of Dante Gabriel Rossetti, who remains so remarkable a figure in the great artistic and poetic revival of the latter half of the 19th century. To William Morris himself, in his artistic career, it was no small advantage to gain the ear of the English public first by his poetry. His verse-craft helped his handicraft, but both lived side by side. The secret of Morris's great influence in the revival was no doubt to be attributed to his way of personally mastering the working details and handling of each craft he took up in turn, as well as to his power of inspiring his helpers and followers. He was painter, designer, scribe, illuminator, wood-engraver, dyer, weaver and finally printer and paper-maker, and having mastered these crafts he could effectively direct and criticize the work of others. His own work and that of Burne-Jones were well known to the public, and in high favour long before the Arts and Crafts Exhibition Society was formed, but though largely helped and inspired by the work of these two artists, the aims and objects of the society rather represented those of a younger generation, and were in some measure a fresh development both of the social and the artistic ideas which were represented by Ruskin, Rossetti and Morris, though the society includes men of different schools. Other sources of influence might be named, such as the work of Norman Shaw and Philip Webb in architecture and decoration, of Lewis Day in surface pattern, and William de Morgan in pottery. The demand for the acknowledgment of the personality of each responsible craftsman in a co-operative work was new, and it had direct bearing upon the social and economic conditions of artistic production. The principle, too, of regarding the material, object, method and purpose of a work as essential conditions of its artistic expression, the form and character of which must always be controlled by such conditions, had never before been so emphatically stated, though it practically endorsed the somewhat vague aspirations current for the unity of beauty with utility. Again, a very notable return to extreme simplicity of design in furniture and surface decoration may be remarked; and a certain reserve in the use of colour and ornament, and a love of abstract forms in decoration generally, which are characteristic of later taste. Not less remarkable has been the new development in the design and workmanship of jewellery, gold and silversmiths' work and enamels. Among the arts and crafts of design which

blossomed into new life during this active period—and there is hardly one which was not touched by the new spirit—book-binding must be named as having attained a fresh and tasteful development through the work of Mr. Cobden-Sanderson and his pupils. The art and craft of the needle also must not be forgotten, and its progress is a good criterion of taste in design, choice of colour and treatment. The increase of late years in these exhibitions of designs worked out in the actual material for which they were intended is very remarkable, and is an evidence of the spread of the arts and crafts movement (fostered no doubt by the increase of technical schools) of which it may be said that if they have not turned all craftsmen into artists or all artists into craftsmen, they have done not a little to expand and socialize the idea of art, and (perhaps it is not too much to say) have made the tasteful house with its furniture and decorations a model for the civilized world. (W. CR.)

The craftsmen, having successfully revolted against the crushing influence of academic thought, perhaps carried their spirit too far in the resentment toward the machine and its influences. A new trend is distinctly perceptible—that of making use of the machine for the accomplishment of better arts and crafts—and there is no doubt but that this trend will lead to a most interesting new era of art.

Along with this trend another movement occurred, attributed by many to the World War. The younger generation who were involved in the conflict, naturally questioned the old standards—in religion, in ethics as applied to daily life, and in speculative philosophy. With this doubt came a questioning of the standards of art, alike in Germany, France and later England and America. As a result nearly every art school in these countries laid chief stress upon originality as opposed to the teaching of technique or old standards, and a further reason for this spirit of revolt was that the machine introduced so many new elements into consideration.

Not, for the most part, until the 20th century did artists learn to master the machine and to make it turn out works of art which they desired and had foreseen, and with this mastery of the machine there became evident the tendency toward the greater stressing of technique. The days of William Morris are past and the hand-craftsman will ever find it more difficult to compete with the machine, and the modern craftsman of intelligence does not attempt this competition but turns the machine to his uses. By "the machine" we do not mean only mechanical contrivances, but all of those scientific aids such as photography, moving photography, etc., which are now available. The one loss is the lack of that delicately personal touch which the artist's hand can give to a piece of craftsmanship, but daily we see new evidence of the possibilities which the machine has for the expression of this touch. Modern potters in Copenhagen and elsewhere are turning out vases which, though different, are just as beautiful as those which were executed by hand in China. Modern glass is equally fine and shows a mass of new technical possibilities. Modern textiles show a range of colour and techniquenever before possible. Moreover, in bookbinding and also in printing the various presses prove almost daily that real beauty can be obtained through the use of the machine. Modern jewellery has benefited by the advanced methods of treating metals and of cutting precious stones. Thus, we may be in the midst of what may possibly be one of the greatest periods in the history of art, and craftsmanship and the use of the machine are the two keynotes of this period, no longer warring with each other, but collaborating to a better purpose. (W. E. Cx.)

ARTSIBASHEV, MIKHAIL PETROVICH (1878–1927), Russian novelist, was born in south Russia, Oct. 18, 1878, and died at Warsaw March 3, 1927. His family was of Tartar descent, and on the mother's side he mas a great-grandson of Kosciusko. He at first followed an artistic career and attained some fame as a caricaturist, but subsequently began writing short stories, followed by novels. In 1912 he was imprisoned for several months by the Imperial Government as a revolutionary. His first novel, *Sanin*, 1907 (Eng. trans. 1915), showed him in revolt against all social restraints, and both it and his later novels exhibit a society in dissolution and give a grotesquely exaggerated picture of crime and folly. He was a violent misogynist, even more violent than Tolstoi in the *Kreutzer* Sonata. His novels had a great vogue in Russia in their time.

His collected works published in Moscow (1912–17, 10 vols.) contain:—Razskazi (Tales); *U* poslednei chertiy ("At the Extreme Limit," translated into English as The Breaking Point, 1915); Zakon dikurya ("The Law of a Misanthrope"); *Revnost* ("Jealousy"); a play Voina ("War," translated into English 1918 under the same title) and Sanin (translated into English as *Sanine,* 1915).

ART TEACHING. As art lost touch with production art teaching inevitably grew in importance in the national consciousness. The story of State systems of art education is mainly an endeavour to reunite the personality of art to the processes of industry. In simpler forms of society, education was parental and productive. Theories of art education have evolved since the Renaissance, and before this, productive education was carried on in the workshops of the craft gilds, which, put simply, were corporate bodies of workers, who handed down the experiences of generations, in the making of things of the highest standard of quality. Gild circles were inevitably outgrown by municipal organizations, and gradually, with the growth of national life, and its ever widening range of intercourse and interchange, the traditional processes of production were lost, and the experimentation of individual genius took their place.

The Renaissance.—The Renaissance stands for the emancipation of the individual, in matters of art teaching, as in scientific, literary and artistic expression. This emancipation of the individual, together with the weakening of the craft gilds, finally resulted in the separation of the so-called "Fine Arts" from the crafts. Painting, sculpture, architecture, engraving were associated with the studio and the artist, and all other products were relegated to the workshop and the craftsman; and finally, with the advent of mechanized production, in the 19th century, the factory despoiled the craftsman of his traditional birthright as an independent creator of beautiful things for the needs of life.

Professional Art Teaching.—With this disintegration of the autonomy of the arts, and the change from a productive and traditional process of education, art teaching as a profession became a protective necessity, first, so that the "Fine Arts" might maintain their new and aristocratic appeal to the wealthy connoisseur, and later, so that the arts might survive the inroads of commercial production. So long as masters of art engaged in voluntary and private teaching, of special pupils, the system of small studio schools was efficient within such needs. It was a specialized professionalism with a specialized appeal. Art had lost control of the necessities of life, and had yielded its traditional prerogative to the industrial producer. Professional art teaching accepted the definition of art training introduced by the Italianized revival of classic art, in the 16th century. The human figure, through the media of antique statues, claimed the dominant place in such training. Styles, associated with "schools" and "periods" were dominating influences, and coincident with certain national characteristics we have ebbs and flows between naturalism in its manifold expression and conventional severities. With the development of experimentation the "Fine Arts" fully occupied educational interests until the demands of industry and international rivalry began to claim attention. From the early 19th century to the present time is a long story of experimental attempts, through systems of education, to reinstate the artist in his right position relative to production.

Art teaching has been accepted as a State responsibility, and is developing on lines of scientific psychology in close relationship with other branches of education, which function as a very highly synthesized antidote to organized processes of devitalizing if not dehumanizing interests. The claims of human life and human expression are becoming the paramount stimulus in the new theories of all education.

Great Britain.—State art education in Great Britain commenced in earnest in 1827, under the control of the Board of Trade, governed by a council of royal academicians, when an art school was opened at Somerset House, and provincial schools multiplied to fill the need.

The Exhibition of 1851, at the Crystal Palace, seemed to emphasize further this national necessity. The influence of this exhibition was felt on the Continent, and Germany and Austria responded to the call. France was already ahead of other countries; the productions of French art industries appearing in London at this time showed to much advantage, and it was evident that organized training of workers for English art trades was imperative. All three countries undertook the re-organization and strengthening of schools already in existence, and the development of new foundations. Special attention was also given to industrial art museums. In view of the absence of specialists in industrial design at this time, these museums were vitally important factors in the dissemination of standards of taste, though the inevitable tendency to accept period productions as unquestionable guides to the design for industrial processes is a danger that is only now beginning to be fully recognized. State art education in its early years leaned too much on the authority of traditional work, as exemplified by historical collections of fine examples intermingled with doubtful ones.

The general dissatisfaction with the training given in industrial design in the schools, the passing of the Technical Instruction Act of 1889, the re-organization of the National Art Training school and the inauguration of the Royal College of Art in 1897, are the factors which brought about more vigorous and vital methods in English art teaching generally. The Royal College of Art may be rightly considered the centre of stimulus in the directing policy of our national art education. Dating from its re-organization, a wider view as to what constitutes right training for the designer, whether for industry or crafts, has gradually evolved, consisting of a process of practical productive work, in the various schools and workshops, wherein theories have given place to experience in the realization of the possibilities of material; coincident with this the training of teachers has been established on a wider interpretation of principles of teaching. There is also the recognition of the principle that designers for industries are best trained locally, in touch with the industry as far as possible, and that manufacturers may best be helped not by sacrificing the artist's ideals, but by conserving the mentality of the artist; that a concentration on the problem of training the designer and the teacher to the detriment of the wider view cannot be successful.

Art teaching has tried to discover permanent principles upon which to base a reasonable standard of training. The authority of great masters and great periods seemed to offer permanency to some, hence we have traditionalists who mainly look to the past for inspiration. But the art teacher has to interpret tradition in terms of progress and the authority of past achievements indicates the way. A living art must express contemporary life. A change in technical processes must influence methods of teaching. It is hardly questionable that oil painting as distinct from tempera has done more to alter the artist's visualization of his subject than more abstract theories of aesthetics. Processes of printing have revolutionized book production, and ferro-concrete is changing conditions of building and architectural ideas. The modern teacher of art will be constantly alive to new conditions and new traditions which are evolving through them; for tradition in art is a living force, for ever progressing, developing and governing creative work.

If art is to reflect and express the age which brings it forth, then nothing in the cosmos of our existence is outside the realm of interest for the artist. Something of this wider view is permeating educational systems. With the commencement of the present century organization became the watchword. The consciousness of a more scientific co-ordination, induced by a better understanding of the psychology of education promoted a healthier relationship between the pupil and teacher, and inspired a more comprehensive interweaving of subjects of study; much still has yet to be done. The Education Act of 1902, which gave the county council control of elementary and secondary education, helped the co-ordination of a progressive scheme, and whilst drawing had been included previously in the syllabus of elementary schools, it was from this period onwards that art became a definite subject in the curriculum of English elementary and secondary education. An increasing interest in the arts and crafts about this time promoted the development of a scheme for technical schools, which subsequently included "Day Continuation Schools," "Evening Institutes," "Junior Technical Schools," Trade Schools and later "Junior Art Departments of Art Schools." All these included courses of art study for vocational training in the trade crafts. They were intended as progressive steps from elementary education through courses of an apprenticeship character to the skilled trades.

The formation of the junior art department of art schools has already proved its efficacy in offering a field of employment in the arts and crafts to boys and girls who had previously looked for work of a commercial character or of an unskilled nature. Scholarships from the elementary and secondary schools into art schools as well as trade schools are offered. The junior art student is a growing factor in the schools, and may be accounted a healthy influence in re-establishing that serious application to vocational training which the trend of modern life, with its passion for saving time, and desire for "short cuts," is only too apt to undermine. These juniors, at the age of 17, have been sent out into commercial studios and industrial workshops as draughtsmen and designers, in ever increasing numbers. A more specialized value of the junior department is in the opportunity it offers more talented students to continue their studies in the higher branches of art, and thus the personnel of the schools is recruited from a new and invigorating source.

It has been said that the further education in technical schools has been planned so as to enlarge, so far as is reasonable, the educational discretion of the responsible school authorities, and it would therefore appear to be an organization, which has almost unlimited powers of expansion, under sympathetic regulations of the Board of Education. A much more comprehensive scheme is in process of maturing, to form part of the curriculum of elementary, secondary and public schools. Success will depend on having teachers of the widest possible educational outlook. Something much more than specialized technical skill is needed in such teachers. The value of a wide humanistic quality, which will interpret life through art, is incalculable.

The establishment of the Burnham scales of salaries for teachers in 1921, and the Pension Act of 1925, have raised the economic status of the art teacher, with the result that increasingly large numbers are taking up secondary school work, which now offers professional security.

The training of teachers is being handled on the broadly conceived plan that art can best be taught by the technician, with specialized ability, encouragement being given to those taking a course in pedagogy and psychology, as endorsement to their art qualifications. This course is organized as "Methods of Teaching," and in so far as it widens the outlook of the student in training, and breaks down the barriers which have separated art from other phases of culture, it is entirely necessary. Art in the elementary schools is handled by the teacher of general subjects with a special bent towards drawing. The pedagogic value of such lessons is to some extent safeguarded by the issue of Board of Education "Suggestions," as to methods, but the most beneficial offer to such teachers is the course of training arranged by art schools, in relation to the school drawing certificates for elementary teachers, offered by the National Society of Art Masters. The fact that such teachers spend some time in close touch with vocational art students in the atmosphere of an art school, is of very real worth.

Art and Industry.—A more liberal recognition by industry that the training offered should be something more than technical, would place art schools on a really healthy basis. Trade has yet to learn that whilst there is much for the student to acquire in the matter of mere skill in the handling of mechanical processes, on the other hand these processes might well evolve an art which possessed aesthetic qualities peculiar to themselves, and were in no way poor plagiarisms of hand crafts. But this would mean greater freedom allowed to the designer, and 2 more enlightened attitude by the producer.

It is probably in this that Germany has taken the lead. A closer

relationship exists between the factory and the school; the directors of the latter are often men of noteworthy excellence in some practical field of art. If salaries paid to professors in Germany are not large, allowances for house rent increase this value and opportunities for outside practice are offered and encouraged. Private studios adjoining class-rooms are often supplied in which the professor may pursue his profession. The amount of time required in actual teaching is limited, but the honour attached to the position is considerable. Again, there is no fetish worship of numbers. The classes of the industrial art schools are never large, and it is not unusual in the more advanced courses to find but half-a-dozen students at work.

France recognized earlier than any other nation the value of encouraging art as a national asset. Louis XIV. established the Manufacture Royale des Gobelin, which brought together workers in furniture, ceramics, metal and tapestry. This stimulus to designers and craftsmen soon placed France in the van of European nations. Since 1824, one of the cabinet offices has been a Ministry of Public Instruction and Fine Arts, exercising supervision over all art schools in France.

Germany believes that a nation cannot afford to refuse art training to the few, if the quality is high enough; France puts her faith in a Ministry of Fine Arts, controlling her educational destinies; and England believes mainly in individual enterprise. The prevailing idea that art should serve industry threatens to become a fetish. That Industry needs inspiration from the artist is true; but industries should be controlled in the interests of art. To train artists for industry is rather like hitching the star to the wagon. The great problems of art teaching will ever remain in a state of fluidity and growth. How far can technical skill in representational accuracy help or hinder the expression of emotional qualities? Concentration on representational accuracy has been proved a failure, the reaction in favour of so-called "free expression," without the disciplinary training of grammatical study would seem uncultured licence. For the time the sane path appears to tend towards representational accuracy restricted by the material and implements of expression, in the hands of the individual. Individual interpretation through material is the basis of modern art teaching, on the technical side. This would neither debar training in manual dexterity or formal exercises, nor does it deny the personal vision. (D. HE.)

THE UNITED STATES

Drawing, as a subject of instruction, was introduced by thoughtful teachers into their own schools in several States in the early part of the 19th century, without public recognition. The chief aggressive spirit of that period was "Master Fowle" of Boston. About this time Henry Barnard, editor of the *Connecticut School Journal,* was urging that drawing be taught in the common schools throughout the country. In 1842 Rembrandt Peale, an artist in Philadelphia, agreed to superintend without charge the introduction of drawing into the elementary schools of that city. Horace Mann introduced drawing into the grammar schools of Massachusetts in 1848, and in that same year drawing was being taught in the high schools of Baltimore by William Minifie. One of his published manuals was used for some time as a text-book in England after 1852.

In 1864 John D. Philbrick, superintendent of schools, Boston, secured the vote of his school board to make drawing a required study in grammar grades, and William Bartholomew's text-books were introduced. In 1869 the Massachusetts State board of education was directed to arrange for free instruction in drawing in all cities and towns of 5,000 inhabitants and upward. In 1870 drawing was required in every Massachusetts city and town having more than 10,000 inhabitants, for all scholars over 15 years of age, either through day or evening school. That same year the State authorized the establishment of free technical schools for the leading industries.

In 1870 Walter Smith came from South Kensington, England, to Boston. This was made possible through the co-operation of Boston merchants and the Boston school committee. Smith came as supervisor of drawing for the Boston schools, and director of drawing for the State. Later he became the principal of the Massachusetts Normal Art school, established by act of legislature in 1873. For 12 years Smith taught, lectured, published text-books and circulated exhibitions everywhere. To him more than to any other one person credit is due for laying the foundation for American art education.

Walter Smith's exhibit at the Centennial, 1876, included work from the Normal Art school and 24 towns in Massachusetts. Shortly thereafter cities and towns in all parts of the United States began to foster art instruction. In 1879 the National Association of school superintendents resolved that "Industrial drawing should form one of the fundamental branches of study in all grades." In 1895 the Committee of Fifteen of the N.E.A. recommended that "drawing be taught for at least an hour a week from the second to the eighth year." Since that date few communities have opposed the introduction of drawing, and it is now regarded almost universally as a desirable subject of instruction in the public schools throughout the United States.

Behind all this development stands first in influence, as the alma mater *par excellence,* the Massachusetts Normal Art school, organized by Walter Smith and developed by Otto Fuchs and George H. Bartlett. Next to the Massachusetts Art school in its influence upon art education in the United States stands Pratt institute. Its graduates are found in positions of commanding importance in city school systems, normal schools, colleges and art schools in almost every State in the Union. Other art schools of outstanding importance in the art educational development of the country are Columbia university; the Carnegie institute, Pittsburgh; the New York school of fine and applied art; the Maryland institute; the Cincinnati Art academy; the Cleveland school of art; the Chicago Art institute; the San Francisco Art institute; the California school of arts and crafts; and Newcomb college, New Orleans.

The Eastern Arts association, the Western Arts association and the Pacific Arts association, supplemented by the American Federation of Arts, together with the College Art association, the American Institute of Architects and the Association of Museum Directors, have recently organized the Federal Council on art education which seems destined to have a potent and salutary influence upon all future development in art education.

Dr. H. H. Powers, through the organization of the Bureau of University Travel, initiated a programme combining travel with scholarly instruction, which has been imitated and promoted by an ever-increasing number of travel companies, with a total annual membership of thousands. These travellers, returning to their States, have leavened with higher ideals all the population.

The museums of art have had an influence on art education, especially since the militant advocacy of aggressive educational work for museums by John Cotton Dana, of Springfield, Mass., and Newark, New Jersey. In the field of circulating exhibitions the pioneer work of Mrs. Melville Johnstone of Richmond, Ind., and the more extensive activities of the American Federation of Arts, are of primary importance.

The *American Art Annual,* founded by Florence N. Levy, and published by the American Federation of Arts, gives data for 1927 concerning organizations which are promoting art education in the United States as follows: national organizations 24, State organizations 928, art schools 419, summer schools 107, art magazines 91.

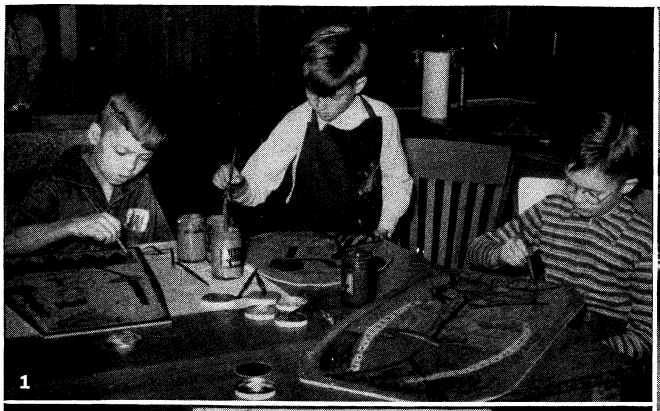
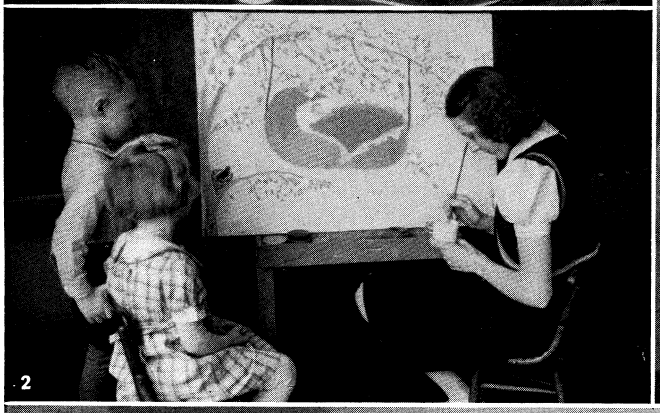
MODERN VIEWS

In the teaching of art, it must first be realized that the artistic sense cannot be acquired by instruction; it can only be awakened and fostered. The qualities on which an art teacher's value depends are the power to recognize artistic talent where it exists, and the desire to respect it as a rare phenomenon. So much depends on the personality of the teacher that no systems of instruction can

ART TEACHING





BY COURTESY OF (1) GRAND RAPIDS, MICHIGAN PUBLIC SCHOOLS, (2) OMAHA PUBLIC SCHOOLS, (3, 4) WPA ART PROGRAM, FEDERAL WORKS AGENCY

ART CLASSES IN THE UNITED STATES

1. Fourth-grade students of Grand Rapids, Mich., designing shields for an African jungle ceremony. Art is closely correlated with social and industrial studies in many American primary schools
2. An eighth-grade student painting a panel for a kindergarten in the Omaha public schools
3. Children's class at WPA art gallery, Fairfax, Virginia
4. Clay-modelling class sponsored by the WPA art program at Washington, D.C.

be adopted without this being borne in mind. It has never been found a good plan to lay down strict rules regarding previous studies for the admission of students. Real talent, once it is awakened, will always find means, in civilized countries, of making up deficiencies in past instruction. A gifted student in such circumstances feels a natural urge towards knowledge which makes study a necessity to him and no burden. The teacher should encourage him in his work, and try to win his full confidence by discussing his plans with him in a frank and friendly way. His first efforts, no matter what direction they may take, gradually help him to understand himself, and enable him to choose his own course. It is an advantage if the teacher's own work is well known, and also if he is in sympathy with the efforts of the younger generation. This will make his work very much easier, for the mere fact of his presence will spur the pupil on to greater efforts, provided he does not do more harm than good by exercising too exclusive an influence over him or leading him into direct imitation.

Experience shows that gifted students of architecture may develop into excellent draughtsmen, fashion artists or even sculptors. The students should be allowed to do their individual work. Nothing must be done under compulsion; to work against the grain dries up the secret springs of talent. A student learns an immense amount from the work of his fellow-pupils, and, conversely, it often happens that one student of unusual talent will inspire the others to do better work than their own powers would warrant. Such considerations show how necessary it is for a good teacher to keep a close watch over all that happens in his school, and to give full scope to students of exceptional gifts. He must be able to set a standard, and to keep away all disturbing elements, whether internal or external.

A teacher who is at the same time one of the leaders of the artistic movement of the day can do much to shorten the way for his pupils, for he can indicate to them the questions which are of the greatest importance at the moment and thus help them to advance farther. The realization that artistic movements in all countries are working towards a common aim will greatly assist the students. They must be made to feel that they are taking part in a great common effort to which they can devote their whole energies. Progressive and creative work must be a genuine pleasure to them. They must acquaint themselves with all the most up-to-date movements, and must try not to look backwards, but to press forwards with energy, even at the risk of occasional failures.

Instead of being subjected to the strict discipline of the older schools, which was such a bugbear to young people, students must discipline themselves by their own sense of responsibility, by setting themselves definite aims and by taking their work seriously. It is most valuable for them to try their hand at real work, *i.e.*, work which is actually required by outside people. They should enter for open competitions and work for industrial purposes whenever possible. With the old educational methods it was impossible, in the time available, to give students a thorough knowledge of building construction, interior finishing and the various other technical matters required in architecture. A student trained by the stimulating methods of the present day will, however, try to approach any task which may beset him in the proper way, and deal with it according to his capacity.

Creative Art.—In the study of architecture the older system of training tried to achieve its objects by detailed study of historical styles. The industrious pupil with a good memory had the greatest chance of success, and it was the man who had the best grasp of some historical style who won the teacher's approval. The results of this system may be seen in many a town where buildings with Gothic, classical and Renaissance facades, all built at the same period, stand side by side. Most of them have considerable technical merit, but they are spoilt by the half-hearted and insincere spirit in which they were designed. At this period no one appreciated the greatness of the old building guilds, and the marvellous unity of spirit which prevailed among their members even at great distances apart. The true nature of their creative activity was entirely unrecognized.

Only a man of extraordinary powers could succeed in doing good and original work in circumstances such as these. It was quite forgotten that there had been ages in which it seemed almost impossible for bad work to be done at all—when even the humblest craftsman, even the inhabitant of a remote mountain district, was inspired by the same marvellous artistic sense, and when the same imaginative and inventive power was displayed in the making of the simplest articles as in the construction of great buildings. To-day we are intensely interested in the characteristics of such periods; we want to release the same creative forces as existed then; we try to understand how it was that the men of those days could continue to do such magnificent work in spite of the intense misery and distress into which the nations were plunged by the political vicissitudes of the time. We are gradually coming to understand that we have sunk to so low a level in our own period that our work has been imitative—sometimes indeed nothing less than counterfeit—and we are hastening to return to the right path.

Ruskin, much as he added to our knowledge of art, had no real conception of purely creative work; hence his constant reference to models. It was for the same reason that he regarded Chinese art, for example, as barbaric; indeed he did not really recognize any kind of art except the Gothic. Although a thinker of genius and a wonderful connoisseur, he knew nothing of the true nature of artistic creation and of the hidden processes by which inspiration works—the powers which lie almost entirely outside a man's control, but which are born with him and are quite independent of study, so that they may be found in the African negro as well as in the Greek of the classical age.

In our own age, too, original work has been done outside the official province of art. Technical progress has been made in all branches,, and new forms have been invented in the sphere of costume and of articles of daily use of all kinds. The feeling which produced these changes was unconscious, but we must become fully conscious of it. It would be ridiculous to decorate a motor car in the Gothic or classical style, and it is just as ridiculous for us, in our modern clothes, to live in buildings which were designed for mediaeval knights and ladies. We shall always admire them for their marvellous beauty, but our very reverence for them should prevent us from imitating them when we are designing new buildings; though at the same time we should protect them from the criminal attempts at restoration made by those whose business it should be to understand ancient art.

We are now beginning, driven perhaps by the necessities of the age, to recognize the beauty of simple technical work perfectly adapted to its purpose, and to make such work not merely a matter of calculation, but to bring it within the sphere of creative and expressive work. In short, we want to deal with work of all kinds from the standpoint of the cultivated and modern-trained engineer; we attach as much importance to the manufacture of a good box as to the building of a railway carriage or a skyscraper. We do not want either our box or our skyscraper to be plastered over with a sham ornamental facade; we feel that if our work is adapted to its purpose, and if materials and workmanship are thoroughly good, we are in harmony with the spirit of the age. We must not play tricks with these new inventions; we must use them as natural and inevitable forms. The one way in which our work represents an advance on that of the engineers of the preceding period is that in our constructional work we do not leave beauty out of account. Something similar may be seen any day in the work of a good tailor. The beauty of a tailor's work depends on fine tact in the choice of materials, good cut and perfection of workmanship; and this is very similar to what we want from a modern constructional engineer.

Machine Work **and Hand** Work.—We live in an age when the great masses of the population have little to spare for luxuries, and this makes it our special duty to see that all objects manufactured for use are well and simply made without unnecessary additions. They can be made beautiful without any increase in cost if their shape and proportions are beautiful and if the material is treated in a suitable way. It is an elementary principle that machine work ought not to try to imitate hand work. The machine is a well-contrived means of enabling man to do work in a rapid

and reliable manner; it is not meant simply to reproduce what was designed to be made by hand. The machine can produce a given object out of a given material, but without individuality. It is thus suitable for making things like well-designed and well-executed metal saucepans, handsome motor cars—in short, anything which must be produced in large quantities in a standardized form in order to bring it within the purchasing power of the population. Again, anything which cannot be made by ordinary means, but requires special machinery to handle the great masses of material involved, would look ridiculous if antique forms were artificially grafted on to it. Radiators decorated in antique style would be hideous.

When an object is made by hand, the material can be treated much more freely, and the artist will unconsciously impress his own characteristics on it, thus giving it originality. For example, it is possible to recognize the maker of a vessel of beaten or repoussé metal simply from his characteristic hammer strokes. Handwork allows of free and sensitive design, and creates a living surface, which will delight the connoisseur if its refinement is not destroyed by bad ornament. Workmanship will constantly improve, and its effect need not be lost even if richer treatment is adopted for special purposes. Objects which are intended to be the property of the community, such as ceremonial vessels of all kinds, sports cups and so on, may be of considerable value. Frequently it is necessary for them to symbolize their origin and purpose in an original and yet generally recognizable way; if so, they lend themselves to creative and imaginative treatment.

If a modern student is to become fully acquainted with all these questions, he must have an opportunity of working in well equipped workshops. He must, of course, not work mechanically as in the old technical schools; he must constantly be receiving intellectual stimulus and food for thought, and be encouraged to use his inventive faculties. In the actual work he must, of course, first learn all the known methods. The teacher will not expect him to discover for himself the tools and ways of using them which have been known and been in use for hundreds of years. A few hints such as are given in any good workshop will teach what would otherwise need long study.

Young people delight in working for themselves in this way; it acts as a stimulus, and it teaches them both to understand ancient art and to judge it properly. Interest in modern discoveries is awakened, new things are attempted, and new inventions aimed at. An architectural engineer who has been trained on this system would never think of designing electric chandeliers to imitate lighted candles. He would realize the difference between the open candle flame which used to make the crystal lustres glitter, and the electric bulb, which also burns upwards, but with a still, unflickering light. Once the student realizes why considerations of this kind are necessary, the battle is won. He will no longer feel himself superfluous, but be happy because he has a place in the scheme of modern production. Even minor talents can do good and useful work in such circumstances. There is little danger that such detailed work will injure the student's capacity for work on a large scale.

Schools where the curriculum is excellent on paper, but is in the hands of dull and uninspiring teachers, will be useless and sterile, however well equipped they may be. To find the right staff must always be the first concern. It should be emphasized that women often make very inspiring teachers. If women attend an architectural school it is because they have an intense enthusiasm for art, while men often come because their parents have selected a profession for them, and not because they have any genuine vocation.

Technical and artistic work, pure and applied, is so important that it is absolutely essential to be able to complete one's studies, up to the most advanced stage, at the same institution; intermediate schools, technical schools and colleges should not be three separate institutions. Unfortunately, other less desirable schemes are still in existence, under which architecture, in itself a somewhat abstract conception, is taught at three different institutions: at a technical college, an academy of plastic arts and at a school of applied arts. Thus there is an immense amount of duplication of work for no purpose. The same absurd position may exist in schools of painting and sculpture, although these are surely subjects where the teacher's personality matters more than questions of formality.

With the money which this threefold organization costs, it would be possible to set up one institution of the first rank, which could meet all the requirements of modern art education. The various subsidiary courses could be thorough and would not have to be triplicated. The history of art, the technical subjects relating to the properties of the materials used, and the various branches of engineering could be taught thoroughly and in their entirety. A proper basis would at the same time be provided for the teaching of the history of art at the universities, and the disastrous gulf which exists between artists and art critics would be bridged. The very fact that the art critics of the future would have been in close contact with practising artists would make them better fitted to carry out their important functions.

The same school would provide for the education of the future clients of the artistic professions, and more particularly of business men. A business man is not really fit for his work unless he has a full appreciation of quality, and has learned as a young man to abominate all the artistic horrors which he would otherwise perpetrate without scruple, to the waste of valuable labour and material, and to the injury both of the individual and of the community as a whole. Unity in all the branches of art education is the only thing which can make national art flourish as in former days. It is useless if the artist, on completing his studies, feels himself solitary, misunderstood and unwanted, and surrounded by an atmosphere of hostility.

It should be realized how necessary a single complete educational system of this kind is, and it should be carried out thoroughly. The kind of education given in old-fashioned art schools means nothing to the man of the present day, and he instinctively avoids it. Technical skill can make up for a good deal, but the present generation needs men of outstanding ability in the sphere of art as well as in that of literature.

The Public Attitude. — The modern theatre, the cinema, advertisement, men's and women's dress—in short, everything which modern man uses or sees around him, stands in constant need of reform. It is most important that the great masses of the population should be brought to realize what happiness can be derived from the various forms of artistic expression, and induced in their millions to collaborate in the work. It would then be found that, as in all great movements, the natural leaders would emerge. Every school child in the lower forms of the elementary schools ought to be made to realize what art may mean to him individually; we might then once more see a race of happy men and women. But real success cannot be attained until the whole population has been drawn into the movement, and until we cease to cast discredit on all that is done, however well meant it may be.

The old systems of examinations must give place to a thorough study of the student, his work and his characteristics. His capacities should be judged by his achievements as a whole, and not by a mere test. If however his powers are to find no outlet in his future life, as is so often the case to-day, all efforts are in vain, and it would almost be better to lay aside the whole system of education for a time and wait until something new was spontaneously created. Isolated attempts, even if they are entirely on the right lines as in the case of the *Bauhaus* at Dessau, must inevitably remain mere attempts which cannot cover the whole field; and they are unfortunately unlikely to endure, as bitter experience has shown. The belief that the present generation has no feeling at all for art, whether ancient or modern, and regards it as quite superfluous, is surely false, and is due to confusion between the artistic and the creative. As long as we have to use all the various objects with which we are surrounded, we must inevitably want to make their form better, purer and freer. Even if we build fewer churches to-day, we build more orphanages, baths, hospitals, schools and dwelling-houses. We believe that a child who is well cared for and lives in a healthy, suitable and dignified environment is likely to grow up into a good citizen, and that such a citizen will

do his work better and with more self-respect if he is provided with the right equipment and clothing.

Artists are often accused of preaching simple form but practising ornamentation. Surely, however, there is no real contradiction if what we care about is not ornament in itself, but a new and creative treatment of ornament. Men are made so differently that there will always be some who like to wear patterned ties; but then the simplicity, colouring and fabric of the ties should be such as to reflect the age. Materials for curtains and upholstery, and so on, cannot always be made in plain colours; and to be able to understand the feeling for such things is a sign of a fresh mind and of vitality. The modern designers' aim has been to satisfy requirements such as these as long as they exist. They are satisfied if they can produce objects of all these different kinds which it will be possible to recognize hundreds of years hence as being the product of our age, and which cannot be dismissed as mere superficial and imperfect imitations of bygone styles. It is absurd that intensive art study should have no other aim than the production of imitations.

All that has been said above holds good from the economic standpoint. When it is remembered that mere industrialism has produced little that is not worthless, and that quantities of material have been simply wasted, instead of having been used properly so that their value was preserved or indeed heightened, it will be realized how much the old system has to answer for. To-day as 1,000 years ago we can only dignify our existence by the creation of beauty. Beauty in all departments of our life, from the highest to the lowest, is the only thing which can really make us better and happier.

ARTUSI, GIOVANNI MARIA, Italian composer and theorist (born in Bologna during the second half of the 16th century; died 1613) is to-day remembered only for his attacks upon Monteverde (*q.v.*) embodied in his *Delle imperfezioni della musica moderna* and other controversial works.

See Dr. G. Vogel and O. Riemann, *Vierteljahrsschrift fzir Musikwissenschaft* (Leipzig), vol. iii., pp. 326, 380, 426.

ARU ISLANDS, in the government of the Great East ("Groote Oost"), Netherlands Indies, between 5° 18′ and 7° 5′ S. and 134° and 135° E. The group lies on the edge of the submarine continental shelf of Australia and New Guinea. They are composed of one large island, Tana-besar, 122 mi. long and 58 mi. wide, and nearly 100 smaller islands, the total area of the group being 3,244 sq.mi. Tana-besar, of irregular, oblong form, traversed by three narrow channels of varying width and less than three fathoms in depth, is almost divided into several separate islands. A. R. Wallace held that the land between the Arus and southwest New Guinea had subsided—the sea between is still very shallow—and that these rivers were once connected with present-day rivers in southwest New Guinea, and formed their mouths. All the islands are low, mostly of coralline limestone, and covered with a dense forest; the coast is often very swampy, The vegetation includes screw pines, palm trees, kanari and tree ferns; in Tarangan, the southern portion of Tana-besar, there are grassy plains, and along the coast and river banks are mangroves. Pop. (1930) 18,176, of mixed Papuan blood, as in Tenimber, but of darker colour, smooth rather than curly-haired; the skin less dark than that of Papuans proper; and lips thin. The natives, divided into *Pata-lima* and *Pata-siwa*, showing influence af Tidor and Ternate, are mostly pagan, though Christianity has made a little headway, and some are Mohammedans. In the western islands, the Voormal, where the Mohammedans and Christians mostly live, including Chinese, Buginese, and Macassarese settlers, the villages are as in Amboina; near the coast and nearly hidden amongst clumps of trees. In the eastern islands, the Achterwal, they stand on high rocks. The houses of the pagans are often of rough wood and *atap*, crowded together, and crowded; they are entered by a trap-door in the middle of the floor.

Usually a shed in the centre of the village harbours the protective spirit of the community, to whom offerings are made. The Aru islanders are a gentle quiet race; there is little crime among them, and they retain their old laws and customs, and are largely governed by their own chiefs under Dutch surveillance. Many of the men wear a single short garment round the waist, and the women a very short and tight *sarong*, home woven, but they decorate themselves with bead necklaces, anklets, bracelets, ear-rings of copper, and plaited leaves, and combs of bone or wood. The fauna is quite Papuan and includes several birds of paradise, including the king bird of paradise. Many natives find occupation in hunting this magnificent bird for its plumes, which are used for ornaments. Little ground is tilled, except by the Christians and Mohammedans, and the communally owned uncultivated ground is hunted and explored for sago and other food products. Wives are purchased, a man becoming absolute master of his wife, and his brother having the right to marry her on his death. The principal means of subsistence are agriculture (amongst the Voorwal peoples), sale of bird of paradise plumes, and collection of trepang and pearl and tortoiseshell for Chinese and Macassar traders.

The capital, and practically the only port, is Dobo, on the small island of Wamar in the west, though few Aru islanders live on it, only visiting it to take their produce there for sale. It has a very small population. All trade centres there, and there is much pearl fishing. The islanders retained certain rights in the pearl fishing of the east coasts, but it was leased by the Dutch government to an Australian concern, the Celebes Trading company. The headquarters of the fleet of over 100 luggers are at Dobo: pearls and mother-of-pearl of the value of about 150,000 guilders are obtained annually.

The Aru Islands were occupied by Japan in Aug. 1942, during World War II.

See A. R. Wallace, *The Malay Archipelago* (1890).

ARUM, a genus of monocotyledonous plants of the family Araceae (*q.v.*), containing 12 species found in Europe and the Mediterranean region, and represented in the British Isles by the well-known lords-and-ladies, cuckoo-pint (*q.v.*) or wake-robin (*A. maculatum*), native to Europe and northern Africa. The black calla (*A. palaestinum*), native to Syria and Palestine, is occasionally grown by gardeners. Many plants formerly referred to *Arum* are now placed under other genera, and numerous plants belonging to other genera are popularly called arums, as the water arum or wild calla (*Calla palustris*), cosmopolitan in the northern hemisphere, and the arum lily, calla lily or calla of the gardeners (*Zantedeschia aethiopica*), native to South Africa. (*See* CALLA; CUCKOO-PINT.)

ARUNDEL, EARLS OF. According to Cokayne (*Complete Peerage*, i. *p.* 138, note *a)* there is an old Sussex tradition to the effect that

> —Since William rose and Harold fell
> There have been earls of Arundel.

This, he adds, "is the case, if for 'of' we read 'at'."

RICHARD FITZALAN (1267–1302), earl of Arundel, fought for Edward I. in France and Scotland, and died March 9, 1302.

He was succeeded by his son, EDMUND (1285–1326), who married Alice, sister of John, earl de Warenne. A bitter enemy of Piers Gaveston, Arundel was one of the ordainers appointed in 1310; he declined to march with Edward II. to Bannockburn, and after the King's humiliation he was closely associated with Thomas, earl of Lancaster, until about 1321, when he became connected with the Despensers and sided with the King. He was faithful to Edward to the last, and was executed at Hereford by the partisans of Queen Isabella on Nov. 17, 1326.

His son, RICHARD (c. 1307–76), who obtained his father's earldom and lands in 1331, led one of the divisions of the English Army at Creçy and took part in the siege of Calais; he also fought in the naval battle with the Spaniards off Winchelsea in August 1350. He was regent of England in 1355, and died Jan. 24 1376, leaving three sons, the youngest of whom, Thomas, became Archbishop of Canterbury.

Richard's eldest son, RICHARD (1346–97), earl of Arundel and Surrey, was a member of the royal council during the minority of Richard II., and about 1381 was made one of the young King's governors. As admiral of the west and south he gained a victory over the French and their allies off Margate in 1387. About 1385 the earl joined the baronial party led by the King's uncle, Thomas of Woodstock, Duke of Gloucester, and in 1386 was a member of the commission appointed to regulate the kingdom and the royal household. Then came Richard's rash but futile attempt to arrest Arundel, which was the signal for the outbreak of hostilities. The Gloucester faction quickly gained the upper hand, and the earl was again a member of the royal council. After a personal altercation with the King at Westminster in the same year Arundel underwent a short imprisonment. In 1397 he was tried, was attainted and sentenced to death, and was beheaded on Sept. 21 1397. His tomb in the church of the Augustinian Friars, Broad-Street, London, was long a place of pilgrimage.

His only surviving son, THOMAS (1381–1415), was a ward of John Holand, duke of Exeter, from whose keeping he escaped about 1398 and joined his uncle, Archbishop Thomas Arundel, at Utrecht, returning to England with Henry of Lancaster, afterwards King Henry IV., in 1399. After Henry's coronation he was restored to his father's titles and estates. Arundel joined the party of the Beauforts, and was one of the leaders of the English Army which went to France in 1411; then after a period of retirement he became lord treasurer on the accession of Henry V. He died Oct. 13 1415. His wife was Beatrix (d. 1439), a natural daughter of John I., king of Portugal, but he left no children, and the lordship of Arundel passed to a kinsman, JOHN FITZALAN, Lord Maltravers (1385–1421), who was summoned as earl of Arundel in 1416.

John's son, JOHN (1408–35), did not secure the earldom until 1433, when as the "English Achilles" he had already won great distinction in the French wars. He was created duke of Touraine, and continued to serve Henry VI. in the field until his death, June 12 1435, at Beauvais from the effects of a wound. The earl's only son, Humphrey, died in April 1438, when the earldom passed to John's brother, WILLIAM (1417–88).

HENRY FITZALAN (1517–80), 12th earl of Arundel, son of William, 11th earl, by Anne, daughter of Henry Percy, 4th earl of Northumberland, was born about 1517 and succeeded to the earldom in 1554. He was one of the council of 12 appointed by Henry VIII. to assist the executors of his will during the minority of Edward VI. He was twice arrested and twice released on various charges at the instigation of Northumberland. In June 1553 he alone of the council refused the "engagement" of the council to support Edward's "device" for the succession which passed over his sisters, Mary and Elizabeth, as illegitimate, in favour of Lady Jane Grey, though he signed the letters patent. On Edward's death, while pretending to support Northumberland, he secured the proclamation of Mary as soon as Northumberland had left London. Under Mary he held a series of high appointments, and retained the lord-stewardship under Elizabeth. But as one of the leaders of the Catholic nobility he fell under suspicion, and was more than once disgraced. In 1569 he was implicated in the Norfolk plot, but although he appears to have received money from Spain, the evidence against him was insufficient, and he was released in March 1570 and even recalled to the council. After the discovery of the Ridolfi plot he was once more arrested, and only liberated after the execution of Norfolk in 1572. He died Feb. 24 1580. At his death the title passed through his daughter Mary to the Howards.

PHILIP HOWARD (1557–95), 1st earl of Arundel, eldest son of Thomas Howard, 4th duke of Norfolk, executed for high treason in 1572, and of Lady Mary, daughter and heiress of Henry Fitzalan, 12th earl of Arundel, was born on June 28 1557. He was married in 1571 to Anne, daughter and co-heiress of Thomas Dacre, Lord Dacre (1566). On the death of his maternal grandfather in Feb. 1580 he became earl of Arundel. In 1582 his wife joined the Church of Rome, and was committed to the charge of Sir Thomas Shirley by the Queen. He was himself suspected of disloyalty, and was regarded by the discontented Roman Catholics as the centre of the plots against the Queen's government, and even as a possible successor. In 1583 he was with some reason suspected of complicity in Throgmorton's plot and prepared to escape to Flanders, but his plans were interrupted by a visit from Elizabeth at his house in London, and by her subsequent order to confine himself there. In Sept. 1584 he became a Roman Catholic and made another attempt to leave England. He was then brought before the Star Chamber and condemned to fine and imprisonment for life. He was released for a time, but again arrested on a charge of high treason and condemned to death. The sentence was not executed, and he died in the Tower on Oct. 19 1595. Arundel wrote three treatises on Virtue. In 1929 he was beatified.

Biography* and authorities there collected; the contemporary *Lives of Philip Howard, Earl of Arundel and of Anne Dacre his Wife*, ed. by the duke of Norfolk (1857); M. Tierney, *History of Arundel* p. 357 (1834); C. H. Cooper, *Athenae Cantabrigenses* (1861), with bibliography, ii. 187 and 547; H. Howard, *Memoirs of the Howard Family* (1824).

THOMAS HOWARD (*c.* 1585–1646), 2nd earl of Arundel, and earl of Surrey and of Norfolk, son of Philip, 1st earl of Arundel and of Lady Anne Dacre, was born in 1585 or 1586 and educated at Westminster school and at Trinity College, Cambridge. At the accession of James I. he was restored to his father's earldoms of Arundel and Surrey, and to the baronies of his grandfather, Thomas, 4th duke of Norfolk. He had a chequered career under James I. and Charles I., holding many high offices and being more than once imprisoned. In 1641 as lord high steward he presided at the trial of Strafford. This closed his public career. He again became estranged from the court, and in 1641 he escorted home Marie de' Medici, remaining abroad, with the exception of a short visit to England in 1642, and taking up permanent residence at Padua. He contributed a sum of £34,000 to the king's cause, and suffered severe losses in the war. On June 6 1644, he was created earl of Norfolk. He died at Padua, when on the point of returning home, on Sept. 14 1646, and was buried at Arundel.

Lord Arundel's claim to fame rests upon his patronage of arts and learning and his magnificent collections. He employed Hollar, Oughtred, Francis Junius and Inigo Jones; included among his friends Sir Robert Cotton, Spelman, Camden, Selden and John Evelyn, and his portrait was painted by Rubens and Vandyck. He is called the "Father of vertu in England," and was admired by a contemporary as the person to whom "this angle of the world oweth the first sight of Greek and Roman statues." He was the first to form any considerable collection of art in Great Britain. His acquisitions, obtained while on his travels or through agents, and including inscribed marbles, statues, fragments, pictures, gems, coins, books and manuscripts, were deposited at Arundel House, and suffered considerable damage during the Civil War; and, owing to the carelessness and want of appreciation of his successors, nearly half of the marbles were destroyed. After his death the treasures were dispersed. The marbles and many of the statues were given by his grandson, Henry, 6th duke of Norfolk, to the university of Oxford in 1667, became known as the Arundel (or Oxford) Marbles, and included the famous Parian Chronicle or *Marmor* Chronicon, a marble slab on which are recorded in Greek events in Grecian history from 1582 B.C. to 354 B.C., said to have been executed in the island of Paros about 263 B.C. Its narration of events differs in some respects from the most trustworthy historical accounts, but its genuineness, challenged by

some writers, has been strongly supported by Porson and others, and is considered fairly established.

Other statues were presented to the university by Henrietta Louisa, countess of Pomfret, in 1755. The cabinets and gems were removed by the wife of Henry, 7th duke of Norfolk, in 1685, and after her death found their way into the Marlborough Collection. The pictures and drawings were sold in 1685 and 1691, and Lord Stafford's moiety of the collection in 1720. The coins and medals were bought by Heneage Finch, and earl of Winchelsea, and dispersed in 1696; the library, at the instance of John Evelyn, who feared its total loss, was given to the Royal Society, and a part, consisting of genealogical and heraldic collections, to the College of Heralds, the manuscript portion of the Royal Society's moiety being transferred to the British Museum in 1831 and forming the present Arundel Collection. The famous bust of Homer reached the British Museum after passing through various hands.

Lord Arundel married in 1606 Lady Alethea, daughter and heir of Gilbert Talbot, 7th earl of Shrewsbury, by whom, besides three sons who died young and one daughter, he had John, who predeceased him, Henry Frederick, who succeeded him as 3rd earl of Arundel and earl of Surrey and of Norfolk, and William, Viscount Stafford, executed in 1680. In 1849 the Arundel Society for promoting artistic knowledge was founded in his memory. Henry Frederick's grandson Thomas, by the reversal (1660) of the attainder of 1572, succeeded to the dukedom of Norfolk, in which the earldom has since then been merged.

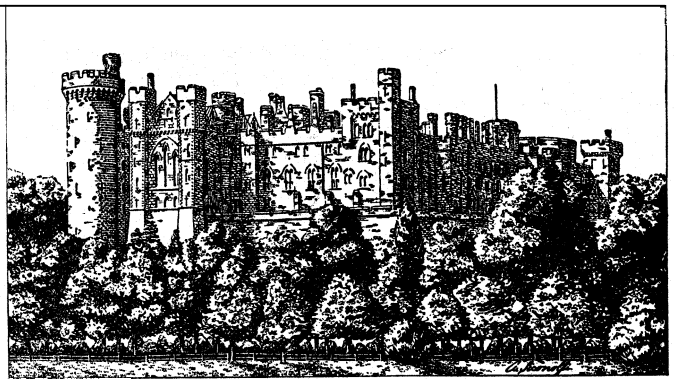
ARUNDEL, THOMAS (1353–1414), archbishop of Canterbury and lord chancellor of England, was the third son of Richard Fitzalan, earl of Arundel and Warenne, by his second wife, Eleanor, daughter of Henry Plantagenet, earl of Lancaster. In 1373 he became archdeacon of Taunton, and in April 1374 he was consecrated bishop of Ely. In 1388 he became archbishop of York, and in 1396 archbishop of Canterbury. During the early years of the reign of Richard II. he was associated with the party led by Thomas, duke of Gloucester, Henry, earl of Derby, afterwards King Henry IV., and his own brother Richard, earl of Arundel. He was three times lord chancellor under Richard II. After the arrest of Gloucester, Warwick and Arundel, the archbishop was impeached by the Commons, with the king's consent, although Richard held out hopes of safety to him. He was charged with assisting to procure the commission of regency in derogation of the royal authority, and sentence of banishment was passed, 40 days being given him during which to leave the realm. Towards the end of 1397 he started for Rome. He then became associated with Henry of Lancaster, but did not return to England before 1399, and the account which Froissart gives, telling how he was sent by the Londoners to urge Henry to come and assume the crown is thought to refer to his nephew and namesake, Thomas, earl of Arundel. Landing with Henry at Ravenspur he took his place at once as archbishop of Canterbury, witnessed the abdication of Richard in the Tower of London, led the new king, Henry IV., to his throne in presence of the peers, and crowned him on Oct. 13, 1399.

The main work of his later years was the defence of the Church and the suppression of heresy. To put down the Lollards he called a meeting of the clergy, pressed on the statute de *haeretico comburendo,* and passed sentence of degradation upon William Sawtrey. He resisted the attempt of the Parliament of 1404 to disendow the Church, but failed to induce Henry to pardon Archbishop Scrope in 1405. In 1407 he became chancellor for the fourth time, and in 1408 he summoned a council at Oxford, which drew up constitutions against the Lollards. In 1411 he went on an embassy abroad, and in 1412 became chancellor again, his return to power being accompanied by a change in the foreign policy of Henry IV. In 1413 he took a leading part in the proceedings against Sir John Oldcastle, Lord Cobham. He died on Feb. 19, 1414, and was buried at Canterbury.

See the Monk of Evesham, *Historia* vitae et regni Ricardi *II.*, ed. T. Hearne (1729); *Eulogium* historiarum *sive* temporis, ed. F. S. Haydon (1858–63); W. F. Hook, Lives of the Archbishops of Canterbury, vol. iv. (1860–76); T. Walsingham, *Historia Anglicana,* ed. H. T. Riley (1863–64).

ARUNDEL, municipal borough in the Chichester parliamentary division of Sussex, England, 58 mi. S.S.W. of London by the Southern railway. Pop. (1938) 2,368. Area 3.2 sq.mi. It lies on a hill slope above the river Arun, which is navigable for small vessels to Littlehampton at the mouth, six miles south. Arundel Castle, rising from the summit of the hill, was admirably placed to guard the passage along the river, through the South Downs on the north. The town takes its name, according to a whimsical etymology, from *hirondelle* (a swallow) as shown on the corporation seal. The first mention of Arundel (Harundell) comes as early as 877. In the time of Edward the Confessor the town seems to have consisted of the mill and an earthwork probably thrown up by Alfred as a defense against the Danes; but it appears in Domesday as a thriving borough and port. It was granted by the Conqueror to Roger de Montgomery, who built the castle on the site of the ancient earthwork. From very early times markets were held within the borough on Thursday and Saturday, and in 1285 Richard Fitzalan, earl of Arundel, obtained a grant of two annual fairs on May 14 and Dec. 17. The town was half destroyed by fire in 1338, but was soon rebuilt. The stronghold was frequently assaulted and greatly damaged in the 17th century civil wars; but it was restored by Charles, 11th duke of Norfolk (d. 1815), who made it one of the most splendid baronial mansions in England. The borough returned two members to parliament from 1295 to 1832, and one member until 1868. There are no early charters extant but in 1586 Elizabeth acknowledged rights claimed to have been exercised from time immemorial. The borough was incorporated in 1688. The church of St. Nicholas, founded about 1375, is Perpendicular. In the north aisle of the chancel there are several ancient monuments of the earls of Arundel. The church is otherwise remarkable for its reredos and iron work. The Roman Catholic church of St. Philip Neri was built by the duke of Norfolk (1873). Some remains of a *Maison Dieu,* a hospital, erected in the time of Richard II., still exist.



THE CASTLE AT ARUNDEL IN SUSSEX, ENGLAND. OVERLOOKING THE RIVER ARUN IS POPULARLY BUT ERRONEOUSLY SUPPOSED TO CONFER UPON ITS POSSESSOR THE EARLDOM OF ARUNDEL, THE PREMIER EARLDOM OF ENGLAND. WHICH DATES FROM HENRY I'S TIME

Arundel is now a quiet market town. It was formerly a flourishing seaport, having canal connection (1813) with London. The borough is under a mayor, four aldermen, and 12 coun-

cillors. Water for domestic purposes is supplied free by the Duke of Norfolk.

See also ARUNDEL, EARLS OF.

ARUNBELL OF WARDOUR, THOMAS ARUNDELL, 1ST BARON (*c.* 1562–1639), son of Sir Mathew Arundell of Wardour Castle, Wiltshire, served with great distinction as a soldier of fortune under the Emperor Rudolf II. against the Turks, and was created a count of the Holy Roman Empire. His assumption of a foreign title was strongly resented by Elizabeth, who sent him to the Fleet Prison on his arrival in England in 1596. He was soon released, but next year was again imprisoned for a short time on another charge. James I. gave him his English peerage in 1605, but he repeatedly fell under suspicion on account of his Catholic faith under James I. and Charles I. He died on Nov. 7 1639. Arundell was a devout Catholic, but the accusations of disloyalty made against him appear to have been unfounded.

Henry Arundell, 3RD BARON (*c.* 1607–94), grandson of the preceding, succeeded in 1643. He fought on the Cavalier side in the Civil War, and at the Restoration the family estates were restored to him, and he became an officer of the Queen's household. He was employed by Charles II. in negotiating the Treaty of Dover. Denounced by Titus Oates as a participator in the "Popish Plot," Arundell, with four other Roman Catholic peers, was impeached and imprisoned. He was released in Feb. 1684. After the accession of James II., the charge was annulled, and Arundell was for a time keeper of the privy seal. He died Dec. 28, 1694, leaving a reputation for piety and of benevolence to his co-religionists.

ARUNTA. In Central Australia, around Alice Springs, are still found representatives of the Arunta tribe—a typical stone age hunting people with peculiar beliefs, ritual and customs. The tribe is divided into two patrilineal, exogamous intermarrying sections which are split into two, and in some cases into four. The natives believe that the tribe is composed of two groups with differing physical characters. They are totemic in their own fashion. A child has the totem from the spot where its mother believes the child to have been conceived. The totems are therefore localized in distribution. Marriage is regulated by the child's position in the moiety, section, or sub-section to which he or she belongs by birth, and a man marries the daughter of his mother's mother's brother's daughter. Complicated ceremonies, closely associated with the breeding of the totem animals or the flowering of the totem plants, are held when conditions seem to be favourable—as when there is promise of the approach of a good season. Initiation rites—circumcision, sub-incision and headbiting are practised in prolonged ceremonies. Women have their analogous rites. The authority of custom—the power of the elder men—the belief in magic, the presence of a quasi-hereditary local headman (Inkata) with a vague, indefinite power, which, if he possess personality and ability, may be great, the belief in the sacred nature and magically efficacious association of the Churinga, are among the more prominent features of this group, whose peculiarities have lent weight to the criticism that in them we approach most nearly to primitivity. They may, however, be degenerates, or freaks, whose philosophizings have drawn them to strange conclusions. (See AUSTRALIA: Ethnology.)

BIBLIOGRAPHY.—Sir B. Spencer and F. J. Gillen, The Arunta (1927).

ARVAL BROTHERS, in Roman antiquities, a college or priesthood (Fratres Arvales, "brothers of the field"), consisting of twelve members, elected for life from the highest ranks in Rome, and always apparently, during the empire, including the emperor. Their chief duty was to offer annually public sacrifice for the fertility of the fields. There is proof of the high antiquity of the college, which was said to have been older than Rome itself, in the verbal forms of the song with which, down to late times, a part of the ceremonies was accompanied, and which is still preserved. No mention of the Fratres occurs in Cicero or Livy, and literary allusions to them are very scarce; but we possess a long series of the *acta* or minutes of their proceedings, drawn up by themselves, and inscribed on stone. Excavations (1570–1869) in the grove of the Dea Dia about 5m. from Rome, have yielded 96 of these records, dating from A.D. 14 to 241. The brotherhood, almost forgotten in republican times, was revived by Augustus. In his time the college consisted of a master ('tagister), a vice-master (*promagister*), a *flamen* and a praetor, who were assisted at the sacrifices by four chorus boys, sons of senators, having both parents alive. Each wore a wreath of corn, a white fillet and the praetexta. The election of members was by co-optation on the motion of the president, who, with a *flamen,* was himself elected for one year.

The great annual festival was held in honour of the anonymous Dea Dia, probably identical with Ceres or Acca Larentia, on three days in May. It is a matter of dispute whether this festival was identical with that called *Ambarvalia* (*q.v.*). The ceremony of the first day, on which a sumptuous banquet took place, followed by a distribution of doles and garlands, was held in Rome itself. On the second and principal day of the festival the ceremonies were conducted in the grove of the Dea Dia. They included a dance in the temple of the goddess, at which the song of the brotherhood was sung, in language so antiquated that it was hardly intelligible (text and translation in Mommsen, *Hist.* of Rome, bk. i.-ch. xv.) even to Romans of the time of Augustus Special mention should be made of the ceremony of purifying the grove, which was held to be defiled by the felling of trees, the breaking of a bough, or the use of any iron tools. The song and dance were followed by the election of officers for the next year, a banquet and races. On the third day the sacrifice took place in Rome, and was of the same nature as that offered on the first day. The Arvales also offered sacrifice and solemn vows on behalf of the imperial family on the 3rd of January and on other extraordinary occasions. The brotherhood is said to have lasted till the time of Theodosius. The British Museum contains a bust of Marcus Aurelius in the dress of a Frater Arvalis.

BIBLIOGRAPHY.—*See* G. L. Marini, *Atti* e *Monumenti* de' *Fratri* Arvali (1795); W. Henzen, *Acta Fratrum* Arvalium (1874); W. W. Fowler, Greek and Roman Festivals, 1899; G. Wissowa, Religion und *Kultus* der *Römer,* 1912; J. Marquardt, *Römische* Staatsverwaltung (iii., 1885)

ARVALS, ARVELS or **ARTHELS,** primarily the funeral dinner, and later, a thin, light, sweet cake, spiced with cinnamon and nutmeg, served to the poor at such feasts. The funeral meal was called the Arvel-dinner. The custom, of British origin, seems to have been to hold on such occasions an informal inquest, when the corpse was publicly exposed, to exculpate the heirs from all accusations of foul play.

ARVERNI (ahr-vur'ni), an ancient Gaulish tribe in the Auvergne, which still bears its name. It resisted Caesar longer than most of Gaul; when once vanquished it adopted Roman civilization readily. Its tribal deity, the god of the mountain, the Puy de Dôme, rechristened in Roman phrase Mercurius Dumias, was famous far beyond its territory. Part of his temple has been excavated.

ARVICULTURE is that branch of agronomy (*q.v.*) which relates to the culture of field crops specifically and to their actions and reactions under agronomic or horticultural conditions. Derived from L. *arvum,* field, and *cultus,* cultivation.

ARYABHATTA (b. 476), Indian astronomer and mathematician, was born at Pâtalipatua on the upper Ganges. He was the author of the *Aryabâthíyam,* written in verse couplets, which gives the rules of mathematics as known in his time. The greater part of this work is astronomy and spherical trigonometry, the remainder being 33 rules in arithmetic, algebra and plane trigonometry, including quadratic equations, the sums of powers of the first *n* natural numbers, and a table of sines. The work was published in Sanskrit at Leyden in 1874 (French trans. 1879).

See L. Rodet, *Leçons* de *calcul d'Aryabhata.*

ARYANS. This word is used by some of the "Satem" speakers of Indo-European languages with the meaning "noble" and is the name of one of the tribes of these people. As Sir George Grierson points out "Indians and Iranians who are descended from an Indo-European stock have a perfect right to call themselves Aryans but we English have not." (Report of *the* Linguistic Survey of India, vol. i., p. 96, 1927.) Max Müller, who used the term, was always cautious and distinguished clearly between the data which fall to the physical anthropologist, those

which the student of culture investigates, and the linguistic material which demands the scrutiny of the philologist. It takes time to eradicate the errors of enthusiasm, but scientific and careful workers accept the view expressed by Boas (Mind *of* Primitive Man, 1927) "that a people may remain constant in type and language and change in culture: that it may remain constant in type but change in language: or that it may remain constant in language and change in type and culture." There is no better nor more striking example in science than this of the danger of affixing labels without due scrutiny and intelligent discrimination.

ARYA SAMĀJ, a Hindu reforming sect, founded by Dayanand Saraswati, a Brahman of Guzerāt, who, born in 1825, was brought up as a Shiv-worshipper, but renounced idol-worship. He sought in the Vedas a solution of the problems of human misery and final salvation. After 1866 he gathered disciples and assailed the Christian scriptures, maintaining that the Rig Veda not only supported his own beliefs but that in it all modern discoveries in science were described. Thus he discerned the endowment of true learning, the arts of manufacture, chemistry, popular instruction, etc., all in the *yajna* or sacrificial cult. While denying that the Vedas recognized Caste, he retained the four classes as social units into which entrance was to be dependent on examinations. Such ideas naturally antagonized the Brahmans, so he turned to the masses, and founded numerous *samājes,* "associations," the earliest at Bombay ih 1875. He died at Ajmere in 1888. The Arya Samāj is not eclectic, like the Brahma Samāj, but narrower in scope and intenser in conviction. It attracted educated men whose Hinduism had been undermined, but who were opposed to the teachings of foreign creeds, while they wished to reconcile modern science and Western ethics with the faith of the Vedas.

ARYBALLOS, a Greek vase, sometimes used as a drinking-vessel, with a wide base and small, flaring mouth. One variety has a jug-like handle near the mouth. The decorations on these vases were often executed in the Asiatic style, the designs including fantastic animals, monsters and winged goddesses.

ARYTENOID, a term meaning "funnel-shaped," applied to cartilages, such as those of the larynx.

ARZAMAS, (1) a district, (2) a town in the Nizhegorod province of the R.S.F.S R. The district has an area of 8,040 sq.km. Pop. (1926) 350,964: urban, 18,535, *i.e.,* the town of Arzamas, rural 332,429. The town, 55° 22' N., 43° 50' E., is at the confluence of the rivers Tesha and Arsha and is also a railway junction. It is thus a centre for local products, with cold storage facilities. Its chief occupation is timber-milling, with tanneries, tallow and soap works and flour mills. It trades in sheepskins, sailcloth and the products of koustar (home) industries, especially knitted goods.

AS, the Roman unit of weight and measure, divided into 12 *unciae* (whence both "ounce" and "inch"); its fractions being deunx $\frac{11}{12}$, dextans $\frac{5}{6}$, dodrans $\frac{3}{4}$, bes $\frac{2}{3}$, septunx $\frac{7}{12}$, semis $\frac{1}{2}$, quincunx $\frac{5}{12}$, triens $\frac{1}{3}$, quadrans $\frac{1}{4}$, sextans $\frac{1}{6}$, sescuncia $\frac{1}{8}$, uncia $\frac{1}{12}$. *As* really denoted any integer or whole; whence the English word "ace." The unit or as of weight was the *libra* (pound= about $11\frac{4}{5}$ oz. avoirdupois); of length, *pes* (foot=about $11\frac{3}{5}$in.); of surface, *jugerum* (= about $\frac{2}{3}$ac.); of measure, liquid amphora (about $5\frac{3}{55}$gal.), dry modius (about $\frac{9}{10}$ peck). In the same way as signified a whole inheritance; whence heres ex asse, the heir to the whole estate, heres ex *semisse,* heir to half the estate. It was also used in the calculation of rates of interest.

As was also the name of a Roman coin (see NUMISMATICS: *Roman*). The old as was composed of the mixed metal aes an alloy of copper, tin and lead, and was called as *libralis,* because it nominally weighed 1 lb. or 12 oz. (actually 10). Its original shape seems to have been an irregular oblong bar, which was stamped with the figure of a sheep, ox, or sow. This, as well as the word *pecunia* for money (pecus, cattle), indicates the fact of cattle having been the earliest Italian medium of exchange. The value was indicated by little points or globules, or other marks. After the round shape was introduced, the one side was always inscribed with the figure of a ship's prow, and the other with the double head of Janus. The subdivisions of the as had also the ship's prow on one side, and on the other the head of some deity. The weight and value of the as steadily diminished. Before silver coinage was introduced (269 B.C.) the value of the as was 6d. or 12c., in the time of Cicero less than a halfpenny. In the time of the emperor Severus its weight was lowered to about $\frac{5}{24}$ of an ounce. During the commonwealth and empire aes grave was used to denote the old as in contradistinction to the existing depreciated coin; while *aes* rude was applied to the original oblong coinage of primitive times.

See J. E. Sandys, Companion to Latin Studies (1925).

ASA, in the Bible, son (or perhaps, rather brother) of Abijah, the son of Rehoboam and king of Judah (I. Kings xv. 9–24). He was a contemporary of Baasha, Zimri and Omri of Israel, but little is recorded of his long reign except some religious reforms and conflicts with the first-named. Baasha fortified Ramah (*er-Rām*), jm. north of Jerusalem, and Asa was compelled to use the residue of the temple-funds, to bribe the king of Damascus to renounce his league with Baasha and attack Israel. Galilee was invaded and Baasha was forced to return, the building material which he had collected at Ramah being used by Asa to fortify Geba, and Mizpah to the immediate north of Jerusalem. The Book of Chronicles relates a story of a sensational defeat of Zerah the "Cushite," and a great religious revival in which Judah and Israel took part (II. Chron. xiv.–xv. 15). Asa was succeeded by his son Jehoshaphat.

ASAFOETIDA, a gum-resin obtained chiefly from an umbelliferous plant (*Ferula* foetida), allied to the giant fennel (*q.v.*), native to Persia and Afghanistan. It grows to 5 or 6 ft., and when four years old is ready for yielding asafoetida. The stems are cut down close to the root, and a milky juice flows out which quickly sets into a solid resinous mass. A freshly exposed surface of asafoetida has a translucent, pearly-white appearance, but it soon darkens in the air, becoming first pink and finally reddish-brown. In taste it is acrid and bitter and emits a strong onion-like odour, due to the presence of organic sulphur compounds.

Asafoetida is found in commerce in "lump" or in "tear," the latter being the purer form. Medicinally, given in doses of 5 to 1j grains, it stimulates the intestinal and respiratory tracts and the nervous system, and is sometimes useful in hysteria and malingering. The gum-resin is relished as a condiment in India and Persia, and is in demand in France for use in cookery, In the regions of its growth the whole plant is used as a fresh vegetable, the inner portion of the full-grown stem being regarded as a luxury.

ASAF-UD-DOWLAH, nawab wazir of Oudh from 1775 to 1797, was the son of Shuja-ud-Dowlah, his mother and grandmother being the begums of Oudh, whose spoliation formed one of the chief counts in the charges against Warren Hastings. When Shuja-ud-Dowlah died he left £2,000,000 sterling buried in the vaults of the zenana. The widow and mother of the deceased prince claimed the whole of this treasure under the terms of a will which was never produced. When Warren Hastings pressed the nawab for the payment of debt due to the East India Company, he obtained from Asaf's mother a loan of 26 lakhs of rupees, for which he gave her a *jagir* of four times the value; he subsequently obtained 30 lakhs more in return for a full acquittal, and the recognition of her jagirs without interference for life by the company. These jagirs were afterwards confiscated on the ground of the begum's complicity in the rising of Chai Singh, which was attested by documentary evidence. The evidence now available seems to show that Warren Hastings did his best throughout to rescue the nawab from his own incapacity, and was inclined to be lenient to the begums.

See G. W. Forrest, The Administration of Warren Hustings, *1772–1785* (1892).

ASAPH: see PSALMS.

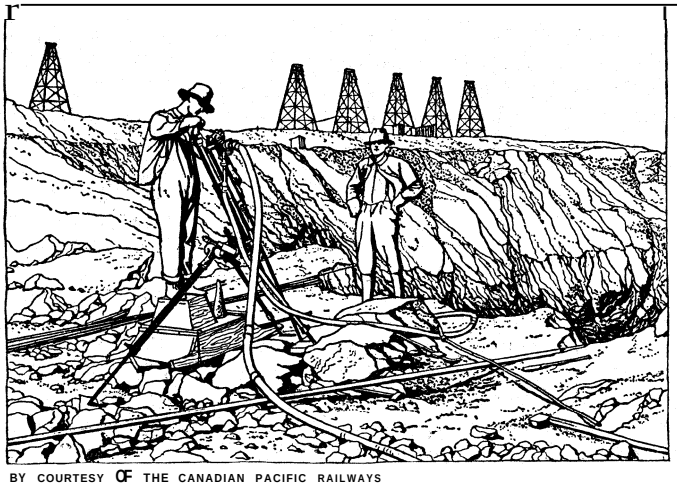
ASARABACCA (*Asarum europeum*), a low, stemless, perennial plant of the birthwort family (Aristolochiaceae), native to the woods of Europe and north temperate Asia, and occurring wild in some English counties. It is a small creeping herb with a pungent-aromatic rootstock, kidney-shaped leaves and small pur-

plish bell-shaped flowers. It was formerly grown for medicinal purposes, the underground stem having cathartic and emetic properties. The allied North American species are commonly called wild ginger (*q.v.*).

ASBESTIC, a fine ground serpentine sand containing small quantities of short fibred chrysotile asbestos. This is a trade name for the mill-treated residue from which the shortest commercial fibre has been extracted; the product, almost white in colour, is used to strengthen certain plasters and stuccos, and can be used in many places where a coarse ground mineral filler is required.

ASBESTINE, LOOMITE, SNOFIBRE, synthetic trade names used in the United States to describe short fibred talc products (*q.v.*) produced in New York State and used as mineral fillers in many industries. *See* also MICRO-ASBESTOS.

ASBESTOS, a generic name for a group of minerals possessing crystalline fibrous structure and which can be spun or felted

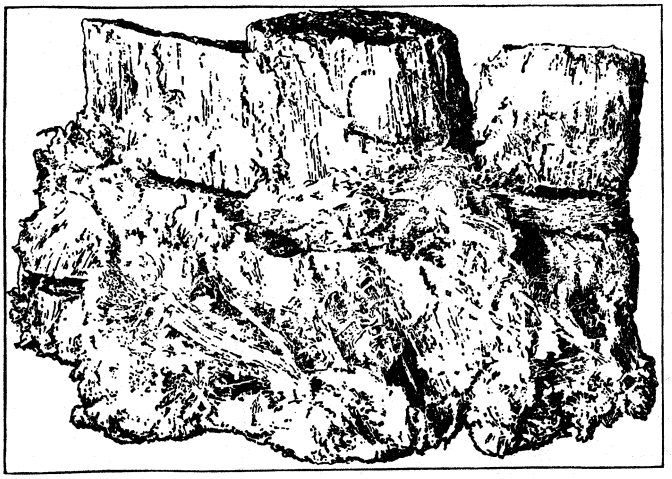


BY COURTESY OF THE CANADIAN PACIFIC RAILWAYS

HOW ASBESTOS IS MINED WITH THE AID OF MODERN ENGINEERING. PNEUMATIC DRILLS ARE BORING HOLES FOR DYNAMITE CHARGES

to make non-combustible fabrics for heat insulation and for other purposes where resistance to fire is essential. The name is derived from the ancient Greek name (ἄσβεστος) for a fabulous stone which once set on fire could not be quenched, probably unslaked lime.

The non-combustible character and spinning qualities of asbestos fibre were undoubtedly known to the ancient world. Plutarch



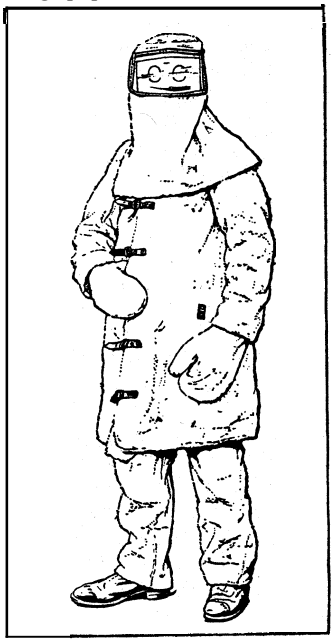
CANADIAN ASBESTOS FIBRE AS IT COMES FROM THE MINE. ITALY PROVIDED THE FIRST ASBESTOS FIBRE USED COMMERCIALLY IN 1871. IMPORTANT DEPOSITS WERE AFTERWARDS DISCOVERED IN QUEBEC AND RHODESIA. WHILE YET ANOTHER SOURCE OF SUPPLY IS THE URAL MOUNTAINS

mentions "perpetual" lamp wicks used by the Vestal Virgins, and Pausanian records a lamp that had a wick which was not consumed, being made of "Carpasian linen," or mineral fibre from Carpasius in Cyprus; shrouds of woven asbestos appear to have been used in ancient times for cremations. Pliny refers to it as *linum vivum*—"the funeral dress of kings."

Varieties.—Three minerals possess varieties known as "asbestos." These are anthophyllite, amphibole and serpentine. The first two are silicates of lime and magnesia, with or without the presence of iron and related elements; the last named is a hydrous silicate of magnesia, with or without iron.

Anthophyllite is a magnesium-iron silicate which in some localities occurs in long thin plates and fibres. It is of mineralogical importance only.

Amphiboles include five principal types characterized by fibrous structure: (1) *tremolite,* a calcium-magnesium silicate, occurs in long blade-like crystals or in long thin fibrous or columnar masses, grey to almost white in colour, and rather brittle; (2) *actinolite* which is an iron-calcium-magnesium silicate that occurs in fibrous and radiating crystalline masses, bright green in colour, used for weighting paper, and as an inert adulterant. Both these and other varieties of amphibole which are free from alumina, pass by insensible gradations into (3) *asbestos,* otherwise called "amphibole-asbestos" or "hornblende-asbestos," which consists of fine flexible fibres resembling flax, usually of a dull green colour and nacreous lustre; (4) *mountain leather* and *mountain cork* consist of flexible sheets of interlaced fibres, difficult to separate; *mountain wood* is compactly fibrous, grey to brown in colour, and resembles dry wood or petrified wood; (5) *blue asbestos* or *crocidolite,* found in Griqualand, South Africa and in Australia, possesses a very silky lustre, is of a dull blue colour, and its fibres are elastic and occasionally several inches in length. Chemically it is a soda-iron silicate; it possesses higher tensile strength than chrysotile *(see* below) but is less resistant to high temperatures.



BY COURTESY OF BELL'S CO., LTD.

AN ASBESTOS SUIT FOR FIREMEN

Unburnable, material woven from asbestos is applicable to any fireproof purpose, and is much used in modern industry

Serpentine is a hydrous silicate of magnesia, generally found in massive forms but also occurring with a banded or slaty structure; closely related to serpentine is *talc* (*q.v.*) which is, however, soft and brittle. There are two fibrous minerals derived from serpentine: (1) *Picrolite* occurs in fibrous masses in fissures of the massive serpentine. The fibres are sometimes 12in. in length but they are not flexible nor easily separable; (2) *Chrysotile* occurs in narrow veins traversing the serpentine rocks as a mass of fine silky crystals. These veins are usually various shades of green but amber to brown shades also occur. The crystals are easily separated into fine, white, silky, flexible fibres. This mineral constitutes the great bulk of the commercial asbestos.

To be of commercial value asbestos must possess length and fineness of fibre combined with infusibility, toughness or relatively high tensile strength and flexibility. Asbestos fibre resembles fine polished wire, free from serrations of any kind. This adds to the difficultiesof spinning. In cross section, fibres are either circular or polygonal. Under high magnification a fibre is seen to consist of numerous fine threads crowded together. The smallest fibre yet measured had a diameter of 0·00075mm., according to Dr. H. T. Barnes, McGill university.

INDUSTRIAL USES

The incombustible and insulating properties of asbestos make it invaluable to industry. The first modern experiments in weaving asbestos were made in Italy. The longer fibre can be carded and spun into yarns, either alone or with additions such as cotton or small sizes of brass or copper wire. Spun products are woven into

fabric of varying weights, thickness and densities to meet numerous industrial needs. Some of the principal uses are for drop curtains in theatres, for fireproof wall linings and for boiler pipe packing. Yarns spun with fine wires are used for fabric for brake linings; woven asbestos belts convey cement clinker and other hot products; when impregnated with rubber, asbestos is utilized for heat insulation and for gaskets; asbestos yarns, impregnated with graphite and suitable greases are used for steam and pump packings; ropes, cords, twine and threads are made for various purposes; various products are used to insulate electric conductors; fibre shorter than spinning stock is used for making steam pipe, hot water pipe and boiler coverings. Certain classes of short asbestos fibre are mixed with cement and moulded into various shapes for special purposes or pressed into millboard, wallboard, shingles or tiles. Asbestos sheets deaden sound and asbestos papers are used where damp-proof and fireproof coverings are required.

ASBESTOS BOILER PACKING USED AS A PROTECTIVE AND HEAT-CONSERVING PACKING BETWEEN BOILERS AND THEIR OUTER CASING

Consumption.—The world's present rate of consumption of asbestos of all grades is about 358,000 tons per annum, of which approximately 78% is produced in Canada, 9·4% in Rhodesia, 5·6% in Russia, 4% in the Union of South Africa, 1·7% in Cyprus and the balance in Italy and the United States, with a very small production elsewhere. About 93% of this production is chrysotile asbestos.

Asbestos products are manufactured in England, the United States, France, Germany, Austria, Russia, Italy, Spain, Belgium, Canada and Australia. The production of the raw material has risen from 200 tons (Italian) in 1868 to a total from all sources of over 250,000 tons a year. The United States is the largest consumer, and the asbestos factories there absorb about three-fourths of the output of the raw material from the Canadian mines. In 1926, the exports of asbestos manufactures from the United Kingdom were 24,889 tons, valued at £1,116,000, while the imports of raw asbestos, including fibre and waste, were 27,720 tons, valued at £709,708.

In 1927, 199,726 tons of unmanufactured asbestos were imported into the United States, valued at $8,150,000; and the manufactures 135,441 tons, valued at $2,177,000. The exports comprised a small amount of unmanufactured asbestos, and miscellaneous manufactures. with a total value of $1,918,000. (See Statistical Abstract of the United States, U.S. Department of Commerce.)

ASBJÖRNSEN, PETER CHRISTEN (1812–85), and **MOE, JÖRGEN ENGEBRETSEN** (1813–82), collectors of Norwegian folk-lore, so closely united in their life's work that it is unusual to name them apart. Asbjornsen was born in Christiania on Jan. 15 1812; as early as 1832 in his twentieth year, he had begun to collect and write down all the fairy stories and legends which he could encounter. Later he began to wander on foot through the length and breadth of Norway, adding to his stores. Moe, who was born at Mo i Hole parsonage, in Sigdal Ringerike, on April 22 1813, met Asbjörnsen first when he was 14 years of age. A close friendship began between them, and lasted to the end of their lives. In 1834 Asbjornsen discovered that Moe had started independently on a search for the relics of national folk-lore; the friends eagerly compared results, and determined for the future to work in concert. By this time, Asbjornsen had become by profession a zoologist, and with the aid of the university made a series of investigating voyages along the coasts of Norway, particularly in the Hardanger fjord. Moe, meanwhile, having left Christiania University in 1839, had devoted himself to the study of theology, and was making a living as a tutor in Christiania. In his holidays he wandered through the mountains, in the most remote districts, collecting stories. In 1842–43 appeared the first instalment of the great work of the two friends, under the title of Norwegian Popular Stories (Norske Folkeeventyr), which was received at once all over Europe as a most valuable contribution to comparative mythology as well as literature. A second volume was published in 1844, and a new collection in 1871. Many of the Folkeeventyr were translated into English by Sir George Dasent in 1859. In 1845 Asbjornsen published, without help from Moe, a collection of Norwegian fairy tales (Huldreeventyr og *Folkesagn*). In 1856 Asbjornsen was appointed forest-master, and was sent by Norway to examine in various countries of the N. of Europe the methods observed for the preservation of timber. He died in Christiania on Jan. 6 188 j. From 1841 to 1852 Moe travelled almost every summer through the southern parts of Norway, collecting traditions in the mountains. He took holy orders in 1853 and he was appointed in 1875 bishop of Christiansand, after holding various cures. In Jan. 1882 he resigned his diocese on account of failing health, and died on the following March 27. Moe has a special claim on critical attention in regard to his lyrical poems, of which a small collection appeared in 1850. He wrote little original verse, but in his slender volume are to be found many pieces of exquisite delicacy and freshness. Moe also published a delightful collection of prose stories for children, In the Well and *the Churn* (I Bronde og *i* Kjaernet), 1851; and *A* little Christmas Present (En *Liden Julegave*), 1860. Asbjornsen and Moe had the advantage of an admirable style in narrative prose. It was usually said that the vigour came from Asbjornsen and the charm from Moe, but the fact seems to be that from the long habit of writing in unison they had come to adopt almost precisely identical modes of literary expression.

ASBURY, FRANCIS (1745–1816), the second bishop of the Methodist Episcopal Church and the first consecrated in the United States, was born in Handsworth, Staffordshire, England, on Aug. 20, 1745. His parents gave him a good elementary schooling of about seven years while he was between the ages of six and thirteen. Apprenticed in his 14th year to learn the business of making "buckle chapes," he devoted his odd moments to the study of Methodist theology and sermonic literature. At 18 he was licensed as a local preacher. At 21 he was received into the Wesleyan Conference and four years later was sent as a missionary by 'Wesley to America. The Methodists in America in 1771 numbered a little less than 400, chiefly in the neighbourhood of New York and Philadelphia. In 1772 Asbury was appointed by Wesley "general assistant in America" but this assignment lasted only one year.

At the outbreak of the Revolutionary War Asbury cast in his lot with the Americans. His loyalty to America, however, was under so much suspicion that he was forced into hiding in Delaware for two years, 1778–79. But the discovery of a letter which he had written to England revealed such devotion to the Colonies that he was thereafter recognized as ardently American. In 1784 Wesley appointed him a superintendent of the Methodist work in America. Wesley's selection was confirmed by the meeting of all the Methodist preachers in conference. From the outset Asbury was known as bishop, though Wesley objected strenuously to this title. Asbury however, with his keener discernment of the realities 3,000 miles distant from England, saw that Methodism could succeed only by highly centralized organization, and accepted the title of bishop as indicating such centralization.

From 1784 until his death in 1816 Asbury threw all his energy

into the Methodist work. At the time of his death the Methodist Episcopal Church in the United States numbered about 214,000 members with 2,000 ministers. Asbury travelled on horseback between 5,000 and 6,000 miles every year during the term of his bishopric. His duties made it imperative for him to supervise all the conferences between Maine and southern Georgia, and between the Atlantic coast and the settlements in Kentucky. It was said of him that he had been seen by more people in America than had any other person up to the time of his death. Though he insisted upon keeping supervisional power almost wholly in his own hands, he won and kept the regard of the Methodist ministers and laymen to a greater degree than any other leader in the history of the Church. Throughout his life he suffered from a stubborn disease of the throat which added greatly to the discomforts of his task, but he never relaxed in a Spartan self-control, which makes the story of his life an almost incredible narrative of triumph over hardship. After coming to America he learned to read the Scriptures in the original Hebrew and Greek. At his death he left a *Journal* which has proved an indispensable source-book for American social history for the first 40 years of the independence of the new nation. The style of Asbury's writing was simple and direct, with a tendency to over-seriousness, and yet with shrewd insight into the central issues in the successive ecclesiastical crises which he faced. He died in Spottsylvania, Va., March 31, 1816.

ASBURY PARK, a city of Monmouth county, N.J., U.S.A., on the Atlantic ocean, about 35m. S. of Kew York city (50m. by rail). It is served by the Central railroad of New Jersey, the Pennsylvania and the New York and Long Branch railways. The population in 1920 was 12,400, and in 1940 it was 14,617. It is a popular seaside resort, with 42 hotels in 1927, and numerous boarding-houses and private cottages. Fresh-water lakes and an abundance of green vegetation add to its attractions. Even in the winter months there is a large transient population. The beach, bordered for a mile by a "board walk," is owned and controlled by the municipality. The city had 15 manufacturing establishments in 1937, which produced commodities valued at $1,668,256.

Asbury Park was founded in 1869, and named after the Rev. Francis Asbury. It was incorporated as a borough in 1874 and chartered as a city in 1897. In 1915 a commission form of government was adopted.

ASCANIUS or IULUS, in Roman legend, the son of Aeneas (*q.v.*) by Creusa or Lavinia, and ancestor of the gens Iulia. On the death of Aeneas, the government of Latium was left in the hands of Lavinia, Ascanius being too young to undertake it. After 30 years he left Lavinium, and founded Alba Longa.

See references under AENEAS.

ASCARIS, the generic name of certain round worms, which are parasitic on various animals. *A. lumbricoides* is found in the human intestine, the closely allied *A. suilla* in the pig and *A. megalocephala* in the horse. *Ascaris,* which belongs to the Nematoda (*q.v.*), has only two chromosomes (*q.v.*) in the fertilized egg, and is therefore often used in the study of cytology (*q.v.*).

ASCENSION, a small island in the South Atlantic, 700m. N.W. of St. Helena. Area, 34 sq. miles. The island lies within the influence of the south-east trades (8° south lat.). The lee side is subject to "rollers," which break on the shore with great violence. The island is of volcanic origin. Green mountain, a huge elliptical crater, is 2,820ft. above the sea, while the surrounding tablelands vary from 1,200 to 2,000 feet. Steepravines, linedwithmasses of lava and ending in small bays, are typical. Ascension was originally bare, save for the summit of Green mountain, but the lower hills have been planted with grasses and shrubs. The climate is remarkably healthy. The average rainfall is about 20in., March and April being the rainy months. The island is the resort of the sea turtle, who come in thousands to lay their eggs on the shores between Jan. and May. The turtles are caught and kept in large ponds. The coasts abound with a variety of fish of excellent quality. Like St. Helena, the island does not possess any indigenous vertebrate land fauna. Rabbits, wild goats and partridges are fairly common. The "wideawake" birds (sooty tern) frequent the island in vast numbers to lay their eggs. The flora includes purslane, rock roses, ferns and mosses.

The island was discovered by the Portuguese João da Nova, on Ascension Day, 1501. In 1701 William Dampier was wrecked on its coast. It remained uninhabited till after the arrival of Napoleon at St. Helena (1815), when it was garrisoned by the British government. A settlement named George Town (locally known as Garrison) was made on the north-west coast, water being obtained from "Dampier's springs" in the Green mountain, 6m. distant. The island was under the rule of the Admiralty till 1922, when it was transferred to the administration of the Colonial Office and annexed to St. Helena. There are cable connections with Europe and Africa, and the island is in the postal union. The population (1931), 188, consists of seamen, marines, and Krumen from Liberia. Phosphates and guano are collected, and about 10ac. under cultivation produce vegetables and fruit. It was at Ascension that Mr. (aftenwards Sir) David Gill determined, in 1877, the solar parallax.

See C. Darwin, *Geological Observations on the Volcanic Islands visited during the Voyage of H.M.S. "Beagle"* (1844); *Report of the Scientific Results of the Voyage of the "Challenger"* vol. i. part 2 (1885); *Africa Pilot,* part ii. 5th ed. (1901).

ASCENSION, FEAST OF THE, known also as Holy Thursday in the Anglican Church, the 40th day after Easter, commemorating Christ's ascension to heaven; one of the oecumenical festivals of the Christian Church, ranking with Christmas, Easter and Pentecost. St. Augustine (*Ep.* 54 *ad Januar.*) mentions it as having been kept from time immemorial and as probably instituted by the apostles. Chrysostom mentions its celebration in a church outside Antioch, and Socrates (*Hist. eccles.* vii. 26) records that in the year 390 the people of Constantinople "of old custom" (ἐξ ἔθους) celebrated the feast in a suburb of the city. Adamnan, abbot of Iona, describes a pilgrimage at Jerusalem in the 7th century, when the feast was celebrated on Mount Olivet *(de loc. sanct.* i. 22). The *Peregrinatio* of Etheria (Silvia), *c.* A.D. 385, says that the festival was held in the Church of the Nativity at Bethlehem (Duchesne, *Chr. Worship,* p. 515). In the West, in the middle ages, a procession with candles and banners outside the church symbolized Christ's triumphant entry into heaven. In the East the festival is known as ἀνάληψις, "taking up," or ἐπισωζομένη, "salvation."

In the Roman Catholic Church the most characteristic ritual feature of the festival is now the extinction of the paschal candle after the Gospel at High Mass. Other customs, *e.g.,* the blessing of the new beans (Duchesne, p. 183) were formerly associated with the liturgy of this feast. In some churches an image of Christ was raised from the altar through a hole in the roof, through which a burning straw figure representing Satan was immediately thrown down.

In the Anglican Church Ascension Day and its octave continue to be observed as a great festival, with a special preface in the communion service. The Lutheran churches also retain the Feast.

See Herzog-Hauck, *Realencyklopadie* (1900), s. *"Himmelfahrtsfest"; L.* Duchesne, *Christian Worshzp* (2nd Eng. ed., London, 1904); *The Catholic Encyclopaedia* (London and New York, 1907).

ASCETICISM, the theory and practice of bodily abstinence and self-mortification, generally religious. The word is derived from a Greek word (ἀσκέω) meaning "to practice," or "to train," and it embodies a metaphor taken from the ancient wrestling-place, where victory rewarded those who had best trained their bodies. The ultimate origin of asceticism is the antithesis between sacred (or holy) and profane, from which comes the idea that he who belongs to the former sphere, or seeks to enter it, must refrain as much as possible from, or even destroy, all that belongs

to the latter. This is originally a non-moral idea *(see* CONSECRATION; *TABU)*. It is the note of every great religious reformer, Moses, Buddha, Paul, Mani, Mohammed, St. Francis, Luther, to enlighten and direct it to higher aims, substituting a true personal holiness for a ritual purity or *tabu,* which at the best was viewed as a kind of physical condition and contagion, inherent as well in things and animals as in man.

It is useful, therefore, to begin with the facts as they can be observed among less advanced races, or as survivals among people who have reached the level of genuine moral reflection; and then to proceed to a consideration of self-denial consciously pursued as a method of ethical perfection. The latter is, as a rule, less cruel and rigorous than primitive forms of asceticism. Under this head fall the following:—Fasting, or abstention from certain meats and drinks; denial of sexual instinct; subjection of the body to physical discomforts, such as nakedness, vigils, sleeping on the bare ground, etc., vows of silence; avoidance of baths, of hair-cutting and of clean raiment, living in a cave; actual self-infliction of pain, by numerous, often ingenious, modes of torture. Such customs repose on various early ideas: for example, the self-mutilation of the Galli or priests of Cybele (*q.v.*) was probably a magical ceremony intended to fertilize the soil and stimulate the crops.

Fasting (*q.v.*) is used in primitive asceticism for a variety of reasons, among which the following deserve notice. Certain animals and vegetables are *tabu; i.e.,* too holy, or (what among Semites and others was the same thing) too defiling and unclean, to be eaten. Thus most or all of the creatures which are unclean in the Jewish law are holy (possibly in origin totemic) animals among many Semites. Such abstinences are ascetic in so far as they involve much self-denial. Examples are the ritual prohibitions of pork and beef. Similar prohibitions are common in primitive groups. That such dietary restrictions were merely ceremonial and superstitious, and not intended to prevent the consumption of meats which would revolt modern tastes, is certain from the fact that the Levitical law freely allowed the eating of locusts, grasshoppers, crickets and cockroaches, while forbidding the consumption of rabbits, hares, storks, swine, etc. The Pythagoreans were forbidden to eat beans.

Another widespread reason for avoiding flesh diet altogether was the fear of absorbing the soul of the animal, which especially resided in the blood. Hence the rule not to eat meats strangled, except in sacramental meals when the god inherent in the animal was partaken of. It is equally a soul or spirit in wine which inspires the intoxicated. The mediaeval Jews held that there is a cardiac demon in wine which takes possession of drunken men; and the Mohammedan prohibition of wine-drinking is based on a similar superstition. Belief in transmigration of souls often arouses a scruple against flesh diet. Examples of both ways of thinking will be found in Porphyry (*q.v.*) *De Abstinentia* (neo-Pythagorean).

The same fear of imbibing the soul of animals, and thereby reenforcing the lower appetites and instinct of the human being, inspired the vegetarianism of the Jewish Therapeutae. An early belief long survived among the Manichaean sects that fish, being born in and of the waters, and without any sexual connection on the part of other fishes are free from the taint which pollutes all animals *quae copulatione generantur.* Fish, therefore, unlike flesh, could be safely eaten.

The Manichaeans held that in every act of begetting, human or otherwise, a soul is condemned afresh to a cycle of misery by imprisonment in flesh—a thoroughly Indian notion, under the influence of which their perfect or elect ones scrupulously abstained from flesh. The prohibition of taking life, which they took over from the Farther East, in itself entailed fasting from flesh. A fully initiated Manichaean would not even cut his own salad, but employed a catechumen to commit on his behalf this act of murder, for which he subsequently shrived him.

We come to a third widespread reason for fasting, common among savages. Famished persons are liable to morbid excitement and fall into imaginative ecstasies. Among the North American Indians ecstatic fasting is regularly practised. All over the world fasting is a recognized mode of evoking, consulting, and also of overcoming the spirit world. This is why many primitive races distrust a medicine man who is not an ascetic and lean with fasting. In the Semitic East it is an old belief that a successful fast in the wilderness of *40* days and nights gives power over the Djinns. From the first, fasting was practised in the church for similar reason. In the *Shepherd of Hermas* a vision of the church rewards frequent fasts and prayer; not a few saints were rewarded for their fasting by glimpses of the beatific vision.

Among the Semites and Tartars worshippers lacerate themselves before the god. So in I. Kings xviii. 28, the priests of Baal engaged in a rain-making ceremony, gashed themselves with knives and lances till the blood gushed out upon them. The Syriac word *ethkashshaph,* which means literally to "cut one-self," is the regular equivalent of to "make supplication." At first sight these rites seem intended to call down the pity of heaven on man, but as Robertson Smith points out, their real import was by shedding blood on a holy stone or in a holy place to tie or renew a blood-bond between the god and his faithful ones. But such practices may develop into penances like those of the Flagellants (*q.v.*) of *1259* and 1349.

Asceticism then, in its origin, was usually not ascetic in a modern sense; that is, not ethical. It was rather of the nature of the savage *tabu* (*q.v.*). Above all, fasting was a mode of preparing oneself for the sacramental eating of a sacred animal, and as such often assisted by use of purgatives and aperients. Indian and Buddhist asceticism, in its essence is a more ethical and philosophical product than some of the forms so far considered. The keynote is deliverance from life and its inevitable suffering. The hermit, or wandering beggar, was a familiar figure in India. Such ascetics were common, and their life was and is recommended for those who have lived the life of a householder and, having begotten sons according to the sacred law and offered sacrifices, desire in their old age to abandon worldly objects and direct their mind to final liberation. Very similar is the self-portrait of a Manichaean adept of about A.D. *400* as given in St. Augustine *(Contra Faustum* v., i.).

The Greek Cynics *(see* **CYNICS)** played a great part in the history of asceticism, and they were the precursors of the Christian hermits. In striving to imitate their master Socrates, they went to such extremes as rather to caricature him. They affected to live like beggars, bearing staff and wallet, owning nothing, renouncing pleasures, riches, honours. For Plato and Aristotle the perfect life was that of the citizen and householder; but the Cynics were individualists, citizens of the world without loyalty or respect for the ancient city State, the decay of which was coincident with their rise. Their zeal for renunciation often extended not to pleasures, marriage and property alone, but to cleanliness, knowledge and good manners as well, and in this respect also they were the forerunners of later monks.

Philo *(20* B.C.–A.D. *40)* has left us many pictures of the life which to his mind impersonated the highest wisdom, and they are all inspired by the more respectable sort of cynicism, which had taken deep root among Greek Jews of the day. His own favourite ascetics, the Therapeutae, whose chief centre was in Egypt, had renounced property and all its temptations, and fled, irrevocably abandoning brothers, children, wives, parents, throngs of kinsmen, intimacy of friends, the fatherlands where they were born and bred *(see* THERAPEUTAE). Here we have the ideal of early Christian renunciation at work, but apart from the influence of Jesus. In the pages of Epictetus the same ideal is constantly held up to us.

In the Christian Church there was from the earliest age a leaning to excessive asceticism, and it needed a severe struggle on the part of Paul, and of the Catholic teachers who followed him, to secure for the baptized the right to be married, to own property, to engage in war and commerce, or to assume public office. One and all of the permanent institutions of society were condemned by the early enthusiasts, especially by those who looked forward to a speedy advent of the millennium, as alien to the Kingdom of God and as impediments to the life of grace.

Marriage and property had already been eschewed in the Jewish Essene (*see* ESSENES) and Therapeutic sects, and in Christianity the name of Encratite was given to those who repudiated marriage and the use of wine. They did not form a sect, but represented an impulse felt everywhere. In early and popular apocryphal histories the apostles are represented as insisting that their converts should either not contract wedlock or should dissolve the tie if already formed. This is the plot of the *Acts of Thecla,* a story which probably goes back to the 1st century. Repudiation of the tie by fervent women, betrothed or already wives, occasioned much domestic friction and popular persecution. In the Syriac churches, even as late as the 4th century, the married state seems to have been regarded as incompatible with the perfection of the initiated. Renunciation of the state of wedlock was imposed on the faithful during the lengthy, often lifelong, terms of penance imposed upon them for sins committed; and later, as monasticism took the place, in a church become worldly, partly of the primitive baptism and partly of that rigorous penance which was the rebaptism and medicine of the lapsed, celibacy and virginity were held essential thereto.

Together with the rage for virginity went the institution of *virgines subintroductae,* or of spiritual wives; for it was often assumed that the grace of baptism restored the original purity of life led by Adam and Eve in common before the Fall. Such rigours are encouraged in the *Shepherd of Hermas,* a book which emanated from Rome and up to the 4th century was read in church. They were common in the African churches, and in Antioch in 260; in the Celtic church of St. Patrick, and, as late as the 7th century, among the Celtic elders of the north of France. In the Syriac Church as late as 340 such relations prevailed between the "Sons and Daughters of the Resurrection." It continued among the Albigenses and other dissident sects of the middle ages, among whom it served a double purpose; for their elders were thus not only able to prove their own chastity, but to elude the inquisitors, who were less inclined to suspect a man of the catharism which regarded marriage as the "greater adultery" (*maius adulterium)* if they found him cohabiting (in appearance at least) with a woman. There was hardly an early council, great or small, that did not condemn this custom. In the Catholic Church, however, common sense prevailed, and those who desired to follow the Encratite ideal repaired to the monasteries.

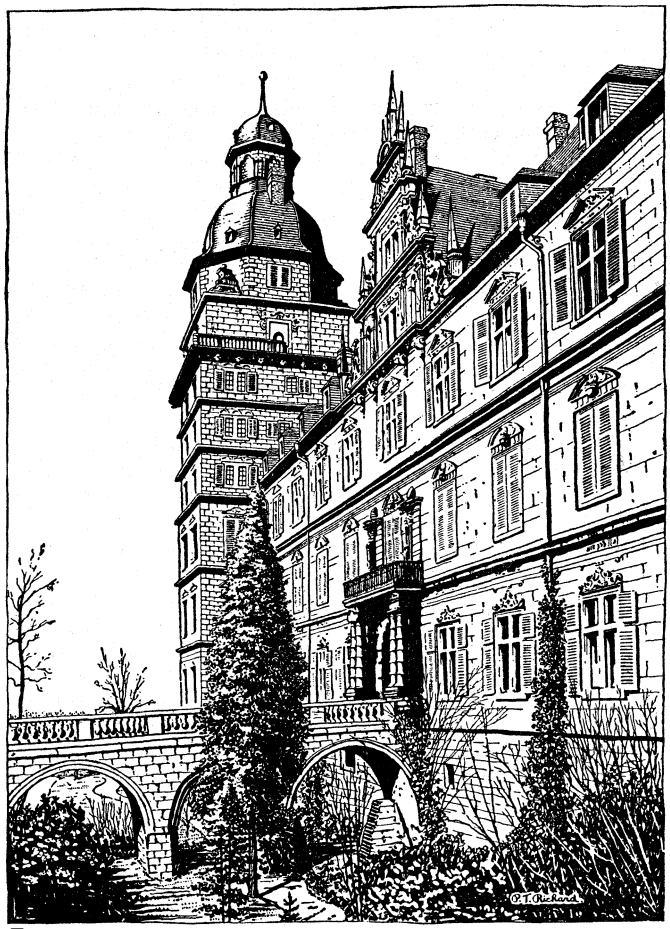
ASCHAFFENBURG, Bavaria, Germany, on right bank of the Main, near the foot of the Spessart, 26 mi. S.E. of Frankfurt. Pop. (1939) 45,370. Called in the middle ages Aschafaburg (or Askenburg), it was originally a Roman settlement. On the site of the *castrum* the Frankish mayors of the palace built a castle. Bonifacius erected a chapel and founded a Benedictine monastery. A stone bridge over the Main was built by Archbishop Willigis in 989. In 1292 a synod was held here, and in 1474 an imperial diet, preliminary to that of Vienna, in which the *Aschaffenburg Concordat* was decided. The town suffered greatly during the Thirty Years' War. In 1866 the Prussians defeated the Austrians in the neighbourhood.

The principality of Aschaffenburg formed part of the electorate of Mainz in the middle ages. In 1806 it was annexed to the grand-duchy of Frankfurt; and in 1814 was transferred to Bavaria. Its chief buildings are the Johannisburg, which has some of the earliest examples of printed books, the *Stiftskirche,* or cathedral, founded in 980 by Otto of Bavaria, but mainly 12th and 13th centuries, with various monuments by the Vischers; a theatre, formerly the house of the Teutonic order; and several old mansions. The town has been remarkable for its educational establishments since the 10th century. There is an archaeological museum in the old abbey buildings. Coloured and white paper, ready-made clothing, cellulose, leather, beer and spirits, electrical



THE CASTLE AT ASCHAFFENBURG. ONCE THE RESIDENCE OF BAVARIAN NOBLES, NOW USED AS AN ART MUSEUM

apparatus and machinery, wax, chemicals and liqueurs are the chief manufactures, and there are smithies and brickworks and an important harbour on the Main.

ASCHAM, ROGER (c. 1515–1568), English scholar and writer, was born at Kirby Wiske, a village in the North Riding of Yorkshire, near Northallerton, and was educated in the house of Sir Humphrey Wingfield, who became speaker of the House of Commons in 1533. Sir Humphrey "ever loved and used to have many children brought up in his house," where they were under a tutor named R. Bond. Their sport was archery, and Sir Humphrey "himself would at term times bring down from London both bows and shafts and go with them himself to the field and see them shoot." Hence Ascham's earliest English work, the *Toxophilus,* the importance which he attributed to archery in educational establishments, and probably the provision for archery in the statutes of St. Albans, Harrow and other Elizabethan schools.

From this private tuition Ascham was sent "about 1530," at the age, it is said, of 15, to St. John's College, Cambridge, then the largest and most learned college in either university. He remained there for some time after taking his degree, and became the first regius professor of Greek in 1540. He was also letter-writer to the university, and became public orator in 1546. In 1542–43 he wrote *Toxophilus,* which he presented to Henry VIII. at Greenwich soon after his triumphant return from the capture of Boulogne. He was rewarded by the grant of a pension of £10 a year, equal to some £200 of our money. A novelty of the book was that the author had "written this Englishe matter in the Englishe tongue for Englishe men," though he thought it neces-

sary to defend himself by the argument that what "the best of the realm think it honest to use" he "ought not to suppose it vile for him to write," It is a Platonic dialogue between Toxophilus and Philologus, and its chief interest for us lies in its incidental remarks. It may probably claim to have been the model for Izaak Walton's *Compleat Angler*.

Shortly after the beginning of the reign of Edward VI., Ascham made public profession of Protestant opinions in a disputation on the doctrine of the Mass, begun in his own college and then removed for greater publicity to the public schools of the university, where it was stopped by the vice-chancellor. Thereon Ascham wrote a letter of complaint to Sir William Cecil. This stood him in good stead. In Jan. 1548, Grindal, the Princess Elizabeth's tutor, died. Through Cecil and at the princess's own wish, Ascham was selected as her tutor against another candidate pressed by Admiral Seymour and Queen Katherine. He taught Elizabeth—then 16 years old—for two years, chiefly at Cheshunt. In 1550 Ascham quarreled with Elizabeth's steward and returned to Cambridge, when Sir John Cheke procured him the secretaryship to Sir Richard Morrison (Moryson), appointed ambassador to Charles V. It was on his way to join Morrison that he paid his celebrated morning call on Lady Jane Grey at Bradgate, where he found her reading Plato's *Phaedo*, while every one else was out hunting.

The embassy went to Louvain and then to Innsbruck and Venice. Ascham read Greek with the ambassador four or five days a week. His letters during the embassy, which was recalled on Mary's accession, were published in English in 1553, as a "Report" on Germany. Through Bishop Gardiner he was appointed Latin secretary to Queen Mary with a pension of £20 a year. His Protestantism he must have quietly sunk, though he told Sturm that "some endeavoured to hinder the flow of Gardiner's benevolence on account of his religion." In 1555 he resumed his studies with Princess Elizabeth, and soon after Elizabeth's accession, on Oct. 5, 1559, he was given, though a layman, the canonry and prebend of Wetwang in York minster.

In 1563 he began the work which has made him famous, *The Scholemaster*. The occasion of it was, he tells us (though he is perhaps merely imitating Boccaccio), that during the "great plague" at London in 1563 the court was at Windsor, and there on Dec. 10 he was dining with Sir William Cecil, secretary of state, and other ministers. Cecil said he had "strange news; that divers scholars of Eaton be run away from the schole for fear of beating"; and expressed his wish that "more discretion was used by school-masters in correction than commonly is." A debate took place, the party being pretty evenly divided between floggers and anti-floggers, with Ascham as the champion of the latter. Afterwards Sir Richard Sackville, the treasurer, came up to Ascham and told him that "a fond schoolmaster" had, by his brutality, made him hate learning, much to his loss, and as he had now a young son, whom he wished to be learned, he offered, if Ascham would name a tutor, to pay for the education of their respective sons under Ascham's orders, and invited Ascham to write a treatise on "the right order of teaching." *The Scholemaster* was the result. It is not a general treatise on educational method, but "a plaine and perfite way of teachyng children to understand, write and speake in Latin tong"; and it was not intended for schools, but "specially prepared for the private brynging up of youth in gentlemen and noblemens houses." The perfect way simply consisted in "the double translation of a model book"; the book recommended by this professional letter-writer being "Sturmius' *Select Letters of Cicero.*"

As a method of learning a language by a single pupil, this system (which seems to have been taken from Cicero himself) might be useful; as a method of education in school nothing more deadening could be conceived. Nor was the famous plea for the substitution of gentleness and persuasion for coercion and flogging in schools, which has been one of the main attractions of the book, novel. But Ascham's was the first definite demonstration in favour of humanity written in the vulgar tongue and in an easy style by a well-known "educationist." What largely contributed to its fame was its picture of Lady Jane Grey, whose love of learning was due to her finding her tutor a refuge from pinching, ear-boxing and bullying parents; some exceedingly good criticisms of various authors, and a spirited defence of English as a vehicle of thought and literature, of which it was itself an excellent example. The book was not published till after Ascham's death, which took place Dec. 23, 1568, owing to a chill caught by sitting up all night to finish a New Year's poem to the queen.

BIBLIOGRAPHY.—Ascham's letters were collected and published in 1576, and went through several editions; they were re-edited by William Elstob in 1703. His English works were edited by James Bennett with a life by Dr. Johnson in 1771, reprinted in 1815. Dr. Giles in 1864–65 published select letters with the *Toxophilus* and *Scholemaster* and the life by Edward Grant. Prof. Edward Arber edited *The Scholemaster* in 1870, and republished the *Toxophilus* in 1902.

ASCHERSLEBEN, a town in Prussian Saxony, Germany, 36 mi. N.W. of Halle. Pop. (1939) 31,607. The town was probably founded in the 11th century by Count Esico of Ballenstedt, ancestor of the house of Anhalt. On the death of Otto III. (1315) it passed to the bishop of Halberstadt, and, after 1648, to Brandenburg. The manufacture of woollen wares, long famed, is carried on; also industries of vinegar, paraffin, potash and beet sugar. There are also iron, zinc and chemical manufactures, and agricultural seeds are grown. Its aerodrome was bombed by the British on Sept. 29, 1940.

ASCIANO, a town in Tuscany, Italy, 19 mi. S.E. of Siena by rail. Pop. (1936) 2,075 (town), 9,268 (commune). Surrounded by walls built by the Sienese in 1351, it has some 14th century churches with paintings of the period. Remains of Roman baths, with a fine mosaic pavement, have been found in the town. Six miles south is the large Benedictine monastery of Monte Oliveto Maggiore (1320), famous for frescoes by Luca Signorelli (1497–98) and Antonio Bazzi, called Sodoma (1505), in the cloister, illustrating scenes from the legend of St. Benedict; Sodoma is perhaps nowhere better represented. The church contains fine inlaid choir stalls by Fra Giovanni da Verona.

ASCITES, the term in medicine applied to an effusion of non-inflammatory fluid within the peritoneum. It is not a disease in itself, but is one of the manifestations of disease elsewhere—usually in the kidneys, heart, or in connection with the liver (portal obstruction). Portal obstruction is the commonest cause of well-marked ascites. It is produced by (1) diseases within the liver, as cirrhosis (usually alcoholic) and cancer; (2) diseases outside the liver, as cancer of stomach, duodenum or pancreas, causing pressure on the portal vein, or enlarged glands in the fissure of the liver producing the same effect. Ascites is one of the late symptoms in the disease, and precedes dropsy of the leg, which may come on later, due to pressure on the large veins in the abdominal cavity by the ascitic fluid. In ascites due to heart disease the dropsy of the feet and legs precedes the ascites, and there will be a history of palpitation, shortness of breath, and perhaps cough. In the ascites of kidney troubles there will be a history of general oedema—puffiness of face and eyes on rising in the morning probably having attracted the attention of the patient or his friends. Other causes are chronic peritonitis, either tuberculous in the young, or due to cancer in the aged and more rarely still pernicious anaemia.

ASCLEPIADACEAE, the milkweed (*q.v.*) family, a distinctly marked group of dicotyledonous plants comprised chiefly of shrubs and woody vines, though many are perennial herbs, mostly with a milky juice. Like the Apocynaceae (*q.v.*), to which they are closely related, most of the species, about 1,700 in number and divided into some 320 genera, are tropical. The continent of Africa is the headquarters of the family. The flowers are regular, sympetalous and usually arranged in umbels, though sometimes in cymes or racemes; the fruit from each flower consists of a pair of more or less fleshy pods containing numerous seeds which are usually appendaged with a long tuft of hairs. The pollen is coherent in masses in the anther cells, forming pollinia, an adaptation, found also in the Orchidaceae, for insect pollination. The Asclepiadaceae ranks among the most unusual of plant families. Many are rope-like lianas of equatorial forests. Others are epiphytes with greatly modified leaves, which, in some species, take the form of pitchers for holding water. Cer-

tain South African species are fleshy. cactus-like plants. Still others form a cluster of leafless, whip-like stems. In some species the stems develop tuberous bases in which water is stored.

Although the family contains no economic plants of the first rank, numerous species are useful. Many are of value medicinally; the milky juice of the so-called cow-plant (*Gymnena lactiferum*), of Ceylon, is edible as is that of its South African counterpart (*Oxystelma esculentum*), and the tender shoots of various species are eaten as salads and pot herbs. Others are dye-plants, as, for example, Marsdenia tinctoria; various species produce caoutchouc, and others yield bast fibres. The juice of Gonolobus is used for poisoning arrows, and that of Cynanchum for poisoning fish. A large number are cultivated as ornamental plants, among which are the mosquito plant (Cynanchum), the silk-vine (*Periploca* graeca), the carrion-flower (*Stapelia variegata*), and the fragrant wax-plant (Hoya carnosa) and stephanotis (*S. floribunda*). The madar or oschur (*Calotropis procera*), native to southwestern Asia, is believed to be the sodom apple of the Bible; the bark of the Indian madar (C. gigantea) yields a fibre and the seeds a floss.

Of some 80 representatives of the family native to the United States and Canada, the most common and conspicuous are the milkweeds (*Asclepias*). Among the best known of these are the butterfly-weed (*q.v.*) and the swamp milkweed (*A. incarnata*), both with showy, handsome flowers. The blood-flower (*A. curassavica*), native to tropical America, and frequently grown in greenhouses, has become naturalized in the southern United States.

ASCLEBIADES, of Samos, epigrammatist and lyric poet, friend of Theocritus, flourished about 270 B.C. He was the earliest and most important of the convivial and erotic epigrammatists. The majority of his compositions are love-songs. It is doubtful whether he is the author of all the epigrams (some 40 in number) which bear his name in the Greek anthology. He possibly gave his name to the Asclepiadean metre.

ASCLEPIADES, Greek physician, was born at Prusa in Bithynia in 124 B.C., and flourished at Rome at the end of the 2nd century B.C. He travelled much when young, and seems at first to have settled at Rome as a rhetorician. In that profession he did not succeed, but he acquired great reputation as a physician. He founded his medical practice on a modification of the atomic or corpuscular theory, according to which disease results from an irregular or inharmonious motion of the corpuscles of the body, His remedies were, therefore, directed to the restoration of harmony, and he trusted much to changes of diet, accompanied by friction, bathing, and exercise, though he also employed emetics and bleeding. He recommended the use of wine. His pupils were very numerous, and the school formed by them was called the Methodical. Asclepiades died at an advanced age.

ASCLEPIODOTUS, flourished in the 1st century B.C., the supposed author of a treatise on Graeco-Macedonian tactics (Τακτικὰ Κεφάλαια), which is probably the outline of the lectures of his master, Posidonius the Stoic.

ASCOLP, GRAZIADIO ISAIA (1829–1907), Italian philologist; of Jewish family, was born at Goerz. He founded the Archivio *glottologico* italiano in 1873, publishing in it his *Saggi Ladini,* and making it in succeeding years the great organ of original scholarship on this subject. He was universally recognized as the greatest authority on Italian linguistics.

ASCOLI PICENO[1] (anc. Asculum), episcopal see, Marches, Italy, capital of province of Ascoli Piceno, 17m. W. of Porto d'Ascoli (station on coast railway, 56m. S.S.E. of Ancona), and 53m. S. of Ancona direct, on south bank of Tronto (anc. Truentus) at its confluence with the Castellano, 500ft. above sea-level, and surrounded by mountains. Pop. (1936) town, 20,665; commune, 38,111. The Porta Romana is double-arched; adjacent are remains of ancient city walls, in rectangular blocks two feet high, and remains of still earlier fortifications. The church of S. Gregorio is built into a Roman tetrastyle Corinthian temple, two columns of which and the *cella* are still preserved; the site of the Roman theatre can be distinguished; and the church and convent of the Annunziata (two fine cloisters and fresco by Cola d'Amatrice in the refectory) stand on large Roman substructures of concrete. The mediaeval castle stands high and has a fine view of town and mountains. The picturesque colonnaded marketplace contains the fine Gothic church of S. Francesco and the original Palazzo del Comune, now the prefecture (Gothic with Renaissance additions). The cathedral is in origin Romanesque, much altered, and restored in 1888. The fortress of the Malatesta (1349) is destroyed save for a part now a prison. The Palazzo Comunale contains the picture gallery, with works by local masters; while in the Palazzo del Popolo there is a fine museum, with contents of prehistoric tombs, and a large collection of acorn-shaped lead missiles (glandes) used by slingers, belonging to the time of the siege of Asculum during the Social War (89 B.C.). The Ponte di Porta Cappucina is a very fine Roman bridge, with a single arch of 71ft. span. The Ponte di Cecco (so named from Cecco d'Ascoli), with two arches, is also Roman and belongs to the Via Salaria; the Ponte Maggiore and the Ponte Cartaro are, on the other hand, mediaeval. Near Ascoli is Castel Trosino, with an extensive 7th century Lombard necropolis. The ancient Asculum was the capital of Picenum in a strong position in difficult country. Taken in 268 B.C. by Rome, the Via Salaria was continued to it (120m. from Rome). It played a prominent part in the Social War against Rome, the proconsul Q. Servilius and all the Roman citizens within its walls being massacred by the inhabitants in 90 B.C. It was captured after a long siege by Pompeius Strabo in 89 B.C. The leader, Judacilius, committed suicide, the principal citizens were put to death, and the rest exiled. Caesar occupied it, after crossing the Rubicon. In A.D. 301 it became the capital of Picenum Suburbicarium. In 545 it was taken by Totila, but it is spoken of by Paulus Diaconus as the chief city of Picenum afterwards. Prince-bishops ruled it from Charlemagne's time and had coinage rights; it became a free republic in 1185 and a papal possession in the 15th century.

See C. Mariotti, Ascoli *Piceno* (Bergamo, 1913); and Saggi di *storia* ed arte Ascolana (Ascoli Piceno, 1932).

ASCONIUS PEDIANUS, QUINTUS (9 B.C.–A.D. 76; or A.D. 3–88), Roman grammarian and historian, was probably a native of Patavium (Padua). In his later years he resided at Rome. During the reigns of Claudius and Nero he compiled for his sons, from various sources—*e.g.,* "The Gazette" (*Acta Publica*), shorthand reports or "skeletons" (commentarii) of Cicero's unpublished speeches, Tiro's life of Cicero, speeches and letters of Cicero's contemporaries, various historical writers; *e.g.,* Varro, Atticus, Antias, Tuditanus, and Fenestella (a contemporary of Livy)—historical commentaries on Cicero's speeches, of which only five; viz., in *Pisonem,* pro *Scauro,* pro *Milone,* pro *Cornelio* and in toga *candida,* in a very mutilated condition, are preserved. These valuable notes, written in good Latin, relate chiefly to legal, historical and antiquarian matters. A commentary on Cicero's Verrine orations is universally regarded as spurious.

Both works were found by Poggio in a ms. at St. Gallen in 1416. This ms. is lost, but three transcripts were made by Poggio Zomini (Sozomenus) of Pistoia and Bartolommeo da Montepulciano. That of Poggio is now at Madrid (Matritensis x. 81) and that of Zomini is in the Forteguerri library at Pistoia (no. 37). A copy of Bartolommeo's transcript exists in Florence (Laur. liv. 5). The later mss. are derived from Poggio's copy. Other works attributed to Asconius were: a life of Sallust, a defence of Virgil against his detractors, and a treatise (perhaps a symposium in imitation of Plato) on health and long life.

Edition by Kiessling-Schoell (1875), and one by A. C. Clark (Oxford, 1906), which contains a previously unpublished collation of Poggio's transcript. See also Madvig, De Asconio Pediano (1828). C. Lichtenfeldt, De Q. Asconii Pediani fontibus *ac fide* (Dissert, Breslau, 1888); J. Humbert, Contribution *à l'étude* des *sources d'Asconius* (Paris, 1925).

ASCOS, a Greek vase of the drinking-vessel type, with a handle extending over the top and connecting with a large spout, giving it a tea-kettle appearance. (See **POTTERY** AND PORCELAIN: Greek Pottery.)

ASCOT, village of Berkshire, England, in the south-east of the county, famous for its race-meetings. The station on the Southern Railway, 29 m. from London, is called Ascot and Sunninghill. The race-course is on Ascot heath, in which parish the village of Ascot is included, and was laid out by order of Queen Anne in 1711. Pop. (1931) 2,617.

[1]The epithet distinguishes it from Ascoli Satriano (anc. Ausculum, see APPIA, VIA), which lies 19m. S. of Foggia by rail.

ASCUS, a botanical term for the membranous sacs containing the reproductive spores of fungi (*q.v.*) belonging to the group *Ascomycetes* (Gr. ἀσκός, a bag). Various compounds of the word are used, *e.g., ascogenous,* producing *asci; ascospore,* the spore developed in the ascus; *ascogonium,* the organ producing it, etc.

ASELLI, ASELLIUS or **ASELLIO, GASPARO** (1581–1626), Italian physician, was born at Cremona about 1581, became professor of anatomy and surgery at Pavia, and practiced at Milan where he died in 1626. To him is due the discovery of the lacteal vessels, published in De *Lactibus* (Milan, 1627).

ASEN or **ASSEN,** the name of the greatest mediaeval Bulgarian dynasty. Its real surname was apparently Belgun. The family is said to have been of Vlach origin; Nicetas states that a prisoner spoke to Asen in Vlach, "which was also his own language"; the Crusader chroniclers (*e.g.,* Villehardouin, *Conquête,* c. xliii., sect. 202) state that Kalojan was a Vlach, and refer to him as "king of the Vlachs and Bulgars," and Pope Innocent III., in his correspondence with Kalojan, refers to him as "descended from an ancient race of the city of Rome." The Asens also claimed descent from the old (Slavonic) dynasty of the Šišmanovtsi, of Western Bulgaria.

Two brothers, Peter and Ivan Asen Belgun, were in 1185 boyars of the twin rock-fortresses of Tsarevitsa and Trapesitsa at Trnovo, on the north edge of the Balkans. In that year, on their request for a more independent position being refused by Byzantium, they called together the neighbouring Vlachs and Bulgars, proclaimed independence from Greece, and gave the signal for a general rising. Defeated at first, they allied themselves with the Cumans and soon freed almost all North Bulgaria. In 1187 they concluded an armistice with the emperor Isaac Angelos, to whom they sent their younger brother, Kalojan, as hostage; but on Kalojan's escaping they renewed hostilities and defeated the emperor completely near Stara Zagora. About 1196 Ivan Asen died, and Peter was murdered by his own boyars shortly after. Kalojan was then proclaimed tsar of all the Bulgars and Vlachs. This very able but cruel king, also known as Joanitsa, and (scurrilously) as Skulojan or "Whelp-John," completed the conquest of North Bulgaria in 1201, and opened up negotiations with Pope Innocent III., in the hope of obtaining from him the title of emperor. The pope sent a cardinal to crown him, but only as king, in 1204; but in the remarkable correspondence between them he declared to Kalojan that he "extolled him above all other Christian rulers," and "loved him so much that he thought only of his interests and glory," while the Crusaders, who captured Constantinople in 1204, were very curtly ordered to make their peace with the pope's new friend. The Latin emperor Baldwin, however, when offered an alliance by Kalojan, ordered him to approach the Crusaders, as a slave approaches his master, to renounce the throne he had usurped and return to the status of a slave. The incensed Bulgarian, after defeating the Crusaders at Adrianople (1205), captured and perhaps murdered Baldwin (see BALDWIN I.). After ravaging Thrace with his Cumans for two years, Kalojan was murdered, while besieging Salonika, by the leader of his Cuman forces, perhaps at the instigation of his own wife, who was a Cuman.

The throne was now seized by his nephew Boril, who, however, proved unsuccessful and unpopular, and was dethroned and blinded in 1218 by his cousin Ivan Asen II., son of Ivan Asen I. Ivan Asen II. was one of the greatest of Balkan sovereigns. He was a brilliant soldier and his humanity and piety were admitted by the Greeks themselves. In 1230, by defeating Theodore, despot of Epirus, at Klokotnitsa, he added to his realms Macedonia, Epirus and much of Albania; and soon after he conquered most of Serbia. He now assumed the title of "tsar of the Greeks and Bulgars." but his ambition to wear the imperial crown in Constantinople was never fulfilled. He had been virtually protector of the weak Frank empire, and his daughter Helen had been betrothed to Baldwin II.; but the contract was dissolved by the pope, who excommunicated Asen. and his siege of Constantinople in 1225–26, in alliance with the emperor of Nicaea, was abandoned on account of an invasion of North Bulgaria by the Mongols. Ivan Asen II. died in 1241. An interesting inscription in the church of the Forty Martyrs at Trnovo, his capital, records his exploits. He was succeeded by his sons Caliman I. (1241–46) and Michael (1246–57), the latter under the regency of his mother, the Greek Irene. Their sister Tamara married the Byzantine emperor Michael Palaeologos. Caliman II. (1257–58) was a cousin of the above and the last of the male line of Asen. Mitsa, nephew of Caliman and Michael, seized the throne in 1262, but was expelled, fled to Constantinople, and was settled by the emperor on an estate near Troy. His son, Ivan III., married Irene, daughter of Michael Palaeologos, and was crowned at Trnovo in 1279, but, defeated by his rival, the swine-herd Ivailo, he fled from Bulgaria in 1280.

See under BULGARIA, CRUSADES, and ROMAN EMPIRE, LATER; also Du Cange, *Familiae* Dalmatirae, pp. 318–20; and Gesta Innocent *III.,* cc. 66–82, pp. 513–25, for the correspondence between Kalojan and the pope. (C. A. M.)

ASEPSIS: see ANTISEPTICS AND ASEPSIS.

ASGILL, JOHN (1659–1738), English writer, was born at Hanley Castle, Worcestershire, the author of a tract (1700) to prove that Christians need not die. He made a considerable fortune in legal practice in Ireland, and was returned to the Irish Parliament. for Enniscorthy (1703), and the English Parliament for Bramber (1705–07), but was expelled from both because the burning of his "blasphemous pamphlet" had been ordered. In 1707 he was arrested for debt, and the remainder of his life was spent in the Fleet Prison, or within the rules of the King's Bench. He died in 1738. Asgill also wrote in 1714–15 pamphlets defending the Hanoverian succession against the claims of the Pretender.

ASH, the common name of a number of trees from several unrelated genera. The European ash (Fraxinus excelsior), belongs to the olive family (Oleaceae), a group of trees and shrubs which include also lilac, fringetree, privet, jasmine, goldenbell, and olive. The Hebrew word *Oren,* translated "ash" in Isaiah xliv. 14, cannot refer to an ash, as none is native to Palestine, but probably refers to the Aleppo pine (*Pinus* halepensis). This ash is a native of Great Britain and most of Europe and also extends to certain parts of Asia. It attains a height of from 50 to 80 ft. and flowers in March and April before leaf emergence. The inconspicuous, reddish, naked (*i.e.,* without sepals and petals) flowers are produced in dense clusters. They are usually imperfect, wanting either stamens or pistil. The large leaves, which are late in their appearance, are pinnately compound and bear four to seven pairs of gracefully tapered, toothed leaflets borne on a slender stalk (rachis). The dry, terminally winged, paddle-like fruit (samaras), the so-called keys, are a pertinent feature and remain attached to the branchlets long after the leaves have fallen in the autumn. The grayish twigs and few-scaled, black buds are conspicuous features of the tree during the winter months.

Several varieties of the European ash are recognized. One with simple leaves (var. *heterophylla*) occurs naturally in the forests of England and continental Europe. Another (var. *pendula*), with pendulous or weeping branches, is occasionally encountered, a form which has been propagated from a single sport found at Wimpole in Cambridgeshire. This variety is sometimes grafted on a tall stem of the common species to produce a tree of unusual ornamental effect. Two other types, one with curled leaflets (var. *crispa*), the other with warty stems and branches (var. *verrucosa*) are also recognized.

The flowering ash or manna, Fraxinus *ornus* (see MANNA), is a handsome tree with greenish-white flowers indigenous to southern Europe. Two other species, the small-leaved ash (F. *parvifolia*), also native to southern Europe, and the Himalayan ash (F. *floribunda*), a large tree with terminal panicles of white flowers, are both suitable for decorative purposes.

The center of distribution of the ashes appears to be in North America, where there are about 20 endemic species. Several are valuable timber trees. the most important of which are the white ash (F. *americana*), the black ash (F. *nigra*), the red ash (F. *pennsylvanica*), the green ash (*F. pennsylvanica* var. *lanceolata*), of the central, eastern and southern United States, and the Oregon ash (F. *oregona*), of the Pacific northwest. Other noteworthy American ashes include the blue ash (*F. quadrangulata*) of the Ohio and central Mississippi valleys; the Carolina ash (F. *caroliniana*), of the southeastern Atlantic coastal plain; the Florida ash (F. *paucifolia*), of southern Georgia and Florida; the pumpkin ash (F. profunda) of the southern states; and the velvet (*F. velutina*) and single-leaf (*F.*

anomala) ashes of the arid southwest. Especially interesting is the foot-hill ash (F. dipetala), a small shrub with showy white flowers, scattered along the lower slopes of California's mountains. The American flowering ash (F. cuspidata), featuring large, white, fragrant blossoms, is a small tree of Texas and New Mexico. The American ashes range in size from small shrubs to large graceful trees; the white ash, one of the finest American hardwoods, attains in the lower Ohio valley a height of 120 ft. and a diameter of 40 to 60 in.

The production of ash lumber, like most hardwoods in the U.S.A., declined after the first decade of the 20th century. In 1940 the cut of ash was estimated to be 129,183,000 ft. B.M. Of this amount, 88,238,000 ft. were cut into lumber, 376,000 ft. made into veneer, and 40,569,000 ft. of logs and bolts were used for specialty products.

The European and American mountain ashes are *Sorbus* aucuparia and S. *americana,* respectively; these belong to the rose family (Rosaceae), which includes also the apples, pears, hawthorns, and many other beautiful flowering shrubs. Poison sumac (Rhus *vernix*), a member of the cashew family (Anacardiaceae), is the poison ash of many localities. The bitter ash of the West Indies is Simaruba *excelsa,* a member of the quassia family, while the cape ash, a native of the Cape of Good Hope, is Ekebergia capensis, of the mahogany family (Meliaceae). A small armed shrub of eastern United States, the prickly ash (Zanthoxylon americanum) belongs to the rue family (Rutaceae), famous for its citrus fruits. Two Australian genera, *Flindersia* and Tarrietia are productive of silver ash and crow's ash timbers respectively. The former is also a memher of the Rutaceae while the latter is included in the cocoa family (Sterculiaceae).

(E. S. HR.)

A'SHA (MAIMUN IBN QAIS), Arabian poet, was born before Mohammed, and lived long enough to accept the mission of the prophet. He was born in Manfūha, a village of al-Yemāma in the centre of Arabia, and became a wandering singer, passing through all Arabia from Hadramut in the south to al-Hira in the north. Even before the time of Mohammed he is said to have believed in the resurrection and last judgment, and to have been a monotheist. These beliefs may have been due to his intercourse with the bishop of Nejrān (Najrān) and the 'Ibādites (Christians) of al-Hira. His best-known poem is that in praise of Mohammed.

His poems have been collected from various sources in L. Cheikho's Les *Poètes* arabes *chrétiens* (Beirut, 1890), pp. 357–399. His eulogy of Mohammed has been edited by H. Thorbecke, *Al Aša's* Lobgedicht *auf* Muhammad (Leipzig, 1875).

ASHANTI, an inland country of West Africa, annexed by Great Britain in 1901. It lies immediately north of the Gold Coast colony, and while preserving a separate entity is administered by a chief commissioner under the authority of the governor of the Gold Coast. Area 24,379sq m.; pop. (1931 census) 578,702.

Physical Features, **Etc.**—A great part ot Ashanti is covered with primaeval and almost impenetrable forest. Many of the trees, chiefly silk-cotton and hardwood, attain splendid proportions, the bombax reaching a height of over 200ft., but the monotony is oppressive, and is seldom relieved by the sight of flowers, birds or beasts. Ferns are abundant, and the mimosa rises to heights of from 30 to 60ft. All over the forest spread lianas, or monkey-ropes, their usual position being that of immense festoons hanging from tree to tree. In the north-eastern districts the primaeval forest gives place to park-like country, consisting of plains covered with high coarse grass, and dotted with occasional baobabs, as well as with wild plum, shea-butter, dwarf date, fan palms and other small trees. About 25m. south-east of Kumasi is Lake Busumchwi, the sacred lake of the Ashanti. It is surrounded by forest-clad hills some 800ft. high, is nearly circular, and has a maximum diameter of 6m. The Black Volta, and lower down the Volta (*q.v.*), form the northern and eastern frontier, and various tributaries of the Voita, running generally in a northerly direction, traverse the eastern portion of the country. In the central parts are the upper courses of the Ofin and of some tributaries of the Prah.

Inhabitants.— The most probable tradition represents the Ashanti as deriving their origin from bands of fugitives, who in the 16th or 17th century were driven before the Muslim tribes migrating southward from the countries on the Niger and Senegal. Having obtained possession of a region of dense forest, they defended themselves with a valour which, becoming part of their national character, raised them to the rank of a powerful and conquering nation. They are of the pure negro type, and are supposed to be originally of the same race as the Fanti, nearer the coast, and speak the same language. The Ashanti are divided into a large number of tribes, of whom a dozen may be distinguished, viz., the Bekwai, Adansi, Juabin, Kokofu, Kumasi, Mampon, Nsuta, Nkwanta, Dadiassi, Daniassi, Ofinsu and Adjisu. Each tribe had its own king, but from the beginning of the 18th century the king of Kumasi was recognized as paramount and was spoken of as the king of Ashanti. Under British rule the kingship has been abolished, but each tribe has its paramount chief styled Omanhene. The principal symbols of authority are the stool (chiefs are "enstooled" not crowned) and umbrella. Land is held in common by the tribes, lands unallotted being attached to the office of head chief and called "stool lands." Human sacrifice, practised among the Ashanti until the closing years of the 19th century, was founded on a sentiment of piety towards parents and other connections—the chiefs believing that the rank of their dead relatives in the future world would be measured by the number of attendants sent after them. The Ashanti are skilful in several kinds of manufacture, particularly in weaving cotton.

BY COURTESY OF THE PHELPS STOKES FUND
THE RULER OF ASSUNATSI. A SECTION OF ASHANTI, IN HIS ROBES OF STATE AND TURBAN, ACCOMPANIED BY ONE OF HIS CHIEFS

Their pottery and works in gold also show considerable skill. A large quantity of silver-plate and goldsmiths' work of great value and considerable artistic elaboration was found in 1874 in the king's palace at Kumasi, not the least remarkable objects being masks of beaten gold. The influence of Moorish art is perceptible. Unlike many West African races, the Ashanti in general show a repugnance to the doctrines of Islam; but large numbers have become converts to Christianity (chiefly to the Anglican and Wesleyan churches). Education is much sought after by the Ashanti. They are keen farmers and keen traders.

Towns, **Trade** and Communications.— The capital is Kumasi (*q.v.*); pop. (1940) 43,413. It is served by a railway, 167m. long, from the port of Sekondi (Takoradi), completed in 1903, and by another railway, 196m. long and completed in 1923, which has its sea terminus at Accra. North of Kumasi is Mampon, on the main motor road, and still farther north Kintampo, formerly a great slave and ivory mart and now the entrepôt for trade with the northern territories and the French Sudan. Sunyani and Goaso are towns in the west; Bekwai and Obuasi are south of Kumasi on the railway to Sekondi. There is an extensive system of motor roads and a public motor transport system. The chief product for export is cocoa. Cultivation began about 1905 and within 20 years the prosperity of the country had come to depend largely upon the cocoa crop, the seasonal production having reached 60,000 tons. Next in importance come the production of kola nuts, and timber; and although collection of wild rubber has now ceased, a small quantity is produced on plantations. There is also an overland trade with the north in cattle and sheep, kolas and shea butter. The production of minerals has greatly increased in later years, and the Obuasi district produced 254,983 oz. of gold in 1937–8. Manganese and diamonds are also mined. While cultivation is almost entirely in the hands of Ashantis, the traders include many Syrians, Hausas and Lagosians. Trade, as also revenue, statistics are included in those of the Gold Coast.

The administrative system of Ashanti was reorganized in 1934, and in 1935 the native Confederation of Ashanti was re-established after a lapse of 35 years. A considerable measure of authority is exercised by the Confederation either directly or through the various tribal councils. (X.)

HISTORY

When it came under the notice of Europeans early in the 18th century the Ashanti confederation had been brought under the hegemony of the Kumasi tribe. Previously other tribes, such as

the Denkera (Denkyira), had claimed the overlordship. The real founder of the kingdom of Ashanti was Osai Tutu, who is described as the fourth king of Kumasi. According to legend there came to his court a magician who affirmed that he was commissioned by 'Nyame (the god of the sky) to make of the Ashanti a great nation, and in proof thereof he drew down a black cloud from which there descended a wooden stool partly covered with gold which came to rest on the knees of Osai Tutu. This stool, the magician declared, contained the soul of the nation. Afterwards, greatly enriched, it became the famous Golden Stool of Ashanti. It had its own umbrella (another adjunct of sovereignty) and its own attendants. On great occasions the Golden Stool was placed next the king's stool and the king rested his arm upon it.

Osai Tutu was a great warrior. To him is attributed the building of Kumasi town; it is more probable that he greatly expanded an existing town. In 1719 he opposed the king of Denkera's demand for tribute; defeated him in battle and executed both him and his queen. Thereafter he greatly extended his conquests. At length (c. 1730) he was defeated and slain at Koromanti in battle with the Akims but his successor, Osai Apoko, made further conquests towards the coast. This trend of the Ashanti to the coast was marked during the reign of Osai Tutu Kwadwo (Quamina), who in 1807 made war on the Fanti (the ruling people of the coast) because they had given asylum to two Assin chiefs whom he had defeated. Kwadwo reached the coast near Anamabo, where was a British fort. A pitched battle was fought with great slaughter, but the Ashanti failed to storm the fort, though the garrison was reduced from 24 to eight men. Colonel G. Torrance, then governor of Cape Coast, concluded a humiliating peace. He agreed to surrender the Assin chiefs--one escaped, the other was executed by the Ashanti—and half the fugitives in Anamabo fort: most of the remainder were sold by Torrance and his council as slaves. Torrance also acknowledged the Ashanti conquest of Fantiland and agreed to pay rent to the Ashanti for Anamabo fort and Cape Coast Castle.

Notwithstanding this settlement disputes continued, the British alternately supporting and abandoning the coast people. In 1821 the British Government assumed direct control of the British settlements on the Gold Coast. The governor, Sir Charles M'Carthy, espoused the cause of the Fanti, but was killed in battle with the Ashanti on Jan. 21, 1824, at Essamako. He had but 500 men to 10,000 of the enemy. The skull of Sir Charles was afterwards used at Kumasi as a royal drinking cup, but not by Kwadwo, who died on the same day as Sir Charles fell. A state of chronic warfare ensued. It ended in a signal defeat of the Ashanti by the British at Dodowa, near Accra, on Aug. 7, 1826. Peace was not formally made until 1831, when by a treaty concluded with Mr. George Maclean the Ashanti acknowledged the Prah as their southern boundary.

The War of 1873–74.—Kwaka Dua I., who became king in 1838 was a rare exception among Ashanti rulers, a peace-loving monarch who encouraged trade. He could not refrain, however, from asserting authority over the Fanti, and in 1863 he went to war because of the refusal of the British to surrender a fugitive chief and a runaway slave. The Ashanti were successful in two actions and were allowed to retire unmolested. "The bush" said Kwaka Dua, "is stronger than the cannon of the white men." The prestige of the Ashanti increased and when after Kwaka Dua's death in 1867, and the usual interval of civil strife, Kofi Karikari ("King Coffee" as he was popularly called in England) was enstooled he swore that his business should be war. The chief event which caused the war which followed was the transfer (April 2, 1872) of Elmina from the Dutch to the British. The Ashanti regarded the Elmina people as their subjects, and they held the Elmina "custom note"—that is, the king received from the Dutch an annual payment, in its origin ground rent for the fort, but looked upon by the Dutch as a "dash" (present) for trade purposes. A minor cause of the war was the holding in captivity at Kumasi of four Europeans, including Mr. Fritz Ramseyer, of the Basel Mission, and his wife. In Jan. 1873 an Ashanti force crossed the Prah and advanced to the neighbourhood of Cape Coast. Fortunately for the British the Ashanti army was greatly weakened by the outbreak of small-pox and fever. Sir Garnet (afterwards Viscount) Wolseley was sent from England to deal with the situation. His force, which included 2,400 white troops, occupied Kumasi after severe fighting on Feb. 4, 1874. Kofi Karikari fled into the bush and refused to surrender. Wolseley, encumbered with many sick and wounded, with fever prevalent, provisions scarce and the rainy season beginning, was compelled to retire, having first set Kumasi in flames. On Feb. 12, however, Captain (later Sir John) Glover, R.N., administrator of Lagos, who with native levies was co-operating with Wolseley from the east, reached the deserted ruins of Kumasi. Glover's appearance induced Kofi Karikari to sue for peace and on Feb. 13 at Fomana a treaty was signed. The Ashanti king renounced all claims to Elmina, promised to pay an indemnity, pledged himself to use his best endeavours to check the practice of human sacrifice and to promote freedom of trade. The British, however, neglected to take the opportunity offered to encourage the secession of various states from the Ashanti confederation and thus the power of Kumasi was reconsolidated.

Deposition of **Prempeh.**—Shortly after the war the Ashanti deposed Kofi Karikari, and placed on the stool his brother Mensa. This monarch broke almost every article of the Fomana treaty. His rule was tyrannous and stained with repeated human sacrifices. In 1883 a revolution displaced that monarch, who was succeeded by Kwaka Dua II.—a young man who died (June 1884) within a few months of his election. In the same month died the ex-king Kofi Karikari, and disruption threatened Ashanti. After a desolating civil war, Prempeh—who took the name of Kwaka Dua III.—was chosen king (March 26, 1888), and for a time peace and prosperity came to Ashanti. However, in 1893, there was fresh trouble between Ashanti and the tribes of the Gold Coast. The British Government was forced to interfere, and in 1895 called upon Prempeh to fulfil the terms of the 1874 treaty, and further, to accept a British protectorate. The king declined to treat with the governor of the Gold Coast, and despatched informal agents to England, whom the secretary of state refused to receive. To enforce the British demands an expedition was at length decided upon. The force was placed under Colonel Sir Francis Scott, and, after most careful organization, the main column started from Cape Coast on Dec. 27, 1895. On Jan. 17, 1896, Kumasi was occupied, and on the 20th Prempeh made submission to Mr. (afterwards Sir W. E.) Maxwell, the governor of Cape Coast, in native fashion. After this act of public humiliation, the king and the queen-mother with the principal chiefs were arrested and after being kept at Elmina for some time were exiled to the Seychelles Islands. The fetish buildings at Bantama were burned, and on Jan. 22, leaving a Hausa garrison at Kumasi, the expedition began the return march of 150m. to Cape Coast. Although no fighting occurred, fever claimed many victims, among whom was Prince Henry of Battenberg, who had volunteered for the post of military secretary to Sir Francis Scott.

Siege and Relief of **Kumasi.**—After the deportation of Prempeh no successor was appointed to the throne of Ashanti. Whilst the other States of the confederacy retained their hereditary chiefs the affairs of the Kumasi were administered by chiefs under British guidance. But although outwardly submissive the Kumasi were not reconciled to British rule, and in 1900 the action of Sir Frederic Hodgson, the governor of the Gold Coast, precipitated a revolt. In March of that year Sir Frederic, in a public palaver at Kumasi, bitterly reproached the chiefs with not having brought to him the golden stool. Sir Frederic, like almost all Europeans at that time, believed the golden stool to be the king's throne. He did not know that it was regarded as containing the soul of the nation, and if it were captured or destroyed the Ashanti would perish. Hence when Prempeh surrendered, the stool had been hidden. Attempts made by Sir Frederic's orders to find the stool had failed and the rebellion*began with an attack on Hausa soldiers whose chief object was the discovery of the stool. The British at Kumasi were now obliged to take refuge in the fort (April 1900). Reinforcements brought the garrison of the fort up to 700 men in May, the 20 Europeans

in the fort including Lady Hodgson and three other women. Outside the fort were gathered 3,000 native refugees. The Kumasi chiefs and their Adansi and Rokofu allies had 40,000 warriors, They sat down to invest the fort, and famine and disease soon began to work havoc. When conditions had become desperate the governor and all the Europeans save three, together with 600 Hausas sallied out of the fort (June 23), attacked a weakly-helal stockade and, though suffering about 100 casualties, succeeded in getting clear. The governor's party, taking a circuitous route, reached Cape Coast on July 10.

Three white men—Captain F. E. Bishop, Lieut. J. C. Ralph, Dr. J. B. Hay, colonial surgeon—with 100 Hausas were left in Kumasi fort with rations for three weeks. Meanwhile a relief expedition had been organized at Cape Coast by Colonel (afterwards General Sir) James Willcocks. Carriers could scarcely be obtained, there were no local food supplies, the rainy season was at its height, all the roads were deep mire, and the enemy were both brave and cunning, fighting behind concealed stockades. It was not until July 2 that Colonel Willcocks was able to advance. There was smart fighting on the 14th, and at 4 30 P.M. on the 15th, after a march since daybreak through roads "in indescribably bad condition," the main rebel stockade was encountered. It was carried at the point of the bayonet by Yoruba troops, who proved themselves fully equal to the Hausa. Kumasi was entered the same evening, a bugler of the war-worn garrison of the fort sounding the "general salute" as the relieving column came in view. Most of the defenders were too weak to stand. Outside the fort nothing was to be seen but burnt-down houses and putrid bodies. On Sept. 30 the Kumasi were completely beaten at Obassa.

An Era of Progress.-On Sept. 26,1901, Ashanti was formally annexed to the British dominions. After the annexation the relations between the governing power and the governed steadily improved, great credit being due to the wise administration of Sir Donald Stewart, the first chief commissioner, and to Sir Francis Fuller, who was chief commissioner from 1905 to 1920. The maintenance of the tribal system and the support given to the lawful chiefs did much to win the confidence and respect of a people naturally suspicious, and mindful of their exiled king. The accidental discovery in 1921 of the Golden Stool showed how greatly understanding between the British and the Ashanti had increased. The stool. placed in a box and buried in the ground was found by native workmen and shortly afterwards was robbed of its golden ornaments by a number of Ashanti. News of the desecration of the stool caused national mourning. The culprits were arrested and were tried by the principal chiefs, who recommended their execution. This punishment was changed by the Government into banishment: the chief whose duty it had been to guard the stool was also banished. For its part the Government intimated that it no longer desired possession of the stool and that no attempt to interfere with it would be made, unless use were made of it for seditious purposes.

The changed attitude of the people was due also to improved economic conditions following the opening of the railway to Kumasi in 1903 and, later on, the cultivation of cocoa on a large scale. Education was greatly prized and Christian missions gained large numbers of converts. The loyalty of the Ashanti to the Crown was manifest throughout World War I. The Ashanti generally, and the Kumasi in particular, much desired, however, the return of Prempeh, and at length their request was granted. After 28 years' exile Prempeh, who had in the Seychelles become a Christian and had adopted European ways and clothes, came back in 1924 to Kumasi, but as a private citizen. He was received by a great crowd, the pagans joining with the Christians in singing the "Old Hundredth." In 1926 Prempeh was restored to the Kumasi stool, that is, to the position of Omanhene (paramount chief) of the Kumasi tribe, but not to the Kingship of Ashanti. He chose his sister to fill the position of "Queen-Mother." Nine years later, the old confederation of Ashanti *(see* above), which had been abolished by the British, was re-established; and a nephew of Prempeh who in the meantime succeeded his uncle as Prempeh II was placed at its head.

BIBLIOGRAPHY.—Of early works the most valuable are *The Golden Coast . . .* (1665) and *A new . . . description . . . of Guinea* in Dutch (Eng. trans., 2nd ed., 1721), both by Willem Bosman; T. E. Bowdich, *A Mission from Cape Coast Castle to Ashantee* (1819); and J. Dupuis, *Journal of a Residence in Ashantee* (1824). For history generally, *see* Col. A. B. Ellis, *A History of the Gold Coast of West Africa* (1893); C. C. Reindorf (a native pastor of the Basel mission), *History of the Gold Coast and Asante, . . . from about 1500 to 1860* (Basel, 1895), and Sir Francis Fuller, *A Vanished Dynasty: Ashanti* (1921).

For the British military campaigns, in addition to the official blue-books, consult: Sir Henry Brackenbury, *Narrative of the Ashantee War* (1874); Sir H. M. Stanley, *Coomassie,* being the story of the 1873–74 expedition (new ed., 1896); Gen. R. S. S. Baden-Powell, *The Downfall of Prempeh,* an account of the 1895–96 expedition (1896); Lady Glover, *Life of Sir John Hawley Glover,* chs. iii.–x. (1897); Capt. C. H. Armitage and Lieut.-Col. A. F. Montanaro, *The Ashanti Campaign of 1900* (1901); Capt. H. C. J. Biss, *The Relief of Kumasi* (1901); Viscount Wolseley, *The Story of A Soldier's Life,* vol. ii. chs. xliii.–l. (1903); Sir James Willcocks, *From Kabul to Kumasi,* chs. xv. to end (1904). The two books following are by besieged residents in Kumasi. Lady Hodgson, *The Siege of Kumasi* (1901); *Dark and Stormy Days at Kumasi, 1900,* from the diary of the Rev. Fritz Ramseyer (1901). The annual reports issued since 1906 by the Colonial Office, London, contain historical notes. Capt. R. S. Rattray's books, *Ashanti* (1923) and *Religion and Art in Ashanti* (1927) deal with anthropology; E. W. Smith in *The Golden Stool,* ch. i. (1926) gives the history of the stool. (F. R. C.)

ASH'ARI (Abu'l Hssan 'Ali ibn Isma'il al-Ash'ari) (873–935), Arabian theologian, was born of pure Arab stock at Basra, but spent the greater part of his life at Baghdad. Although belonging to an orthodox family, he became a pupil of the great Mu'tazalite teacher al-Jubba'i, and himself remained a Mu'tazalite until his fortieth year. In 912 he returned to the faith of his fathers and became its most distinguished champion, using the philosophical methods he had learned in the school of heresy. His theology, which occupied a mediate position between the extreme views on most points, became dominant among the Shafi'ites. He is said to have written over a hundred works, of which only four or five are known to be extant.

See W. Spitta, *Zur Geschichte Ahu 'I-Hasan al Aš'ari's* (Leipzig, 1876); A. F. Mehren, *Exposé de la réforme de l'Islamisme commencée par Abou 'l-Hasan Ali el-Ash'ari* (Leyden, 1878); and D. B Macdonald's *Muslim Theology* (1903), especially the creed of Ash'ari in Appendix iii. (G. W. T.)

ASHBOURNE, EDWARD GIBSON, 1ST BARON (1837–1913), Irish lawyer and politician, was born in Dublin Sept. 4, 1837, and was educated at Trinity College, Dublin. He was called to the Irish bar in 1860, and in 1872 became a Q.C. In 1875 he was elected for Dublin University as a Conservative, and in 1877 became attorney-general for Ireland in Disraeli's Government. In 1885 he was made lord chancellor of Ireland with a seat in the Cabinet, and raised to the peerage. holding the same office in the Conservative Governments of 1886–92 and 1895–1905. Lord Ashbourne took a prominent part in the early negotiations for land purchase in Ireland. He died in London May 22, 1913, and was succeeded as 2nd baron by his eldest son, William Gibson (1868–1942)

ASHBOURNE, urban district, Derbyshire, England, 13 mi. W.N.W. of Derby. Pop. (1938) 4,796. Area 1.7 sq.mi. It is well situated on rising ground between two small valleys opening into that of the Dove, and the beautiful scenery of Dovedale is not far distant. The church of St. Oswald is cruciform, Early English and later; a fine building with a central tower and lofty octagonal spire. Its monuments and brasses are of much interest. The town has a large agricultural trade. The making of corsets is a feature, and growing numbers are employed in the metal trades of the neighbourhood. The local streams are in favour with trout fishermen. Ashbourne Hall, an ancient mansion, has associations with "Prince Charlie," who occupied it both before and after his advance on Derby in 1745. There are many associations with Dr. Johnson, a frequent visitor here to his friend Dr. Taylor, who occupied a house opposite the grammar school.

ASHBURNHAM, JOHN (*c.* 1603–1671), English Royalist, son of Sir John Ashburnham, entered parliament as member for Hastings in 1629, and sat for the same borough in the Long Parliament. He was treasurer of the royal army during the Civil War, commissioner in the Uxbridge negotiations (1644), escaped with

Charles to the Scots from Oxford (1646), and then went abroad, being employed by Charles at the court of the Prince of Orange. After the seizure of Charles by the army, Ashburnham joined him at Hampton Court in 1647 When Charles escaped from Hampton Court on Nov. 11, he followed Ashburnham's advice in opposition to that of Sir John Berkeley, who urged the king to go abroad, and took refuge in the Isle of Wight, being placed by Ashburnham in the hands of Robert Hammond, the governor. "Oh, Jack," the king exclaimed when he understood the situation, "thou hast undone me!" when Ashburnham, "falling into a great passion of weeping, offered to go and kill Hammond." By this fatal step Ashburnham incurred the unmerited charge of treachery and disloyalty. Clarendon, however, who censures his conduct, absolves him from any crime except that of folly and excessive self-confidence, and he was acquitted both by Charles I. and Charles II. He was separated with Berkeley from Charles on Jan. 1, 1648, waited on the mainland in expectation of Charles's escape, and was afterwards taken and imprisoned at Windsor, and exchanged during the second Civil: War for Sir W. Masham and other prisoners. He was specially exempted from pardon in the Treaty of Newport. In November he was allowed to compound for his estates, and declared himself willing to take the covenant. After the king's death he remained in England, an object of suspicion to all parties, corresponded with Charles II., and underwent several terms of imprisonment in the Tower and in Guernsey. At the Restoration he was reinstated in his former place of groom of the bedchamber and was compensated for his losses. He represented Sussex in parliament from 1661 till his expulsion, in 1667, for taking a bribe of £500 from French merchants for landing their wines. He died on June 15, 1671.

A descendant of his, Bertram (1797–1878), the 4th earl, was the collector of the famous Ashburnham library, which was dispersed in 1883 and 1884.

A Letter from Mr. Ashburnham to a Friend, defending John Ashburnham's conduct with regard to the king, was published in 1648. His longer *Narrative* was published in 1830 by George, 3rd earl of Ashburnham (the latter's championship of his ancestor, however, being entirely uncritical and unconvincing); *A Letter to W. Lenthall (1647)* repudiates the charge brought against the king of violating his parole *(Thomason Tracts,* Brit. Museum, *E* 418 [41]).

ASHBURTON, ALEXANDER BARING, 1ST BARON (1774–1848), English politician and financier, 2nd son of Sir Francis Baring (the founder of the house of Baring Brothers and Co.), was brought up in his father's business. He was a member of parliament from 1806–35. He regarded politics from the point of view of the business man, opposed the orders in council and the restrictions on trade with the United States in 1812, and in 1826 the act for the suppression of small bank-notes. He was a strong antagonist of Reform. He became chancellor of the exchequer in the duke of Wellington's projected ministry of 1832; but afterwards, alarmed at the scene in parliament, declared "he would face a thousand devils rather than such a House of Commons," and advised the recall of Lord Grey. In 1834 he was president of the board of trade and master of the mint in Sir Robert Peel's government, and on the latter's retirement was created Baron Ashburton *(see* below for the earlier creation) on April 10, 1835. In 1842 he was despatched to America, and the same year concluded the Ashburton or Webster-Ashburton treaty. *(See* ASHBURTON TREATY.)

He was also a trustee of the British Museum and of the National Gallery, a privy councillor and D.C.L. of Oxford. He published, besides several speeches, *An Enquiry into the Causes and Consequences of the Orders in Council* (1808), and *The Financial and Commercial Crisis Considered* (1847). He died on May 13, 1848.

ASHBURTON, JOHN DUNNING, 1st BARON (1731–1783) English lawyer, was born at Ashburton, Devonshire, on Oct. 18, 1731. At first articled to his father, he was admitted, at the age of 19, to the Middle Temple, and called to the bar in 1756, where he came very slowly into practice. He went the western circuit for several years without receiving a single brief. In 1762 he was employed to draw up a defence of the British East India Company against the Dutch East India Company, which had memorialized the Crown on certain grievances. This masterly document procured him at once reputation and emolument. In 1763 Dunning distinguished himself as counsel on the side of Wilkes, whose case he conducted throughout. His powerful argument against the validity of general warrants in the case of *Leach* v. *Money* (June 15, 1763) established his reputation, and his practice from that period gradually increased to such an extent that in 1776 he is said to have been in the receipt of nearly £10,000 per annum. In 1766 he was chosen recorder of Bristol, and in Dec. 1767 he was appointed solicitor-general. The latter appointment he held till May 1770, when he retired with his friend Lord Shelburne. In 1771 he was presented with the freedom of the City of London. From this period he was considered as a regular member of the opposition, and distinguished himself by many able speeches in parliament. He had entered parliament as member for Calne in 1768. In 1780 he brought forward a motion that the "influence of the Crown had increased, was increasing, and ought to be diminished," which he carried by a majority of eighteen. He strongly opposed the system of sinecure officers and pensions; but in 1782, when the marquis of Rockingham became prime minister, Dunning was appointed chancellor of the duchy of Lancaster, a rich sinecure. About the same time he received his peerage. Under Lord Shelburne's administration he accepted a pension of £4,000 a year. He died at Exmouth on Aug. 18, 1783.

Besides the answer to the Dutch memorial, Lord Ashburton is supposed to have assisted in writing a pamphlet on the law of libel, and to have been the author of *A Letter to the Proprietors of East India Stock, on the subject of Lord Clive's Jaghire, occasioned by his Lordship's Letter on that Subject* (1764). He was at one time suspected of being the author of the *Letters of Junius.*

ASHBURTON, an urban district, South Devonshire, England, on a branch of the G.W.Ry. from Totnes. Pop. (1938) 2,395. Area 10.6 sq.mi. It lies under Dartmoor, in a valley surrounded by hills, at a short distance from the River Dart. Ashburton (Essebretona, Asperton, Ashperton) is a borough by prescription and an ancient stannary town. In Domesday the manor was held in chief by Osbern, bishop of Exeter. Fairs and a Saturday market were instituted in the reign of Edward II. A market for the sale of wool, and fairs for the sale of cattle, corn and merchandise were granted in 1672 and 1705 respectively. The town was represented at various times by either one or two members from 1298 to 1885. It is in the Totnes division of Devonshire. The church of St. Andrew, with its lofty tower, was built early in the 15th century and has a fine oak roof over the north aisle. The grammar school was founded as a chantry in 1314, but it was closed in 1938, separate schools for boys and girls having been opened. The town has seen many kinds of industry and there are corn mills and a malthouse. Four fairs are still held annually.

ASHBURTON, a river in the north-west division of Western Australia. It drains north-westward from the interior plateau (average elevation: 2,000–3,000ft.) which its upper tributaries dissect. The greater part of its course of 400m., however, is through wide alluvial plains traversed by low ridges, though there are gorge sections along the main stream and its tributaries. The highly-inclined and folded (Pre-Cambrian) rocks are traversed by quartz reefs in which gold, as well as some lead and copper, occur in widely scattered localities. Gold has been exploited but the yield has not been great. Along the lower course of the Ashburton, the wide coastal plains are utilised for pastoral purposes. The rainfall is here very unreliable (Onslow [1891–1910] shows a variation of 1–27in. annual fall) and the temperatures are high (mean annual 75–80°). In the area inland from Onslow is one of the hottest parts of Australia, with an average of 90° for January. These drawbacks, however, have not proved prohibitive. Artesian water is available southwards from Onslow and the provision of a railway line would stimulate development. At the mouth of the Ashburton river the port of Onslow (924m. by sea from Fremantle) has a jetty (1,120ft. long), but a shallow and exposed anchorage. Its population includes some 100 Europeans, and it exports cattle, sheep, wool, hides and skins,

and mineral ores derived from its hinterland. Pearl fishing is also carried on in the adjoining coastal waters and pearl shell is shipped from Onslow. The Ashburton itself is not navigable.

"ASHBURTON TREATY, THE," a treaty negotiated in 1842 between Great Britain and the United States of America by Lord Ashburton (see ASHBURTON, ALEXANDER BARING) and Daniel Webster.

In particular it decided the boundary dispute between Maine and Canada; and the M'Leod case which had brought the two countries to the verge of war.

ASHBY-DE-LA-ZOUCH, urban district, Leicestershire, England; on the river Mease, 21 mi. N.W. of Leicester and 118 mi. from London by the London Midland and Scottish railway. Population (1938) 5,880. At the time of the Domesday survey Ashby (Essebi) formed part of the estates of Hugh de Grantmesnie, passing later by female descent to the family of la Zouch, whence it derived the adjunct to its name. In 1219 Roger la Zouch obtained a grant of a weekly market and a two days fair at the feast of St. Helen. The manor was granted in 1461 to Lord Hastings, who obtained royal licence to empark 3,000 acres and to build and fortify a castle. At this castle Mary queen of Scots was detained in 1569. During the Civil War Colonel Henry Hastings fortified and held it for the king, and it was visited by Charles in 1645. At the close of the war it was dismantled by order of parliament. It plays a great part in Sir Walter Scott's Zvanhoe. In the 18th century Ashby was one of the best markets for horses, and had prosperous factories for woollen and cotton stockings and for hats. The church of St. Helen, a fine Perpendicular building, contains an old finger-pillory. The Ivanhoe baths, erected in 1826, are frequented for their saline waters. The springs are at Moira, three miles west. To the south of the town are the remains of Ashby Castle. There are extensive coal-mines in the neighbouring districts; *e.g.,* at Moira, whence the Ashby-de-la-Zouch canal runs south to the Coventry canal. Area 9.7 sq.mi.

ASHDOD, an ancient village in Palestine, pop. c. 4,500, about 3m. inland from the Mediterranean and about equidistant (18m.) from Gaza and Jaffa. It is now on the railway. It stands close to a large hillock of red sand (137ft.), probably the Mt. Azotus on which Judas Maccabaeus fell (I. Macc. ix., 15ff.); this may well have been the acropolis of the ancient city. Behind it extending to the shore cliffs lie dunes of sand under which in all probability are buried the remains of the Ashdod of old. At the southern entrance to the village are the ruins of a mediaeval *khan,* and amongst the houses and mosques are to be found fragments of ancient columns and walls.

History. — Ashdod was the most important of the Philistine Confederation of five towns with a commanding position on the military road between Syria and Egypt and a centre of Dagon worship. In Joshua xv. it is assigned to Judah, but still remained the refuge of the *'Anakim* (Josh. xi. 22). It does not appear that Israel ever subdued the city in spite of II. Chr. xxvi. 6. In 711 B.c., Ashdod was besieged by Sargon's army commander (or Tartan) and captured (Is. xx. 1), the reason being that the city had revolted, set up a ruler of its own choosing in place of the Assyrian nominee, and had allied itself with Philistia, Judah, Edom, Moab and the Pharaoh of Egypt against Assyria. During Assurbanipal's reign (668–625 B.C.) it was beleaguered for 29 years by Psammetichus (Herod. ii. 157). Its inhabitants showed themselves hostile to the repair of the walls of Jerusalem at the time of the return (Neh. iv. 7), and Nehemiah's curse on the Jews who had married women of Ashdod and whose children could only speak a mixture of the two languages indicates the conditions prevailing in the city at that time (Neh. xiii. 23ff.). Ashdod was captured and cleared of idols by Judas Maccabaeus (c. 163 B.c.), and later (148) taken by Jonathan, who burned the temple of Dagon. After the Jewish wars it was restored by Gabinius and enfranchised by Pompey. From the 4th to the 6th centuries it was the seat of a bishopric. With the Muslim conquest it gradually sank into insignificance until by crusading times the once mighty city had been transformed into a mean and squalid village.

ASHE, THOMAS (1836–1889), English poet, studied at Cambridge and then became a schoolmaster. Of his complete works (ed. 1886), the most notable are *Dryope* (1861), Pictures (1865), and the classical drama, The Sorrows of *Hypsipyle* (1867). Ashe is diffuse in style and at times his poetic quality is scarcely discernible.

A-SHE-HO, a town of Manchuria, China, 12; m. N.E. of Kirin, and 30 m. S. of the Sungari. It was governed by a mandarin of the second class, but is now under the administration of the local government. Pop. about 75,000.

ASHER, a tribe of Israel, called after the son of Jacob and Zilpah, Leah's maid (Gen. xxx. 12 seq.). The district held by this tribe bordered upon Naphtali, and lay to the north of Issachar and Zebulun, and to the south of Dan. Asher is blamed for taking no part in the fight against Sisera (Judges v. 17), and although it shares with Zebulun and Naphtali in Gideon's defeat of the Midianites (Judges vi. 35, vii. 23), the incorporation of the name is probably due to a late redactor. It lay in the closest proximity to Phoenicians and Aramaeans, and contained a strong Canaanite element. In the Blessing of Moses it is bidden to defend itself— evidently against invasion (Deut. xxxiii. 25).

Even in the time of Seti I. and Rameses II. (latter half of 14th century B.c.) the district to the west of Galilee appears to have been known to the Egyptians as Aser(u), so that it is possible to infer either (a) that Asher was an Israelite tribe which, if it ever went down into Egypt, separated itself from its brethren in Egypt and migrated north; or (b) it was a district which, if never closely bound to Israel, was at least regarded as part of the national kingdom, and treated as Israelite by the genealogical device of making it a "son" of Jacob.

'ASHER BEN YEHIEL (known as *Rosh*), Jewish rabbi and codifier, was born in the Rhine district *c.* 1250, and died in Toledo 1327. Endangered by the persecutions inflicted on the German Jews in the 13th century, 'Asher fled to Spain, where he was made rabbi of Toledo. A disciple of Meir of Rothenburg, 'Asher's sole interest was in the Talmud. He was a man of austere piety, profound and narrow. He was a determined opponent of the study of philosophy, and thus was antipathetic to the Spanish spirit. Compiled between 1307 and 1314, 'Asher's *Compendium* is printed in most editions of the Talmud, and it differed from previous compendia in greater simplicity and in the deference shown to German authorities. 'Asher's son Jacob, who died at Toledo before 1340, was the author of the four *Turim,* a very profound and popular codification of rabbinical law. This work was the standard code until Joseph Qaro (Karo) directly based on it his widely accepted code of Jewish law, the *Shulhan 'Arukh.*

ASHEVILLE, a city of North Carolina, U.S.A., the county seat of Buncombe county; in the southern Appalachian highlands, about 210 mi. W. of Raleigh, at the junction of the French Broad and Swannanoa rivers; on a plateau 2,300 ft. above sea level, which extends from the Blue Ridge on the east to the Great Smoky mountains on the west. Asheville is served by the Southern railway system, and is on federal highways 19, 23, 25, 70 and 74. The climate is dry and equable, with an average annual snowfall of only 10·3 in. and there is magnificent mountain scenery in every direction. The city has a land area of 14·7 sq. miles. The resident population was 50,193 in 1930, of whom 14,255 were Negroes; and was 51,310 in 1940.

Asheville has been a health and all-the-year-round pleasure resort ever since the first wooden hotel was erected about 1830. Its hotels now have accommodation for 2,500 guests; there are many boardinghouses and apartments for visitors, and many inns in the surrounding mountains. Recreation facilities include an 18-hole municipal golf course, planned by Donald Ross, and four belonging to private clubs; a municipal recreation park with a 56-acre lake; municipal swimming pools and tennis courts; a city auditorium; a fine baseball park, and a baseball team that is owned and managed by the city; and a financially successful summer season of grand opera. Within a short drive are the Pisgah Cherokee, Nantahala and Unaka national forest preserves; Mt. Mitchell (6,684 ft.), the highest peak east of the Rockies; and

the Great Smoky Mountains national park, dedicated in 1940, with many acres of primeval wilderness. There are nearly 100 summer camps for boys and girls in the region, and several religious assemblies have their permanent headquarters in the vicinity. Sanatoria for the treatment of tuberculosis were established there early, and some of them have a national reputation.

Near the outskirts of the city lies Biltmore, the home of the late George W. Vanderbilt. The grounds were laid out by Frederick Law Olmsted, and the mansion (780 by 150 ft.) was designed after the Château de Blois. Originally the estate included 125,000 ac. but part of it was deeded to the federal government as the nucleus of the Pisgah national forest, and the village of Biltmore has been incorporated as a suburb of Asheville.

Since the war of 1914–18 Asheville has made marked industrial and civic progress. The leading industries include wood-working and furniture plants, textile and paper mills, tanneries, foundries, machine shops and railway repair shops. In 1937 the value of manufactured products amounted to $6,583,175. Power is supplied by hydroelectric plants located on the waterways. A city plan was adopted in 1925; a successful method of smoke abatement is in operation; and a water system, adequate for a population of 300,000, is in use. Asheville is the centre of 10,000 sq.mi. of recreational area, and its prosperity is reflected in the use of this area. During the summer season of 1940, 132,000 campers and an additional 800,000 tourists visited Pisgah national forest alone. The city is the eastern gateway to the Great Smoky Mountains national park, which is connected to Shenandoah national park in Virginia by the Blue Ridge parkway. This highway, 480 mi. in length and extending along the crest of the Blue Ridge mountains, runs within 6½ mi. of the city.

Asheville was founded by John Burton, who in 1794 laid out a town at first called Morristown or Buncombe Court House. It was incorporated as Asheville in 1797; chartered as a city in 1835; and adopted a commission form of government in 1905. It was named after Samuel Ashe (1725–1813), chief justice of North Carolina (1777–96), and John Ashe (1720–81), a North Carolina soldier.

ASHFIELD, ALBERT HENRY STANLEY, 1ST BARON (1874–), British business man, was born at Derby Nov. 8, 1874. He spent his early years in the United States, and was educated at American technical schools and colleges. He entered the service of the Detroit City Street Railways and had a successful business career, becoming general manager of the company and subsequently of the Public Service Corporation of New Jersey, In 1907 he returned to England, and became general manager of the Metropolitan District Railway and soon after chairman and managing director of the tramc combine which included the London Underground Electric Railway companies and the London General Omnibus Company.

In 1914 he was knighted. On the formation of Lloyd George's Government in 1916 Sir Albert Stanley was elected to Parliament as a Coalition Unionist for Ashton-under-Lyne, being included in the Cabinet as president of the board of trade. He resigned in May 1919, and, Jan 1920, was raised to the peerage. He was chairman of the Underground Group of Companies from 1919 to 1933, when he became chairman of the London Passenger Transport Board.

ASHFORD, urban district, Kent, England, 56 mi. S.E. of London by the Southern railway. Population (1938) 22.590. Area 8.8 sq.mi. It lies on a slight hill in the plains under the downs near the confluence of the upper branches of the River Stour, and is a considerable road and rail centre. Ashford (Esselesford, Asshatisforde, Essheford) was held at the time of Domesday by Hugh de Montfort. A Saturday market and an annual fair were granted to the lord of the manor in the 13th century, and further annual fairs were granted by Edward III and Edward IV. The fertility of the pasture land in Romney marsh to the south caused the cattle trade to increase from the latter half of the 18th century, and a stock market was established in 1784. The fine Perpendicular church (St. Mary's) has a lofty tower and many interesting monuments. At Bethersden, between Ashford and Tenterden, marble quarries were formerly worked extensively, supplying stone for the cathedrals of Canterbury and Rochester and for many local churches. Ashford has agricultural implement works, brick yards and breweries, and large locomotive and carriage works of the Southern railway.

The parishes of Kennington and Willesborough were added to the urban district in 1934 and a town planning scheme was adopted.

ASH HANDLING. The boilers required for generation of power in a large electric or industrial plant often burn thousands of tons of coal a day; and since perhaps 10 to 15% of the average coal is incombustible ash, hundreds of tons must be removed each day. The handling of such volumes of waste material deserves careful consideration, as improper methods or apparatus may double or treble the cost. Thus, good ash handling methods and facilities may represent ½ to 1% of the total cost of power generation, whereas systems improperly applied may raise the cost to 1 or 1½%.

In designing an ash-handling system certain precautions should be taken. In the first place all material coming in contact with the ashes should be of cast iron or other corrosive-resisting substances, since most ashes are alkaline and highly corrosive. It is furthermore important that all ashes should be thoroughly quenched before handling, otherwise there is danger from carbon monoxide poisoning and burns. In general two standardized methods of ash handling are now used in most large boiler houses: the hydraulic system and the purely mechanical system.

Hydraulic **Ash** Handling.— In this method ashes are stored in hoppers beneath the furnace for a period of eight to 24 hours, depending upon conditions. Beneath these hoppers a conduit capable of carrying water for removal of the ashes to a centrally located sump, is installed horizontally and the water is introduced from pressure mains. When the ash hoppers are filled, they are, discharged into the conduit at a rate well below the carrying capacity of the flowing water. The ashes may be taken from the ash sump by centrifugal pumps, generally made of manganese steel, in which case (1) the ashes and water may be discharged to low points within half a mile of the boiler house, where the ashes are deposited and the water leaches into the ground; (2) the ashes and water may be pumped into an overhead storage bin, the water being run off the top and returned to the sump: the ashes remaining as a residue, which is dumped into cars. Alternatively, the ashes may be taken directly from the sump by means of a grab bucket or other elevating machinery, and loaded into an overhead storage bin or directly into railroad cars or motor trucks.

The hydraulic system of ash removal is applicable where coal is burned as powder. In such cases the ashes are removed either as a molten slag (which is chilled and disintegrated by the stream of water into which it falls) or as a dry powder. In the latter case it is essential to carry this material in an enclosed system, otherwise the ash dust permeates the entire boiler house with results deleterious to moving machinery. Hydraulic systems are also applicable to the continuous discharge type of mechanical stokers such as chain grate stokers or underfeed stokers equipped with mechanical grinders. The water required for a hydraulic ash removal system will vary from 3 to 6lb. of water per ton of ash moved, if the water is allowed to discharge to waste from the sump. If re-circulated, about one-tenth of a pound of water per pound of ash is required for make-up to prevent concentration.

The advantages of the hydraulic ash removal systems can be stated as follows: (1) no labour is required other than the opening and closing of the valves controlling the flow of ash and the flow of water; (2) the ashes are handled in a totally enclosed system,—they are always under water and thus no dirt, dust or vapour can escape; (3) no moving machinery in the system comes in contact with the ashes; (4) the cost of running is low, varying from 1 to 3kw. hours per ton of ash moved; (5) the height of the power house building is generally 2 to 10ft. less since no cars run beneath the ash hoppers: the saving in building often more than pays the total cost of the ash handling system; (6) where the ashes can be pumped to low outlying property, there is no rehandling of the material.

Mechanical **Ash** Handling.— This system is also in common use in large boiler houses. The ashes in the hoppers beneath the furnace are dropped into cars, the control generally being maintained by horizontal piston-operated gates. In large plants where the final disposal of ashes is to be made by railroad cars, these are often run directly beneath the ash hoppers. This entails large building expense, as the entire boiler room must be raised sufficiently to allow the railroad cars to run beneath it; however, it obviates the necessity of rehandling the ashes. In smaller plants where this expense is not warranted, industrial cars of small height may be run beneath the ash hoppers. In this case a skip hoist is installed at the end of the building. the industrial cars are dumped into the skip hoist bucket and the ashes lifted into a storage bin, which latter discharges directly into railroad cars or wagons. This system is advantageous where underfeed stokers are used and the ashes are intermittently discharged. Such practice generally results in comparatively large clinker formations, which can best be handled in cars or by skip bucket.

There are other systems of ash handling generally applied in special cases and usually in the smaller boiler houses or in densely populated sections of cities, such as in hotels and in office buildings. Steam jets, bucket conveyors and the like are then employed. (See MECHANICAL HANDLING.) These systems, however, usually entail a high maintenance and operating expense and are generally used where it is impossible or impracticable to apply either of the two systems outlined above. (F. B. A.)

'ASHI (352–427), Jewish *'amora,* the first editor of the Talmud, was born at Babylon. He was head of the Sura academy, and there began the Babylonian Talmud, spending 30 years of his life at it. He left the work incomplete, and it mas finished by his disciple Rabina just before A.D. 500. *(See* TALMUD.)

ASHINGTON, urban district, Northumberland, England, 4 mi. E. of Morpeth, on the Newbiggin branch of the L.N.E. Ry. Pop. (1938) 29,870. Area, 9.5 sq.mi. The district, especially along the river Wansbeck, is not without beauty, but there are numerous collieries, one claiming to be the largest in the world, to which is due the rapid development of the town. The population is almost entirely composed of miners. though some ironworkers are found. At Bothal on the river (from which parish that of Ashington was formed) is the castle belonging to the Bertram family in the reign of Edward III. The church of St. Andrew there has early English to Perpendicular work, and in the neighbouring woods is a ruined chapel of St. Mary.

ASHKHABAD, formerly POLTORATSK. (1) A district in the Turkmenistan S.S.R. Area 195,000 sq.km. Pop. (1926) 237,570. (2) A town, the centre of the district, in 38° N. and 58′ 20° E. Pop. (1926) 54,107. It is situated in the fertile Akkal oasis, watered by hill streams from the Kopet Dagh, which lose themselves in the desert to the north. It is a Russian town dating from 1883 and is well laid out with broad, tree-lined streets, and has cotton, tanning, brick and mineral water factories and is on the Trans-Caspian railway. An electric power station is under construction. Near it are the sanatoria of Firuza (2.800 ft) and Khayrabad (5,800 ft.). Twenty miles E.S.E. is Anau (*q.v.*), a site inhabited possibly 3900 B.C. with remains of geometrical pottery.

See R. Pumpelly, *Explorations in Turkestan* (1905).

ASHLAND, a city of Boyd county, Ky.. U.S.A., on the Ohio river, 125 mi. S E. of Cincinnati and 4 mi. below the mouth of the Big Sandy river, where Ohio, Kentucky and West Virginia meet.

Ashland is on federal highways 23 and 60 and connected with federal highway 52 by a bridge across the river at this point It is served by the Chesapeake and Ohio railway and (through the station at Coal Grove, across the river) by the Norfolk and Western.

A government system of locks and dams gives a minimum 9-ft. stage of water on the Ohio the year round, and daily packets run from Pittsburgh to Cincinnati.

Many private boats hauling coal, gasoline, oil, etc., operate regularly on the Ohio river. The population according to 1940 federal census was 29,537.

The city lies on a plain along the river, rising to hills on the south. There are beautifully shaded residence streets, and in the heart of the city is a 50-acre park, of blue grass and virgin forest.

The assessed valuation of property in 1940 was $20,184,182. Ashland is an important shipping and manufacturing town. The surrounding country is rich in coal, iron, fireclay, sandstone, asphalt, limestone, shales, oil, gas and hardwood timber. The principal manufactured product of the city is sheet steel; other important industries are refining of gasoline and oil, coke and by-products, leather, brick, hollotv tile and lumber mills. Ashland was settled in 1854 and incorporated as a city in 1870.

ASHLAND, city of Ohio, U.S.A., the county seat of Ashland county; 60 mi. southwest of Cleveland, on the Erie railroad. The population increased from 4,087 in 1900 to 6,795 in 1910, and to 12,453 in 1940 by the federal census, 97% being native-born white. Ashland manufactures pump and haying tools, rubber in all forms, poultry foods, electros, auto supplies, toys, furnaces, raincoats, and concrete vaults.

The city of Ashland is surrounded by an excellent farming, dairying and fruit-raising region.

Ashland college, a coeducational institution established by the Brethern church in 1878, is there.

ASHLAND, a city of Oregon, U.S.A., on Bear creek, in the southern part of the state. It is on federal highways 66 and 99, and is served by the Southern Pacific railway. The population was 4,544 in 1930 and 4,744 in 1940 by the federal census. It lies in a valley 1,900 ft. above sea level. with peaks of the Siskiyou mountains on every side, and has a number of mineral springs, most of which are owned by the city. Fruit is grown in the region, and there are gold mines (both placer and quartz) near by. Ashland is the home of the Southern Oregon College of Education (established 1925). The city was founded about 1852 and was incorporated in 1874.

ASHLAND, a borough of Schuylkill county, Pa., U.S.A., in the anthracite region, about 15 mi. N W. of Pottsville. It is served by the Lehigh Valley and the Reading railways. The population in 1940 was 7,045. The borough is built on the slope of Locust mountain, about 885 ft. above sea level. Coal mining is the principal occupation, but there are foundries and machine and garment factories. The Ashland State hospital is there. Ashland was laid out in 1847 and incorporated in 1857.

ASHLAND, a town of Hanover Co., Virginia, U.S.A., on a high plateau 15 mi. N. of Richmond; on the Richmond, Fredericksburg and Potomac railroad, and connected with Richmond by a bus line. The population in 1940 was 1,718. Ashland is the seat of Randolph-Macon college, the oldest member of the Randolph-Macon system of colleges and academies, established under the auspices of the Methodist Episcopal Church South to provide secondary and collegiate instruction for both sexes in separate institutions, and owned by one chartered, self-perpetuating board of trustees. The college in Ashland is for men, and has an annual enrolment of about 300. It was chartered in 1830, and opened near the village of Boydton, in Mecklenberg county, in 1832. removing to Ashland in 1868. About 7 mi. and 15 mi. respectively from Ashland are the birthplaces of Henry Clay and of Patrick Henry. The town was settled in 1845 and incorporated in 1856. It is at the intersection of federal highway 1 and the Charlottesville highway.

ASHLAND, a city in the northern part of Wisconsin, U.S.A, on the Chequamegon bay, an arm of Lake Superior; at an altitude of 660 ft., about 60 mi. E by S. of Duluth and Superior; county seat of Ashland county It is on federal highway 2, and is served by the Soo, the Chicago and North Western, and the Northern Pacific railways and by lake steamers. The high points in the city command a view of the picturesque Apostle islands, outside the bay, which were formerly a rendezvous of the Ojibway Indians. The population of the city in 1920 was 11,334; 1930, 10,622; 1940, 11,101 by federal census.

The harbour has a controlling depth of 20 ft. and a navigation season from the middle of April to the early part of December. The bulk of the vessel traffic consisted of shipments of iron ore

from the near-by Gogebic range, and receipts of coal. Major industries of the city include wood pulp and paper products, ironwork, granite polishing and dairy products. In 1933 the output of the manufactures was valued at nearly $2,000,000. Northland college (Congregational; chartered 1907) is located there.

The first house built by white men in what is the state of Wisconsin was constructed at the head of Chequamegon bay about 1661, and its site is indicated by a historical marker. Ashland was settled about 1854, incorporated as a village in 1863 and chartered as a city in 1887.

ASHLAR, also written **ASHLER, ASHELERE,** in architecture, squared stone used for facing walls; also as an adjective, of a wall built of squared stones. Sometimes the word is used of any stone wall facing which is worked or tooled, whether squared or not, but such work is usually known as "rough" or "uncoursed" ashlar. An ashlar piece in English carpentry is a vertical timber inserted between the rafters and the wall plate. *(See* CARPENTRY.)

ASHLEY, SIR WILLIAM JAMES (1860–1927), English economist, was born in London on Feb. 25, 1860, and educated at St. Olave's grammar school and Balliol college, Oxford. He was successively professor of political economy and constitutional history in Toronto university (1888), professor of economic history at Harvard university (1892), professor of commerce and finance in Birmingham university (1901) and dean of the faculty of commerce there (1902). Prof. Ashley made most important contributions to the history of English industry and the economic development of England in general in his *Early History of the English Woollen Industry* (1887) and his *Introduction to* English *Economic History and Theory* in two parts (Part i "The Middle Ages," 1888; Part ii "The End of the Middle Ages," 1893). This *Introduction* is the standard work on the subject and has been translated into German, French and Japanese. He was foremost among the economists who supported Joseph Chamberlain in his campaign for protection for British industry, His *Tariff Problem* (1903) was republished in a new and enlarged edition in 1920. In addition to his professional and literary work Sir William Ashley sat on many important public committees and commissions of inquiry — on coal prices (1915), food prices (1917), cost of living (1918), agriculture (1919–23), tariffs (1923), industry and trade (1924). He also did important work on wages and prices, and was joint author of the *Report* of the Unionist social reform committee on industrial unrest (1914).

ASHLEY, a borough of Luzerne county, Pa., U.S.A., 3 mi. S. of Wilkes-Barre. It is served by the Central railroad of New Jersey. The population in 1940 was 6.371. The name of Ashley, adopted in 1871, was the tenth under which the city had been known since it was first settled in 1810. It is named for a family of coal operators. The main industries are mining, lace manufacture and railroad workshops,

ASHMOLE, ELIAS (1617–1692), English antiquarian, and founder of the Ashmolean museum at Oxford. was born at Lichfield, the son of a saddler. In 1638 he became a solicitor, in 1644 was appointed commissioner of excise, and subsequently obtained a commission as captain of horse. In 1649 he married as his second wife Lady Mainwaring. This marriage enabled him to devote his whole time to his favourite studies. His interest in astrology, aroused by Sir George Wharton and by William Lilly, seems, in the following years, to have subsided in favour of heraldry and antiquarian research. Ashmole was in high favour at the court of Charles II. He was made successively Windsor herald, commissioner, comptroller and accountant general of excise, commissioner for Surinam and comptroller of the White Office. He afterwards refused the office of Garter king-of-arms in favour of Sir William Dugdale, whose daughter he had married after the death of his second wife in 1668. In 1672 he published his exhaustive *Institutions, Laws and Ceremonies of the Order of the Garter,* the fruit of years of patient antiquarian research. Five years later he presented to the University of Oxford the Ashmolean museum, the first public museum of curiosities in the kingdom, the larger part of which he inherited from a friend, John Tradescant. He stipulated that a suitable building should be erected for its reception, and the collection was not finally installed until 1683. Subsequently he made the further gift to the university of his library.

ASHMUN, JEHUDI (1794–1828), U.S. missionary, was born in Champlain, N.Y., on April 21, 1794. He was educated at Middlebury college, Vt., and at the University of Vermont. He first became interested in the work in which he was to spend the rest of his life when he was made editor of the *Theological Repertory,* an Episcopalian journal. Among the articles he wrote for that paper were several on the work of the American Colonization society, which at that time was attempting to settle the slavery problem by setting up a colony in Liberia for freed Negroes. Because of his interest, the society asked Ashmun to act as its agent in helping to establish the settlement at Cape Mesurado (now Monrovia). He arrived in 1822, just in time to save the small group of Negroes from almost certain extinction. Many of the original settlers had died and most of the others were ill. None of the white agents had remained, there was little food left, and the African natives were planning to attack. Ashmun's efforts saved the colony. He enlisted the help of all those capable of fighting. although one report says there were only 27, and with this handful he repulsed the attack of an estimated 800 natives. Until 1828 Ashmun remained almost continuously in charge of the colony, and when ill health forced him to leave. there were 1,200 inhabitants. He died only a few days after his return to the United States. Although Ashmun was not the first white agent in Liberia, he was the first to give the new colony enough help to enable it to survive by its own efforts.

ASHRAF (plural of Arabic *sharaf,* "noble," "revered"), a term applied throughout the Muslim world to descendants of the Prophet Mohammed, but more particularly to a small Arab tribe scattered around Suakin, who call themselves Bani Hashim, "sons of Hashim," the prophet's uncle. In India the term is said to include Muslims of foreign descent from higher Hindu castes as opposed to the Ajlaf or commonalty and Arzal (almost= "outcasts"). In Persia, too, the term is vaguely used. In Arabia. Burton limits Sharif (a singular of Ashraf) to descendants of the prophet through Hassan, Ali's elder son.

ASHSHUR: *see* ASSUR.

ASHTABULA, a city of Ashtabula county, O., U.S.A., on Lake Erie, at the mouth of the Ashtabula river, 55 mi. N.E. of Cleveland.

It is on the Yellowstone trail, and is served by the New York Central, the Nickel Plate and the Pennsylvania railways. The population was 23,301 in 1930 and was 21,405 in 1940

The city is 680 ft. above sea level, and is built on the high bank of the river. Ashtabula harbour, 2 mi. from the city but within the corporate limits, has a controlling depth of 20 ft, and a navigation season lasting from April 20 to Dec. 5.

Large quantities of iron ore are received from the northwest and sent on by rail to Youngstown, Pittsburgh and other iron manufacturing centres.

Large quantities of coal come up by rail from the Ohio and Pennsylvania coal fields for transshipment to other ports on the Great Lakes.

The leading manufacturing industries are machine shops, toolworks, shipyards and tanneries.

The name *Ashtabula* is an Indian word, meaning "fish river." The first white settlement was made about 1801. The village was incorporated in 1831 and received a city charter in 1891. In 1916 the charter was amended to provide for a city manager and proportional representation.

In 1926, after ten years of experience with these features, the citizens voted to retain them.

ASHTAROTH or **ASHTORETH:** *see* ASTARTE.

ASHTON-IN-MAKERFIELD, urban district, Lancashire, England, 4 mi. S. of Wigan, on the London and North-eastern railway. Population (1901) 18,687; (1938) 19,440. It is situated on the Lancashire coal field and its development has been entirely due to the mining of coal and iron during the last century. Most of the coal is used in the neighbouring cotton mills although

iron goods are manufactured on the spot.

ASHTON-UNDER-LYNE, municipal and parliamentary borough, Lancashire, England, on the river Tame, a tributary of the Mersey, 63 mi. E. of Manchester. Pop. (1931) 51,573; (1938 est.) 48,540. It is served by the London Midland and Southern and London and North-eastern lines. The derivation from the Saxon aesc (ash) and tun (an enclosed place) accounts for the earliest orthography, Estun. The addition *subter lineam* is found in ancient deeds because the place is below the line or boundary of Cheshire, which once formed the frontier between Northumbria and Mercia. The manor was granted to Roger de Poictou by William I, but before the end of his reign came to the Greslets as part of the barony of Manchester. The lord of the manor still holds the ancient court-leet and court-baron half-yearly. A church or chapel is mentioned there in 1261–62, but the present church of St. Michael is almost entirely modern. One of the markets dates back to 1436. The ancient industry was woollen, but soon after the invention of the spinning frame the cotton trade was introduced, and as early as 1769 the weaving of cotton yarn by machinery soon became the staple industry, and has remained so. Hatmaking and iron founding and machinery works are also important, and there are large collieries in the neighbourhood.

Stamford park, presented by Lord Stamford, is shared by the towns of Ashton and Stalybridge. The town has a technical school, a school of art and free library. Ashton-under-Lyne had long enjoyed the name of borough, but it was not until 1847 that a charter of incorporation was granted. The parliamentary borough, which includes the urban district of Hurst, returns one member. Area of municipal borough, 2.1 sq.mi.

ASHUR: *see* ASSUR.

ASH WEDNESDAY, in the Western church, the first day of Lent (*q.v.*), so-called from the ceremonial use of ashes, as a symbol of penitence, in the service prescribed for the day. The custom is still retained in the Roman Catholic Church, the day being known as *dies cinerum* (day of ashes). The ashes, obtained by burning the remains of the palms blessed on the previous Palm Sunday, are placed in a vessel on the altar and consecrated before High Mass. The priest then invites those present to approach and, dipping his thumb in the ashes, marks them as they kneel with the sign of the cross on the forehead (or in the case of clerics on the place of tonsure), with the words: *Memento, homo, quia pulvis es, et in pulverem reverteris* (Remember, man, that thou art dust and unto dust thou shalt return). He himself receives the ashes from the priest of highest dignity present, or puts them on his own head in silence.

This ceremony is derived from the custom of public penance in the early Church. At what date the custom was extended to the whole congregation is not known. A passage in Aelfric's *Lives of the Saints* (996–997) implies that it was then in common use; it certainly was so in 1091 (synod of Beneventum).

Of the reformed Churches the Anglican Church alone marks the day by any special service. This is known as the Commination, its distinctive feature being a solemn "denouncing of God's anger and judgments against sinners." In the Prayer Book of the American Episcopal Church, the office of Commination is omitted, except the three concluding prayers. The ceremonial of the ashes was not proscribed in England at the Reformation; it was indeed enjoined by proclamation in 1538, and again in 1550, but it had fallen into complete disuse by the beginning of the 17th century.

See Wetzer and Welte, *Kirchenlexikon,* and Herzog-Hauck, *Realencyklopadie* (3rd ed.) *s.* "Aschermittwoch"; L. Duchesne, *Christian Worship,* trans. *by* M. L. McClure (London, 1904).

ASHWELL, LENA (1872–), English actress, was the daughter of Commander Pocock, R.N. In 1896 she married the actor Arthur Playfair, whom she divorced in 1908; later in the latter year she married Dr. (later Sir H.) Simson. In 1895 she played Elaine in Irving's production of *King Arthur* at the Lyceum and again acted with him in 1903 in *Dante.* She made her first striking success, however, on the London stage in Mrs. *Dane's Defence* with Sir Charles Wyndham in 1900, and a few years later her acting in *Leah Kleschna* confirmed her position as one of the leading actresses in London. In 1907 she started under her own management at the Kingsway theatre. During the war Miss Ashwell formed a company for organizing entertainments for soldiers at the front; after the war she inaugurated a scheme for bringing drama to the doors of the people through the popular performances, in public halls and other places, of the "Lena Ashwell Players."

ASIA, the name of one of the great continents of the earth's surface, embracing the north-east portion of the great land mass constituting the Old World, of which Europe forms the north-west and Africa the south-west region.

Much doubt attaches to the origin of the name. The early Greek geographers divided their known world into two portions only, Europe and Asia, in which last Libya (the Greek name for Africa) was included. Herodotus ranks Libya as one of the chief divisions of the world, separating it from Asia, but is unable to explain the origin of the name. It is probable that it has an Assyrian or Hebrew root and was used first of all with a specific or restricted local application, a more extended signification having eventually been given it, though it continued in use among the Greeks to denote the country around Ephesus.

GEOGRAPHY

Asia, the great land-mass of the Old World, stretches from well within the Arctic Circle to 13° N. of the Equator in south Arabia, 6° in Ceylon and within a degree and a half at the tip of the Malay peninsula.

On the west the continent reaches the shores of the Mediterranean — Cape Baba in 26° E. being the outpost. The boundary passes thence in one direction through the east Mediterranean and down the Red sea to the south point of Arabia, and in the other direction through the Black sea to the Caucasus, the lower Volga and the Ural mountains to the Arctic ocean. Asia's eastern outpost is East cape at the entrance to Bering strait 190° east. The boundary from this point to the Malay peninsula follows the coast of the North Pacific and the China sea. Asia viewed as a whole (on the globe) forms a great isosceles spherical triangle, having its north-eastern apex at East cape in Bering strait; its two equal sides, in length about a quadrant of the sphere, or 6,500m., extending on the west to the south point of Arabia, and on the east to the extremity of the Malay peninsula; and the base between these points occupying about 60° of the great circle, or 4,500m., and being deeply indented by the Arabian sea and the Bay of Bengal on either side of the Indian peninsula. A great circle, drawn through East cape and the south point of Arabia, passes nearly along the coast line of the Arctic ocean, over the Ural mountains, through the western part of the Caspian and, with the exception of Asia Minor and the north-west half of Arabia, indicates, with fair accuracy, the north-west boundary of Asia. In like manner a great circle through East cape and the extremity of the Malay peninsula passes nearly over the coasts of Manchuria, China and Cochin-China.

The series of highlands from Lake Baikal south-westwards to the Hindu Kush and the Elburz have on their northern and western sides the great Euro-Asiatic lowland that reaches from the Carpathians to the Yenisei and, in the form of the Angara plateau of moderate height, beyond it to the Lena river and the Verkhoyansk mountains where it abuts upon the Pacific coastal region, widely characterized by land forms arranged in steps, the edges of which are raised. South-east of the highlands from Baikal to Hindu Kush, and west of the Pacific coast region are the basins of inland drainage of the high plateaux of east central Asia, for the most part more than 3,000ft. above sea level. To its south again is the mountain land of Tibet with even valley floors near or above the 12,000ft. level in many places. The above four regions constitute what zoological geographers all agree to call the Asiatic portion of the Palaearctic region. Asia south of the line from the Armenian mountain knot and the Elburz mountains to the Himalaya we may divide into four chief regions. The first is south-west Asia with the Euphrates lowland between the

9. Corner of a town on the Yangtze Kiang river, in China, showing the Pagoda

Arabian block and the mountains; the next is the series of basins between mountain curves complicated by fragments of old blocks and forming the countries of Persia, Afghanistan and Baluchistan; the third is India with the old block of the Deccan separated from the Himalaya by the Indo-gangetic lowland; in the fourth, the Indo-Malayan region, the great mountain folds bend suddenly southward between the old block of the Deccan on the south-west and old blocks in south-east China, Cambodia and Borneo on the east. These folds are continued as determinants of the land-forms of the East Indian archipelago.

The Euro-Asiatic lowland rarely rises beyond 1,500ft. over sea-level and huge expanses are below the 600ft. contour. The drainage, especially in the Ob basin, is thus slow and imperfect and when snows melt in the south, but ice holds fast farther north, there are wont to be widespread floods. The Arctic ocean receives drainage of a larger Asiatic area (4,367,000sq.m.) than the Pacific (Asiatic drainage area 3,641,000sq.m.) or the Indian ocean (Asiatic drainage area 2,873,000sq.m.) and by far the greater part of the drainage to the Arctic is via the Ob, Yenisei and Lena and lesser rivers, which serve the Euro-Asiatic lowland and rise on its eastern and south-eastern mountain borders. The Ob basin is one of the world's most extensive areas of pure lowland. The Yenisei, fed from Lake Baikal and the Sayan mountains, is also the collector of the drainage of the western edge of the Angara plateau. The Lena drains the east of that plateau, and the arc of highland (Verkhoyansk, etc.) which bounds our region on the east. The Lena's length is estimated at 3,000m., the Yenisei is 2,700m. and the Ob 2,400m. South of the rather higher zone of Semipalatinsk (one area above the 3,000ft. contour) the lowland is continued as the world's most remarkable internal drainage area, containing Lake Balkash and the Aral and Caspian seas, each and all now without outlet. To this part of the lowland the name of Turkistan is often applied. The general soil of the northern part of the Euro-Asiatic lowland is alluvial or glacial mud with some more stony areas on the Angara plateau, but in several parts at the foot of the mountains and elsewhere, and very notably south of the Oxus in Afghan Turkistan, there are huge accumulations of loess (*q.v.*).

To the north of the northern steppe the soil remains so cold that pine forest is the natural vegetation (this is called the Taiga) with riverside meadows, so that men have migrated, probably under pressure, in this direction along the rivers, using them for fish, as food from flocks and herds diminished. On the tundra, north of the pine forest in Asia, man has found the reindeer and with it has penetrated westward to Lapland. The Ural mountains (maximum height 5,537ft., average probably well below 3,000ft., passes in some cases 1,400ft. above sea level) form an incomplete boundary towards Europe, but to the west of them the greater amount of summer rain permits a much larger extent of oak forest, which can be cleared for cultivation, than occurs on the Asiatic side. In the south part of the Urals are important mineral resources.

The High Plateaux. — The high land stretching west from the Yablonoi mountains and the Vitim plateau includes a number of ranges of old and much denuded mountain-arcs such as the Sayan, Tannu Ola, Khangai and Altai ranges, drained partly by feeders of the Ob and Yenisei to the north-west, and the Lena and Amur to the north-east, as well as by the Selenga which flows into Lake Baikal. The depressions between the Altai on the one hand, and the Khangai and Tannu Ola on the other, have lakes without outflow, and south-west of the Altai is Lake Balkash, now also without outflow but still fresh.

This country is on the whole fairly well watered and has a good deal of pasture, and some of its better valleys have been the homes of groups dependent largely upon the horse. It contrasts strikingly with the great plateau-waste of Gobi, at a lower altitude but still almost everywhere more than 3,000ft. over sea level. Here are great undulating stretches with areas of grass here and there, and remains of ancient drainage sometimes indicated by salt swamps. Oases of relative fertility occur, but the rigours of winter make them very different from the intensively developed fertile spots of the warmer Sahara.

To the west, the Gobi plateau descends westward to the northern steppe-lowland of Turkistan by the historic Dzungarian gate, bounded on the south by the Tien Shan range, a sharp-featured, ridged range of great length and height (Khan Tengri 23,600ft.), contrasting very markedly with the older mountains north-east of the Dzungarian gate. Between the Tien Shan and the Altyn Tagh, the northernmost of the Tibetan mountain arcs, lies the Tarim basin with the Yarkand Daria and Tarim rivers draining into a northerly depression, and with the lake-swamp of Lob Nor occupying an easterly depression. Feeders of the Yarkand Daria come down from the pass between the Tien Shan and the Pamir, the pass which has the famed market town of Kashgar at the entry to the Tarim basin. This basin has been studied in much detail by Stein, who finds many indications of desiccation of what seems to have been an area of much importance. The eastern end of the great Gobi plateau is marked by the Khingan mountains, one of the steps from the high Asiatic interior down to the coasts and deeps of the Pacific; and the north-east of the plateau is drained by the Amur which goes round the north end of the Khingan mountains. Huge amounts of loess near and beyond the eastern border of this region, in Kansu, and the Wei-ho and associated valleys, have played a great part in the development of Chinese civilization, and have furnished ways into China from the desert, to bar which was built the famous wall, so that in a sense the wall of China may be considered the boundary of our region.

The Pacific Coasts. — Here is a unique series of land forms, festoons of islands, which seem to be formed largely of folds, in part submerged, but much complicated by vulcanicity. The Kuril islands, the Japanese chain, the Ryūkyū islands and the Philippines are an outer set of arcs enclosing the seas of Okhotsk, Japan, east China and south China, each with a considerable area of deep water out of which the arc of islands arises. The continental coasts of these seas show a considerable zone of shallow water from Tongking to the Korea strait, where the continent has either alluvium or fragments of old blocks along its coasts, but north of Korea strait the coast becomes marked more and more by formations akin to mountain arcs, and the extent of shallow sea is less, but there is a good deal in the sea of Okhotsk.

In the north the mountain arcs form a complex transition zone between the Pacific coastlands and the Euro-Asiatic lowlands. In the latitude of Japan a very interesting step-structure is noticeable. East of Japan are the deepest hollows of the ocean, west of Japan the sea has considerable, but by no means comparable, depth, then the edge of Korea and the Sikhota Alin rise sharply. Beyond them again are the shallow waters of the Yellow sea, the lowland of Manchuria and of the middle and lower Amur. Beyond this again is the step up to the high plateaux, marked by the Khingan mountains. South of this interesting zone of step-forms, the physiography is complicated by interaction of fold mountains and old blocks in China. The great river basins here are those of the Hwang-ho (2,400m.) and the Yangtse-kiang (3,000m. or more), cut deeply into the highlands and ending in a large alluvial area which is the great agricultural region of north China, and offers the most striking contrast to the deeply dissected plateau country of the old block of south China. Whereas the alluvium of north China has become thronged with cultivators using the soil most intensively, south China is relatively less thickly peopled, and retains remnants of pre-Chinese peoples. The social and economic contrasts based on physiographical differences, and on the varying ranges of influences of the immigrant cultures from the loess of the north-west, form the fundamental difficulty of the problem of political organization in modern China.

Formosa is essentially a continental island on the Tropic of Cancer with an axial ridge that reaches 12,939ft. near the centre. It has ancient elements and immigrant Chinese, and now also some Japanese in its population. In the Philippines and beyond we have the continuation of the festoon of mountain curves that girdles the Pacific, but in this section it is complicated by its inter-relations with the fold mountains of Indo-Malaya.

Tibet.—The southern border of the high plateaux discussed above is formed by the Nan Shan and Altyn Tagh ranges, south of which run the closely packed mountain ranges of Tibet, the Kunlun in the north being separated from the Nan Shan by the one large depression, the Tsaidaman swamp, which, however, is itself more than 6,000ft. above sea level. Apart from this, only parts of the floors of the great corridor valleys of the Indus and Brahmaputra and the Salween, Mekong and Yangtse-kiang are below 12,000ft. in height, while immense stretches are over 18,000ft. above sea level and K_2 (Godwin-Austen) in the Karakoram reaches 28,250ft., while the giant Himalayas form the southern boundary with Everest (29,140ft.) and Kinchinjunga (28,146ft.). The country, known to its people as Bod, or Bodyul, must have remained uninhabitable for a long time ere the ice-sheets had retreated enough to give men an opportunity. They have managed to inhabit the land, partly thanks to the yak as a domestic animal; partly because patches of riverside alluvium could be cultivated in summer; partly because corridors, such as that of the upper Indus and Brahmaputra valleys, and some mountain passes have permitted caravan trade and have thus contributed to the importance of Lhasa. One should note the sanctity of both Lhasa and Mecca, both stations in desolate surroundings on caravan routes.

South-west Asia.—The Armenian mountain knot is separated from the Caucasus by the lowlands of Georgia on the west, and Azerbaijan on the east, with Tiflis, the capital of the former, in the pass between them. What is, in 1928, called Armenia is but a fragment of the historic Armenia which included the mountains dominating from both sides the high corridors from Kars and Erivan to Erzerum and Erzinjan. The highest peak, Ararat, reaches 16,025ft. and the mountain system is unique in the Old World in containing great sheets of water that are bitter lakes without outlet, Lake Van and Lake Urumiya being the chief. To the west the Pontus and Taurus mountains diverge on either side of the Anatolian plateau, partly basins of internal drainage, and partly the basin of the Halys (Kizil Irmak). The sinking of the Aegean area has brought about complex inter-relations of broken folds and edges, sunken valleys and islands at the west end in Asia Minor.

South of the Armenian mountain knot is the ancient block of Arabia, with the "fertile crescent" of the Mesopotamian lowland and Syria separating the two. Relief is complicated by the fact of the great rift system (see AFRICA) which has contributed to give west Arabia a high edge with much lava. Palestine is the country between the Mediterranean and the north part of the rift system, *i.e.*, the Jordan valley and the Dead sea. Mesopotamia and the shallow Persian gulf form one depression between the Arabian block and the Persian mountain arcs. Here land and water have had varied relations, and there seems every reason to think that in early historic times (c. 4000–2000 B.C.), at least, the gulf shores were much farther north than they now are, as Ur of the Chaldees was a port; changes are due largely to silting. The contrast between the southern steppe (*i.e.*, the borders of the Arabian desert, with its proximity to the "fertile crescent," a great cradle of civilization), and the northern steppe of the Euro-Asiatic lowland is of the utmost interest in connection with the interpretation of history. In the fertile crescent, as nowhere else in the ancient world, wandering, trading patriarchal herdsmen came into contact with settled cultivators living in agglomerations near the waterside, and organization taking both into account in various ways grew **up.**

Persia, **Baluchistan,** Afghanistan.—East-north-east of the Mesopotamian lowland and the Persian gulf, the Armenian mountain knot branches, forming the Elburz mountains (Mt. Demavend, 18,600ft.) of the south coast of the Caspian eastwards, and the Zagros mountains stretching south-eastwards as the boundary between Mesopotamia, in the physical sense, and the Persian highland, though politically Persia includes the Karun basin and reaches down to the Euphrates just below Basra. Farther south the mountains turn into a west-to-east direction and proceed towards the Indian border in lines behind the Baluchistan coast, whereafter they turn north as they front the Indus lowland. Analogously, from the Pamir's south-western region the great Hindu Kush extends south-westwards, with branch mountain lines fanning out in Afghanistan, the easternmost fronting the Indus lowland while the northernmost are continued with only a slight break right to the Elburz. The Afghan and Baluch highlands of the border of the Indus basin come into relation with one another, but the famous Bolan pass (Quetta-Kandahar) is near their junction. There is thus in Persia, Afghanistan and Baluchistan a collection of mountain arcs not compressed closely as in Tibet but set round about basins, in which old blocks play their part. The basins are mostly without outlet and include the Salt desert of north Persia, the Lut desert of east Persia, the basin of Seistan and the Helmand (Registan) in south Afghanistan, the basins of Jaz Murian Hamun and Hamun-i-Mashkel in south-east Persia and south Baluchistan. These and other similar smaller basins usually have salt lakes or swamps in their desert floors. The mountain sides in many parts are far more fertile.

India.—The essential facts here are that the Deccan is a part of the ancient Gondwanaland, projecting northward on the west into Rajputana and separated from the fold mountain ranges of the Indian borders by the Indo-gangetic lowland. The mountain frame is roughly parallel to the edges of the ancient block, as though the newer folds had become set in some way in relation to it, but at a distance from it. The western coast of the Deccan is dominated by the sharp edge of the western Ghats, the hills of west Mysore and smaller hills down to Cape Comorin, and Ceylon is a continental island separated from the Deccan peninsula by the shallow Palk strait. As in Africa, so in the Deccan, there is a general tilt of the plateau, in this case down to the east, and there are basin depressions on the plateau (basins of Mahanadi, Godavari and Kistna). The heavy monsoonal rainfall of the east part of the Indo-gangetic trough against the Himalayan flanks gives rise to the many feeders of the Ganges running through what was once swamp and forest, but has been much altered by man. Rajputana and the west of the Indo-gangetic trough get little rain, monsoonal or other, at present, and the trough is watered by the Indus draining the great longitudinal valley of Ladakh and Baltistan, high between Himalaya and Karakoram and then turning sharply through great gorges down to the plains. The rivers of the Punjab, feeding the Indus on its left bank, mostly have analogous, longitudinally placed, upper valleys, that of the Jhelum being the vale of Srinagar in Kashmir, famed for its beauty. The Sutlej probably reached the sea independently of the Indus in early historic times. The Brahmaputra, after a long course through a longitudinal valley north of the Himalayas, turns south through a great gorge only recently explored, into the Assam lowland, a narrow depression between the Himalaya and the Patkoi, Naga and Khasi ranges. The south-east peninsula of Asia shows the sudden southward bending of the great Tertiary fold mountain ranges after they have formed the giant Himalayas. They bend apparently in face of the resistance of older blocks, parts of which survive as south-east China, the Cambodian region and a part of Borneo, the two latter being separated by very shallow sea, which rarely, if ever, reaches a depth of 70 fathoms. As the folds bend south they diverge on either side of Cambodia and form the corridor basins of Irrawaddy, Salween and Mekong. Still farther south one may trace these lines in the Andamans, Nicobars and in Sumatra and Java, as well as through the Malay peninsula, while the Philippines represent the scheme of folding along the Pacific border. East of the Philippines and south of Sumatra and Java the ocean is very deep, but the sea between Java and Malay on the one hand and Borneo on the other is very shallow. Beyond the zone formed by the Philippines, Borneo, Java and Bali the two fold lines approach one another and we find islands and chains of islands in complex fragmented curves around the deep basins called the Banda and Celebes seas. (See also NEW GUINEA.) (H. J. F.)

GEOLOGY

The fundamental feature in the geological structure of Asia appears to he the presence in the north and in the south of large

areas which have remained relatively rigid since the beginning of the Cambrian period, while between and around them folding of mountain-building type has taken place at different dates.

The Siberian Massif.—This is limited on the north-west by the arc of the Byrranga hills in the Taimir peninsula, convex towards the south-east, in which folding of a date not yet determined occurs. On the north and north-east it is bounded by the Verkhoyansk range and its continuations across the Lena. Here the Trias is marine and the folding belongs, perhaps, to an early phase of the Alpine system. Towards the south-east the massif sends a spur across the Lena into the Aldan region, but before the Stanovoi range is reached folding begins to affect the Palaeozoic beds. Southwards the rigid area is bounded approximately by the east Sayan range and the ranges south-east of Lake Baikal, but overthrust masses appear before this limit is reached. Westwards the massif disappears beneath the later deposits of the Ob plain and in this direction its boundary cannot be determined.

The southern portion of the region thus defined consists chiefly of a platform of Cambrian and Ordovician beds, which are generally horizontal or nearly so. The deposits are mostly marine, but red sandstones and gypsum in the Ordovician suggest salt lakes. These Lower Palaeozoic beds are overlaid in places by plant-bearing beds of terrestrial origin, to which Suess has given the general name of the Angara series. The series, which is widely spread in northern Asia, probably ranges from the Permian to the Cretaceous, but in Siberia the deposits are mostly Jurassic.

While the southern portion of the area thus seems to have been land since the later part of the Palaeozoic era the sea at times overspread it from the north at least as far as 62° N., but not continuously. Marine deposits of various Jurassic and Cretaceous horizons have been found, but there is no indication of marine Trias such as occurs in the Verkhoyansk range.

Extensive flows of basic lava cover a wide area, with little indication of actual volcanoes. The age of the flows is uncertain. They may be Cretaceous or Tertiary.

The Sinian Massif.—The limits of the Sinian massif are very imperfectly known. Over large areas in northern China, especially in Shansi, Shensi and the Ordos region, the Cambrian beds are nearly horizontal, but the Tsin-ling-shan with its strongly folded beds defines its southern border. The horizontal Cambrian beds are marine and they are succeeded by marine deposits of Upper Carboniferous age, which in turn are followed by coal measures. The coal measures are overlaid by a thick sandstone upon which rest plant-bearing beds of the Angara series. Throughout the Mesozoic era the area seems to have been land.

The Indian Massif.—This includes Ceylon and the whole of the peninsula south of the Indo-gangetic plain. The oldest fossiliferous beds are called the Gondwana series and are characterized especially by the presence of *Glossopteris* and other fern-like forms. The series is entirely of terrestrial origin, except in the upper part, in which near the present coast marine beds are sometimes intercalated. In age it seems to extend from the Upper Carboniferous to the Upper Jurassic. Throughout the peninsula no marine deposits of earlier date than the Upper Jurassic are known and these are confined to the borders of the mass. The sea reached its greatest extension in the Upper Cretaceous period. Marine deposits of this age are found about 150m. up the valley of the Narbada. Elsewhere they are limited to the coastal regions. There is thus no indication that the peninsula was ever beneath the sea excepting near its borders and there is positive evidence that the greater part of it has been land since the Carboniferous period. There is also evidence that that land was connected with the southern part of Africa throughout the greater part of the Mesozoic era.

Most of the north-westem part of the peninsula is covered by a thick series of basaltic lava flows, known as the Deccan Trap, which occupies an area of about 250,000sq in. Very little evidence of any explosive action has been found and the eruptions took place from fissures. They belong either to the later part of the Cretaceous or the early part of the Tertiary period. The fact that this series several thousand feet in thickness, is abruptly cut off at the western coast is a clear proof that the land mass formerly extended much farther in that direction than it does at present.

The Arabian Massif.—This includes most of Syria and the whole of Arabia except Oman. In Palestine Cambrian beds with trilobites near the Dead sea, and limestones with marine Carboniferous fossils over a wide area indicate that during the Palaeozoic era the northern portion was at times beneath the sea. Jurassic beds occur in Lebanon and in the north of the Sinai peninsula, but throughout the greater part of the region the earliest marine deposits belong to the Upper Cretaceous. Like the other rigid areas the Arabian massif seems to have been land through most of the Mesozoic era. Whether it was connected with the Indian massif is still uncertain, but the existence of a strongly folded zone in Oman which runs out to sea upon its southern coast and in which marine Mesozoic beds are involved, suggests that the two were independent.

In Syria and north-western Arabia several high-lying plateaux are formed of basic lava-flows, but they are not comparable with the Deccan Trap of India in extent and seem to be of later date. Probably the eruptions took place largely from fissures, but towards the western edge of the Arabian plateau there are many small volcanic cones which are still nearly perfect, and there is a record of an eruption east of Medina in A.D. 1256.

The great belt of folding which runs from Asia Minor to the coast of China occupies the site of an ancient sea which lay between the northern and the southern massifs and which Suess named "Tethys." Marine deposits play a much larger part than upon the massifs and the geological succession is much more complete. Folding took place at various periods and the effects of the different periods have not yet been disentangled. From the Tien Shan and Kunlun northwards and also in south-eastem China the chief folding took place during the Palaeozoic era. The Caledonian system of Europe may perhaps be represented in the ranges near the Siberian massif, but this is still uncertain. The Hercynian system is dominant in the Tien Shan, the Kunlun and in China. But it must not be supposed that the present mountain ranges are the direct consequence of this ancient folding. The old ranges have been worn down and broken up and the actual topography is largely due to a remarkable system of trough-faulting of much later date.

Farther south the principal folding is of Tertiary age and belongs to the Alpine System. The southern limit is marked by the depression of Mesopotamia, the Persian gulf and the Indo-gangetic plain. The whole mass is being pushed forward over the rigid regions of the south and is crumpling in the process. Similarly the Burmese ranges, which are of about the same age, were produced by crushing against the eastern border of the Indian massif.

Although the Alpine system of earth movements is believed to have culminated in the Tertiary period, there is clear evidence of an earlier and independent phase. In the Oman zone already referred to, the principal movements took place during the earlier part of the Cretaceous period. Movements of the same age occur in central Persia, and it is not impossible that the folding of the Ural mountains may have taken place about this time. The latter is usually referred to the Hercynian system but on very imperfect evidence. All that is really proved concerning it is that a part of the Russian Permo-Carboniferous is involved and that the folding was completed before the deposition of the Upper Cretaceous. Whether there was any connection with the Urals or not it seems clear that in western Asia an earlier Cretaceous folding cuts across the line of the later Tertiary movements, and much work will be necessary before the effects of the two phases are unravelled.

Movement in the Himalayas and in other parts of the Alpine system has not yet entirely ceased, but the island arcs off the east coast of Asia seem to belong to a system which has not even reached its culmination. Wegener has attributed them, in a vague way. to a dragging effect as the continent drifted westward. Judging from the history of other mountain arcs they must have been produced by the thrusting of Asia against and over the

floor of the Pacific, which seems to function as a rigid area. The great deeps which lie outside the island arcs would then correspond with the depressions common on the convex side of mountain arcs, such as the Persian gulf and the deep hollow filled by the deposits of the Indus and Ganges.

It is common ground to all geologists that the folded bell of Asia has been produced by lateral compression, and this compression implies that the rigid regions of the north and the south have approached one another; but there are differences of opinion as to the cause of this approach. Suess would attribute it to contraction of the earth's interior, Wegener to movement of sial masses floating in the sima. The former hypothesis supplies a force of ample power, but whether the amount of contraction has been sufficient cannot be finally determined until we know more about what happens in the interior of the earth. The latter allows movement of the required extent: it has not yet provided a force capable of lifting the floor of the sea to the level of central Asia against the force of gravity. **(P. LA.)**

CLIMATE

The great area of Asia and its extension from 77° N. at Cape Chelyuskin almost to the Equator at Singapore, give this continent a very great range of climates. It may conveniently be divided into four sections, Siberia and western Turkistan; south-west Asia; India and Farther India; China and Japan; but even in these smaller areas the range is still very great.

Siberia and Western **Turkistan.**—This section extends from the Urals and the Caspian to the Pacific, and from the Arctic ocean to the great mountain ranges of central Asia—Tien Shan, Altai and Yablonoi mountains. The southern part is occupied by extensive steppes, becoming true desert in Turkistan. North of this is a belt of forest, succeeded by the tundras of the Arctic coast. The climate is characterized by a remarkably clear cold winter and a hot summer, which is the chief rainy season. In the west the moderating effect of the Atlantic can be traced at times as far as the Yenisei, the Urals not being high enough to act as a marked climatic divide, but in the east a temperate maritime climate is only found in the peninsula of Kamchatka.

In winter Siberia is occupied by a vast anticyclone, in which the highest known pressure on the globe (1,072 millibars reduced to sea level) was recorded at Irkutsk on Dec. 20, 1896. The intensity of the anticyclone is mainly due to the severity of the cold, forming a great pool of cold air, but the basin-like topography of the Baikal region is also an important factor by preventing the cold air from flowing away, hence the centre of the anticyclone is found south of Irkutsk instead of at the "cold pole" near Verkhoyansk. From this anticyclonic centre an axis of high pressure extends towards the Black sea in the west and Bering strait in the east; to the north of this axis the winds tend to be westerly, and to the south of the axis, easterly. Winds are in general light in the interior, but violent blizzards termed *poorgas* and *buran* occur, often causing loss of life. In the main river valleys the cold air flows down the valleys irrespective of direction. On the east coast strong, very cold, northerly winds prevail. The anticyclone lasts from September to April inclusive; in June, July and August it is replaced by a large shallow area of low pressure over eastern Siberia and China, and south-easterly winds prevail over eastern Siberia, bringing much cloud and a moderate rainfall, while over western Siberia the winds are mainly north-westerly.

Northern Siberia is among the coldest regions on the surface of the globe, the Lena delta having an average annual temperature of 1° F, while the isotherm of 32° reaches 49° N. (the latitude of Jersey) near Kharbarovka. The annual variation is extreme over the interior, the winters being frightfully cold and the summers comparatively hot. Verkhoyansk, with an average January temperature of −59° F and an extreme of −94° F, has the coldest winter of any permanently inhabited portion of the globe. Other average January temperatures are −46° F at Yakutsk, −6° F at Irkutsk, −9° F at Yeniseisk, −14° F at Obdorsk and −5° F at Omsk, and almost everywhere extremes of −50° F are recorded. These temperatures sound appalling but are bearable because of the extreme dryness of the air and the general absence of wind. The hard dry snow surface is excellent for sleighs, and winter is the favourite season for travel. The effect of the winter on vegetation is negligible, and in parts of Siberia plants thrive in the open which in England need the protection of a glasshouse; this is because the temperature rises so rapidly in spring that once the growing season begins there is no further danger of frost. The summer is short, but in the interior it is hot, the average July temperature exceeding 60° F over most of Siberia. The mean daily range is about 15° F in winter but 25° F in summer; the highest temperatures frequently exceed 100° F and 113° F has been recorded at Olekminsk. On the Arctic coast the summer consists of two months of cool, foggy, dismal weather. Turkistan has moderately cold winters, with an average temperature of about 30° F in January, and extremely hot summers, the July temperature at Tashkent being 80° F.

The annual rainfall is less than 10in. a year over the tundras and again in southern Siberia, falling below 4in. in parts of Turkistan. The rainiest regions are the forest belt of western Siberia and south-eastern Siberia, with aoin. or more, and southern Kamchatka with 40 inches. The precipitation in winter is everywhere small, and is entirely in the form of snow; spring is the wettest season in Turkistan but is dry elsewhere. Summer has fairly heavy rains over the whole of Siberia, while southern Kamchatka has its rainy season in autumn.

South-west Asia.—This area includes Asia Minor, Syria and Palestine, Arabia, Mesopotamia, Persia and Afghanistan. We may sub-divide it into three belts, a northern belt of plateaux and mountains, an intermediate belt of steppe and desert, and the south coast. The northern belt, including Asia Minor, Armenia and the highlands of Persia and Afghanistan, has a climate resembling that of the Spanish plateaux but drier and more severe. The winters are cold, with a moderate but irregular snowfall, and the summers are hot and dry. Thus Angora has a temperature of 31° F in January and 71° F in July and August, the extremes are 100° F and −13° F and the annual precipitation is only 9 inches. The prevailing winds are north-easterly. The western and southern coasts of Asia Minor and the northern part of the Syrian coast have much warmer winters and a greater rainfall, reaching 36in. at Beirūt. Farther east the rainfall in this belt is generally between ro and aoin. a year, and the temperatures at heights of 5,000 to 6,000ft. range from 32° F in January to 80° F in July.

The steppe and desert belt includes Syria, most of Arabia, southern Rlesopotamia and the greater part of Persia. Owing to its lower elevation, the temperatures are higher than in the plateaux, but cold weather is often experienced in winter; heavy snowfalls have occurred in Jerusalem and even the northern part of the Arabian desert has been seen carpeted with snow for many miles. At Baghdad a temperature of 19° F has been recorded. In summer the heat is intense, the average temperature exceeding go° F in July and August, while the extremes exceed 110° F almost every year and 123° F has been recorded at Baghdad. The prevailing winds are northerly throughout the year (except in Palestine, where they are westerly) and are sometimes of great strength, especially in summer. Strong dust-laden northerly winds are termed *Shamal* in Mesopotamia and Persia. The province of Seistan in eastern Persia is noted for the *Seistan* or "wind of 120 days" (June to September) which often exceeds 70m. per hour and has reached 120 miles. In southern Palestine and Arabia the *Sirocco* occurs as a dry dust-laden south-east wind. The rainfall averages about aoin. a year in the west but decreases eastwards, and in Arabia, Mesopotamia and eastern Persia there are large desert areas with less than 10in., often less than zin. a year. The rainfall is limited to the winter and spring months and is very variable from year to year. The southern Red sea, the south coast of Arabia and the Persian gulf have a moister climate with frequent south-west winds in summer and some rain at that season. The winters are very mild (Aden January average 76" F) and the summers are characterized by a moist heat, which is very unpleasant, especially in the Persian gulf.

India.— In India the year falls into three seasons, the cold weather, the hot weather and the rains. The "cold weather" extends from November to March, January being the coldest month with temperatures (reduced to sea-level) rising from 55° F in the north-west to nearly 80° F over Ceylon, the average for the whole country being 67·5° F. There is some rain in the north-west, brought by storms which have come from the Mediterranean across Persia; Ceylon also has an appreciable rainfall, brought by the prevailing north-east trades blowing across the Bay oi Bengal, but the greater part of India is dry. In March and April temperature rises rapidly, and April, May and June are very hot, the average temperature of the whole country being 87" F, and exceeding 95° F in central India in May and in the north-west in June. The dry weather lasts through May and the early part of June, but heavy rain begins to fall towards the end of June; July and August are generally the wettest months. but the rain continues through the greater part of September. The cloudy skies and rain lower the temperature over most of India, and the average for July, August and September is only 83" F. In the north-west the rainfall is very small, and temperature is much higher, averaging 99° F at Jacobabad in June and 97° F in July, while a maximum of 126° F has been recorded. Owing to the vertical decrease of temperature at the rate of 3" F per 1,000ft., stations at a height of several thousand feet have a pleasant climate during the hot weather on the plains, and are employed as summer resorts. The prevailing winds are north-easterly from October to February, irregular in March, and south-westerly from April until September. The north-east winds are naturally dry (except in Ceylon); during April and May the south-west winds are also dry, because they originate as northerly winds in Persia, curving round the Arabian sea. Towards the end of June there is a change in the general pressure distribution; the south-westerly winds over India originate in the south Indian ocean and arrive heavily charged with moisture. The north-east and south-west winds are termed *monsoons,* but owing to the economic importance of the summer rains, the term monsoon is often applied to the rainy season and not to the wind. The winds are generally light, except during the passage of cyclones.

The distribution of rainfall over India is very irregular. The heaviest falls occur where the rain-bearing winds strike directly against high ground, and the amount exceeds 100in. a year over the whole streich of Western Ghats from Cochin to beyond Bombay, in central Ceylon, the whole coast of Burma, and the high ground in Assam and Bhutan. The Khasi hills in Assam are reputed to be the rainiest region on the globe, Cherrapunji having an average of 424in. a year (the average for July alone being 102in.) while a five-year record at Manoyuram gave an average of 499 inches. It may be remarked that in the western Ghats 546in. fell in one monsoon. The smallest rainfall is found in the north-west, where Jacobabad has an average of only 4in. a year; while part of the Deccan, in the rain-shadow of the Western Ghats, receives less than 20 inches.

The Malay peninsula has a uniformly hot climate, the average temperature being about 80° F throughout the pear, with a daily range of about 12°. The rainfall is generally heavy (about 100in.) and is distributed evenly through the year. In Siam and Cambodia the year is divided into a hot rainy summer and a dry winter, which is hot in the south but is relatively cool in the north. Annam has a considerable rainfall in all months, the largest amounts falling in autumn. The alternation of a north-east monsoon in the winter months with a south-west monsoon in the summer months is found over all this region.

China and Japan.— Under this heading we include the whole of the old Chinese empire from the Pacific to eastern Turkistan, Korea and the whole of Japanese territory from southern Sakhalin to Formosa. This region includes a great variety of climates, from sub-tropical in the south, where the sugar-cane and banana flourish in a mean annual temperature of 72" F, to boreal in the northern interior, with a mean of 36" F and occasional readings below —30° F, but the whole area has a regular alternation of two monsoons, the cold dry northerly monsoon of winter and the warm moist southerly monsoon of summer, which is almost everywhere the rainy season. The western and north-western parts of China have an exceedingly continental climate, with a small rainfall and great extremes of temperature, while the sub-tropical islands of Japan are highly oceanic. The main Japanese islands are greatly influenced by two conflicting systems of ocean currents, the warm Kuro Siwo and a cold current which originates in the Sea of Okhotsk. Korea and the east coast of China are for their latitude the coldest parts of the northern hemisphere; this is due in the first place to the intense cold of winter brought about by the northerly winds and the absence of east-west mountain ranges; the summers, being very cloudy, are not hot enough to balance the winter cold. Over the interior of China the northerly winds of winter are not so strong, and are warmed by compression during their descent from the northern plateau, while the summers are less cloudy than the coast, hence the interior is generally warmer than the coast throughout the year, especially in the south. Japan has comparatively mild winters on both coasts. The winter climate of the high ground of Tibet is very severe. Spring and autumn are everywhere short, the cold of minter giving place quickly to the heat of summer and vice versa.

The mean annual rainfall varies from less than 10in. a year over the Tarim basin, western Tibet and the Gobi desert to nearly 300in. in north-east Formosa. Eastern Turkistan is one of the driest regions of the earth. Generally speaking the coast and islands have sufficient rain, the interior of China too little, except in the south-east. The greater part of the rain falls in the period of the south-east monsoon or summer, the only exceptions being coasts which directly face the north-east winds—the east coast of Japan and northern Formosa—but there is an appreciable winter rain in the Yangtse valley also. Snow falls in winter over almost the whole area. In the coastal regions, especially over south-east Japan, the summer monsoon is the season of typhoons, which do a great deal of damage, not only by the strength of the winds but also by the heavy rainfall and floods which accompany them. (C. E. P. B.)

FAUNA

Sclater's Palaearctic region includes Asia, north of the Himalayas and Hindu Kush, and Europe. South-west Asia has a good many animals like those of the Mediterranean lands or those of Africa. East of Sind we enter the Oriental region, which reaches out over shallow sea to Sumatra, Java, Bali and Borneo. The Sunda islands beyond Bali, as far as Timor, and Celebes and the Moluccas are to some extent intermediate between the oriental and the Australian regions. New Guinea may be reckoned with the latter, as the island has a good number of Monotremes and Marsupials, and a pig and a mouse are the only two mammals of higher orders, save the bats. The Moluccas have only two Marsupials (*Cuscus* and *Belideus*) and only the first of these two survives in Celebes or in Timor and the eastern Sunda islands. Celebes has an ape, *Cynopithecus niger,* and the so-called pig-deer, *Babirusa,* which occur in some of the Moluccas as well, but may have been taken thither by man. It also has the pig, a peculiar bull-antelope (*Anoa*), several squirrels, and, on an island off its north coast, the lemuroid *Tarsius.* Timor has the Cuscus and a shrew as indigenous forms.

Coming west to Java, Borneo and Sumatra, one finds no trace of Australian forms, but oriental types are numerous, though on the whole less so in Java than in the other two, which share with the mainland the Indian elephant, some deer, the tapir and *Galeopithecus* (a flying Insectivore peculiar to this region). The chevrotain (*Tragulus*), the rhinoceros and the Malayan bear occur on the mainland and in Sumatra. The orang-utan and *Tarsius* inhabit Sumatra and Borneo; the gibbon also occurs in Further India, south China and south Assam, and in Java, but its relative, the siamang, occurs in the Malay and Sumatra. Some monkeys in addition to those named above have reached as far as Java and Borneo. The old-fashioned scaly anteater (*Manis*) occurs in all three islands and on the mainland as far west as India, and the same distribution holds good for some lemurs and the *Tupaiidae* or squirrel-shrews.

These examples, not a complete list for Java, Sumatra or Borneo, are given to illustrate transitions between the Australian and the oriental fauna, and to show that in the islands of the oriental region one finds several types peculiar to them, some at least of which are old-fashioned forms. One might give at least as interesting a sketch of the reptiles or of the birds, showing that the babbling thrushes are almost absolutely restricted to the oriental region and include peculiar forms in Celebes. The Australian *Megapodius,* or mound-building bird, extends to the lesser Sunda islands, the Moluccas, Celebes and the Philippines, while a supposedly indigenous form is found on the Nicobar islands. The continental part of the oriental region is especially the home of the hunting leopard and the tiger, but they have spread north and west as well. The rhinoceros and elephant have been mentioned as highly characteristic forms. The analogies between the oriental and the intertropical African fauna (see AFRICA: *Fauna*) may be followed out with profit. Though south-west Asia is in many ways a link between the two, it lacks the anthropoids, lemurs, rhinoceros, elephant, scaly anteater and other forms which might be expected to show that linkage as they occur in both. South-west Asia is also linked with the Mediterranean lands. The lion, the hyena, antelopes and the coney (Hyrax) are African forms that reach into Asia; though Hyrax does not get in very far, the lion does not go east of the Indian desert, and the hyena avoids the forested parts of India, the antelopes do stretch far into India. Deer, absent from Africa save near the western Mediterranean, are important in Mediterranean lands, south-west Asia and the Palaearctic region.

South-west Asia shares with the Palaearctic region, in which it is often included, asses, antelopes, sheep and goats and the camel, the one-humped form being apparently indigenous in Arabia, while the two-humped or Bactrian camel belongs to the plains farther north. The oxen and buffaloes belong to oriental Palaearctic, south-west Asiatic and African regions, and the antelopes, their relatives, though especially African, also range far north on the open lands of central Asia. The open lands of central Asia, or lands which formerly had similar conditions, are the primary home of the horse, and probably of the two-humped camel, and it seems to be breeds of horse, ox, and sheep from the great steppes and their borders that are most widespread among domesticated types generally. The yak of Tibet, the musk deer of north-central Asia, the ermine, sable, glutton, reindeer, lemming and lynx of the north are characteristic forms of the Palaearctic region. The mysterious seal and *Comephoridae* (related to the mackerel) of Lake Baikal should be mentioned as indicating the great changes which have separated that lake from the ocean. Belt long ago suggested that during some phases of the glacial epoch the rivers of Siberia were probably dammed up, giving immense sheets of water between Baikal and the Arctic. Seals also inhabit the Aral and Caspian seas. Eastern Asia yields a few monkeys, penetrating from farther south, a remarkable large carnivore (*Aelurus*), the raccoon dog (*Nyctereutes*) and a few special moles, deer, etc. Though some subtropical forms have reached Japan, their numbers are not very large, and this has been held to suggest that continental land connections of Japan have been rather northwards than southwards. The Philippine islands have traces of connections southwards in the presence of *Tarsius, Galeopithecus* and *Tupaia,* along with a few more continental mammals, including three deer; it is, however, remarkable that the Philippines seem to lack the gibbon, the rhinoceros, the scaly anteater, etc., which belong to the East Indies. The birds of the Philippines include many forms peculiar to those islands and a number shared with the East Indian islands.

The tiger and leopard (panther) require special mention apart in view of their remarkably wide range; the former is found over a wide area from farther India to Siberia northward and to the Caspian westward; the leopard is also very widespread and occurs in Africa as well.

Among marine mammals the dugong (Halicore) is found only in the Indian ocean and a dolphin (Platanista) is peculiar to the Ganges, which it ascends for a long distance from the sea.

Among fishes should be named especially the sturgeon, migrating up rivers from the Black and Caspian seas, and the related *Scaphirhynchus* found in the rivers of Aral, of eastern Asia and of the United States of America. (H. J. F.)

FLORA

The vegetation met with over northern Asia much resembles that of the adjacent parts of Europe. The climates are similar and the rainfall, though moderate, is still sufficient to maintain the supply of water in the great rivers flowing into the Arctic sea and to support an abundant plant life. A similar affinity exists between the southern parts of Europe and the zone of Asia extending from the Mediterranean across Asia Minor, northern Persia and Afghanistan to the Himalayas and northern China. The plants and animals along it are found to have a marked similarity in character to those of south Europe, with which region the zone is virtually continuous.

The extremely dry and hot tracts forming an almost unbroken desert from Arabia through south Persia and Baluchistan to Sind show a considerable uniformity in the types of life closely approaching those of the neighbouring hot and dry regions of Africa. The region of heavy periodical summer rains and high temperature which comprises India, the Indo-Chinese peninsula, southern China and the western part of the Malay archipelago, is also marked by much similarity in its plants. The area between south Siberia and the margin of the temperate zone of the Himalaya and north China, including what are commonly called central Asia, Turkistan, Mongolia and western Manchuria, is an almost rainless, high-level region having winters of an extreme severity and summers of intense heat. Its life has a special character suited to the peculiar climatic conditions, more closely allied to the northern Siberian tract than to the other bordering regions. The south-eastern parts of the Malay archipelago have much in common with the Australian continent, though their affinities are chiefly Indian. North China and Japan have many forms of life in common and many special forms of China and eastern Asia extend to the Himalayan zone while others clearly indicate a connection with North America.

The foregoing brief review of the principal territorial divisions according to which the forms of life are distributed in Asia, indicates how close is the dependence of this distribution on climatic conditions, and this will be made more apparent by a somewhat fuller account of the main features of the flora.

Northern Asia.—The flora of the whole of northern Asia is in essentials the same as that of northern Europe, the difference being due rather to variations of species than of genera. The absence of the oak and of all the heaths east of the Urals may be noticed. Pine, larch and birch are the principal trees on the mountains; willow, alder and poplars on the lower ground. The northern limit of the pine in Siberia is about 70° N. The whole of the far north, along the Arctic ocean is covered with tundra consisting of a low growth of flowering plants—species of *Ranunculus,* dwarf *Salix,* etc., with numerous mosses and lichens.

South-west Asia.—The flora of the rainless region of south-western Asia is continuous with the desert flora of northern and eastern Africa. It includes the peninsula of Arabia, the shores of the Persian gulf, south Persia, Afghanistan and Baluchistan. In southern Arabia the aspect of the vegetation is very peculiar, and is commonly determined by the predominance of some four or five species, the rest being either local or sparingly scattered over the area. The absence of the ordinary bright green colours of the vegetation is another peculiarity of this flora, almost all the plants having glaucous or whitened stems. Foliage is reduced to a minimum, the moisture of the plant being stored up in massive stems against the long-continued drought. Aridity has favoured the production of spines as a defence from external attack, sharp thorns are frequent and asperities of various kinds predominate. Among the more mountainous regions of the south-western part of Arabia, the rainfall is sufficient to develop a more luxuriant vegetation and the valleys have a flora like that of similarly situated parts of southern Persia, and the less elevated parts of Afghanistan and Baluchistan. partaking of the characters of that of the hotter Mediterranean region. Here aromatic shrubs

are abundant. Trees are rare and prickly forms of *Statice* and *Astragalus* cover the dry hills

The flora of the northern part of Afghanistan approximates to that of the contiguous western Himalaya. *Quercus Ilex,* the evergreen oak of southern Europe, is found in forests as far east as the Sutlej, with other European forms.

In Asia Minor and northern Persia the mountains are clothed, where the rainfall is abundant, with forests of *Quercus, Fagus, Ulmus, Acer, Carpinus* and *Corylus,* and various Coniferae. Of these the only genus that is not found on the Himalaya is *Fagus.* Fruit trees of the plum tribe abound. The cultivated plants are those of southern Europe.

Central Asia.—The vegetation of the dry region of Central Asia is remarkable for the great relative number of Chenopodiaceae, *Salicornia* and other salt plants being common; Polygonaceae also are abundant, leafless forms being of frequent occurrence, which gives the vegetation a very remarkable aspect. Species of *Caragana* and other peculiar forms of Leguminosae also prevail, and these, with many of the other plants of the southern and drier regions of Siberia or of the colder regions of the desert tracts of Persia and Afghanistan, extend into Tibet where the extreme drought and the hot sun compensate for the greater elevation, and the summer climate resembles that of the plains farther north. Assemblages*of marine plants are frequently met with growing at elevations of 14,000 to 15,000ft. above the sea in the vicinity of the many salt lakes of central Tibet.

China and Japan.—The flora of north China and Japan is related to that of Siberia and to the neighbouring American continent as would he expected from the geographical position. On the other hand there is a close connection between the flora of the Central Provinces of China and the eastern United States of America; the oaks and a number of other genera reach their greatest development in these two countries and have very closely allied species in these parts of the Old and New Worlds respectively. In Hong-Rong and the tropical parts of China some three-fifths of the species are common to the Indian region, and nearly all the remainder are local Chinese forms. The number of species common to southern China, Japan and northern Asia is small. The cultivated plants of China are, with few exceptions, the same as those of India.

The flora of west and south-west China and the bordering parts of south-east Tibet and upper Burma has only recently become well known through extensive botanical exploration. Together with that of the eastern Himalaya with which it is very closely connected, this mountainous area now comprises the richest temperate flora in the world. A striking feature is the presence of a very large number of species belonging to several genera of alpine plants; viz., *Rhododendron, Primula, Gentiana* and *Pedicularis,* many species being restricted to a very small area. Dwarf species of *Rhododendron* cover large areas of the moorlands at an altitude of 15,000ft. while the high meadow-lands are luxuriant with a very varied vegetation. In Yunnan every altitudinal zone is represented from tropical jungle to permanent snow. Formosa has largely an endemic flora, but as a remarkable example of discontinuous distribution *Taiwania cryptomerioides* may be cited. This tree is only known from this island and south-west China.

Indo-Malayan Region.—Recent research has added greatly to the number of plants known to cccur in south-eastern Asia. The principal families arranged in order of specific numerical importance are: Orchidaceae, Leguminosae, Graminaceae, Rubiaceae, Euphorbiaceae, Acanthaceae, Compositae, Cyperaceae, Labiatae and Urticaceae. With the exception of the Compositae and Labiatae these are all more tropical than temperate and but for the temperate and alpine Himalayan species the Compositae would occupy a much lower place still. Within the region, however, there are very great variations, principally under the influence of humidity and elevation, so that the above order does not hold good for individual subregions. In short we have a somewhat heterogeneous assembly of tropical, temperate and alpine plants, of which, however, the tropical are so far dominant as to give their character to the flora viewed as a whole. The Indian flora contains a more general and complete illustration of almost all the chief natural families of all parts of the world than that of any other country.

India and Ceylon.—This subregion contains a by no means homologous vegetation, but presents almost as great a diversity as the region itself. Roughly it may be subdivided into the following zones: Himalayan, characterized by conifers, oaks, rhododendrons, and a number of Compositae. Peninsular, with a large assortment of deciduous trees, including many Leguminosae, that have adapted themselves to the drier conditions, particularly of the genera *Butea, Dalbergia, Pterocarpus, Bauhinia, Cassia, Acacia* and *Albizzia,* as also some genera of other families such as: *Cochlospermum, Shorea, Sterculia, Grewia, Terminalia, Gyrocarpus, Euphorbia* and *Givotia.* The teak tree, though not confined to or characteristic of this subdivision, occurs over widespread areas in the central portion, and in the south the sandal tree appears as an outlier of the genus the focus of which lies in the middle of the Malay islands. The desert zone in the north-west with a small semi-desert zone in the south-east, characterized by a number of xerophytic species belonging to various genera among which may be cited: *Capparis, Tamarix, Balanites, Zizyphus, Crotalaria, Prosopis, Acacia* and *Euphorbia.* The humid Malabar zone, which comprises a belt running along the west coast from north Kanara to the extreme south of Travancore and includes the highest hills (8,800ft.) south of the Himalayan chain. The most distinctive feature of this zone, which is akin to the Malayan subregion, is the presence of dense evergreen forests with orders and genera almost absent in the other zones; viz., Guttiferae, Dipterocarpaceae, Anacardiaceae, Meliaceae, Myrtaceae, Melastomaceae, Ampelidaceae, Piperaceae, Myristicaceae, Araceae and several palms and bamboos; among the shrubs there is a large development of *Strobilanthes* and other Acanthaceae and Rubiaceae and of *Impatiens* among the herbaceous plants. The peculiar small plants found clinging to rocks in the stream beds belonging to the family Podostemonaceae occur in considerable number. On the higher hills there are large tracts of open grass lands with an admixture of herbaceous or shrubby Leguminosae, *Rubus,* Rubiaceae, Compositae, Labiatae and terrestrial orchids and *Curcuma.* The eastern semi-evergreen zone, which runs parallel with and close to the east coast from Orissa to the south, characterized by species of *Acacia, Albizzia, Diospyros, Mimusops* and *Strychnos,* with a considerable proportion of thorny species. The estuarial or mangrove zone, which occurs intermittently along both coasts of the peninsula as well as along those of all the other subregions.

Ceylon exhibits great affinity with the peninsula and with it some to east Africa. The drier zone lies in the north and the higher ranges of the centre together with the coastal areas of the centre and south correspond more or less with the humid zone in character but present a number of endemic forms.

Burma.—The vegetation of Burma links up that of India with the Indo-Chinese and Malayan floras. In the north there is an extension of Himalayan flora, which continues into western China, with a wealth of *Rhododendron, Primula, Meconopsis, Quercus* and *Castanopsis* as welt as some conifers. Towards central Burma a drier tract is met with and there the plant life is comparable to that of peninsular India, with, however, a larger number of Dipterocarpaceae and a far greater number of species of bamboos. Within this drier zone lies a more or less arid area which does not differ greatly from the desert zone of India. In the southernmost part the vegetation becomes more tropical and more and more akin to the Malayan flora. Here the Anonaceae, Dipterocarpaceae, Guttiferae, Meliaceae, Anacardiaceae, Myrtaceae, Melastomaceae, Myristicaceae, Euphorbiaceae and Orchidaceae abound.

Indo-China.—The knowledge of the flora of this subregion is hardly sufficiently advanced to warrant the framing of a general account. It may be said that as might, indeed, be expected, it corresponds, fairly closely with that of Burma at corresponding latitudes.

Malay Peninsula.—The best represented families in order of their specific numerical strength are: Orchidaceae. Leguminosae, Euphorbiaceae, Rubiaceae, Anonaceae, Graminaceae, Melastomaceae, Cyperaceae and Moraceae; a sequence that, except for the first two, shows a considerable divergence from the Burmese flora as a whole. In this subregion *Nepenthes* appears in increasing

numbers as also the Dilleniaceae, Flacourtiaceae, Guttiferae, Dipterocarpaceae, Meliaceae, Anacardiaceae, Myrtaceae, Melastomaceae, Myristicaceae and especially Palmaceae. A feature strongly contrasting with the Indian, and Burmese floras is the comparative poverty in species of Impatiens.

Malay Archipelago. — The vegetation of the individual islands composing this subregion shows considerable specific divergence but in general it forms a fairly homologous whole. Essentially tropical, it connects the northern portions of the region with the flora of Australia. At the higher levels there is a definite resemblance to the eastern Himalayan zone. The Monocotyledons are specially well developed, particularly the Orchidaceae, Pandanaceae and Araceae. The numerical strength of the genera Eugenia, Psychotria, Ardisia, Piper and *Ficus* is striking.

The cultivated plants of the Indo-Malayan region include wheat, barley, rice and maize; various millets, *Sorghum, Pennisetum, Panicum, Eleusine;* many pulses, peas and beans, mustard and rape; ginger, turmeric and cardamoms; pepper and capsicum; several Cucurbitaceae and brinjal; tobacco, sesamum, poppy, Crofolaria and *Cannabis;* cotton, indigo and sugar; coffee and tea; oranges, lemons of many sorts, pomegranate, mango, custard-apple, figs, peaches, vines and bananas. Of late years the Para rubber has also been extensively introduced. The more common cultivated palms are *Cocos, Phoenix, Borassus* and *Areca,* which supply coconut, toddy, molasses and betel-nut. Indian agriculture combines the harvest of the tropical and temperate zones.

North of the tropic the winter cold is sufficient to admit of the cultivation of almost all the cereals and vegetables of Europe, wheat being sown in November and reaped early in April. In this same region the summer heat and rain provide a thoroughly tropical climate, in which rice and other tropical cereals are freely raised, being as a rule sown early in July and reaped in September or October. In southern India, and the other parts of Asia and the islands having a similar climate, the difference of the winter and summer half-years is not sufficient to admit of the proper cultivation of wheat or barley. The other cereals may be seen occasionally where artificial irrigation is practised, in all stages of progress at all seasons of the year, though the operations of agriculture are, as a general rule, limited to the rainy months, when alone is the requisite amount of water commonly forthcoming.

Many of the trees of the region produce timber of excellent quality. The teak tree, Tectona *grandis,* supplies the finest timber, for certain purposes the finest in the world. It is found in greatest perfection in the comparatively humid forests of the west coasts of Burma and the Indian peninsula, where it grows to a height of 150ft. or more, mixed with other trees and bamboos. The sal, *Shorea robusta,* produces a fine, heavy, durable timber, particularly useful for railway sleepers. It is found from the foot of the Himalayas to the Central Provinces and north Madras. The Himalayan cedar, *Cedrus* Deodara, is the chief timber of that range. Among many other genera yielding excellent timber may be mentioned *Dipterocarpus, Hopea, Canarium, Chloroxylon, Gluta,* Dalbergia, *Pterocarpus, Acrocarpus,* Acacia, *Terminalia, Diospyros* and Gntelina. The cinchona, from the bark of which quinine is derived, has been introduced and grown with much success in wlantations. (C.E.C.F.; C. V. B. M.)

ANTHROPOLOGY AND ETHNOLOGY

Asia presents to the anthropologist the widest range of different types of any of the continents. So vast is its area, so varied its climate, that ethnic types of all kinds are found within its borders. This being so, no complete anthropologic or ethnologic study of Asia as a whole is yet possible; the work of research and classification is still proceeding. Old divisions are found to be unsuited to new developments in our knowledge, and surveys, official and private, are annually penetrating old fields to emerge with new data.

FARTHER ASIA

Anthropology. — In south-eastern Asia there is a heterogeneous mixture of racial elements, and a population which contains very varied elements at all stages of culture and much confused by race mixture. The wooly-haired peoples are represented by the Negrito and Papuasian races, the wavy-haired by the Pre-Dravidians, Dravidians and Xesiots, and the straight-haired by the Pareoean or south Mongoloid race, while invading elements of Chinese, Tibetans, Arabs, Portuguese, French, Dutch and British have added to the general mixture, so that owing to the absence of accurate data and to the fusion of races and types accurate classification is almost impossible. A group of Mongoloid tribes stretches from Assam to Formosa and includes the Khasi, Mikir, Bodo and Garo of Assam, the Lisu of Yunnan and the Lolos of Szechuan, who are probably more allied to white-skinned races than to yellow-skinned Mongolians. This, the protomorphus, apparently represents an unspecialized strain surviving from the original type from which both the white European stocks and the yellow-skinned stocks of eastern Asia are derived. A definite Caucasian stock appears to be present in the aboriginal population of Indo-China and has doubtless survived as a submerged element in other hill tribes in south-east Asia.

Negritos.—The earliest inhabitants of south-east Asia were probably Negrito or Pre-Dravidian in race and representatives of both these races survive in a submerged condition and generally more or less mixed in blood by contact with their neighbours. They are naturally hunters and collectors of food, not cultivators, and where they possess cultivation it seems to be a recent acquisition from outside, and is communal in character. Generally they move about in family groups where game, fish, and wild yams are easiest to obtain. The social unit is the family, and the social structure of the simplest description. Excluding the Andamanese the Negrito is represented in this area principally by the Aeta of the Philippines and the Semang of East Sumatra and the Malay peninsula. They have no domestic animals and their dwellings are of the frailest description; they have separate quarters, probably, for the bachelors and spinsters of each community, the dead are buried or exposed in trees, and religious ideas are of the vaguest, but a land of the dead is believed in and spirits on their way thither have to pass over a perilous bridge guarded by a demon. This belief is characteristic of the Indonesian area generally and extends alike to the pure Negrito of the Andaman islands and to tribes in which Negrito affinities are unsuspected. So, too, the segregation of the unmarried is typical of the area in general and the practice extends, from central India to Formosa and southwards into the Pacific. The typical weapon of the Negrito is the bow and arrow, and both Aeta and Semang poison the arro s. Though naturally kind and gentle the Negrito once embittered evinces the most implacable hostility towards his enemies. He survives, however, as a distinct tribe only in the Andamans, the Malay peninsula (Semangs) and in the Philippine islands (Aetas), though traces of his blood are to be seen elsewhere in the archipelago and the mainland. Even in Assam the physique of some of the hill tribes and their traditions of the past suggest their survival to a comparatively recent date.

Pre-Dravidians. — The Pre-Dravidians of this area are represented primarily by the Sakai (*q.v.*) of the Malay Peninsula whose mode of life is not dissimilar to that of the Negrito, but others (Pre-Dravidians) of less pure stock survive in East Sumatra and in the Celebes, as the Toalas, and no doubt the race has contributed to other existing stocks in the East Indian archipelago, and perhaps on the mainland, where the strain is probably present in the hill tribes of Assam and Burma, and in Dutch Borneo it has been suspected in a slightly larger proportion in the Ula Ayar tribe. Their distinctive weapon for war and the chase is the blow-gun (*q.v.*).

Papuasian Negroes. — The Papuasian branch of the Oceanic Negroes was perhaps a later arrival in this area than the Negrito branch, but is less definitely represented among the present inhabitants. Even in the most south-easterly islands of Indonesia where it is best represented it has generally been modified by contact with other races, but traces of its presence are to be found in Assam again both in the physique and disposition of some of the Naga tribes, particularly in the inaccessible interior of the hills, where individuals, and sometimes whole communities show decided signs of Papuasian blood in their frizzly hair, prominent or aquiline noses, in their very excitable disposition,

RACIAL TYPES OF ASIA

1. A Mohammedan sheik of central China, descendant of an assimilated Arabian tribe
2. A Lambarda woman, typical of the Dravidian race, Mysore, southern India
3. A Lama in the Himalayas, near Darjeeling holding a prayer wheel and a rosary
4. A rug-seller of Russian Turkistan, in western Asia, displaying his merchandise
5. An elderly Japanese of Nikko, Japan, carrying his young granddaughter on his back
6. A merchant of the city of Hamadan, Persia, sitting in the sun, reading the Koran

mirthful, voluble and cruel, and in the artistic bent which shows itself in wood-carving, as well as in a number of minor items of material culture, which can be traced from Assam at any rate to Fiji. Their typical culture, however, should be sought in Papua and Melanesia (*q.v.*).

Cultural History. — The Oceanic Negroes and the Pre-Dravidians are present in south-east Asia merely as archaic survivals, and have probably contributed little to its culture. As far as can be inferred from existing data, the first known civilization of the area seems to be that of a race which may be described as Indonesian, which was probably composed of a Caucasic stock which occupied this part of Asia at a very early date, and was modified by Mongolian infiltration. This race, though now everywhere submerged by the flood of Pareoean invasion is probably responsible for certain general features still found throughout the less accessible parts of the area in societies showing every diversity of political structure. How far the general features here described are typical of the submerged Indonesian race is largely a matter of conjecture, but it is sometimes possible to indicate a definite change which has taken place or is taking place suggesting that the disappearing element belonged to an earlier culture than those which now predominate. Thus the Mon-Khmer language is now represented by isolated languages surviving in patches in Cambodia, in Yünnan, and in the Wa and Palaung lands in Burma, in the Khasia hills in Assam and in the Munda-speaking areas of Chota Nagpur in India, suggesting that the area once covered by languages of this stock stretched across the Irrawaddy river into the Ganges basin, though it has since been superseded by the tonal Tibeto-Burman tongues.

Social Structure. — So, too, the existing patrilineal society seems to have been preceded in most tribes by a matrilineal system such as survives in the Khasia and Garo hills in Assam, and the prevailing policy of government by secular chiefs is strongly associated with recent Pareoean invaders and probably superseded a highly democratic structure such as that which survives in parts of Assam, but which may itself have been merely the result of degeneration from a society dependent upon highly tabued priest-chiefs like those surviving in the Ronyak Naga tribe, where the recent tendency seems to have been to replace such chiefs by rather amorphous democratic societies, in which age-grades play a prominent part. Exogamy is everywhere the rule rather than the exception, and endogamy, where reported, appears generally to be rather a matter of linguistic or social convenience than of principle. Exogamous clans, though usually claiming to have originated in a patronymic ancestor, sometimes show what seem to be traces of a pre-existent totemism. Traces are frequent and tangible of a dual organization (*q.v.*) of society, which may perhaps be due to Chinese influence, particularly as the two moieties sometimes seem to represent the earth and sky. This dual system has perhaps been intensified by the need in founding a new village for two exogamous clans to combine in order to provide each other with marriageable women, and three-group systems may have sometimes been produced by the fusions of conquering and conquered dualities, in which the superior conquered class has been identified and fused with the inferior of the two classes of the conquerors. The "Khel" system, under which a particular class occupies a particular quarter of a village, and is more often than not in a state of avowed or latent hostility to the other clans in the other quarters of the village, appears to be another result of the same process, and gives way, under the secular chiefly rule, to a mere division into wards governed by different chiefs, the clan bond disappearing, as also the bachelors' hall, which is prominent and necessary as a local centre of clan activity under the democratic system, and appears as an important appendage of the chief's house under the sacrosanct priest-chief organization. This bachelors' hall has been shown to be by origin the communal house from which private dwellings split up (vide Peal "On the Morong," etc., *Jrnl. Anthropl.* Inst., xxii., p. 256 and pl. xviii.), and while it appears to retain its original form in the "Long House" in Borneo (q v), and to remain as an appanage of the sacrosanct *Ang's* house in the Konyak Naga country, it has become a village club house in the democratic Naga communities, and survives in the Kachari and Hinduized plains tribes in the village *Namghar* or prayer-house, while in the societies which have secular chiefs like the Semas or Thados it has almost entirely disappeared, though in some such tribes it still survives with some of its former functions as in the case of the Lushei *zawlbak*. It has already been noted that it is a widespread institution and is shared even by the Negritos of the Andamans.

Material Culture. — Another item probably to be associated with the Indonesian culture is the tanged and shouldered celt, a very distinctive form of polished stone adze which has been found in Indo-China, Malaya, the Irrawaddy basin, Assam, and in Chota Nagpur in India. It survives in the form of shouldered iron hoes still used by some hill tribes as by the Khasi and by some Nagas. The use of the throwing spear seems also typical of a pre-Pareoean people, and simple bamboo and sago-palm javelins, innocent of iron, but sometimes "feathered" like an arrow, usually with pandanus leaf, are still used in the remote interior of the Naga hills. A straight two-handed iron sword is, or was till recently, used as a sword of state by the Rings of Siam; it is depicted as carried by foot-soldiers on the bas-reliefs of Angkor Wat in Cambodia and it is still handed down as an heirloom in Naga, Khasi, and Kachari families in Assam. It is possibly an introduction from India, where the straight two-handed sword was in vogue at the time of Alexander's invasion. The carved lion, more symbolic than naturalistic, which is so popular from Assam eastwards in regions in which the lion is not known at all, may also be of Indian origin, though if so he has perhaps been hybridized by the Chinese dragon. It seems to belong to the Shan and Burman elements rather than to the Indonesian, and the true Naga tribes have no word for "lion," though the Kukis above have one. So, too, the use of the cross-bow seems to be of Mongolian origin, and it is popular with the hill tribes of Indo-China and with many of those of Burma; only some of the Assam tribes use it, and it does not reach the Western Nagas, who have only the bullet-bow, or the Khasis who, like the Thado Kukis, use a simple bow, a weapon which may perhaps be associated with Negrito survivals.

Tattooing is practised generally throughout Farther Asia, but the extent of its use varies greatly. With the Burmese it holds the rank of a fine art, and it is generally practised by all the Tai peoples and by some others. But whereas the Burmese and Shans seem to tattoo the male only, some of the Assam-Burman hill tribes tattoo the female only, and others, as in Borneo, both sexes, the operation being performed in the Naga hills as by the Kayans of Borneo by women. In Borneo as in Assam tattoo patterns usually have reference to rank, or to head-hunting exploits, or to recognition in the next world.

A feature of many hill tribes in this area, which calls for notice, is the use of a large wooden xylophone or "drum" (it has no membrane) made from a hollow top and sometimes described as a canoe-drum. Its distribution is not universal, but it is frequent in the Naga hills, and the Rhasi uses what is perhaps a degenerate form of it; it is found among the Wa of Burma, occurs in the Malay Peninsula and in Borneo, and appears to be connected with the Fijian *lali,* and with the Melanesian upright type. Some Amazon tribes in South America use a similar instrument. Its Indonesian origin is perhaps indicated by the buffalo into which its head is so often carved, even where the gayal or mithun has superseded the buffalo as the principal domestic animal, by the occasional use of a crocodile pattern (reported and depicted by Peal, *loc. cit.*) by tribes who have never seen a crocodile, and by the tradition of the "wooden drum" that belonged to the pre-Burmese king of Arakan. It may possibly be associated with the use of the war-canoe, as its construction appears to be attended in the Naga hills by tabus identical with tabus common in the construction of canoes in Melanesia, and canoes have been used, occasionally at any rate, for drumming in Manipur, in Papua and in Oceania.

Cultivation.—The buffalo appears to be associated with the Mon-Khmer culture. It appears in Borneo, used by the Murut tribe, and in the Philippines, in both rases associated with irri-

gated terraces. In Assam it is generally used in the plains, but has been superseded in the Naga hills, where it was probably once universal, by the gayal or mithun, a much more tractable animal when kept in a semi-feral state. The mithun appears very definitely to have been introduced by the Kuki-Kachin migration from the Himalayas down the Chindwin valley to the Bay of Bengal. Irrigated rice cultivation, however, though now general in the plains is far from universal in the hills. Millet undoubtedly preceded it as a staple crop as in Formosa and in Assam, and probably also in the hill tracts of Burma and Indo-China, and terracing combined with the regeneration of land by the preservation of pollarded alders appears in the Naga hills to have preceded irrigated terraces for rice, which has spread at the expense of millet faster than irrigation, and is often grown as a dry crop.

Megaliths. — The megalithic culture of this area has also been associated with irrigated terracing, but it appears to exist also where irrigation is not practised, and in some cases where rice is not grown. This megalithic culture usually takes the form of menhirs and dolmens. It is to be intimately connected with a cult of the dead, and also with a phallic cult. The general theory underlying it seems to be that the soul of the dead takes up its abode in the erect or the recumbent stone according as the sex is male or female, and that the fertilization of the crop and propagation of all life is dependent on the action of the soul which is assisted by a process of sympathetic magic dependent on the symbolic form of these megalithic erections. The survival of this idea is probably to be seen in the forms taken by the temples of the more civilized religions of the area, *e.g.*, in Assam, and which reach their culmination in the marvellous structures of ancient Cambodia and Java, such as the famous Angkor Wat. The survival of this cult in Chota Sagpur in India, in Assam, in parts of Indo-China and in Madagascar, though in the intervening areas it seems to have died out, suggests that it originated at a very early date in the history of the area, and perhaps preceded the expansion of the Proto-Malay race.

Head-Hunting. — Intimately associated with this phallo-megalithic cult is the practice of head-hunting (*q.v.*), the purpose of which is to secure souls to add to the general village stock of soul matter which is required for the successful propagation of animal and cereal life. Read-hunting is still practised by the wilder tribes of Assam, Burma, the Indonesian archipelago and Formosa. Connected with it is a conception of a material soul permeating the body, and also apt to infect any object directly associated with the body. It is, therefore, dangerous for believers in this principle to touch objects which may already be impregnated with soul matter stronger than theirs, or to allow anything likely to be imbued with their own soul to pass into the possession of a stranger who might through it be able to influence them adversely. Beliefs of this kind are strong in many of the less sophisticated tribes such as the Toradja of the Celebes, and the Konyak Nagas of Assam, while the Karen of Burma hold the theory of the soul as a fertilizer in a peculiarly concrete form. Other tribes hold a rather vague and ill-defined belief in what amounts perhaps to *mana* (*q.v.*), or a dynamic soul-principle giving the possessor power to control unconsciously the forces of nature so as to enhance his own happiness, prosperity and good luck, but this belief is probably much the same as the other in origin, this principle, called aren by the Ao Nagas, probably consisting in emanations of soul matter, which attracts other soul matter to itself.

Head-hunting also serves as an instrument of the vendetta, a feeling for which is strong throughout the area, though in places it finds expression rather in the taking of slaves than of heads, and in the Moi word *comam* means both "slave-hunter" and "avenger." Slavery, however, is generally a mild institution and the domestic slave is commonly treated as a member of the family.

Houses. — Among the less cultured communities houses are built of bamboo, and the difference of two types, one on the ground, the other on piles, is noticeable as the two forms used by different tribes exist together in Assam, as they do in Java, where the true Javanese builds on the ground, while the Malayan Sundanese builds on piles. Bridges are made of cane ropes, slung sometimes across tremendous gorges with astonishing skill, and in places ficus trees are cultivated by the riverside and their aerial roots trained so as to span the stream with living timbers. In the hills villages are concentrated and palisaded and defended with caltrops of bamboo spikes.

Religion. — The most prevalent religion is probably Buddhism, but Mohammedanism is strong in the islands and the coast, and Hinduism, at one time ascendant, has left many survivals. Probably, however, these more civilized faiths nowhere go very deep, while the whole population is steeped in ideas based on a sort of polytheistic animism, and the worship of the dead. Some of these ideas have already been alluded to, but many other beliefs, apparently more or less inconsistent, exist alongside them, and are held simultaneously. The idea of a beneficent, but remote, Creator (or Creatrix) is frequent, and so is that of a village of the dead in reaching which the soul has to travel on a perilous path guarded by a malignant demon. This is usually located underground, though sometimes the souls of the blest ascend to the sky. In the case of the islands, the land of the dead is sometimes overseas. Ideas of metempsychosis (*q.v.*) also occur independently of Buddhism, and the soul is reborn as an insect. The dead are treated with great variety, burning, burial, and platform exposure all being practised, the latter being accompanied sometimes by separate disposal of the head. Boat-shaped coffins are used, sometimes where boats are unknown, and a sort of urn burial is still common in parts of the Naga hills, the pot being covered with a flat stone. Corpses of persons dying by "bad deaths," as in childbirth, suicide, by wild animals, etc., are usually treated differently from those of persons who die normally. Burning, when practised, does not seem necessarily to have any reference to Hindu influence, as it is practised by the Maru branch of the Singphos, and in preliminary funerals by the Khasis. Some tribes, *e.g.*, the Kacharis and Manipuris, attach special importance to the frontal bone and dispose of it in running water.

Origins **and** History. — The origin of the Mon-Khmer culture is still obscure. It was much influenced by India, and the connection probably dates to the pre-Aryan epochs of the history of that country. It is now generally recognized that the (so called) Dravidian inhabitants of India, probably a branch of the Mediterranean race, had acquired a high state of culture before the more barbaric Aryans entered from the north, and it is likely that southern India was the source of the Indonesian and Mon-Khmer cultures. Certain it is that in southern India early iron age graves have been discovered disclosing items of culture which must be associated with the existing Naga tribes of Assam. So, too, on now deserted uplands in southern India round cenotaphs appear associated with terracing strongly suggesting the culture of Angami Nagas. The Karens of the Golden Chersonese seem to have a tradition of origin from the Indian coasts of the Bay of Bengal. Colonies of South Indian elements have from time to time migrated further east, and the Klings of Malaya and the Talaings of Pegu, who were absorbed by, but gave their name to, the Mons of that kingdom, are merely offshots of the Telinga peoples, Dravidians from southern India. Therefore, we may perhaps look to southern India for the first source of culture in Indonesia. The connection continued through Brahminical and Buddhist times and survived the Mongolization of south-east Asia. In the south-east, however, the Mongolian connection must have begun at a very early date. Chinese influence was felt in Annam in the third millennium B.C., and from that era, perhaps, we must date the beginnings of the movement by which the Champa race in Cambodia, with its oceanic affinities, was gradually submerged; though the Shans themselves, the most prominent of the invading Mongolians, were still located in China in the second millennium B.C., and the Khmers, who effectively invaded Siam in the sixth century, mere still powerful in the third century B.C., though very strongly influenced by China.

Of the spread of the Oceanic Mongols or Proto-Malays nothing is yet known; their range includes the oceanic domain of Farther Asia from Formosa to the Nicobars and Madagascar. Nearly everywhere also they are found forming hybrid groups

by fusion with Negritos, Papuans, pre-Dravidians or Indonesians, and the latter in particular has almost everywhere been modified by the proto-Malay stock.

The expansion of Hinduism in Farther Asia had started by the fourth century A.D., by which time it had reached Burma; it had arrived in the Malay peninsula in the fifth and in Java in the seventh century, and the seventh century saw the introduction of its off-shoot Buddhism into Siam, while the same century witnessed the advance of the Shan race towards the sea. The expansion of the true Malays from their home in Sumatra began in the 12th century, and the spread of Islam in the oceanic area took place in the thirteenth.

Mean hile on the mainland the expansion of the Burmese race had begun (in the 11th century), and their long struggle with the Shans for supremacy in what is now Burma. The Chinese invasion of the 13th century, however, led to the rise of the Shans which lasted from that to the 16th century, the 14th being that of the greatest expansion of the Siamese empire. The Burmese, however, were in the ascendant by the 17th century, and the 18th was that of their greatest expansion.

The latest of all the Mongolian movements has been that of the Kuki-Kachin racas, which is still in progress. The various branches of the Kuki race that inhabit Assam have come from the south up the range dividing Assam from Burma, but there has been an uninterrupted flow of migration from the sources of the Chindwin river down that valley to the sea, of which the northward flow to Assam is the backwash (v. Fryer, Khyeng *People* of *Sandoway,* J.A.S.B., *1878).* It appears probable that the Kayans of Borneo formed part of the advance-guard of this stream. The Thado Kukis, at the head of the Assam backwash, were still moving northwards in 1917, and the Kachins, the rear-guard of the whole movement, are still moving southwards into Burma.

With the advent of the Portuguese in the 16th century the European influence began to be felt, but it is only the Portuguese and the Spaniards who have affected the population racially, and that hardly outside the Philippines, where their half breeds may be reckoned by the hundred thousand. The climate prevents northern Europeans from taking root, and the Oceanic hlongols, modified by the Indonesian and by minor isolated strains, possess the islands, as the southern Mongolians do the mainland except where the previous populations survive in the fastnesses of their inclement hills.

BIBLIOGRAPHY.—A. C. Haddon, *Wanderings of Peoples,* 1911; J. P. Mills, *The Lhota Nagas,* (introduction *by J.* H. Hutton), 1921; Roland B. Dixon, *The Racial History of Man,* 1923. (J. H. H.)

CENTRAL ASIA

The racial history of this vast central area is obscure. Up to the present, despite much archaeological work, excavators have concentrated rather on the history of the last 2,000 years than on the prehistoric period. In support of the theory that man originated in this region, Dr. Davidson Black concludes that the differentiation of the earliest human stock from the common ancestors of the anthropoid apes and man may be correlated with the progressive changes which occurred in Central Asia during recent geological periods — recent, that is, in relation to the history of life on the earth, though in actual years the period is one of remote antiquity. In the Eocene period, during which the London Clay and the Paris beds were laid down, Central Asia was low-lying and covered with semi-tropical rain-forest. During the succeeding geological periods the country became slowly higher and drier until in the Pleistocene it became a region of open plains, with only small forests. These changes either started or at any rate encouraged the separation of the prehuman stocks into two divisions, one of which, the archaic, became the ancestor of the modern anthropoid apes, and the other, the progressive, the ancestor of man. So far there is no direct evidence of this attractive theory.

No human fossils have as yet been found in Central Asia. Pères Licent and Teilhard have, however, explored certain palaeolithic rites in the great Ordos bend of the Hwang Ho (Yellow River). Here at various depths under the loess they found hearths and the implements of palaeolithic man, belonging to the middle and upper divisions of that period associated with the bones of prehistoric animals. They conclude from the evidence so far discovered that man was living in this region during and possibly before the formation of the loess, which seems to correspond to the latest stages of the glacial epoch of Europe and North America. Dr. N. C. Nelson has collected implements and pottery from the succeeding periods. They are believed to belong to the Mesolithic and Neolithic epochs. So far, however, the complete racial history cannot be written. The Chinese claim to have originated in the Tarim basin, at a period when that region was less inhospitable than now. There they developed an oasis culture and subsequently migrated down the Wei Ho into the plain of China. (*See* CHINA, section *Ethnology.*) There are reasons for believing that at one time the people who may have been the ancestors of the Nordic race of Western Europe were widely distributed, certainly over northern and possibly over Central Asia. It seems difficult to account for the present distribution of peoples of the Far East without believing that there was at one time a continuous distribution of Yellow Man over the Far East, due probably to a migration which separated the various divisions of the Proto-Nordic stock. Then, owing to ethnic movements of the peoples now known as Turks and Mongols, Yellow Man was separated into two great divisions and Central Asia became the home of tribes who, although they have mixed considerably with Yellow Man show affinities rather with the West than with the East.

The inhabitants of Central Asia, excluding the Chinese who form no inconsiderable proportion of the population, may be divided into two main groups, Turks and Mongols, who, while differing in some respects, on the whole present many close resemblances; indeed some of the characters which are considered by Czaplicka to form some of the most marked characters of the Turks are in some places at least equally characteristic of the Mongols.

Social Organization. — The differences which occur in social organization depend to a certain degree on religion. The Turks have only a lay system, organized on the patriarchal nomad household, and an increasingly large number of households, ten, a hundred, and a thousand. The Mongol system is more complicated by the dual lay and ecclesiastical systems side by side and a hereditary nobility, organized more or less on a war footing, with serfs, who may be presented by their chieftain to the ecclesiastical authority. The lamas, who must obtain permission of their chieftain to take the vows, are exempted from all civil and military duties.

Apart from the two great religions of Islam and Buddhism, a good deal of Shamanism survives among the Mongols (*q.v*). The most noticeable feature of their religious life is, however, the extraordinary hold that Buddhism has had on these people, transforming the whole of their life and possibly being responsible for the great change that has come over Central Asia since the days of the great Khan. Buddhism has transformed one of the most warlike people in the world into a small and until recently an entirely dependent nation.

In Central Asia a great ebb and flow of peoples has taken place. During the Ming dynasty most of Inner Mongolia was cultivated by the Chinese in a region which to-day is most typical nomad territory. At present the Chinese agriculturalists are advancing again and driving the nomads back. This ebb and flow has been a practically continuous process, but the sudden incursions of the nomads into cultivated land have produced at various times some of the most cataclysmic movements of history.

NORTH AND EAST ASIA

This region includes China proper, Manchuria — now included within the borders of China — and Japan, and is most conveniently

divided on a geographical basis into two parts, the mainland and the island portion. The remoteness of the latter from other parts of the world and its geographical isolation divided it from the main currents of human migration in the past, and have given it a very different ethnological history, as far as we know at present, from its western neighbour.

Although it seems probable that man existed in China before or at the beginning of the deposition of the loess *(see* preceding section, CENTRAL ASIA), at present there is no certain evidence of palaeolithic man in Central China. Fossil remains found in Honan by Matsumoto, and at Chou Kou Tien, south-west of Peking. by Black, have been claimed to possess a high antiquity *(see* CHINA: Ethnology). It is more than possible however that the remains, if not of early man, at least of his handiwork, may lie buried under the loess. In the island region no claim has been made about discoveries of palaeolithic man.

In the neolithic period the two regions also present a great contrast. The earliest Chinese culture so far discovered is clearly of chalcolithic date, that is to say that elaborate pottery has been found but no actual trace of metal, whereas in Japan, and to a lesser extent in the coastal region opposite, in Korea and Manchuria there are remains of a different culture which can only be described as Neolithic, without any reference to actual date.

The actual human remains found with this earliest culture in China are similar, with certain differences, to the present inhabitants of modern China, whereas in Japan the earliest remains resemble those of the modern Ainu (*q.v.*), although in the middle stone age of the Japanese archaeologists there first appear in Japan racial types akin to the modern Japanese.

The racial history of the whole region then appears to have been a series of migrations eastwards. As far back as we can trace it at present the Chinese racial type, but not Chinese culture, has existed in China, whereas in the Japanese islands me find first a primitive type, whose kinsmen still survive in the northern island, and secondly a type akin to the mainlanders, who probably crossed over the sea at a comparatively recent date. It also seems probable that at various times there have been racial movements in a north-easterly direction from the plain of China to the regions north of the Amur river.

Principal Groups. — The Chinese republic claims to include within its borders five nations, three of these, Tibetans, Mongols and Chinese Muslims are discussed elsewhere *(see* TIBET; CHINA; MONGOLIA). The other two are Chinese and Manchus. Although they are considered of little worth by the Chinese, the aboriginal tribes are of great interest ethnologically. Within the limits of China proper the Chinese form the greater part of the population. The Manchus who conquered the empire in the seventeenth century were scattered throughout the land as garrisons and have to a very large extent become absorbed in the population, and even in Manchuria itself the Manchus to-day are proportionately few.

The aboriginal tribes are found in the more inaccessible mountain districts of the south and west. In the north and west there are considerable numbers of Muslims, who form, as they have always formed, a turbulent element separated from the Chinese by the almost impassable boundary of the pig, an animal so essential to Chinese culture, and so utterly repugnant to the Muslim.

Korea forms a transition region between the racial groups of the Chinese and the Manchus on the one hand and the Japanese on the other. The term Korean is rather a national than an ethnological term, and intermarriages both between the royal families and the commoners of China and Korea have taken place since an early period. The Japanese form to-day an important element along the railway line in Manchuria and more widely in Korea. The third group of people in the Japanese empire are the Ainu, to-day confined to Hokkaido, but with kinsfolk in the southern islands of Ryūkyū.

Social Organization. — The social organization of the Far East is in general based on a closely organized family, in which the father is the responsible head of the household which includes his unmarried children and married sons and daughters-in-law, the house mother being supreme wirhin the house. The father was, and still is in many places, responsible not only for the well-being of his household but also for their moral rectitude. In China the magistrate was the "father and mother" of his district, and eventually the "Son of Heaven," the Emperor, was responsible to heaven for China as though he were the head of a household. While this system in China developed into a democracy, in Japan, owing no doubt to their constant warfare with the Ainu, there grew up three classes, nobles, retainers and people, each maintaining the family system within its own limits. In China polygamy was generally practised, but the Japanese claim to have abolished the legal secondary wife at an early stage. Both countries practise the system of adoption, whereby the family can be continued in the absence of legal issue. In this way some of the old families, as for instance that of Confucius, go back to an immense antiquity.

Apart from the more highly organized religions Buddhism — (the Zen sect is most popular in Japan), Taoism, Shintoism, Confucianism, and to-day, Christianity, the religion of the greatest interest ethnographically is ancestor-worship, which is practised both in China and Japan, although in thelatter country Christianity appears gradually to be driving out ancestor-worship. In China, however, it still forms one of the most important bulwarks of the social structure, and preserves both the structure of the family and that regard for home which is so important a character of the Chinese. Ancestor worship is a definitely localized religion; all Chinese, therefore, are bound by strong ties to their ancestral home, and if possible endeavour to arrange when they die for their bodies to be carried back to the fields already sorely diminished by the graves of the previous ancestors.

The general characteristics of the culture of this area are the presence of a method of life and religion bound up with agriculture on ancestral acres. Among the Ainu this culture is only in an embryonic state, the men being still largely hunters and fishermen, and agriculture being in the hands of the women.

In China agriculture has for a long time been highly developed, and Japan has inherited much of the culture of China which she has subsequently developed along her own lines, in some cases retaining features which have died out in China. The shape of the "chop-stick" in Japan is similar to the shape of those used in China in the Han Dynasty, and quite unlike the modern Chinese. On the other hand the Chinese have retained the primitive form of the abacus, while the Japanese have developed it. But in spite of differences the two cultures are in essentials similar, and all depend ultimately on an ancient and efficient method of agriculture to support a population which, owing to social customs, always threatens to exceed the means of subsistence.

ARCHAEOLOGY AND ANTIQUITIES

In eastern Iran, *i.e.,* Sogdiana, Bactria (including Gandhrira, or the north-west corner of the Punjab), in Chorasmia, Merv and Seistan, lie the keys to the problems of early Iranian culture and its influence on the culture of India and China. Again, southern Siberia contains antiquities, which will, undoubtedly, reveal some day the still obscure relations between its nomad "Scythian" inhabitants, the Pontus and China.

Excepting the work done in Gandhrira, the only scientific excavations on a larger scale have been made in eastern or Chinese Turkistan, a bowl-shaped depression hemmed in on all sides except the east by enormous mountain-chains with difficult passes, and in the east approached through the Gobi desert. The only safe trade routes between China and the Hellenistic Orient passed through the rich oases along the northern and the southern margin of the bowl. By them the silks of China reached the West and the products of the Hellenistic Orient, of Iran, of India, and the Buddhist religion, the most powerful propagator of Indian religious thought and of modified Hellenistic art, reached China and the Far East.

These routes were of the highest importance to China, and whenever a vigorous dynasty ruled that country, they were regularly protected by military garrisons,

There had been in the Neolithic age a movement of peoples, which can be studied in the pottery they left behind them. The Swedish geologist, Prof. Gunnar Andersson, discovered in Kansu, Honan and S. Manchuria specimens of a rather advanced ceramical art, showing peculiar ornaments in red and white, or in black and white of a type unknown in China but similar to articles found in Moldavia, Scythia in Europe, as well as in Transcaspia, Babylonia and Susa in Persia. These finds show, that before the 3rd century B.C. a stream of higher culture elements reached China from the north-west, along this great culture corridor. (See CHINA: Archaeology, and EUROPE: *Archaeology*, Eastern Europe.)

Along the northern declivity of the Tien Shan mountains, where even to-day the presence of grass and water permits the nomad Kirghiz and Kalmuks to rear their flocks, are found burial mounds or kurghans, capped, in many instances, with rude stone sculptures of men holding a drinking vessel in their hands. These sculptures resemble similar statues from the Crimea, from the districts now comprised under the name of southern Russia. The German expeditions saw many of them on their way to eastern Turkistan through southern Siberia, but could not acquire any, the Kirghiz and Kalmuk considering them as objects of veneration. It was not possible to observe whether they wore the curious strings attaching their boots of soft leather to the belt, an arrangement occurring in several such sculptures from Scythia in Europe in the Berlin museum, and again in the wall-paintings from Turfan, mainly where red-haired, blue-eyed men of European aspect are depicted. They are not worn by the Persians there depicted, and this trifling ethnographical indicium supports the belief that at one time the ruling class, the Tokharians, in the eastern oasis of eastern Turkistan, were a Scythian race.

These races were probably, in the main, of Iranian stock, but may have included other tribes of the Indo-European family, following their mode of life and imbued with their culture, such as the Tokharians, whose language was found in Central Asia. We need not suppose any Turkish tribes were among the ancient Scythians of Europe before the arrival of the Huns, who, having absorbed, probably, many of the Siberian Scyths on their road through Central Asia to Europe, had accepted, to a certain degree, many of the arts and the cultures of these conquered tribes; the old Iranian allies of the Huns, the Alans, may have been a people of Sassanian culture. These conjectures deserve mention. The misleading name of "Southern Russia" should be abandoned in favour of "Scythia in Europe," the "Pontine country," or some such term. It is to be regretted that this term is constantly employed, because it tends to create an impression that the Russians had something to do with the culture there developed by the Scythian races.

These burial mounds, which can be followed far into Mongolia, mark the route followed by migrating Scythian tribes through Central Asia. That this movement came from the West, is made apparent by the presence of the Indo-European language, Tokharian, and its cognate dialect, both in books, which might have been brought from elsewhere, and in beautifully-executed temple inscriptions in Central Asiatic Brāhmī characters, deriving from India, and in numerous *sgraffitti* in a cursive variant of this.

If they had come from the East, they would probably have used the Chinese language; both the language itself and the characters in which it is written point to the West.

Besides, the Chinese annals inform us of the invasion of China by a race of mounted archers, the Yue-chi, who were driven back by the Hiung-nu (the ancestors of the Huns and of the Turks) after a great battle (*c.* A.D. 170). They returned to the West, dislodging the Iranian Sacae from their seats in the Ili valley, and using, in all likelihood, the road by which they had reached China. The Sacae destroyed the kingdom of the Greeks in Bactria and there founded the empire of the Indo-Scythians, in which, later on, they mere succeeded by the Kushan, who are identified with the Yue-chi. Some of the latter people appear to have made themselves masters of the eastern oases of Chinese Turkistan, or, perhaps better, Serindia, for at that date that country was peopled by Iranians and Indians, and not by Turks.

But, long before these events took place and were recorded in the Chinese annals and in the works of Western historians, this route along the northern declivities of the Tien Shan evidently served as a line of communication between the Greek cities on the Pontus, the northern provinces of the Achaemenian empire and China, on the art of which latter country the peculiar style of representing animals had made a fecund and lasting impression.

No scientific excavations have been made in these Kurghans by trained archaeologists, but the objects found there by casual explorers show irrefutably, that the bronze, iron and other objects contained in them are in direct relation to similar finds in Scythia in Europe, which often show the traces of classical art. Thus quite recently, the Russian explorer, Kozlov, found important Scythian antiquities near Urga in Mongolia, amongst other things the remains of a carpet, showing plainly Greek influence. So, we may safely assume, that Greek motives were carried along this route in early times.

It appears, however, that this corridor between China and the West was only open to intertribal intercourse, ordinary traders hardly trusting themselves amongst these (probably turbulent) nomads. This, probably, is the reason why the silk-route trade roads, the via regia through Serindia, came to be frequented, in spite of the difficulty of the mountain passes intersecting them.

In later times, again, in the time of the Sassanian kings, and stimulated by the Buddhist religious propaganda evidently fostered by Iranian rulers of Bactria belonging to that faith, but imbued with Sassanian culture, a new wave of Hellenistic art elements, modified by Indian and Iranian influences, started from the vicinity of Kabul, Bamiyan being evidently an important centre, towards Serindia and China, following the routes of the silk trade and leaving manifest traces in the cave-temples of Serindia. This was first pointed out by the French explorers, MM. Foucher, Hackin and Godard, and Mme. Godard.

While the Eastern Iranian sites contain relics possibly dating back to early Iranian history, the ruined cities and monasteries of Serindia (and of Gandhāra, which is culturally indissolubly connected with Serindia) offer only remains of the period between the last century before Christ, in the West, and the 10th to 11th centuries of our era.

However, the archaeological work done in these comparatively late sites, by Russian, English, German, French and Japanese explorers, has proved that the ultimate basis of Buddhist art in China, as in all other eastern Buddhist lands, is the Hellenistic antique as developed in Gandhāra.

The Tokharians.—Until the Uighur Turks began their conquest, from the north-east, in the 8th century, the many oasis-States were occupied by Iranians (Sacae and Sogdians) in the west, south-west and north, and by Indians in the south-west and south. From the oasis of Kucha in the north, to that of Turfan in the north-east, the ruling race appears to have been a tribe speaking a language of the European (centum) group. They are called Tokharians in the Middle Turkish texts dug out from temple ruins near Turfan, and the energetic heads, on the mural paintings from these temples, of blue-eyed, red-haired men with European features, differing entirely in everything but dress from pictures of Iranian or eastern Asiatic donors, may well be portraits of men of this remarkable race.

Mss. Discoveries.—The numerous mss. finds are written on wood, leather, palm-leaf, birch-bark and paper, in Tokharian (till then unknown), in the lost languages of the Sacae and Sogdians, in Sanskrit, Pehlevi and at least two Iranian dialects, Middle Turkish in two dialects, Tangutan, Tibetan, Syriac, a few lines of Greek, in Chinese and Mongol, with yet undeciphered mss. fragments of the lost language of the Ephthalites (*q.v.*), or White Huns, and small fragments in two other unknown alphabets. All this literature is strictly religious, excepting fragments of a Middle Turkish translation of the fables of Aesopus and remains of two mss. of the legend of Barlaam and Josaphat, also in Turkish, found in the Turfan oasis, close to the borders of China proper.

The religions represented are Buddhism, Christianity, Zoroastrianism (one fragmentary leaf) and Manichaeism, which, introduced by way of China and accepted by the Uighur kings in

the 8th century, is represented by many mss., sometimes beautifully illuminated, in the Sogdian, Middle Persian and Middle Turkish languages. These remains are written in no fewer than 24 scripts. Islam is not associated with this culture. When this religion began to encroach upon it in the 10th century, the decline of the mainly Buddhist States of East Turkistan had begun.

Art Problems. — In sculpture and painting the basis of all this art is the Hellenistic antique, as developed in Gandhiira and in Bactria under Indian and Iranian influences. The Buddhist religion, and with it the modified Graeco-Buddhist art of Gandhāra, entered Central Asia by the royal road through the Rhyber pass and Bactria, through Udyana and later by the trade routes through Kashmir.

Architecture — The architecture is purely ecclesiastical; domestic buildings probably did not differ materially from similar erections in the present day. Iranian or Indian models are strictly followed. All traces of Chinese influence are absent, and of antique elements only the beautiful *caisson* ceilings occur occasionally. Two groups are found, *(a)* rock-cut temples and cells, *(b)* temples, *stūpas* and monasteries built with sun-dried bricks *(adobe)*.

Cave Temples. — The cave temple settlements follow Bactrian rather than Indian prototypes in their general plan. They are mostly crowded together, often in hundreds, on the perpendicular faces of steep cliffs, in glens of difficult access, near running water and in wild and romantic scenery. The cells of the monks are simple, small, vaulted rooms, with a fireplace, and often a bench cut out of the stone. The walls are plain white-washed, without any ornament. There are very few such cells in even extensive temple groups.

Settlements. — The cave buildings in the older settlements were connected by extensive stone-cut galleries, provided with few windows for the admission of air. Light in the temples and cells must have been mainly artificial, as proved by great masses of remains of wicker lanterns.

The commonest type of cave temple is of Indian origin. It consists of a square, vaulted anteroom, opening on a cella of the same description. The back-wall of the cella has a recess, in which the cult-statue was placed. To the right and left of the statue, two short, low, vaulted corridors were cut into the rock opening into a third corridor, at right angles to them, and parallel to the back-wall of the cella.

The square or rectangular block of stone thus resulting often contained, in a hidden receptacle, relics, manuscripts, coins and other valuables. These receptacles had always been opened and despoiled. This block stands for the *stūpa*. The corridors were used for processional circumambulation. On the walls of the cella were painted the effigies of the donors, the life story of the Buddha in a number of pictures separated by decorative borders, or rows of paintings representing certain Buddhist legends.

The vaulted roof is decorated with tiers of conventionalized representations of mountain landscapes, each containing some birth story (*jātaka*). The middle line between the two topmost tiers contained representations of flights of ducks, constellations, the sun and the moon, wind goddesses and the effigies of the sun- and moon-gods in their chariots, most of these representations following Hellenistic prototypes. In later temples (after A.D. 700) the mountains are replaced by rows of Buddhas.

Iranian Types. — Two other common types are Iranian. The first consists of a square room covered by a cupola rising from profiled mouldings at the upper edge of the walls. The second is similar but covered by a *lantern roof*, such as exists to this day in wooden houses from Armenia through Bactria to Kashmir and western Tibet, as described by Moorcroft. In later cave temples further east (Turfan) this roof was often painted only on the vaulted temple roof. These two Iranian types are used by the Chinese and Koreans as models in their cave temples (*e.g.*, Tunhwang). Another type is a long, narrow, tun-vaulted apartment, with, or without, a socle for the cult-figure.

Brick Temples. — The temples built with sun-dried bricks are erected on the same lines as the cave temples. The "lantern roof," however, never occurs in these buildings, as this construction is impossible with bricks, but the middle of the ceiling vault in the eastern oases (7th–9th centuries) often bore a painted representation of such a roof. These painted lantern roofs were commonly used to decorate ceilings in Chinese cave temples.

The **Stūpa.**—The *stūpa* is either (1) a (massive) building of pyramidal shape, plain on the outside, with a receptacle for relics, coins, mss., etc., or (a) a dome-shaped erection on a quadrangular base, or (3) in the eastern oases, a pyramid with rows of niches for Buddha statues, or (4) a remarkable quadrangular building in several tiers, diminishing in size upwards, like a gigantic staircase. A number of large, vaulted niches for Buddha statues are built in on the four faces of each tier. These erections are often of great size, one having as much as 20 metres length. Another rarer Indian type, of much smaller size generally, is a beautifully-proportioned building of polygonal cross-section.

Monasteries. — The monastery is usually a square or rectangle, surrounded by a strong wall, with towers, with one or more temples and rows of cells arranged along the inner course of the walls, built of sunburnt bricks of most excellent quality, evidently made on the spot in the required shape and size.

Paintings. — In most temples the walls and vaulted ceilings of the rooms were richly decorated with mural paintings in tempera colours. The colours vary in the different settlements, the most ancient ones being distinguished by a lavish use of true ultramarine. In some temples the floor was of stucco, often with most artistic paintings in *al fresco*.

The walls were found in all stages of preparation. Some were simply roughened, awaiting the application of a layer of smoothed, stamped clay, in others this finish had been applied, after which the smooth surface was covered with a very thin layer of stucco. On this smoothened surface the painters drew a "net" of rectangles, one within the other, into which the patterns for the pictures were fitted.

Designs. — These patterns were larger or smaller pieces of paper, on which the artist drew his pictures with India ink. The lines were then perforated, the pattern fixed to the wall and beaten with a bag containing powdered charcoal. The contours thus obtained were then traced in India ink and the colours filled in. Sometimes, in young settlements, an ancient pattern may have been used, so that critical analysis of style, in paintings and still more in sculpture, is not a safe guide to the age of the work.

Art Influence and Sources. — All paintings are intensely influenced by late antique schools of painting, originating in Gandhāra, the Punjab and Bactria. According to the province whence the painters came, or drew their inspiration, the paintings of Turkistan show Hellenistic elements modified in an Indian, or in an Iranian sense. Purely antique and purely Sassanian elements also occur, especially in friezes.

Chinese elements are wanting absolutely in the older, western oases. But China accepted the syncretistic arts of painting and sculpture produced in these regions, and, misunderstanding and modifying the forms received from the West in a Chinese sense, created the splendid art of Thang times on the basis of modified Hellenistic Buddhist art.

After Buddhism declined in India, China became the leading Buddhist power, and this new syncretistic Chinese art gained influence only in the eastern settlements (Turfan), and, as far as we can tell, not farther west than the oasis of Kutchā.

Main Styles. — Five principal well-marked styles of painting were observed by A. Griinwedel. (1) Several styles, directly containing late antique elements, such as are found in the Gandhiira sculptures, are united under the name Gandhāra. In certain temples antique elements preponderate, while others show these elements modified in Iranian or Indian sense (presumably 5th–6th century A.D.). (2) The style of the "knights with the long swords" (Tokharians), is presumably a local continuation of style No. 1 (probably 6th–7th century A.D.). (3) The older Turkish style has a pronounced syncretistic character; the forms of style 1 and 2 are incorporated, but Chinese elements begin to occur. The decorative borders of the wall-paintings and the ceilings show a remarkable and charming flower ornamentation. The costume of the donors differs completely from that of the donors

in the older styles. The inscriptions are in Chinese and Central Asian Brāhmī (presumably 7th–9th century A.D.). (4) The younger Turkish style, more properly the Uighur style, shows a further syncretistic development of style 3 in a Chinese sense—it is only found in the Turfan oasis and is the final development of the older elements into Chinese forms (8th–11th century A.D.). (5) The Lamaistic style has evident relations to Tibetan art.

Sculpture.—All sculpture in eastern Turkistan derives from the late antique school of Gandhāra and pure Hellenistic types appear even in late times in the eastern settlements, where the paintings had assumed an essentially Chinese character.

The perseverance, in sculpture, of Hellenistic forms is simply explained by the fact that, Turkistan being a loess country, without stone fit for the sculptor, the art-craftsmen were forced to use stucco moulds, of which quantities were found, mostly for the production of half-relievo figures. The larger kinds were moulded in pieces and afterwards put together, often very roughly, with straw ropes, twigs, coarse pegs, etc. The statue was prepared in the rough, its surface was remodelled, finished off with a fine layer of stucco and richly painted and gilded.

In the older western oases the material for the statues was often stucco; in the later (eastern) settlements the common clay of the country, mixed with chopped straw, vegetable fibres and animal hair. In spite of the crudeness of this material, the effect resulting is frequently imposing.

The moulds were probably imported from Gandhāra and replaced, when broken, by exact duplicates, produced mechanically from their own former products. Thus antique forms persisted long after paintings had begun to undergo Eastern Asiatic modifications. When the Sassanians cut the road to the West, no new Western influences could penetrate, while communications with China continued to be easy and frequent.

Change of Type.—In consequence, the ideal type of beauty began to change, and gradually the craftsmen deliberately changed their moulds to suit the Eastern Asiatic type of beauty. The nose became shorter, the brows were made slanting, the eyes more prominent, etc., while the late antique hairdresses, utterly incomprehensible to the Easterns, were changed.

Thus the evolution of a late antique head can be followed through many stages, until a typically Chinese head results.

EXPLORATION

No great river, no large arm of the sea leads to Asia's vast interior. This region remained, as desert conditions spread, unknown to all save a few individuals at different times in the great civilizations that have flourished around its "golden fringe." The movements of early traders, the records of travellers and the labours of military surveyors, from all the surrounding lands, have built up the now detailed topographical knowledge of the continent and so prepared for modern geographical study of the earth as the scene of man's activities. The expeditions of R. Pumpelly, Sir M. A. Stein, Sven Hedin and de Filippi have helped to elucidate the early climates of the interior and the consequent location, distribution and movements of early men

Early Period.—The intrinsic value and religious significance of salt made it an early object of trade. The salt mines of north India were known to the West before the time of Alexander. The salt of Palmyra was traded between Syrian ports and the Persian gulf. The cultivation of silk was known during the early Chinese dynasties and its knowledge spread westwards through Khotan, Persia and Central Asia into Europe. It was imported as raw material at Cos before classical times and is mentioned by Aristotle. Later on we hear of the Chinese pilgrims Fa hien (A.D. 399–415), Song-yun and Hwei-seng (518–521) and Hsuan-Tsang (629–645) journeying in Turkistan. The advancing Mongols under Jenghiz Khan drew the attention of the later middle ages eastwards, although ships of Venice and Genoa had long met at the Levant caravans laden with silk and other commodities of the East. Two Franciscan friars, John de Plano Carpini in 1245–47, and William of Rubruk (Rubruquis), 1253, made journeys through central Asia and they were followed by another Franciscan, John of Monte Corvino, who about 1295 entered south China by way of the Indian sea. But it was the work of Marco Polo (*q.v.*) that really made the East known to the West. We read of the journeys of the brothers Polo to the court of Kublai Khan about 1260 and again in 1271. The Polos were the first to trace a route across the whole breadth of Asia and to describe what had been seen as well as to tell of Japan, Java, Sumatra, the Andaman islands and Ceylon.

Later Journeys.—Central Asia was still almost unknown when explorations from the surrounding lands became numerous about the middle of the 19th century. Father Huc (*q.v.*) 1813–60, crossed the upper region of the Hwang-ho and the terrible sandy tract of the Ordos desert in 1844 and later crossed the desert of Koko Nor and entered Lhasa in 1846. In 1871–73 the Russian explorer Nicolai Prjevalsky crossed the Gobi and made maps of the sources of the Hwang Ho, Salween and other great rivers of China, Burma and Siam. In the next forty years Bonvalot. Prince Henri d'Orleans, Rockhill, Bower, Margary, Dutreuil de Rhins, Curzon, St. George Littledale, Wellby, Deary, Wahab, Holdich, Ryder, Rawling, St. George Gore, Talbot, Schindler and others traversed Tibet and Central Asia in all directions. Many of these were military officers who mapped unknown regions by accurate triangulation. At the same time (1875–1900) the geodetic surveys of Russia in Asia moved apace and a topographical connection was established between the Indian and Russian surveys. Pundits Nain Singh and Krishna may be mentioned in connection with trans-Himalayan explorations by native surveyors (1865–82).

In 1886 Capt. (afterwards Sir Francis) Younghusband completed a journey across the heart of the continent by crossing the Muztagh between China and Kashmir, and in 1904 conducted a mission to Lhasa and extended the survey by triangulation to that city. Sven Hedin explored in Persia and Mesopotamia in 1885–86 and in 1890 he travelled through Khurasan and Turkistan, reaching Kashgar in 1891. During 1893–97 he traversed Asia leaving Orenburg near the Urals and moving over the Pamir and the plateau of Tibet to Peking. During two expeditions 1899–1902, 1906–08 he explored the sources of the Sutlej and the Brahmaputra. In 1896 he found not far from Khotan objects of terracotta, bronze images of the Buddha, coins, etc. He excavated, in Takla-Makan, ancient cities overwhelmed by sand, where he found among other things mural paintings illustrating lake scenery, pottery, etc. He also discovered (1901) the ancient city of Lou-Lan in the heart of the Lop desert. He was followed in this work by Sir Aurel Stein who had made important journeys to central Asia and west China. Stein journeyed to Endeir, Kara, Rawak and other sites where he recorded finds of pottery, images, frescoes, etc.

Modern Times.—Ellsworth Huntington's explorations in the neighbourhood of the Tien Shan and Altai systems in 1903 together with the publication of his book The Pulse of ***Asia*** (1907) brought to the fore the significance of his theory of the cyclic desiccation of the interior of Asia. His views can be more carefully studied since Dainelli in the reports (1922 onwards) of the Filippi expedition to the Himalayas and Kara Koram, besides

giving valuable anthropological and sociological data, offers important evidence suggesting various periods of glaciation for the great mountain arcs of central Asia, parallel to most of those worked out for the Alps by Penck. It is now generally thought (following the view of Stein) that even after the passing away of the ice age many large glaciers remained among the mountains and their melting gave supplies of water to the lowland regions. The increasing drought about the beginning of the Christian era would, in Stein's view, be brought about by the marked reduction of these glaciers.

Besides the works of Stein and Sven Hedin mention must be made of A. D. Carruther's books on Mongolia and Dzungaria, Baddeley's work on Russia, Mongolia and China, Dr. Legendre's work on the Upper Yalung in West China, Kingdon Ward's From *China* to *Hkamti Long* and the reports *(Geog.* Jour., 1926) of this worker's investigations of the Himalayan gorges of the Brahmaputra, J. W. Gregory and Teichman on Eastern Tibet. Pioneer work on China and the Chinese interior was done by von Richthofen who, during the latter half of the 19th century, made seven remarkable journeys covering almost the whole of the Chinese empire. He studied the geology, geography and economic resources of these regions and his great works published between 1877 and 1912 opened up in a scientific manner many problems in Far Eastern Asia. His labours have been continued by the Japanese Geological Survey, whose geological map of China is an acquisition to our knowledge of these regions. This field of exploration has recently been advanced by the American Museum of Natural History under the direction of Roy Chapman Andrews. The reports of their work east and south of Chinese Turkistan in 1922–25 abound in interest. Andersson and Arne, Teilhara, Weidenreich, Li, Wa, Pei, Criel and others have exposed ancient sites and greatly added to our knowledge both of Palæolithic China and of the dawn of civilization. As early as 1864 Prince Kropotkin journeyed in north Manchuria from Transbaikalia to the Amur, and later he investigated the Sungari river and moved into the heart of Manchuria. Baron Toll investigated the Lena basin in 1892, and much work has been done in Northern Siberia in the 20th century. The opening of the century brought the results of D. W. Freshfield's explorations in the Caucasus, and the present century may truly be held remarkable for revelations by the spade of the glories of the ancient civilizations of the Near East. Stein and Sven Hedin have worked in Central Asia, and the former notably in Iran. Woolley and others have carried out large excavations in Mesopotamia: and Prof. Dorothy Garrod and others have investigated early Palestine. Huzayyin and, later, Miss Caton-Thompson have begun the archaeological examination of S. Arabia. Bertram Thomas and H. St. J. Philby have crossed the Rub' al-Khali in S. Arabia, and the latter has contributed greatly to our knowledge (especially as regards the oasis fortress-towns) of interior Arabia, which, with the rise of the Sa'udi kingdom, has acquired added importance.

Generally speaking, primary exploration has given place to more specialized study attacking specific problems, but Russian geographers have done much primary work, notably on the north coast *(see* ARCTIC REGIONS), in the north-east, and in the Pamirs and Tien-Shan.

The outstanding features in India have been the extension of trigonometrical survey under the military authorities; the attempts, made year after year, to climb Mt. Everest (*q.v.*) and to explore its higher slopes; the publication of important studies of various peoples especially of north-east India; and the exploration of the ancient cities of Harappa and Mohenjo Daro in the Indus basin under the direction of Sir John Marshall. English, Dutch, Swiss and German works have contributed much to study of the island groups off the south-east of Asia.

HISTORY

Asia, in a narrow sense, the name of the first Roman province east of the Aegean, formed (133 B.C.) out of the kingdom left to the Romans by the will of Attalus III. Philometor (*q.v.*), king of Pergamum. It included Mysia, Lydia, Caria and Phrygia, and therefore Aeolis, Ionia and the Troad. In 84 B.C., on the close of the Mithridatic War, Sulla reorganized the province. From 80 to 50 B.C. the upper Maeander valley and all Phrygia, except the extreme north, were detached and added to Cilicia. In 27 B.C. Asia was made a senatorial province under a pro-consul. As the wealthiest of Roman provinces it had most to gain by the *pax Romana,* and therefore welcomed the empire, and established and maintained the most devout cult of Augustus. In this cult the emperor came to be associated with the common worship of the Ephesian Artemis. By the reorganization of Diocletian, A.D. 297, Asia was broken up into several small provinces, and one of these, of which the capital was Ephesus, retained the name of the original province *(see* ASIA MINOR).

Boundaries.—The borders assigned to Asia on the west are somewhat arbitrary. The Urals indicate no real division of races and in both Greek and Turkish times Asia Minor has been connected with Europe rather than with the lands to the east. A juster view of early history is obtained by thinking of the Mediterranean countries as interacting on one another than by separating Asia Minor and Palestine as Asiatic.

The words Asiatic and Oriental are often used as if they denoted a definite and homogeneous type, but Turks, Indians, Chinese, etc., differ in so many important points that the common substratum is small. Asiatics stand on a higher level than the natives of Africa and America but do not possess, although they are acquiring, the special material civilization of Western Europe. They have not shown the same sentiment of independence and freedom. Individuals are thought of as members of a family or state rather than as entities with rights of their own. Hence Asiatic history has large, simple outlines. Though longer than the annals of Europe, it is less eventful and offers fewer personalities of interest. But the same conditions which render individual eminence difficult procure for it, when once attained, more ready recognition. Jenghiz and Timur covered more ground than Napoleon and no one European has had such an effect on the world as Mohammed.

Religions.—Not only the great religions of the world—Buddhism, Christianity, Hinduism and Islam—but those of secondary importance such as Judaism, Parseeism, Taoism, etc., all arose on Asiatic soil. On the other hand Christianity, though Asiatic in origin, has assumed its present form in Europe and its most important manifestations—notably the Roman Church—are European reconstructions in which little of Asia remains. Christianity has made little way to the east of Asia Minor. Modern missions have made no great conquests there, and though in earlier times

ARCHAEOLOGICAL DISCOVERIES IN ASIA MINOR

1. Sculpture of a god or king found in the excavations at Boghaz-Keui, a small village in Cappadocia
2. Relief showing procession of musicians, discovered by German excavators at Sinjerli, Syria
3. Statue of the god Hadad discovered by German excavators at Sinjerli
4. Incised inscription on basalt, showing a man capturing animals, taken from the Djerbis ruins
5. Marble sarcophagus, found at Sidon, said to be that of Alexander the Great. His sculptured effigy appears on the lower part of the sarcophagus
6. Ruins of the temple of Jupiter at Baalbek, Syria
7. Gateway to the church of Kalat Seman, in central Syria, which was built about A.D. 500 and was dedicated to St. Simeon Stylites, the anchorite

the Nestorians penetrated even to China, they never had anything like the success which attended Buddhism and Islam. Yet Buddhism never produced much impression west of India and Islam is repugnant to Europeans, for even under Muslim rule (as in Turkey) they refused to accept it in a far larger proportion than did the Hindus in similar circumstances. There is clearly a profound difference between the religious feelings of the two continents.

The north of Asia is less important than the corresponding region of Europe, few tribes or places of note being found north of lat. 50°. In many parts of the south are semi-barbarous races representing early peoples, such as the Veddahs of Ceylon and various tribes in China and the Malay archipelago. In northern Asia are other aborigines such as the Ainus and Chukchis, but no materials are forthcoming for their history. We have some record of invasions by later races. The Chinese came from the west, though from how far west is unknown; the Hindus and Persians from the north-west; the Burmese and Siamese from the north.

The antiquity of Asiatic history is often exaggerated. With the exception of Babylonia and the West, we can hardly conjecture the condition of the continent before 1500 B.C. At that period the Chinese were advancing along the Hwang-ho and the Aryans were entering India. Babylonian influence was probably widespread. All Indian alphabets seem traceable to a Semitic original and connection between China and Babylon is suspected, though not proved.

Spheres of Influence. — Apart from European conquests the history of Asia in the last 2,000 years is the result of the interaction of four main influences: (a) Chinese, (b) Indian, (c) Mohammedan, (d) Central Asian. Of these the first three represent different types of civilization; the fourth has little originality but has been of great importance in affecting the distribution of races and political power.

China has moulded the civilization of the eastern mainland and Japan. In the sphere of direct influence fall Korea, Japan and Annam; in the outer sphere are Mongolia, Tibet, Siam, Cambodia and Burma, where Indian and Chinese influence are combined, the Indian being often the stronger. Wherever Chinese influence had full play, it introduced Confucianism, a special style of art and the Chinese script.

Indian influence may be defined as Buddhism, if it is understood that Buddhism was not always clearly distinguishable from Hinduism. Its sphere includes Indo-China, much of the Malay archipelago, Tibet and Mongolia. China and Japan themselves may be said to fall within this sphere, so far as they are Buddhist. It is noticeable that the influence was not reciprocal, and that Indian culture was not affected by Chinese art, literature or ethics. Buddhist influence is not merely religious for it is always accompanied by Indian art and literature and often by an Indian alphabet, as in Tibet, Java and Cambodia.

Mohammedanism or Islamism is perhaps the greatest transforming force which the world has seen. It has profoundly affected and to a large extent subjugated western Asia, eastern and northern Africa, as well as eastern Europe and Spain. Until recently it implied the fusion of secular and religious power, so that the Muslim Church was a Muslim state characterized by slavery, polygamy and, subject to the autocracy of the ruler, the theoretical equality of Muslims who in political status were superior to non-Muslims. Islam is still the principal religion of western Asia: in India it is strong in the north and centre but only one-fifth of the whole population is Muslim. Beyond India it has spread to the Malay peninsula and archipelago, where it overwhelmed an earlier Hindu civilization. But it made no progress in Indo-China or Japan, and though Mohammedans are numerous in some parts of China, it is there merely one of many religions and has never aspired to identify itself with the state.

Even tnore than Buddhism, Islam has carried with it a special style of art and civilization. It is usually accompanied by the use of the Arabic alphabet, and in the languages of Muslim nations a large proportion of the vocabulary is Arabic.

The great part which Central Asian tribes have played in history is obscured by the absence of any common name for them. Linguistically they fall into several groups such as Turks, Mongols and Huns, but they were from time to time united into states representing more than one group, and their armies were recruited like the Janissaries from all the military races in the neighbourhood. Soon after the Christian era, Central Asia began to boil over and at least seven great invasions can be ascribed to these tribes: (1) The early invasion of Europe by the Avars, Huns and Bulgarians, (2) the invasion of Russia by the Mongols, (3) the conquests of Timur, (4) the conquest of Asia Minor and Eastern Europe by the Turks, (5) the conquest of India by the Moguls, (6) the conquest of China by the Mongols under Kublai, (7) the later conquest of China by the Manchus. To these may be added numerous lesser invasions of India, China and Persia.

These tribes have a genius for war rather than for government, and with few exceptions (*e.g.*, the Moguls in India) have proved poor administrators. But their movements helped to keep up communications in Central Asia and to transport religions and civilizations from one region to another. Thus they are mainly responsible for the introduction of Islam into India and Europe and in earlier times they facilitated the infiltration of Graeco-Bactrian civilization into India.

Recent excavations in Central Asia have made surprising discoveries. In the Tarim basin there flourished in the early centuries of our era small states, such as Khotan and Kucha, which possessed a singularly mixed civilization comprising Chinese, Indian, Iranian and even Greek elements. Buddhist, Christian and Manichaean edifices have been unearthed, as well as libraries in many languages, two of which were previously unknown.

In the early history of both Europe and Asia small feudal or aristocratic states tended to grow into monarchies, but whereas in Europe from ancient Rome onwards royalty has often been replaced temporarily or permanently by more popular forms of government, until recently this change did not occur in Asia, where democracy was represented chiefly by remote tribes which had not developed into states. But within the last 1j years China and Turkey have abolished the imperial power and several territories in Central Asia have become republics, affiliated to the Soviet Government of Russia.

Babylonia, Assyria, **etc.**—The movements mentioned above have been the chief factors of relatively modern Asiatic history, but in early times the centre of activity and culture lay farther west in Babylonia and Assyria. These ancient states began to decline in the 7th century B.C. and gave way to the Persian empire. Recent researches have thrown much light on their history but have also shown that it was complex and that we have to deal with more nations than was supposed. Excavations at Susa and at Anau in Transcaspia indicate the existence of a very early civilization extending over south-western Asia whence probably descended the Sumerians, a race speaking an agglutinative language who have left written records anterior to 4000 B.C. In Mesopotamia they met with Semitic tribes, sometimes called Akkadian. Dynasties of both races ruled in various towns, but after 2500 B.C. the Sumerians began to decline and Babylon came to the front as metropolis under Hammurabi, the Lawgiver (2123–2081). Semitic rule however collapsed before new invaders from Elam, the Kassites, who controlled Babylon for more than five centuries (c. 1750–1200). They adopted the civilization and Semitic language of their subjects, but little is known of their original culture. The Hittites, who invaded Babylonia about 1950, developed into a considerable empire which ruled northern Syria and the greater part of Asia Minor in the 14th and 13th centuries. Their hieroglyphic inscriptions have not yet been satisfactorily deciphered. Nor is there much that is certain which can be said about the important kingdom of Mitanni in Central and Eastern Asia Minor. The ruling class were apparently Aryan, but according to most philologists the language of the people was not. The Assyrians now come to the front. They seem to have been an offshoot of the Babylonians using almost the same language, though they had an individuality which showed itself in art and religion. In the 9th and 10th

centuries they became the chief power within their sphere and the suzerain of their parent Babylon. But they succumbed before the advance of the Medo-Persian power in 606 B.C., whereas it was not till 555 that Cyrus took Babylon. Assyria, being an essentially military power, disappeared with the destruction of Nineveh, but Babylon continued to exercise an influence on culture and religion for many centuries after the Persian conquest.

China.—This is the oldest of existing states, though its authentic history does not go back much beyond 1000 B.C. The origin of the Chinese is uncertain but it is clear that they came from the west and entered their present territory along the course of the Hwang-ho, possibly about 3000 *B.C.* In early historical times China consisted of a shifting confederacy of feudal states, but about 220 *B.C.* the state of Tsin or Chin (whence the name China) became prominent and formed a brief empire. The subsequent history of China is mainly a record of struggles with various tribes commonly but not very correctly called Tartars. The empire was frequently broken up by incursions or divided between rival dynasties, but at least twice became a great Asiatic power, under the Han dynasty (*c.* 206 B.C.–A.D. 220) and the T'ang (AD. 618–907). The dominions of the latter extended across Central Asia to India, but were dismembered by the attacks of the Kitans (whence the name Cathay). China proper, minus these external provinces, was again united under the Sung dynasty, but split into the northern and southern kingdoms. In the 13th century arose the Mongol power and Kublai Khan conquered China. His dynasty lasted less than a century, but the native Chinese dynasty called Ming which followed reigned for nearly 300 years. In 1644, the Manchus, a northern tribe, captured Peking and founded an imperial house which lasted till 1912, when a republic was proclaimed.

Though the government of China has hitherto been monarchical, there have been many intervals of chaos like the present period and the divine right to rule has never been regarded as inherent in one family, for there have been ao dynasties since the Christian era. But until the advent of Europeans the Chinese were aiways in contact with inferior races. Whether they incorporated weaker neighbours or were conquered by more robust invaders, Chinese civilization prevailed and assimilated alike the conquerors and the conquered. The present situation differs from anything in the past because China is now assimilating European and American ideas, with the result that dislike of foreigners and desire to imitate them are both strong motives.

The most conspicuous figure in the literature and, indeed, the history of China, is Confucius (551–475 B.C.). Though he claimed no originality and merely sought to systematize the traditions of antiquity, his influence in the Far East has been extraordinary, and he must be pronounced one of the most powerful advocates of peace and humanity that have ever existed.

Tibet was an important power in Central Asia in the 8th century, but later became a vassal of China, though practically independent and possessing a culture of its own, which is chiefly derived from India. Its most striking feature is the religion, a form of late Indian Buddhism called Lamaism, which attained temporal power and developed into an ecclesiastical state curiously like the papacy.

The Mongols, who were once a terror to Europe and who conquered China, ceased to be a political power after the 14th century. They live on nominally Chinese territory or in Russia, and such culture as they possess is a mixture of Indian (through Tibet) and Chinese. Their alphabet is a curious instance of transplantation, being derived from the Syriac script introduced by early Nestorian missionaries.

Japan.—The oldest known inhabitants are the Ainus, who were gradually driven to the northernmost island, but though their wars with the Japanese are historical, there is no record of whence the latter came. Native tradition regards them as autochthonous, but they are probably a mixed race combining Central-Asian with Malay or Polynesian elements. Authentic history hardly begins till the 6th century *A.D.* when Chinese civilization and Buddhism were introduced from Korea. In 645 the whole government was reorganized on the model of Chinese bureaucracy, but a characteristic feature of Japanese politics—the power of great families who overshadowed the throne—also appeared. First came the Fujawaras and then the rivalry between the houses of Taira and Minamoto. The latter won and in 1192 established a dual system under which the emperor ruled only in name, and the real power was in the hands of a hereditary military chief called Shogun, or even of his deputy, for the Hōjō regents of Kamakura practically reigned from 1205 to 1333 and repulsed the invasion of Kublai Khan. The chief power then passed to the Ashikaga dynasty of Shoguns (1338–1565), distinguished for their patronage of art. The middle and end of the 16th century was a period of ferment marked by the arrival of the Portuguese, who attempted to introduce Christianity, and by the rise of some remarkable leaders one of whom, Hideyoshi, invaded Korea. Death interrupted his plans and his successor Ieyasu decided on a policy of isolation. Ideas of external conquest were abandoned, Christianity was forbidden and Japan closed to foreigners for 216 years, only the Dutch being allowed a limited commerce. It was not till 1854 that the Christian powers, beginning with the United States, asserted their right to trade. The influx of ideas caused an upheaval in which the Shogunate was abolished and the authority of the Emperor restored. Seeing that their only chance of competing with Europeans was to fight them with their own weapons, the Japanese set themselves to imitate the material civilization and to some extent the institutions of Europe, such as constitutional government. Their progress and success are without parallel. In 1895 they defeated the Chinese and ten years later the Russians.

This sudden development of the Japanese is of singular importance, since it marks the rise of an Asiatic power capable of competing with Europe. Their history is so different from that of other Asiatic states that it is not surprising if the result is different. The nation hardly came into existence until India and China had passed their prime and was free from the continual struggle against barbarian invaders which drained the energies of its neighbours. It was left untouched by Mohammedanism, and for a long period kept Europeans at bay without wasting its strength in hostilities. The military spirit was evolved, not in raids and massacres of the usual Asiatic type, but in feudal struggles which restrained ferocity and tended to create a temper like European chivalry.

Korea is peculiar in race and language but derived its civilization from China, to which it was nominally tributary at most periods, though practically independent. In the 16th century the Japanese occupied it for a short period and in 1894 they went to war with China to contest her suzerainty. As a result, Korea was declared independent, but after the Russo-Japanese War Japan's "paramount interests" in the country were recognized and she annexed it in 1910.

India.—The earliest stratum of population seems to be represented by the speakers of the Munda languages (*e.g.*, the Santals and other uncivilized tribes). Next came the Dravidians (Tamils, Kanarese, etc.) who probably entered from the north-west, but at an unknown date, and attained some degree of culture. In prehistoric times they were apparently spread over all India but were driven to the centre and south by the advance of the Aryans. These appear to have originated in Europe but one section wandered to the north of the Hindu Kush and divided into two branches, Indian and Iranian, the former of which migrated into the Punjab about 1joo B.C. But Mitannian inscriptions of 1400 B.C. which mention Indian deities have been found in Asia Minor, and are explained by supposing either that the Aryans took this route eastward or that there was a secondary migration to the west. The life of the ancient Indians as portrayed in their sacred songs, the Rig Veda, was quasi-nomadic but by the 6th century B C. settled states had been formed in the Ganges valley. They were monarchies but the power of the king was tempered by the extraordinary influence of the hereditary priestly class or Brahmans. The position of this class, which has survived to the present day, is connected with the institution of caste, a division of the population into groups founded partly on race, partly on occupation. Somewhat opposed to Brahmanism

PAINTED FOR THE ENCYCLOPEDIA BRITANNICA

ASIATIC ANIMALS, BY PAUL BRANSOM

Upper panel: Leopards. Among the catlike animals leopards are surpassed in size only by the lion and the tiger, with which they vie in swiftness, courage and ferocity. Left to right: Clouded Leopard; Common Leopard; Black Leopard, a colour variant of the common leopard; Snow Leopard or Ounce

Middle panel. Upper left to right: Two White-handed Gibbons (tailless monkeys), showing the light grey and the typical colouration; Asiatic Elephant, anciently domesticated in India, differing in appearance from the African chiefly in its much smaller ears; **Hanuman** Monkey, sacred in India; **Crab-eating** Macaque. Left centre: Sambar Deer, with antlers sometimes 4 ft. **long.** Right centre: Water Buffalo, larger but less **docile** than the ox, domesticated since remote antiquity. Lower row, left to right: Tiger, the most destructive beast of prey, sometimes exceeding the lion in size; **Nilgai,** a large antelope; **Indian** mongoose, an agile, weasel-like destroyer of venomous snakes; Cobra, the most deadly of serpents

Lower panel, left to right: Tahr, a Himalayan **wild** goat; Yak, the **"grunting** ox of **Tartary,"** long domesticated **in** Tibet; Bactrian Camel, **employed** for centuries in the trans-Asian caravan trade; Takin, a Tibetan **antelope;** Giant Panda, a catlike animal allied to the **American** raccoon. For **further** details see the articles on the various animals

was the doctrine of the Indian prince, Gautama, called the Buddha, which grew into one of the greatest religions of the world. For many centuries the intellectual development of the Hindus depended mainly on the interaction of Buddhism and the old religion. Buddhism was finally absorbed and disappeared in India itself, but being a missionary religion it flourished elsewhere and spread Indian influence over all eastern Asia.

In 1924 excavations in the Punjab and Sindh discovered at two sites brick structures as well as pottery, coins and seals bearing figures and inscriptions in unknown characters. No authoritative statement has yet been made as to the probable date and origin of these objects, but they are said to be unlike anything known in Indian art and to suggest affinities with Susa or Sumerian civilization. All that is clear is that further investigation may reveal a new and hitherto unsuspected phase of early Indian history.

In 326 Alexander invaded the Punjab. The immediate result was small, but the rise of Hellenistic kingdoms in Central Asia had a powerful effect on art and culture and may also have familiarized the Hindus with the idea of an empire, which appeared among them later than elsewhere. The first empire called Maurya reached its zenith under Asoka (c. 274–236), who rultd from Afghanistan to Madras. He was a zealous Buddhist, and by his exertions the faith was spread all over India and Ceylon. No Hindu empire has lasted long and the Maurya dominions broke up soon after his death.

In the next period (c. B.C. 150–A.D. 300) India was invaded by tribes partly of Parthian and partly of Turki origin. The most important were the Kushans whose king, Kanishka, founded a state which comprised northern India and Kashmir. The date of Kanishka's accession is still disputed and variously given as 78 and 125 A.D. Another native empire known as Gupta arose on the ruins of the Kushan kingdom and embraced nearly the whole peninsula, but it broke up in the 5th century under the attacks of new invaders, the Huns. From 606 to 646 Harsha established a brief but brilliant empire in the north, but after his death Hindu history is lost in a maze of small and transitory states, incapable of resisting the ever advancing Mohammedan peril. As early as 712 the Arabs conquered Sind and by 1200 most of northern India was in Muslim hands. Two periods may be distinguished, the Turki (1000–1526) and the Mogul empire. The former comprised several dynasties of mixed race, but was wanting in coherency. In the neighbourhood of the Muslim capitals Islam spread rapidly, but in such districts as Rajputana, Orissa and Vijayanagar, Hindu civilization and religion maintained themselves.

In 1526 the Moguls descended from Transoxiana and seized Delhi. They never subjugated the south, but the Empire which they founded in the north was for about two centuries under such rulers as Akbar and Shah Jehan one of the most brilliant which Asia has seen. After 1707 it began to decline; the governors became independent, a powerful Maratha confederacy arose, Persians and Afghans made repeated invasions and the power of England and France increased (see EUROPEAN INFLUENCE). Amidst such confusion the authority of the Mogul empire rapidly disappeared but it lasted as a name till the Mutiny.

Neither the Hindu nor the Muslim rulers of northern India succeeded in completely subjugating the Dravidian kingdoms of the south nor did these ever combine into one state. Though far from unimportant for the history of literature and culture, their history presents few salient events. This indeed is true of Hindu history generally. Until Mohammedan times it is marked by the unusual prominence of religion and is a record of intellectual rather than political changes. Even the great Hindu dynasties have left few traces, and it is with difficulty that the historian disinters the minor kingdoms from obscurity. But Hindu religion, literature and art have influenced all Asia from Persia to Japan, and there were once Indian states in such remote regions as Khotan and Cambodia.

Ceylon was, according to tradition, invaded by Aryans from north-western India in the 6th century B.C. It received Buddhism in the time of Asoka and as a religious centre has influenced Burma and Siam. Its mediaeval history is a record of struggles with Tamil invaders. A powerful native dynasty ruled in the 12th century but subsequently the island mas partially subjugated, first by the Portuguese and then by the Dutch. In 1796 the Dutch were expelled by the British.

Persia.—The Persians, with whom are often coupled the Medes, appear to be Aryans in origin, and the earliest form of their language and religion offers remarkable analogies to the Vedas. Their ancestors and those of the Hindus formed a single tribe somewhere in central Asia. The religion was remodelled by Zoroaster probably once. There is no agreement as to his date, but many authorities place him in the 7th century B.C. About that time they shook off the domination of Assyria. From the 6th century onwards their empire, then known as Median, began to expand at the expense of the surrounding states. They destroyed Nineveh in alliance with the Babylonians, and half a century later Cyrus took Babylon and founded the great dynasty of the Achaemenidae. The substitution of the Persian for the Median power, which took place with the advent of Cyrus, seems to indicate the pre-eminence of a particular tribe rather than a foreign invasion. The power of the Achaemenidae, when at its maximum, extended from the Oxus and Indus in the east to Thrace in the west and Egypt in the south, but fell before Greece, after lasting for rather more than zoo years. Darius and Xerxes were repulsed in their efforts to subjugate the Greek peninsula, and Alexander the Great conquered their successor Darius III. in 329. But the greater part of the empire continued to exist under new masters, the Seleucids, as a Hellenistic power which was of great importance for the dissemination of Greek culture in the East. About the same period (250 B.C.–A.D. 22j) the Parthian empire arose under the Arsacids in Khorasan and the adjacent districts. The Parthians were probably a Turanian tribe who had adopted Persian customs. They successfully withstood the Romans, and at one time their power extended from India to Syria. They succumbed to the Persian dynasty of the Sassanids, who ruled for about four centuries, established the Zoroastrian faith as their state religion, and maintained a creditable conflict with the East Roman empire. But in the 7th century they were defeated by Heraclius, and shortly afterwards were annihilated before the first impetus of the Mohammedan conquest, which established Islam in Persia and the neighbouring lands, sweeping away old civilizations and boundaries. During the greater part of the Mohammedan period Persia has been ruled by troubled and short-lived dynasties. It attained a certain dignity and unity under Abbas Shah (1585–1628), but in later times was distracted and disorganized by Afghan invasions. The Anglo-Russian convention of 1907, which demarcated spheres of influence, guaranteed Persian independence.

Afghanistan, which is now recognized as an independent state, first became a kingdom under Ahmad Shah *c.* A.D. 1738.

The Turks.—The Turks are first heard of on the frontiers of China in A.D. 545. A Turkish state had relations with Byzantium. Inscriptions in ancient Turkish on the Orkhon river are dated A.D. 733. Among the branches of this formidable conquering race may be mentioned (1) the Uighurs, whose kingdom comprised Kashgar and Khotan in the 11th century; (2) the Seljuks, who conquered large parts of Persia, Syria and Asia Minor between the 11th and 13th centuries; (3) the Osmanlis, first heard of in 1237, who took Constantinople in 1453 and founded the Ottoman empire. It is also clear from linguistic evidence that the Mongol and Mogul armies which invaded Russia and India were largely composed of Turks. By an amazing change the Ottoman empire became the republic of Turkey in 1922. The Government moved to Angora and Constantinople, so long considered the capital of the Levant, was abandoned. Turkey thus seemed to become an Asiatic power, but the sultanate and caliphate were abolished and European customs imitated wholesale.

The Jews.—The Israelites appear to have been originally a nomadic tribe akin to the Arabs whom they resemble in their extraordinary religious genius and their want of political instinct. They have been distinguished from early times by a species of commensalism or power of living among other nations without becoming either socially merged or politically distinct. But their place is in European rather than in Asiatic history. The great majority of them prefer Europe as a residence. but anti-Jewish

excesses in Central Europe have given an impetus to colonization movements in Palestine; so that in 1939 about a third of Palestine's population was Jewish.

The Arabs.—The Arabs have hardly any history before the time of Mohammed, though their name is mentioned by surrounding nations from the 9th century B.C. onwards. They appear to have had few states and kings but rather tribes and chiefs. Language indicates their relationship to the Babylonians, Jews and Abyssinians, who were probably immigrants into Africa from Arabia. The Hyksos or Shepherd kings of Egypt, were a similar invasion.

With the rise of Islam came a sudden effervescence of the Arabs who during some centuries threatened to impose not only their political authority but their new religion on the whole known world. They invaded India, Persia and Central Asia in the east, Spain and Morocco in the west. The caliphate under the Omayyads of Damascus and then the Abbasids of Baghdad became the principal power in the Near East. It had not, however, a sufficiently coherent organization for permanence; parts of it became independent, others were annexed by the Turks. Arab rule in Spain, which once threatened to overwhelm Europe, lingered on till the 15th century. The collapse of the political power of Arabia was singularly complete. It is still one of the least known parts of the globe and has few links with the outside, for the Arabs of northern Africa form separate states. Nevertheless, Arabic religion and literature are a great power in western Asia, and northern Africa and were so until quite recently in eastern Europe.

Since the World War the Kingdom of Saudi Arabia has become the dominant state in Arabia and Turkish suzerainty has ceased.

The Malays.—This widely scattered race has no political union. It occupies the Malay peninsula, Java, Sumatra, the Philippines, and islands of the Malay archipelago as well as Formosa and Madagascar, while the natives of the South Sea islands speak languages which, if not Malay, have at least been influenced by it. This distribution suggests that the Malays are a sea-faring race with exceptional powers of dispersal who have spread from some island centre, perhaps Java. Philologists, however, hold that there is a great linguistic group called Austronesian, which comprises the Munda, Malay, Polynesian and Micronesian languages and that the movement which distributed them started from the extreme west. Three periods can be distinguished in the history of the Malays. In the first they were semibarbarous, as are the natives of Borneo at present. In the second Hindu civilization reached Java, Sumatra and the Malay peninsula. The Sumatran empire called Srivijaya was a considerable power from the 7th to the 14th century. In the third period Islam superseded Hinduism except in Bali.

Indo-China is an appropriate name for Burma, Siam, Cambodia, Annam, etc., for both in position and civilization they are intermediate between India and China. The population belongs to many races, of whom the first with any history were the speakers of the Mon-Khmer languages still used in Pegu and Cambodia. (1) Early in the Christian era one, or perhaps two, Hindu invasions established in Cambodia or the land of the Khmers a kingdom whose former importance is attested by a series of remarkable buildings dating from A.D. 800–1200. It still exists as a French protectorate. (2) In southern Annam a Hindu kingdom called Champa, which also has left considerable ruins, was founded about the end of the 2nd century A.D. It is not known how Hindu invaders reached these regions but possibly via Java. (3) The Annamites, a race apparently allied to the Chinese, absorbed Champa and founded a kingdom which was independent, though nominally tributary to China, from the 10th to the 19th century. (4) The Burmese are linguistically allied to the Tibetans and entered Burma from the north-west. Their early history consists largely of conflicts with the Talaings of Pegu. About 1750 Alompra united his countrymen, destroyed the power of the Talaings and founded a kingdom which was eventually annexed by Great Britain in 1885. (5) The Thai or Siamese, who speak a language of the Chinese type but use an Indian alphabet, are a late invasion from southern China whence they descended about the 13th century.

At present the eastern part of this region, consisting of French protectorates or colonies, is known as French Indo-China; Siam is an independent kingdom; the Malay peninsula and Burma are British, the latter having been annexed to British India in 1886.

In historic times Asia has attempted to assert her influence over Europe by a series of invasions, most of which were repulsed. Such were the Persian wars of Greece and perhaps one may add Hannibal's invasion of Italy, if the Carthaginians were Phoenicians transplanted to Africa. The Roman empire kept back the Persians and Parthians but could not prevent the incursions of the Avars, Huns, Bulgarians and later of the Mongols and Turks. The earlier Asiatic invasions had little result, for the invaders retired after a time (like Alexander from India) or more rarely (*e.g.*, Huns and Bulgarians) settled down without maintaining any connection with Asia. The Turks, and to some extent the Arabs, were more permanent, because they began by occupying the adjacent parts of Asia and Africa, so that the final invaders were in touch with Asiatic settlements. But though the Turks have affected all eastern Europe, the result of their conquests was not so much to plant Asiatic culture there as to arrest development.

The influence of Asia on Africa has been considerable and until the middle of the 19th century greater than that of Europe. Some authorities hold that Egyptian civilization came from Babylonia and that the so-called Hamitic languages are older and less specialized members of the Semitic group. The connection between Carthage and Phoenicia is more certain, and the ancient Abyssinian kingdom was founded by Semites from southern Arabia. The traditions of the Somalis represent them as coming from the same region, and there was a continuous stream of Arab migration to East Africa which founded a series of cities on the coast, including Zanzibar. There was also a fairly ancient connection between this region and India. The whole of northern Africa has become Mohammedan as far south as Timbuktu and Wadai.

The relation of the pre-European civilizations of America to Asia is a much debated question, and some facts support the theory that they were due to Asiatic immigrants.

European Influence.—European influence on Asia has been especially strong at two epochs, first after the conquests of Alexander the Great and secondly from the 16th century onwards. Alexander's conquests resulted in the foundation of Hellenistic kingdoms in Asia which produced some effect on India, and brought oriental ideas to Egypt, Greece and Rome. There followed a long period in which eastern Europe had to repel Asiatic invasions and had little opportunity of influencing the East beyond Asia Minor. Indian astronomy, however, appears to owe a debt to Greece. Though attempts have been made to prove that certain developments of Indian religion in the early centuries of our era were due to Christianity, the contention has not been established. Somewhat later the Crusades kept up communication with the Levant, but intercourse with farther Asia was limited to the voyages of a few travellers. Looking at eastern Europe and western Asia only one must say that up to the 20th century Asiatic influences prevailed, though the tide is turning, for Islam was paramount and European culture at a low ebb. But the case is different if one looks at the two continents as a whole, for better communication brought about strange vicissitudes, and western Europe asserted its power not in western but in middle and eastern Asia.

In the 16th century a new era began with the discovery of the route round the Cape, and the naval powers of Europe started on careers of oriental conquest. The movement was maritime and European (excluding Russian) power in Asia is based almost entirely on improved navigation. There was no attempt to overwhelm by land invasions, but commerce was combined with territorial acquisition and a continuity of European interest secured by the presence of merchants and settlers. The course of annexation followed the events of European politics and European possessions in the east often changed hands according to the fortunes of their masters at home. Portugal was first on the scene and in the 16th century established a considerable empire on the coasts of East Africa, India and China, fragments of which still remain such as Goa and Macao. Before the century was out the Dutch appeared as the successful rivals of the Portuguese and in 1565

the Spaniards acquired the Philippines, which they held till 1899, when they ceded them to the United States. But the severest struggle for supremacy took place between France and England about 1740–83. Both entered India as commercial companies, but the disorganized condition of the Mogul empire necessitated the use of military force to protect their interests and allured them to conquests. The companies gradually undertook the financial control of the districts where they traded and were recognized by the natives as political rulers. At the end of the Napoleonic wars, Holland had Java, Sumatra and other islands, France some odds and ends in Cochin China and India, while Great Britain emerged with the Straits Settlements, Ceylon and a free hand in India. The East India Company assumed more and more definitely the functions of government, and when, after the mutiny of 1857, it became desirable to define British authority, there seemed nothing unnatural in transferring the entire administration from the company to the Crown.

Other European possessions were acquired towards the end of the 19th century, such as Indo-China (France), Burma (Britain), and Tsing-tao (Germany). Whereas the earlier conquests were mostly the results of large half-conscious movements, these later ones were annexations deliberately planned by European cabinets. It seemed to be assumed that Asia was to be divided among the Powers and each was anxious to get as much as was conveniently possible.

The advance of Russia was different from that of the other powers, since it took place by land and not by sea. Though the extent of Russian territory in Asia is enormous, she has always moved along the line of least resistance. She was a moderately strong empire lying to the north of the great Muslim states and having for neighbours weak principalities and semi-civilized tribes. The conquest of Siberia and Central Asia presented no real difficulties. Persia and Constantinople were left on one side, and Russia mas defeated as soon as she was opposed by a vigorous adversary in the Far East. (C. EL.)

BIBLIOGRAPHY.—It is impossible to refer to all that has been written in the survey reports and gazetteers of the Government of India, or in the records of the Royal Asiatic Society, its branches in Bengal, Korea, Malaya and elsewhere. ASIAGO, BATTLE OF, 1916. The Asiago plateau was the scene of various battles on the Italian front during World War I (*q.v.*); but the more distinctive name of the battle of Asiago was given to the fighting which took place on the Trentino front during the Austrian offensive of 1916.

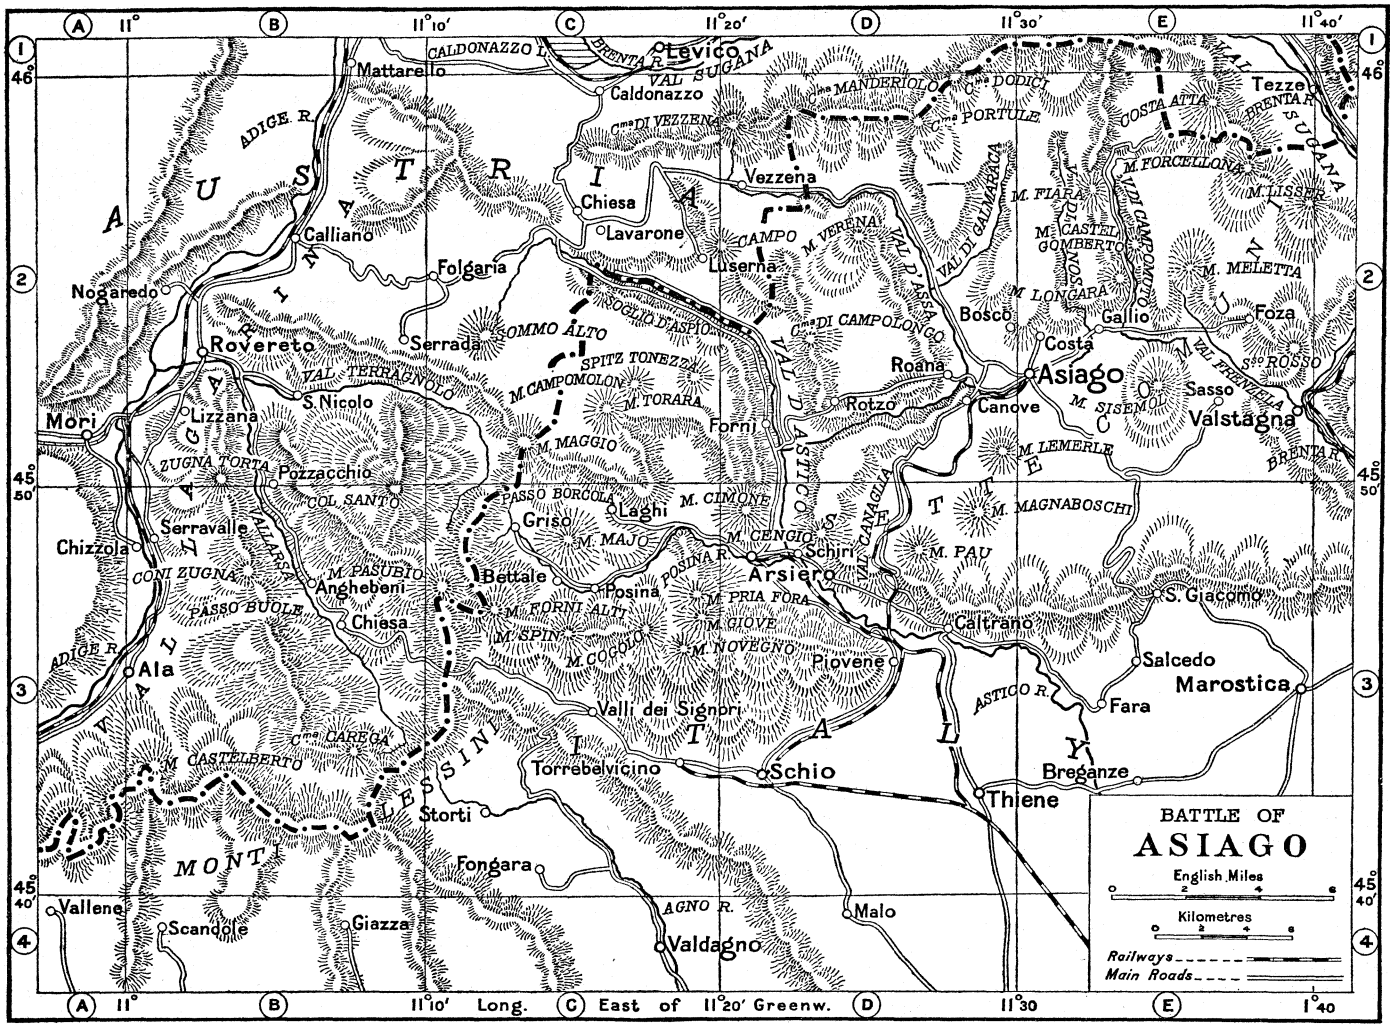
An attack from the Trentino with the object of cutting the Italian communications with the Julian front, and so bottling Cadorna's main force in what Krauss (in his book *Die Ursachen* unserer Niederlage) calls "the Venetian sack," was an operation which could not but commend itself to the Austrian general staff. Even Falkenhayn, who refused his co-operation to the proposal made by Conrad von Hotzendorf in Dec. 1915, admits that "it was very inviting." He did not, however, agree with Conrad and with Krauss, then chief of the staff to the archduke Eugene, that a completely successful attack would have a decisive effect. He doubted the possibility of collecting the force he considered necessary for the enterprise (25 divisions), and did not think that the railway communications were adequate to supply such a force. He was, moreover, anxious about the Russian front. Conrad's plan was to attack through the Asiago and Arsiero uplands, in the direction of Vicenza and Bassano, and when he failed to convince Falkenhayn that the effort should be a joint one, he determined to attack independently.

Cadorna's Plans.—Cadorna's line of argument, when rumours of attack began to arrive, resembled that of Falkenhayn. He did not think that Conrad could spare troops for an offensive on the grand scale, and he was of opinion that the railway communications in the Trentino were insufficient for such an offensive. He concluded that the reported movements in the Trentino signified a limited attack, to be undertaken with the object of hampering his own offensive action towards the east. He had continually urged upon Brusati, who commanded the 1st Army, that his rôle was strictly defensive, now that his first duty, that of reducing the length of the Trentino front and occupying strong defensive positions previously selected, had been successfully performed. On various occasions Cadorna had emphasized the necessity of strengthening the positions chosen by him for defence, but his instructions had been insufficiently regarded and the front was not prepared to resist an attack.

When Cadorna went to visit the lines in person, at the end of April, he found that while the front lines, in many cases unsuitable for prolonged resistance, had been elaborately fortified, in various sectors the reserve lines which he had indicated as the "battle positions" were almost untouched. Cadorna ordered the positions to be modified, and the work of preparation was hastened on; but the enemy attack seemed imminent, and it was impossible to set about a complete reorganization under the immediate threat. On May 8 Brusati was replaced by Gen. Pecori-Giraldi, the commander of the 7th Corps (3rd Army), and within a week the Austrian offensive was launched.

Disposition of Forces.—The Austrian attacking force was arranged in two armies, one behind the other, Dankl's 11th Army in front with nine divisions, Kövess's 3rd Army in support, with five divisions. The troops in the Val Lagarina and Val Sugana were not included in this force, which was to make its offensive between the two valleys, where only supporting attacks were to be carried out. Krauss, as chief of the staff to the archduke Eugene, was opposed to the disposition of the two armies and to the limitation of the attack to the hill country. He urged that the front of attack should from the outset be divided between Dankl and Kövess, and pressed for the concentration of attacking masses in the valleys, especially in the Val Sugana. But the original plan, prepared in all its details by Conrad and his staff, was not modified; it would seem that the archduke and his chief of the staff had little freedom of action. The tactical direction of the attack was entrusted to Dankl, who had at his disposal some 180 battalions.

To meet the attack, Pecori-Giraldi had in line and immediate reserve, between Lake Garda and the Val Cismon (north of the Val Sugana), 130 regular battalions, seven battalions of Customs Guards and 45 battalions of Territorial Militia, the latter at very low strength and of small fighting value. But his centre was weak, for 28 battalions of regular troops were in the Val Sugana sector, and on the actual front of attack he had only 90 regular battalions. Another division was concentrating at Desenzano, and five more were on the Tagliamento ready to be sent in support in case of need. The artillery strength consisted of 851 guns, of which 348 were of heavy or medium calibre and 259 were light guns of position. Dankl had, initially, a big superiority in infantry, but his great advantage lay in his preponderance of artillery strength. Between the Val Lagarina and the Val Sugana were concentrated some 2,000 guns, of which nearly half were of heavy or medium calibre, including 40 305-mm. howitzers, four 380's and two or three German 420's.



THE PLATEAU OF **ASIAGO** SHOWING THE MOUNTAINOUS NATURE OF THE REGION. THE **MAIN** BATTLE LASTED FROM MAY 14 TO 25. 1916. AND ENDED IN THE FAILURE OF THE AUSTRIANS TO BREAK THROUGH THE ITALIAN DEFENCES TO THE PLAINS

Austrians' Attack — The offensive opened on May 14 with a very heavy bombardment along the whole line from the Val Lagarina to the Val Sugana, but the concentration of fire was most intense between the Vallarsa and the Upper Astico, and against this sector, the following day, the main infantry attack was launched. The plan was to attack first with the right wing of the 11th Army, commanded by the archduke Charles, supported not only by its own artillery, but by flanking fire from the massed guns on the Lavarone plateau. When the right wing had made sufficient ground the left wing was to come into action against the Italian line north of the Upper Astico.

For a time everything went well with the attack. The Italians were driven back from their ill-chosen front lines, losing many prisoners and guns, and by May 19 'their position was very grave all along the line from the Vallarsa to the Astico. The retiring troops had failed to make a prolonged stand on the insufficiently prepared battle positions. On the left Monte Pasubio, the key position, was only lightly held by reserves, which had been hurried up in the nick of time, and in the centre the Austrians had driven the defenders off the main line of defence, which ran from Monte Maggio by Campomolon to Spitz Tonezza. The 37th Division, which had held this line, had been forced back beyond the Posina and the Astico, and there were gaps both to right and left of it. The Austrian right was pressing hard on the Italian main positions west of the Vallarsa (Coni Zugna and Passo Buole), and was collecting forces to attack Pasubio. There was breathing space for a moment in the centre, but the Austrian left now came into action, Krautwald von Annan's 3rd (Graz) Corps being launched against the Italian 34th Division. Ample Italian reserves were now on the move, but it was a race. Krauss blames the archduke Charles for waiting with his 20th Corps until the guns could be brought up to support a new attack, instead of driving through at once to Arsiero with all available troops. The risk was not taken, and the short respite gave time to close the door in the face of the invader.

The course of the battle, with the necessity of bringing up reserve divisions, led to a reorganization of the attacking forces, Kovess taking command of the left wing and Dankl of the right. In the Vallarsa and Pasubio sector the attack developed strongly, but without success. Farther north the archduke Charles was waiting for his guns and reserves, and between his left and the 3rd Corps, Kirchbach's 1st Corps was coming into action. The 3rd Corps was hammering against the Italian 34th Division, which was not to resist for long.

The situation in the centre was critical, and Cadorna considered that if the Austrians were able to concentrate on the weak spot and keep up the impetus of their attack they might succeed in breaking through to the plain. On May 20 he went to Udine, and after consultation with the duke of Aosta and Frugoni gave orders for the concentration of a reserve army in the Venetian plain. The first four corps of this reserve army (the 5th), which were made up of units drawn from the 2nd and 3rd Armies, were ready on June 2.

Meanwhile the Austrians were continuing their advance in the centre, but they could gain no ground against the Italian left. By May 22 Bertotti's 44th Division, sent up from Desenzano, was in solid possession of both sides of the Vallarsa road and of Pasubio, and in touch with Ricci-Armani's 37th Division on his left. It was in this sector that the Austrian offensive met its fate. Owing to the steadfast resistance of the troops under Ricci-Armani and Bertotti, Dankl could never secure a sufficient width of front for his ad-

vance. If the Zugna ridge had fallen, the effect upon the Pasubio position, already a salient, would have been more than serious, and upon the holding of the Pasubio lines depended the maintenance of the positions to the eastward. If Pasubio went, the line south of the Posina was turned, and the Austrians had a new route to the plain by the Valli dei Signori, as well as the opening they were now making for, by the Lower Astico. Till May 30 the attacks on the Zugna ridge were continuous, but no progress was made. The attempts upon Pasubio were as incessant, and lasted longer. The Austrian infantry advanced along the great ridge from Col Santo; they came up from Anghebeni and Chiesa in the Vallarsa and from the Val Terragnolo by the Borcola Pass. All efforts were in vain.

North-east of Pasubio, along all the rest of the mountain front to the rim of the Val Sugana, the Austrians gained notable successes. Kovess drove back the Italians across the Val d'Assa, and thence still farther east, across the parallel valleys of Nos and Campomolon. To the south-west Dankl's left crossed the Astico, and after heavy fighting pushed the Italians back across the Val Canaglia, while his centre gained ground across the Posina, south of Arsiero. At the end of May the Italian position still seemed critical, and Cadorna gave orders for the withdrawal of stores and heavy guns from the Isonzo front to beyond the Sile, south of Treviso. He believed he had the measure of the Austrians, but he omitted no precautions. His confidence, in fact, was justified. The impetus of the Austrian attack was dwindling. Losses had been very heavy; the attacking divisions were beginning to lose their offensive value, and the reserves were insufficient. Already on May 27 Conrad had been compelled to ask Falkenhayn to send a division of the Austrian 12th Corps, which belonged to Prince Leopold's Army Group. And Cadorna's 5th Army was practically ready in the plain.

On June 4 Brusilov broke through at Luck. The first news of the Russian attack did not perturb Austrian headquarters, for Conrad thought that his line in the east was firmly held. In a few days the situation was changed altogether. But even before the news of the disaster had reached Bozen it was clear that the offensive against Italy had failed. Kövess was to gain a little more ground. By June 8 the Austrians were only three miles from Valstagna, low down in the Brenta valley, but they had shot their bolt. South of Asiago and south of the Posina the attack was continued for ten more days. Here were the shortest routes to the plain and here the Austrians had been able to bring up their guns in sufficient numbers. Kirchbach made a great effort against the Monte Lemerle-Monte Magnaboschi line, while the archduke Charles strove hard to win room south of Arsiero by incessant attacks in the Novegno sector. No further ground was gained.

The Austrian Retreat. — By the middle of the month Cadorna had begun the first move of a counter-attack, but the Austrians were now getting ready to go out of the salient and back to a strong line which they had already selected. Attacking on May 25, all along the line, the Italians found the invaders in retreat. It was too late to develop the counter-offensive which was to have been directed against the two sides of the Austrian salient, and Cadorna relinquished the idea of a big attack as soon as he found a resistance which could only be overcome by long preparation and the use of artillery in mass.

Casualties on both sides were very heavy, and indicate the severity of the fighting. The Austrian losses were estimated at over 100,000; the Italian figures, up to the end of the counter-movement, were 35,000 killed and 75,000 wounded, with 45.000 prisoners, many of whom should be reckoned among the wounded. The Austrian attempt to break through ended in definite failure but the attack was well planned and conducted with skill and determination. Failure was due to the fact that Conrad met with a resistance which went beyond his calculation. Falkenhayn and Cadorna had summed up the situation rightly.

ASIA **MINOR,** the general geographical name for the peninsula forming the bulk of the republic of Turkey, on the extreme west of the continent of Asia, bounded on the north by the Black Sea, on the west by the Aegean, and on the south by the Mediterranean, and at its north-west extremity parted from Europe only by the narrow straits of the Bosporus and Dardanelles. On the east no natural boundary separates it from the Armenian plateau. The term Asia Minor was not used by classical geographers (it is first found in Orosius in the 5th century A.D.) and is not in local or official use now. The name might have arisen as a vague distinction between the larger continent and the Roman province of "Asia" (*q.v.*), which at one time included most of the western section of the peninsula. Geographically, however, the name has a far deeper significance; the country is but "a small Asia" with its highland interior and its fringe of rich, less arid, well-peopled coastlands. The name Anatolia (*Anadol*) is used locally for the part of the peninsula west of the Halys, *i.e.*, with Cappadocia and Pontus. This name appears first in literature in the work of Constantine Porphyrogenitus (10th century).

A central core of ancient rocks with newer folds rucked round about it, it is comparable in size and structure to the Iberian peninsula, its counterpart in the western Mediterranean. The function of Asia Minor as a great "landbridge" between the continents has made its study important, and from its shorelands from early times Europe has received varied immigrations of men and culture. The interior has been through many changes of fortune which some students are inclined to associate with changes of climate and especially with variations of rainfall.

Structural Features and Mountain Ranges. — The central plateau of Asia Minor consists largely of nearly horizontal strata, while the edges are intensely folded and form mountain ranges allied to the systems of Tertiary date in both Europe and Asia. Tertiary deposits are found both on the coastal lowlands and among the mountains and there are late Tertiary fresh-water strata on the plateau. The southern system of folds forms the great arc of the Taurus with its north-eastward continuation the Anti-Taurus. The Taurus is composed mainly of Eocene and Cretaceous limestones, but Miocene strata also have been markedly uplifted, though they are not deeply involved in the folding. The average height is some 7,000ft. but there are summits above 10,000ft. in both Lycia and Cilicia (Bulghar Dagh). In the Anti-Taurus the folding has affected the Eocene, but not the Miocene, strata. The sharp north-south ridge of the Ala Dagh (11,000ft.) is a conspicuous feature. The name Anti-Taurus is variously used by different authors: (1) some give this name to the northern buttress of the plateau, parallel to the Taurus; (2) for some it means the whole line of heights separating streams running to the Black sea and Anatolian plateau from those running to the Mediterranean and the Persian gulf, *i.e.*, the line from the source of the Kizil Irmak through the Ala Dagh to the Taurus; (3) others use it for bare hills south of Sivas, traceable right along, in more forested heights, to the Taurus. The range of Amanus (Giaour Dagh in the north) is separated from the Taurus and Anti-Taurus line (3rd sense) by the deep valley of the Jihun and its continuation, the Gulf of Alexandretta. It forms the limit between Cilicia and Syria and is highest at Kaya Duldul (6,500ft.) above the Jihun. Groups of volcanic peaks rise above the plateau and extend for about 150m. from Kaisarieh to Karaman, with Argaeus or Erjish Dagh rising above Kaisarieh itself to a height of 13,100ft., the highest point in Asia Minor. The north side of the plateau is formed by the Pontic arcs. Along the eastern arc from Trebizond to Sinope a well defined system includes large amounts of Cretaceous limestones and serpentines, and Oligocene beds are involved in the folds. West of Sinope, Cretaceous beds form a long strip parallel to the shore line, and this system culminates in Ilkaz Dagh, south of Kastamuni.

On the west of the plateau the main direction of folds is east-to-west but, on the borders of Phrygia and Mysia, they meet the north-westward extension of the Taurus folds and bend around the ancient block of Lydia; there are zones of serpentine and of crystalline and schistose rocks, believed to be Palaeozoic, and it is known that portions of the old block are mingled with newer fold schemes on the western coasts. There are many evidences of volcanic activity in the district of Kula and in hot springs con-

nected with the Lycus, Maeander and other valleys. The valleys of the Maeander, Hermus and Caicus communicate between the plateau and the Aegean coast while those of the Kara Su and Sangarius lead to the sea of Marmora, the coast of which continues the Mesozoic band mentioned for the Black sea coasts west of Sinope (see above), but here the rocks are Jurassic and Triassic as well a; Cretaceous. Devonian fossils have been identified near the Bosporus. Marine Eocene beds occur near the Dardanelles but the Tertiary beds of western Asia Minor are mostly fresh-water and late Tertiary; it is interesting that in the west they are much disturbed, as this points to the recent date of important movements in the Aegean area. In this last area we meet with broken mountain arcs that link the Dinaric and Greek mountain lines with those of Asia Minor and partial submergence has brought into existence islands, the disposition of which in chains led them to play a very important part in the early development of maritime intercourse in the 3rd millennium B.C. Here again volcanic activity is conspicuous (Milo, Santorin, etc.), among the fold-lines.

Lakes and Rivers.—The salt lake Tuz Geul (anc. Tatta) on the central plain, said to be 60m. by 10–30m. in winter, becomes a mere marsh in the summer drought. Other salt lakes are Buldur Geul (2,900ft. above sea-level) and Aji-tuz Geul (2,600ft.). Beishehr Geul (anc. *Karalis*) at 3,770ft. is a fine freshwater lake with an outflow stream discharging into the lower Soghla Geul which in its turn loses itself on the arid south part of the plateau. Egirdir Geul (probably anc. *Limnae*) at 2,850ft. is fresh and noted for its fish. In north-west Asia Minor, in the lowlands between the ridges that run out westwards to the south-east coast of the Sea of Marmora, are Isnik Geul (Ascania), Abulliont Geul (*Apol*-Zonia) and Maniyas Geul (*Miletopolis* Lake).

The older drainage of Asia Minor seems to have been westwards towards the Aegean depression, but some phase of this depression was attended by uplift on the west of the peninsula converting the western ends of streams flowing to the Aegean into a plateau-edge drainage, and giving rise to a large lake on the plateau, the remnants of which include the plateau lakes above named and the salt incrustations between Tuz Geul and the stream from Soghla Geul. The subsidence of the Black sea allowed northward streams to cut back into the plateau and the Sakaria (*Sangarius*), the Kizil Irmak (Halys, 600m. long) and Yeshil Irmak (Iris) have captured portions of the old east-to-west drainage. The depression between the blocks of Arabia and Asia Minor has analogously helped the Euphrates to cut back and capture a part of the east-to-west drainage. Old names include *Tembris* (Pursak Su), a tributary of the Sangarius; *Cappadox* (Delije Irmak), a tributary of the Halys; and the Lycus (Kelkit-Irmak), a tributary of the Iris.

Of the western plateau-edge drainage one should mention Edrenos Chai (anc. *Rhyndacus*), and Susurlu Chai (*Macestus*), which unite 12m. before they flow into the sea of Marmora; Bigha Chai (*Granicus*), which flows into the west of the Sea of Marmora; and Menderes Su (*Scamander*), which reaches the Dardanelles. The last two rise in Kaz Dagh (Mt. Ida). Bakir Chai (Caicus), Gediz Chai (*Hermus*), Kuchuk Mencleres (*Caystrus*) and Menderes Chai (Maeander) flow to the Aegean and bring down so much silt from the plateau edge that, for example, the Caystrus silt has filled up the port of Ephesus; while the Hermus has changed its course more than once, for as recently as 1880 it reached the sea near Smyrna, but now follows a parallel valley farther north. The silt of the Maeander long ago filled up the harbour of Miletus and converted its islands into mounds standing out of a swamp. The chief tributary of the Hermus is Kun (*Phrygius*), which receives Gurduk (*Lycus*) and Kuzu (*Cogamus*); those of the Maeander include, on the right, the *Glaucus,* Banaz (*Senarus*), and *Hippurius,* and on the left, Churuk Su (*Lycus*), flowing by Colossae, Ak (*Harpasus*) and China (Marsyas).

The southward drainage to the Mediterranean works back along structural lines of the Taurus fold mountains and is thus varied in its directions, but it consists mainly of rather short streams which flood down quantities of water in winter and spring. They are probably helped also by subterranean drainage. In Lycia are the Gereniz Chai (*Indus*) and the Eshen (*Xanthus*); in Pamphylia the Ak Su (*Cestrus*), Keupri Su (*Eurymedon*) and Menavgat Chai (Melas). Farther east the two branches of the Geuk Su (*Calycadnus*) run south-east between lines of the Taurus. The Tersous Chai (Cydnus) has three streams, one of which flows through the Cilician Gates; in its lower course it deposits so much silt that Roman Tarsus is covered to a depth of 20 feet. The Sihun (*Sarus*) and its tributaries flow through precipitous ravines in the Taurus, and one of the tributaries (Kerkhun Su), cutting back westwards through the Bulghar Dagh, opens a way for the roads from the Cilician Gates to Konia. Apparently at one time the Sihun flowed south-eastwards to join the Jihun (*Pyramus*). This river is made up of a number of streams and in its lower course runs through the defile between the Taurus and the Giaour Dagh to reach the Cilician plain near Budrun, whence it flows west and south-west to the sea past Missis, being navigable up to this point. East of the Kezil Irmak and the Jihun basins we enter that of the Euphrates.

Passes.—Over the principal passes of the Taurus there went Roman or Byzantine roads:—(I) from Laodicea to Adalia (Attalia), by way of the Khonas pass and the valley of the Istanoz Chai; (2) from Apamea or from Pisidian Antioch to Adalia, by Isbarta and Sagalassus; (3) from Laranda by Coropissus and the upper valley of the southern Calycadnus to Germanicopolis and thence to Anemourium or Kelenderis; (4) from Laranda by the lower Calycadnus to Claudiopolis and thence to Kelenderis or Seleucia; (j) from Iconium or Caesarea Mazaca through the Cilician Gates (Gulek Boghaz, 3,300ft.) to Tarsus; (6) from Caesarea to the valley of the Sarus, and thence to Flaviopolis on the Cilician plain; Germanicia (Marash) is the name of this pass.

In the Anti-Taurus region (in the sense of the ranges from south of Sivas down to the Taurus), the chief passes are those followed by old roads: from Sivas (Sebasteia) to Divrik (*Tephrike*) and the upper valley of the western Euphrates; from Sivas to Malata (*Melitene*) by the pass of Delikli Tash and the basin of the Tokhma Su, and from Kaisarie to Marash (*Germanicia*) by the Kuru Chai and the valley of Geuksun (*Cocysus*). The Giaour Dagh (*Amanus* Range) is crossed by two famous passes:—Baghche (*Amanides* Pylae), with the road from the Cilician plain to *Apamea Zeugma* on the Euphrates, and Beilan (Pylae Syriae or Syrian Gates), with the Roman road from Tarsus to Syria.

The valleys of the Maeander, Hermus and Caicus give ways from the plateau to the Aegean and the descent to the Sea of Marmora along the Kara Su and Sangarius is easy. The best roads from the plateau to the Black sea are those due to the Romans, from *Tavium* and Sebasteia to *Sinope* and *Amisus* and those from *Sebasteia* to Cotyora and *Cerasus-Pharnacia.*

The subterranean drainage, added to the tectonic instability, accounts to some extent for the number of thermal and mineral springs. The most important are:—Yalova, in the Ismid sanjak; Brusa, Chitli, Terje and Eskishehr, in the Brusa vilayet; Tuzla, in the Karasi; Cheshme, Ilija, Hierapolis (with enormous alum deposits), and Alashehr, in the Aidin; Terzili Hammam and Iskelib in the Angora; Boli in the Kastamuni; and Khavsa, in the Sivas. Many of these were famous in antiquity and occur in a list given by Strabo. The Maeander valley is especially noted for its hot springs.

Climate, Vegetation and Animal Life.—The north coastal regions have a very heavy rainfall, especially during the autumn and winter. The rainfall here is lightest in the west but increases to over 100in. per annum in the more mountainous east. The high ground behind the patches of coastal lowland has forests of pine, fir, cedar, oak and beech, while the more sheltered valleyways have very luxuriant vegetation resembling the Mediterranean flora. West of the promontory of Sinope the vegetation tends to be poorer and the olive in particular is not found. East of Sinope, where the Caucasus shelters the coast from the cold north-east winds of the Russian steppe, the olive grows abundantly and the vegetation is more luxuriant. The apple, pear, cherry and plum are grown extensively in northern coastal Asia Minor. The wheat of the Sivas vilayet is well known.

The southern and western coasts have a Mediterranean climate, with a tendency towards greater extremes of temperature than is the case further west. The summers are warmer and drier, with less rain, and there is greater cold in winter than on the French or Italian Riviera. A great feature is the *inbat* or strong north wind which blows fiercely almost daily from noon to sunset off the sea in summer along the west coast. Cold winds from the Russian steppe are felt as far south as Smyrna in winter. The fig, olive and vine are grown everywhere, while on the west coast the ilex, plane, oak, valonia oak and pine predominate. The mountain slopes of the Taurus are clad with forests of oak and fir and there are numerous *"yailas"* or grassy "alps" with abundant water to which the villagers and nomads move with their flocks during the summer months. The sheltered southern valleys produce the orange, lemon, citron, sugar cane and date palm.

The interior plateau region is more allied to the Russian steppe in both climate and vegetation. The rainfall is slight, being less than 10in. per annum on an average, and what rain occurs falls in spring or early summer. The seasonal range of temperature is extreme, conditions becoming more continental towards the Armenian Highlands in the east, which experience a heavy snowfall in winter. Near streams willows, poplars and chestnut grow, but elsewhere the country is almost entirely steppe or scrubland.

The wild animals include the bear, boar, chamois, fallow, red and roe-deer, gazelle, hyena, ibex, jackal, leopard, lynx, moufflon, wild sheep and wolf. Amongst domestic animals are the buffalo, the Syrian camel, and a mule camel bred from a Bactrian sire and a Syrian mother. A large number of sheep and Angora goats are reared on the plateau, and fair horses are bred on the Uzan Yaila, while small hardy oxen are largely bred for ploughing and transport. The larger birds are the bittern, great and small bustard, eagle, francolin, goose, partridge, sand grouse, pelican, pheasant, stork and swan. The rivers and lakes are well supplied with fish. (X.)

ETHNOLOGY

Ethnologically Asia Minor forms a unit with Arabia, and the latter country will therefore be treated with the former in the present article.

Owing to the important ancient empires which flourished in the Near East this region has in places been thoroughly explored, and although much remains to be done, there are already abundant materials for reconstructing the racial history. Asia Minor remains at present the least known country.

Zumoffen found near Antioch skeletal remains which are alleged to be Neanderthaloid, although no complete report has yet been published. Turville-Petre found in a cave near the Sea of Galilee the remains of a skull which, though differing in certain respects from the Neanderthal clearly belongs to this type. The Mousterian culture associated with this type of man is widely spread throughout the region, and has been proved by Buxton to extend even into the desert regions between the Jordan and the Euphrates, although no remains of man have actually been found in the valley of the twin rivers; either they are covered by living on the high desert which to-day is only penetrated at certain seasons by Bedouin. Palaeolithic implements of a later date are also found in the same regions, but none have so far been found in the valley of the twin rivers; either they are covered by silt or else the region was at this early period too marshy for habitation. The earliest type of man known in this area comes from graves of about 3,000 B.C., a type which in form is almost identical with the people who were living in Europe in Aurignacian times and who survive to-day in remote places, Fleure having found them on the Plynlimmon moorland. This very long-headed, slender stock still forms to-day the main part of the Arab population of much of the Near East. Two other types appear in early times in northern Mesopotamia and over all the northern part of the Near East, one type identical with what is usually called "the Mediterranean race." They are long-headed but their skulls are much more round in contour than the Eurafrican type mentioned above. The third type is round-headed and has been called Armenoid owing to the prevalence of this type among the modern Armenians. They are especially associated with the bridgeland of mountains which stretches from the Pamir westwards into Asia Minor, and ultimately to the Alps. Von Luschan considered that they were the oldest inhabitants of Asia Minor, and though they may have been the first dwellers in the mountains they were certainly late comers into the plains. On the whole the racial history of the entire region has consisted of the gradual blending of these three stocks since the dawn of history, but the Armenoid types have probably increased in a larger proportion than the others.

The modern populations consist of different groupings of these main racial stocks and can be most conveniently divided partly on a geographical and partly on a political and linguistic basis. There are four main areas: first, Turkey, including Turkey proper, Armenia and Cyprus; secondly, Syria and Palestine; thirdly, Mesopotamia; and fourthly, Arabia. Within these larger areas the most important groups may be summarized as follows: in the first, Turks, Greeks, Kurds, Armenians and various religious communities, who are endogamous and often keep themselves apart from the rest of the population. In Syria and Palestine, although there are representatives of the groups already mentioned, the three most important groups are the Jews, Arabs and again certain important religious communities, the most noticeable being the Druses and Maronites of the Lebanon district. In Mesopotamia the bulk of the population are Arabs, although there are important racial differences.

Apart from aberrant groups there are several different forms of social organization, the dividing lines cutting across one another. On a basis of religion there is a profound cleavage between Muslim and Christian, though even here there are certain intermediate people, Linobambakoi, Linsey-woolsies, who to a certain extent show, at least on the surface, the characters of both. Environment and natural surroundings have been practically responsible for three types of social organization, urban, common to Jew, Christian and Muslim, agricultural also common to the three though to a lesser extent to the Jews, except in ancient and in very modern times, and pastoral nomadism, practised almost entirely by the desert and steppe dweller. The Muslim communities are, at least in theory, polygamous, though polygamy is becoming increasingly uncommon. The women were secluded and never saw any men except their husbands and their immediate relations, though naturally among the poorer classes this rule did not hold, for they had to work in the fields or go to market. As a general rule the towns are mixed, though different religions have different quarters, both mixed and pure Turk or Christian villages exist, and in Palestine there are Jewish communities. In the desert the group of tents is organized on a war footing in which the sheikh has an absolute position, unlike the position of the elected or appointed village elder. Among the more powerful tribes the groups are organized into a single unit, this unit being not infrequently at war with its neighbours. This region gave birth to three of the great religions of the world, Christianity, Judaism and Islam. It still is the home of innumerable heretical cults of all these three religions. They have all influenced one another, and some of the sects partake of the nature of more than one of these mutually intolerant religions. Of these heretical sects the most interesting are the various crypto Christians, outwardly Muslims, secretly Christians, the Druses and Maronites, the Dancing Dervishes, the Yezidis or Devil worshippers and the Babis.

ARCHAEOLOGY

Continued study at Hissarlik, and at Yortan, 160km. to the S.E., has shown the long life of Hissarlik I and the continuation of its culture by the larger Hissarlik II. Alişar-höyuk, 160km. N.E. of Ankara (Angora), has early settlements with black pottery, later replaced by red ware mhich came in with Aegean figurines from Hissarlik. Alaça-höyuk, further north, has rich

early graves with internal wooden constructions like those of S. Russian kurgans; they yield black ware though red had come into use in the locality.

Kusura, south of Afion-Karahissar, gives analogous evidence. Mersin, in Cilicia, is the latest (1939) site to acquire importance, and here, beneath a layer of 3500–3000 B.C., is an enormous accumulation of settlement debris, suggesting a very high antiquity, and relationships with both western Anatolia and Mesopotamia.

THIRD MILLENNIUM B.C.

Anatolia.—Probably as early as the epoch of the Agade dynasty (28th century), Anatolia was invaded by Semites from Syria, who there founded a permanent colony, whose archives dating from the last centuries of the 3rd millennium have been discovered at Kül-Tepe, near Kaisaryieh. A text, half historical, half legendary, belonging to the days of Sargon the Old (c. 2800), describes a campaign of this king from the other side of the Taurus in order to help a colony engaged in commerce. which complained of oppression at the hands of the inhabitants of the country. These archives consist of cuneiform tablets, letters and contracts, relating to the commercial undertakings of the great merchants of the district. They are written in the ancient Assyrian language; the writing resembles that used at the time of the Ur dynasty (25–24th centuries). An impression of a cylinder seal bearing a dedication to King Ibi-Sin of this dynasty, gives the earliest date of these tablets for it seems probable that this ancient seal was in long use, and that most of the tablets only date from c. 2100. Side by side with the Semitic names of the members of this colony appear those of the inhabitants of the country. They are Asianics of the type called "protohittite," speaking the dialect in use in Anatolia before the supremacy of invaders of Indo-European stock, who established successfully the Hittite confederation of the 2nd millennium B.C. On these tablets the impression of Asianic seals appears along with that of seals of the Semites of Cappadocia. The Asianic seals are flat, usually circular, of slight dimensions, ornamented with the heraldic eagle, with ornamental designs based on animal motives, with concentric circles or with spirals. The Semitic seals are cylindrical, and, retaining the complexity of Sumerian art, by which they are inspired, represent the combat of the hero Gilgamesh with wild beasts, animals crossed in an X, a divinity seated on a chariot, and the adoration of an idol in the form of a bull. So single great monument can be attributed either to the Semites of Cappadocia or to the Asianic peoples who were their contemporaries.

Troy II.—The excavations on the hill which bears the famous city of Troy (Hissarlik) were begun by the German, Schliemann, assisted by Dorpfeld, in 1870, and were continued intermittently until 1894, on the site of nine successive cities, of which only two are of real importance: Troy II., discovered by Schliemann and wrongly regarded as the Troy of Homer, which belonged to about 2400–1900 B.C., and Troy VI., discovered by Dorpfeld, which is really the Troy of Homer (1500–1180). The second Troy, which was destroyed by fire, had foundations of stones joined by a mortar of clay, on which rose walls of rough bricks with wood supports. The town was surrounded by a rampart with towers. At Troy II. appeared vases with human figures, and pitchers with vertical and elongated lips. Rich jewels, discovered by Schliemann in a hiding place, and erroneously described as "the treasure of Priam," comprise golden diadems with many small chains finished off with the simplified image of an idol, earrings of the same metal and technique, libation vases, one of which is in gold and is shaped like a sauce tureen with two handles. There are also flat bronze axes with widened edges, bronze knives and daggers, together with stone weapons, sometimes sumptuously set in a metal mount. The antiquities of Troy II. show that it spread copper, red ware, etc., to the Aegean and acquired thence ideas of marble figurines, stone vessels, and various ornaments. Its relations with Cyprus, which became important for copper, are becoming clearer, but the links by land with south-east Europe and with Anatolia now stand out

SECOND MILLENNIUM B.C.

The Hittites.— The interior of Asia Minor was at this epoch under the influence of the Hittites, whose ancient capital Khattushash (Boghaz Keui), flourished in the second half of the 2nd millennium. Many monuments of Hittite origin are spread over the whole of the peninsula, and as a whole, with one or two exceptions, belong to a very homogeneous art, which is sober, if somewhat crude. with traces of oriental as well as of Aegean influence.

Troy VI.—The sixth city of Troy which, as Dorpfeld recognized, is the Troy of Homer, was destroyed about 1180. The ruins of Troy VI. amount to very little, for when the Romans built on the site, they razed the top of the hill to obtain a large oval base for their structures and destroyed all the buildings of the VI., VII., and VIII. cities; nothing remains of Troy VI. but a few foundation-elements on the slopes of the hill below the Roman levelling. A part of the rampart four or five metres thick is a strong fortification flanked by towers, with three gates of a more modern type than in the earlier buildings. At Troy, as at Tiryns and Mycenae, no enemy could reach the gates without exposure on a portion of the rampart, which made defence easier. What pillage and fire left unhurt was destroyed by the Romans, and of the Troy of Homer there remains little to-day save memory.

FIRST MILLENNIUM B.C.

The empire of Boghaz Keui had been destroyed by the Sea peoples, but its artistic traditions were carried by the Mushki people, perhaps akin to the Phrygians, occupying the territory of which Boghaz Keui was the centre, then by the Phrygians, whose kingdom corresponded to the country situated to the west of the area occupied by the Hittites of Boghaz Keui, by the Lydians, the Carians and the Lycians.

The **Mushki.**—At the beginning of this period Hittite influence is still dominant. Art, however, displayed a decadence, which showed itself in a grossness of shape and a general clumsiness, as in a certain number of the sculptures at Üyük, the basreliefs on rocks at Bor and Ivziz (north of the Taurus), representing a local king before his god. These sculptures typify the transition from those of Anatolia under the Hittite empire to those of Syria of the 1st millennium B.C.

Phrygia and Lydia.— The most important Phrygian monuments are funerary and fall into two principal groups. The first is in the neighbourhood of the town of Ayazinn, the second to the north of it. To the first group belongs the tomb, called the tomb of Midas, in which the facade hewn out of the rock itself is a great flat surface, divided in the form of a cross into equal parts, surrounded by regular scrolls in relief. The facade is surmounted by a triangular pediment slightly raised, crowned by a double scroll. In the lower part of the façade a false door is carved. This arrangement appears also in a monument in the valley of Thyndakos, called the Delikli-tash (the pierced stone). The real entrance to such tombs was in the upper part. They consisted, therefore, of shafts sunk in the rock itself, the external face of which was ornamented. Sometimes these monuments were purely commemorative and consisted of the single facade sculptured from the rock, in the style of the monument of Midas. The group of tombs situated near Ayazinn are not distinguished from the first group; they have the same facades with geometric ornamentation in relief, with or without a false door, and surmounted by a triangular pediment more or less raised. In certain cases the scheme of shafts has not been adopted, and the door, in that case a real one, gives access to the tomb. Resides the geometrical type of decoration, a naturalistic and very effective one exists. Thus in the necropolis of Ayazinn a rock-face shows half way up the door of a tomb. On either side gigantic lions, cut out of the living rock, stand erect, facing each other, their forepaws resting on the top of the door. This motive of lions guarding the tomb is found on other monuments of the necropolis. Quite a different type of tomb (at Ayazinn, at Yapuldak, at Gherdek-kaïa-si) shows Greek influence in its facades, columns and decorative ornaments;

these are the most recent of all the series, which belong, without doubt, to the period between the 8th and 4th centuries B.C.

In Sipyle, near Smyrna, another kind of tomb is to be found, a tumulus; the most celebrated is the so-called tomb of Tantalus, easily comparable to those in Lydia, where very few specimens remain except of funerary architecture. The type of tumulus tomb is due to Thracian influence. The finest monument of this kind is the tomb of Alyattes, the father of Croesus, near Sardis. It consists of a funerary chamber sunk into a circular base made of stones and earth, and surmounted by a cone of worked earth. A pillar with an expanded base should adorn the summit. This type of tumulus tomb occurs frequently in this area, most of them dating perhaps from the beginning of the 6th century B.C. The coins, however, and the jewels found in Lydia, at Tralles, for example, display also Eastern influences, chiefly Assyrian, with occasional use of Egyptian designs. Decorative Lydian art manifests individual taste, but situated like that of Phoenicia, was similarly subject to varied influences at that epoch.

Lycia.—In funerary architecture, Lycia draws its inspiration chiefly from Phrygia in the arrangement of the tomb; carved out of a rock wall itself. But the style is quite different; generally the artist reproduces the front of a wooden house with projecting beams, in which the jutting ends have been intentionally preserved. This scheme is found in the tombs of Kenibachi, Hoïran, A-Myra and Antiphellos; the façade is surmounted by a triangular pediment in the second case, arched in the first; a scheme which is found in the so-called Lycian sarcophagus in the royal necropolis of Saïda.

THE GRAECO-ROMAN EPOCH

During the last centuries of this millennium and the first centuries of the Christian era, Greek and Roman influence became predominant in the country. There are, therefore, changes in the character of the monuments. The art, which at first was purely oriental, then hellenized, gives place to Graeco-Roman art, and can be distinguished from that of the continent only by its oriental exuberance of detail, this being the case also at this time in Syria.

Assus.—Among the principal ruins of the Aegean coast and its neighbourhood, we must cite in going from north to south: Assus, facing the north-eastern point of the island of Mitylene, built on terraces cut into the side of a hill, where an agora, a theatre, a gymnasium and a street of tombs have been unearthed. The sculptures of Assus use the Dorian order, but in a hybrid form, a feature not found in Asia Minor except at Pergamus. The temple, of which nothing remains but the bare surface of the stylobate, dates probably from the middle of the 5th century.

Pergamus.—At the junction of the Selinus and the Caicus, is the ancient capital of a State, which became independent of the Macedonian empire of Alexander's successors, and which maintained its independence from 220 to 133 B.C. The German excavations at Pergamus have revealed baths, amphitheatre, theatre, an *asklépieion*, and on the Acropolis, the agora and gymnasia, remains of the sanctuary of Athene Polias and of the temple of Trajan and Hadrian.

Ephesus.—The Austrian and the British excavations have laid bare the great monuments of the city, the agora, baths, library, theatre, gymnasium and porticos. At the Odéon a long portico of 23 columns, the bases of the columns still occupying their original positions, and several of their capitals, decorated with bulls' heads have been found. The most celebrated monument of Ephesus is the Artemision, the temple of Artemis. The old temple was built in the 6th century B.C., on the site of three previous sanctuaries; it was burnt in 356, rebuilt and finished at the end of the 4th century.

Priène.—In the deep valley of the Maeander German excavations have revealed a hellenistic city with streets cut at right angles; the theatre, the sanctuary of Demeter and the temple of Athene Polias, built in 334 B.C., are still to be seen. These ruins show us what was the type of hellenistic city in Asia Minor.

Miletus, near Priène, explored by the Germans, the most luxurious town of Ionia, possessed four gates, which have been partly cleared by the excavations. Its theatre is one of the most beautiful buildings of its kind. On a hummock near the town have been found traces of an earlier Miletus, destroyed by the Persians in 494 B.C.

Didyma is situated near Miletus; the French, and then the Germans, have made excavations there, which have brought to light the remains of the oracular shrine of Apollo; begun at the end of the 4th century B.C., it was not finished at the beginning of the Christian era. It was a long building surrounded by columns (122 in all) which were more than 20 metres high, only three of which remain standing. The sculptures on the door leading from the naos to the cellar are an indication of the richness of the ornamentation of this temple. "The way of the Branchides," ornamented with the statues of priests of that name, leads from the temple to the sea.

Halicarnassus, to the south of Miletus, was the capital of a small State, which became independent under Mausolus, a Persian satrap. The British Museum possesses important fragments of the famous tomb (from which the word mausoleum is derived) which was raised by his widow.

SYRIA: THIRD AND SECOND MILLENNIUM B.C.

Byblos.—The excavations of M. P. Montet at Byblos (Djebail to-day, 30km. to the north of Beyrouth) have thrown some light on the archaeology of Phoenicia at the dawn of history. About 3000 B.C. the kings of Egypt maintained regular relations with Byblos; they held in peculiar veneration the local goddess of the place, the "Baalat Gebal," *i.e.*, the "Lady of Byblos," and sent her offerings. In 1926 a piece of an alabaster vase was found bearing the name of Khufa, the Pharaoh who built the Great Pyramid of Giza (c. 30th century B.C.).

During the 2nd millennium B.C. relations between Egypt and Phoenicia had not lessened in any way; Virolleaud and Montet have discovered at Byblos a hypogeum of the local kings, contemporary with the Pharaohs of the 12th dynasty. The king of Egypt was then overlord of the city; he sent presents, such as perfume vases made of obsidion set with gold, to the local petty kings, who, in imitation of Egypt, had made locally breast-plates in cloisonné, or in wrought gold. They wrote their names clumsily in Egyptian hieroglyphics on the arms, which were the insignia of their authority (that called the *harpé* is of Babylonian origin, and the ancestor of the oriental scimitar).

Kafer-ed-Djarra.—In the vicinity of Sidon, at Kafer-ed-Djarra, several burial areas have been excavated, first by Dr. Contenau and then by M. Guigues. The tombs, in the form of a baker's oven, contain a great deal of pottery. A 12th dynasty Egyptian faience balsam vase was discovered there, as well as scarabs of the Hyksos type, with an imitation of Egyptian wax in which designs derived from the spiral play a large part. Further, many types of pottery, some Egyptian, but more often copies of Aegean pottery, have been found there.

The Tomb of **Ahiram.**—Another hypogeum, also discovered at Byblos by M. P. Montet, dating from the end of the 2nd millennium B.C., contains a sarcophagus with the oldest Phoenician inscription known at present, in the name of Ahiram, a vassal of the Pharaoh. The tomb of Ahiram represents on its four sides funeral scenes in a border of lotus blossom; the bearers of offerings for the dead and the lamenting mourners. A certain number of objects found in the tomb, bearing the name of the Pharaoh, Rameses II., give the date of the tomb of Ahiram and its inscription as the 13th century B.C. This date has been disputed; but even if it should be ascribed to the extreme end of the millennium (and indeed it cannot be later), the inscription still remains the oldest in the Phoenician language known up to the present time.

Kadesh, **Mishrifeh.**—The explorations of Pézard on the site of Tell-Nebi-Mend, near Homs, the ancient Kadesh, a strong place of the Hittites against the Egyptians, came to a premature end owing to the death of the excavator, and nothing has been done at Homs itself, at Damascus or at Aleppo, which, history tells us, passed under Hittite dominion in the 1st century of the 2nd millennium B.C. The researches of Du Mesnil du Buisson at

Mishrifeh, in northern Syria, near Homs, show that Egyptian influence (a sphinx of the 12th dynasty has been discovered there) had reached there. Cuneiform tablets record the inventory of the treasures of the Mesopotamian goddess, Ninegal, who had a sanctuary there, and from them we learn that the old name of the site was Katna. Mesopotamian influence can be traced also in several monuments at Mishrifeh (heads of statues) and at Damascus and its neighbourhood (the lion of Cheik-Saad in the museum of Damascus, a bas-relief of Salihiyeh representing a warrior, in the British Museum). Eut it is by no means the only influence. The Anatolian art has had an effect, and for this reason the term Syro-Hittite must be given to this art. This corresponds to historic fact, for the Hittites in the 2nd millennium had settled in Palestine. This view is strengthened by the great number of cylinder seals of the period found in this region. Their general style is a development of the style of the Cappadocian cylinders; on profound examination they betray the distant influence of Sumerian art; but in detail—the types, attitudes, costumes of the people—they continue the tradition of Boghaz Keui.

FIRST MILLENNIUM B.C.

The Interior of Syria: Zendjirli, Carchemish, Tell-Halaf. —German excavations at Zendjirli (the old kingdom of Samal) to the north-west of Aleppo near the Amanus, and the British work at Carchemish on the Euphrates, which after the fall of Boghaz-Keui was the capital of the new Hittite confederation, have produced some important inscriptions and have reconstituted the art of the Arameans. Here Hittite and Mesopotamian influences contend. A type of city based on a circular plan, surrounded by one or several walls has been revealed. In these are found *bit-hilani* (Assyrian for these buildings), which are more wide than deep, with steps and a peristyle with columns and often flanked by two square towers. In conformity with technique found in Assyria, the courts and halls of the palace are decorated with plinths of carved stone, representing mythological scenes, lines of palace guards, or winding processions. Roaring lions guarded the doors. But this art is earlier than the glorious Assyrian period, for it starts with the beginning of the 1st millennium and is distinguished from the Assyrian by the use of basalt, and by a vigorous, bold, almost primitive, style, where massiveness is compensated by sincerity. This art, in comparison with the Assyria of the Sargonides, is provincial, but its date makes it independent of Assyria. It is related in a general way, though not directly, to the art of Boghaz Keui. Some of the oldest sculptures, those of Üyük for example, explain this art of upper Syria at the beginning of the 1st millennium, though there is missing the translation in relationship with the Hittite art of Anatolia of the 13th century. The German excavations of von Oppenheim at Tell-Halaf (on the Chabur) have revealed monuments of the same style, the most vigorous being the oldest; others, which are analogous to the most recent specimens from Zendjirli, exhibit in decadence the formula, of which they are the extreme branch in the direction of Assyria.

Phoenicia.—The majority of the Phoenician monuments which have come down to us date from the 1st millennium, and to a large extent from the middle of it, when Persian rule was established in the country. We learn from this epoch the funerary art of the Phoenicians, and as a result of Renan's mission we also possess several ruins of their temples. Interment is usually made in vaults, to which access is by an upright square shaft. The sarcophagi are plain stone cases, with a lid having a slightly shelving ridge. Certain Sidonian monarchs, Tabnit and his son, Eshmunazar, were interred in Egyptian sarcophagi, which shows how great the influence of Egypt (5th century B.C.) still was in Phoenicia, In imitation of these sarcophagi, of which the first is in the museum of Constantinople, and the second in the Louvre, the Phoenicians cut sarcophagi out of marble from the islands in the shape of a mummy case, with the head raised in high relief on the cover. These are known as the "anthropoid" sarcophagi (5th and 6th centuries). They were buried in the true subterranean dwellings, to which access is by shaft, or often, more conveniently, by stairs. Such necropoli are found all along the coast, notably at Sidon, at Tortose (Tartous) and Amrit. In this last necropolis there are still vestiges of the commemorative monuments which the Phoenicians placed in their tombs; they are cylindrical in shape with a rounded end.

To the same epoch date the foundations of temples, which prove the continuity of the Semitic worship in this area. At Amrit, in a great court a small *naos* (shrine) is cut out of the rock itself, showing that it was a place of worship. At Sidon, on the side of a hill on a terrace overlooking the river, are the ruins of a temple, dedicated to Eshmun, the Phoenician Aesculapius. The most important Phoenician inscriptions, found in Phoenicia itself, come from Sidon and from the dynasty to which Tabnit and Eshmunazar belonged. We may conclude that Phoenician art, in the course of its history, remained under the direct influence of the conquerors and of the countries with which Phoenicia had intercourse. Phoenician art is a compound of Egyptian, Aegean and Mesopotamian motives, which local artists have utilized and combined with real taste.

The Sarcophagi of **Sidon.**—As forming a link between the art of the East and that of the Graeco-Roman period the sarcophagi, discovered in the hypogeum, where Tabnit was buried, may be mentioned. Though of a more recent period, they belong entirely to Greek art. These sarcophagi, rightly famous, are in the museum of Constantinople. The most famous is termed the "Sarcophagus of Alexander," not because that monarch was buried there, but because his effigy is reproduced among the sculptures of the bottom part. It is made of Pentelian marble. The artist has depicted on the sides scenes of battle and the chase, in which the Macedonian conqueror is taking part. The sculptures have an admirable finish and style, and were originally enlivened with touches of colour. It dates from the end of the 4th century B.C. and has a lid in the form of a roof, ornamented at the four corners with small recumbent lions. Of the other sarcophagi of this series, which, though bearing no name, to judge by their richness must surely have sheltered the sovereigns of Sidon, the sarcophagus known as the "Lycian" is made of sculptured marble (c. 400 B.C.), while that called "the Satrape," which depicts some man of rank inspecting his horses, or taking a part in a banquet, or at a hunt, is dated to the middle of the jth century. A third, known as "The Weepers," represents a temple in outline, with columns between which are mourners in the funeral procession of the dead man (middle of the 4th century). Therefore, at least from the Persian epoch, oriental art in Phoenicia was in competition with Greek art, which little by little was to oust it.

The Graeco-Roman Period.—From the beginning of this era it is no longer necessary to draw distinctions in Syrian art between the region of the interior and that of the coast. The whole country was under Graeco-Roman influence, and art was permeated with it in varying degrees. The great Syrian ruins date from this age, such as the old temple of Boetocécé (called to-day Hosn Suleiman) on the road from Tripoli to Hamah, a vast enclosure of Semitic type, restored in the 1st century A.D. (The original enclosure was left open to the sky.)

Baalbek.—Here in the ancient Heliopolis, situated on the line from Rayak to Homs, are the remains of two great temples with their adjoining buildings, constructed within an enclosure of high walls, some of the stones being of gigantic size. The propylaea led to a hexagonal court 60 metres in diameter, at the end of which was the temple of the sun. Nothing remains of it but the foundations and six tall columns. In front of the temple was a sacrificial altar and basins for lustral water. Theodosius, at the end of the 4th century A.D. partly demolished the temple in order to build a church, itself ruined. At the side of the Temple of the Sun is a smaller sanctuary called the Temple of Bacchus, doubtless because one of the doors is decorated with vines. It was probably dedicated to Atargatis, the goddess spouse of the chief god of Heliopolis. It is in better preservation than the Temple of the Sun. The rich floral decoration used by the artists of Syria and Palestine in their profuse ornament of the buildings constructed at this epoch is very conspicuous here.

Palmyra, situated in an oasis, about 85m. east of Homs, was *an* important town at the time of the Assyrian empire (7th century B.c.), but its splendour dates from the and, and still more from the 3rd century A.D., when, under Queen Zenobia, it was the head of an immense empire. The temple of "the sun" presents many analogies with that of Baalbek, and is surrounded in the same way by walls. Other monuments of less importance, temples, a theatre, and in particular a colonnade, in which a number of the columns are still standing, are decorated as lavishly and richly as those at Baalbek. Most of the treasures from Palmyra, now in museums, come by reason of their funerary practices. The custom of placing in the tombs the bust of the dead in high relief, accompanied by an epitaph, produced an easy form of sculpture of beautiful decorative effect, which is a good source of information as to the dress and the customs of the people. (See PALMYRA.)

At the beginning the temple of Jupiter at Damascus (later the church of St. John and then the mosque of Ommeiádes) must have been a magnificent building. The court of the present mosque corresponds to the temple enclosure, which was formerly set in a still greater enclosure, which to-day is entirely covered by buildings, nothing remaining except the ruins of the gates.

Doura.—After the occupation of Mesopotamia by English troops, on the edge of Syria, at Salihiyeh on the Euphrates, to the north-west of Abou Kemal, in 1920, were discovered the remains of the old city of Doura-Europos (1st century A.D.), which Breasted and Cumont have partially explored. The excavations have uncovered a building ornamented with precious frescoes, representing a sacrifice offered by a dignitary of the town, surrounded by all his followers, and a sacrifice offered to the local goddess, Fortuna of Doura and Palmyra, by the Roman legion which was in garrison there (3rd century A.D.). These paintings exhibit the influence of Palmyra (perhaps the artist was a Palmyrian) and afford interesting evidence of the influence which oriental art, as known through the important works at Palmyra and Doura, had on Byzantine art. From the beginning of the 1st millennium A.D. a number of funerary monuments have been found, sarcophagi, statues in Graeco-Roman style, tombs painted with frescoes, especially near Sidon, and finally a marked preference for the use of mosaic. A good example is the mosaic of Kabr Hiram discovered by Renan near Tyre, and a funeral stele with portraits of the deceased found on the outskirts of Sidon in 1914 and now in the museum of Beirut.

The Christian Epoch *in* Syria has left an appreciable number of monuments. In the north the most celebrated is the monastery of Qala'at Semân on the road from Aleppo to Alexandretta, where St. Simon Stylites lived. The church was built, undoubtedly, at the beginning of the 6th century, a little time after the death of the saint. It is composed of a central octagon, 30 metres in diameter: an essentially Syrian arrangement, making the centre of a cross. Not far from Qala'at Semân are the ruins of Tourmanîn, a church of the 6th century, and a large two-storied building for the use of pilgrims.

At El-Barah, near the caravan route from Hamah to Aleppo, and at Serdjilla, an hour's distance away, many houses of the jth century are still in an admirable state of preservation. They were abandoned at the time of the Arab occupation. They owe their preservation to the fact that stone was used almost entirely in their construction. Beautiful specimens of Syrian silver work of this period, chalices, vials for holy oil, vases, sumptuous bookbindings of the Gospels, belonging, many of them, probably to the middle of the 6th century, are to be seen in the important museums.

HISTORY

Asia Minor has been known from the earliest period as a battleground between the East and the West. The central plateau with no navigable rivers and few natural approaches, its monotonous scenery and severe climate, is a continuation of Central Asia. The west coast, with its fertile valleys and fine climate, is almost a part of Europe. These conditions are unfavourable to permanence, and the history of Asia Minor is that of the march of nomad tribes and colonists, and of the rise and fall of small states.

About 1950 B.C. western Asia Minor appears to have been held by the 1st dynasty of Hittites (*q.v.*), with their capital at Kushara (?). Two centuries later Aryan races seem to have invaded the country and imposed at least their language on the Hittites, who about 1500 B.C. emerged suddenly as a powerful empire at Hati (Boghaz-Keui of to-day, Greek Pteria), ruling over Asia Minor and fighting the Egyptian Pharaohs for the mastery of Syria, and Assyria for the mastery of Mittani (Jernblus).

The Hittite sculptures and inscriptions have been found in their own capital at Boghaz-Keui and at various places between Smyrna and the Euphrates.

This Hittite empire was overthrown by Indo-European races, possibly Greeks, who, crossing the Hellespont from Europe to Asia, with their iron weapons defeated the Hittites possessing only bronze weapons. These Indo-European races established many colonies all along the Aegean coast and in the hinterland, from which arose the Phrygian kingdom. Traces of this kingdom remain in various rock tombs, forts and towns, and in legends preserved by the Greeks. In the 8th century B.C. the Cimmerians coining from Armenia overran the Phrygian kingdom, and on its decline rose the kingdom of Lydia, with its centre at Sardis. A second Cimmerian invasion, followed later by Cyaxares, almost destroyed the rising kingdom, but the invaders were stopped by Alyattes (617–586 B.C.; see SCYTHIA). The last King Croesus (?560–546 B.C.) carried his boundaries to the Halys, and subdued the Greek colonies on the coast. These flourishing Greek colonies formed a chain of settlements extending from Trebizond to Rhodes. Too jealous of each other to combine, and too demoralized by luxury to resist, they fell an easy prey to Lydia. After the capture of Sardis by Cyrus, 546 B.C., these colonies passed to Persia without resistance. Under Persian rule Asia Minor was divided into four satrapies, but the Greek cities were governed by Greeks and the tribes in the interior retained their native princes and priest-dynasts. The conflicts between Persians and Greeks are told in the article GREECE: History. Beginning with Darius' attempt to conquer the European, as well as Asiatic, Greeks, they ended in **334** B.C. when Asia Minor was invaded by Alexander the Great. (See GREECE; PERSIA; IONIA.)

After the death of Alexander various *diadochoi* (succession rulers) established their rule over various parts of the peninsula.

Rhodes became a great maritime republic. The Ptolemies of Egypt ruled over the Mediterranean coast of Asia Minor. A small independent kingdom was founded at Pergamum 283 B.C., which lasted a century and a half. Bithynia became an independent monarchy, Cappadocia and Paphlagonia tributary provinces under native princes. In the south the Seleucids founded Antioch, Apamea, Attalia, the Laodiceas and other cities as centres of commerce, some of which afterwards played an important part in the Hellenization of the country and in the spread of Christianity. During the 3rd century B.C. certain Celtic tribes crossed the Bosporus and established their power in districts between the Sangarius and Halys, called Galatia. Its capital was at Ancyra—the modern Angora, the capital of republican Turkey.

The defeat of Antiochus the Great at Magnesia, 190 B.C., placed Asia Minor at the mercy of Rome, but it was only in 133 B.C. that the first Roman province, Asia, was formed to include the western Anatolia. Under Mithridates the Great (*q.v.*) Pontus rose into a formidable power; but he was driven from his country by Pompey and died in 63 B.C. The Romans organized the peninsula into various provinces, leagues and almost independent principalities, and under their dominion Asia Minor developed and became prosperous. At the end of the 3rd century A.D., in reorganizing the empire, Diocletian broke the great military commands and united the provinces into groups called dioceses. A great change followed the introduction of Christianity, which gradually spread over the region. The seven Christian Churches of Asia Minor were built up in this period.

When the Roman empire mas divided into two in 395, Asia Minor fell to the Eastern Roman empire with its capital at Constantinople; the native languages and old religions partly disappeared and the country was thoroughly Hellenized. At the close of the 6th century Asia Minor had become wealthy and prosperous, but centuries of peace and over-centralization produced a state of affairs which is embodied in the term Byzantine. The vigorous Persian monarch Chosroes II. (Khosrau) invaded Asia Minor from 616 to 626 and pitched his camp on the Bosporus. The emperor Heraclius, however, restored the Byzantine power by marching his army to Kurdistan; but soon after the Arabs entered Asia Minor, and in 668 A.D. laid siege to Constantinople. For the following three centuries Byzantium and the caliphs of Baghdad waged occasional warfare for the mastery of the bridgeheads of the Euphrates and the Cilician gates. But a more dangerous enemy was soon to appear from the East. In 1067 the Seljuk Turks ravaged Cilicia and Cappadocia; in 1071 they defeated and captured the emperor Romanus Diogenes; in 1080 they took Nicaea. One branch of the Seljuks founded the empire of Rum with its capital at Iconium. During the 12th century a number of Seljuk Atabeks ruled in different districts of Asia Minor; the Mamelukes of Egypt in Syria and farther East; Greeks in Pontus, Armenians in Cilicia, Danishmends (an Armenian family) at Sivas, Bayandurs (a Greek family) at Erzerum, etc. The Mongols swept the whole region and in 1243 subdued the Seljuk sultan of Rum. In the ensuing struggle for power among the Turkoman tribes, the Osmanli Turks eventually assumed supremacy and established their state at Brusa. In 1400 Sultan Bayazid I. held almost all Asia Minor west of the Euphrates. But he was defeated and imprisoned by Timur, who swept through the country to the shores of the Aegean. On the death of Timur, the Osmanli power was re-established after a prolonged struggle which ended with the annexation by Mohammed II. (1451–81) of Karamania and Pontus. The later history of Asia Minor is that of the Ottoman empire. The Turks have dominated Asia Minor since in the widest sense, until their supreme power was challenged in 1832 by an Egyptian army under Ibrahim Pasha, and their rule shattered in the World War.

The devastation of Asia Minor, initiated by the Seljuk hordes in the 11th century, was followed by a long succession of nomad Turkish tribes. The latter did not ill-treat the native people; but as they passed onwards they left the country bare and desolate. Whole provinces passed out of cultivation and the natives, taking to the mountains or to towns, abandoned their lands to these nomads, who replaced wheeled traffic by the pack horse and the camel. The native peasants were thus forced to be nomads themselves. The Mongols, as they advanced, sacked towns and historic monuments; they razed to the ground even mounds and "all that might serve as a place of armed resistance." Timur conducted his campaigns with a ruthless disregard of life and property. Entire Christian communities and almost all who attempted any self-defence were massacred; flourishing towns were completely destroyed and all Asia Minor was ravaged. From these disasters the country never recovered, and many traces of Hellenic civilization disappeared with the enforced use of the Turkish language and the wholesale conversions to Islam under the early Osmanli sultans.

In modern times, Asia Minor slowly recovered under western influences; but the construction of railways and the consequent growth of trade and local industries were seriously interrupted by the disaster of the World War. When the Turks signed the Armistice on Oct. 30, 1918, they were utterly beaten. The British armies had captured all the Arab-speaking lands of Asia Minor. In May 1919 a Greek army seized Smyrna and most of the Ionian coast and gradually extended its occupation to Eski-Shehir (the ancient Dorylaeum) and Afiun-Karahissar. At one moment it was thought that the Hellenic civilization was again rising in its historic centres.

The Treaty of Sèvres (*q.v.*), signed by the Turks in Aug. 1920, reduced Asia Minor to its geographical and ethnic boundaries as it had been established by five centuries of Turkish domination. Great Britain assumed the mandates of Palestine and 'Iraq, and France that of Syria. Meanwhile Great Britain, France and Italy had signed a tripartite agreement, by which they divided south and south-eastern Asia Minor into spheres of influence. The Turkish nationalist movement, however, led by Mustapha Kemal Pasha soon reasserted itself. The Turks drove the French from Cilicia and the Greeks from Smyrna. The Treaty of Sèvres was not ratified and was superseded by the Treaty of Lausanne (July 1923) which left Turkey absolutely sovereign in Asia Minor in the narrow sense. After the suppression of the sultanate in Nov. 1923, soon followed by that of the caliphate, Turkey declared itself a republic' with its capital at Angora.

Under the auspices of the Allied Powers and in conjunction with the Treaty of Lausanne a convention for the exchange of populations was signed between Turkey and Greece, by which about one million Greeks, the oldest civilized natives of western Asia Minor, were driven from their ancestral homes and lands and transferred to Greece and Macedonia, thus wiping out the last traces of Hellenism in Anatolia.

ASIANIC **LANGUAGES.** The languages described as Asianic were spoken in Asia Minor by non-Hellenic peoples before the arrival of Greek, by which most of them have been slowly ousted or absorbed. The term is purely geographical and comprises a number of ancient languages, of different families and modes of writing whose only common feature is their obscurity. They are mainly (1) recorded in cuneiform, as Sumerian (*q.v.*), Hittite Cassite, Vannic and Elamite; or (2) languages whose name alone survives, as Pisidian, Lycaonian, Cappadocian, Paphlagonian, Phrygian (an Indo-European language); and (3) the speech of the peoples of the coast of Asia Minor, Mysian, Lydian (Maiones), Carian and Lycian (Termiles), recorded by alphabets akin to or derived from the Greek.

Mysian.—According to Herodotus the Mysians were related to the Carians and Lycians, and of their speech we have only three glosses surviving on which no conclusions can be based.

Lydian.—Excavations conducted by the American school, 1910–13, produced numerous inscriptions dating from the 5th and 4th centuries B.C. written in an alphabet closely resembling

the Greek, usually from right to left. Mostly funerary inscriptions, they contain with variations the common formula—"This is the tomb of X son of Y. May he who damages it be punished by the divinity, himself and his family." We have a few short bilingual (Greek and Lydian) inscriptions and one (Lydian-Aramaic) dating 45j or 394 or 349 B.C. which, despite many obscurities, is the basis of our decipherment and interpretation. We have a fairly accurate knowledge of Lydian, although the value of some signs is problematic and the greater part of the vocabulary remains unknown, while the longest texts available, metrical inscriptions from Sardis, are still a riddle.

Phonetics.—Lydian has the vowels, a, e, *i,* o and *u;* nasalized vowels *ã, ẽ;* an aspirate h, two *l*'s, one plain and one rolled, two series of occlusives, surd and sonor, with an absence of aspirated occlusives. There are accumulations of consonants due perhaps to habits in writing or perhaps indicating a modification of the short vowels, possibly the result of accent.

Grammar.—Nouns seemingly have two genders and three cases in the singular, less certainly in the plural. The nominative masculine and feminine in the singular is *-s* for roots in *-i* and *-ś* in others. The oblique case (dative and perhaps locative) is *-λ* and the accusative *-n* as also probably the oblique plural. Demonstratives and adjectives have the case forms as the nouns to which they belong. Thus the demonstrative es- is in the masculine-feminine nominative es-S which becomes *eśś;* in the neuter it is es-d becoming est; thus we have *eśś vãnaś,* this tomb, and *est mrud,* this monument. In all genders the form es λ is used in oblique cases. Possession is indicated by an adjective in *-l-* which can be associated with the oblique case form *-λ* and takes the same case forms as the noun. Thus *vãnaś* Atalis, the tomb of Atas. Verbal forms are less clear. Lydian seems to have had a third person singular form in *-d* and a third person plural form in *-ent.* The numerals are not known. The post-position *-k* means 'and' as *-c* in Etruscan. Negative forms are *nik . . . nik,* neither . . . nor, and a negative or indefinite element *nã-* combines with the pronoun pis, *pid* forming *napis, napid* somebody, something. The alternative *buk* means or, and the conditional form is ak in the protasis, sometimes. lengthened to akit or by adding *it-in* to *aktin,* while fak, then, introduces the leading element in the apodosis. The order of words is subject, verb, object. The exact meaning of individual words is not known save in a few cases such as the words for tomb, monument, court, house, water, fire, priest, divinity, destroy, with a certain number of words explained by glosses.

Carian.—Our knowledge of Carian rests on about 80 small inscriptions recorded in an alphabet containing several signs identical with Greek forms. The earliest date from the middle of the 7th century B.C., and three are bilingual, Egypto-Carian. Decipherment is still uncertain, and the meaning of a large number of the signs is conjectural despite the work of Sayce. Herodotus mentions the tradition that the Carians were once the inhabitants of the islands. Sundwall with some probability relates Carian to Lycian. The evidence is, however, based on place-names and on the glosses recorded mainly by Stephen of Byzantium. The material does not enable us to verify the association of Carian with Cretan or the relationship of Carians to Mysians and Lydians.

Lycian.—Discoveries made over the last century from 1811 onwards have brought to light about 150 inscriptions dating from the 5th and 4th centuries B.C. written in an alphabet of Greek origin, which come mainly from Limyra, Xanthos, Myra, Pinara and Tlos. Nearly all are funeral inscriptions and uniform in purport and language except the second part of the long stele of Xanthos and the inscription of Antiphellos which are metrical in an archaic, perhaps different, dialect and much more obscure. A few very short and varying bilingual (Greco-Lycian) inscriptions give some help towards interpretation.

Phonetics.—Lycian possessed as vowels, a, e, *i* (marked *ϵ*), *u* (marked *o*), nasalized vowels *ã, ẽ,* sonants *w* and y, a series of occlusives in frequent alternation, like *l* and *r,* sign *m̃* and *ñ* whose value is doubtful, two spirants, *x* and *θ,* two sibilants s and *z* and the aspirate *h.* An equivalence of e, a, or a is found but not explained. A few signs have not been surely identified.

Grammar.—Two genders seem to have existed with a declension with a nominative, an oblique case in *-i* (plural *-e*) and an accusative with nasalization. The possessive of the 1st person is emi or mine. The relative is ti. In the verb the singular third person was, it seems, *t* or d, and the third person plural was *nt* and there was a vowel conjugation, the timbre of the vowel varying with the variations of time. The usual negative form is ne, *ni.* A certain number of words have been elucidated by the bilingual inscriptions so that the meaning of certain phrases can be established with some accuracy, although it is as yet impossible to deal satisfactorily with the larger inscriptions.

Affinities of the Asianic Languages.—As to the relationship of these languages to one another, all that can be said is that they have certain identical tendencies in pronunciation, in nasalized vowels, which prove nothing, some grammatical coincidences (accusative in -n; verb forms for the third person in *-t* and *-nt*) which are of little aid. Neither Lydian nor Lycian display any certain marks of relationship. Their vocabularies are very different, a fact which does not prevent their having a common origin. Too little is known of Carian, which must be omitted, and as regards Lydian and Lycian such facts as we have do not as yet indicate a close affinity. Fundamental resemblances have been found between Lydian and Indo-European, such as case forms, the adjectival concord, the system of relative and demonstrative pronouns, the verbal forms for the third person, singular and plural, the negative forms. On the other hand, not one Lydian word has a clear Indo-European origin and the oblique case in X- is definitely alien to Indo-European declension though known in Etruscan and the southern Caucasus. Lycian has similar but less numerous points of likeness and many features in it are common in Etruscan (*q.v.*), such as a large number of proper names, some words and elements of common derivation. If these languages are really to be regarded as related and if we may apply to them the term "Asianic family," which is probable, though not proved, their position with regard to Indo-European languages may be that they have retained some features of their common origin but have from early times diverged independently; similarly as regards the relationship with Etruscan and the southern Caucasus, unless the features shared with these languages are accidental. But before this or any other hypothesis can be taken as beyond doubt, more investigations are necessary.

ASIENTO or **ASSIENTO,** a Spanish word meaning a farm of the taxes, or contract. The word acquired notoriety on account of the "Asiento Treaty" of 1713. After the establishment of the Spanish Bourbon dynasty in 1700, a French company was formed which received the exclusive privilege of the Spanish-American slave trade. At the peace of Utrecht the British Government claimed the monopoly. The Asiento Treaty (March 16, 1713) accordingly authorized British subjects to introduce 144,000 slaves in the course of 30 years, at the rate of 4,800 per annum and to send one ship of 500 tons per annum, laden with manufactured goods, to the fairs of Porto Bello and La Vera Cruz. This privilege was conveyed by the British Government to the South Sea Company, and formed the solid basis of the fit of speculative fever called the South Sea Bubble (*q.v.*). Until 1739 the trade in blacks went on without interruption, but amid increasingly angry disputes between the Spanish and the British Governments. The right to send a single trading ship to the fairs of Porto Bello or La Vera Cruz was abused. Under pretence of renewing her provisions the ship was followed by tenders loaded with goods, and thus arose what was in fact a vast contraband trade. The smugglers were guilty of many piratical excesses, and the Spanish revenue officers acted often with violence on mere suspicion, After many disputes,

war was declared in 1739. When peace was made at Aix-la-Chapelle (*q.v.*), in 1748, Spain undertook to allow the asiento to be renewed for the four years which were to run when war broke out in 1739. But the renewal for so short a period was not considered advantageous, and by the Treaty of El Retiro of 1750, the British Government agreed to the recession of the Asiento Treaty altogether on the payment by Spain of £100,000.

"AS IF," THE PHILOSOPHY OF. The expression was coined by Hans Vaihinger and applied to his own system of philosophy, according to which all human knowledge, all explanations in the realm of science, philosophy, law, religion, etc. are merely so many fictions or assumptions which tell us that the things or events, etc., referred to are or behave "as if" they had such or such a character, or "as if" they had been produced in such and such a way. Thus, for instance, in physics the conceptions of ether, electric fluid, etc., are merely fictions which facilitate our grasp of the transmission of certain forms of energy "as if" there were such a medium as ether, or an electric fluid, etc. In law a company is treated "as if" it were a person. In morals and religion certain imperatives of conduct are conceived "as if" there were a God, a hereafter, and rewards and punishments, etc. Vaihinger does not regard these fictions as deliberate fictions or mere make-beliefs. His contention rather is that human knowledge, be it pursued never so earnestly, is at best only a series of fictions, or "as ifs," by which man with his finite capacities endeavours to make the world intelligible to himself so as to feel at home in it.

The philosophy of "as if" traces its descent from Kant, through Lange (the historian of materialism) and Nietzsche. Kant, by limiting human knowledge to phenomena, that is, to things as they appear to man, not as they are in themselves, and by regarding human knowledge as moulded by certain a *priori* forms innate in the human mind, obviously, if unintentionally, gave an impulse to the philosophy of "as if." Nietzsche promptly pointed out that other beings than man may have other a priori forms of apprehending reality, and that the human forms of apprehension instead of revealing the true nature of reality may only conceal it in order to make human existence tolerable. The whole philosophy of "as if" may be regarded as one expression of the sceptical and agnostic tendencies of the age, of which pragmatism and hominism are other expressions.

See H. Vaihinger, *The Philosophy* of *"As if"* (English trans., 1926).

ASIOLI, BONIFACIO (1769–1832), Italian composer. A child prodigy, he had already written three masses and much other music by the time he was eight. In 1808 he was made censor of the Milan conservatory, and in 1810 he entered the service of the Empress Marie Louise of France, remaining until the fall of the empire. Besides his music, he wrote *Principi elementari di musica* (1809), which was reprinted six times and translated into four languages.

'ASIR, a district of West Arabia between 17° 31′ and 21° N. and 40° 30′ and 45° E.; bounded north by Hejaz, east by Nejd, south by Yemen and west by the Red Sea. Apart from Rub' Al Khali no district of Arabia is less known to Europeans who have only visited As Sabya and a few places near the coast. It consists of a maritime plain with an average width of 25 mi. rising gradually to the foot of a mountain range, whose eastern flank falls to a highland plateau merging gradually with the steppes of Nejd. It is about 230 mi. long and 180 mi. broad. Its mountains contain a number of fertile valleys and coffee is cultivated on its mountain slopes as in Yemen. Kunfuda, Jizan and Maidi are the most important of many petty ports on the Red sea, and As Sabya is the lowland capital (and residence of the Idrisi ruler), as Abha (or Ibha) is that of the highlands. Wadis Bisha, Ranya and Turaba, each with a considerable population, are the principal valleys of the eastern plateau, while Khamis Mushait and Wadi Shahran are among the most notable in the highlands. The population is a hardy race of mountaineers with a tendency towards Wahhabi fanaticism, while the principal element in the east is the Qahtan tribe centring on Ranya. The Turkish occupation of 'Asir was never very effective beyond the coast, though Turkish expeditions penetrated the country frequently between 1814 and 1837 and garrisons have been maintained in a desultory fashion at Abha and Rhamis Mushait. The Idrisi dynasty of Sabia and Abu Arish is of comparatively recent advent to the country, its founder, Said Ahmad, having established himself in the latter part of the 19th century with a doctrine akin to that of the Sanusis of North Africa. Under Said Mohammed 'Asir first acquired political importance, his rebellion in 1911 against the Turks having with Italian assistance achieved a measure of success. From 1915 he was in treaty relations with Great Britain and in 1920 occupied Hudaida after the departure of the temporary British garrison. In 1920 the Wahhabis occupied Ibha and all upland 'Asir, while Imam Yahya recovered Hudaida in 1921. The following year Said Mohammed died and his son, 'Ali, proving incapable of maintaining his position, fled the country in 1925. His uncle, Hasan, in 1926 placed his remaining territory under a Wahhabi protectorate by formal treaty, under which he was appointed governor of the province for life. The Farisan islands off the coast belong to 'Asir and came into prominence owing to the grant by the Idrisi in 1926 of an oil-prospecting concession to a member of the Shell group. There has been much unrest on the southern boundary of 'Asir, in dispute with the Imam, but the steady extension of Ibn Sa'ud's effective administration of the province exercised a calming effect on the tribes of the border.

ASISIUM: *see* ASSISI.

ASKALON, now a desolate site on the sea-coast 12m. N. of Gaza and about 3m. from El-Majdal on the Kantara-Jerusalem railway. It occupies a rocky amphitheatre embracing about ¾m. of shore with traces of an old harbour in the south-west corner. Protruding from this sand-swept terrain shattered columns and the remnants of ruined buildings and broken walls bear ample testimony to a past magnificence. The site is studded with wells (*θαυμαστὰ φρέατα* Origen c. Cels. IV. 44), and the ruins are interspersed with gardens which belong to the inhabitants of the neighbouring village of El-Jōrah. The country around is fertile. Vines, olives, and a variety of fruit trees flourish. Its most characteristic product, however, is the onion Ascalonia *coepa* whence Ital. scalogno, Fr. *échalotte,* Eng. *shalot.* Its wine and its henna were renowned of old.

History.— In the Amarna letters (c. 1400 B.C.) Askalon is one of the cities which write to the Pharaoh for help against the Habiru. Also it would appear that Askalon was leagued with Gezer and Lachish against Abd-Khipa the pro-Egyptian ruler of Jerusalem. In 1285 B.C. Rameses II. took Askalon by storm. The scene is depicted on a wall of the Ramesseum at Thebes. In 1223 B.C. certain Palestinian cities, amongst them Askalon, revolted against their overlord, Merneptah, to their own undoing. "Carried off is Askalon" sings the Egyptian poet laureate of the period. Askalon is not mentioned amongst the cities of Judah in Joshua XV. and it appears as Philistine from the days of Samson to the Hellenic age. In 701 B.C. it fell to Sennacherib. About 630 B.C. the Scythian invasion engulfed Palestine and Herodotus tells us of their sack of the temple at Askalon. With the conquest of Alexander the city became Hellenized and following his time its fate as a tributary was determined alternately by Egypt and Syria. Although a stronghold of Hellenism it prudently opened its gates to Jonathan the Maccabee (147 B.C.) and later to Alexander Jannaeus. It was the birthplace of Herod the Great who adorned it with fine buildings. During the Roman period it was a noted centre of Hellenic scholarship. It became also the seat of a bishopric. From 104 B.C., for four and a half centuries it was an *oppidum liberum* of the Roman empire. In A.D. 636 it passed into the hands of the Arabs. During the Crusades Askalon was the key to south-west Palestine. In 1099 its gates were shut against the defeated Egyptian host and the panic-stricken refugees from fallen Jerusalem. Over 30,000 are said to have perished at that time beneath its walls. When eventually Askalon was taken after a six months' siege by Baldwin III., its capture completed the Frankish conquest of the country (1153). In 1187 it was retaken by Saladin after but feeble resistance. The approach of Richard Coeur de Lion, fresh from his triumph at Acre, caused Saladin to burn the city and demolish the defences (1191). The English king promptly set about their restoration with zeal, but under the terms of the truce arranged with Saladin the following year the

walls were once more destroyed and the city abandoned. In 1240 Richard of Cornwall began the task of rebuilding, but the city was captured in 1247 by Fakhr ed-Din. Finally Sultan Beibars, in accord with his scheme of defence, destroyed the fortifications in 1270 and blocked the harbour with stones.

Excavations.— In 1815 Lady Hester Stanhope employed from 100 to 150 men for several weeks excavating, but with no scientific method, a part of the site. After a preliminary survey in 1913, the Palestine Exploration Fund commenced their post-war campaign here (1920–23) under the supervision of Garstang and Phythian–Adams. Herod's cloisters—the "court surrounded by columns" of Josephus—have been exposed and a number of statues, amongst them one of Isis-Tyche, recovered. The remains of a Byzantine theatre, which has proved to be an earlier senate house converted to this purpose, have been revealed. A statue of Peace was discovered close to the mouth of a well, probably the "Well of Peace" familiar from the description of Antoninus Martyr (A.D. 560–570). The stratification of the site has been determined and a date of about 1800 B.C. for the earliest traceable habitation established. Sufficient supplies of pottery, etc., have been unearthed in the appropriate stratum to enable experts to recognize a distinctive Philistine handiwork. The Palestine Department of Antiquities has established here a local museum.

Phythian-Adams, "History of Askalon," *P.E.F.Q.S.* pp. 76 *ff.* (1921); Reports on the Excavations in *P.E.F.Q.S.* for the years 1921 to 1924.

ASKAULES, probably the Greek word for bag-piper, although there is no documentary authority for its use. Neither it nor ἄσκαυλος (which would naturally mean the bag-pipe) has been found in Greek classical authors, though J. J. Reiske—in a note on Dio Chrysostom, *Orat.* lxxi. ad *fin.,* where an unmistakable description of the bag-pipe occurs ("and they say that he is skilled to write, to work as an artist, and to play the pipe with his mouth, on the bag placed under his arm-pits") —says that ἀσκαύλης was so used.

ASKE, ROBERT (d. 1537), English rebel, was a country gentleman who belonged to an ancient family long settled in Yorkshire. In 1536 Aske led the insurrection called the "Pilgrimage of Grace." Marching with the banner of St. Cuthbert and with the badge of the "five wounds," he occupied York on Oct. 16, and on the 20th captured Pontefract Castle, with Lord Darcy and the archbishop of York, who took the oath of the rebels. He caused the monks and nuns to be reinstated, and refused to allow the King's herald to read the royal proclamation, announcing his intention of marching to London to declare the grievances of the commons to the sovereign himself, secure the expulsion of counsellors of low birth, and obtain restitution for the church. Aske, followed by 30,000 or 40,000 men, marched on Doncaster, where lay the Duke of Norfolk with the royal forces, which, inferior in numbers, would probably have been overwhelmed had not Aske persuaded his followers to accept the King's pardon and the promise of a Parliament at York, and to disband.

Aske then went to London under the guarantee of a safe-conduct and was well received by Henry. He put in writing a full account of the rising and of his own share in it; and fully persuaded of the King's good intentions returned home Jan. 8 1537, bringing with him promises of a visit from the King to Yorkshire, of the holding of a parliament at York, and of free elections. Shortly afterwards he wrote to the King warning him of the still unquiet state not only of the north but of the midlands, and stating his fear that more bloodshed was impending. The same month he received the King's thanks for his action in pacifying Sir Francis Bigod's rising.

But the new rising had given the court an excuse for breaking off the treaty and sending another army under Norfolk into Yorkshire. Possibly in these fresh circumstances Aske may have given cause for further suspicions of his loyalty, and in his last confession he acknowledged that communications to obtain aid had been opened with the imperial ambassador and were contemplated with Flanders. In any case Aske was persuaded to go to London on false assurances of security. He was arrested in April, tried before a commission at Westminster, and sentenced to death for high treason on May 17; on June 28 he was taken back to Yorkshire, being paraded in the towns and country through which he passed. He was hanged at York in July, expressing repentance for breaking the King's laws, but declaring that he had promise of pardon both from Cromwell and from Henry. Aske was a real leader, who gained the affection and confidence of his followers.

Rev.,* v. 330, 550 (account of the rebellion, examination and answers to interrogations); *Chronicle of Henry VIII.,* tr. by *M.* A. S. Hume (1889); Whitaker's *Richmondshire,* i. 116 (pedigree of the Askes).

ASKED PRICE, the price which the owner of any property places upon it for the purpose of sale. A prospective buyer will usually make an offering price or "bid" at a lower figure. When the bid and asked price coincide, either through the purchaser's raising his offer to meet the asked price, or through the seller's reducing his asked price to meet the bid, or by a compromise price somewhere between the two, a sale may be consummated. On the stock and produce exchanges bid and asked prices are regularly quoted on all items, and such quotations are carried in the financial reports of the daily papers, on the ticker systems, and in other financial information media.

ASKEW or **ASCUE, ANNE** (1521?–1546), English Protestant, born at Stallingborough about 1521, second daughter of Sir William Askew (d. 1540) of South Kelsey, Lincoln. She came to London and made friends with Joan Bocher, who was already known for heterodoxy, and other Protestants. Anne was examined for heresy by the lord mayor (March 1545), then by Bishop Bonner, and then (June 13 1545) brought up as a sacramentarian at the Guildhall. These efforts having failed, she was brought on June 18 1546 before a special commission without jury and without witnesses, and was condemned, on her confession, to be burnt. On the following day she was racked, and after four weeks in prison was burnt at Smithfield (July 16).

It is probable that the pertinacity displayed against Anne was due to the desire of the reactionary party to intimidate Hertford and Catherine Parr who were suspected of sympathy with her.

BIBLIOGRAPHY.—Bale's two tracts, printed at Marburg in Nov. 1546 and Jan. 1547, are the basis of Foxe's account. *See* also *Acts of the Privy Council* (1542–47), pp. 424, 462; Wriothesley's *Chron.* i. 155, 167–9; *Narratives of the Reformation,* passim; Gough's *Index to Parker Soc. Publications;* Burnet's *Hist. of the Reformation;* Dixon's *Hist. of the Church of England; Dict. Nat. Biog.*

Her torture, disputed by Jardine, Lingard and others, is substantiated not only by her own narrative, but by two contemporary chronicles, and by a contemporary letter; *ibid., Narratives of the Reformation,* p. 305; Ellis, *Original Letters,* 2nd ser. ii. 177.

ASMA'Ī, Abd al-Malik ibn Kuraib (c. 739–831), Arabian scholar, was born of pure Arab stock in Basra and died in Baghdad. He became tutor to the son of Harūn-al-Rashīd, and acquired property in Basra, where he again settled for a time. Asma'i was one of the greatest scholars of his age. While Abū 'Ubaida followed (or led) the Shu'ūbite movement and declared for the excellence of all things not Arabian, Asma'i was the avowed supporter of the superiority of the Arabs over all people, and of the freedom of their language and literature from all foreign influence. Of Asma'ī's many works mentioned in the catalogue known as the *Fihrist,* only about half a dozen are extant. Of these the *Book of Distinction* has been edited by D. H. Miiller (1876); the *Book of the Wild Animals* by *R.* Géyer (1887); the *Book of the Horse,* by A. Haffner (1895); the *Book of the Sheep,* by A. Haffner (1896).

For life of Asma'i, *see* Ibn Khallikān, *Biographical Dictionary,* translated from the Arabic by M'G. de Slane (1842), vol. ii. pp. 123–127. For his work as a grammarian, *see* G. Flügel, *Die grammatischen Schulen der Araber* (1862).

ASMARA, the capital of the Italian colony of Eritrea, north-east Africa. It is built on the Hamasen plateau, near its eastern edge, at an elevation of 7,765ft. It is some 40m. W.S.W. in a direct line from the seaport of Massawa but 75m. by railway. (The line from Massawa, which had reached Ghinda, at the foot of the plateau, in 1904, was completed to Asmara in 1912.) Pop.

(1939) 85,000, of whom 50,000 were Italian. The natives are Abyssinian. The European quarter contains several fine public buildings. Fort Baldissera is built on a hill to the south-west of the town and is considered impregnable.

Asmara (Amharic, "good pasture place") is an old town. It was in the maritime province of northern Abyssinia, governed by the Bahar-nagash (ruler of the sea). By the Abyssinians the Hamasen plateau was known as the plain of the thousand villages, of which Asmara was one of the most prosperous, and it grew through being on the high road from Axum to Massawa. The Franco-German War (1870) killed a project of W. Munzinger French consul at Massawa, to annex the Hamasen to France (cf. A. B. Wylde, *Modern* Abyssinia, 1901). In 1872 Munzinger, now in Egyptian service, annexed Asmara to the khedivial dominions, but in 1884, owing to the rise of the Mahdi, Egypt evacuated her Abyssinian provinces and Asmara was chosen by Ras Alula, the representative of the negus Johannes (King John), as his headquarters. Shortly afterwards the Italians occupied Massawa, and in 1889 Asmara. In 1900 the seat of government was transferred from Massawa to Asmara, which is surrounded by rich lands, cultivated in part by Italian immigrants, and is a busy trading centre.

ASMODEUS or **ASHMEDAI,** an evil demon who appears in later Jewish tradition as "king of demons." He is sometimes identified with Beelzebub or Apollyon (Rev. ix. 11). In the Talmud he plays a great part in the legends concerning Solomon. In the apocryphal book of Tobit (iii. 8) occurs the well-known story of his love for Sara, the beautiful daughter of Raguel, whose seven husbands were slain in succession by him on their respective bridal nights. At last Tobias, by burning the heart and liver of a fish, drove off the demon, who fled to Egypt. From the part played by Asmodeus in this story, he has been often familiarly called the genius of matrimonial unhappiness or jealousy, and as such may be compared with Lilith. Le Sage makes him the principal character in his novel Le Diable boiteux. Both the word and the conception seem to have been derived originally from the Persian. The name has been taken to mean "covetous"; it is in any case no doubt identical with the demon Aēshma of the Zend-Avesta and the Pahlavi texts, but the meaning is not certain. It is generally agreed that the second part of the name Asmodeus is the same as the Zend *daēwa, dēw,* "demon." The first part may be equivalent to Aēshma, the impersonation of anger. But W. Baudissin (Herzog-Hauck, *Realencyklopädie*) prefers to derive it from *ish,* to drive, set in motion; whence *ish-mīn,* driving, impetuous.

See *Jewish Encyclopaedia* (*s.v.*). *See* also the articles in the *Encyclopaedia Biblica,* Hastings' *Dictionary of the Bible,* and Herzog-Hauck, *Realencyklopadie.*

ASMONEUS or **ASAMONAEUS** (so Josephus), great-grandfather of Mattathias, the father of Judas Maccabaeus. Nothing more is known of him, and the name is only given by Josephus (not in 1 Macc. ii. 1). But the dynasty was known to Josephus and the Mishna (once) as "the sons (race) of the Asamonaeans (of A.)"; and the Targum of 1 Sam. ii. 4 has "the house of the Hashmoneans who were weak, signs were wrought for them and strength." If not the founder, Asmoneus was probably the home of the family (cf. Heshmon, Jos. xv. 27).

See Schurer, *Geschichte des jüdischen Volkes,* i. 248 *N*; art. "Maccabees" §2 in *Ency. Biblica.* (J. H. A. H.)

ASNIÈRES, a town, department of Seine, France, on the left bank of the Seine, practically an extension of Paris and 1½m. N N.W. of its fortifications. Pop. (1936) 71,831, compared with 35,883 in 1906. It is a boating centre for Parisians. Industries include boat-building and the manufacture of perfumery, colours, etc.

ASOKA, a famous Buddhist emperor of India who reigned from 264 to 228 or 227 B.C. Thirty-five of his inscriptions on rocks or pillars or in caves still exist (see LUMBINĪ), and they are among the most remarkable and interesting of Buddhist monuments (see BUDDHA AND BUDDHISM). Asoka was the grandson of Chandragupta, the founder of the Maurya (Peacock) dynasty, who had wrested the Indian provinces of Alexander the Great from the hands of Seleucus, and he was the son of Bindusāra, who succeeded his father Chandragupta, by a lady from Champā. The Greeks do not mention him and the Brahman books ignore him, but the Buddhist chronicles and legends tell us much about Asoka.

The inscriptions, which contain altogether about 5,000 words, are entirely of religious import, and their references to worldly affairs are incidental. They begin in the 13th year of his reign, and tell us that in the 9th year he had invaded Kalinga, and had been so deeply impressed by the horrors involved in warfare that he had then given up the desire for conquest, and devoted himself to conquest by "religion." What the religion was is explained in the edicts. It is purely ethical, independent alike of theology and ritual, and is the code of morals as laid down in the Buddhist sacred books for laymen. He further tells us that in the 9th year of his reign he formally joined the Buddhist community as a layman, in the 11th year he became a member of the order, and in the 13th he "set out for the Great Wisdom" (the *Sambodhi*), which is the Buddhist technical term for entering upon the well-known, eightfold path to Nirvana.

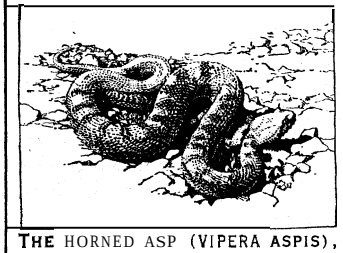
The extent of Asoka's dominion included all India from the 13th degree of latitude up to the Himalayas, Nepal, Kashmir, the Swat valley, Afghanistan as far as the Hindu Kush, Sind and Baluchistan. It was thus as large as, or perhaps somewhat larger than, British India before the conquest of Burma. He was undoubtedly the most powerful sovereign of his time and the most remarkable and imposing of the native rulers of India.

"If a man's fame," says Roppen, "can be measured by the number of hearts who revere his memory, by the number of lips who have mentioned, and still mention him with honour, Asoka is more famous than Charlemagne or Caesar." At the same time it is probable that, like Constantine's patronage of Christianity, his patronage of Buddhism, then the most rising and influential faith in India, was not unalloyed with political motives, and it is certain that his vast benefactions to the Buddhist cause were at least one of the factors that led to its decline.

See also Vincent Smith, *Asoka* (1901), revised edition (1920); E. Senart, *Inscriptions de Pzyadasi* (1891); chapters on Asoka in T. W. Rhys David's *Buddhism* (20th ed. 1903), and *Buddhist India* (1903); *V.* A. Smith, *Edicts of Asoka* (1909). (T. W. R. D.)

ASOLO (anc. Acelum), Venetia, Italy, province of Treviso, about 19m. N.W. direct from Treviso, some 10m. E. of Bassano by road and 10 mi. W N W. of Montebelluna by tram. Pop. (1936) town, 760; commune, 10,042. It is on a hill. 690 ft. above sea-leve! Remains of Roman baths and of a theatre have been discovered in the course of excavation. It became an episcopal see in the 6th century. Catherine Cornaro, queen of Cyprus, retired here on abdication and was visited by Pietro Bembo, who conceived here his *Dialoghi degli Asolani,* and by Andrea Navagero (Naugerius). Paulus Manutius was born here.

ASOR, an instrument "of ten strings" mentioned in the Bible, about which authors are not agreed. The word occurs only three times in the Bible, and has not been traced elsewhere.



THE HORNED ASP (VIPERA ASPIS), A POISONOUS SNAKE OF EUROPE CLOSELY ALLIED TO THE ADDER

ASP (Vipera *aspis*), a species of venomous snake, closely allied to the common adder of Great Britain, which it represents throughout the southern parts of Europe, being specially abundant in the region of the Alps. It differs from the adder in having the head entirely covered with scales, shields being absent, and in having the snout somewhat turned up. The term "Asp" as it is used in literature is applied to several species of poisonous snake, that by which Cleopatra is said to have ended her life is generally supposed to have been the cerastes, or horned viper (Cerastes *cornutus*), of northern Africa and Arabia, a snake about 15in. long, exceedingly venomous, and provided with curious horn-like protuberances over each eye. The snake, however, to which the word "asp" has been most commonly applied is the haje of Egypt, the spy-slange or spitting-snake of the Boers (Naja haje), one

of the very poisonous Elapidae, from 3 to 4 ft. long, with the skin of its neck loose, so as to render it dilatable at the will of the animal, as in the cobra of India, a species from which it differs only in the absence of the spectacle-like mark on the back of the neck. Like the cobra, the haje has its fangs extracted by jugglers, who afterwards train it to perform various tricks.

ASPARAGINE, a naturally occurring base found in plants belonging to the families Leguminosae and Cruciferae, and noticeably in asparagus. It has the structure

$$CO_2H.CH[NH_2].CH_2.CO.NH_2,$$

and belongs to the important group of amino-acids, being both an acid, by virtue of the carboxyl (CO_2H) group, and a base, by virtue of the two amino (NH_2) groups. Owing to the presence of an "asymmetric carbonation" (C above), it should exist in two optically active forms and one inactive form (see STEREOCHEMISTRY).

A. Piutti (1887) synthesized the asparagines from the monomethyl ester of inactive aspartic acid by heating it with alcoholic ammonia. In this way both asparagines were obtained and were separated by picking out the hemihedral crystals. Laevo asparagine, which was isolated by L. N. Vauquelin in 1805, is slightly soluble in cold water and readily soluble in hot water and crystallizes in prisms, containing one molecule of water of crystallization, the anhydrous form melting at 234–235° C. Nitrous acid converts it into malic acid, $HOOC.CHOH.CH_2.COOH$. It is laevo-rotatory in aqueous or in alkaline solution, and dextro-rotatory in acid solution (L. Pasteur, 1851). Dextro-asparagine was first found in 1886 in the shoots of the vetch (Piutti). It forms rhombic crystals possessing a sweet taste. It is dextro-rotatory in aqueous or alkaline solution, and laevo-rotatory in acid solution.

Hydrolysis by means of acids or alkalis converts the asparagines into aspartic acid; while on heating with water in a sealed tube they are converted into ammonium aspartate.

ASPARAGUS, a genus of the lily family (Liliaceue), comprising upwards of 120 species, widely distributed in the temperate and warmer parts of the old world. They are erect or climbing, extensively branching and sometimes more or less woody plants, rising from cord-like, thickened or tuberous rootstocks (Rhizomes). The leaves are reduced to minute scales bearing in their axils tufts of green, needle-like or flattened branches (cladodes or *cladophyls*), which perform the function of leaves. Some species climb or scramble, in which they are aided by the development of the scale-leaves into spines. Asparagus is dioecious; the flowers are small, whitish and pendulous; the fruit is a berry. Several climbing species are grown as house plants and in greenhouses for their ornamental foliage. The so-called asparagus-fern (A. *plumosus*), native to South Africa, with numerous horticultural varieties, is an especially elegant species, highly prized for its delicate, feathery branches. The vine-like smilax of the florists (A. asparagoides), with stiffish, shining, many-veined "leaves" (*cladodes*), is likewise a native of South Africa.

Garden Asparagus.—Economically the most valuable species is the common perennial vegetable (A. *officinalis*). The plant is a native of the north temperate zone of the old world, grows wild on coasts and sandy areas in the south of England and on the steppes of Russia. It has escaped from cultivation and become extensively naturalized in North America, especially around salt marshes from New Brunswick to Virginia, sparingly along roadsides and in fields in the interior, and also on the Pacific coast. Since Greek and Roman times the young shoots have been in high repute as a culinary vegetable.

In the United States about 125,000 ac. of asparagus were grown annually in 15 states that had an average commercial production from 1930 to 1939 of about 120,000 tons. In 1941 about 100,000 tons were grown for market and 39,000 tons for canning and freezing. It is also grown in home gardens. Asparagus will not thrive long in regions of hot summers and very mild winters where freezing rarely occurs. However, in a favorable climate, well-prepared and properly managed plantings on good soil may remain productive 12 to 15 years or more. Asparagus does best on a loose, medium to light, deep, rich sandy loam soil or a muck soil. In growing the crop, seeds are sown in early spring about 3 in. apart in rows about 3 ft. apart. The plants grow for one season in these nursery rows, then the year-old roots or "crowns" are dug for transplanting into the permanent fields about 2 ft. apart in rows 4 to 5 ft. apart. The soil should be well manured and fertilized before planting and annually thereafter. The roots may be transplanted in the fall where the winters are not severe, or in the spring. In transplanting, the crowns are placed in a furrow 6 to 8 in. wide and 8 in. deep in soil that has been thoroughly worked to the depth of a foot or more. The roots are well spread out and the crowns covered about 4 in. deep. As the tops grow, the remaining soil is filled into the furrow. If it is desired to harvest green asparagus shoots the field is cultivated nearly flat, with no more soil over the crowns than is needed to protect them from the cultivating tools. For producing white or blanched shoots the soil is ridged up deeply over the rows each spring before harvest begins so that the developing shoot reaches a length of about 10 inches before it emerges. The ridges are worked down after the cutting season. Asparagus should be harvested daily during the cutting season of usually 8 to 10 weeks in the spring.

ASPARAGUS-PEA, the name of a group of cultivated leguminous plants mostly derived from *Psophocarpus tetragonolobus*, native to India. All varieties are rapidly-growing vines, 10 ft. to 50 ft. long, producing quadrangular, green-winged pods, 3 in. to 9 in. long. The tender young pods are eaten like string beans and have a distinct flavour resembling that of asparagus. The seeds, which are about the size of peas, are very rich in proteins. Because of their extreme hardness when ripe, they are difficult to cook, hence usually only the immature seeds are eaten. The plant is a quasi-perennial, bearing almost continuously for one or two years. Its cultivation is increasing in most tropical countries and it is also grown as a cover-crop.

ASPASIA, born at Miletus, was the most famous of the Ionian courtesans who settled at Athens. She became Pericles' mistress, for by his own law of 451 she could not, as a foreigner, be his legal wife, and her charm and talents seem to have won her an important place in the intellectual society of the time. The comic poets represent her as the political adviser of Pericles, and as the cause of the Samian and Peloponnesian wars (Plutarch, and Aristoph. Ack. 497), but this is probably mere caricature. Shortly before the Peloponnesian war she was accused of impiety, and only the tears and entreaties of Pericles secured her acquittal (see Cambridge Ancient History, vol. v., note 8). After the death of his two legitimate sons, he procured the passing of an enactment legitimizing his son by Aspasia.

See Plutarch, *Pericles;* Plato, Menexenus; Xenophon, *Oecon.* 52, 14; Natorp, Philologus, 51, p. 489 (attempted reconstruction of the dialogue *"Aspasia"* by Aeschines the Socratic); Le Conte de Bièvre, Les Deux *Aspasies* (1736); J. B. Capefigue, Aspasie et *le Siècle* de *Périclès* (1862); L. Bec de Fouquières, Aspasie de *Milet* (1872); H. Houssaye, Aspasie, *Cléopâtre, Théodora* (1899); E. Meyer, Forschungen, vol. ii, pp. 55–56, in opposition to Wilamowitz-Mollendorf, in Hermes, xxxv. (1900); A. E. Zimmern, Greek *Commonwealth,* part iii., chap. 12, pp. 334–342. See also PERICLES.

ASPASIUS, a Greek peripatetic philosopher, and a prolific commentator on Aristotle. He flourished probably towards the close of the 1st century A.D., or perhaps during the reign of Antoninus Pius. Commentaries on books 1–4, 7 (in part), and 8 of the *Nicomachean* Ethics are preserved; that on book 8 was printed with those of Eustratius and others by Aldus Manutius at Venice in 1536. They were partly (2–4) translated into Latin by Felicianus in 1541, and have frequently been republished, but their authenticity has been disputed. The most recent edition is by G. Heylbut in *Commentaria* in *Aristotelem* Graeca, xix. i. (1889).

Another ASPASIUS, in the 3rd century A.D., was a Roman sophist and rhetorician, son or pupil of the rhetorician Demetrianus. He was secretary to the Emperor Maximin.

ASPECT RATIO, of an aeroplane wing, the ratio of the span to the chord, the latter being the length of the straight line drawn from the leading to the trailing edge, at right angles to the length of the wing. (See AEROPLANE.)

ASPEN, a section of the poplar genus (*Populus*) of which the common aspen of Europe, P. *tremula,* may be taken as the type. This is a tall, fast-growing tree with a slender trunk, and gray bark that becomes rugged when old. The roundish leaves, toothed on the margin, are slightly downy when young, but afterwards smooth, dark green on the upper and grayish green below; the long slender petioles, flattened towards the outer end, allow of free lateral motion by the lightest breeze, giving the foliage its well-known tremulous character. By their friction on each other the leaves give rise to a rustling sound. The flowers, which appear in March and April, are borne on pendulous hairy catkins, 2 or 3 in. long; male and female catkins are, as in the

other species of the genus, borne on separate trees (dioecious).

The aspen is found in moist places, sometimes at more than 1,600 ft. above sea-level in Scotland. It is an abundant tree in northern Britain, and is found occasionally in the coppices of the southern counties; it abounds in the forests of northern Europe, while in Siberia its range extends to the Arctic circle.

The wood is light and soft, though tough; it is employed for pails, herring-casks, butchers' trays, pack-saddles, and various articles for which its lightness recommends it; in mediaeval days it was valued for arrows; the bark is used for tanning; cattle and deer browse on the young shoots and suckers. Charcoal prepared from it is light and friable, and has been employed in gunpowder manufacture. The powdered bark is given to horses as a vermifuge; it possesses tonic and febrifugal properties, containing salicin. The aspen is propagated by cuttings or suckers.

The American aspen (P. *tremuloides*). called trembling aspen, closely allied to the European species, is the most widely distributed tree in North America. It ranges from Labrador to the mouth of the Mackenzie river and the valley of the Yukon and southward to Pennsylvania, Missouri and Nebraska, and in the Rocky mountains and the Sierra Nevada to Chihuahua and Lower California, often ascending to 10,000 ft. altitude. It attains a maximum height of 100 ft. and a trunk diameter of 3 ft., but is usually much smaller. The bigtooth aspen (P. *grandidentata*), has ovate or roundish leaves deeply and irregularly serrated on the margin. The wood of both these species is manufactured into wood-pulp. (E. S. HR.)

ASPENDUS, an ancient city of Asia Minor, mod. *Balkis Kale',* or, more anciently in the native language, *Estvedys* (whence the adjective *Estvedijys* on coins), very strongly situated on an isolated hill on the right bank of the Eurymedon at the point where the river issues from the Taurus. The sea is now about 7m. distant, and the river is navigable only for about 2m. from the mouth; but in the time of Thucydides ships could anchor off Aspendus. Really of pre-Hellenic date, the place claimed to be an Argive colony. It derived wealth from great *salines* and from a trade in oil and wool, to which the wide range of its admirable coinage bears witness from the jth century B.C. onwards. There Alcibiades met the satrap Tissaphernes in 411 B.C., and thence succeeded in getting the Phoenician fleet, intended to co-operate with Sparta, sent back home. The Athenian, Thrasybulus, after obtaining contributions from Aspendus in 389, was murdered by the inhabitants. The city bought off Alexander in 333, but, not keeping faith, was forcibly occupied by the conqueror. In due course it passed from Pergamene to Roman dominion, and, according to Cicero, was plundered of many artistic treasures by Verres. It was ranked by Philostratus the third city of Pamphylia, and in Byzantine times seems to have been known as Primopolis, under which name its bishop signed at Ephesus in A.D. 431. In mediaeval times it was evidently still a strong place but is now a wretched hamlet.

With the Roman theatre, the finest in the world, the ruins have earned for the place a connection with Solomon's Sheban queen. On the summit of the hillock, surrounded by a wall with three gates, lie the remains of the city. The public buildings round the forum can all be traced, and parts of them are standing to a considerable height. They consist of a fine nympheum on the north with a covered theatre behind it, covered market halls on the west, and a peristyle hall and a basilica on the east. In the plain below are large thermae, and ruins of a splendid aqueduct. But all else seems insignificant beside the huge theatre, half hollowed out of the north-east flank of the hill. This was completely planned and described by Count Lanckoronski's expedition in 1884. It is built of local conglomerate and is in marvellous preservation. Erected to the honour of the emperors Marcus Aurelius and L. Verus by the architect Zeno for the heirs of a local Roman citizen (as an inscription repeated over both portals attests), its auditorium has a circuit of 313ft. There are 40 tiers of seating, divided by one *diazoma,* and crowned by an arched gallery of rather later date, repaired in places with brick. This auditorium held 7.500 spectators. The seats are not perfect, but so nearly so as to appear practically intact. The wooden stage has, of course, perished, but all its supporting structures are in place, and the great scena wall stands to its full height and produces a magnificent impression whether from within or from without. Inwardly it was decorated with two orders of columns, one above the other, with rich entablatures, much of which survive. In the *tympanum* is a relief of Bacchus (wrongly supposed to be of a female, and called the Bal-Kys, *i.e.* "Honey Girl"). The position of the sounding board above the stage is apparent. Under the forepart of the auditorium, built out from the hill, are immense vaults. The whole structure was enclosed within one great wall, pierced with numerous windows. This structure was probably put to some ecclesiastical Byzantine use, as certain mutilated heads of saints appear upon it; and later it became a fortress.

ASPER, AEMILIUS, Latin grammarian, possibly lived in the 2nd century A.D. He wrote commentaries on Terence, Sallust and Virgil.

Editions in Keil, *Probi in Vergilii Bucolica Commentarius (1848);* *see* also Suringar, *Historia Critica Scholiastarum Latinorum (1834);* Grafenhan, *Geschichte der klassischen Philologie im Alterthum,* iv. (1843–50).

ASPERGES, the ceremony of sprinkling the people with holy water before High Mass in the Roman Catholic Church, so called from the opening words *Asperges me, Domine, hyssopo* (Ps. li. 7). The brush for sprinkling is an *aspergillum,* and a vessel for holy water an *aspersorium.*

ASPERN-ESSLING, BATTLE OF (1809), was fought on May 21 and 22, 1809, between the French and their allies under Napoleon and the Austrians commanded by the Archduke Charles (*see* NAPOLEONIC CAMPAIGNS). When Austria, with her army reorganized, reopened hostilities in 1809, the swift opening move of Napoleon split her army asunder and enabled him to push down the south bank of the Danube and occupy Vienna, left exposed by the Austrian retreat across the river. Napoleon then aimed to complete the overthrow of the Austrian forces, but the bridges over the Danube had been broken, and the archduke's army had reassembled on and about the Bisamberg.[1] The first task of the French was the crossing of the Danube. Lobau, one of the numerous islands which divide the river into minor channels, was selected as the point of crossing, but rough weather caused 24 hours' delay in the bridging of the channels from the right bank to Lobau and it was not until midday on May 20 that the troops, other than the advanced detachments, crossed to the island. By the evening of the 20th a large force had been collected there and the last arm of the Danube, between Lobau and the left bank, bridged. Masséna's corps at once began to cross to the left bank and dislodged the Austrian outposts. Undeterred by the news of heavy attacks on his rear from Tirol and from Bohemia, Napoleon hurried all available troops to the bridges, and by midday on the 21st 25,000 men were collected on the edge of the Marchfeld, the broad open plain of the left bank, which was also to be the scene of the battle of Wagram. The archduke did not seriously resist the passage; it was his original intention to await developments, but a misleading, if happily misleading, report led him to seize the opportunity for a blow before the bulk of the French army had crossed. Napoleon seems to have taken the risk too lightly, both underestimating his opponents and the need for preparatory measures, but he sought to minimize it by concentrating close to the river before pushing forward—and thus also to avoid attention. His forces on the Marchfeld were drawn up in front of the bridges facing north, with their left in the village of Aspern (Gross-Aspern) and their right in Essling (or Esslingen). Both places lay close to the Danube and could not therefore be turned. But the French had to fill the gap between the villages, and also to move forward to give room for the main body to form up. Whilst they were thus engaged the archduke moved to the attack with his whole army of 98,000 men in five columns. Three under Hiller, Bellegarde and Hohenzollern were to converge upon Aspern, the other two, under Rosenberg, to attack Essling. The Austrian cavalry was in the centre, ready to move out against any French cavalry which should attack the heads of the columns During the 21st the bridges became more and more unsafe, owing

[1] *See* sketch map in the article WAGRAM.

to the violence of the current, and the passage of the French reinforcements was frequently delayed.

The battle began at Aspern; Hiller carried the village at the first rush about 4 P M, but Masséna recaptured it, and held his ground with the same tenacity he had shown at Genoa in 1800. The French infantry, indeed, fought on this day with the old stubborn bravery which it had failed to show in the earlier battles of the year. The three Austrian columns, hindering each other by their convergence on a single point, were unable to do more than drive the French out to the far edge of the village before night fell. In the meanwhile nearly all the French infantry posted between the two villages and in front of the bridges had been drawn into the fight on either flank. Napoleon therefore, to create a diversion, sent forward his centre, now consisting only of cavalry, to charge the enemy's artillery, which was deployed in a long line and firing into Aspern. The first charge of the French was repulsed, but the second attempt, made by heavy masses of cuirassiers overrode the guns, but failed to break Hohenzollern's infantry squares, and in the end retired to their old position. Even so, they effectively discouraged any further attack on the French centre In the meanwhile Essling had been the scene of fighting almost as desperate as that of Aspern. The French cuirassiers made repeated charges on the flank of Rosenberg's force, and for long delayed the assault, and in the village Lannes with a single division made a heroic and successful resistance, till night ended the battle. The two armies bivouacked on their ground, and in Aspern the French and Austrians lay within pistol shot of each other.

All through the night more and more French troops were put across, and at the earliest dawn of the zznd the battle was resumed. Masséna by degrees cleared Aspern of Austrians, but at the same time Rosenberg stormed Essling at last Lannes, however, resisted desperately, and reinforced by St Hilaire's division, drove Rosenberg out. By 7 AM. Napoleon had 77,000 troops across and he launched a great attack on the Austrian centre Beginning with Lannes on the right, the whole French centre, with the cavalry in reserve, moved forward. The Austrian line mas broken through, between Rosenberg's right and Hohenzollern's left, and the French squadrons poured into the gap. Victory seemed within reach when the archduke brought up his last reserve, himself leading on his soldiers with a colour in his hand. Lannes was checked, and with his repulse the impetus of the attack died out all along the line. Meantime Aspern had been lost to a counter-attack by Hiller and Bellegarde, and graver news reached Napoleon at the critical moment. The Danube bridges had at last been cut by heavy barges, which had been set adrift down stream for the purpose by the Austrians. Napoleon thereupon (11 A M) suspended the attack and decided to retire to Lobau. About 3 P M. Essling fell to another assault of Rosenberg, and though again the French, this time part of the Guard, drove him out, the Austrian general then directed his efforts on the flank of the French centre, slowly retiring on the bridges. The retirement was costly, and the French must have been driven into the Danube but for the steadiness of Lannes, the exhaustion of the assailants, and the archduke's inexplicable action in drawing back part of his force about 4 P M. Although he turned them about again on hearing that the French were retiring across to Lobau, he did not seek a renewal of the struggle. The French lost 20,000 and amongst the killed were Lannes and St. Hilaire. The Austrians lost 23 360. Even this, the first serious defeat of Napoleon did not shake his resolution. The beaten forces were at last withdrawn safely into the island. On the night of the 22nd the great bridge was repaired, and the army awaited the arrival of reinforcements, not in Vienna, but in Lobau But it had been a narrow escape from disaster, and its special historical significance is an illustration of the over-confidence which was fastening more and more strongly on Napoleon's mind. (B. H. L. H.)

ASPHALT. According to the standard definition of the American society for testing materials, asphalts are "black to dark brown solid or semi-solid cementitious materials which gradually liquefy uhen heated, in which the predominating constituents are bitumens all of which occur in the solid or semi-solid form in nature or are obtained by refining petroleum, or which are combinations of the bitumens mentioned with each other or with petroleum derivatives thereof " In more popular terms asphalt may be defined as a semi-solid sticky residue formed by the partial evaporation or distillation of certain petroleums. This is as true of native asphalts as of those obtained by refining petroleum

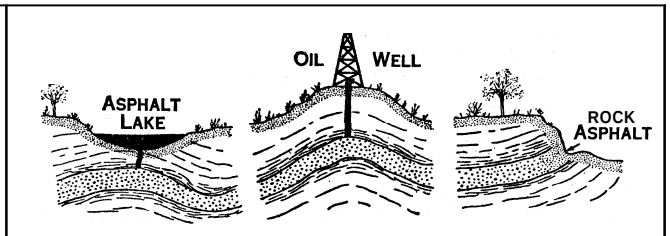


DIAGRAM SHOWING HOW ASPHALT IS FOUND IN NATURE

The solid or semi-solid native bitumens were termed ἄσφαλτος by the Greeks Only native asphalts were known, but late in the 19th century it was found that asphalt was a constituent of certain petroleums and could be recovered by distilling off the volatile oils which held it in solution In 1928 over 80% of the world's supply of asphalt was produced at petroleum refineries

Sandstones and limestones naturally impregnated with asphalt —commonly known as rock asphalt or bituminous rock—are found in various parts of the world, the most widely known deposits being at Val de Travers in Switzerland; Seyssel in France and Mons in Belgium; San Valentino and Cesi in Italy; Ragusa in Sicily; Limmer, Lobsann and Vorwohle in Alsace; and in Texas, Oklahoma, Alabama and Kentucky in the United States. The largest and best known deposit of relatively pure asphalt occurs as an asphalt or pitch lake on the Island of Trinidad, British West Indies, and covers an area of about roo acres. A sample of crude contains approximately 39% of pure asphalt or bitumen, the balance being gas, water, light oils and organic and mineral matter. The surface of the lake forms a crust which may be removed by means of picks. The plastic material from beneath flows into the excavations and rapidly hardens into a new crust. A more extensive but shallower deposit is found at Bermudez lake in Venezuela. This asphalt is softer than that found at Trinidad and contains less mineral matter. An exceptionally pure asphalt of very brittle nature known as Gilsonite, is obtained in Colorado and Utah. Other varieties are known as manjak, glance pitch, wurtzelite, etc.

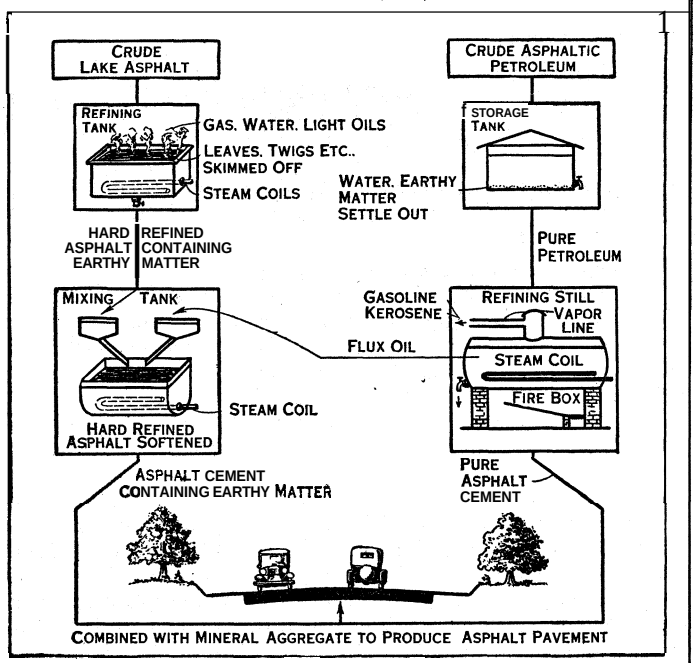
Practically all native asphalt is too hard for direct use and must be heated until water, gas and other volatile materials are driven off and then fluxed or softened to the desired consistency by mixing with it the proper amount of residual petroleum. On the other hand asphalt recovered directly from petroleum (*q.v.*) by distillation does not require fluxing, as the process is stopped when the product reaches the desired consistency. When a high melting-point is desired, the asphalt is heated to fluidity and air is blown through it, producing what is known as "blown" or oxidized asphalt.

Asphalt Cements.—The hardness of asphalt is determined by measuring the distance that a standard needle, under a load of 100g. applied for five seconds, will penetrate the asphalt at 77°. This "penetration" test classifies asphalts into grades, and when a consistency suitable for some commercial use is reached, the products are known as "asphalt cements." These are used primarily as nater and weather resisting binders Their value for these purposes was utilized in ancient times for preserving mummies and in some cases for coating and binding masonry.

Asphalt is extensively used in paving, roofing and water-proofing Over 75% of the total production is employed in the construction of highways in which it is used to bind together the stone, sand and mineral dust which constitute the bulk of the wearing surface Approximately 140,000,000sq yd. of asphalt pavements are constructed annually in the United States alone. Relatively fluid asphalt products known as "cut-backs" and "road oils," are used for the surface treatment of macadam and gravel roads.

Asphalt is also employed in the manufacture of mats for underwater revetment, wall boards, flooring, floor coverings, sheathing, moisture-proof wrapping paper, paints, varnishes, enamels, japans, acid-proof coatings. pipe dips, sealing compounds, insulating products, emulsions and moulding composition. The roofing industry consumes about 15% of the total production in the manufacture of asphalt-impregnated roofing and shingles.

The total annual production and importation of asphalt into the United States amounts to over 6,000,000 tons of which some



HOW LAKE AND PETROLEUM ASPHALTS ARE REFINED

5,500,000 tons are recovered directly from domestic petroleum and petroleum imported to the American refineries from South American countries.

ASPHODEL, a much misunderstood term. The asphodel of the poets is often a narcissus; of the ancients it is either of the genus *Asphodeline* or belongs to Asphodelus, a genus of the lily family (Liliaceae), containing seven species in the Mediterranean region. These are hardy herbaceous perennials with narrow tufted radical leaves and an elongated stem bearing a handsome spike of white or yellow flowers. *Asphodelus albus* and A. *fistulosus* have white flowers and grow from 1½ to 2 ft. high; A. *ramosus* is a larger plant, the large white floners of which have a reddish-brown line in the middle of each segment. Bog-asphodel (*Narthecium ossifragum*), a member of the same family, is a small herb in boggy places in Britain, with rigid narrow radical leaves and a stem bearing a raceme of small golden yellow flowers. In the United States, the American bog-asphodel (N. americatzum) of the pine-barrens of New Jersey and Delaware, and the western bog-asphodel (N. *californicum*), of the coast ranges of California and Oregon, are both rare plants.

In Greek legend the asphodel is the most famous of the plants connected with the dead and the underworld. Homer describes it as covering the great meadow (ἀσφόδελος λειμών), the haunt of the dead (*Od.*xi 539,573; xxiv.13). It was planted on graves, and is often connected with Persephone, who appears crowned with a garland of asphodels. Its general connection with death is due no doubt to the greyish colour of its leaves and its yellowish flowers, which suggest the gloom of the underworld and the pallor of death. The roots were eaten by the poorer Greeks; hence such food was thought good enough for the shades (*cf.* Hesiod, Works and Days, 41; Pliny, *Nat. Hist* xxi. 17 [68]; Lucian, De *luctu,* 19). The asphodel was also supposed to be a remedy for poisonous snakebites and a specific against sorcery; it was fatal to mice, but preserved pigs from disease.

See Pauly-Wissowa, Realencyklopadie, *s.v.;* H. O. **Lenz,** Botanik *der alten* Griechen und *Römer* (1859); J. Murr, **Die** *Pflanzenwelt* in *der griechischen* Mythologie (1890).

ASPHYXIA, a term in medicine signifying arrest of respiration from some hindrance to the entrance of air into the lungs. (*See* RESPIRATORY SYSTEM, DISEASES OF.)

ASPIC, a poisonous African snake popularly supposed to give a quick and easy death. "The worm's an odd worm," said the clown to Cleopatra, "those that do die of it do rarely recover," and the aspic was welcomed by the queen as the means of swift dispatch. The French have a proverb *froid* comme *un* aspic, and it is to be supposed that French cooks, when they invented as a dainty savoury a bit of meat, game or fish imbedded in calf's-foot jelly, called it an aspic because it was cold to the touch like a snake. Aspic is also the botanical name of the Lavandula spica, or spikenard, from which a white aromatic and highly inflammable oil is distilled, called *huile d'aspic.*

ASPIDISTRA, a small genus of the lily family (Liliaceae), native of the Himalayas, China and Japan. Aspidistra *elatior* is a favourite pot-plant, bearing large green, or white-striped leaves (var. variegata) on an underground stem, and small dark purplish, cup-shaped flowers close to the ground. It is very resistant to unfavourable conditions and will live in the low light intensity of an ordinary dwelling room.

ASPIRIN is the trade-name of acetyl salicylic acid. Its dose is 0·3 to 1·0g. (5 to 15 grains). Like other salicylates it is of great use in acute rheumatic fever, in which it seems to have almost a specific action, as it causes the temperature to drop and the pain and swelling of the joints to decrease. Recent studies seem to point to a beneficial action on the heart itself in this disease. Aspirin also relieves headaches and neuralgia but does not cure the cause of these pains. It is much safer to use than the so-called antipyretics. The symptoms of an overdose are ringing in the ears, some dimness of vision at times, nausea and vomiting. With the lowering of temperature in fever there may be great sweating. Exposure to cold after its administration is therefore unwise.

ASPROMONTE, mountain, Calabria, Italy, behind Reggio di Calabria, the western extremity of the Sila range. It is 6,420ft. high and has forest-clad slopes. Here Garibaldi was wounded and taken by Italian troops under Pallavicini (1862).

ASQUITH, HERBERT HENRY: see OXFORD AND ASQUITH. HERBERT HENRY ASQUITH, 1ST EARL OF.

ASS, a common name for varieties of the subgenus *Asinus,* belonging to the horse tribe, and especially for the domestic ass; it differs from the horse in its smaller size, long ears, the character of its tail, fur and markings, and its proverbial dullness and obstinacy. The fifth proposition of Book i. of Euclid is known as the Pons *Asinorum,* "bridge of asses."

ASS, FEAST OF THE, a festival formerly held on Jan. 14 in Northern France, in commemoration of the biblical flight into Egypt. A girl with a baby at her breast and seated on an ass splendidly caparisoned was led through the town to the church where mass was said. The ceremony degenerated into a burlesque in which the ass of the flight became confused with Balaam's ass. So scandalous became the popular revels associated with it, that the celebration was prohibited by the church in the 11th century. (*See* FOOLS, FEAST OF.)

ASSAB, a bay and port on the African shore of the Red sea, 60m. N. of the strait of Bab-el-Mandeb. Assab bay was the first territory acquired by Italy in Africa. Bought from the sultan of Raheita in 1870, it was not occupied until 1880. (See ERITREA: History.)

ASSAI (Ital.), though meaning originally "enough" (cf. Fr. assez) has acquired also the secondary meaning of "very," in which sense alone it is employed in musical terminology, as in Presto *assai,* meaning "very fast."

ASSAM, a province of British India. Area (including the State of Manipur) 67,334 sq.mi. Pop. (1941) 10,204,733.

The Brahmaputra emerges from Himalayan gorges into a valley, 50m. wide, with steep mountain sides, and flows west and west-south-west till it turns south around the bastion of the Garo Hills. This broad valley is the main region of Assam but the province also includes the hills that bound this valley on the south. They are named from their peoples — the Garo, Khasi, Jaintia and North Cachar hills and the highest point in them is Shillong peak (6,450 ft.). South of these hills are the districts of Sylhet and South Cachar, essentially the Surma valley, flat below the very abrupt slope of the Khasi and Jaintia hills. To the east and south-east, Assam is bordered by hill ranges which make a barrier between it and Burma; these are a part of the mountain curve that stretches down the west side of Burma. The hills of the Assam-Burma border are named from their peoples the Naga hills and rise to nearly 10,000 feet at Japro peak. Within the general limits of the province are petty feudatory states in the Khasi hills, while south of the Naga hills and east of Cachar lies the feudatory state of Manipur (area 8,620sq.m.; pop. [1931] 445,606).

BY COURTESY OF THE NORTHERN BAPTIST CONVENTION

THE BATTLE ARRAY OF A WARRIOR OF THE NAGAS, THE LARGEST HILL TRIBE IN ASSAM

Rivers. — The Brahmaputra may be said to be formed by the union of a number of streams at the head of the valley of Assam. The Dihang, called Tsang-po in Tibet, has its source far to the west on the north side of the Himalaya and flows parallel to that range for hundreds of miles until it breaks through Himalayan gorges in a series of waterfalls and rapids and emerges into the Assam valley. The Sesiri, Dibang and Luhit rivers from the north-east unite with it to form the Brahmaputra which receives further tributaries from the Himalayas on the north and from the other hills named on the south-east. The former include the Subansiri, Bhareli, North Dhansiri, Barnadi, Manas and Sankosh rivers, mostly glacier-fed. Among the latter are the two Dihings (Noa and Buri), the Disang, Dhansiri and Kalang, streams which dwindle as the dry season progresses. The valleys of the Dhansiri and Kalang isolate the Mikir and Rengma hills from the southern hill framework. The Brahmaputra becomes a sheet of water several miles broad in the rainy season.

Soils and Geology. — Geographically the Assam hills (Garo, Khasi and Jaintia, North Cachar, etc., hills), lie in the angle between the Himalayas and the Burmese ranges, but geologically they belong to neither. The greater part of the mass consists of gneiss and schists overlain unconformably by cretaceous beds, consisting chiefly of sandstones with seams of coal, the whole series thinning out northwards as though towards a shore line; they are covered by tertiary rocks, including nummulitic beds and valuable seams of coal. These rocks show neither Himalayan nor Burmese folding but, while nearly horizontal towards the north, they are bent sharply downwards to the south in a simple monoclinal fold. The hill sides are generally forested. A good deal of the valley is raised well above flood-level and is rich agricultural land, partly under rice, partly in tea and other plantations. The alluvial deposits of the Brahmaputra and its tributaries show much variation of fertility and elevation; there are vast *chars* of pure sand inundated every year but easily and rapidly transformed into pastures in many places, and there are also terraces and islands of firm soil raised well above the floods. Many of the wetter lands are occupied by great reeds and grasses. The Himalayan and Burmese mountain frame includes great masses of tertiary rocks, with coal seams in the Burmese ranges.

Climate. — In January the high pressure over the land gives rise to frequent winds down the valley of the Brahmaputra, though there may be some rain and fogs are common; the temperature at this season averages 61° F. But the wind from the sea soon begins to penetrate along this corridor and Assam thus contrasts strongly with many parts of North India which have a dry hot season whilst the rains have been watering Assam from early March onwards, merging finally into the great monsoonal rainfall. The Khasi hills are said to have the heaviest rainfall in the world, with an average of 424 inches at Cherrapunji overlooking the low-lying land of the Surma, which, in monsoon time, becoines a lake of almost warm water. Sylhet on the southern lowland has an annual rainfall of 159 inches, and Gauhati on the floor of the Brahmaputra valley, that is north of the hills, only 67in. The heavy and long continued rains keep the temperature relatively moderate, the mean temperature of the warm season not reaching above 84° F.

Earthquakes. — Assam is liable to earthquakes. By far the severest shock known is that of 1897, the focus of which was in the Khasi and Garo hills. In the station of Shillong every masonry building was levelled to the ground. Throughout the country bridges were shattered, roads were broken up like ploughed fields and the beds of rivers were dislocated. In the hills there were terrible landslips which wrecked the little Cherrapunji railway and caused 600 deaths. The total mortality recorded was 1,542. In 1918 another severe earthquake, which had its centre in the Balisera hills in Sylhet, caused considerable damage to property but very little loss of life.

Fauna.—Wild elephants are numerous on the lower slopes of the Assam range and in the Brahmaputra valley. The Government *keddah* establishment captures large numbers, and the right of hunting is also sold by auction to private bidders. The rhinoceros is found in swampy places along the Brahmaputra. Tigers, leopards and bears are numerous. Another formidable animal is the wild buffalo or *gaur* which is of great size, strength and fierceness. Wild game is plentiful; pheasants, partridges, snipe and waterfowl of many descriptions make the country a tempting field for the sportsman.

Forests. — An area of 6,645 square miles is occupied by Government reserved forests. The most valuable are those bearing *Sal (Shorea robusta)* in the districts of Goalpara, Kamrup and the Garo hills.

Agriculture. — The principal and almost the only food-grain grown is rice. In 1936 there were 4.8 million acres under rice, amounting to 72% of the total cultivated area. Mustard and jute are grown in important quantities, and cotton and tobacco are cultivated on the lower slopes. The production of fruit and vegetables has increased and, in addition to meeting local needs, a considerable proportion is now exported to Bengal; potatoes being raised in the Khasi hills, which are also the centre of orange cultivation supplying most of Bengal and Assam.

Tea Plantations. — The most important article of commerce produced in Assam is tea, and tea growing has been the basic factor in the development of the province. At the end of 1936 there were 1,103 tea gardens, covering 439,000 acres, and over half a million persons were employed. The production of rice is sufficient for local consumption only, and so additional quantities have to be imported in order to feed workers in the tea-gardens. The tea plantations are the great source of wealth to the province, and the necessities of tea cultivation are the chief stimulants to the development of Assam.

The gardens, which are mainly European-owned, are situated in the Brahmaputra and Surma valleys. The Assamese themselves are too prosperous to work in the tea gardens, and coolie labour is therefore brought in from outside, the number averaging 15,000 per annum. Elaborate legislation has been designed to protect the labourer and, at the same time, to ensure fulfilment of contract. The first of these enactments dates back to 1863, but the now general *sardari* system, by which selected men or women are sent to their native districts to induce relations, friends, etc., to emigrate, came into operation in 1915, in which year an act was passed abolishing recruitment by contractors.

Industries. — Difficulties of transport and lack of capital have impeded development of the natural resources. Apart from the manufacture of tea, the industries are not of great importance. Coal mining is carried on at Makum and Nazira, but the output has tended to decline (annual average 1931–36, 250,000 tons). The production of petroleum has greatly increased within recent years,

the principal wells being at Lakhimpur (1936, 55 million gal.). The limestone and iron-ore of the Khasi hills formerly provided the materials for important metallurgical industries, but the lime trade has declined, and iron smelting has disappeared. The manufacture of tea chests from the timber of the forests is a minor industry.

Trade. — The greater proportion of the external trade of Assam is still mainly carried by its water ays, although railway traffic is steadily increasing year by year. Calcutta handles about 70% of the total trade, since it is the focus of both rail and water communications. The Eastern Bengal State railway runs from Dhubri north of the Brahmaputra to Gauhati, whence it follows the Kalang valley eastwards to Lumding. Here it meets the Assam-Bengal railway which has come north from Chittagong via Karimganj and across the hills. From Lumding the railway goes along the Dhansiri valley to the towns of north-east Assam. The Assam-Bengal railway has branches to Sylhet and Silchar. All these lines are of metre gauge.

Inhabitants. — The total population of Assam, according to the census of 1931, was 9,247,857, of whom 56% were Hindus, 30% Mohammedans and 11% Animists. The number of Christians was almost doubled in the decade and in 1931 was 249,246: the increase was specially remarkable in the Lushai hills, where mass conversion brought up the number from 2,000 to 59,000, nearly half the entire population. The total density is only 137 persons per square mile and there are extraordinary variations. As explained in the Government review of the census of 1921. some of the sources of these variations are physical and climatic, but some at least are to be sought in history, and the devastation caused in the Brahmaputra valley by the Moamaria insurrection and the Burmese invasion left a scanty population at the time of the British annexation. Until recent years an unhealthy climate and the absence of communications, in spite of the opening up of the country by tea gardens, prevented speedy development. In the Surma valley also, Cachar and the east and south portions of the Sylhet districts suffered too much from the raids of the neighbouring hill tribes to be inviting places of residence. In the hills it is not so long since head-hunting was considered to be the only proper occupation of a man, while the primitive conditions of agriculture militate against a large population. Assam has moreover in the past suffered from the ravages of "black fever" or Kala *Azar* to an extent of which there is no record elsewhere. An intensive campaign undertaken by the Government and the discovery of effective methods of treatment have done much to counteract this terrible disease.

BY COURTESY OF THE NORTHERN BAPTIST CONVENTION

A WOMAN OF ASSAM

Assamese women are considered among the most beautiful in India

About one-sixth of the population is foreign born and consists of immigrants such as those who have come to cultivate waste land or to work in the tea gardens, the majority from Bengal and Behar and Orissa. The population is consequently somewhat heterogeneous; there are, for instance, 88,000 Nebans. Of the total population 4,723,000 (in round figures) are inhabitants of the Brahmaputra valley, 2,724,342 of the Surma valley, and 1,262,535 of the hill districts. No less than 120 distinct languages, of which 60 are native to Assam, were returned at the census—figures significant of a heterogeneous population of which immigrants form a large constituent. Altogether 43% of the people speak Bengali, 22% Assamese and 18% various Tibeto-Burman languages. Bengali is the mother-tongue of the great majority of the people of the Surma valley. Assamese is written in nearly the same alphabet as Bengali, and the vernacular Assamese possesses a close affinity to that language. Indeed, so close was the resemblance that for a time Bengali was used as the court and official language; but with the development of the country the Assamese tongue asserted its claim to be treated as a distinct vernacular, and the Government in 1873 re-established it as the language of official life and public business.

Hill Tribes. — The Singphos, Daphlas, Miris, Khamtis, Mishmis, Abors, etc., are found near the frontiers of Lakhimpur district. The Nagas inhabit the hills and forests along the eastern and south-eastern frontier of Assam, residing partly in the British district of the Naga hills and partly in independent territory under the political control of the deputy-commissioner of the adjoining districts. Under regulation V. of 1873, an inner line has been laid down in certain districts, up to which the protection of British authority is guaranteed, and beyond which, except by special permission, it is not lawful for British subjects to go. This inner line has been laid down in the Balipara Frontier tract towards the Bhotias, Akas and Daphlas; in the Sadiya Frontier tract and Lakhimpur towards the Daphlas, Miris, Abors, Mishmis, Khamtis. Singphos and Nagas, and in Sibsagar towards the Nagas. The line is marked at intervals by frontier posts held by military police and commanding the roads of access to the tract beyond, and any person from the plains who has received permission to cross the line has to present his pass at these posts. The inner line formerly maintained along the Lushai border has since 1895 been allowed to fall into desuetude. (For the ethnology of Assam *see* ASIA: *Anthropology* and Ethnology, § Farther Asia.)

Administration. — Assam was constituted a provin'ce under a chief commissioner in 1874, but in 1905 it was merged in the nemly created province of Eastern Bengal and Assam. Five years later it was restored to its former status, and in 1921 it was constituted a province under a governor with an executive council (of two members) and two ministers. Under the provisions of the Government of India Act, Assam became an autonomous province in 1937, with a legislature composed of two chambers—the Legislative Council consisting of 21 members, three of whom are nominated and the rest elected, and the Legislative Assembly, consisting of 118 elected members. The North-East Frontier (Sadiya, Balipara and Lakhimpur regions) together with the Naga Hills, Lushai Hills and North Cachar Hills districts are excluded areas, and the Garo Hills, Mirkir Hills. and British portions of the Khasi and Jaintia Hills district (excluding Shillong) comprise a partially excluded area. The capital of the province is Shillong.

HISTORY

Assam was the province of Bengal which remained most stubbornly outside the limits of the Mogul empire and of the Mohammedan polity in India. Indeed, although frequently overrun by Mussulman armies, and its western districts annexed to the Mohammedan vice-royalty of Bengal, the province maintained an uncertain independence till its invasion by the Burmese towards the end of the 18th century, and its final cession to the British in 1826. It seems to have been originally included, along with the greater part of north-eastern Bengal, in the old Hindu territory of Kamrup. Its early legends point to great religious revolutions between the rival rites of Krishna and Siva as a source of dynastic changes. Its roll of kings extends deep into pre-historic times, but the first rajah capable of identification flourished about the year A.D. 76.

When Hsüan Tsang visited the country in A.D. 640, a prince named Kumar Bhaskara Barman was on the throne. The people are described as being of small stature with dark yellow complexions; fierce in appearance, but upright and studious. Hinduism was the state religion, and the number of Buddhists was very small. The soil was deep and fertile, and the towns were surrounded by moats with water brought from rivers or banked-up lakes. Subsequently we read of Pal rulers in Assam. It is supposed that these kings were Buddhist and belonged to the Pal dynasty of Bengal. Although the whole of Kamrup appears from time to time to have been united into one kingdom under some unusually powerful monarch, it was more often split up into numerous petty states; and for several centuries the Koch, the Ahom and the Chutia powers contested for the Assam valley. In the early part of the 13th century the Ahoms or Ahams, from northern Burma and the Chinese frontiers, poured into the eastern districts of Assam, founded a kingdom and held it firmly for

several centuries. The Ahoms were Shans from the ancient Shan kingdom of Pong. Their manners, customs, religion and language were and for a long time continued to be, different from those of the Hindus; but they found themselves compelled to respect the superior civilization of this race, and slowly adopted its customs and language. The conversion of their king Chuchengpha to Hinduism took place in the year A.D. 1655, and all the Ahoms of Assam gradually followed his example. From this time dates the deterioration of the Assamese and their decline as a power. In mediaeval history, the Assamese were known to the Mussulman population as a warlike predatory race, who sailed down the Brahmaputra in fleets of canoes, plundered the rich districts of the delta, and retired in safety to their forests and swamps. As the Mohammedan power consolidated itself in Bengal, repeated expeditions were sent out against these river pirates. The physical difficulties which an invading force had to contend with in Assam, however, prevented anything like a regular subjugation of the country; and after repeated efforts, the Mussulmans contented themselves with occupying the western districts at the mouth of the Assam valley. In 1638, during the reign of the emperor Shah Jahan, the Assamese descended the Brahmaputra, and pillaged the country round the city of Dacca; they were expelled by the governor of Bengal, who retaliated upon the plunderers by ravaging Assam. During the civil wars between the sons of Shah Jahan, the king of Assam renewed his predatory incursions into Bengal; upon the termination of the contest, Aurangzeb determined to avenge these repeated insults, and despatched a considerable force for the regular invasion of Assamese territory (1660–62). His general, Mir Jumla, defeated the rajah, who fled to the mountains, and most of the chiefs made their submission to the conqueror. But the rains set in with unusual violence, and Mir Jumla's army was almost annihilated by famine and sickness. Thus terminated the last expedition against Assam by the Mohammedans. A writer of the Mohammedan faith says:—"Whenever an invading army has entered their territories, the Assamese have sheltered themselves in strong posts, and have distressed the enemy by stratagems, surprises and alarms, and by cutting off their provisions. If these means failed, they have declined a battle in the field, but have carried the peasants into the mountains, burned the grain and left the country desert. But when the rainy season has set in upon the advancing enemy, they have watched their opportunity to make excursions and vent their rage; the famished invaders have either become their prisoners or been put to death. In this manner powerful and numerous armies have been sunk in that whirlpool of destruction, and not a soul has escaped." The same writer states that the country nas spacious and populous; that the paths and roads were beset with difficulties; and that the obstacles to conquest were more than could be expressed. The inhabitants, he says, were always prepartd for battle, and the approach to their forts was opposed by dangerous jungles, and broad and boisterous rivers. From the middle of the 17th century internal dissensions, invasion and disturbances of every kind convulsed the province, and neither prince nor people enjoyed security. Late in the 18th century some interference took place on the part of the British government, then conducted by Lord Cornwallis; but his successor, Sir John Shore, adopting the non-intervention policy, withdrew the British force, and abandoned the country to its fate. Its condition encouraged the Burmese to depose the rajah, and to make Assam a dependency of Ava. The extension of their encroachments on a portion of the territory of the East India company compelled the British government to take decisive steps for its own protection. Hence arose the series of hostilities with Ava known in Indian history as the First Eurmese War, on the termination of which by treaty in Feb. 1826, Assam remained a British possession. In 1832 that portion of the province denominated Cpper Assam was formed into an independent native state, and conferred upon Purandhar Singh, the ex-rajah of the country; but the administration of this chief proved unsatisfactory, and in 1838 his principality was reunited with the British dominions. After a period of successful administration and internal development, under the lieutenant-governor of Bengal, it was erected into a separate chief commissionership in 1874.

In 1886 the eastern Dwars were annexed from Bhutan; and in 1874 the district of Goalpara, the eastern Dwars and the Garo hills were incorporated in Assam. In 1898 the southern Lushai hills were transferred from Bengal to Assam, and the north and south Lushai hills were amalgamated as a district of Assam, and placed under the superintendent of the Lushai hills. Frontier troubles occasionally occur with the Akas, Daphlas, Abors and Mishmis along the northern border, arising out of raids from the independent territory into British districts. In Oct. 1905, the whole province of Assam was incorporated in the new province of Eastern Bengal and Assam.

See E. A. Gait, *The History of Assam* (1906); *L.* W. Shakespear, *History of Upper Assam (1914).*

ASSAMESE LANGUAGE, the Indo-Aryan tongue spoken in the Assam valley. In its grammar it closely resembles Bengali (*q.v.*), since both are derived from a common source. Its vocabulary is mainly tadbhava. It has been affected by its proximity to Tibeto-Burman dialects both in vocabulary and in structure, as in the use of pronominal suffixes, and in phonetics, though following Bengali generally in its accentuation. The chief glory of Assamese literature is in history. The *buranjis* or historical works are voluminous and have been carefully preserved.

Tadbhava means "of the same character as" Sanskrit, contrasted with tatsama, "identical with" the Sanskrit word. The French word ange is tadbhava, while angelus is tatsama, identical with the Latin.

See *Linguistic Survey of India,* vol. v. pt. 2 p. 393, for grammar and list of authorities.

ASSARY or **ASSARION,** a Roman copper coin, the "farthing" of Matthew x. 29.

ASSASSIN, a general term for a secret murderer (properly *Ḥashīshīn,* from *Hashish,* the opiate made from the juice of hemp leaves), originally the name of the Ismā'īlī branch of the Shiite sect founded by Ḥasan-i-Sabbāḥ at the end of the 11th century, and from that time active in Syria and Persia until crushed in the 13th century by the Mongols under Hūlāgū in Persia, and by the Mamluk Baybars in Syria. Ḥasan, a native of Ḵhurasan and a Shiite, after many adventures settled near Kuhistan and gradually spread his peculiar modification of Ismā'īlī doctrine. Having collected a considerable number of followers he formed them into a secret society. In 1090 he obtained, by stratagem, the strong mountain fortress of Alamūt in Persia, and, removing there with his followers, settled as chief of the famous Assassins.

The speculative principles of this body were identical with those of the Ismā'īlīs, but their external policy was marked by one peculiar and distinctive feature—the employment of secret "assassination" against all enemies. This practice was introduced by Ḥasan, and formed the essential characteristic of the sect. At their head was the supreme ruler, the *Shaykh-al-labal, i.e.,* Chief, or, as it is commonly translated, Old Man of the Mountains. Under him were three *Dā'ī-al-Kirbāl,* or, grand priors, who ruled the three provinces over which the shaykh's power extended. Next came the body of *Dā'īs* or priors, who were fully initiated into all the secret doctrines, and were the emissaries of the faith. Fourth were the *Rafiqs,* who were in process of initiation, and ultimately advanced to the dignity of *da'is.* Fifth came the most distinctive class, the *Fidā'īs* (*i.e.,* the devoted ones), who were the guards or assassins proper—young men who were kept uninitiated, and the blindest obedience was exacted from and yielded by them. Finally, the sixth and seventh orders were the *Lāsiqs,* or novices, and the common people.

The Assassins soon began to make their power felt. One of their first victims was Ḥasan's former friend, Nizām-al-Mulk (*see* SELJUKS), whose son also died under the dagger of a secret murderer. After a long and prosperous rule Ḥasan died at an advanced age in 1124, and was succeeded by his chief *dā'ī,* Kiyā Buzurg-Ummēd.

During the 14 years' reign of this second leader, the Assassins were frequently unfortunate in the open field, and their castles were taken and plundered; but they acquired a stronghold in Syria, while their numerous murders (*e.g.,* of the caliphs Mustar-

shid and Rāshid) made them an object of dread to the neighbouring princes, and spread abroad their evil renown. Buzurg-Ummēd was succeeded by his son Muhammad I. (1138–62) in whose reign the fortress of Masyāḍ became the chief seat of the Syrian branch of the society. His son Ḥasan (1162–66) declared himself to be the promised Imam, the caliph of God upon earth, and a lineal descendant of Ismāil. His son and successor Muhammad II. (1166–1210) had to contend with many powerful enemies, especially with the great Atabeg sultan Nūr ad-Din, and his more celebrated successor, Saladin, who had gained possession of Egypt after the death of the last Fatimid caliph, and against whom even secret assassination seemed powerless. During his reign, also, the Syrian branch of the society, under their *dā'ī,* Sinān, made themselves independent, and remained so ever afterwards. It was with this Syrian branch that the Crusaders made acquaintance; and it appears to have been their emissaries who slew Count Raymund of Tripoli and Conrad of Montferrat.

During the reign of his son, Ḥasan III. (1210–1220), no assassinations occurred, and he obtained a high reputation among the neighbouring princes. Like his father, he was removed by poison, and his son, 'All ad-Din Muhammad III. abandoned the mild principles of his father and a fresh course of assassination was entered on. In 1255, after a reign of 35 years, 'Alā ad-Din was slain, with the connivance of his son, Rukn ad-Din, the last ruler of the Assassins. In the following year Hūlāgū, brother of the Tatar, Mangū Khān, invaded the hill country of Persia, took Alamiit and many other castles, and captured Rukn ad-Din. (See MONGOLS.) He treated him kindly, and, at his own request, sent him under escort to Mangū, who ordered Rukn ad-Din to be put to death, and sent a messenger to Hūlāgū commanding him to slay all his captives. 'About 12,000 of the Assassins were massacred, and their power in Persia was completely broken. The Syrian branch flourished for some years longer, till Baybars, the Mamlūk sultan of Egypt. ravaged their country and nearly extirpated them. Small bodies of them lingered about the mountains of Syria, and are believed still to exist there. Doctrines somewhat similar to theirs are still to be met with in north Syria, Persia and India.

ASSAULT, in English law, "an attempt or offer with force or violence to do corporal hurt to another, as by striking at another with a stick or other weapon, or without a weapon, though the party misses his aim." Mere words, be they ever so provoking, will not constitute an assault. Coupled with the attempt or threat to inflict corporal injury, there must in all cases be the possibility of carrying the threat into effect, and so if the person threatened is out of range there can be no assault. A battery is more than a threat or attempt to injure the person of another; the injury must have been inflicted, but it makes no difference however small it may be, as the law does not "draw the line between degrees of violence," but "totally prohibits the first and lowest stage of it." Every battery includes an assault. A common assault is a misdemeanour, and is punishable by imprisonment with or without hard labour to the extent of one year, or by fine, and if it occasions bodily harm, with penal servitude for five years, or imprisonment to the extent of two years, with or without hard labour. There are various different kinds of assaults of a more serious description which are provided against by particular enactments of parliament, such as the Offences against the Person Act 1861; and there are also certain aggravated assaults for which the punishment is more severe than for common assault, as an assault with intent to murder, with intent to commit a rape, etc. An assault may be both a tort and a crime, giving a civil action for damages to the person injured, as well as being the subject of a criminal prosecution.

United States.—In the United States assault and battery, although sometimes defined by statute, usually follow the common law definitions. The statutes usually define an assault as an unlawful attempt to commit immediate bodily injury upon another, and battery as an unlawfui touching of another by an assailant in a rude and insolent manner, with or without a weapon. Intent is a constituent part of civil assault, thus an accident cannot constitute an assault since it lacks negligence and intention. The apparent intention must be to inflict physical injury on the person assaulted. However, if an action is for assault and battery the intention is not a material element, for, if the act was wrongful, the intent is presumed from the act. If the act was lawful the element of malice or recklessness enters and this is a necessary part of the action in such case, and must be stated under United States practice. A criminal assault and battery may be committed although the person injured does not know of, realize or fear the existence of the assault and battery. It may be stated as a general rule in assault and battery that the intention of the aggressor and the fear or apprehension of the person assaulted are not in any way controlling, thus if a person throws a stone at A and strikes B, he is guilty of assault and battery upon B upon the principle of constructive intent; *i.e.,* that a man is presumed to intend the natural and probable consequences of his acts. For when one puts into motion an injurious or deadly agency he assumes responsibility for all the natural and probable consequences of his conduct. There is an irreconcilable difference of opinion in the United States as to what constitutes a criminal assault in a case where A points a gun at B, within shooting distance, knowing that the gun is not loaded, and threatens to "blow his head off." Some courts hold that this is not a criminal assault because A has no actual intention and lacks the ability to injure B in the manner threatened. Other courts hold that it is a criminal assault because there is an apparent present intention and ability to injure B, and the outward demonstration of A may lead to defensive measures on B's part which might produce, at least, a breach of the peace. The weight of authority is in favour of the latter position. A battery may be committed by the administration of a drug to another who is innocent as to its nature and content. So, in battery, deception may be the equivalent of force, since the deceit practised is a fraud on the will of the innocent consumer of the drug equivalent to force. An officer of the law, or one who aids him, in the enforcement of his lawful duties is privileged in the use of such force as is reasonably necessary to uphold the law and preserve order.

In military language, the word is used of the culminating phase of an attack, when the advancing troops come to close quarters with the enemy, surging into and overrunning his positions.

ASSAYE, a village of Hyderabad or the Nizam's Dominions, in southern India, just beyond the Berar frontier. The place is celebrated as the site of a battle fought on Sept. 23, 1803, between the combined Mahratta forces under Sindhia and the rajah of Berar and the British under Maj.-Gen. Wellesley, afterwards the duke of Wellington. The Mahratta force consisted of 50,000 men, supported by 100 pieces of cannon served by French artillerymen, and entrenched in a strong position. Against this the English had but a force of 4,500 men, which, however, after a severe struggle, gained the most complete victory that ever crowned British valour in India. Of the enemy 12,000 were killed and wounded; and Gen. Wellesley lost 1,657—one-third of his little force—killed and wounded. Assaye is 26 1m. N. W. of Hyderabad.

ASSAYING, a term originally applied to the trying or testing of ores and alloys for their contents of gold or silver. Later it has received a wider significance; from meaning to test any ore or metallurgical product, in order to find its proportion of valuable constituents, it has even been extended to cover the determination of alkaloids (*q.v.*) in plants. It will, however, be used in this article in a metallurgical sense only. It is essentially a commercial process, hence the difference between assaying and chemical analysis. Analysis is an end in itself: the greater the accuracy, the more satisfactory is the result. In assaying it is desired to determine the value of a material, and a degree of accuracy which exceeds that required to obtain this value is uneconomical for it requires excessive time and care which might be more valuably employed. This does not mean that great accuracy is never required, as the value of the substance to be determined must be taken into account. For example, in the

assay of ores, iron is usually reported to 0·1%, whereas platinum may be carried beyond an accuracy of 0·0001%.

The origin of the art is lost in antiquity. The trial by "Touchstone" and by "Fire" are mentioned by Theophrastus (371–288 B.C.), and the early alchemists were well acquainted with such processes as precipitation, cupellation, etc., which are still in everyday use. The earliest known books on assaying were published in Germany at the beginning of the 16th century. The most interesting of these is Agricola's De Re *Metallica,* which devotes considerable space to the subject.

Assaying is closely allied to the metallurgical industry. In early times it was merely a small-scale smelting operation, and followed the large-scale processes in detail. Hence the "Dry" or "Fire" assays originated, in which the assay sample was smelted in a small crucible with suitable reagents, using a wood or charcoal furnace. The simultaneous development of chemistry led to the introduction of analytical or "Wet" methods, which are now used for the majority of metals. The old smelting, or "Fire" assay, has survived for some materials, and is still the only method available for the determination of gold and silver in ores.

The trial by "Touchstone," or "Lydian stone," to estimate the gold proportion of alloys, probably dates from the time of the Lydians (500 B.C.). The colour of the streak made on a black stone by the metal under examination, was compared with similar streaks made by "needles" of metal of known composition, called "Touchneedles." These needles were used in sets, one of golden-silver alloys, another of gold-copper alloys, and a third of "Triple" alloys, containing gold, silver, and copper. Touch needles were introduced later for testing silver-copper alloys.

DRY OR FIRE ASSAYING

Gold and Silver Ores.—Gold and silver are bought by the ounce (Troy), and, for convenience in the evaluation of ores, the contents of precious metals are not reported in percentages, but in oz., or decimals of an oz. (Troy), per ton of ore. The ton (Avoirdupois) contains 32,666.6 oz. (Troy), and, to save calculation, the weight of ore taken for assay is 32.67 grammes, or some multiple of this. This weight is known as the Long Assay Ton (A.T.). and has the advantage that every 0·001 gramme of metal found represents 1 oz. (Troy) per ton of ore. In some countries it is more usual to employ the Short Ton of 2,000 lb., and the Short Assay Ton of 29·17 grammes is used in assaying. In many of the Latin countries the Metric Ton of 1,000 kilos is the standard, and the values are reported in grammes per ton, no Assay Ton being required. Sometimes the gold or silver present is reported in its money value (*e.g.,* $42.50 per ton).

The assay consists of three operations: (1) fusion, (2) cupellation, and (3) parting.

(1) Fusion.—This may be carried out by two methods.

(a) In the "Pot Fusion" method, one A.T. or more of the crushed ore is mixed and fused in a clay crucible, or pot, with lead oxide (about 30 grammes), a reducing agent such as charcoal, argol, or flour (up to about 5 grammes), and a suitable quantity of reagents called "fluxes" which combine with the "gangue," or waste matter in the ore, forming a "flowing," or fusible slag. The fluxes used depend upon the nature of the ore. If the gangue contains silica, tin or zinc, soda is required; for iron, lime, or other basic materials, borax, crushed quartz, or similar fluxes are introduced. The quantity of these fluxes is varied to suit the requirements of the ore under examination, and will be nearly twice the weight of the ore. The crucible is placed in a coke, oil, or gas furnace at a fairly low temperature, and kept at a dull-red heat for about ten minutes, to allow the chemical reactions to be completed. By the action of the reducing agent, metallic lead is formed, which sinks through the charge to the bottom of the pot, alloying with, and so collecting the gold and silver. The temperature is then raised until the whole charge is molten and thoroughly fluid, and the contents of the pot are poured into a dry, iron mould. When cold, the brittle slag is broken away with a hammer, leaving a "button" of lead which contains the precious metals.

Certain types of ore require special treatment. Sulphide ores may be given a preliminary roasting at a red heat to burn off the sulphur, or the ore is desulphurised during fusion by adding suitable reagents to the charge. Cupriferous ores are treated with acid before fusion, to dissolve away the copper. Arsenical ores are roasted before fusion, and antimonial ores are oxidised by adding nitre to the charge.

(b) In the "Scorification" method, about 10 grammes or ½ A.T. of ore is mixed with 30–35 grammes of granulated lead in a "Scorifier," which is a shallow fireclay dish. Another 30–40 grammes of granulated lead are placed on top of the charge, and about 1 gramme of borax is added as a thin cover. The scorifier is placed in a muffle furnace at a very high temperature, when simultaneous oxidation of the lead and of the ore takes place. Some impurities volatilise, and the remainder combines with the oxidised lead and the borax, forming a slag. A ring of this slag soon forms round the surface of the molten lead, and, as oxidation proceeds, the ring extends towards the centre and finally covers the whole surface. At this point the oxidation ceases, and the charge is poured as before. The quantities of granulated lead and borax required will depend upon the nature of the ore, and are variable. It will be seen that, as a smaller quantity of ore is used, the method is only suitable for rich materials, and hence is practically confined to the assay of rich silver ores, very high grade gold ores being rarely found.

(2) *Cupellation.*—By this process the gold and silver are isolated from the lead obtained in the first operation. A cupel is a shallow cup made of bone-ash or some other absorbent matter, which, when hot, is capable of absorbing any molten material which wets its surface. The lead button is fused upon a red-hot cupel in a muffle furnace. The lead melts and oxidises, forming molten litharge, which is absorbed, together with any oxidised impurities, into the cupel. The gold and silver do not oxidise, but remain on the cupel, forming a small bead of "Bullion," which is weighed.

(3) Partifig.—The bullion bead is attacked with nitric acid which dissolves, or "parts," the silver from the gold. Before commencing this operation, it is necessary to ensure that the alloy is of such a composition that the whole of the silver will be dissolved away from the gold. The proportion, by weight, of silver to gold should be at least 4:1 if the gold present exceeds 0·01 gramme, and this ratio is increased for smaller amounts of gold. If there is insufficient silver present, more must be added by the process of "Inquartation." This consists of adding a sufficient weight of silver to the bead, either by melting the metals together with a blow-pipe flame, or by recupelling them in a small piece of pure lead. The name "Inquartation" was introduced in early times, when it was believed that the proportion of silver to gold should always be 3:1. The inquarted alloy is flattened under a hammer and dropped into boiling nitric acid. The silver dissolves, leaving a brown residue of gold. This is washed with distilled water, dried, and annealed by heating it to redness, when it takes on the familiar yellow colour of pure gold. The weight of this residue gives, by calculation, the gold content of the ore, and the silver is determined by difference from the weight of the bullion.

Gold Bullion.—This is assayed by cupellation. A representative sample of 0·5 gramme of the alloy is wrapped in 2–6 grammes of pure, silver-free lead foil, the exact weight of the lead depending on the purity of the alloy. The lead packet is cupelled in the usual manner, and the resulting bead of gold and silver is weighed. The bead is again wrapped in lead foil, together with sufficient silver to form a parting alloy, the proportion of silver to gold in this case being 2¼:1. The bead obtained after cupellation, is cleaned and rolled into a thin strip, or "fillet," which is curled into a small "cornet" or coil. The comet is treated twice with boiling nitric acid, and is then washed, dried, annealed, and weighed. Errors introduced during cupellation and parting are corrected by carrying out simultaneous "check" assays on test pieces made up to the same composition as the alloy. The gold present is reported as so many parts of gold in 1,000 parts of alloy. This is called "Fineness," and British gold coinage is said

to be "916·6 Fine."

Lead Ores.—The assay consists of fusion with suitable fluxes and a reducing agent, in a clay or iron crucible. The charge is varied to suit the ore. A typical example being about one part of ore, $2\frac{1}{2}$ parts of soda, one half part of borax and one half part of argol. When a clay crucible is used, a piece of hoop iron, in length about twice the height of the crucible, is pushed down into the mixture to act as a desulphurising agent. When an iron crucible is used, the pot itself acts in this way. The crucible is heated in a wind furnace, and it is important to work the charge at the lowest temperature which will give a fluid slag, in order to prevent undue loss of lead, and to minimise the amount of metallic impurities which will pass into the button. On completion of the fusion, the charge is poured into a mould, and the lead button is separated from the slag and weighed.

Tin Ores.—The smelting assay is unsuitable for crude tin ores, but satisfactory results may be obtained with high-grade concentrates, provided the charge is run at a low temperature and is not left in the fire longer than necessary. The sample of ore is mixed with four times its weight of crude potassium cyanide, and is placed in a clay crucible. The pot is put in a furnace, and the temperature is raised to dull redness, and kept there until the charge is thoroughly fused. The temperature is further raised for a few minutes to render the slag quite fluid, and the charge is poured as usual. Many metallic impurities in the ore are reduced and pass into the tin button; consequently the method is unreliable except for fairly clean concentrates.

WET ASSAYING

This employs the volumetric, gravimetric, and electrolytic methods. Volumetric methods are in particular favour; as less manipulation is required, and the sample may often be titrated without lengthy chemical separations. The weight of ore taken for assay is much smaller than in Fire Assaying, 0·25–2·0 grammes generally being sufficient. It is essential that the sample shall be finely crushed, especially if it is to be dissolved in acids, as particles of the mineral may be encased in the insoluble gangue. Minerals which are not decomposed by acids are fused with a flux which will render them soluble in water or acids.

Silver Bullion.—The cupellation assay was used formerly, for the determination of silver in many of its alloys. This method has been replaced in the majority of mints and assay offices by volumetric methods. The chief of these is the "Gay Lussac" assay, which was introduced into the Paris mint in 1830, and has since been adopted in most offices. An exact weight of the bullion is dissolved in nitric acid, and very nearly all the silver is precipitated at once by the addition of a known volume of a standard solution of salt. When the precipitate has settled, the remaining silver is precipitated by the further addition of a small quantity of a more dilute solution of salt, the precipitate forming a white cloud in the supernatant liquid. The quantity of this silver is judged by the appearance of the white cloud.

Copper.—The material is attacked with suitable acids, and the copper is carried into solution. There are three methods of assay available. (1) In the cyanide assay, the solution is rendered ammoniacal, which results in the formation of a deep blue liquid. This colour is discharged by titration with a standard solution of potassium cyanide, the volume of the latter being a measure of the copper present. (2) In the iodide assay, the copper is first separated from the other metals present, and is then redissolved in Nitric acid. The mineral acid is destroyed by adding an excess of zinc acetate. Potassium iodide is then added, which results in the reduction of the copper and the liberation of a quantity of iodine which is proportional to the amount of copper present. This iodine is measured by titration with a standard solution of sodium thiosulphate, using starch solution as an inside indicator (*q.v.*), towards the end of the titration. **(3)** In the electrolytic assay, any hydrochloric acid is expelled from the solution, and the acidity is carefully adjusted to the correct strength. The solution is then subjected to electrolysis, the copper being deposited on the cathode. The increase in weight of the latter gives the amount of copper present.

Iron.—The ore is brought into solution by acid attack, the iron is reduced by one of the usual chemical processes, and the ferrous solution is oxidised by titration with a standard solution of potassium dichromate, or of potassium permanganate. In the former case a weak solution of potassium ferricyanide is used as an outside indicator (*q.v.*).

Lead.—Minerals of this metal are dissolved in hydrochloric acid, sometimes assisted by nitric acid. The lead is separated by evaporation with sulphuric acid, and the solution is cooled, diluted, and filtered. The precipitated lead sulphate is redissolved in hot ammonium acetate solution, and titrated, just below the boiling point, with a standard solution of ammonium molybdate. A solution of tannic acid is used as an outside indicator. An alternative method is to reprecipitate the lead as chromate, filter, and dissolve the precipitate in a hydrochloric acid solution of salt. Potassium iodide is added, which results in the liberation of iodine. This is titrated with thiosuplhate as in the copper assay.

Tin.—The ores of tin are decomposed by fusion with sodium peroxide in an iron or nickel crucible, or by ignition with zinc oxide and metallic zinc. In either case the residue is leached out with water and dissolved in hydrochloric acid. The tin is reduced by suspending a nickel coil in the solution and boiling vigorously for 40–60 minutes. The solution is cooled in an atmosphere of carbon dioxide, and the tin is oxidised by titration with a standard solution of iodine, using starch as an inside indicator.

Zinc.—These ores are attacked with acids, and the solution is subjected to a process of separation which follows, in principle, the system adopted in Qualitative Analysis. (See CHEMISTRY: Analytical.) The clear zinc solution is rendered slightly acid, and is titrated, just below the boiling point, with a standard solution of potassium ferrocyanide. A solution of uranium nitrate is used as an outside indicator.

Smith, *The Sampling and Assay of the Precious Metals* (new edition in preparation); E. A. Wraight, *Assaying* in *Theory and Practice* (1914); W. W. Scott, *Technical Methods of Metallurgical Analysis* (1924). *(C. W. D.)*

ASSAY OFFICE, a department operating under the United States mint as a laboratory for the purpose of assaying, *i.e.*, chemically and otherwise testing for purity, content and value, metals submitted to it for this purpose. The metals brought for assay are usually gold and silver, and may be in the forms of bullion, jewellery, ornaments, metal-ware and others. The Assay Office is authorized to buy gold, although no longer allowed to coin it, and to pay for it with an order on the U. S. Treasury for an equal amount in currency or Federal Reserve notes. It will also, for a reasonable charge, assay metals for others than prospective sellers to the Government or analyse sample ores brought in, the latter activity forming a considerable part of the work in the western branch. The U.S. Assay Office is in New York city and has very heavy duties owing to the vast movements of gold passing through the city. All foreign gold received is here submitted to test. In recent years special facilities for the assaying of platinum have been installed in the New York office. There are branches of the Assay Office at New Orleans, Louisiana and Seattle, Washington.

The Assay Commission, established by the United States government, meets annually to examine and test, in the presence of the Director of the Mint, the fineness and weight of certain coin indiscriminately withheld at the various mints for that purpose. The number of coins reserved for such examination must be not less than one piece for each two thousand of silver coins and they must be taken out at every delivery of coins made by the coiner. Gold is no longer coined. The commission is composed of the judge of the district court for the Eastern district of Pennsylvania, the Comptroller of the Currency, the assayer of the assay office at New York, and such other persons as the President shall from time to time designate, the entire Commission usually numbering from ten to fifteen persons.

ASSAY OFFICE BAR, a bar of fine, meaning pure, gold which has been made from metal assayed by the U.S. Assay Office. Such a bar bears the Government stamp certifying to its

weight and fineness. Bars of precious metals turned out by private assayers cannot carry the Government stamp, and are known as "commercial bars."

ASSEGAI or **ASSAGAI** (from Berber-Arab as-zalzayah, through Portuguese azagaia), a weapon for throwing or hurling, a light spear or javelin made of wood and pointed with iron, particularly the spear used by the Zulu and other Kaffir tribes of south Africa. In addition to the long-handled assegai there is a shorter weapon for use at close quarters.

ASSEMANI, the name of a Syrian Maronite family of oriental scholars.

JOSEPH SIMON (1687–1768), a Maronite of Mount Lebanon. He was sent to the Maronite college in Rome, and entered the Vatican library. In 1717 he was sent to Egypt and Syria to search for valuable mss., and returned with about 150 very choice ones. The pope again sent him to the East in 1735, and he returned with a still more valuable collection. On his return he was made titular archbishop of Tyre and librarian of the Vatican library.

His two great works are the Bibliotheca Orientalis *Clementino-Vaticana* rec. *manuscr.* codd. Syr., Arab., Pers., Turc., Hebr., Samarit., *Armen., Aethiop.,* Graec., Aegypt., Iber., et *Malab., jussu* et *munif.* Clem. XI. (1719–28), and *Ephraemi* Syri opera omnia quae extant, Gr. Syr., et Lat. (1737–46). Of the *Bibliotheca* the first three vols. only were completed. The work was to have been in four parts but only the first—Syrian and allied mss., Orthodox, Nestorian and Jacobite—was completed. There is a German abridgment by A. F. Pfeiffer.

His brother, JOSEPH ALOYSIUS (*c.* 1710–82), was professor of oriental languages at Rome, and a nephew, STEPHEN EVODIUS (1707–82), was assistant to his uncle at the Vatican library, and held various ecclesiastical preferments. His most important work is Bibliotlzecae *mediceo-Laurentianae* et Palatinae codd. *manuscr. Orientalium Catalogus* (Flor. 1742). Another member of the family, SIMON (1752–1821) was professor of oriental languages at Padua.

ASSEMBLE, a term of great significance in modern productive methods. It explains the difference between the older practice of fitting parts to one another, and the modern way of finishing components so that they can be brought together or "assembled" without the need for any cutting or alteration; if spares and replacements are needed, they may then be supplied in tens of thousands, all certain to fit without alteration.

There is often a modified procedure in manufacturing parts of large and elaborate structures, the primary assembling being done at the works, with a moderate amount of hand fitting, and then all the joints are marked with paint or stencilling for the final assembly *in situ.* Perfection of assembling occurs in the smaller all-metal products and parts such as screws and bolts, brass fittings, steam and water valves, ball bearings, clocks, typewriters, sewing-machines, magnetos, small arms, machine-guns, cartridges, shells, small engines, pumps and motor cars. The practice originated in the United States because of the great demand for sewing-machines and small arms, and later for typewriters.

An elaborate equipment and routine system becomes necessary to make parts ready to assemble. All the cutting tools on the machine-tools must keep their size for a certain period without wear, and to test the results therefrom numerous gauges have to be employed, the germ of the system being the "limit-gauge." This has two measuring portions, called and marked the "go" and "not go." No machine tool can cut or grind a piece of metal to exact size (commercially), but if a definite limitation of error each may is ensured, then the piece will assemble with its other component. Hence the limit-gauge is made oversize one end, say 4 in. plus one 2,000th of an inch, and undersize at the other, one 2,000th of an inch less than 4 inches. A shaft must, therefore, be made of such diameter that it will neither be too large to pass into the + opening of the gauge, nor so small that it will pass into the − opening. Thus the limits of size are guaranteed.

The assembling department of a factory may contain merely benches, with bins full of the parts within reach, the assemblers putting the details together without any special holding arrangements, the product being taken away by hand or trucks. This is not a suitable system for the larger articles, and conveyor outfits have to be installed, such as plain rails on which the objects arc moved away, travelling chains or plates, turntables, etc. Motor cars are assembled while running on dummy flanged wheels rolling on rail tracks, each assembler adding some portion as the chassis reaches his standpoint.

Motion-study becomes essential in these highly organized systems, and special tools greatly assist, such as ratchet screwdrivers and spanners, screwdriver braces, and pneumatic and electric wrenches for rapid rotation without labour.

(See CONVEYORS IN MASS PRODUCTION; MASS PRODUCTION.)

ASSEMBLY, UNLAWFUL, the term used in common law for an assembly of three or more persons with intent to commit a crime by force, or to carry out a common purpose (whether lawful or unlawful), in such a manner or in such circumstances as would in the opinion of firm and rational men endanger the public peace or create fear of immediate danger to the tranquillity of the neighbourhood. In the Year Book of the third year of Henry VII.'s reign assemblies were referred to as not punishable unless in *terrorem populi domini regis.* An assembly, otherwise lawful, is not made unlawful if those who take part in it know beforehand that there will probably be organized opposition to it, and that it may cause a breach of the peace (Beatty v. Gillbanks, 1882, 9 Q. B. D. 308), but if words are said or acts done indirectly inducing others to commit a breach of the peace, the meeting becomes unlawful (Wise v. Dunning, 1902, 1 K. B. 167). All persons may, and must if called upon to do so, assist in dispersing an unlawful assembly (*Redford* v. Birley, 1822, 1 St. Tr. n.s. 1215; R. v. Pinney, 1831, 3 St. Tr. n.s. 11). This is merely one aspect of the common law duty of every man to assist in keeping the peace and it is an indictable misdemeanour to refuse so to assist (R. v. Sherlock, 1 C. C. R. 20). An assembly which is lawful cannot be rendered unlawful by proclamation unless the proclamation is one authorized by statute (R. v. Fursey, 1833, 3 St. Tr. n.s. 543, 567; R. v. *O'Connell,* 1831, 2 St. Tr. n.s. 629, 656; see also the Prevention of Crimes [Ireland] Act 1887). Meetings for training or drilling, or military movements, are unlawful assemblies unless held under lawful authority from the Crown, the lord-lieutenant, or two justices of the peace (Unlawful Drilling Act 1820, s. 11).

An unlawful assembly which has made a motion towards its common purpose is termed a *rout,* and if the unlawful assembly should proceed to carry out its purpose, *e.g.,* begin to demolish a particular enclosure, it becomes a riot (*q.v.*). All three offences are misdemeanours in English law, punishable by fine and imprisonment. The common law as to unlawful assembly extends to Ireland, subject to the special legislation referred to under the title RIOT. The law of Scotland includes unlawful assembly under the same head as rioting.

ASSEMBLYMAN, the official who is elected to serve as a member of the more numerous branch of the State legislature in New Jersey and New Tork, where he is elected for a term of one year. In most of the other States such official is called a "representative" and serves for a term of either one or two years, generally the latter. There is no constitutional prohibition against the re-election of such official and the office is frequently used as a stepping-stone in a man's political career to some higher position, such as State senator, district or circuit judge or representative in Congress.

ASSEN, capital of the province of Drente, the Netherlands, 16 mi. by rail S. of Groningen, at the junction of two canals running north and south to Groningen and Meppel respectively. Pop. (1940) 20,235. Many remains of early man from this region are in the Leyden museum. Assen was the site of a small convent in the middle ages around which the present town gathered. Bishop Otto II (of Utrecht) was murdered here in 1237. There is a museum of antiquities, and it is an important market town. It was occupied by Germany in 1940.

ASSER or **ASSERIUS MENEVENSIS** (died c. 910), English bishop, author of a life of Alfred the Great, was born in Wales. He became a monk at St. David's, and having acquired some reputation for learning, he was invited by King Alfred to

his court. He agreed to spend six months of each year with the King and six months in his own land; but his first stay at the royal court extended to eight months, and it is probable that the annual visit to Wales was curtailed, if not altogether discontinued. It is difficult to fix the date of Asser's arrival in England, but it was probably about 885. He was bishop of Exeter, and before 900 became bishop of Sherborne. His death is recorded in the Anglo-Saxon *Chronicle* under the date 910, although it is possible that it occurred a year or two earlier.

Asser's work, *Annales rerum gestarum Alfredi magni,* written about 893, contains a chronicle of English history from 849 to 887, and an account of Alfred's life, largely drawn from personal knowledge, down to 887. The only manuscript of which there is any record dates from about 1000, and that was destroyed by fire in 1731. From that manuscript an edition was printed in 1574 under the direction of Matthew Parker, Archbishop of Canterbury; but this contained many interpolations and alterations which were copied by subsequent editors. The text has since been the subject of careful study, and the edition edited by W. H. Stevenson (Oxford, 1904) distinguishes between the original work of Asser and the later additions. Some doubt has been cast upon the authenticity of the work, especially by T. Wright in the *Biographia* Britannica literaria (London, 1842), who ascribes the life to a monk of St. Neots; but the latest scholarship regards it as the work of Asser, although all the difficulties which surround the authorship have not been removed. The life was largely used by subsequent chroniclers, among others by Florence of Worcester, Simeon of Durham, Roger of Hoveden, and William of Malmesbury.

BIBLIOGRAPHY.—see W. H. Stevenson, introduction to Asser's Life of *King Alfred* (1904); *R.* Pauli, introduction to Koenig *Aeljred* (1851).

ASSESSED VALUATION, the value placed upon real or personal property by governmental authority for purposes of taxation. It may or may not be an indication of the market value of the property, but in any case, provided the assessments are equitable, it supplies a guide to the relative values of similar kinds of property in the same assessment district. Methods of assessing the valuation of real estate for tax purposes differ in various places. Sometimes valuations are based upon full market value and at other times upon some fraction of the market value. Of the two general methods of raising taxes, a high assessment value with a low tax rate, and a low assessment value with a correspondingly higher tax rate, the latter is much more generally used.

A study of real estate assessment and assessed valuation is of great importance to the dealer and investor in municipal bonds. The debt of a municipality is usually limited by law to a certain percentage of the assessed valuation of the property and the holder of municipal bonds should know the assessed value to be sure that the limit of debt has not been exceeded. Where the assessment is for practically full market value of property the debt limit should be considerably below the assessed valuation to make the bonds sound; but where the assessment represents only one-half or one-third of the market value, as is the case in many communities, the bonded debt may safely approach much more closely to the assessed valuation. Investment bankers who offer municipal bonds frequently state in their circulars not only the assessed valuation of the municipality in question and the ratio of total debt to it, but also the method of assessment and the total estimated market value of all property.

ASSESSMENT, a demand or call made by a corporation upon stockholders for a specified sum of money per share of stock in addition to that already paid in. Such assessments are generally made when the company is financially embarrassed and it is a question of the stockholders meeting the assessment or the company becoming insolvent. Reorganizations of corporations frequently involve the placing of an assessment on the stockholders and sometimes even upon bondholders.

For English law see DAMAGES; TAXATION; VALUATION AND VALUERS.

ASSESSMENT INSURANCE: see FRIENDLY SOCIETIES; BENEFIT SOCIETIES and APPROVED SOCIETIES.

ASSESSOR, a Roman term originally applied to a trained lawyer who sat beside a governor of a province or other magistrate, to instruct him in the administration of the laws (see Roll, De *assessoribus magistratuum Romanorum,* Leipzig, 1872). The system is still exemplified in Scotland, where it is usual in the larger towns for municipal magistrates, in the administration of their civil jurisdiction, to have the aid of professional assessors. In England, by the Judicature Act 1873, the court of appeal and the High Court may in any cause or matter call in the aid of assessors. The Patents Act 1907 makes special provision for assessors in patent and trade-mark cases. By the Supreme Court of Judicature Act 1891 the House of Lords may, in appeals in admiralty actions, call in the aid of assessors, while in the admiralty division of the High Court it is usual for the Elder Brethren of Trinity House to assist as nautical assessors. In admiralty cases in the county courts, too, the judge is frequently assisted by assessors of "nautical skill and experience" (County Court Admiralty Jurisdiction Act 1868). In the same courts assessors may be appointed by the rules made under the Employers' Liability Act 1880; while a medical referee may be summoned as an assessor in cases under the Workmen's Compensation Acts. In the ecclesiastical courts assessors assist the bishop in proceedings under the Church Discipline Act 1840, s. 11, while under the Clergy Discipline Act 1892, s. 2, they assist the chancellor in determining questions of fact. By the Appellate Jurisdiction Act 1876, s. 14, the king in council may make rules for the attendance of archbishops and bishops as assessors in the hearing of ecclesiastical cases by the judicial committee of the privy council.

In France and in all European countries where the civil law system prevails, the term assesseur is applied to those assistant judges who, with a president, compose a judicial court.

In Germany an Assessor, or *Beisitzer,* is a member of the legal profession who has passed four years in actual practice and become qualified for the position of a judge. (X.)

United States.—An assessor in the United States is an official who evaluates property for purposes of taxation. An assessor exists as a county officer in virtually all of the States, and is elected by the voters for a term of two, three or four years. Originally, in the early colonial days, the work of the assessor was done by justices of the peace, transferred in later colonial days to county boards of commissioners or supervisors. The duties of the assessor are generally to list all property and persons subject to taxation. Appeals are provided by statutes to county boards of commissioners or supervisors or courts where the person taxed may protest against the amount assessed as being unfair. Some States have provided for township assessors, elected by the voters of the township, to work under the supervision of the assessor, and in others the assessor is permitted a sufficient number of deputies to aid him in the completion of his work, the assessments generally being made annually. Most of the States have State boards of taxation which supervise, to some extent, the work of the assessors. In most of the States this board is named by the governor, but in a few, such as Illinois where it is called the board of equalization, it is elected.

In Roman law, used throughout Europe, wherever the civil law system obtains, an assessor is one who is called by the courts to give legal advice and assistance. In the United States Federal district courts experienced shipmasters serve as assessors in this sense of the word in admiralty matters. In the State probate and surrogate courts in the United States, "appraisers" are frequently appointed to ascertain the value of deceased persons' estates.

See H. G. James, *Local* Government in *the United* States (1921).

ASSIDEANS: see MACCABEES.

ASSIGNATS, a form of paper money issued in France from 1789 to 1796. Assignats were so termed as representing land assigned to the holders. The term is from Lat. assignatus, assigned.

The financial strait of the French Government in 1789 was extreme. Coin was scarce, loans were not taken up, taxes **had**

ceased to be productive, and the country was threatened with imminent bankruptcy. In this emergency assignats were issued to provide a substitute for a metallic currency. They were originally of the nature of mortgage bonds on the national lands. Those lands consisted of the church property confiscated, on the motion of Mirabeau, by the Constituent Assembly on Nov. 2 1789, and the crown lands, which were taken over by the nation on Oct. 7 (*see* FRENCH REVOLUTION).

The assignats were first to be paid to the creditors of the State. With these the creditors could purchase national land, the assignats having, for this purpose, the preference over other forms of money. If the creditor did not care to purchase land, it was supposed that he could obtain the face-value for them from those who desired land. Those assignats which were returned to the State as purchase-money were to be cancelled, and the whole issue, it was argued, would consequently disappear as the national lands were distributed.

A first issue was made of 400,000,000 francs' worth of assignats, each note being of 100 francs' value and bearing interest at the rate of 5%. They were to be redeemed by the product of the sales, and from certain other sources, at the rate of 120,000,000 francs in 1791, 100,000,000 francs in 1792, 80,000,000 francs in 1793 and 1794, and the surplus in 1795. The success of the issue was undoubted, and, possibly, if the assignats had been restricted, as Mirabeau at first desired, to the extent of one-half the value of the lands sold, they would not have shared the usual fate of inconvertible paper money. Mirabeau was a strenuous advocate of the assignats. "They represent," he said, "real property, the most secure of all possessions, the soil on which we tread." "There cannot be a greater error than the fear so generally prevalent as to the over-issue of assignats . . . reabsorbed progressively in the purchase of the national domains, this paper mopey can never become redundant."

EIGHT THOUSAND MILLION ASSIGNATS

In 1790 the interest on the assignats holdings was reduced to 3%, and as the Treasury had again become exhausted a further issue was decided upon; it was also decreed that the assignats were to be accepted as legal tender, all public departments being instructed to receive them as the equivalent of metallic money. This second issue amounted to 800,000,000 francs and carried no interest. It was solemnly declared in the decree authorizing the issue that the maximum issue was never to exceed 1,200,000,000 francs. This pledge, however, was soon broken, and further issues brought the total up to 3,750,000,000 francs. The consequence of these further issues was instant depreciation, and the note of 100 francs' nominal value sank to less than 20 francs' coin. Recourse was then had to protective legislation. The first step was to decree the penalty of six years' imprisonment against any person who should sell specie for a more considerable quantity of assignats, or who should stipulate a different price for commodities according as the payment was to be made in specie or in assignats. For the second offence the penalty was to be 20 years' imprisonment (Aug. 1 1793), for which the death penalty was ultimately substituted (May 10 1794). This severe provision was, however, repealed after the fall of Robespierre. Notwithstanding these precautions the value of assignats still declined, till the proportion to specie had become that of six to one. Then came the passing by the convention, May 3 1793, of the absurd "maximum." The decree required all farmers and corn-dealers to declare the quantity of corn in their possession and to sell it only in recognized markets. No person was to be allowed to lay in more than one month's supply. A maximum price was fixed, above which, under severe penalties, no one was to buy or sell. These measures were soon stultified by further issues, and by June 1794 the total number of assignats aggregated nearly 8,000,000,000, of which only 2,464,000,000 had returned to the Treasury and been destroyed. The extension of the "maximum" to all commodities only increased the confusion. Trade was paralysed and all manufacturing establishments were closed down. Attempts by the convention to increase the value of the assignats were of no avail. Too many causes operated in favour of their depreciation: the enormous issue, the uncertainty as to their value if the Revolution should fail, the relation they bore to both specie and commodities, which retained their value and refused to be exchanged for a money of constantly diminishing purchasing power. Even between the assignats there were differences. The royal assignats, which had been issued under Louis XVI., had depreciated less than the republican ones. They were worth from 8 to 15% more, because of the hope that in case of a counter-revolution they would be less likely to be discredited.

The Directory was guilty of even greater abuses in dealing with the assignats. By 1796 the issues had reached the enormous figure of 45,500,000,000 francs, and even this gigantic total was swollen still more by the numerous counterfeits introduced into France from the neighbouring countries. The assignats had now become totally valueless—the abolition of the "maximum" the previous year (1795) had produced no effect, and though, by various payments into the Treasury, the total number had been reduced to about 24,000,000,000 francs, their face-value was about 30 to 1 of coin. At that value they were converted into 800,000,000 francs of land-warrants or *mandats territoriaux,* which were to constitute a mortgage on all the lands of the republic. These *mandats* were no more successful than the assignats, and even on the day of their issue were at a discount of 82%. They had an existence of six months, and were finally received back by the State at about the 70th part of their face value in coin. (*See* also PAPER MONEY; MONEY.)

BIBLIOGRAPHY.—L. A. Thiers, *Histoire de la révolution française,* gives a full and graphic account of the assignats, the causes of their depreciation, etc.; J. Garnier, *Traitd des Finances* **(1862)**; J. Bresson, *Histoire financière de la France* **(1829)**; R. Stourm, *Les Finances dc E'ancien rdgime et de la révolution* **(1885)**; F. **A.** Walker, *Money* **(1891)**; Henry Higgs, in the *Cambridge Modern History,* vol. viii. (1904).

ASSIGNEE, one to whom property is assigned. (See ASSIGNMENT.)

ASSIGNMENT. An assignment is the term for that kind of total alienation by deed or writing (other than testamentary) of a chattel interest in real property, or of chattels personal, or of an equitable interest in real estate, which is not essentially destructive of such interest. Assignments are either voluntary or for valuable consideration. The former are specifically termed "gifts" (see GIFT). The document evidencing the latter is called a "bill of sale." The technical operative words of an assignment are "assign, transfer and set over"; but any other words showing an intention to make a complete transfer will amount to an assignment. In Scotland the usual term for this contract is assignation. The parties thereto in England and Scotland respectively are called assign and assignee, assignor and cedent. In the United States they are known as assignor and assignee.

In the United States.—An assignment of the property of a debtor is often made to a trustee for the benefit of creditors, the trustee being authorized to administer and to liquidate as far as necessary the assets, and to apply them to the satisfaction of the creditors, the surplus, if any, being returned to the assignor. Such assignment may be partial or general. **A** partial assignment may stipulate what is to be assigned, but a general assignment for the benefit of creditors embraces the entire property of the assignor except such part as may be exempt by statute, and constitutes an act of bankruptcy (*q.v.*). Exemptions vary in different jurisdictions and local laws must be consulted in any given case. A permanent assignment, such as is made in the transference of the title to stock and bonds, is known as an irrevocable assignment.

Assignment in Blank.—This is a formal assignment of a bond or of a certificate of stock in which the name of the party to whom the assignment is made is omitted; it is often called "endorsement in blank." Instruments so assigned are convenient and easy for a broker to handle with promptness, as he merely has to fill in the name of a purchaser to make the instrument transferable on the books of the issuing company. Great care must be exercised to guard against forgery in such stock assignments, and for that reason most corporations will not transfer stock on their books unless the signature of the assignee on the old certificate is guaranteed by a bank or by a stock exchange house or is acknowledged by a notary.

ASSIGNOR, one who assigns property to another. *(See* ASSIGNMENT.)

ASSIMILATION, a term used in psychology to denote the mechanism by which two or more mental processes are drawn into a single unitary whole. What takes place in psychological assimilation can be understood by considering the way in which lines slightly different in length are taken to be equal, or musical intervals slightly out of tune (as in equal-tempered musical instruments) assume the character of the pure intervals. In more complex mental formations, such as perceptions, recognitions, memories and emotions, the parts lose their individual independence and form a single unit of experience.

ASSINIBOIA, a name formerly applied to two districts of Canada, but not now held by any. (1) A district formed in 1835 by the Hudson's Bay Company, having in it Fort Garry at the junction of the Red and Assiniboine rivers in Rupert's Land, Korth America. It extended over a circular area, with a radius of 50m. from Fort Garry. It was governed by a local council nominated by the Hudson's Bay Company. It ceased to exist when Rupert's Land was transferred to Canada in 1870. (2) A district of the North-West Territories, which was given definite existence by an act of the Dominion parliament in 1875. Assiniboia extended from the western boundary of Manitoba (99° W. in 1875, and 101° 25′ W. in 1881) to 111° W., and from 49° N. to 52° N. The name was a misnomer, as it barely touched the Assiniboine river. To the north of the district lay the district of Saskatchewan, with which Assiniboia was united in 1905.

ASSINIBOIN, an American Indian tribe in the northern Plains, of Siouan affiliation, closely related in dialect to the Yankton Dakota, but separately mentioned as early as 1640. Their habitat in the 17th century was about Lake Winnipeg, and in the 18th century on the upper Saskatchewan, where they ultimately gave its name to the province of Assiniboia. Culturally they belong with the Dakota and Plains Cree. *See* R. H. Lowie, *Am. Mus. Nat. Hist. Anthr. Pap.*, vol. iv. (1909).

ASSISI (anc. *Asisium*), episcopal see, Umbria, Italy, province of Perugia, 15 mi. E.S.E. by rail from Perugia. Pop. (1936) town, 4,686; commune, 22,514. The town occupies a fine position on a spur of the Monte Subasio (1,345 ft. above sea-level) with a view over the Tiber and Topino. St. Francis was born here in 1182, and returned here to die in 1226. The Franciscan monastery and the lower and upper church of St. Francis, begun immediately after his canonization in 1228, and completed in 1253, are fine Gothic. The neo-classical crypt was added in 1818, when his sarcophagus was found. The lower church contains frescoes by Cimabue, and famous ones over the high altar by Giotto, illustrating the vows of the Franciscan order; while the upper church has frescoes representing scenes from the life of St. Francis (by Giotto and his pupils) on the lower nave walls, and scenes from the Old and New Testament history by Pietro Cavallini and his pupils on the upper. The church of Santa Chiara (St. Clare), the foundress of the Poor Clares, with its massive lateral buttresses, fine rose-window, and simple Gothic interior, was begun in 1257, four years after her death. It contains the tomb of the saint. Santa Maria Maggiore is also good Gothic. The cathedral (San Rufino) has a fine façade with three rose-windows of 1140. The mediaeval castle (1,655 ft.) was built by Cardinal Albornoz (1367) and added to by Popes Pius II. and Paul III. Two miles to the east in a ravine below Monte Subasio is the hermitage *delle Carceri* (of the prisons) (2,300 ft.), partly built, partly cut out of rock, given to St. Francis by Benedictine monks as a place of retirement. Close to the station is the large pilgrimage church of Santa Maria degli Angeli, begun in 1569 by Pope Pius V., with Vignola as architect, but not completed until 1679, partly destroyed by an earthquake in 1832, and afterwards rebuilt. It contains the original oratory of St. Francis (the Porziuncola) and the cell in which he died.

Discoveries from the ancient city of Asisium include traces of city walls, the so-called temple of Minerva (with six Corinthian travertine columns of the Augustan era), part of the pavement of the forum. and remains of the amphitheatre in the northeast corner. Asisium was the birthplace of the Roman poet Propertius.

ASSIZE or **ASSISE,** a legal term, meaning literally a "session," but in fact sometimes a jury, or the sittings of a court, and sometimes the ordinances of a court or assembly.

It originally signified the form of trial by a jury of 16 persons, which eventually superseded the barbarous judicial combat; this jury was named the grand assize and was sworn to determine the right of seisin of land (*see* EVIDENCE). The grand assize was abolished in 1833; but the term assize is still applicable to the jury in criminal causes in Scotland.

In the only sense in which the word is not now almost obsolete, assize means the periodical session of the judges of the High Court of Justice held in the various counties of England, chiefly for the purposes of gaol delivery and trying causes at *nisi prius.* Previous to Magna Carta (1215) writs of assize had all to be tried at Westminster, or to await trial in the locality in which they had originated at the septennial circuit of the justices in eyre; but, by way of remedy for the great consequent delay and inconvenience, it was provided by this celebrated act that the assizes of *mort d'ancestor* and *novel disseisin* should be tried annually by the judges in every county. By successive enactments, the civil jurisdiction of the justices of assize was extended, and the number of their sittings increased, till at last the necessity of repairing to Westminster for judgment in civil actions was almost obviated to country litigants by an Act, passed in the reign of Edward I., which provided that the writ summoning the jury to Westminster should also appoint a time and place for hearing such causes within the county of their origin. The date of the alternative summons to Westminster was always subsequent to the former date, and so timed as to fall in the vacation preceding the Westminster term, and thus *"Unless before,"* or *nisi prius,* issues came to be dealt with by the judges of assize before the summons to Westminster could take effect. The *nisi prius* clause, however, was not then introduced for the first time. It occurs occasionally in writs of the reign of Henry III. The royal commissions to hold the assizes are (1) general, (2) special. The general commission is issued twice a year to the judges of the High Court of Justice, and two judges are generally sent on each circuit. It covers commissions—(1) of oyer and terminer, by which they are empowered to deal with treasons, murders, felonies, etc. This is their largest commission; (2) of *nisi prius* (*q.v.*); (3) of gaol delivery, which requires them to try every prisoner in gaol, for whatsoever offence committed; (4) of the peace, by which all justices must be present at their county assizes, or else suffer a fine. Special commissions are granted for inquest in certain causes and crimes (*see* CIRCUITS; PRACTICE AND PROCEDURE).

Assizes, in the sense of ordinances or enactments of a court or council of state, as the "assize of bread and ale," the "assize of Clarendon," the "assize of arms," are important in early economic history. As early as the reign of John the observance of the *Assisae venalium* was enforced, and for a period of 500 years thereafter it was considered no unimportant part of the duties of the legislature to regulate by fixed prices the sale of bread, ale, fuel, etc. (*see* ADULTERATION). The word assize is used in a wider legislative connection by early chroniclers and historians—the "assisae of the realme," *e.g.*, occasionally meaning the organic laws of the country. For the "assizes of Jerusalem" *see* CRUSADES.

The term assize, originally applying to an assembly or court, became transferred to actions before the court of the writs by which they were instituted. The following are the more important

Assize of darrein presentment, or last presentation, was a writ directed to the sheriff to summon an assize or jury to enquire who was the last patron that presented to a church then vacant, of which the plaintiff complained that he was deforced or unlawfully deprived by the defendant. It was abolished in 1833 and the action of *quare impedit* (*q.v.*) substituted. But by the Common Law Procedure Act 1860, no *quare impedit* can be brought, so that an action in thr king's bench of the High Court was substituted for it.

Assize of *mort d'ancestor* was a writ which lay where a plaintiff complained of an "abatement" or entry upon his freehold, effected by a stranger on the death of the plaintiff's father, mother, brother, sister, uncle, aunt, etc. It was abolished in 1833.

Assize of *novel disseisin* was an action to recover lands of which the plaintiff had been "disseised" or dispossessed. It was abolished in 1833. *See* Pollock and Maitland, *History of English Law.*

Assize, clerk of, an officer "who writes all things judicially done by the justices of assizes in their circuits." He has charge of the commission, and takes recognizances, records, judgments and sentences, grants certificates of conviction, draws up orders, etc. By the Clerks of Assize Act 1869 he must either have been for three years a barrister or solicitor in actual practice, or have acted for three years in the capacity of subordinate officer of a clerk of assize on circuit.

ASSIZE OF JERUSALEM: *see* CRUSADES.

ASSMANNSHAUSEN, a village of Germany, near Wiesbaden, on the right bank of the Rhine and the railway from Frankfort-on-Main to Niederlahnstein. Pop. 1,344. It has a lithium spring, baths and a *Kurhaus,* and is famed for its red wine *(Assmannshauser).*

ASSOCIABILITY is a term used by Herbert Spencer *(Principles of Psychology,* sec. 160 ff.) to denote the capacity of an experience (state of consciousness or feeling) of one kind for association or integration with others so as to lead subsequently to mutual revival or recall. He pointed out that emotions are less associable with one another than are other mental experiences. He explained this by saying that associability or integration varies directly with the relational character of experiences, and emotions are least relational, whereas visual experiences, *e g,* are among the most relational. *See* ASSOCIATION OF IDEAS; PSYCHOLOGY.

ASSOCIATED BANKS, banks that make daily clearings through the same clearing house, *i.e.,* a group of banks which are members of the same clearing house association. *(See* CLEARING HOUSE.)

ASSOCIATED PORTLAND CEMENT MANUFACTURERS, LTD. This company, formed in 1900, was one of the earliest of British industrial combinations. It amalgamated some 24 businesses, and the 32 works acquired, producing over 1,000,000 tons of cement a year, were nearly all situated on the Thames and Medway, the cradle of the Portland cement industry.

While the company possessed brands of repute, it suffered at the outset from over-capitalization and lack of working capital; these disadvantages were intensified by depression in the building industry. Also at this juncture a revolution was taking place in the method of production. The rotary kiln, an English invention, had been made a practical success in the United States. This method of calcination not only improved the quality of the cement but saved much fuel and labour as compared with the system of hand-operated chamber-kilns. J. Bazley White and Brothers, one of the constituent firms, had already secured a licence to install rotary kilns under American patents, and the company paid a large sum in cancellation of royalties, but the patent rights purchased afforded no exclusive advantages, as the rotary kiln system came to be generally adopted by cement manufacturers.

No dividend was paid on the ordinary share capital down to 1912, which marked a turning-point in the firm's affairs. With the aid of additional finance furnished by a debenture issue, the British Portland Cement Manufacturers, Ltd., was formed. This company absorbed 32 firms and also controlled a number of subsidiary companies. Much competitive tonnage was thus eliminated; the total tonnage controlled came to represent some 80% of the productive capacity of Great Britain. By 1926 the British Portland Cement Manufacturers, Ltd., had absorbed the assets of its subsidiary companies.

In recent years considerable sums have been expended in modernizing the plants. The new Bevan works, with an output of 10,000 tons weekly and shipping facilities enabling vessels up to 10,000 tons to be loaded expeditiously at any state of the tide, is probably the largest and most efficient cement plant in Europe. With the completion of other re-construction work, the annual group productive capacity will be 3,000,000 tons of rotary kiln Portland cement excluding all shaft kiln plant. The products of both companies are sold by the Cement Market Company, Limited. Foreign works are successfully operated in Mexico, British Columbia, South Africa and India. It should be added that the company gives close attention to research and welfare work.

The Associated Portland Cement Manufacturers, Ltd., had an issued share capital, at Dec. 31, 1927, of £4,785,000, and outstanding debentures of £4,139,000. The company owns, amongst other important cement properties, about 75% of the ordinary shares of British Portland Cement Manufacturers, Ltd., and at Dec. 31, 1927, the latter company had an issued share capital of £3,080,000 and outstanding debentures of £1,698,000.

ASSOCIATED PRESS. The Associated Press was founded in 1848 by six New York city newspapers which combined to divide the cost of gathering news by telegraph, then in its infancy. This group supplied its news to loosely formed regional associations such as the Western Associated Press, the New England Associated Press, and other imitative organizations. In 1862 the Western Associated Press began a fight for a voice in the management of the parent association. The conflict continued sporadically for 30 years. Finally, in 1892, Victor F. Lawson, of *The Chicago Daily News,* led a final uprising against the proprietary evils which threatened to disrupt systematic news gathering. Out of this struggle, known in journalism as the "Revolution of 1893," emerged the modern Associated Press, first and only world-wide. non-profit, co-operative news-gathering association. Operating on principles entirely different from those of any of its precursors, this organization absorbed the others. In 1940 the AP, as the organization is familiarly known, collected news and news pictures for its 1,437 member newspapers, and distributed this news over 285,000 miles of leased wires The pictures are delivered by Wirephoto over a 20,000-mile network linking major cities in the United States and Canada. The association maintains its own staff of 7,200 in key cities in the United States and foreign lands. The news report compiled by these employees is augmented by the work of the editorial forces on all member papers, which are obligated to supply the association with the news of their localities. In all, approximately 100,000 newspapermen and women contribute, directly or indirectly, to a report which totals upwards of 1,000,000 words of news daily. Originally an Illinois corporation, the co-operative transferred to New York in 1900 and obtained a charter under the membership corporation laws of that State. This charter provided for an organization which has no capital stock, makes no profits, declares no dividends. The association is owned and controlled by the member publishers who annually elect a board of directors which in turn chooses a president and a general manager. The cost of operation in 1939 was $11,081,321.05. Headquarters are in New York city.

ASSOCIATE JUSTICE, a judicial official in the Federal and many of the State courts in the United States. In the United States judiciary there are eight associate justices of the Supreme Court, who have concurrent authority with the chief justice, except that he presides and assigns cases for opinions. Likewise there are eight associate justices of the United States court of customs, with headquarters in New York. Such associate justices have the same authority as the chief justice, except that he assigns the cases for hearings. In the District of Columbia there are five associate justices of the Supreme Court, which is the court of original general jurisdiction. They are assigned to the civil, equity or criminal divisions by their chief justices, who also sit as trial judges. The members of the supreme courts of the Territories who do not preside over the courts are associate justices. In the various States the courts of highest jurisdiction are either the supreme court or the court of appeals, composed of judges or

justices. Where justices sit on the bench, the associate justices are all the members of the body except the chief justice, and their relationship is similar to that of the chief justice and associate justices of the United States Supreme Court. In other States the presiding official is the chief judge or presiding judge, and his associates are known as judges or associate judges. In a few States, such as New York, the courts of general original jurisdiction are presided over by justices rather than by judges.

See C. N. Callender, American Courts, Their Organization and Procedure (1927). (S. LE.)

ASSOCIATION is a term used in a specialized sense in chemistry to denote the union of like atoms of an element or molecules of a compound to give a more complex molecule having the same chemical properties. The term polymerization is not quite synonymous, for it has a wider application (see later). Thus the molecule of white phosphorus is produced by the association of four atoms of the element to give P_4, and the molecules of water are said to be associated because they are complex molecules, each consisting of two or three simple H_2O molecules. The reverse process of complex molecules breaking down to simple ones is known as dissociation, but this term is not necessarily the converse of the term association, since it includes also the breaking down of a molecule into simpler unlike species (ions, atoms, or molecules).

The phenomenon of association is found in solids, liquids, and gases, but its extent can only be determined with certainty in the case of gases; its existence can be detected in the case of liquids, but its extent cannot be determined definitely; whilst in solids, its existence is inferred both because a solid is probably at least as complex as the corresponding liquid or vapour, and because, in many cases, X-ray examination shows that several molecules unite to form a crystal unit.

The existence of association in gases was inferred from vapour-point density determinations by E. Mitscherlich and J. B. A. Dumas, but its extent was only clearly demonstrated when S. Cannizzaro showed how to apply Avogadro's law to such cases. Chiefly owing to the work of Victor Meyer, a mass of data was then accumulated on the molecular complexity of vapours at temperatures up to 2,000°C. Thus, the vapour densities showed that the molecules of most metals were monatomic at temperatures slightly above their boiling points, that phosphorus was P_4 in the vapour state, arsenic As_2 at 1,700°C., and sulphur S_8 under reduced pressure at 2o0°C., decreasing by stages to S_2 at about 1,700°C. This decreasing complexity with increasing temperature is quite general, and even stable molecules like Cl_2 and Br, begin to break up to Cl and Br above 1,000°C.; so also at very high temperatures H,, N_2, and O, show a very slight dissociation to simple atoms. Among compounds, cuprous chloride was shown to be Cu, Cl_2 in a state of vapour, and ferric chloride to be Fe_2Cl_6 at about 500°C., whereas many metallic chlorides and bromides were unassociated; acetic acid was $(C_2H_4O_2)_2$ just above its boiling point, but $C_2H_4O_2$ at about 200°C.; phosphorous, arsenious, and antimonious oxides were P_4O_6, As_4O_6, and Sb_4O_6 at low temperatures, the second being As_2O_3 at 1,800°C. and the last remaining complex even at this high temperature. Phosphoric oxide seems to persist as P_4O_{10} at very high temperatures. In many cases the equilibrium between the higher and lower type of molecule has been shown to conform to the law of mass action (see CHEMICAL ACTION) at each of a number of temperatures. Moreover, according to this law, increase of pressure should decrease dissociation, *i.e.*, favour association, and this also has been verified. The association of nitrogen peroxide can be followed visually by the loss of colour as the deep brown NO, is cooled and assumes the form of the colourless N_2O_4 in increasing proportions.

In a few cases, vapour-density results have led to erroneous conclusions; thus, mercurous chloride was thought to be HgCl until it was shown that the molecule was really Hg_2Cl_2, but that it dissociated into unlike molecules ($Hg_2Cl_2 \longrightarrow Hg + HgCl_2$) and not into like molecules (2HgCl). According to H. B Baker, however, perfectly dry mercurous chloride does not dissociate hut remains as Hg_2Cl_2 in the vapour state (*see* DRYNESS, CHEMICAL)

The association of liquids can be deduced from a variety of phenomena. J. D. van der Waals showed that a certain relation should hold between the critical temperature and pressure and the vapour pressure at any given temperature, and the fact that marked deviations were fbund by S. Young in the case of certain liquids containing hydroxyl groups (*e.g.*, water, alcohols, and acetic acid) was ascribed to association in the case of these liquids. Similarly, the abnormally high boiling point of water (100°C.), when compared with that of hydrogen sulphide (−60°C.), for instance, leads to the same conclusion. Further, F. Trouton showed that for "normal" liquids the equation $ML/T = 20{\cdot}7$ held with fair accuracy at the boiling point (M=molecular weight; L=latent heat of vaporization; T=absolute temperature); marked deviation from this relation is shown by the above hydroxylic liquids and is regarded as evidence of association.

The precise extent of association in the liquid state was first studied by Sir W. Ramsay and J. Shields, using a modification of a formula proposed by R. Eotvos. If γ is the surface tension, M the molecular weight, and v the specific volume at any given temperature T, then they found that the "molecular surface energy" $\gamma(Mv)^{\frac{2}{3}}$ changes at a definite rate with change of temperature: $d\gamma(Mv)^{\frac{2}{3}}/dT = k$, the constant k being approximately 2.121 for all non-associated liquids. In many cases, k was less than this value, and a factor x was introduced, such that the use of Mx instead of M gave the correct value for k. The necessary value of x decreased with rise of temperature and was held to denote the degree of association, and the results were in agreement with the foregoing qualitative methods. Quantitatively, however, the method is open to many objections; P. Walden showed that k was not a constant, even for normal liquids, and was dependent upon the molecular weight, varying from 2 up to about 6, this high value obtaining for tristearin. G. M. Bennett and A. D. Mitchell showed that the "total molecular surface energy," $K = (\gamma - T.d\gamma/dT)\ (Mv)^{\frac{2}{3}}$, was constant over a wide range of temperature for any one unassociated liquid, and that K was an additive function of certain atomic and structural constants even for substances which gave high values for Ramsay and Shields's k; K was not constant for associated liquids, but although the method could be applied to the evaluation of the degree of association of some liquids, it failed in the case of hydroxylic liquids. Walden used the specific cohesion $a^2 = 2\gamma v$ and found that $Ma^2/T = 1{\cdot}162$ for normal liquids, and this constant did not suffer from the same disadvantages as that of Ramsay and Shields. By a modification of this he deduced degrees of association for many substances, but some (e g., benzene, 1·85) seemed improbable as judged by other methods.'

Longuinescu found that for normal liquids $T/d\sqrt{n} = 100$, where d is density at boiling point, T (in absolute degrees), and n is the number of atoms in the molecule. His results for n led to values for the degree of association which were similar to those deduced from other methods. E. C. Bingham, from viscosity data, and J. Traube, from considerations of atomic and molecular volumes, deduced similar results. The general trend of the foregoing methods seems to indicate that water is chiefly $(H_2O)_2$ and $(H_2O)_3$, but this is doubtless a statistical average for all sorts of molecules from H_2O to, possibly, $(H_2O)_6$ (see WATER).

Still more modern views, based on dielectric constants, internal pressure, and other physical properties, tend to supplant all the foregoing results in attributing a considerable but *constant* degree of association to many of the liquids hitherto regarded as "normal," and a similar but variable degree to other liquids.

Although it is not possible to give any very definite information as to solids, yet many cases are on record in which they give complex molecules in solution. Thus, benzoic acid exists as double molecules in benzene solution; trimethylammonium chloride and bromide undergo four- or five-fold association in fairly concentrated bromobenzene solution; phosphorus and sulphur are respectively P_4 and S_8 in carbon disulphide solution; but most metals are monatomic when dissolved in mercury or molten tin.

'In dealing with surface-tension measurements, it must always be remembered that the molecules in the surface layer may differ from those in the bulk of the liquid.

In dealing with solutions, however, so many new factors are involved that the results should not be accepted as conclusive without careful consideration—the solvent plays an important and imperfectly understood part in such cases. For this reason, it is doubtful how to interpret G. Oddo's results that water has an association factor of 1·2—2·0 when dissolved in several organic solvents.

It is important to note that association in the solid state is a fundamental concept of A. Smits's theory of allotropy (*q.v.*), and that the results of both this author and H. B. Baker seem to show that association in the solid and liquid states depends on the degree of dryness (*q.v.*), just as it does in the gaseous state.

As implied at the outset, the terms association and polymerization are not always interchangeable, for the latter was applied by J. J. Berzelius (1833) to cases where the percentage composition remained the same, but the properties (and molecular weight) were different, whereas in association there is no well-marked change in the chemical properties, as far as we are able to tell. In the article POLYMERIZATION, instances are given of organic substances which differ greatly from their "polymerides"; on the other hand, in the cases dealt with here, such differences are not sufficiently pronounced to be detectable as a rule, although the different forms of phosphorus and sulphur may possibly have to be classed as polymerides on account of their altered solubility properties (see ALLOTROPY). It may be that, in the future, improved experimental technique will be able to assign different properties to each of the different stages of complexity in the molecules of all the substances discussed here.

(A. D. M.)

ASSOCIATION ADVERTISING is the co-operative advertising of competitors to promote the sale or use of the product of an industry, *e.g.*, the campaign to increase the buying of cut flowers. While this is really co-operative advertising by competitors, it is usually conducted and paid for by the trade association of the industry; hence is commonly called Association Advertising. It developed early in the 20th century and reached its peak in 1925 when there were 31 associations expending from $30,000 to $1,500,000 annually in co-operative sales promotion. This form of advertising has arisen out of a new conception of competition which recognized that trade rivalry is not merely that of one concern with another in the same kind of business, but rather that of one industry with another; *e.g.*, aggressive advertising for composition roofings curtailed the sale of cedar shingles. The proprietors of the shingle mills, through their association, raised an advertising fund and began vigorously to promote the sale of their product. Behind many other association campaigns there has been a similar development. It may be noted that the result is not merely an advertising battle in which each industry struggles to hold what it already has, for if the advertising is successful even competing industries may prosper more with advertising than without. This is illustrated by the experiences of manufacturers of flat wall-paints and wall-papers. Before makers of the latter started advertising, their products suffered a diminution of sales because of the aggressive advertising of the former. An association advertising campaign for wall-paper resulted in greatly increased sales without reducing the consumption of flat paints. The explanation is that people became "wall conscious," in the language of the marketing man. Whereas walls had frequently gone for years without refreshening or redecorating, under the stimulus of the two advertising campaigns, new wall-paper or new paint was often applied annually or biennially.

See Hugh E. **Agnew,** Co-operative Advertising by Conzpetitors (1926); Neil Borden, Co-operative Advertising (1932) (H. E. A.)

ASSOCIATION OF IDEAS. The chief problem that is involved in a discussion of the Association of Ideas and the Laws of Association is the problem of recollection and the conditions under which it takes place. Although the expression "association of ideas" was introduced by Locke, the problem under consideration was already dealt with by Plato incidentally, and by Aristotle fairly fully. According to Plato. reminiscence takes place in one of the three ways illustrated by the following examples: (1) A lyre or garment belonging to the beloved one puts the lover in mind of him. (2) From beholding a picture of Simmias you may remember him. (3) The sight of a weedy youth may put one in mind of a robust athlete. These examples illustrate what are usually known as association *by* contiguity, similarity and contrast respectively. Aristotle was much more explicit than Plato in formulating these types or laws of association as principles governing the reinstatement of ideas previously experienced. These three laws of association were accepted and taught by various philosophers (Epicureans, Stoics and Scholastics) during the centuries that intervened between Aristotle and Hobbes. But no great importance was attached to these principles. Even Locke, who, as already remarked, coined the phrase "association of ideas," laid no particular stress on the laws of association. Hobbes attached considerable importance to association of ideas in mental life, but did not advance the subject of association to any appreciable extent. It was Hume who marked the next considerable advance beyond Aristotle in this matter. He recognized association by *contiguity*, and by similarity; but instead of association of contrast Hume put forward association by cause and effect—the observation of clouds, for instance, puts one in mind of rain. Strictly speaking this was really tantamount to reducing the laws of association to two, namely, those of contiguity and resemblance, since Hume regarded the idea of causal connection as merely a case of habitual association by contiguity (or contiguous sequence) between an antecedent and a consequent. Hume, however, was interested in the epistemological bearing of the subject of association of ideas rather than in its psychological importance.

The so-called Associationist Psychologists (Hartley, James Mill, etc.) attached exaggerated importance to the association of ideas, which they regarded as occupying in the realm of psychology a place analogous to the Law of Gravitation in the realm of Physics (see ASSOCIATIONISM), as Hume had already vaguely suggested.

Criticism and Restatement. — (a) Thomas Brown, although he may be described as a member of the school of Associationists or Associationist Psychologists, objected to the term Association, for which he substituted the term suggestion. He pointed out that the term association appears to imply some previous association between the idea suggested and the idea which suggested it. Yet in many cases, and especially in cases of so-called association by similarity, there is no previous association—any object seen for the first time may suggest the idea of something resembling it, but which has never been associated with it in the past. Even if the term association be suitable in cases of association by contiguity (even this Brown questioned), it was clearly inappropriate for cases of suggestion by similarity.

(b) F. H. Bradley went far beyond Brown in his criticism of the laws of association, although he did not repudiate association in principle, when properly formulated and kept within its proper bounds. The laws of association most widely accepted in the 19th century were those of contiguity and of similarity—the only ones really acknowledged by Hume. The main points in Bradley's criticism come out most clearly if attention is paid to the way in which the laws were formulated by the best known British psychologist of the 19th century, A. Bain. (1) The Law of Contiguity: "Actions, sensations and states of feeling, occurring together or in close connection, tend to grow together, or cohere, in such a way that, when any one of them is afterwards presented to the mind, the others are apt to be brought up in idea" (Senses *and* Intellect, p. 327). To this Bradley said that sensations, etc., are particular experiences or events that do not recur at all. Consequently the sensations that are contiguous are not really associated in the manner stated by the law of contiguity, whereas the associated ideas were never contiguous before, so that their association could not be due to their contiguity. (2) The Law of Similarity: "Present actions, sensations, thoughts or emotions tend to revive their like among previous impressions or states" (ibid. p. 457). Bradley's criticism based on the non-recurrence of the same sensation, etc., applies here also. And he adds two further criticisms. Two ideas, etc., can only be recognized as

similar if they are both present in the mind; but what the law seeks to explain is how an idea present in the mind calls up another that is absent. Moreover, ideas alleged to be associated by similarity are usually more unlike than like one another; so that the recall cannot be due to mere similarity. Bradley then formulated his own law of association to which he gave the name (borrowed from Hamilton) of the *Law* of Redintegration: "Any part of a single state of mind tends, if reproduced, to reinstate the remainder," or "any element tends to reproduce those elements with which it has formed one state of mind." At first sight this law appears to be exposed to Bradley's own criticism about the non-recurrence of states of mind. But the most characteristic feature in Bradley's account (though it can really be traced to Aristotle) is his view that association only marries universals, that is, it associates not particular experiences as such, but the elements that are identical in the individual of the same type. In this way Bradley's Law of Redintegration is really a law of identity and contiguity.

(c) Physiological Basis of Association.—Of the older psychologists, Aristotle and Hartley were almost the only ones to attempt some sort of explanation of association, namely, by reference to its physiological or neural basis. But until quite recently the subject received very little further attention—most psychologists being content apparently to subscribe to Hume's remark that the causes of association "are mostly unknown, and must be resolved into original qualities of human nature, which I pretend not to explain" (Inquiry Concerning *Human* Understanding, Part I. § v.). But with the increasing vogue of Physiological Psychology, the attempt to find a physiological explanation of association or suggestion has naturally been renewed. So far as association by contiguity is concerned, a physiological account seems to suggest itself readily. W. James pointed to the "laws of habit in the nervous system" as its physiological cause or basis. The idea more or less generally accepted is that if two nerve-centres in the brain are excited simultaneously or in immediate succession, then some connection is established between them, to the extent at least that the resistance at their synapse (the point of contact between two neurones or nerve-centres) is reduced; and the more frequently this simultaneous or successive activity of two neurones occurs, the more does the path between them tend to become a path of least resistance, so that if one of them is afterwards excited, the excitation spreads to the other. If Bradley's Law of Redintegration be accepted as a true account of association, then the foregoing physiological account of association by contiguity may be made to account for all association—similarity being explained by identity and contiguity. And this is so much in favour of Bradley's views on the matter. But the physiological account involves, of course, the larger problem of the relation between body and mind.

(d) J. Ward and G. F. Stout.—Excessive stress on Association, as may be seen most clearly in the case of so-called associationist psychology, has had a tendency to betray psychologists in two ways. It has often misled them to overlook the initial unity of consciousness, to treat experiences as if they were ultimately mere atoms put together and held together by the quasi-gravitation of association. And in the second place, but largely perhaps in consequence of this soulless treatment of psychology, the whole character of association was conceived in a too impersonal and non-conational manner—as if human experiences were the chance result of the play of impersonal tendencies and in no way influenced by the desires and strivings of the individual subject of the experiences. These defects curiously enough are not to be found in Aristotle, who indeed laid emphasis on the activity and purposiveness involved in recollection and association—"we hunt," he says, "for the next in the series, starting our train of thought from what is now present or from something else, and from something similar or contrary or contiguous to it" (Memory *and* Recollection, 452a, p. 111, ed. G. R. T. Ross). The faults in question were mainly the consequence of a tendency to fall into line with the mechanistic ideas of modern science. Ward and Stout have done much to stem this current of thought in psychology, and to remedy the faults under consideration. Association, according to Ward, is largely a matter of selective attention, and attention largely depends on interest. Hence to a considerable extent association is a form of integration or a way of constructing a continuum expressing and subserving some interest of the experiencing mind. Stout likewise emphasizes the importance of interest in the formation of associations. Association and recall are determined by continuity of interest.

BIBLIOGRAPHY.—G. Croom Robertson, *Philosophical Remains* (contains *a* brief history); *G.* R. T. Ross's edition and translation of Aristotle's *De Sensu* and *De Memoria;* works on Psychology by Bain, Sully, Ward, Stout, James, etc.; the works of the other writers mentioned in the text. (A. Wo.)

ASSOCIATIONISM or **ASSOCIATIONIST PSYCHOLOGY.** This is the name of a theory that mental experiences consist in the last resort of certain ultimate elements of consciousness which are variously combined into complex wholes under the laws of association. (See ASSOCIATION OF IDEAS.) In its extreme form this theory treats the whole development of the mind as little more than an increase in the combinations of pre-existing elements. The theory was probably modelled more or less on the atomic theory in physics—the simple elements of experience corresponding to physical atoms, and association to gravitation.

Associationism may be traced to some extent to the ancient Epicureans and Stoics. But it is mainly modern, and, indeed, British, though not without some adherents in France and Germany.

In the modern period, Hobbes is the first thinker of permanent note to whom this doctrine may be traced. Though, in point of fact, he took anything but an exhaustive view of the phenomena of mental succession, yet after dealing with trains of imagination, or what he called mental discourse, he sought in the higher departments of intellect to explain reasoning as a discourse in words dependent upon an arbitrary system of marks, each associated with, or standing for, a variety of imaginations; and, save for a general assertion that reasoning is a reckoning—otherwise a compounding and resolving—he had no other account of knowledge to give. The whole emotional side of mind, or, in his language, the passions, he, in like manner, resolved into an expectation of consequences based on past experience of pleasures and pains of sense. Thus, though he made no serious attempt to justify his analysis in detail, he is undoubtedly to be classed with the associationists of the next century. They however, were wont to trace their psychological theory no further back than to Locke's Essay. Bishop Berkeley was driven to posit expressly a principle of suggestion or association in these terms:—"That one idea may suggest another to the mind, it will suffice that they have been observed to go together without any demonstration of the necessity of their co-existence, or so much as knowing what it is that makes them so to co-exist." (*New* Theory *of* Vision, §25); and to support the obvious application of the principle to the case of the sensations of sight and touch before him, he constantly urged that association of sound and sense of language which the later school has always put in the foreground, whether as illustrating the principle in general or in explanation of the supreme importance of language for knowledge. It was natural, then, that Hume, coming after Berkeley, and assuming Berkeley's results, though he reverted to the larger inquiry of Locke, should be more explicit in his reference to association; but he was original also, when he spoke of it as a "kind of attraction which in the mental world will be found to have as extraordinary effects as in the natural, and to show itself in as many and as various forms." (Human Nature, i. 1, §4). Other inquirers about the same time conceived of association with this breadth of view, and set themselves to track, as psychologists, its effects in detail.

David Hartley, in his *Observations* on Man, published in 1749 (11 years after the *Human Nature,* and one year after the better-known Inquiry of Hume), opened the path for all the investigations of like nature that have been so characteristic of English psychology. A physician by profession, he sought to combine with an elaborate theory of mental association a minutely detailed hypothesis as to the corresponding action of the nervous system, based upon the suggestion of a vibratory motion within

the nerves thrown out by Newton in the last paragraph of the *Principia*. So far. however, from promoting the acceptance of the psychological theory, this physical hypothesis proved to have rather the opposite effect, and it began to be dropped by Hartley's followers (as F. Priestly, in his abridged edition of the Observations, 1775) before it was seriously impugned from without. When it is studied in the original, and not taken upon the report of hostile critics, who would not, or could not, understand it, no little importance must still be accorded to the first attempt, not seldom a curiously felicitous one, to carry through that parallelism of the physical and psychical, which since then has come to count for more and more in the science of mind. Nor should it be forgotten that Hartley himself, for all his paternal interest in the doctrine of vibrations was careful to keep separate from its fortunes the cause of his other doctrine of mental association. Of this the point lay in no mere restatement, with new precision, of a principle of coherence among "ideas," but in being taken as a clue by which to follow the progressive development of the mind's powers. Holding that mental states could be scientifically understood only as they were analysed, Hartley sought for a principle of synthesis to explain the complexity exhibited not only in trains of representative images, but alike in the most involved combinations of reasonings and (as Berkeley had seen) in the apparently simple phenomena of objective perception as well as in the varied play of the emotions, or again in the manifold conscious adjustments of the motor system. One principle appeared to him sufficient for all, running, as enunciated for the simplest case, thus: "Any sensations A,B,C, etc., by being associated with one another a sufficient number of times, get such a power over the corresponding ideas (called by Hartley also vestiges, types, images), *a,b,c,* etc., that any of the sensations A, when impressed alone, shall be able to excite in the mind, *b,c,* etc., the ideas of the rest." To render the principle applicable in the cases where the associated elements are neither sensations nor simple ideas of sensations, Hartley's first care was to determine the conditions under which states other than these simplest ones have their rise in the mind, becoming the matter of ever higher and higher combinations. The principle itself supplied the key to the difficulty when coupled with the notion, already implied in Berkeley's investigations, of a coalescence of simple ideas of sensation into one complex idea, which may cease to bear any obvious relation to its constituents. So far from being content, like Hobbes, to make a rough generalization to all mind from the phenomena of developed memory, as if these might be straightway assumed, Hartley made a point of referring them, in a subordinate place of their own, to his universal principle of mental synthesis. He expressly put forward the law of association, endued with such scope, as supplying what was wanting to Locke's doctrine in its more strictly psychological aspect, and thus marks by his work a distinct advance on the line of development of the experimental philosophy.

The new doctrine received warm support from some, as Law and Priestley, who both, like Hume and Hartley himself, took the principle of association as having the like import for the science of mind that gravitation had acquired for the science of matter. The principle began also, if not always with direct reference to Hartley, yet, doubtless, owing to his impressive advocacy of it. to be applied systematically in special directions, as by Abraham Tucker (1768) to morals, and by Archibald Alison (1790) to aesthetics. Thomas Brown (d. 1820) subjected anew to discussion the question of theory. Hardly less unjust to Hartley than Reid or Stewart had been, and forward to proclaim all that was different in his own position, Brown must yet be ranked with the associationists before and after him for the prominence he assigned to the associative principle in sense-perception (what he called external affections of mind) and for his reference of all other mental states (internal affections) to the two generic capacities or susceptibilities of simple and relative suggestion. He preferred the word suggestion to association, which seemed to him to imply some prior connecting process, whereof there was no evidence in many of the most important cases of suggestion, nor even, strictly speaking, in the case of contiguity in time where the term seemed least inapplicable. According to him, all that could be assumed was a general constitutional tendency of the mind to exist successively in states that have certain relations to each other, of itself only, and without any external cause or any influence previous to that operating at the moment of the suggestion. Brown's chief contribution to the general doctrine of mental association, besides what he did for the theory of perception was, perhaps, his analysis of voluntary reminiscence and constructive imagination — faculties that appear at first sight to lie altogether beyond the explanatory range of the principle. In James Mill's Analysis of the Phenomena of *the Human Mind* (1829) the principle, much as Hartley had conceived it, was carried out, with characteristic consequence over the psychological field. With a much enlarged and more varied conception of association, Alexander Bain re-executed the general psychological task, while Herbert Spencer revised the doctrine from the new point of view of the evolution-hypothesis. John Stuart Mill made only occasional excursions into the region of psychology proper, but sought, in his System of Logic (1843), to determine the conditions of objective truth from the point of view of the associationist theory, and, thus or otherwise being drawn into general philosophical discussion, spread wider than any one before him its repute.

The associationist school has been composed chiefly of British thinkers, but in France also, it has had distinguished representatives. Of these it will suffice to mention Condillac, who professed to explain all knowledge from the single principle of association (liaison) of ideas, operating through a previous association with signs, verbal or other. In Germany, before the time of Kant, mental association was generally treated in the traditional manner as by Wolff. Kant's inquiry into the foundations of knowledge, agreeing in its general purport with Locke's however it differed in its critical procedure, brought him face to face with newer doctrine that had been grafted on to Locke's philosophy; and to account for the fact of synthesis in cognition, in express opposition to associationism, as represented by Hume, was, in truth, his prime object, starting as he did, from the assumption that there was that in knowledge which no mere association of experience could explain. To the extent, therefore, that his influence prevailed, all inquiries made by the English associationists were discounted in Germany. Notwithstanding, under the very shadow of his authority a corresponding, if not related, movement was initiated by J. F. Herbart. Peculiar and widely different from anything conceived by the associationists, as Herbart's metaphysical opinions were, he was at one with them and at variance with Kant, in assigning fundamental importance to the psychological investigation of the development of consciousness, nor was his conception of the laws determining the interaction and flow of mental presentations and representations, when taken in its bare psychological import, essentially different from theirs. In F. E. Beneke's psychology also, and in more recent inquiries conducted mainly by physiologists, mental association has been understood in its wider scope, as a general principle of explanation.

The associationists differ not a little among themselves in the statement of their principle, or when they adduce several principles, in their conception of the relative importance of these. Hartley took account only of contiguity, or the repetition of impressions synchronous or immediately successive; the like is true of James Mill, though incidentally, he made an express attempt to resolve the received principle of similarity, and through this, the other principle of Contrast, into his fundamental law — law of Frequency, as he sometimes called it, because upon frequency, in conjunction with vividness of impressions, the strength of association, in his view, depended. In a sense of his own, Brown also, while accepting the common Aristotelian enumeration of principles, inclined to the opinion that "all suggestion may be found to depend on prior co-existence, or at least on such proximity as is itself very probably a modification of co-existence," provided account be taken of "the influence of emotions and other feelings that are very different from ideas, as when an analogous object suggests an analogous object by the influence of an emotion which

each separately may have produced before, and which is, therefore, common to both." To the contrary effect, Spencer maintained that the fundamental law of all mental association is that presentations aggregate or cohere with their like in past experience, and that, besides this law, there is in strictness no other, all further phenomena of association being incidental. Thus in particular, he would have explained association by contiguity as due to the circumstances of imperfect assimilation of the present to the past in consciousness. A. Bain regarded contiguity and similarity logically, as perfectly distinct principles, though in actual psychological occurrence blending intimately with each other, contiguous trains being started by a first (it may be implicit) representation through similarity, while the express assimilation of present to past in consciousness is always, or tends to be, followed by the revival of what was presented in contiguity with that past.

The highest philosophical interest, as distinguished from that which is more strictly psychological, attaches to the mode of mental association called inseparable. The coalescence of mental states noted by Hartley, as it had been assumed by Berkeley, was further formulated by James Mill in these terms:—"Some ideas are by frequency and strength of association so closely combined that they cannot be separated; if one exists, the other exists along with it in spite of whatever effort we make to disjoin them." (Analysis of the *Human* Mind, 2nd ed. vol. i., p. 93.)

J. S. Mill's statement is more guarded and particular:—"When two phenomena have been very often experienced in conjunction, and have not, in any single instance, occurred separately either in experience or thought, there is produced between them what has been called inseparable, or, less correctly, indissoluble, association; by which is not meant that the association must inevitably last to the end of life—that no subsequent experience or process of thought can possibly avail to dissolve it; but only that as long as no such experience or process of thought has taken place, the association is irresistible; it is impossible for us to think the one thing disjoined from the other."—(Examination of Hamilton's Philosophy, 2nd ed., p. 191.)

It is chiefly by J. S. Mill that the philosophical application of the principle has been made. The first and most obvious application is to so-called necessary truths—such, namely, as are not merely analytic judgments but involve a synthesis of distinct notions. Again, the same thinker sought to prove inseparable association the ground of belief in an external objective world. The former application, especially, is facilitated, when the experience through which the association is supposed to be constituted is understood as cumulative in the race, and transmissible as original endowment to individuals—endowment that may be expressed either, subjectively, as latent intelligence, or, objectively, as fixed nervous connections. Spencer, as before suggested, is the author of this extended view of mental association.

BIBLIOGRAPHY.—(*See* ASSOCIATION OF IDEAS.) (A. Wo.)

ASSOCIATIONS, INDUSTRIAL. Associations whose membership consists of firms engaged in a particular branch of industry or trade are of three kinds:

(1) those which exist for purposes of collective bargaining with their workpeople or their representatives;

(2) those which are concerned with the regulation of prices, output, sales, etc.; and

(3) those which devote themselves to the technical, scientific and informational aspects of the business in which the firms are engaged.

These three types of function are not mutually exclusive, but in Great Britain most industrial associations devote themselves wholly or mainly to one or other kind of activity. In the United States employers' associations for dealing with workpeople are rare, trade unionism being neither so developed nor so recognized as in other countries; price and output associations, being illegal, are not openly existent; therefore all industrial associations fall ostensibly within the third type. Such American employers as have occasion to negotiate collectively with workpeople are tending to do so through the medium of the informational trade association.

Employers' Associations.—There are in Great Britain some 2,500 associations of employers concerned with matters relating to the employment of labour. They may be regarded as the counterpart on the employers' side of the Trade Union on the workpeople's side. They exist for the purpose of establishing a unified policy among the employers in the industry in regard to wages, hours and working conditions generally, and their principal activities culminate in negotiating agreements on these matters with the responsible Trade Unions (see TRADE UNIONS), and in giving effect generally to the collective views of employers in the industry upon labour questions. In some countries there is a central organization whose membership consists not of individual concerns but of the Employers' Associations for the various industries. In Great Britain there is the National Confederation of Employers' Organizations, which exists for the purpose of co-ordinating the industrial and political activities of the many employers' associations or federations which constitute its membership. This body may be regarded as the employers' counterpart of the General Council of the Trades Union Congress.

Associations for the Regulation of Trade.—Associations of business concerns for the regulation of prices, output, tendering, selling areas, etc., exist in very many branches of British trade and industry. They are properly constituted bodies having rules, constitution, officers, subscription, entrance fees, etc. The object of these associations is to control the competition in which firms in the same line of business ordinarily engage, in such a way as to make for remunerative prices, steady trade, and reduction of overlapping and waste. They represent one phase of the persistent tendency towards the replacement of competition in industry by combination (see COMBINES, also COMPETITION IN INDUSTRY), but trade associations must be distinguished from some other forms of industrial combination in that they are terminable alliances and not permanent fusions (see AMALGAMATION; also TRUSTS). The Trade Association is an association, for particular purposes, of otherwise independent and self-governing business concerns. So long as it exists, members must conform to its rules or incur penalties; but if for any reason—stress of external circumstance or internal jealousy or disloyalty—it should break up, the constituent firms revert to their original unfettered independence, competing against each other, it may be, as keenly as before. These internal disruptive forces are on occasion very strong and the history of British associations for the regulation of trade exhibits many instances of dissolution followed after a time by re-formation.

Under English law contracts or agreements in restraint of trade, such as those between members of the associations described above, are not actually illegal unless they involve an illegal act, but they are in principle unenforceable, since the Courts will not in general entertain any legal proceeding instituted with the object of enforcing or recovering damages for the breach of such agreements. In the United States agreements for the limitation of competition are illegal under the Sherman Law (1890). In Canada associations regulating price or output are liable to investigation under the Combines Act of 1923 with punishment under the Criminal Code in case of proved offence. In Australia and New Zealand there is little legal interference with such associations.

Informational Associations.—Associations existing solely for the supply of statistical or credit information to their members or for scientific and technical research and standardization. and concerning themselves not at all with the regulation of trade, are not numerous in Great Britain, though some outstanding examples occur in the iron and steel, electrical, motor, chemical, silk, glass, leather, paint, flint glass, and paper industries. The interchange of information in regard to credit terms, railway rates, shipping freights, forms of contract, methods, and processes, the standardization and interchange of costings, and the collection and dissemination of trade statistics is more frequently carried out as an adjunct to the control of prices or output. The Federation of British Industries may be regarded as the central organization concerned with the co-ordination of the informational activities of trade associations and as the counterpart, in the sphere of

trade, of the National Confederation of Employers' Organizations in that of wages, hours, and working conditions.

In the United States, however, concerted action in fixing prices or regulating output is questionable under the common law and definitely illegal under the various anti-trust statutes. The years onward from the passage of the Sherman act in 1890 have been years of uncertainty as to what a trade association might or might not legally do, but there has, notwithstanding, been a vast increase in the members of such associations. About 1910 the idea of "co-operative competition" through the medium of "Open Price Associations" took shape. Under this plan members were to furnish to the association day by day particulars of enquiries, quotations and orders and, less frequently, of output and stocks. These were to be collated, and a summary statement based on the returns despatched to all members. Since the information so furnished related to past, not future, prices and output, and was in the nature of an ascertainment, not an agreement, it was expected that these activities would be found not to be in contravention of the law, but to be a salutary and legal means of turning blind competition into informed competition. The courts, however, found against these activities where it could be shown that they resulted in fact in approximations to a unified policy in regard to production or price, but the decision of the Supreme Court, in the Maple Flooring and Cement cases in 1925, established the legality of a much wider range of informational activity than had previously been known to be definitely within the law. The trade association on the informational basis is one of the most momentous features of modern industrial developments in the United States. According to an estimate made by the National Industrial Conference Board in 1925 "it is fairly safe to assume the existence of between 800 and 1,000 trade associations of a national or interstate character." (J. H.)

BIBLIOGRAPHY.—For British trade associations, see the Report of the *Committee* on Trusts (Cd. 9,236 of 1919); Reports of 57 Committees appointed under the Profiteering Acts 1919 and 1920; Report of the Committee on Industry and Trade, entitled Factors in Industrial and Commercial *Efficiency*, H. M. Stationery Office (1927); and *Industrial* Combination in *England* by P. Fitzgerald (1927). For American trade associations see A. J. Eddy, The New Competition (1914); Trade Association Activities issued by the Department of Commerce (1923); Public Regulation *of* Competitive Practices, also Trade Associations, their Economic Significance *and* Legal Status, both issued by the National Industrial Conference Board of New York in 1925.

ASSOCIATION TESTS are used in psychology to discover the mental connections which underlie such cognitive functions as perception, learning, memory, language ability, reasoning and judgment, and also in psychopathology to discover the way in which emotional experiences upset normal mental connections. In the usual association test an individual is given a word and is told to respond with the first word which comes into his mind. The exact procedure varies for different purposes. The kind of words with which the individual responds and the length of time it takes him to make his replies are factors which throw important light on the nature of mental constitution, variation and abnormality.

ASSOCIATIVE LAWS, two laws relating to numbers, one with respect to addition and the other with respect to multiplication. These laws may respectively be defined symbolically as follows: $a + (b + c) = (a + b) + c$, and $a(bc) = (ab)c$; that is, the terms or the factors may be associated in any way we choose. (See also COMMUTATIVE LAWS.) The numbers may be either positive or negative, integral or fractional, rational or irrational, and real or imaginary. The laws do not hold throughout the entire range of mathematics, however. For example, the associative law of addition does not hold for certain divergent series. (See SERIES.)

ASSONANCE, a term defined, in its prosodical sense, as "the corresponding or riming of one word with another in the accented vowel and those which follow it, but not in the consonants" (New English Dictionary). Much rustic or popular verse in England is satisfied with assonance, as in such cases as

> And pray who gave thee that jolly red nose?
> Cinnamon, Ginger, Nutmeg and **Cloves,**

where the agreement between the two *o's* permits the ear to neglect the discord between *s* and v. Assonance appears to have preceded rhyme in several of the European languages, and to have led the way towards it. It is particularly observable in the French poetry which was composed before the 12th century, and it reached its highest point in the "Chanson de Roland," where the sections are distinguished by the fact that all the lines in a *laisse* or stanza close with the same vowel-sound. When the ear of the French became more delicate, and pure rhyme was introduced, about the year 1120, assonance almost immediately retired before it and was employed no more, until recent years, when several French poets have re-introduced assonance in order to widen the scope of their effects of sound. It held its place longer in Provençal and some other Romance literatures, while in Spanish it has retained its absolute authority over rhyme to the present day. It has been observed that in the Romance languages the ear prefers the correspondence of vowels, while in the Teutonic languages the preference is given to consonants. Various German poets of considerable merit, and in particular Tieck and Heine, have endeavoured, as English rhymers have done, to mix pure rhyme with assonance, but the result of this in almost all cases is that the assonances are drowned in the stress of pure rhymes. Assonance as a conscious art, in fact, is scarcely recognized as legitimate in English literature. In Irish (Gaelic) poetry, on the other hand, assonance triumphed over pure rhyme, and the Irish poets writing in English who rhymed "Blarney" with "charming" were merely following a national tradition.

ASSUMED BONDS, bonds of a corporation which has been absorbed by another by means of merger, consolidation, purchase or other methods. In a merger, the corporation which retains its identity; in a consolidation, the newly formed corporation; and in a sale, the purchasing company, assumes all the indebtedness of the merged, consolidated or purchased organization, and hence becomes entirely responsible and liable for the payment of the bonds, which then take the name of assumed bonds. Bonds of one existing corporation which are guaranteed as to either interest or principal by the endorsement of another corporation are sometimes loosely called assumed bonds, but for such instruments it is better to reserve the name "guaranteed bonds."

ASSUMPSIT, the Latin word meaning "he has undertaken." It is applied in English law to an obsolete form of action for the recovery of damages by reason of the breach or non-performance of a simple contract, either express or implied, and whether made orally or in writing. Assumpsit was the word always used in pleadings by the plaintiff to set forth the defendant's undertaking or promise, hence the name of the action. See **PRACTICE** AND PROCEDURE.

ASSUMPTION, FEAST OF, the feast of the Assumption of the blessed Virgin Mary (Lat. *assumptio, dormitio depositio, pausatio B.V.M.* (Gr. κοίμησις or ἀνάληψις τῆς θεοτόκου), celebrated by the Christian Church on Aug. 15, commemorating her death and miraculous ascent into heaven. The belief in the latter has its origin in apocryphal sources, such as the εἰς τὴν κοίμησιν τῆς ὑπεραγίας δεσποίνης ascribed to the Apostle John, and the *De transitu Mariae,* assigned to Melito, bishop of Sardis, but actually written about A.D. 400. They were accepted as authentic by Gregory of Tours (d. 593 or 594), who in his De gloria *martyrum* (1.4) gives the following account of the miracle: As all the Apostles were watching round the dying Mary, Jesus appeared with His angels and committed the soul of His Mother to the Archangel Michael. Next day, as they were carrying the body to the grave, Christ again appeared and carried it with Him in a cloud to heaven, where it was reunited with the soul. According to St. John of Damascus, the patriarchs and Adam and Eve also appear at the death-bed; a Jew who touches the body loses both his hands, which are restored to him by the Apostles; and the body lies three days in the grave without corruption before it is taken up into heaven.

The festival is first mentioned by St. Andrew of Crete (b. *c.* 650), and is said to have been fixed on Aug. 15 by the emperor Maurice (d. 602). From the East it was borrowed by Rome, where there is evidence of its existence so early as the 7th century. The belief in the bodily assumption of the Virgin has never

been defined as a dogma and remains a "pious opinion" which the faithful are not bound to accept, though its denial would involve "insolent temerity" as being contrary to the common agreement of the Church. By the reformed Churches, including the Church of England, the festival is not observed, having been rejected at the Reformation as being neither primitive nor founded upon any "certain warrant of Holy Scripture."

ASSUR (country), the land of Assyria, not to be confused with the city of Ashur (modern Shergat) from which it took its name. The country is situated on the Tigris, at the southern extremity of Assyria proper, which was bounded on the north by the foothills of Kurdistan, and lay between the Tigris and its tributary the lesser Zab (Zab al Asfal) in a fertile triangle of land. The early history of Assyria probably consisted in the gradual occupation of this fertile region, from the city of Assur, which retained its position as a holy city long after the political power had been transferred to the more conveniently placed Nineveh. (See MESOPOTAMIA: *Ancient* Geography.)

ASSUR, ASHUR, ASUR, name of the ancient capital of Assyria, the modern ruins, Kalat Sherghat, built on a rocky headland on the west bank of the Tigris, 40 miles above the mouth of the Lower Zab. It is first mentioned in the 46th year of Dungi of Ur, 2376 B.C., where the name is written with the Sumerian ideogram A-USAR, of unknown meaning. At this time the governor of the city was Zariku, who bears a Semitic name. The city then belonged to the kingdom of Ur, and the same Zariku governed the city for Bur-Sin, Dungi's successor. In his own inscription Zariku writes the name of the city A-Shir, and this is the usual writing of the name of the city god in the early inscriptions of the city. It is certain, however, that the Sumerian goddess Innini, *i.e.*, Accadian Ishtar. was the oldest important deity of Assur, and that the site was occupied by the Sumerians many centuries before the rise of this city-state to a place of great political importance in the time of the first Babylonian dynasty (2169–1870). There can be little doubt concerning the racial character of the people of Assur from the period of Zariku onward. They were Semites and possibly from Amurrû, who, like the Semitic colony in Cappadocia of the same period, obtained their culture from Babylonia. Inscriptions of later Assyrian kings mention two early rulers, Ushpia, who built the temple of the god Ashur, in the-north-east corner of the city and Kikia, who built the city walls. There is also an Accadian inscription of a certain Ititi, son of Yakulaba. All of these local rulers bear non-Semitic and non-Sumerian names, and they indicate a period of Gutean or Mitanni occupation of the city, in the interval between the decline of the old Sumerian period and the occupation by Semites in the time of Dungi. It is, therefore, probable that the city-god Xshir, Ashur, is of Sumerian origin.

The old city was bounded on the east by quay walls, extending for 700 metres, along the west bank of the Tigris. An ancient branch of the Tigris flowed past the north side of the city, which was protected by a buttressed wall and a huge building known as the Mushlalu, just north of the great stage tower of the temple of the god Ashur. The north side measured about 800 metres, and on this side of the city stood the temple and stage tower of Ashur (north-east corner), the ancient palace, the double temple of the gods Adad and Anu, and a vast new palace of Tukul-Ninurta (13th century B.C.). The western and southern sides were originally defended by a double wall, whose line sweeps in a return curve to the Tigris, over 1,500 metres long. In the early part of the second millennium the outer wall on the south was extended southward and eastward to enclose a large new precinct of the city. Outside the city, 150 metres from the north-west corner, stood the house of the New Year's festival on the bank of the ancient rivulet, which ran past the northern side of the city. The temple of Ishtar, where excavations revealed the oldest (Sumerian) culture at Assur, lay in the west central part of the city, and a later temple to the god Nebo stood just east of it. The city was occupied continuously down to Parthian times, and a great palace of that period was built over the ruins of the inner southern wall.

The most important city gates are on the western side, the most famous being the Tabara or "gate of the metal workers," on the extreme western curve of the wall. A second great gate pierced the double wall of this side 400 metres south of Tabara. Two more gates pierced the west wall between Tabara and the north-west corner of the city, and there was another gate on the south side near the Tigris.

The antiquities recovered in the excavation of the temple of Ishtar indicate a very advanced Sumerian civilization at Assur, whose origins appear to be almost as ancient as any yet found in Sumer of the south. They prove that the Sumerians were settled here before 3500 B.C., but the city clearly had no independent line of kings either in the Suinerian period down to *c.* 2600 B.C., or in the long period of Semitic governors, when this city-state was a dependency first of Ur and then of Babylon. It is clear that an interval of Gutean domination intervened between the Sumerian period and the Semitic occupation. Assur remained a dependency of Babylon until the end of the first Babylonian dynasty, and Nineveh did not become the capital of Assyria until the end of the reign of Ashurnasirpal II. (883–859). In a triangular space enclosed between the southern inner city wall and the southern extension outer wall, stood the inscribed stelas of the kings of Assyria from Adadnirari I. to Ashurbanipal, including one of Semiramis, and a parallel row of stelas of many provincial governors. It formed a kind of memorial ground for the great rulers and officials of Assyria from the 14th century to the end of the Assyrian kingdom, and proves that Assur remained the holy city of that mighty empire long after it ceased to be the capital. As seat of the cult of Adad, the thunder god, the ideogram IM-(ki) is also employed to write the name of the city.

The **God Ashur.**—It was noted above that this local deity of the city was probably of Sumerian origin, although the meaning of the ideogram, by which his name mas first written, is obscure. He was never admitted into the official Sumerian–Babylonian pantheon, nor is his, or any other Assyrian temple, named in the canonical Sumero-Babylonian liturgies, which were sung in Assyrian temples also. The local deities of the two cities which became capitals of Babylonia and Assyria were at first minor gods, and they owe their importance to political influence. The priests of Assur identified their city-god with the mighty earth-god Enlil of Nippur, and his consort bears the same name as that of the ancient Enlil; viz., Ninlil, the Assyrian; and the name of Ashur's temple Ekhursagkurkurra, "House of the mountain of the lands," also suggests an earth-god. The stage tower of this temple is called E-aratta-kisharra, "House of Aratta of the Universe," and explained by "House of Enlil." Aratta is an ancient title of Enlil at Shuruppak. Ashur replaces Marduk in the Epic of Creation (*q.v.*), and is consequently represented in art with the winged sun disc and assumed many aspects of the sun-god.

ASSURANCE: see INSURANCE.

ASSUR-BANI-PAL ("Assur creates a son"), the grand monarque of Assyria, was the prototype of the Greek Sardanapalus, and appears probably in the corrupted form of Asnapper in Ezra iv. 10. He had been publicly nominated king of Assyria (on the 12th of Iyyar) by his father Esar-haddon, some time before the latter's death, Babylonia being assigned to his twin-brother Samas-sum-yukin, in the hope of gratifying the national feeling of the Babylonians.

After Esar-haddon's death in 668 B.C. the first task of Assur-bani-pal was to finish the Egyptian campaign. Tirhakah, who had reoccupied Egypt, fled to Ethiopia, and the Assyrian army spent 40 days in ascending the Nile from Memphis to Thebes. Soon afterwards Necho, the satrap of Sais, and two others were detected intriguing with Tirhakah; Kecho and one of his companions were sent in chains to Nineveh, but were there pardoned and restored to their principalities Tirhakah died 667 B.C., and his successor. Tandaman (Tanuat-Amon), entered Upper Egypt,

where a general revolt against Assyria took place, headed by Thebes. Memphis was taken by assault and the Assyrian troops driven out of the country. Tyre seems to have revolted at the same time. Assur-bani-pal, however, lost no time in pouring fresh forces into the revolted province. Once more the Assyrian army made its way up the Nile, Thebes was plundered, its temples were destroyed, and two obelisks were carried to Nineveh as trophies

A FRAGMENT OF A SCULPTURED RELIEF SHOWING ASSUR-BANI-PAL, THE GREAT KING OF ASSYRIA IN THE 6TH CENTURY B.C., ENGAGED IN A RELIGIOUS CEREMONY OF POURING LIBATION OVER LIONS

(see Nahum iii. 8). Meanwhile, the siege of insular Tyre was closely pressed, its water-supply was cut off, and it was compelled to surrender.

Assur-bani-pal was now at the height of his power. The land of the Mannā (Minni), south-east of Ararat, had been wasted, its capital captured by the Assyrians, and its king reduced to vassalage. A war with Teumman of Elam had resulted in the overthrow of the Elamite army; the head of Teumman was sent to Nineveh, and another king, Umman-igas, was appointed by the Assyrians. The kings of Cilicia and the Tabal offered their daughters to the harem of Assur-bani-pal; embassies came from Ararat, and even Gyges of Lydia dispatched envoys to "the great king" in the hope of obtaining help against the Cimmerians. Suddenly the mighty empire began to totter. The Lydian king, finding that Nineveh was helpless to assist him, turned instead to Egypt and furnished the mercenaries with whose help Psammetichus drove the Assyrians out of the country and suppressed his brother satraps. Egypt was thus lost to Assyria forever (660 B.C.). In Babylonia, moreover, discontent was arising, and finally Samas-sum-yukin put himself at the head of the national party and declared war upon his brother. Elamite aid was readily forthcoming, especially when stimulated by bribes, and the Arab tribes joined in the revolt. The resources of the Assyrian empire were strained to their utmost. But as a result in some measure of the internecine troubles of Elam, the Babylonian army and its allies were defeated and driven into Babylon, Sippara, Borsippa and Cutha. One by one the cities fell, and Babylon finally was starved into surrender (648 B.C.) after Samas-sum-yukin had burned himself in his palace to avoid falling into the conqueror's hands.

It was now the turn of the Arabs, some of whom had been in Babylon during the siege, while others had occupied themselves in plundering Edom, Moab and the Hauran. Northern Arabia was traversed by the Assyrian forces, the Nabataeans were almost exterminated, and the desert tribes terrorized into order. Elam was alone left to be dealt with, and the last resources of the empire were therefore expended in preventing it from ever being again a thorn in the Assyrian side.

But the effort had exhausted Assyria. Drained of men and resources, it was no longer able to make head against the Cimmerian and Scythian hordes who now poured over western Asia. The Cimmerian Dugdammē (Lygdamis in Strabo i. 3, 16), whom Assur-bani-pal called "a limb of Satan," after having sacked Sardis, had been slain in Cilicia, but other Scythian invaders came to take his place. When Assur-bani-pal died in 626 (?) B.C., his empire was already in decay, and within a few years the end came. (*See* SARDANAPALUS.)

ASSUS (mod. BEHRAM), an ancient Greek city of the Troad, on the Adramyttian gulf. The situation is magnificent. The natural cleavage of the trachyte into joint planes had already scarped out shelves which it was comparatively easy for human labour to shape; and so, high up this cone of trachyte, the Greek town of Assus was built, tier above tier, the summit of the crag being crowned with a Doric temple of Athena. The view from the summit is very beautiful and of great historical interest. In front is Lesbos, one of whose towns, Methymna, is said to have sent forth the founders of Assus, as early, perhaps, as 1000 or 900 B.C. The whole south coast-line of the Troad is seen, and in the south-east the ancient territory of Pergamum, from whose masters the possession of Assus passed to Rome by the bequest of Attalus III. (133 B.C.). The great heights of Ida rise in the east. Northward, the Tuzla is seen winding through a rich vallev. This valley was traversed by the road which St. Paul must have followed when he came overland from Alexandria Troas to Assus, leaving his fellow travellers to proceed by sea. The north-west gateway, to which this road led, is flanked by two massive towers, of Hellenic work. On the shore below, the ancient mole can be traced by large blocks under the clear water. Assus affords the only harbour on the 50m. of coast between Cape Lectum and the east end of the Adramyttian gulf; hence it must always have been the chief shipping-place for the exports of the southern Troad. The great natural strength of the site protected it against petty assailants, but, like other towns in that region, it has known many masters—Lydians, Persians, the kings of Pergamum. Romans and Ottoman Turks. From the Persian wars to about 350 B.C. Assus enjoyed at least partial independence. It was about 348–345 B.C. that Aristotle spent three years at Assus with Hermeas, an ex-slave who had succeeded his former master Eubulus as despot of Assus and Atarneus. Under its Turkish name of Behram, Assus is still the commercial port of the southern Troad, being the place to which loads of valonia are conveyed by camels from all parts of the country. Explorations were conducted at Assus in 1881–83 by Mr. J. T. Clarke for the Archaeological Institute of America.

See J. T. Clarke, *Assos*, 2 vols. *1882* and *1898 (Papers of Arch. Inst. of America, i.–ii.)*; and authorities under TROAD.

ASSYRIA. The two great empires, Assyria and Babylon, which grew up on the banks of the Tigris and Euphrates, can be separated as little historically as geographically. From the beginning their history is closely intertwined; and the power of the one is a measure of the weakness of the other. (See BABYLONIA AND ASSYRIA.)

ASSYRIAN LANGUAGE. The Babylonians, though Semites, learnt the cuneiform (*q.v.*) script from the non-Semitic Sumerians, whom they found in southern Mesopotamia in the 3rd millennium B.C.; and 1,000 years afterwards the northern Assyrians adopted it. Sumerian had 600 signs, constituting thousands of ideograms (signs depicting ideas). Some signs had only word-values, others both these and syllable-values. The Babylonians primarily used only the syllable-values of these signs. But they freely borrowed their word-values, as a kind of short-hand, using in reading (as variants show) the Babylonian equivalent.

The use of Sumerian, when no longer spoken, in the temple-services led the Babylonians and Assyrians to compile lists of signs and vocabularies, sometimes of more than 300 ideograms, giving the sign together with its name, Sumerian pronunciation and Semitic meaning, which they often glossed with synonyms. They also drew up lists of Sumerian paradigms and dialectical forms with Semitic renderings in parallel columns. Some lists contain foreign (*e.g.*, Cossaean or Hittite) words. These and liturgical texts with interlinear translations have proved indispensable in the decipherment of cuneiform documents.

Assyro-Babylonian (Xccadian), the oldest known member of the eastern group of the Semitic languages (see SEMITIC LANGUAGES), had affinities with all the other groups, yet not enough to be called a mixed language. Thus with the central (Amorite-Aramaic) it prefers a to *u* or o (cf. Bab.-Ass. *ṭābu*=Aram. *ṭābh* with Hebr. *ṭôbh* "good"); with the western (Canaanite-Hebrew-Phoenician) group it shared much of its vocabulary (cf. Ass.-Bab. *anâku*=Can. *anuki*=Hebr. *'ānōkhî*=Phoen. anech with Aram. *'ănâ* "I"); and with the southern group it retained the case-endings (as in Arabic) and employed *-k* instead of *-t* for the first person singular in the permansive or perfect tense (as in Ethiopic). Babylonian and Assyrian differed only dialectically; *e.g.*, Bab. *gâtu*=Ass. *qâtu* "hand" and Bab. *ashṭur*=Ass. *alṭur* "I wrote." During more than 2,000 years changes crept in; *e.g.*, Bab. *lawû* or *lamû*=Ass. *lamû, labû* or *lapû* "to surround." Each also exhibited variations within itself: thus s was sometimes preferred to sh in early Babylonian (as in *sû* for *shû* "he") and late (vulgar) Assyrian (as in *Asdudu*=Hebr. *'ashdôdh* "Ashdod"). Cappadocian, an Assyrian offshoot, also substituted *s* for *sh* before *i* and showed other peculiarities, such as the change of k to *g* before a and of *t* to d before *u* and the loss of the more strongly articulated consonants.

Assyro-Babylonian stood out from the Semitic languages in several ways. Its script showed the primitive vocalization and, partially, the accentuation. Its connection with Sumerian brought in foreign words under a Semitized form. The gutturals ' (*'āleph*), *h*, h and ' ('ayin) were mostly weakened into vowels: *e.g.*, Bab.-Ass. *alâku* "to go" (cf. Hebr. *hālakh* "went") and Bab.-Ass. *bêlu* (=Hebr. *ba'al* "lord"), although *ḫ* always and ' and h sometimes were preserved, as in Bab.-Ass. *ma'âdu* "to be much" (cf. Hebr. *mĕ'ōdh* "very"); so w and y generally disappeared, as in Bab.-Ass. *idû* "to know" (cf. Hebr. *yādha'* "knew"). Assimilation of vowels (as in *unikkir* for *unakkir* "changed") was common and of consonants (as in *nidittu* for *nidintu* "gift") regular; final vowels were sometimes dropped, as in *kashdâk* for *kashdâku* "I am seized." Many uncontracted forms, lost in the cognate languages, were preserved in the older, though contracted in the later, speech; *e.g.*, Capp. *idu(w)ar*=Bab.-Ass. *ituar* and *itâr* "returns." It sometimes had sh where the other languages have h or ' (*'āleph*); namely, in certain pronouns, as in *shû* (cf. Hebr. *hû*) "he" and so on, and in the causative prefix, as in *shuzkur* (cf. Hebr. *hizkîr* and Aram. *'adhkar*) "mentioned." The pronominal suffixes with verbs alone expressed the direct, but with an affixed *-m* the indirect, object.

Certain nouns took the feminine ending in Assyro-Babylonian but not in the cognate languages, like Ass.-Bab. *irṣitu*=Hebr. *'ereṣ* "earth," or, though elsewhere masculine, were feminine in it, like Ass.-Bab. *kabittu*=Hebr. *kābhēdh* "liver." Special vowels distinguished the cases (sing. nom. *-u*, acc. -a, gen. -i; du. nom. *-â*, acc.-gen. -8; plur. nom. 0, acc.-gen. *-î*), to which various affixes might be added, though with little change in significance. These endings, however, soon sporadically and later generally, were used indiscriminately, and various transcriptions (*cf.* Gr. *μιτερθ*=Bab.-Ass. *miṭertu* "rain") show that they were usually disregarded in speaking. The dual, too, tended to fall into desuetude.

The verbs employed the usual Semitic inflections and derived themes, with modifications. There were three instead of two tenses: a "permansive" which expressed state, corresponding with the Semitic perfect (Bab.-Ass. sakir "was remembered"=Hebr. *zākhar* "remembered"); a preterite corresponding with the imperfect (Bab.-Ass. izkur "remembered"=Hebr. *yizkōr* "was remembering," "remembers," "will remember"); and a present corresponding with the Ethiopic imperfect (Bab.-Ass. *izákar* "remembers"=Eth. *yezâker* "is remembering," "remembers," "will remember"). Subordinate verbs were marked by the termination *-u* or sometimes -a, which often in independent clauses had also the sense of the German *her*. The derived themes are nearly as numerous as those of Ethiopic, and one of these, or the permansive, was used in place of a passive formed by modification of the vowels.

Syntactically, it showed no definite affinities. It shared several idioms with Hebrew and used the enclitic -mu for *u* "and," like the Hebrew "*wāw*-consecutive" but without its effect on the following tense, to connect each fresh verb in the narration of a series of events; unlike Hebrew, it often employed asyndeton and was rich in adverbs, co-orclinate and subordinate conjunctions, and other particles. Like Aramaic and Syriac, it often substituted a periphrasis with *shâ* "of" for the "construct state," and it tended under Sumerian influence to throw the verb to the end of the sentence, as Syriac and Ethiopic frequently did. In prohibitions it used *lâ* "not" with the present or *ê* "not" with a tense resembling but hardly identical with the preterite: for example, *lâ tazákar* or *ê tazkur* "do not remember."

In prose the style was heavy and unadorned, often almost barbarous. In poetry there was little attempt at grace or charm, but the order of the words was more varied and the vocabulary somewhat fuller; the lines, which a caesura sometimes broke, were of roughly the same length, and there were occasional attempts at parallelism and rhythmic beat. (G. R. D.)

ASSYRIAN LAW: see BABYLONIAN LAW.

AST, GEORG ANTON FRIEDRICH (1778–1841), German classical scholar, was born at Gotha and died at Munich, where he was professor of classical literature for 1j years. His works are *Platons* Leben und *Schriften* (1816), an edition of Plato's works (1819–32), with Latin translation and commentary, and Lexicon *Platonicum* (1834–39). Ast denounced as spurious many of the Platonic dialogues which had hitherto been accepted as genuine. He also wrote many books on philosophy.

ASTARA, a small port in the Azerbaijan S.S.R. on the Caspian sea at the mouth of Astara river. Lat. 38° 25′ N. Long. 48° 52′ E. The river is the boundary between Persia and Russia and trade from Tabriz in rice, timber, rushes and piece goods is carried on, though the lack of railway transport hampers the town.

ASTARABAD, a province of Persia, bounded north by the Caspian sea and the Atrak river, south by the Elburz mountains, west by Mazandaran and east by Khurasan. Area about 5,630 sq.m. with a sparse population. The land is thickly wooded but marshy in parts, and the soil is exceedingly productive, even with little culture. Among the products rice must have first mention, then wheat, sesame-oil and walnut wood. In the middle ages there was considerable rearing of silk-worms. The province is malarial owing to the extensive swamps. Affluence and industry nowhere exist, and apart from the capital and its port, Bandar Jaz, trade and commerce are insignificant. The district formerly suffered from frequent excursions of the Turkomans, but these have ceased in recent years. In many villages of Astarabad and Mazandaran reside Gudars, an energetic tribe, though despised by the Persians, which is engaged in agriculture, cattle-rearing and the drying of fruit. The revenue of the province was 1,206,700 krans in 1926–27.

ASTARABAD, chief town of Astarabad province, Persia; on the Astar, a tributary of the Kara Su, in 36° 40' N. lat. and 54° 30′ E. long., 23m. from the Caspian sea, at the foot of a thickly wooded spur of the Elburz. Occupying a commercially and strategically important position the town dates back to a remote antiquity. During the recurring disorders in Persia in the 18th century, Astarabad was frequently ravaged; it attained its present compass of 3½m. under Nadir Shah. Jonas Hanway, pioneer trader, visited the town in 1744 and endeavoured to open up a direct commerce through it between Europe and Asia. The town, built four square, is surrounded by a high wall flanked by bastions now much dilapidated. The frequent rains compel the inhabitants to build their houses of stone. The population, which must have been more numerous in earlier centuries, is estimated at 10,000–12,000. The chief articles of trade are cotton, rice, sugar-cane, salt, sesame-oil, soap and carpets; but the trade has suffered heavily by the opening of the Trans-Caspian line. The climate is unhealthy especially during the hot weather.

ASTARTE, a Semitic goddess whose name appears in the Bible as Ashtoreth. She is everywhere the great female principle, answering to the Baal of the Canaanites and Phoenicians and to the Dagon of the Philistines. She had temples at Sidon and at Tyre (whence her worship was transplanted to Carthage), and the

Philistines probably venerated her at Ascalon (I. Sam. xxxi. 10). Solomon built a high-place for her at Jerusalem which lasted until the days of King Josiah (I. Kings xi. 5; II. Kings xxiii. 13), and the extent of her cult among the Israelites is proved as much by the numerous biblical references as by the frequent representations of the deity turned up on Palestinian soil. The Moabites formed a compound deity, Ashtar-Chemosh (see MOAB), and the absence of the feminine termination occurs similarly in the Babylonian and Assyrian prototype Ishtar. The old South Arabian phonetic equivalent 'Athtar is, however, a male deity. Another compound, properly of mixed sex, appears in the Aramaean Atargatis ('At[t]ar-'athe), worn down to Derketo, who is specifically associated with sacred pools and fish (Ascalon, Hierapolis-Mabog). (See ATARGATIS.)

As the great nature-goddess, the attributes of fertility and reproduction are characteristically hers, as also the accompanying immorality which originally, perhaps, was often nothing more than primitive magic. As patroness of the hunt, later identification with Artemis was inevitable. Hence the consequent fusion with Aphrodite, Artemis, Diana, Juno and Venus, and the action and reaction of one upon the other in myth and legend. Her star was the planet Venus, and classical writers give her the epithet Caelestis and Urania. Robertson Smith argues that Astarte was originally a sheep-goddess, and points to the interesting use of "Astartes of the flocks" (Deut. vii. 13) to denote the offspring. To nomads, Astarte may well have been a sheep-goddess, but this, if her earliest, was not her only type, as is clear from the sacred fish of Atargatis, the doves of Ascalon (and of the Phoenician sanctuary of Eryx), and the gazelle or antelope of the goddess of love (associated also with the Arabian Athtar).

ASTATIC COILS, when passing an electric current, produce no external magnetic field. Conversely, a varying external magnetic field does not induce in them an electromotive force. (See ELECTRICITY.)

ASTELL, MARY (1668–1731), English author, was born at Newcastle-upon-Tyne. She published, in 1697, a work entitled A Serious Proposal to the Ladies, *wherein* a Method is offered for the *Improvement* of their Minds. A scheme of hers for an Anglican sisterhood which was favourably entertained by Queen Anne, was frustrated by Bishop Burnet. Mary Astell was attacked in the Tatler (No. 52) under the name of Madonella.

ASTER, a large genus of plants of the family Compositae, so named from the radiate or star-like appearance of the flowers, and known as asters or star-worts (Gr. ἀστήρ, a star). There are some 400 species, found chiefly in North America but scattered sparsely in Asia, Europe and South America. They are usually perennial, leafy-stemmed herbs, sometimes somewhat woody at the base, and bearing in late summer and autumn a profusion of flowering heads, mostly in clusters, but sometimes solitary. In each head numerous showy blue, red, purple or white rays surround a central disc of minute yellow tubular flowers. Many are strikingly handsome, and cultivated as ornamental fall-flowering plants. The Michaelmas daisy is the finest of the cultivated sorts, its scores of varieties having been developed by hybridizing chiefly American asters. The only species (*A. Tripolium*) native to Great Britain grows abundantly in saline marshes near the sea.

In North America there are upwards of 250 species, most numerous in the northeastern United States and adjacent Canada. They are generously represented in the Rocky Mountain region, some 50 species being found in Utah and Nevada, and about 20 occur in California. In the region east of Manitoba and Kansas and north of Tennessee, the asters, together with the goldenrods, dominate the floral landscape in autumn, filling fields, woodlands and roadsides with masses of brilliant colour. Among the many conspicuous kinds the New England aster (*A. novae-angliae*), found abundantly from Quebec to Alberta and south to South Carolina and New Mexico, is the best known. It grows 3 ft. to 5 ft. high with handsome purple heads 1½ in. to 2 in. across. Other noteworthy species are the New York aster (*A. novi-belgii*) and the smooth blue aster (A. *laevis*), both of which, like the foregoing, are widely cultivated.

In California the common aster is A. chilensis; other noteworthy species are the somewhat woody desert aster (A. *tortifolius*) and the reed-like spiny aster (A. *spinosus*), which grows 9 ft. high in the southwestern deserts and is popularly called Mexican devil-weed. The China aster (Callistephus chinensis) is also a member of the family Compositae. It is a hardy annual. a native of eastern Asia, and has yielded a great variety of forms. They are commonly known as garden asters in spite of not belonging to the genus Aster.

ASTER or **ASTROSPHERE,** the term used in biology for the star-shaped structure produced by the centrosome immediately prior to cell-division. Two asters arise in the cell and these unite to form the spindle. (See CYTOLOGY.)

ASTERIA or **STAR-STONE,** a name applied to varieties of ruby and sapphire which exhibit a six-rayed star. Cymophane, or chatoyant chrysoberyl, may also be asteriated. The asterism is due to the reflection of light from twin-lamellae or from fine tubular cavities or thin enclosures definitely arranged in the stone. The astrion of Pliny is believed to have been the modern moonstone.

ASTERISK, the sign * used in typography (from the Gr. ἀστερίσκος, a little star). The word is also used in its literal meaning, a small star, and as a description of an ornamental form in one of the utensils in the Greek Church.

ASTERIUS, bishop of Amasia, in Pontus, *c.* 400. His fame rests chiefly on his Homilies, which were much esteemed in the Eastern Church. Twenty-one of these are given in full by Migne (Patrol. Ser. Gr. xl. 164–477), and there are fragments of others in Photius (Cod. 271).

ASTERIUS, of Cappadocia, sophist and teacher of rhetoric in Galatia, was converted to Christianity about the year 300, and became the disciple of Lucian, the founder of the school of Antioch. He is best known as an able defender of the semi-Arian position, and was styled by Athanasius the "advocate" of the Arians. He is last heard of at the synod of Antioch in 341.

ASTEROIDS, the minor planets, over 1,000 in number, which describe orbits round the sun, lying between those of Mars and Jupiter (q v.), and having various eccentricities. (See MINOR PLANET.)

In zoology, a group of Echinoderma (q v.). the starfish as opposed to the brittle-stars or Ophiuroids (see STAR-FISH).

ASTHENIA, lack or loss of strength, a condition in which the body lacks or has lost strength either as a whole or in any of its parts. General asthenia is found in certain individuals with a characteristic physical build. They are thin, have small bones, underdeveloped musculature and are subject to neurotic affections. General asthenia occurs in many chronic wasting diseases such as anaemia and cancer. It is probably most marked in diseases of the adrenal gland, where it dominates the whole picture. Asthenia may be limited to certain organs or systems of organs. Thus there is asthenopia, which is characterized by ready fatiguability of vision, and myasthenia gravis, in which there is progressive increase in the fatiguability of the muscular system until death results from inability of the heart muscle to continue its work. In neurasthenia and psychasthenia there is a strong subjective sense of fatigue in the absence of real weakness.

ASTHENOPIA, a condition in which the eyes are weak and tire too easily. It may be brought on by disorders in any of the various complicated functions involved in the visual act. Thus imbalance between the muscles that keep the eyes parallel leads to fatigue in the constant effort to prevent double vision. Errors in refraction lead to fatigue of the muscles of accommodation in the continued compensation demanded of them. Clouding of the lens or of the media which transmit the light may bring it about, and finally disorders of the retina, where the impressions are received, will lead to fatigue. The symptoms are pain in the eyeball, frontal headache, blurring of vision and smarting and watering of the eye. These are usually worse toward evening and are aggravated by close work such as reading and sewing.

ASTHMA, a disorder of respiration characterized by severe paroxysms of difficult breathing (*dyspnoea*), usually followed by a period of complete relief, with recurrence of the attacks at

more or less frequent intervals. The term is often loosely employed in reference to states of embarrassed respiration, which are plainly due to permanent organic disease of the respiratory organs (see RESPIRATORY SYSTEM, DISEASES OF).

The attacks occur quite suddenly; in some patients at regular, in others at irregular, intervals. They are characterized by extreme difficulty both in inspiration and expiration, but especially in the latter, the chest becoming distended and the diaphragm immobile. In the case of "pure," "idiopathic" or "nervous" asthma there is no fever or other sign of inflammation. But where the asthma is secondary to disease of some organ of the body, the symptoms will depend largely on that organ and the disease present. Such secondary forms may be bronchitic, cardiac, renal, peptic or thymic.

The mode of onset differs greatly in different cases. In some the attack begins suddenly and without warning, but in others various sensations well known to the patient announce that an attack is imminent. The commonest warning is that of an intense desire for sleep, so overpowering that though the patient knows his only chance of warding off the attack is to keep awake he is utterly unable to fight against his drowsiness. Among other patients a condition of unwonted mental excitement presages the attack. The secondary forms of the disease may be ushered in by flatulence, constipation and loss of appetite, and a common symptom is a profuse diuresis, the urine being watery and nearly colourless. In the majority of instances the attack begins during the night, sometimes abruptly but often by degrees. A few hours after midnight he is aroused from sleep by a sense of difficult breathing. In some cases this is a slowly increasing condition, not becoming acute for an hour or more. But in others the attack is so sudden, so severe, that the patient springs from his bed and makes his way at once to an open window, struggling for breath. The face is pale, anxious, and it may be livid. The veins of the forehead stand out, the eyes bulge and perspiration bedews the face. The head is fixed in position, and likewise the powerful muscles of the back to aid the attempt at respiration. The breath is whistling and wheezing, and if it becomes necessary for the patient to speak, the words are uttered with great difficulty. The chest is almost motionless, and the respirations may become extraordinarily slowed. Inspiration is difficult as the chest is already over-distended, but expiration is an even greater struggle. The attack may last from an hour to several days, and between the attacks the patient is usually quite at ease. But notwithstanding the intensely distressing character of the attacks, asthma is not one of the diseases that shorten life, except by way of secondary changes it induces in the heart.

Though the causes of asthma are known to be diverse, recent investigation has shown that it depends essentially upon swelling of the mucous lining of the bronchioles and local outpouring of a mucous secretion. It is possible, too, that the muscular coats of the air-tubes are in a state of spastic contraction during an attack. Asthma is a special example of *anaphylaxis* (*q.v.*); the patient being hypersensitive to some protein or derived substance, exposure thereto by way of inspired air leads to anaphylactic phenomena predominating in the lungs. On subcutaneous inoculation with minute quantities of infusions of various substances the occurrence with one of them of a local oedema will indicate the substance to which the asthmatic patient is hypersensitive and should avoid in order to be free from attacks.

See F. M. Rackemann, "Clin. Study of 150 cases of bronchial Asthma," Arch. Int. *Med.* (1918), xxii., p. 517; F. Coke, Asthma (1923); W. M. Duke, Allergy, Asthma, Hay Fever, etc. (1925); J. Adam, Asthma and its *radical* treatment (1926).

ASTI (anc. Hasta), episcopal see, Piedmont, Italy, province of Alessandria, on the Tanaro, 22m. W. by rail from Alessandria. Pop. (1936) town, 26,476; commune, 48,898. Remains include 8th-century baptistery (S. Giovanni), 11th-century octagonal baptistery (S. Pietro), mediaeval towers, and a fine 14th-century Gothic cathedral. It was the birthplace of the poet Vittorio Alfieri. It is now famous for its sparkling wine (*Asti spumante*).

ASTIGMATISM, a form of aberration in optical systems, including the eye, resulting in rays proceeding from a point source forming an area instead of a point and thus causing blurred vision. (*See* OPTICS and VISION.)

ASTLEY, JACOB ASTLEY, BARON (1579–1652), royalist commander in the English Civil War, came of a Norfolk family. In 1598 he joined Counts Maurice and Henry of Orange in the Netherlands, and afterwards fought under the elector palatine Frederick V. and Gustavus Adolphus in the Thirty Years' War. Returning to England with a well-deserved reputation, he was employed by Charles I. in various military capacities. At the outbreak of the Great Rebellion (1632) he was made major-general of the foot. His characteristic battle-prayer at Edgehill has become famous: "O Lord, Thou knowest how busy I must be this day. If I forget Thee, do not forget me. March on, boys!" At Gloucester he commanded a division, and at the first battle of Newbury he led the infantry of the Royal Army. With Hopton, in 1644, he served at Arundel and Cheriton. At the second battle of Newbury he made a gallant and memorable defence of Shaw House, and at Naseby he once more commanded the main body of the foot. He afterwards served in the west, and with 1,500 men fought stubbornly but vainly the last battle for the King at Stow-on-the-Wold (March 1646). His remark to his captors has become as famous as his words at Edgehill, "You have now done your work and may go and play, unless you will fall out amongst yourselves." His scrupulous honour forbade him to take any part in the Second Civil War, as he had given his parole at Stow-on-the-Wold. He died in Feb. 1652.

ASTLEY, SIR JOHN DUGDALE, BART. (1828–1894), English soldier and sportsman, was in the army from 1848 to 1859. He married an heiress in 1858 and thenceforth devoted himself to horse-racing and sport. He lost large sums of money on the turf, where he was known as "the mate." He was Conservative M.P. for North Lincolnshire 1874–1880 and died on Oct. 10, 1894.

ASTON, FRANCIS WILLIAM (1877–), British scientist, was born at Harborne, Birmingham, Sept. 1 18; *j*, and educated at Malvern College and the universities of Birmingham and Cambridge. In 1909 he became assistant lecturer in physics at Birmingham University; and in 1920 was elected fellow of Trinity College, Cambridge. In 1920 he received the Mackenzie Davidson Medal of the Rontgen Society, and in 1922 the Hughes Medal of the Royal Society. He received the Nobel Prize for chemistry in 1922 for his work in connection with isotopes and also the John Scott Medal, Philadelphia, and the Paterno Medal, Rome, both in 1923. He has written Isotopes (1922) and numerous papers in scientific periodicals on electric discharge in gases, mass-spectra, isotopes, etc.

ASTON, HUGH (early 16th century), an old English musician, of considerable historical importance. He mas one of the first composers of purely instrumental works, and is further regarded by some authorities as the actual inventor of the instrumental variation form. He composed also a number of choral works (masses, motets, and so forth) some of which have been preserved.

ASTON MANOR, a district in the N.E. of Birmingham, Warwicks., England. It was originally a municipal borough of its own but was amalgamated with Birmingham (*q.v.*) in 1911. Aston Manor is an industrial district with large motor works. It is a parliamentary division of Birmingham, returning one member.

ASTOR, JOHN JACOB (1886–), younger son of the 1st Viscount Astor, was born May 20, 1886. Educated at Eton and New College, Oxford, in 1906 he joined the 1st Life Guards. and, from 1911 to 1914, was aide-de-camp to the viceroy of India. In 1916 Major Astor married Lady Violet Mary, daughter of the 4th Earl of Minto and widow of Lord Charles Mercer-Nairne. At the outbreak of World War I he went to France with the Household Cavalry, and served there four years. He was wounded at the first battle of Ypres and again severely in Sept. 1918. In 1922, Major Astor purchased the holding of the late Viscount Northcliffe in The Times Publishing Company, and became its chairman and the chief proprietor of *The* Tintes. Shortly afterwards he caused to be established a body of trustees consisting of the holders of certain important non-political offices, whose consent he made necessary to any future transfer of the

control of that journal. He was Conservative member for the Dover division of Kent in Nov. 1922 and again in 1923 and 1924. In 1925, as treasurer of the Empire Press Union, he attended the press conference in Australia.

ASTOR, JOHN JACOB (1763–1848), American merchant, was born at the village of Walldorf, near Heidelberg, Germany, on July 17, 1763. For four years he was employed in the piano and flute factory of an uncle, of the firm Astor and Broadwood, London. In 1783 he emigrated to America, and settled in New York. On the voyage he became acquainted with a fur-trader, by whose advice he devoted himself to the same business. He was also the agent in New York of the firm of Astor and Broadwood. By his energy, industry, and business judgment he amassed an enormous fortune—the largest up to that time made by any American. He devoted many years to organizing the fur trade from the Great Lakes to the Pacific ocean, and thence by way of the Hawaiian islands to China and India. In 1811 he founded a central depot, Astoria, at the mouth of the Columbia river, but two years later the settlement was seized by the English. The incidents of this undertaking are the theme of Washington Irving's *Astoria*. A series of disasters frustrated the gigantic scheme. Astor made vast additions to his wealth by investments in real estate in New York city. He died in New York city on March 29, 1848, his fortune then being estimated at about $30,000,000. He made various charitable bequests by his will, his chief benefaction being a bequest for the foundation and endowment of a public library in New York city, now a part of the New York public library.

See Parton's ***Life of*** *John Jacob Astor* (1865).

His eldest son, WILLIAM BACKHOUSE ASTOR (1792–1875) was sometimes known as the "Landlord of New York." Under his direction the building for the Astor library was erected. His son, JOHN JACOB ASTOR (1822–1890) was also well known as a capitalist and philanthropist.

The son of the last named, WILLIAM WALDORF ASTOR (1848–1919) served in the New York legislature from 1877 to 1881. He was United States minister to Italy from 1882 to 1885. He published two romances, *Valentine* (1885) and *Sforza* (1889). In 1890 he removed to England, and in 1899 was naturalized. In 1893 he became proprietor of the *Pall Mall Gazette*, and afterwards started the *Pall Mall Magazine*, and in 1916 was created a peer, assuming the title of Baron Astor of Hever Castle. He was made a viscount in 1917, and died in England Oct. 18, 1919.

ASTOR, NANCY WITCHER, VISCOUNTESS (1879–), daughter of Chiswell Dabney Langhorne, was born on May 19, 1879, at Mirador, Virginia. In 1897 she married Robert Gould Shaw of Boston, from whom she obtained a divorce in 1903, and in 1906 married Waldorf Astor. When her husband succeeded to the viscountcy, Lady Astor, who had been his constant comrade-in-arms in his constituency at Plymouth, was adopted as Unionist candidate in his place, and after a stirring campaign was elected by a substantial majority on Nov. 28, 1919. She was the first woman to sit in the House of Commons, though Countess Markieviecz, who did not take her seat, had been elected by an Irish constituency in the Sinn Fein interest at a slightly earlier date. Lady Astor was continuously returned for Plymouth at subsequent general elections. She took a lively interest in the questions before the house, but the fact that she was for two years the only woman member made it inevitable that the various women's organizations should look to her especially to represent the interests of women and children. Her sympathy and power of work helped her in this rôle. As soon as she entered parliament she arranged a deputation from the women's organizations to interview the prime minister on the subject of widows' pensions. She advocated the amendment of the legitimacy laws, and the equal guardianship of children; and in 1924 supported the Guardianship of Infants bill, which became law in that year. Lady Astor served on the joint select committee of both houses of parliament for the consideration of criminal law amendment, in and on the Home Office committee on the employment of women in police duties in Feb. 1920. Lady Astor inaugurated a movement for co-operation between the different women's organizations, and was chairman from the outset of the consultative committee of women's organizations established (1921) to secure that co-operation.

Outside questions relating exclusively to women, her chief work has been done for a progressive educational policy, for temperance, and for the extension of the Trade Boards Acts; in the advocacy of these causes she has shown a courage which compelled admiration even from those who were indifferent or opposed to them. She constantly advocated the raising of the school age, in 1923 she carried through the Intoxicating Liquor (Sale to Persons under 18) bill, and she maintained a continuous interrogation of the ministers of labour as to the low rates of wages existing in certain branches of the distributive and catering trades. Throughout her parliamentary career, as a representative of a dockyard constituency, she took an active interest in the naval and dockyard services. It may be said that Lady Astor's vitality and trenchancy, her energy and the variety of her interests, her fearlessness and gaiety combined to render her a noteworthy member of parliament, and emphasized the significance of a great departure—the election of women as members of the British House of Commons. She was created C.H. in 1937.

ASTOR, WALDORF ASTOR, 2ND VISCOUNT (1879–), British politician, born in New York May 19, 1879, and educated at Eton and New College, Oxford. He married in 1906, the daughter of Chiswell Dabney Langhorne *(see* ASTOR, NANCY WITCHER). He represented Plymouth as a Unionist 1910–18, and the Sutton division of Plymouth 1918–19, when he vacated his seat on succeeding to his father's peerage. He was chairman of the Government committee on tuberculosis and of the State medical research committee. During World War I he was inspector of quartermaster-genera1 services, and in 1918 became private secretary to the prime minister, Lloyd George. He acted as Parliamentary secretary to the ministry of food, 1918–19, and to the local government board in 1919, retaining the same position on the formation of the ministry of health up to 1921. Since 1915 he has been the proprietor of *The Observer* and active on behalf of many causes of social progress, especially temperance reform. At the same time he was one of the leading British owners and breeders of race horses.

ASTORGA, EMANUELE GIOACCHINO CESARE RINCON, BARON D' (1680–*c.* 1755), Italian musical composer, was born at Naples, and had a romantic career which has lost nothing at the hands of his biographers; he is said, on doubtful evidence, to have been the son of a baron of Sicily who was executed for his activities in the attempts to throw off the Spanish yoke, and to have been a pupil, at Palermo, of Francesco Scarlatti. The established facts concerning him are indeed few enough. They are: that the opera *Dafne* was written and conducted by the composer in Barcelona in 1709; that he visited London in 1714; that his *Stabat Mater* had its first public performance at Oxford many years later; and that he retired eventually to Bohemia, where he died in a castle which had been given to him in the domains of Prince Lobkowitz, in Raudnitz. Astorga deserves remembrance for his dignified and pathetic *Stabat Mater,* and for his numerous chamber-cantatas for one or two voices. He was one of the last composers to carry on the traditions of this form of chamber-music as perfected by Alessandro Scarlatti.

See Hans Volkmann, ***Emanuele*** *d'Astorga* (1911 **and** 1919).

ASTORGA, a city of N.W. Spain, province of León; on the right bank of the river Tuerto. Pop. (1930) 8,743. Astorga was the Roman Asturica Augusta, the administrative centre of one Asturian district and the point of convergence of the great military roads connecting the north-west with the Pyrenean passes and with Baetica. The route followed by this last road, which used the valley of the river Alagón to cross the Central Sierras, is in essence the route of the modern railway lines connecting the south-west with the north-west via Mérida, Plasencia and Astorga, the junction with the main line from Madrid to Corunna. Astorga has been the see of a bishop since the 3rd century, but the city was left in partial or total abandonment in the Muslim period from the time of the expulsion of the Berbers (c. 750) until the repopulation under Ordoño I of León (*c.* 860). Its Gothic cathedral dates from the 15th century.

ASTORIA, a city and a port of entry, the county seat of Clatsop county, Oregon, U.S.A., on the south bank of the Columbia river, which is about 6 mi. wide there, 10 mi. from the open ocean, and about 75 mi. in a direct line N W. of Portland. Astoria is at the junction of federal highways 30 and 101; it is served by the Spokane, Portland and Seattle railway. by intercity bus lines, and by river and coastwise steamers, and is a port of call for vessels operating between north Pacific ports. The population was 14,027 in 1920, of whom 4,509 were foreign born, and was 10,389 in 1940 by federal census.

Federal engineering deepened the channel at the entrance to the Columbia river to a minimum of 46 ft. at mean low tide. The port of Astoria, a municipal corporation embracing all Clatsop county, has constructed and operates modern deepwater terminals, with warehouses and facilities for handling grain, flour, lumber, coal and other bulk freight. The total water-borne foreign commerce in 1937 amounted to 46,550 tons—all exports. The principal industrial establishments are salmon canneries, creameries, lumber mills and flour mills. In 1937 there were 31 manufacturing establishments in Astoria with 598 wage earners who were paid $747,977. The value of products manufactured was $10,061,619. On Coxcomb hill stands a column 125 ft. high, on which a spiral frieze, 535 ft. in length, depicts the early history of Oregon.

Astoria is the oldest white settlement in the northwest. It was founded by John Jacob Astor in 1811 as a fur-trading post. From 1813 to 1818 the settlement was in the hands of the British. The first saw-mill was erected in 1851, and the salmon-packing industry dates from 1866. The city was chartered in 1876. On Jan. 1 1923 a city-manager form of government was adopted.

ASTRAEA, in ancient Greek mythology, the "star maiden," daughter of Zeus and Themis, or of Astraeus the Titan and Eos ("the dawn"), in which case she is identified with Dikē. During the golden age she remained among men distributing blessings, but when the iron age began, she left the earth in disgust and was placed amongst the stars as the constellation Virgo. She is represented with a pair of scales and a crown of stars.

ASTRAGAL, in architecture, a small torus. The term is sometimes restricted to the combination of a small torus and a fillet used between the shaft and capital of a classic order (see ORDER). It is frequently carved with a "bead and reel" ornament.

ASTRAGALUS, a very large genus of the pea family (Leguminosae or Fabaceae), widely distributed throughout the world, except in Australia, but most numerous in the steppe region of northern Asia, the high plains of western North America and the tropical Andes. The common species of Great Britain and of the eastern United States and Canada are called milk-vetch. They are mostly low herbs though some are shrubby, with leaves usually divided into many narrow leaflets. Astragalus contains upwards of 1,600 species. More than 275 of these are found in North America, 95% of which occur west of the Mississippi river. Although in number of species *Astragalus* ranks among the largest of plant genera, only a few are of economic importance. Gum tragacanth is derived from A. *gummifer* and other related low spiny shrubs native to Asia Minor. In Persia a sort of manna is obtained from A. *florulentus*. In northern Europe *A.* boeticus is cultivated for its seeds, which are used as a substitute for coffee, sometimes called Swedish coffee.

The long roots of A. *aboriginum*, which occurs from Saskatchewan to Alaska and southward to British Columbia, Nevada and Colorado, are used for food by the Crees and other North American Indians; in the plains region of the United States, extending from Nebraska and Wyoming southward to Texas and New Mexico A. *mollissimus* and other related species called loco-weed are poisonous to grazing animals. Many highly ornamental old-world species of Astragalus are in cultivation and several native to North America are now sparingly planted.

For North American species, *see* P. *A.* Rydberg, *Flora* of *the Rocky* Mountains *and Adjacent Plains* (1917); *M.* E. Jones, ***Revision*** of *North-American Species of Astragalus* (1923); Ivar Tidestrom, *Flora* of *Utah and Nevada* (1925); and *W.* L. Jepson, *Manual of the Flowering Plants* of *California* (1925); "Locoweed Disease," *U.S.* D. *Ag, Farmer's* Bull. 1054 (1936); "Timber Milk Vetch," *Colo. Ag. Exp. B.* 425 (1936).

ASTRAKHAN. (1) A former province in the U S S.R. consisting of a narrow strip on either side of the Volga river from about lat. 48° 2′ N. to the Caspian sea; later incorporated into the Stalingrad region of the Russian S.F.S R. The Akhtuba river runs parallel with the Volga river and the area lying along their courses consists of chains of lagoons, with darkish, alluvial, damp soil, in places impregnated with salt, and in the south-east are shifting sand hills and sand dunes. In the ravines and adjoining the lagoons are belts suitable for plough culture and in some years considerable crops are raised, but the rainfall is unreliable and the province is one of frequent famine, the 1921 famine being of unprecedented severity. Near the Volga is a flowery oasis, with melon and other vegetables, but the rest of the area is steppe-desert in type, blossoming in spring, but a monotonous yellow gray waste in summer. At Astrakhan the average rainfall is only 5·9in. per annum; average temperatures, January 19·0°F, July 77·9°F. The population consists of Russians, Tatars, Kalmucks and Kirghiz and the chief occupation is fishing (herring, sturgeon, perch, carp, salmon), which employed 250,000 men before 1914–18. There are indications of a conflict of interests between the need of the agriculturists for irrigation and of the fisheries for a quiet breeding place for fish. Home industries are leather, furriery, linen and cotton hosiery. Salt is obtained from the lakes in the north and in some places the vine is cultivated.

(2) A town which is situated on the left bank of the Volga river at the head of the delta. Lat. 46° 22′ N. Long. 48° 6′ E. Alt. soft. below sea-level, frozen 3–4 months. Its Caspian trade is hampered by the need for dredging the Volga delta and by the unsatisfactory state of the dry cargo fleet. though oil transport is adequate.

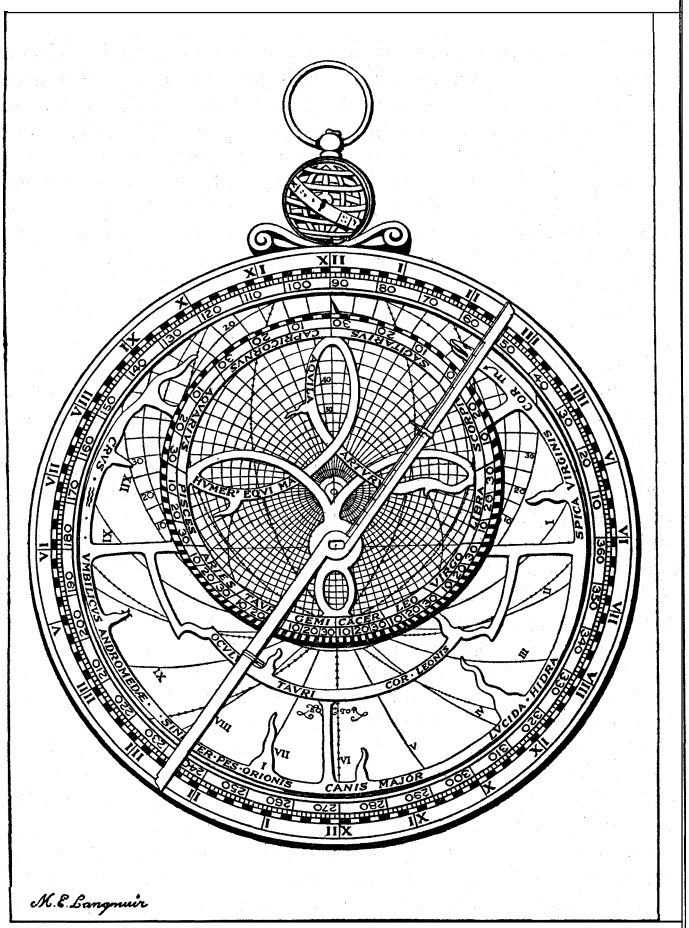
Astrakhan's chief exports are fish, caviare, watermelons and wine from its own area, grain, salt, metal, cotton and woollen goods from the interior, along with timber floated down the river from the north in spring. It is an entrepôt for naphtha and kerosene from Baku, cotton and dried fruits from Turkestan, rice, fruit and carpets from Persia and timber from the Caucasus. The skin of the new-born Persian lamb "astrakhan" is named from the city. Tanning, shipbuilding, brewing and small manufactures, *e.g.*, soap and tar products are carried on. The city is divided into three parts. (1) the Kreml or fortress (1 j50) on a hill, with a brick cathedral, an archbishop's palace and a monastery, (2) the White Town, with administrative offices and bazaars, (3) suburbs with wooden houses and irregular unpaved streets. The Greek Catholics, the Armenian Church and the Lamaists all had centres here. In 1919 a university was founded and there are technical schools, museums, wide squares and public gardens.

Formerly the city was the capital of a Tatar State and stood gm. to the north but it was destroyed by Timur in 1395 and the present city built. Ivan IV. expelled the Tatars in 1556, the Turks besieged it in 1 j69 and Stenka Razin captured it in 1670. Peter the Great made it the centre for his campaign against Persia and Catherine II. gave it special trading privileges. In the 18th century it was plundered by the Persians. It has been several times almost destroyed by fire, and was decimated by cholera (1830) and by famine (1921).

ASTRINGENT, a term comprising a group of agents that tend to shrink mucous membranes and raw surfaces and to dry up secretions. They are usually classed according to their mode of action into (1) those that decrease the blood supply by narrowing the small blood-vessels (adrenalin and cocaine are in this group); (2) those that abstract water from the part as glycerine and alcohol; and (3) those that coagulate the superficial layers and form a crust, as the metallic astringents. They are used in medicine to reduce swollen mucous membranes in inflammations of the nasal, alimentary and urinary passages. They are frequently employed in attempts to dry up excessive secretions and to stop the oozing of blood.

ASTROLABE, an instrument used for the taking of altitudes of heavenly bodies, from which time and latitude are deducible.

The planispheric astrolabe, to which the name is now commonly restricted, is believed to have been a Greek instrument invented by Hipparchus (150 B.C.), or even by Apollonius of Perga (c. 240 B.C.). It has recently been revived by Prof. Jenkin, of Oxford, as a useful educational instrument, so with a history of 2,000 years it may claim to be the oldest scientific instrument in the world, and has played a correspondingly important part in the history of civilization.



FROM "ARCHAEOLOGIA," BY COURTESY OF THE SOCIETY OF ANTIQUARIES, LONDON

THE FACE VIEW OF HUMPHREY COLE'S ASTROLABE, 1574, SHOWING THE ALIDADE, OR SIGHT RULE, THE RETE OR STAR MAP, REMOVABLE PLATE WITH LINES OF ALTITUDE, AND HOURS WITHIN THE GRADUATED RIM. PROPER USE OF THIS INSTRUMENT AT SEA WILL FIND THE SHIP'S LATITUDE AND GIVE THE TIME OF DAY

In its most usual form it consists of an evenly-balanced circle or disc of metal or wood, hung by a ring and provided with a rotatable alidade or diametral rule with sights, turning within a circle of degrees for measuring the altitudes of sun or stars. Seamen from the time of Martin Behaim (c. 1480) to the middle of the 18th century, when the astrolabe and cross staff were superseded as navigational instruments by Hadley's quadrant (see SEXTANT), relied largely upon such instruments and tables of the sun's declination for finding their latitude.

On the back is a circular map of the stars, the rete, beautifully designed in fretwork cut from a sheet of metal, with named pointers to show the positions of the brighter stars relatively to one another and to a zodiac circle showing the sun's position for every day of the year. Lying below the rete are one or more interchangeable plates engraved with circles of altitude or almucantars.

To obtain the time, first measure the altitude of the sun, then, having noted the sun's position for the day in the zodiac circle, rotate the rete until the sun's position coincides with a circle on the plate corresponding to the observed altitude. A line drawn through this point of coincidence and the centre of the instrument to a marginal circle of hours shows the time,

Among the accessories often introduced in the earlier astrolabes were "shadow scales," for simple surveying, measuring heights and distances; calendar scales showing the sun's place in the zodiac for every day of the year; magnetic compasses, usual in instruments of the 16th and 17th centuries, which thereby became useful to surveyors as circumferentors; and lastly, various lines and tables of use to astrologers. The principal varieties of astrolabes in use in the different countries of Europe and of the nearer East may be studied in the Lewis Evans collection in Oxford. The finest English examples, a great zft. astrolabe by Cole, of 1575, and a seaman's astrolabe by Elias Allen (1616) belong to St. Andrews university.

ASTROLOGY, the ancient art or science of divining the fate and future of human beings from indications given by the positions of the stars and other heavenly bodies. The study of astrology and the belief in it, as part of astronomy, is found in a developed form among the ancient Babylonians, and, directly or indirectly through the Babylonians, it spread to Greece about the middle of the 4th century B.C., and reached Rome before the opening of the Christian era. In India and China astronomy and astrology largely reflect Greek theories and speculations; and similarly, with the introduction of Greek culture into Egypt, both astronomy and astrology were actively cultivated in the region of the Nile during the Hellenistic and Roman periods. Astrology was further developed by the Arabs from the 7th to the 13th century, and in the Europe of the 14th and 15th centuries astrologers were dominating influences at court.

Babylonian Astrology.— In Babylonia, as well as in Assyria, astrology takes its place officially as one of the two chief means at the disposal of the priests for ascertaining the will and intention of the gods, the other being through the inspection of the liver of the sacrificial animal (see OMEN; HEPATOSCOPY). Astrology is based on a theory of divine government of the world, which assumes a scientific or pseudo-scientific aspect. Starting with the indisputable fact that man's life and happiness are largely dependent upon phenomena in the heavens, that the fertility of the soil is dependent upon the sun shining in the heavens as well as upon the rains that come from heaven, that on the other hand the mischief and damage done by storms and inundations, to both of which the Euphratean Valley was almost regularly subject, were to be traced likewise to the heavens, the conclusion was drawn that all the great gods had their seats in the heavens. With the moon and sun cults thus furnished by the "popular" faith it was a natural step for the priests to perfect a theory of a complete accord between phenomena observed in the heavens and occurrences on earth.

If moon and sun, whose regular movements produced the conception of the reign of law and order in the universe as against the more popular notion of chance and caprice, were divine powers, the same held good of the planets, of which five were recognized—Jupiter, Venus, Saturn, Mercury and Mars—to name them in the order in which they appear in the older cuneiform literature; in later texts, Mercury and Saturn change places. These five planets were identified with the great gods of the pantheon as follows:—Jupiter with Marduk (*q.v.*), Venus with the goddess Ishtar (*q.v.*), Saturn with the god Ninib, Mercury with Nebo (*q.v.*), and Mars with Nergal (*q.v.*). The movements of the sun, moon and five planets were regarded as representing the activity of the five gods in question, together with the moon-god Sin (*q.v.*) and the sun-god Shamash (*q.v.*), in preparing the occurrences on the earth. The priests of Babylonia accordingly applied themselves to the task of perfecting a system of interpretation of the phenomena to be observed in the heavens, and it was natural that the system was extended from the moon, sun

and five planets to the more prominent and recognizable fixed stars. That system involved not merely the movements of the moon, sun and planets, but the observation of their relative position to one another and to all kinds of peculiarities noted at any point in the course of their movements. To all these phenomena some significance was attached, and this significance was naturally intensified in the case of such a striking phenomenon as an eclipse of the moon. By the same method of careful observation of the sun and planets, and later of some of the constellations and of many of the fixed stars, the body of observations and the interpretations assigned to the nearly endless variations in the phenomena thus observed grew to enormous proportions. The interpretations themselves were based chiefly (1) on the recollection or on written records of what in the past had taken place when the phenomenon or phenomena in question had been observed, and (2) on association of ideas, involving sometimes merely a play upon words in connection with the phenomenon or phenomena observed. Thus if on a certain occasion the rise of the new moon in a cloudy sky was followed by victory over an enemy or by abundant rain, the sign in question was thus proved to be a favourable one and its recurrence would be regarded as a good omen. On the other hand the appearance of the new moon earlier than was expected was regarded as an unfavourable omen prognosticating in one case defeat, in another death among cattle, not necessarily because these events actually took place after such a phenomenon, but on a general principle resting upon association of ideas, whereby anything premature would suggest an unfavourable occurrence.

Astrology in this its earliest stage is marked by two characteristic limitations. In the first place, the movements and position of the heavenly bodies point to such occurrences as are of public import and affect the general welfare; individual interests are not in any way involved. In Babylonia and Assyria the cult centred almost exclusively in the public welfare and the person of the king, because upon his well-being and favour with the gods the fortunes of the country were dependent in accordance with the ancient conception of kingship *(see* J. G. Frazer, *The Early History of Kingship).* In the second place, the astronomical knowledge presupposed and accompanying early Babylonian astrology is essentially of an empirical character. In a general way the reign of law and order in the movements of the heavenly bodies was recognized, and indeed must have led to the rise of a methodical divination. We have, probably, as early as the days of Khammurabi, the combinations of prominent groups of stars with outlines of pictures fantastically put together. The theory of the ecliptic as representing the course of the sun through the year, divided among twelve constellations with a measurement of 30° to each division, is also of Babylonian origin, perfected after the fall of the Babylonian empire in 539 B.C. The golden age of Babylonian astronomy belongs to the Seleucid period, *i.e.,* after the advent of the Greeks in the Euphrates Valley. The beginnings at least of the calculation of sun and moon eclipses belong to the earlier period. Recent investigations have shown that the precession of the equinoxes was known to Babylonian astronomers.

The Influence of Greece.—To the Greek astronomer Hipparchus was given the credit of the discovery (*c.* 130 B.C.) of the theory of the precession of the equinoxes, but such a signal advance in pure science did not prevent the Greeks from endeavouring to trace the horoscope of the individual from the position of the planets and stars at the time of birth, or, as was attempted by other astrologers, at the time of conception. The system was taken up almost bodily by the Arab astronomers, it was embodied in the Kabbalistic lore of Jews and Christians, and through these and other channels came to be the substance of the astrology of the middle ages, forming, under the designation of "judicial astrology," a pseudo-science which was placed on a perfect footing of equality with "natural astrology" or the more genuine science of the study of the motions and phenomena of the heavenly bodies.

Chiefly under Greek influences, the scope of astrology was enlarged until it was brought into connection with practically all of the known sciences: botany, chemistry, zoology, mineralogy, anatomy and medicine. Colours, metals, stones, plants, drugs and animal life of all kinds were associated with the planets and placed under their tutelage. In the system that passes under the name of Ptolemy, Saturn is associated with grey, Jupiter-with white, Mars with red, Venus with yellow, while Mercury, occupying a peculiar place in Greek as it did in Babylonian astrology (where it was at one time designated as *the* planet par *excellence*), was supposed to vary its colour according to changing circumstances. The sun was associated with gold, the moon with silver, Jupiter with electrum, Saturn with lead, Venus with copper, and so on, while the continued influence of astrological motives is to be seen in the association of quicksilver, upon its discovery at a comparatively late period, with Mercury, because of its changeable character as a solid and a liquid. In the same way, stones were connected with both the planets and the months; plants, by diverse association of ideas, were connected with the planets, and animals likewise were placed under the guidance and protection of one or other of the heavenly bodies. By this curious process of combination the entire realm of the natural sciences was translated into the language of astrology with the single avowed purpose of seeing in all phenomena signs indicative of what the future had in store. The fate of the individual, as that feature of the future which had a supreme interest, led to the association of the planets with parts of the body. Here, too, we find various systems devised, in part representing the views of different schools, in part reflecting the advancing conceptions regarding the functions of the organs in man and animals. From the planets the same association of ideas was applied to the constellations of the zodiac, which in later phases of astrology are placed on a par with the planets themselves, so far as their importance for the individual horoscope is concerned. The fate of the individual in this combination of planets with the zodiac was made dependent, not merely upon the planet which happened to be rising at the time of birth or of conception, but also upon its local relationship to a special sign or to certain signs of the zodiac. The zodiac was regarded as the prototype of the human body, the different parts of which all had their corresponding sections in the zodiac itself. The late Egyptian astrologers set up a correspondence between the 36 *decani* recognized by them and the human body, which is thus divided into 36 parts; to each part a god was assigned as a controlling force. Many diseases and disturbances of the ordinary functions of the organs were attributed to the influence of planets or explained as due to conditions observed in a constellation or in the position of a star; while, on the other hand, the influence of planetary lore appears in the assignment of the days of the week to the planets, beginning with Sunday, assigned to the sun, and ending with Saturday, the day of Saturn. In later periods, Saturn's day was associated with the Jewish Sabbath; Sunday with the Lord's Day; Tuesday with Tiw, the god of war, corresponding to Mars of the Romans and to the Nergal of the Babylonians. Wednesday was assigned to the planet Mercury, the equivalent of the Germanic god R'oden; Thursday to Jupiter, the equivalent of Thor; and Friday to Friga, the goddess of love, who is represented by Venus among the Romans and among the Babylonians by Ishtar. Astrological considerations regulated in ancient Babylonia the distinction of lucky and unlucky days, which passing down to the Greeks and Romans *(dies fasti* and *nefasti)* found expression in Hesiod's *Works and Days.*

Judicial Astrology.—In the science of judicial astrology a horoscope or "nativity" is a map of the heavens at the hour of birth, showing, according to the Ephemeris, the position of the heavenly bodies, from which their influence may be deduced. Each of the twelve signs of the zodiac (*q.v.*) is credited with its own characteristics and influence, and is the controlling sign of its "house of life." The sign exactly rising at the moment of birth is called the ascendant. The benevolent or malignant influence of each planet, together with the sun and moon, is modified by the sign it inhabits at the nativity; thus Jupiter in one house may indicate riches, fame in another, beauty in another, and Saturn similarly poverty, obscurity or deformity.

Judicial astrology, as a form of divination, is a concomitant of natural astrology, in its purer astronomical aspect, but mingled with what is now considered an unscientific and superstitious view of world-forces. Francis Bacon abuses the astrologers of his day no less than the alchemists because he has visions of a reformed astrology and a reformed alchemy. Sir Thomas Browne, too, while he denies the capacity of the astrologers of his day, does not dispute the reality of astrological science. But Aristarchus of Samos, Martianus Capella (the precursor of Copernicus), Cicero, Favorinus, Sextus Empiricus, Juvenal, and in a later age Savonarola and Pico della Mirandola, and La Fontaine, a contemporary of the neutral La Bruyère, were all pronounced opponents of astrology. In England Swift may fairly claim the credit of having given the death-blow to astrology by his famous *Prediction for the Year 1708, by Isaac Bickerstaff, Esq.* Many passages in the older English poets are unintelligible without some knowledge of astrology. Chaucer wrote a treatise on the astrolabe; Milton constantly refers to planetary influences; in Shakespeare's *King Lear,* Gloucester and Edmund represent respectively the old and the new faith. In modern languages words with astrological associations are still in use, such as *lunatic, saturnine, malheureux* and *ill-starred.*

ASTRONOMICAL ARTICLES. Besides the article ASTRONOMY, this subject is dealt with under the following heads:

SOLAR SYSTEM.—1, *Sun; Eclipse; Chromosphere; Corona;* 2, *Planet; Mercury; Venus; Earth; Moon;* Mars; *Jupiter; Saturn; Uranus; Neptune;* 3, *Minor Planet; Eros; Trojan Planets;* 4, *Comets; Meteor.*

STELLAR UNIVERSE.—1, *Star; Nova; Sirius; Algol;* 2, *Star Cluster; Nebula; Cosmogony; Stellar Evolution.*

METHODS AND INSTRUMENTS.—1, METHODS—*Parallax; Time Measurement; Photometry; Plzotography, Celestial;* 2, INSTRUMENTS—*Observatory; Telescope; Transit Circle; Spectroheliograph; Micrometer; Altazimuth; Zenith Telescope; Blink Microscope; Coelostat; Heliostat; Photography;* 3, COMPUTATION—*Ephemeris HISTORICAL.— 1, History of Astronomy* (forming part of the article *Astrononty); Constellation; Ancient Eclipses* (in article *Eclipse);* 2, *Astrolabe; Armillary Sphere; Dial.*

Thirty-two short articles on individual constellations are given *(see* table at the end of the article *Constellation).* These contain, besides a reference to the mythology of the constellation, notes on the principal objects of astronomical interest.

Further articles deal with various phenomena of fundamental importance either cosmically or from their effect on questions of practical life:—*Precession of the Equinoxes, Aberration of Light, Equation of Tinte.*

ASTRONOMICAL SOCIETIES. The *Royal Astronomical Society* was founded in 1820 as the *Astronomical Society of London* and was incorporated March 7, 1831. Its headquarters are at Burlington House, London, and *Memoirs* (1882, etc.) and *Monthly Notices* (1831, etc.) are published. The first *International Astronomical Congress* met at Heidelberg in 1863 and in 1887 the first international conference for celestial photography assembled in Paris. The *International Astronomical Union,* organized at Brussels in 1919, held meetings at Rome in 1922, Cambridge, Eng., in 1925 and at Leiden, Holland, in 1928. Other astronomical societies: *British Astronomical Association* (London) and societies at Bristol (1869), publishing *Reports;* Leeds (1859), Manchester and Liverpool (1881); the *Roy. Astr. Soc. of Canada,* Toronto (1890), *Transactions* (1890), *Proceedings* (1902), *Journal* (1907, etc.); *Soc. Astr.,* Paris (1887), *Bull.; Kgl. Astr. Rechneninstitut,* Berlin (1897); *Astronomische Ges.,* Leipzig (1863), *Publ.* (1865, etc.) and *Vierteljahrschrift* (1866, etc.); *Soc. Astr. Ital.,* Milan (1920), *Revista; Soc. Belge. d'Astr. de Météorol. et de Physique du Globe,* Brussels (1893), *Bull. mens.; Soc. d'Astr.,* Antwerp (1905), *Gazette; Soc. Astr.,* Mexico (1902), *Boletin* (1902, etc.). The *American Astronomical Society* was originally founded in 1899 as the *Astronomical and Astrophysical Society of America.* The *Astronomical Society of the Pacific* was founded in 1889. The *American Association of Variable Star Observers* was organized in 1911.

ASTRONOMY. The earth on which we live is the fifth largest planet belonging to one of the lesser stars. Perhaps it is less necessary now than it used to be to insist on the smallness of our planet. Scientific inventions and ease of travel seem to have brought different parts of the earth near together, and we no longer hold an exaggerated idea of its immensity. But it is when we look up into the vault of the heavens that we realize the insignificance of the earth in the scheme of the material universe. Our sight penetrates space beyond space revealing world beyond world of unimaginable grandeur; and the greatest of these orbs is but as a speck in the vast intervening void. All this world beyond the earth is the field of the science of astronomy.

Of the objects of the sky the sun and moon stand out from the rest in prominence. Both appear to us of much the same size. In fact the phenomenon of eclipses gives a delicate test showing that the apparent angular sizes are almost identical; for when the moon passes between us and the sun, sometimes it is just able to cover it completely, sometimes it just fails to cover it and leaves a narrow ring of the sun showing all round it. But this apparent agreement is only a coincidence; the sun and moon are bodies of altogether different size and cosmical importance.

The moon is a smaller globe than the earth, of no particular importance except to the earth which it attends as satellite; it is probable that in the remote past its material formed part of the earth, that it broke away in a great convulsion, and has gradually receded to its present distance of 240,000 miles. Thus the first halting point in our journey through space tends rather to enhance our idea of the dignity of the earth by showing that a subordinate globe attends it; but that is unique, and when we pass beyond this comparatively small distance over which the earth's domain extends, the "proud father" is seen to be a very humble member of a great community.

The other luminary, the sun, stands to our earth in much the same relation as the earth does to the moon. The sun is the ruler and the earth a subordinate globe travelling round nearly in a circle (but strictly an ellipse) under the controlling force of the sun's gravitational attraction. The sun is of a size that befits the dignity of a ruler. The amount of matter constituting it is equivalent to 300,000 earths rolled into one. This great mass is maintained, by means which are still very largely a mystery, at enormously high temperature so that it pours forth the unceasing stream of heat and light of so much importance to terrestrial life. Our average distance from the sun is 92,870,000 miles; but since the earth's orbit is not exactiy circular its distance varies over a range of about 3,000,000 miles according to the time of year.

When we pass beyond the moon all astronomical distances become inconceivably great, and the reader may be inclined to group them together without distinction as virtually infinite. But it has to be realized that we have passed to a new scale of extension where we must make a distinction of comparatively smaller and greater distances. Great as may be the distance from the earth to the sun it is traversed by light in about eight minutes; or a radio-telegram would take the same time to travel. We see the sun not as it is now but as it was eight minutes ago. This gives a convenient way of realizing how much further our journey through space must extend. There is little doubt that the most remote object in the heavens which can be seen without telescopic aid is

a small fuzzy patch of light in the constellation Andromeda. At first glance this would be taken for one of the fainter stars, but the diffuseness of the light is distinctive, and telescopes show it to be a great spiral nebula. The light which we see to-day left that nebula 900,000 years ago. This is more or less the limit of our exploration; the telescope shows other spiral nebulae, smaller and presumably in many cases more remote, but their distances are at present a matter of conjecture.

The Solar System.—Just as the earth's supremacy comes to an end beyond the moon, so there are limits to the sun's supremacy. The solar system, as it is called, may be regarded roughly as limited by the orbit of the outermost planet, Neptune; though many of the comets obeying the sun's attraction have elongated paths which take them some way out into the space beyond this limit for part of their course. Neptune's distance from the sun is 30 times as great as that of the earth; and as seen from Neptune the brightness and heat would be diminished to about a thousandth; but even so the sun would appear far more brilliant than any of the stars. The isolation of this system from other astronomical bodies or systems can be best realized from the fact that the sun's light takes 4 hours to reach the limits of its domain (Neptune), but 4 years to reach its nearest neighbour among the stars.

For this reason the study of the heavenly bodies falls naturally into two divisions: the solar system and the stellar universe, the latter comprising all that is beyond the solar system.

To the solar system belong, besides the sun and the earth with its moon, the planets or "wandering stars." Such of the planets as are visible to the naked eye are ordinarily mistaken for true or "fixed" stars; they can usually be distinguished by the fact that their light does not twinkle, but that is by no means an infallible test since it depends a great deal on atmospheric conditions. Their special characteristic is that they move from place to place in the sky—not like the stars which form fixed constellations. For this reason it is impossible to give simple directions as to where they are to be found, or to insert positions for them in a map of the heavens. A planet of unusual brilliancy seen towards the west after sunset or the east before sunrise may fairly safely be identified as Venus; after the sun and moon it is much the brightest object of the heavens. Jupiter is also much brighter than any of the stars; its position in the sky is not so circumscribed as that of Venus and it may be visible at any time of the night. Mars is easily distinguished from other planets by its red colour, and when near the earth is conspicuous by its brilliancy; at other times it may easily be mistaken for one of the reddish fixed stars. Saturn can scarcely be distinguished from the bright (first magnitude) stars except by those who have enough familiarity with the normal appearance of the heavens to spot "a bright star in the wrong place." Mercury is rarely seen except in tropical latitudes; at favourable times it is visible as a brilliant point of light in the glow of sunset or sunrise. The other planets, Uranus and Neptune, are telescopic objects. These planets are bodies revolving round the sun and having the same status as the earth. Telescopes show that some of them are attended by satellites as the earth is attended by the moon. A planet more remote than Neptune was discovered at the Lowell observatory in Feb. 1930 in a position agreeing closely with a prediction made by the late Percival Lowell as the result of calculation from the perturbations of Uranus. Its present distance from the sun is between 3,700 and 4,000 million miles. The period is unknown at present but is expected to be about 300 years.

To complete the enumeration of the bodies of the solar system we must mention: (1) The minor planets, of which more than a thousand have been discovered, which in some way seem to represent what ought to have been an ordinary planet between Mars and Jupiter where there is a hiatus in the regular spacing of the successive orbits; (2) the comets, bodies of no great mass, which suffer extremes of heat and cold owing to their very elongated orbits and display "fireworks" at each return to proximity to the sun's heat; (3) swarms of meteors which the earth ploughs through on its way round the sun; these bodies (mostly of very small mass) become incandescent on striking the earth's atmosphere and show themselves as "falling stars"; (4) diffuse gaseous or meteoric matter seen in the zodiacal light and evidenced in other more indirect ways.

The Stellar Universe.—As already stated we have to adapt our minds to a transcendently large scale of size and distance in studying the solar system; but this is only a prelude to another million-fold leap in studying the scale of the stellar universe. Passing outside its own particular domain, the sun is just one of some thousands of millions of stars. It is not a particularly large star. In fact, most of the stars which we see in the night sky are in reality much more brilliant; but this is not quite a fair comparison to make, because naturally it is the more brilliant members of the community that have the best chance of being noticed. Whilst we must recognize that there are numerous stars which outshine the sun, we must also recognize that feebler stars are still more numerous. This part of astronomy includes the study of individual stars and their associations, star clusters, and nebulae. The last term includes three distinct types of objects.

The two main divisions of astronomical knowledge—the solar system and the stellar universe—cannot be kept entirely dissociated. Thus our study of the sun as the leading member of the solar system must be supplemented by a comparative study of him in relation to his compeers in the stellar universe. Moreover, much of astronomical research is directed not so much towards knowledge of individual objects as to the discovery of physical laws and truths of uni ersal application; the problem of the laws of motion of the planets round the sun repeats itself in the motion of the components of a double star; the configuration which in our own system gives rise to the awe-inspiring spectacle of an eclipse is also the secret of the winking of the "demon" star Algol.

Some Practical Uses of Astronomy.—What is the use of astronomy? It is not necessary here to defend the pursui! of pure science whether or not it leads to results which can be used (or, as commonly, misused) for modifying the conditions of human existence. Therefore it is not in any spirit of apology or defence that reference may be made to some of the practical reasons why a study of astronomy is necessary. To begin with, it provides the explanation of certain phenomena of immediate importance to us such as the seasons and the tides. The exact time circulated several times a day by radio is derived from continued astronomical observations. It is of fundamental importance in navigation. Greenwich observatory was founded in 1675 to meet urgent needs of navigation; and in particular its long series of observations of the moon from 1750 onwards has been the basis by which longitudes were determined up to recent times. The radio time-signals have now rendered the moon obsolete for this purpose; but even after 1900 the ownership of many hundreds of square miles of territory hung in the balance until the boundary commissioners were furnished with the latest observations of the moon's position.

All this, it will be said, belongs to the old fashioned type of astronomy, and is no justification of the usefulness of much of the present domain of research which seems to be inspired with the idea of getting as far away as possible from the earth and all terrestrial things. The answer is that scientific knowledge forms a single whole, and if astronomy lags behind, the sister science of physics will suffer. Present-day astronomy has a very definite part to play in the general advance. The stars and diffuse nebulae are physical laboratories where we can watch experiments performed on matter under the most extreme conditions of temperature and density. They supply the gaps in knowledge which the experimental physicist is unable to cover in the limited conditions of a terrestrial laboratory. The element helium, of great practical use to-day, was first discovered on the sun. The theory of relativity has revolutionized the conceptions of physics and is fundamental in our modern knowledge of the atom; but it largely owes its general acceptance to the astronomical tests which were applied. Numerous technical illustrations could be given of the way in which the stars have been invoked to supplement the terrestrial laboratory. At the time of writing (1928) comes the news that the most prominent lines in the spectra of the nebulae are now identified as "forbidden lines" of the spectrum of the oxygen atom in a certain state—forbidden, that is to say, in anything approaching terrestrial conditions but possible at the extremely

low density of a nebula. We cannot foresee what will be the next practical application of the rapidly advancing physical knowledge wrung by joint effort from the laboratory and the stars; but that there will be applications the whole history of science and invention assures us. One thing may be pointed out. The sun and stars hold the secret of releasing from matter vast quantities of energy compared with which all our commercial sources of energy are insignificant. Few scientific men would venture to hold out any expectation that by quest of this secret we may be able to provide the world with a source that will supersede all present fuel; but it would certainly be remiss not to make every effort to learn what we can of the conditions of release of this transcendent power.

Observatories and Their Work.—Numerous observatories have been set up in most countries to carry out astronomical observations. It may be well first to remove the rather amusing popular misconceptions as to the kind of work that goes on in these. The astronomer does not spend his nights with his eye "glued to the telescope." He is not bound to keep a continuous watch over the sky lest something should turn up when he happened to be asleep. Very little of his time is spent in gazing at the show objects of the heavens—the moon, planets, nebulae, etc.—which for the most part can show him nothing more to-night than they have shown him for many years past. He does not relapse into inactivity in those intervals when there is nothing particularly new or striking going on in the sky. Whilst we are on the subject of popular misconceptions, it may be added that the chief preoccupation of astronomers is not the question whether there is intelligent life on Mars or elsewhere in the universe; although an occasional crumb of information that might possibly bear on this subject may happen to be picked up, astronomy can take no responsibility for the speculations that may ensue. Also astronomers do not predict the weather; and, their work being at the mercy of the clouds, they have more cause than most people to rail against failure to foretell the state of the sky a few hours in advance.

What, then, is the work of an observatory? The question is rather like asking what is the work of a factory; no summary can cover all the different kinds of investigation that the different institutions may take up. A few years ago a central feature of every observatory was an accurate astronomical clock, which had to be kept corrected by frequent observations of stars. But now lines of work have developed in which accurate knowledge of time is inessential; and there is at least one famous observatory where no one worries about the time to a minute or so. But it would be nearly true to say that all astronomical work consists of exact measurement. If the eye of the observer is gazing fixedly into the telescope for a few minutes, his fingers are all the time twiddling screws to move cross-wires or other devices; and in the course of the night he has to look as much at terrestrial micrometer-readings as at celestial phenomena. Part, but by no means all, of the work consists of photography, the exposures ranging from less than a minute to many hours according to the nature of the investigation. These photographs are afterwards measured up under the microscope. Many measures are made photographically and visually of the brightness of different stars. Or the light may be split up by a spectroscope before photographing, and the spectra subsequently measured. What is learnt from all these measures forms the subject matter of many separate articles on celestial objects included in this encyclopaedia. The reader will there find evidence that the work is often fruitful; but he may not easily be convinced that there is need for such an enormous amount of measurement. There are several lines of explanation which may help us to understand this.

The Demand for Data.—Few people realize how big the vault of the sky is. If the moon is photographed with an ordinary astrographic telescope its image seems disappointingly small. The usual size of plate is $6\frac{1}{4}$x$6\frac{1}{4}$in.; and the beginner perhaps expects that this will cover only a limited area of the moon. Instead of that the full moon is only a circle just over an inch in diameter. Yet even on this unambitious scale it takes 10,000 plates to cover the whole sky. With more powerful telescopes giving a larger scale the task is correspondingly increased. The number of stars that might be studied is overwhelming, and indeed it is necessary to impose some systematic limitation on the survey; but proper motions determined by the ten thousand, parallaxes and radial velocities by the thousand, fail to satisfy the demands of the theorist for more and more data. Much of our knowledge of the stars has come from statistical studies, and work of that kind swallows up data by the thousand before it can assert results with confidence and accuracy.

It is by spreading our net wide that we catch the objects which will repay an intensive study. The minor planets give a good example of this. After the first few were discovered there seemed little object in continuing to find hundreds more, calculating their orbits, and generally keeping track of them. There was some chance that statistics of their distribution in distance, eccentricity, inclination, etc., might prove interesting; but otherwise they were an unmitigated nuisance in astronomy. But after Ceres, Pallas, Juno, Vesta, the work went on, each new planet being as uninteresting as its predecessor. Then in 1898, No. 433, Eros, was discovered, a body of the greatest astronomical importance which was the subject of thousands of observations at its close approach to the earth in 1901, and which will no doubt be watched with equal zeal at the still closer approach in 1931. Another dull accumulation of these planets followed until No. 588, Achilles, started the interesting Trojan group, which if it has done nothing else has set a new and difficult problem to the dynamical astronomers.

Another illustration may be given. One of the greatest needs in stellar astronomy is a knowledge of the masses of the stars; many important conclusions turn on evidence as to the mass. The only chance of making a direct determination of the mass is when the star is a binary system; but it is rare to find all conditions favourable. Burnham's General Catalogue lists 13,600 visual double stars and to these may be added more than 1,000 spectroscopic binaries. From these we are able to scrape together just about 30 reasonably well-determined masses. It seems a meagre amount of grain to extract from so much chaff; yet the advance that this knowledge of stellar mass makes possible is so great that we should have no reason to feel dissatisfied even if this were the only result of double star observation. When in these astronomical articles a star is mentioned as having given occasion for some new extension of knowledge, it should be recalled that in most cases the observer had no initial reason to suspect that it would prove more fruitful than a hundred other stars on his programme.

Astronomical Telescopes.—A telescope of some kind is employed in nearly all observations. There are two entirely distinct functions which it may fulfil—(1) to collect enough light from extremely faint objects to make them visible or capable of measurement; (2) to resolve and magnify brighter objects. These functions are independent, and any particular telescope is usually specialized for one purpose or the other. Having, for example, employed a wide aperture and long exposure to collect enough light from a faint extension of a nebula or the end of a comet's tail we do not want to squander it over a large area on the photographic plate. A wide dumpy instrument gathering much light on to a small scale picture is best for detecting the faintest objects. On the other hand, when the amount of light permits, we profit by employing a long telescope with high magnification; the accuracy of measurements is enhanced by the increased scale. For these and other reasons there is a tendency to specialization of telescopes for different kinds of work. Owing to conditions of achromatism a refracting telescope cannot ordinarily be used both for visual and photographic work; attempts to combine both functions in one instrument involve extra lenses and considerable sacrifice of light. In some applications of the largest telescopes the perfect figuring of the mirror would seem to be rather wasted. For measurement of the heat of the stars the rays have to be concentrated on a disc enormously greater than the ordinary size of a star-image; and in photo-electric work they merely have to enter the wide mouth of a photo-electric cell. In the spectroscopy of nebulae the perfection of the focus is unimportant. There would seem to be room in an observatory nowadays for a very big, very "bad" telescope.

Besides the largest telescopes mounted equatorially, *i.e.*, so as to keep the same stars in view notwithstanding the apparent diurnal

rotation of the sky, there are instruments (useless for prolonged scrutiny of objects) with which observations of position of the stars and planets are snapped as they traverse the field of view. The transit circle (or meridian circle), the altazimuth and the zenith telescope are the most important of these. They are used for measuring the positions, and hence ultimately the motions of heavenly bodies. With the equatorial telescopes positions can only be measured relative to the stars in the same field. This suffices for some kinds of work: but, for example, in following the motion of the moon and planets round the sky the whole system of reference stars will need to be connected together. This liaison is provided mainly by the transit-circle and forms a very important branch of practical work known as "Fundamental Astronomy."

Finally reference may be made to kinds of work which may perhaps give some colour to the popular misconceptions mentioned at the beginning of this section. There are two things which come on an astronomer without warning—the outbreak of a Nova or temporary star, and the arrival of a comet. The arrival of comets can be predicted sometimes, but the biggest comets come unannounced; outbreaks of Novae are never predicted. The discovery of either is likely to fall to someone who makes a practice of searching the sky night after night, whether with deliberate intention or from delight in its wonders. It is not likely to fall to those who are occupied with the intensive measurements abovementioned. After a comet has been observed on three nights its orbit is worked out, and it is possible to judge whether it is likely, by close approach to the sun or the earth, to give favourable opportunity for studying outstanding questions of cometary structure. The result is generally disappointing and it passes out of notice so far as the majority of astronomers are concerned, though the comet specialists will continue to keep an eye on its behaviour. The announcement of a Nova most decidedly disturbs the even life of an observatory; for these stars present some of the most perplexing problems of present day astronomy and there is great need for observation especially in the earliest stages of the outbreak. At least for spectroscopic workers it is well worth while to suspend other problems and make concentrated efforts to explore the mysterious phenomena.

SPHERICAL ASTRONOMY

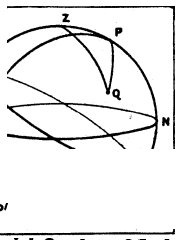
The Celestial Sphere.—In surveying the universe from a fixed point we can define the position of any object by specifying (1) its direction and (2) its distance. Owing to the property of propagation of light in straight lines we can immediately observe the direction of any visible object, but we cannot tell how far away it is. Our knowledge of astronomical distances is derived by more indirect methods, and it never attains the precision of our knowledge of directions. Hence our study of position begins with a study of direction only; or, we may put it, we study the location of heavenly bodies, not in space, but on the celestial sphere.

The celestial sphere, then, is a sphere with the observer as centre, of radius which is arbitrary though it is perhaps convenient to choose it very great; and an observation of direction fixes the object (or projects it) on some point of this sphere. For the present we can regard the fixed stars as fixed points of this sphere (ignoring their very slow proper motions). They play the part of the figures on a clock face, and we observe the sun, moon and planets moving across them like the hands of the clock. Primarily the actual observer himself is the centre of this sphere; but for combining with observations at other times and places we often apply corrections so as to give the positions which would have been observed from the centre of the earth or of the sun—geocentric or *heliocentric* positions. The correction necessary to reduce the original position to geocentric or heliocentric position is called parallax. The closer the object the greater is the parallax; for example, the moon has so large a parallax that if we point a moderately powerful telescope to its geocentric position (the position given in the Nautical Almanac) it will probably be out of the field of view; we, so to speak, look over the top of it.

The first thing we notice is that the celestial sphere carrying the stars is rotating; the stars rise in the east and set in the west. (Of course we know that it is really our earth that is rotating, but this is not the appropriate moment to air our superior knowledge.) R e can determine the axis of rotation because the end of the axis will remain still. One well known star remains nearly still; we always find it in practically the same direction and altitude in the sky. This must accordingly be very near the end of the axis, and the star is called Polaris or the Pole Star. By careful observation we fix the unchanging point or Pole more accurately among the stars, and find that Polaris is about $1°2'$ away from it. There is an opposite pole in the other hemisphere not marked by any bright star but equally locatable; and midway between them runs a great circle called the Equator of the celestial sphere.

The observer can also mark on the celestial sphere the zenith or point which (momentarily) is vertically overhead. This is given by the direction of gravity (including centrifugal force); it is perpendicular to any undisturbed liquid surface, and in practice is generally determined by a method employing reflection from a trough of mercury. Opposite to the zenith is the nadir, and the great circle midway between them is the horizon. This celestial horizon does not quite agree with the observed terrestrial horizon; because if we are on a hill we see rather more than half the celestial sphere. At fixed observatories we usually measure angles from the zenith; but at sea the sailor measures altitudes above the sea-horizon, and he has to subtract a correction called the "dip of the horizon" to give the altitude above the celestial horizon (corrected altitude=$90°$— zenith distance).

Sidereal Time.—The diagram shows our two named points, the pole P and the zenith Z, our two great circles, the equator and horizon, and the south pole P' and nadir Z' in the opposite hemisphere. The equator meets the horizon in the east and west points. The great circle joining PZ is called the meridian, and meets the horizon in the north and south points N, S. Finally the angular distance PN, *i.e.*, the altitude of the pole above the horizon, is called the latitude of the observer. The reason for this last identification is easily seen. If the observer were at the north pole, where the axis of the earth's rotation is the line going straight down to the earth's centre, *i.e.*, to the nadir, it is clear that Z and P would coincide. As we travel towards the earth's equator the angle between Z and P diverges; and at the equator our zenith direction Z is $90°$ away from its original direction P. In fact for stations on the equator P must be on the horizon. Conversely, travelling steadily through $90°$ of terrestrial latitude from the terrestrial equator to the pole, P rises steadily from the horizon through $90°$ to the zenith, and its height at any stage measures the latitude. It may be asked, How does the spheroidal figure of the earth affect the accuracy of this statement? The statement is still exact, because the latitude shown on maps is defined by this astronomical defihition; but the spheroidal shape has the effect of making a degree of latitude greater (in miles) near the pole than near the equator.



THE DIAGRAM OF A CELESTIAL SPHERE

Consider now a star or planet Q. We can specify its position either by giving its zenith distance ZQ and the azimuth from the south point, *i.e.*, the angle QZS; or by giving the north polar distance PQ and the angle QPZ which is called the hour angle. Formulae of spherical trigonometry connect these two methods of defining position. The hour angle introduces us to the problem of time.

The earth rotates once in $23^h.56^m.4.091^s.$ of ordinary time (mean solar time). But although the astronomer supplies mean solar time for the convenience of the general public, he has for his own use another reckoning of time called sidereal time and the foregoing period is equal to 24 sidereal hours. Thus in 24 hours by the sidereal clock the celestial sphere makes one revolution and comes into the same position again. The convenience of such a clock will be evident when we realize that if we have once seen a star in a certain direction at 5 o'clock (sid.), we always find it there at 5 o'clock (sid.). The hour angle (or indeed any angle)

can be expressed in the usual way in degrees, minutes, seconds, but it can also be expressed in time units by converting at the rate of 360° to 24^{h} of time.

When converted into time units in this way the hour angle tells us how long by the sidereal clock the celestial sphere will take to turn through the angle QPZ and so bring Q on to the meridian If it is now 5 o'clock (sid.) and the easterly hour angle of Q is 8 hours, Q will cross the meridian at 13 o'clock (sid.).

We have explained how to regulate the rate of the sidereal clock but we have not yet explained how to set it. At $0^{h}\,0^{m}\,0^{s}$ sidereal time a certain fixed mark of the equator (fixed relative to the stars) must be crossing the meridian NZS. We call this mark "the first point of Aries" and denote it by ♈. Evidently at any moment the sidereal time will be equal to the hour angle of ♈ measured towards the west. Every other star has its fixed time of passing the meridian by the sidereal clock and this time is called the right ascension of the star. This gives the third, and most usual, way of specifying positions on the celestial sphere, viz., Right Ascension, the time by the sidereal clock at which the point passes the meridian, or the angle ♈PQ measured towards the east; *Declination,* the complement of the north polar distance, or 90°-PQ.

In this system it is no longer necessary to refer to the time of observation, since if the point is in a constant position with respect to the stars the right ascension and declination remain constant (subject to corrections mentioned later).

Sun, Moon and Planets. — Turning from the fixed stars to moving bodies, the simplest motion is that of the sun. If we observed the earth from the sun we should see it describe a complete circle round the sphere of the stars once a year, as it went round its orbit. The direction from the earth to the sun is just the opposite, and therefore it sweeps out a great circle round the celestial sphere once a year. This great circle is called the ecliptic; it is the intersection of the plane of the earth's orbit with the celestial sphere. We can, of course, trace this great circle among the stars by observing the sun's right ascension and declination from day to day. The point ♈ (hitherto treated as arbitrary) is defined as the intersection of the equator and ecliptic; the sun in its course round the ecliptic passes through this point at the vernal equinox, about March 21. The ecliptic and equator are inclined at an angle of about $23\frac{1}{2}°$ called the obliquity.

The sun goes round the ecliptic towards the east increasing in declination after passing ♈ and therefore giving us (in the northern hemisphere) the long summer days. After reaching a maximum declination of $23\frac{1}{2}°$ it descends, passes through the point opposite ♈ about Sept. 21, and continues to a minimum declination of $23\frac{1}{2}°$. It has to make a complete circuit in $365\frac{1}{4}$ days and therefore has to do an average of nearly 1" a day. Thus when the celestial sphere has made one complete turn it has still 1° more to go before the sun is brought back to the meridian; that takes 4 minutes more, or, to give the accurate figures, the average sidereal time between two successive passages of the sun over the meridian is $24^{h}\,3^{m}.56{\cdot}55^{s}$. Since our daily affairs are more or less regulated by the sun we set this equal to 24^{h} of ordinary (mean solar) time. Clocks regulated by this time keep pace with the sun on the average throughout the year, but not exactly from day to day (see EQUATION OF TIME). The sidereal clock gives one extra, "day" in the year compared with the mean clock; hence there is only one instant in the year when the two clocks agree. About March 21 the sun coincides with ♈, so that it is on the meridian (noon) when ♈ is on the meridian, *i.e.*, at 0^{h} sidereal time; midnight which is the beginning of the civil day (0^{h}) accordingly coincides with 12^{h} sidereal time about March 21. Thus the time when the two clocks agree is at the autumnal equinox about Sept. 21. These statements, however, need a slight correction because of the equation of time, true midnight on Sept. 21 being at about 11.53 p.m. local mean time.

The orbit of the moon is inclined at a small angle 5°9′ so that the moon's position in the sky is always within this distance of the ecliptic. The principal planets also have small inclinations, so that it is possible to define a zone not much more than 10° wide within which the sun, moon and planets are always to be found This zone is called the zodiac, and its course amongst the stars is marked by the 12 well known constellations of the zodiac. Angular distance from the ecliptic is called *latitude,* and distance round the ecliptic measured from ♈ is called longitude. Positions of objects are often given in longitude and latitude instead of in right ascension and declination. It should be noted, however, that the names are rather misleading, because right ascensions and declinations are the proper analogues on the celestial sphere to longitudes and latitudes on the earth.

Perturbing Factors. — After measurements have been made of the apparent position of a body in the sky a host of corrections must be applied before the results can be reduced to a useful form. Besides the purely instrumental corrections, the chief corrections are: (1) Refraction. The bending of the rays of light in passing through our atmosphere displaces the apparent position of a star by 57″ when the altitude is 45°, and by a rapidly increasing amount at lower altitudes; the correction, moreover, varies according to the thermometer and barometer readings. Considering the magnitude and variability of this correction it is really rather surprising that it should be possible to measure absolute positions with an accuracy approaching 0·1″.

(2) Aberration of light (*q.v.*). This may be anything up to 20·5″, but the correction can be calculated without any uncertainty. It arises because, owing to the fact that the earth's velocity in its orbit is not insignificant compared with the velocity of light, the apparent direction of the light-ray is not the true direction of the object.

(3) Parallax. For bodies belonging to the solar system a sensible correction is required to reduce observations made from the observer's particular station on the earth's surface to a common standard, viz., an imaginary station at the centre of the earth. For a few stars an analogous correction is required to reduce observations from a particular point on the earth's orbit to a standard station coinciding with the sun; but for the most part stellar parallax is a matter of specific observation rather than a serious correction required for other investigations.

(4) Precession. We have hitherto treated the equator and ♈ as fixed marks in the sphere of the stars but actually they are continually moving — a fact which causes the practical astronomer no end of trouble. When positions observed at different times have to be compared or combined together, corrections must be applied for the difference between the equators and equinoxes with respect to which they have been measured. The steady part of this change is called Precession (See PRECESSION OF THE EQUINOXES).

(5) *Nutation.* This is part of the same phenomenon as precession; it comprises the periodic or oscillating part of the motion.

A modern branch of spherical astronomy is concerned with the projection of the celestial sphere on a plane photographic plate. The problem is equivalent to a central projection of the sphere on a plane which is tangent to it; and formulae have been developed for converting position measured on the plate (in plane rectangular co-ordinates) into right ascension and declination on the celestial sphere. Photographic determinations of position are necessarily differential, that is to say, the photograph must include a number of "reference stars" whose right ascensions and declinations are already known; from these the "plate-constants" for the particular plate under discussion are determined; and the plate constants are in turn used for deducing right ascensions and declinations of other objects in the photograph.

BIBLIOGRAPHY.—*Astronomy* by Russell, Dugan and Stewart (1926–27) is a comprehensive manual without any difficult mathematics. A smaller general work is General *Astronomy* by H. S. Jones (1922). Modern *Astrophysics* by H. Dingle (1924) and *Astronomical Physics* by F. J. M. Stratton (1925) deal with the side of astronomy most prominent at the present time, the former being intended for the general public and the latter for the working astronomer primarily. Other references are given under STAR, SUN, etc. Popular astronomical books are very numerous; mention may be made of Hutchinson's *Splendour* of the Heavens (1923), a composite work very fully illustrated.

(A. S. E.)

HISTORY OF ASTRONOMY

A practical acquaintance with the elements of astronomy is indispensable to the conduct of human life. Hence it is most

widely diffused among uncivilized peoples, whose existence depends upon immediate and unvarying submission to the dictates of external nature. Having no clocks, they regard instead the face of the sky; the stars serve them for almanacs; they hunt and fish, they sow and reap in correspondence with the recurrent order of celestial appearances. But these, to the untutored imagination, present a mystical, as well as a mechanical aspect; and barbaric familiarity with the heavens developed at an early age, through the promptings of superstition, into a fixed system of observation. In China, Egypt and Babylonia strength and continuity were lent to this native tendency by the influence of a centralized authority; considerable proficiency was attained in the arts of observation; and from millennia1 stores of accumulated data, empirical rules were deduced by which the scope of prediction was widened and its accuracy enhanced. But no genuine science of astronomy was founded until the Greeks sublimed experience into theory.

ASTRONOMY OF THE ANCIENTS

China.— Already, in the third millennium B.C., equinoxes and solstices were determined in China by means of culminating stars. This is known from the orders promulgated by the emperor Yao about 2300 B.C., as recorded in the the *Shû King*, a collection of documents antique in the time of Confucius (550–478 B.C.). And Yao was merely the renovator of a system long previously established. The *Shû King* further relates the tragic fate of the official astronomers, Hsi and Ho, put to death for neglecting to perform the rites customary during an eclipse of the sun, identified by Professor S. E. Russell with a partial obscuration visible in northern China 2136 B.C. The date cannot be far wrong, and it is by far the earliest assignable to an event of the kind. There is, however, no certainty that the Chinese were then capable of predicting eclipses. They were, on the other hand, probably acquainted, a couple of millenniums before Meton gave it his name, with the nineteen-year cycle, by which solar and lunar years were harmonized; they immemorially made observations in the meridian; regulated time by water-clocks, and used measuring instruments of the nature of armillary spheres and quadrants. In or near 1100 B.C., Chou Kung, an able mathematician, determined with surprising accuracy the obliquity of the ecliptic; but his attempts to estimate the sun's distance failed hopelessly as being grounded on belief in the flatness of the earth. From of old, in China, circles were divided into $365\frac{1}{4}$ parts, so that the sun described daily one Chinese degree; and the equator began to be employed as a line of reference, concurrently with the ecliptic, probably in the second century B.C. Both circles, too, were marked by star-groups more or less clearly designated and defined. Cometary records of a vague kind go back in China to 2296 B.C.; they are intelligible and trustworthy from 611 B.C. onward. Two instruments constructed at the time of Kublai Khan's accession in 1280 were still extant at Peking in 1881. They were provided with large graduated circles adapted for measurements of declination and right ascension, and prove the Chinese to have anticipated by at least three centuries some of Tycho Brahe's most important inventions. The native astronomy was finally superseded in the 17th century by the scientific teachings of Jesuit missionaries from Europe.

Egypt.— Astrolatry was, in Egypt, the prelude to astronomy. The stars were observed that they might be duly worshipped. The importance of their heliacal risings, or first visible appearances at dawn, for the purposes both of practical life and of ritual observance, caused them to be systematically noted; the length of the year was accurately fixed in connection with the annually recurring Nile-flood; while the curiously precise orientation of the Pyramids affords a lasting demonstration of the high degree of technical skill in watching the heavens attained in the third millennium B.C. The constellational system in vogue among the Egyptians appears to have been essentially of native origin; but they contributed little or nothing to the genuine progress of astronomy.

Babylon.— With the Babylonians the case was different, although their science lacked the vital principle of growth imparted to it by their successors. From them the Greeks derived their first notions of astronomy. They copied the Babylonian asterisms, appropriated Babylonian knowledge of the planets and their courses, and learned to predict eclipses by means of the "Saros." This is a cycle of 18 years 11 days, or 223 lunations, discovered at an unknown epoch in Chaldaea, at the end of which the moon very nearly returns to her original position with regard as well to the sun as to her own nodes and perigee. There is no getting back to the beginning of astronomy by the shores of the Euphrates. Records dating from the reign of Sargon of Akkad (3800 B.c.) imply that even then the varying aspects of the sky had been long under expert observation. Thus early, there is reason to suppose, the star-groups with which we are now familiar began to be formed. They took shape most likely, not through one stroke of invention, but incidentally, as legends developed and astrological persuasions became defined. The zodiacal series in particular seem to have been reformed and reconstructed at wide intervals of time. Virgo, for example, is referred by P. Jensen, on the ground of its harvesting associations, to the fourth millennium B.c., while Aries (according to F. K. Ginzel) was interpolated at a comparatively recent time. In the main, however, the constellations transmitted to the West from Babylonia by Aratus and Eudoxus must have been arranged very much in their present order about 2800 B.C. E. W. Maunder's argument to this effect is unanswerable. For the space of the southern sky left blank of stellar emblazonments was necessarily centred on the pole; and since the pole shifts among the stars through the effects of precession by a known annual amount, the ascertainment of any former place for it virtually fixes the epoch. It may then be taken as certain that the heavens described by Aratus in 270 B.C. represented approximately observations made some 2500 years earlier in or near north latitude 40°.

In the course of ages, Babylonian astronomy, purified from the astrological taint, adapted itself to meet the most refined needs of civil life. The decipherment and interpretation by the learned Jesuits, Fathers Epping and Strassmeier, of a number of clay tablets preserved in the British Museum, have supplied detailed knowledge of the methods practised in Mesopotamia in the 2nd century B.C. They show no trace of Greek influence, and were doubtless the improved outcome of an unbroken tradition. How protracted it had been, can be in a measure estimated from the length of the revolutionary cycles found for the planets. The Babylonian computers were not only aware that Venus returns in almost exactly eight years to a given starting-point in the sky, but they had established similar periodic relations in 46, 59, 79 and 83 years severally for Mercury, Saturn, Mars and Jupiter. They were accordingly able to fix in advance the approximate positions of these objects with reference to ecliptical stars which served as fiducial points for their determination. In the Ephemerides published year by year, the times of new moon were given, together with the calculated intervals to the first visibility of the crescent, from which the beginning of each month was reckoned; the dates and circumstances of solar and lunar eclipses were predicted; and due information was supplied as to the forthcoming heliacal risings and settings, conjunctions and oppositions of the planets. The Babylonians knew of the inequality in the daily motion of the sun, but misplaced by 10° the perigee of his orbit. Their sidereal year was $4\frac{1}{2}^{m}$ too long, and they kept the ecliptic stationary among the stars, making no allowance for the shifting of the equinoxes. The striking discovery, on the other hand, has been made by the Rev. F. X. Kugler that the various periods underlying their lunar predictions were identical with those heretofore believed to have been reached independently by Hipparchus, who accordingly must be held to have borrowed from Chaldaea the lengths of the synodic, sidereal, anomalistic and draconitic months.

Greece.--A steady flow of knowledge from East to West began in the seventh century B.C. A Babylonian sage founded a school about 640 B.C. in the island of Cos, and perhaps counted Thales of Miletus (c. 639–548) among his pupils. The famous "eclipse of Thales" in 585 B.C. has not, it is true, been authenticated by modern research; yet the story told by Herodotus

appears to intimate that a knowledge of the Saros, and of the forecasting facilities connected with it, was possessed by the Ionian sage. Pythagoras of Samos (fl. 540–510 B.C.) learned on his travels in Egypt and the East to identify the morning and evening stars, to recognize the obliquity of the ecliptic, and to regard the earth as a sphere freely poised in space. The tenet of its axial movement was held by many of his followers—in an obscure form by Philolaus of Crotona after the middle of the 5th century B.C., and more explicitly by Ecphantus and Hicetas of Syracuse (4th century B.C.), and by Heraclides of Pontus. Heraclides, who became a disciple of Plato in 360 B.C., taught in addition that the sun, while circulating round the earth, was the centre of revolution to Venus and Mercury. A genuine heliocentric system, developed by Aristarchus of Samos (fl. 280–264 B.C.), was described by Archimedes in his Arenarius, only to be set aside with disapproval. The long-lived conception of a series of crystal spheres, acting as the vehicles of the heavenly bodies, and attuned to divine harmonies, seems to have originated with Pythagoras himself.

The first mathematical theory of celestial appearances was devised by Eudoxus of Cnidus (408–355 B.C.). The problem he attempted to solve was so to combine uniform circular movements as to produce the resultant effects actually observed. The sun and moon and the five planets were, with this end in view, accommodated each with a set of variously revolving spheres, to the total number of 27. The Eudoxian or "homocentric" system, after it had been further elaborated by Callippus and Aristotle, was modified by Apollonius of Perga (fl. 250–220 B.C.) into the hypothesis of deferents and epicycles, which held the field for 1,800 years as the characteristic embodiment of Greek ideas in astronomy. Eudoxus further wrote two works descriptive of the heavens, the *Enoptron* and *Phaenomena*, which, substantially preserved in the *Phaenomena* of Aratus (fl. 270 B.C.), provided all the leading features of modern stellar nomenclature.

Greek astronomy culminated in the school of Alexandria. It was, soon after its foundation, illustrated by the labours of Aristyllus and Timocharis (c. 320–260 B.C.), who constructed the first catalogue giving star-positions as measured from a reference-point in the sky. This fundamental advance rendered inevitable the detection of precessional effects. Aristarchus of Samos observed at Alexandria 280–264 B.C. His treatise on the magnitudes and distances of the sun and moon, edited by John Wallis in 1688, describes a theoretically valid method for determining the relative distances of the sun and moon by measuring the angle between their centres when half the lunar disc is illuminated; but the time of dichotomy being widely indeterminate, no useful result was thus obtainable. Aristarchus in fact concluded the sun to be not more than twenty times, while it is really four hundred times farther off than our satellite. His general conception of the universe was comprehensive beyond that of any of his predecessors.

Eratosthenes (276–196 B.C.), a native of Cyrene, was summoned from Athens to Alexandria by Ptolemy Euergetes to take charge of the royal library. He invented, or improved armillary spheres, the chief implements of ancient astrometry, determined the obliquity of the ecliptic at 23° 51′ (a value 5′ too great), and introduced an effective mode of arc-measurement. Knowing Alexandria and Syene to be situated 5.000 stadia apart on the same meridian, he found the sun to be 7° 12′ south of the zenith at the northern extremity of this arc when it was vertically overhead at the southern extremity, and he hence inferred a value of 252,000 stadia for the entire circumference of the globe. This is a very close approximation to the truth, if the length of the unit employed has been correctly assigned.

Among the astronomers of antiquity, two great men stand out with unchallenged pre-eminence. Hipparchus and Ptolemy entertained the same large organic designs; they worked on similar methods; and, as the outcome, their performances fitted so accurately together that between them they re-made celestial science. Hipparchus fixed the chief data of astronomy—the lengths of the tropical and sidereal years, of the various months, and of the synodic periods of the five planets; determined the obliquity of the ecliptic and of the moon's path, the place of the sun's apogee, the eccentricity of his orbit, and the moon's horizontal parallax; all with approximate accuracy. His borrowings from Chaldaean experts appear, indeed, to have been numerous; but were doubtless independently verified. His supreme merit, however, consisted in the establishment of astronomy on a sound geometrical basis. His acquaintance with trigonometry, a branch of science initiated by him, together with his invention of the planisphere, enabled him to solve a number of elementary problems; and he was thus led to bestow especial attention upon the position of the equinox, as being the common point of origin for measures both in right ascension and longitude. Its steady retrogression among the stars became manifest to him in 130 B.C., on comparing his own observations with those made by Timocharis a century and a half earlier; and he estimated at not less than 36" (the true value being 50″) the annual amount of "precession."

The choice made by Hipparchus of the geocentric theory of the universe decided the future of Greek astronomy. He further elaborated it by the introduction of "eccentrics," which accounted for the changes in orbital velocity of the sun and moon by a displacement of the earth, to a corresponding extent, from the centre of the circles they were assumed to describe. This gave the elliptic inequality known as the "equation of the centre," and no other was at that time obvious. He attempted no detailed discussion of planetary theory; but his catalogue of 1,080 stars, divided into six classes of brightness, or "magnitudes," is one of the finest monuments of antique astronomy. It is substantially embodied in Ptolemy's *Almagest* (see PTOLEMY).

An interval of 250 years elapsed before the constructive labours of Hipparchus obtained completion at Alexandria. His observations were largely, and somewhat arbitrarily, employed by Ptolemy. Professor Newcomb, who compiled a very instructive table of the equinoxes severally observed by Hipparchus and Ptolemy, with their errors deduced from Leverrier's solar tables, found palpable evidence that the discrepancies between the two series were artificially reconciled on the basis of a year 6^m too long, adopted by Ptolemy on trust from his predecessor. He nevertheless held the process to have been one that implied no fraudulent intention.

The Ptolemaic system was, in a geometrical sense, defensible; it harmonized fairly well with appearances, and physical reasonings had not then been extended to the heavens. To the ignorant it was recommended by its conformity to crude common sense; to the learned, by the wealth of ingenuity expended in bringing it to perfection. The *Almagest* was the consummation of Greek astronomy. Ptolemy had no successor; he found only commentators, among the more noteworthy of whom were Theon of Alexandria (fl. A.D. 400) and his daughter, Hypatia (370–415).

Arabia.—With the capture of Alexandria by Omar in 641, the last glimmer of its scientific light became extinct, to be rekindled, a century and a half later, on the banks of the Tigris. The first Arabic translation of the Almagest was made by order of Harun al-Rashid about the year 800; others followed, and the Caliph al-Mamun built in 829 a grand observatory at Baghdad. Here Albumazar (805–885) watched the skies and cast horoscopes; here Tobit ben Korra (836–901) developed his long unquestioned, yet misleading theory of the "trepidation" of the equinoxes; Abd-ar-rahman al-Sūfi (903–986) revised at first hand the catalogue of Ptolemy; and Abulwefa (939–998), like al-Sūfi, a native of Persia, made continuous planetary observations, but did not (as alleged by L. Sédillot) anticipate Tycho Brahe's discovery of the moon's variation. Ibn Junis (*c.* 950–1008), although the scene of his activity was in Egypt, falls into line with the astronomers of Baghdad. He compiled the Hakimite Tables of the planets, and observed at Cairo, in 977 and 978, two solar eclipses which, as being the first recorded with scientific accuracy, were made available in fixing the amount of lunar acceleration. Nasir uddin (1201–1274) drew up the Ilkhanic Tables, and determined the constant of precession at 51″. He directed an observatory established by Hulagu Khan (d. 1265) at Maraga in Persia, and equipped with a mural quadrant of 12ft. radius, besides altitude

and azimuth instruments. Ulugh Beg (1394–1449), a grandson of Tamerlane, was the illustrious personification of Tatar astronomy. He founded about 1420 a splendid observatory at Samarkand, in which he re-determined nearly all Ptolemy's stars, while the Tables published by him held the primacy for two centuries.

ASTRONOMY OF THE MIDDLE AGES

Arab astronomy, transported by the Moors to Spain, flourished temporarily at Cordova and Toledo. From the latter city the Toletan Tables, drawn up by Arzachel in 1080, took their name; and there also the Alfonsine Tables, published in 1252, were prepared under the authority of Alphonso X. of Castile. Their appearance signalized the dawn of European science, and was nearly coincident with that of the *Sphaera Mundi,* a text-book of spherical astronomy, written by a Yorkshireman, John Holywood, known as Sacro Bosco (d. 1256). It had an immense vogue, perpetuated by the printing-press in fifty-nine editions. In Germany, during the 11th century, a brilliant attempt was made to patch up the flaws in Ptolemaic doctrine. George Purbach (1423–1461) introduced into Europe the method of determining time by altitudes employed by Ibn Junis. He lectured with applause at Vienna from 1450; was joined there in 1452 by Regiomontanus (*q.v.*); and was on the point of starting for Rome to inspect a manuscript of the *Almagest* when he died suddenly at the age of thirty-eight. His teachings bore fruit in the work of Regiomontanus, and of Bernhard Walther of Nuremberg (1430–1504), who fitted up an observatory with clocks driven by weights, and developed many improvements in practical astronomy.

Copernicus.—Meantime, a radical reform was being prepared in Italy. Under the searchlights of the new learning, the dictatorship of Ptolemy appeared no more inevitable than that of Aristotle; advanced thinkers like Domenico Maria Novara (1454–1504) promulgated *sub rosa* what were called Pythagorean opinions; and they were eagerly and fully appropriated by Nicolaus Copernicus during his student-years (1496–1505) at Bologna and Padua. He laid the groundwork of his heliocentric theory between 1506 and 1512, and brought it to completion in *De Revolutionibus Orbium Coelestium* (1543). The colossal task of remaking astronomy on an inverted design was, in this treatise, virtually accomplished. Its reasonings were solidly founded on the principle of the relativity of motion. A continuous shifting of the standpoint was in large measure substituted for the displacements of the objects viewed, which thus acquired a regularity and consistency heretofore lacking to them. In the new system, the sphere of the fixed stars no longer revolved diurnally, the earth rotating instead on an axis directed towards the celestial pole. The sun too remained stationary, while the planets, including our own globe, circulated round him. By this means, the planetary "retrogradations" were explained as simple perspective effects due to the combination of the earth's revolutions with those of her sister orbs. The retention, however, by Copernicus of the antique postulate of uniform circular motion impaired the perfection of his plan, since it involved a partial survival of the epicyclical machinery. Nor was it feasible, on this showing, to place the sun at the true centre of any of the planetary orbits; so that his ruling position in the midst of them was illusory. The reformed scheme was then by no means perfect. Its simplicity was only comparative; many outstanding anomalies compromised its harmonious working. Moreover, the absence of sensible parallaxes in the stellar heavens seemed inconsistent with its validity; and a mobile earth outraged deep-rooted prepossessions. Under these disadvantageous circumstances, it is scarcely surprising that the heliocentric theory, while admired as a daring speculation, won its way slowly to acceptance as a truth.

The *Tabulae Prutenicae,* calculated on Copernican principles by Erasmus Reinhold (1511–1553), appeared in 1551. Although they represented celestial movements far better than the Alfonsine Tables, large discrepancies were still apparent, and the desirability of testing the novel hypothesis upon which they were based by more refined observations prompted a reform of methods, undertaken almost simultaneously by the landgrave William IV. of Hesse-Cassel (1532–1592), and by Tycho Brahe. The landgrave built at Cassel in 1561 the first observatory with a revolving dome, and worked for some years at a star-catalogue finally left incomplete. Christoph Rothmann and Joost Bürgi (1552–1632) became his assistants in 1577 and 1579 respectively; and through the skill of Bürgi, time-determinations were made available for measuring right ascensions. At Cassel, too, the altitude and azimuth instrument is believed to have made its first appearance in Europe.

Tycho **Brahe** and **Kepler.**—Tycho's labours were both more strenuous and more effective. He perfected the art of pre-telescopic observation. His instruments were on a scale and of a type unknown since the days of Nasir ud-din. At Augsburg, in 1569, he ordered the construction of a 19-ft. quadrant, and of a celestial globe 5ft. in diameter; he substituted equatorial for zodiacal armillae, thus definitively establishing the system of measurements in right ascension and declination; and improved the graduation of circular arcs by adopting the method of "transversals." By these means, employed with consummate skill, he attained an unprecedented degree of accuracy, and as an incidental though valuable result, demonstrated the unreality of the supposed trepidation of the equinoxes.

No more congruous arrangement could have been devised than the inheritance by Johann Kepler of the wealth of materials amassed by Tycho Brahe. The younger man's genius supplied what was wanting to his predecessor. Tycho's endowments were of the practical order; yet he had never designed his observations to be an end in themselves. He thought of them as means towards the end of ascertaining the true form of the universe. His range of ideas was, however, restricted; and the attempt embodied in his ground-plan of the solar system to revive the ephemeral theory of Heraclides failed to influence the development of thought. Kepler, on the contrary, was endowed with unlimited powers of speculation, but had no mechanical faculty. He found in Tycho's ample legacy of first-class data precisely what enabled him to try, by the touchstone of fact, the successive hypotheses that he imagined; and his untiring patience in comparing and calculating the observations at his disposal was rewarded by a series of unique discoveries. He long adhered to the traditional belief that all celestial revolutions must be performed equably in circles; but a laborious computation of seven recorded oppositions of Mars at last persuaded him that the planet travelled in an ellipse, one focus of which was occupied by the sun. Pursuing the inquiry, he found that its velocity was uniform with respect to no single point within the orbit, but that the areas described, in equal times, by a line drawn from the sun to the planet were strictly equal. These two principles he extended, by direct proof, to the motion of the earth; and, by analogy, to that of the other planets. They were published in 1609 in *De Motibus Stellae Martis.* The announcement of the third of "Kepler's Laws" was made ten years later, in *De Harmonice Mundi.* It states that the squares of the periods of circulation round the sun of the several planets are in the same ratio as the cubes of their mean distances. This numerical proportion, as being a necessary consequence of the law of gravitation, must prevail in every system under its sway. It does in fact prevail among the satellite-families of our acquaintance, and presumably in stellar combinations as well. Kepler's ineradicable belief in the existence of some such congruity was derived from the Pythagorean idea of an underlying harmony in nature; but his arduous efforts for its realization took a devious and fantastic course which seemed to give little promise of their surprising ultimate success. The outcome of his discoveries was, not only to perfect the geometrical plan of the solar system, but to enhance very materially the predicting power of astronomy. The Rudolphine Tables (Ulm, 1627), computed by him from elliptic elements, retained authority for a century, and have in principle never been superseded. He was deterred from research into the orbital relations of comets by his conviction of their perishable nature. He supposed their tails to result from the action of solar rays, which, in traversing their mass, bore off with them some of their subtler particles to form trains directed away from the sun. And through the process of waste thus set on foot, they finally dissolved into the aether, and expired

"like spinning insects." (*De Cometis; Opera*, 2d. Frisch, t. vii. p. 110.) This remarkable anticipation of the modern theory of light-pressure was suggested to him by his observations of the great comets of 1618.

The formal astronomy of the ancients left Kepler unsatisfied. He aimed at finding out the cause as well as the mode of the planetary revolutions; and his demonstration that the planes in which they are described all pass through the sun was an important preliminary to a physical explanation of them. But his efforts to supply such an explanation were rendered futile by his imperfect apprehension of what motion is in itself. He had, it is true, a distinct conception of a force analogous to that of gravity, by which cognate bodies tended towards union. Misled, however, into identifying it with magnetism, he imagined circulation in the solar system to be maintained through the material compulsion of fibrous emanations from the sun, carried round by his axial rotation. Ignorance regarding the inertia of matter drove him to this expedient. The persistence of movement seemed to him to imply the persistence of a moving power. He did not recognize that motion and rest are equally natural, in the sense of requiring force for their alteration. Yet his rationale of the tides in *De Motibus Stellae* is not only memorable as an astonishing forecast of the principle of reciprocal attraction in the proportion of mass, but for its bold extension to the earth of the lunar sphere of influence.

Galileo.—Galileo Galilei, Kepler's most eminent contemporary, took a foremost part in dissipating the obscurity that still hung over the very foundations of mechanical science. He had, indeed, precursors and co-operators. Michel Varo of Geneva wrote correctly in 1584 on the composition of forces; Simon Stevinus of Bruges (1548–1620) independently demonstrated the principle; and G. B. Benedetti expounded in his *Speculationum Liber* (Turin, 1585) perfectly clear ideas as to the nature of accelerated motion, some years in advance of Galileo's dramatic experiments at Pisa. Yet they were never assimilated by Kepler; while, on the other hand, the laws of planetary circulation he had enounced were strangely ignored by Galileo. The two lines of inquiry remained for some time apart. Had they at once been made to coalesce, the true nature of the force controlling celestial movements should have been quickly recognized. As it was, the importance of Kepler's generalizations was not fully appreciated until Sir Isaac Newton made them the corner-stone of his new cosmic edifice.

Galileo's contributions to astronomy were of a different quality from Kepler's. They were easily intelligible to the general public; in a sense, they were obvious, since they could be verified by every possessor of one of the Dutch perspective-instruments, just then in course of wide and rapid distribution. And similar results to his were in fact independently obtained in various parts of Europe by Christopher Scheiner at Ingolstadt, by Johann Fabricius at Osteel in Friesland, and by Thomas Harriot at Syon House, Isleworth. Galileo was nevertheless by far the ablest and most versatile of these early telescopic observers. His gifts of exposition were on a par with his gifts of discernment. What he saw, he rendered conspicuous to the world. His sagacity was indeed sometimes at fault. He maintained with full conviction to the end of his life a grossly erroneous hypothesis of the tides, early adopted from Andrea Caesalpino; the "triplicate" appearance of Saturn always remained an enigma to him; and in regarding comets as atmospheric emanations he lagged far behind Tycho Brahe. Yet he unquestionably ranks as the true founder of descriptive astronomy; while his splendid presentment of the laws of projectiles in his dialogue of the "New Sciences" (Leyden, 1638) lent potent aid to the solid establishment of celestial mechanics.

MODERN ASTRONOMY

The Law of Gravitation.— The accumulation of facts does not in itself constitute science. Empirical knowledge scarcely deserves the name. *Vere scire est per causas scire.* Francis Bacon's prescient dream, however, of a living astronomy by which the physical laws governing terrestrial relations should be extended to the highest heavens, had long to wait for realization. Kepler divined its possibility; but his thoughts, derailed (so to speak) by the false analogy of magnetism, brought him no farther than to the rough draft of the scheme of vortices expounded in detail by René Descartes in his *Principia Philosophiae* (1644). And this was a *cul-de-sac.* The only practicable road struck aside from it. The true foundations of a mechanical theory of the heavens were laid by Kepler's discoveries, and by Galileo's dynamical demonstrations; its construction was facilitated by the development of mathematical methods. The invention of logarithms, the rise of analytical geometry, and the evolution of B. Cavalieri's "indivisibles" into the infinitesimal calculus, all acconiplished during the 17th century, immeasurably widened the scope of exact astronomy. Gradually, too, the nature of the problem awaiting solution came to be apprehended. Jeremiah Horrocks had some intuition, previously to 1639, that the motion of the moon was controlled by the earth's gravity, and disturbed by the action of the sun. Ismael Bouillaud (1605–1694) stated in 1645 the fact of planetary circulation under the sway of a sun-force decreasing as the inverse square of the distance; and the inevitableness of this same "duplicate ratio" was separately perceived by Robert Hooke, Edmund Halley and Sir Christopher Wren before Newton's discovery had yet been made public. But Newton was the only man of his generation who both recognized the law, and had power to demonstrate its validity. And this was only a beginning. His complete achievement had a twofold aspect. It consisted, first, in the identification, by strict numerical comparisons, of terrestrial gravity with the mutual attraction of the heavenly bodies; secondly, in the following out of its mechanical consequences throughout the solar system. Gravitation was thus shown to be the sole influence governing the movements of planets and satellites; the figure of the rotating earth was successfully explained by its action on the minuter particles of matter; tides and the precession of the equinoxes proved amenable to reasonings based on the same principle; and it satisfactorily accounted as well for some of the chief lunar and planetary inequalities.

Euler, Clairault and d'Alembert.—Newton's investigations, however, were very far from being exhaustive. Colossal though his powers were, they had limits; and his work could not but remain unterminated, since it was by its nature interminable. Nor was it possible to provide it with what could properly be called a sequel. The synthetic method employed by him was too unwieldy for common use. Yet no other was just then at hand. Mathematical analysis needed half a century of cultivation before it was fully available for the arduous tasks reserved for it. They were accordingly taken up anew by a band of continental inquirers, primarily by three men of untiring energy and vivid genius, Leonhard Euler, Alexis Clairault, and Jean le Rond d'Alembert. The first of the outstanding gravitational problems with which they grappled was the unaccountably rapid advance of the lunar perigee. But the apparent anomaly disappeared under Euler's powerful treatment in 1749, and his result was shortly afterwards still further assured by Clairault. The subject of planetary perturbations was next attacked. Euler devised in 1753 a new method, that of the "variation of parameters," for their investigation, and applied it to unravel some of the earth's irregularities in a memoir crowned by the French Academy in 1756; while in 1757, Clairault estimated the masses of the moon and Venus by their respective disturbing effects upon terrestrial movements. But the most striking incident in the history of the verification of Newton's law was the return of Halley's comet to perihelion, on the 12th of March 1759, in approximate accordance with Clairault's calculation of the delays due to the action of Jupiter and Saturn. Visual proof was thus, it might be said, afforded of the harmonious working of a single principle to the uttermost boundaries of the sun's dominion.

Lagrange and Laplace.—These successes paved the way for the higher triumphs of Joseph Louis Lagrange and of Pierre Simon Laplace. The subject of the lunar librations was treated by Lagrange with great originality in an essay crowned by the Paris Academy of Sciences in 1764; and he filled up the lacunae in his theory of them in a memoir communicated to the Berlin

Academy in 1780. He again won the prize of the Paris Academy in 1766 with an analytical discussion of the movements of Jupiter's satellites (Miscellanea, Turin Acad. t. iv.); and in the same year expanded Euler's adumbrated method of the variation of parameters into a highly effective engine of perturbational research. It was especially adapted to the tracing out of "secular inequalities," or those depending upon changes in the orbital elements of the bodies affected by them, and hence progressing indefinitely with time; and by its means, accordingly, the mechanical stability of the solar system was splendidly demonstrated through the successive efforts of Lagrange and Laplace. The proper share of each in bringing about this memorable result is not easy to apportion, since they freely imparted and profited by one another's advances and improvements; it need only be said that the fundamental proposition of the invariability of the planetary major axes laid down with restrictions by Laplace in 1773, was finally established by Lagrange in 1776; while Laplace in 1784 proved the subsistence of such a relation between the eccentricities of the planetary orbits on the one hand, and their inclinations on the other, that an increase of either element could, in any single case, proceed only to a very small extent. The system was thus shown, apart from unknown agencies of subversion, to be constructed for indefinite permanence. The prize of the Berlin Academy was, in 1780, adjudged to Lagrange for a treatise on the perturbations of comets; and he contributed to the Berlin Memoirs, 1781–1784, a set of five elaborate papers, embodying and unifying his perfected methods and their results.

The crowning trophies of gravitational astronomy in the 18th century were Laplace's explanations of the "great inequality" of Jupiter and Saturn in 1784, and of the "secular acceleration" of the moon in 1787. Both irregularities had been noted, a century earlier, by Edmund Halley; both had, since that time, vainly exercised the ingenuity of the ablest mathematicians; both now almost simultaneously yielded their secret to the same fortunate inquirer. Johann Heinrich Lambert pointed out in 1773 that the motion of Saturn, from being retarded, had become accelerated. A periodic character was thus indicated for the disturbance; and Laplace assigned its true cause in the near approach to commensurability in the periods of the two planets, the cycle of disturbance completing itself in about 900 (more accurately 9293) years. The lunar acceleration, too, obtains ultimate compensation, though only after a vastly protracted term of years. The discovery, just one hundred years after the publication of Newton's *Principia,* of its dependence upon the slowly varying eccentricity of the earth's orbit signalized the removal of the last conspicuous obstacle to admitting the unqualified validity of the law of gravitation. Laplace's calculations, it is true, were inexact. An error, corrected by J. C. Adams in 1853, nearly doubled the value of the acceleration deducible from them; and served to conceal a discrepancy with observation which has since given occasion to much profound research (see Moor;).

After Laplace.—The *Mécanique céleste,* in which Laplace welded into a whole the items of knowledge accumulated by the labours of a century, has been termed the "Almagest of the 18th century" (Fourier). But imposing and complete though the monument appeared, it did not long hold possession of the field. Further developments ensued. The "method of least squares," by which the most probable result can be educed from a body of observational data, was published by Adrien Marie Legendre in 1806, by Karl Friedrich Gauss in his *Theoria Motus* (1809), which described also a mode of calculating the orbit of a planet from three complete observations, afterwards turned to important account for the recapture of Ceres, the first discovered asteroid (see MINOR PLANET). Researches into rotational movement were facilitated by S. D. Poisson's application to them in 1809 of Lagrange's theory of the variation of constants; Philippe de Pontécoulant successfully used in 1829, for the prediction of the impending return of Halley's comet, a system of "mechanical quadratures" published by Lagrange in the Berlin Memoirs for 1778; and in his *Théorie analytique* du *système du* monde (1846) he modified and refined general theories of the lunar and planetary revolutions, P. A. Hansen in 1829 (*Astr.* Nach. Nos. 166–168, 179) left the beaten track by choosing time as the sole variable, the orbital elements remaining constant. A. L. Cauchy published in 1842–1843 a method similarly conceived, though otherwise developed; and the scope of analysis in determining the movements of the heavenly bodies has since been perseveringly widened by the labours of Urbain J. J. Leverrier, J. C. Adams, S. Newcomb, G. W. Hill, E. W. Brown, H. Gyldén, Charles Delaunay, F. Tisserand, H. Poincaré and others too numerous to mention. Nor were these abstract investigations unaccompanied by concrete results. Sir George Airy detected in 1831 an inequality, periodic in 240 years, between Venus and the earth. Leverrier undertook in 1839, and concluded in 1876, the formidable task of revising all the planetary theories and constructing from them improved tables. Not less comprehensive has been the work carried out by Professor h'ewcomb of raising to a higher grade of perfection, and reducing to a uniform standard, all the theories and constants of the solar system. The discovery of Neptune in 1846 by Adams and Leverrier marked the first solution of the "inverse problem" of perturbations. That is to say, ascertained or ascertainable effects were made the starting-point instead of the goal of research.

Practical **Astronomy.**—Observational astronomy, meanwhile, was advancing to some extent independently. The descriptive branch found its principle of development in the growing powers of the telescope, and had little to do with mathematical theory; which, on the contrary, was closely allied, by relations of mutual helpfulness, with practical astronomy. Meanwhile, the elementary requirement of making visual acquaintance with the stellar heavens was met, as regards the unknown southern skies, when Johann Bayer published at Nuremberg in 1603 a celestial atlas depicting twelve new constellations formed from the rude observations of navigators across the line. In the same work, the current mode of star-nomenclature by the letters of the Greek alphabet made its appearance. On the 7th of h'ovember 1631 Pierre Gassendi watched at Paris the passage of Mercury across the sun. This was the first planetary transit observed. The next was that of Venus on the 24th of November (O.S.) 1639, of which Jeremiah Horrocks and William Crabtree were the sole spectators. The improvement of telescopes was prosecuted by Christiaan Huygens from 1655, and promptly led to his discoveries of the sixth Saturnian moon, of the true shape of the Saturnian appendages, and of the multiple character of the "trapezium" of stars in the Orion nebula. William Gascoigne's invention of the filar micrometer and of the adaptation of telescopes to graduated instruments remained submerged for a quarter of a century in consequence of his untimely death at Marston Moor (1644). The latter combination had also been ineffectually proposed in 1634 by Jean Baptiste Morin (1583–1656); and both devices were recontrived at Paris about 1667, the micrometer by Adrien Auzout (d. 1691), telescopic sights (so-called) by Jean Picard (1620–1682), who simultaneously introduced the astronomical use of pendulum-clocks, constructed by Huygens eleven years previously. These improvements were ignored or rejected by Johann Hevelius of Danzig, the author of the last important star-catalogue based solely upon naked-eye determinations. He, nevertheless, used telescopes to good purpose in his studies of lunar topography, and his designations for the chief mountain-chains and "seas" of the moon have never been superseded. He, moreover, threw out the suggestion (in his *Cometographia,* 1668) that comets move round the sun in orbits of a parabolic form.

Paris Observatory.—The establishment, in 1671 and 1676 respectively, of the French and English national observatories at once typified and stimulated progress. The Paris institution, it is true, lacked unity of direction. No authoritative chief was assigned to it until 1771. G. D. Cassini, his son and his grandson were only *primi* inter pares. Claude Perrault's stately edifice was equally accessible to all the more eminent members of the Academy of Sciences; and researches were, more or less independently, carried on there by (among others) Philippe de la Hire (1640–1718), G. F. Maraldi (1665–1729), and his nephew, J. D. Maraldi, Jean Picard, Huygens, Olaus Römer and Nicolas de Lacaille. Some of the best instruments then extant were mounted

at the Paris observatory. G. D. Cassini brought from Rome a 17-ft. telescope by G. Campani, with which he discovered in 1671 Iapetus, the eighth in distance of Saturn's family of satellites; Rhea was detected in 1672 with a glass by the same maker of 34-ft. focus; the duplicity of the ring showed in 1675; and in 1684, two additional satellites mere disclosed by a Campani telescope of 100 ft. Cassini, moreover, set up an altazimuth in 1678, and employed from about 1682 a "parallactic machine," provided with clockwork to enable it to follow the diurnal motion. Both inventions have been ascribed to Olaus Romer, who used but did not claim them, and must have become familiar with their principles during the nine years (1672–1681) spent by him at the Paris observatory. Romer, on the other hand, deserves full credit for originating the transit-circle and the prime vertical instrument; and he earned undying fame by his discovery of the finite velocity of light, made at Paris in 1675 by comparing his observations of the eclipses of Jupiter's satellites at the conjunctions and oppositions of the planet.

Work at Greenwich. — The organization of the Greenwich observatory differed widely from that adopted at Paris. There a fundamental scheme of practical amelioration was initiated by John Flamsteed, the first astronomer royal, and has never since been lost sight of. Its purpose is the attainment of so complete a power of prediction that the places of the sun, moon and planets may be assigned without noticeable error for an indefinite future time. Sidereal inquiries, as such, made no part of the original programme in which the stars figured merely as points of reference. But these points are not stationary. They have an apparent precessional movement, the exact amount of which can be arrived at only by prolonged and toilsome enquiries. They have besides "proper motions," detected in 1718 by E. Halley in a few cases, and since found to prevail universally. Further, James Bradley discovered in 1728 the annual shifting of the stars due to the aberration of light (see ABERRATION), and in 1748, the complicating effects upon precession of the "nutation" of the earth's axis. Hence, the preparation of a catalogue recording the "mean" positions of a number of stars for a given epoch involves considerable preliminary labour; nor do those positions long continue to satisfy observation. They need, after a time, to be corrected, not only systematically for precession, but also empirically for proper motion. Before the stars can safely be employed as route-marks in the sky, their movements must accordingly be tabulated, and research into the method of such movements inevitably follows. We perceive then that the fundamental problems of sidereal science are closely linked up with the elementary and indispensable procedures of celestial measurement.

The history of the Greenwich observatory is one of strenuous efforts for refinement, stimulated by the growing stringency of theoretical necessities. Improved practice, again, reacted upon theory by bringing to notice residual errors, demanding the correction of formulae, or intimating neglected disturbances. Each increase of mechanical skill claims a corresponding gain in the subtlety of analysis; and vice versa. And this kind of interaction has gone on ever since Flamsteed reluctantly furnished the "places of the moon," which enabled Newton to lay the foundations of lunar theory.

Edmund Halley, the second astronomer royal, devoted most of his official attention to the moon. But his plan of attack was not happily chosen; he carried it out with deficient instrumental means; and his administration (1720–1742) remained comparatively barren. That of his successor, though shorter, was vastly more productive. James Bradley chose the most appropriate tasks, and executed them supremely well, with the indispensable aid of John Bird (1709–1776), who constructed for him an 8-ft. quadrant of unsurpassed quality. Bradley's store of observations has accordingly proved invaluable. Those of 3,222 stars, reduced by F. W. Bessel in 1818, and again with masterly insight by Dr. A. Auwers in 1882, form the true basis of exact astronomy, and of our knowledge of proper motions. Those relating to the moon and planets, corrected by Sir George Airy, 1840–1846, form part of the standard materials for discussing theories of movement in the solar system. The fourth astronomer royal, Nathaniel Bliss, provided in two years a sequel of some value to Bradley's performance. Nevil Maskelyne, who succeeded him in 1764, set on foot, in 1767, the publication of the *Nautical Almanac*, and about the same time had an achromatic telescope fitted to the Greenwich mural quadrant. The invention, perfected by John Dollond in 1757, was long debarred from becoming effective by difficulties in the manufacture of glass, aggravated in England by a heavy excise duty levied until 1845. More immediately efficacious was the innovation made by John Pond (astronomer royal, 1811–1836) of substituting entire circles for quadrants. He further introduced in 1821, the method of duplicate observations by direct vision and by reflection, and by these means obtained results of very high precision. During Sir George Airy's long term of office (1836–1881) exact astronomy and the traditional purposes of the royal observatory were promoted with increased vigour, while the scope of research was at the same time memorably widened.

Advances Elsewhere. — Meanwhile, advances were being made in various parts of the continent of Europe. Peter Wargentin (1717–1783), secretary to the Swedish Academy of Sciences, made a special study of the Jovian system. James Bradley had described to the Royal Society on July 2, 1719, the curious cyclical relations of the three inner satellites; and their period of 437 days was independently discovered by Wargentin, who based upon it in 1746 a set of tables, superseded only by those of J. B. J. Delambre in 1792. Among the fruits of the strenuous career of Nicolas Louis de Lacaille were tables of the sun, in which terms depending upon planetary perturbations were, for the first time, introduced (1758); an extended acquaintance with the southern heavens; and a determination of the moon's parallax from observations made at opposite extremities of an arc of the meridian 85° in length. Tobias Mayer of Gottingen (1723–1762) originated the mode of adjusting transit-instruments still in vogue; drew up a catalogue of nearly a thousand zodiacal stars (published posthumously in 1775); and deduced the proper motions of eighty stars from a comparison of their places as given by Olaus Romer in 1706 with those obtained by himself in 1756. He executed besides a chart and forty drawings of the moon (published at Gottingen in 1881), and calculated lunar tables from a skilful development of Euler's theory, for which a reward of £3,000 was in 1765 paid to his widow by the British government. They were published by the Board of Longitude, together with his solar tables, in 1770. The material interests of navigation were in these works primarily regarded; but the imaginative side of knowledge had also potent representatives during the latter half of the 18th century. In France, especially, the versatile activity of J. J. Lalande popularized the acquisitions of astronomy, and enforced its demands; and he had a German counterpart in J. E. Bode.

Between the time of Aristarchus and the opposition of Mars in 1672, no serious attempt was made to solve the problem of the sun's distance. In that year, however, Jean Richer at Cayenne and G. D. Cassini at Paris made combined observations of the planet, which yielded a parallax for the sun of 9·5″, corresponding to a mean radius for the terrestrial orbit of 87,000,000m. This result, though widely inaccurate, came much nearer to the truth than any previously obtained; and it instructively illustrated the feasibility of concerted astronomical operations at distant parts of the earth. The way was thus prepared for availing to the full of the opportunities for a celestial survey offered by the transits of Venus in 1761 and 1769. They had been signalized by E. Halley in 1716; they were later insisted upon by Lalande; an enthusiasm for co-operation was evoked, and the globe, from Siberia to Otaheite, was studded with observing parties. The outcome, nevertheless, disappointed expectation. The instants of contact between the limbs of the sun and planet defied precise determination. Optical complications fatally impeded sharpness of vision, and the phenomena took place in a debatable borderland of uncertainty. J. F. Encke, it is true, derived from them in 1822–1824 what seemed an authentic parallax of 8·57″, implying a distance of 95,370,000 m.; but the confidence it inspired was finally overthrown in 1854 by P. A. Hansen's announcement of its incompatibility with lunar theory. An appeal then lay to the

19th century pair of transits in 1874 and 1882; but no peremptory decision ensued; observations were marred by the same optical evils as before. Their upshot, however, had lost its essential importance; for a fresh series of investigations based on a variety of principles had already been started. Leverrier, in 1858, calculated a value of 8·95″ for the solar parallax (equivalent to a distance of 91,000,000m.) from the "parallactic inequality" of the moon; Professor Newcomb, using other forms of the gravitational method, derived in 1895 a parallax of 8·76″. For more recent researches on this problem *see* PARALLAX.

Improvements in Telescopes. — The first specimen of a reflecting telescope was constructed by Isaac Newton in 1668. It was of what is still called "Newtonian" design, and had a speculum 2in. in diameter. Through the skill of John Hadley (1682–1743) and James Short of Edinburgh (1710–1768) the instrument unfolded, in the ensuing century, some of its capabilities, which the labours of William Herschel enormously enhanced. Between 1774 and 1789 he built scores of specula of continually augmented size, up to a diameter of 4ft., the optical excellence of which approved itself by a crowd of discoveries. Uranus (*q.v.*) was recognized by its disc on March 13, 1781; two of its satellites, Oberon and Titania, disclosed themselves on Jan. 11, 1787; while with the giant 48-in. mirror, used on the "front-view" plan, Mimas and Enceladus, the innermost Saturnian moons, were brought to view on Aug. 28 and Sept. 17, 1789. These were incidental trophies; Herschel's main object was the exploration of the sidereal heavens. The task, though novel and formidable, was executed with almost incredible success. Messier (1730–1817) catalogued 103 nebulae and star clusters; Herschel discovered 2,500, laid down the lines of their classification, divined the laws of their distribution, and assigned their place in a scheme of development. The proof supplied by him in 1802 that double stars are mutually revolving threw open a boundless field of research; and he originated experimental inquiries into the construction of the heavens by systematically collecting and sifting stellar statistics. He, moreover, definitely established, in 1783, the fact and general direction of the sun's movement in space, and thus introduced an element of order into the maze of stellar proper motions. Sir John Herschel continued in the northern, and extended to the southern hemisphere, his father's work. The third earl of Rosse mounted, at Parsonstown in 1845, a speculum 6ft. in diameter, which afforded the first indications of the spiral structure shown in recent photographs to be a very prevalent characteristic of many nebulae. Down to near the close of the 19th century, both the use and the improvement of reflectors were left mainly in British hands; but the gift of the "Crossley" instrument in 1895, to the Lick observatory, and its splendid subsequent performances in nebular photography, brought similar tools of research into extensive use among American astronomers; and they are now, for many of the various purposes of Astrophysics, strongly preferred to refractors. At present the largest instruments are the 100-in. reflector at Mount Wilson, California, and the 72-in. reflector at Victoria, British Columbia.

Sidereal Astronomy. — The progress of science during the 19th century had no more distinctive feature than the rapid growth of sidereal astronomy (*see* STAR). Its scope, wide as the universe, can be compassed no otherwise than by statistical means, and the collection of materials for this purpose involves most arduous preliminary labour. The multitudinous enrollment of stars was the first requisite. Only one "catalogue of precision" — Nevil Maskelyne's of 36 fundamental stars — was available in 1800. J. J. Lalande, however, published in 1801, in his *Histoire céleste,* the approximate places of 47,390 stars. A valuable catalogue of about 7,600 stars was issued by Giuseppe Piazzi in 1814; Stephen Groombridge determined 4,239 at Blackheath in 1806–16; while through the joint and successive work of F. W. Ressel and W. A. Argelander, 324,000 stars were recorded in the *Bonn Durchmusterung* (1859–62). The southern hemisphere was subsequently reviewed on a similar duplicate plan by E. Schonfeld (1828–1891) at Bonn, by B. A. Gould and J. M. Thome at Córdoba. Moreover, the imposing catalogue set on foot in 1865 at thirteen observatories by the Astronomische Gesellschaft was duly completed; and adjuncts to it have, from time to time, been provided in the publications of the royal observatories at Greenwich and the Cape of Good Hope, and of national, imperial and private establishments in the United States and on the continent of Europe. But in the execution of these protracted undertakings, the human eye has been, to a large and increasing extent, supplemented by the camera. Photographic star-charting was begun by Sir David Gill in 1885, and the third and concluding volume of the *Cape Photographic Durchmusterung* appeared in 1900. It gives the co-ordinates of above 450,000 stars, measured by Professor J. C. Kapteyn at Groningen on plates taken by C. Ray Woods at the Cape observatory. And this comprehensive work was merely preparatory to the International Catalogue and Chart, the production of which was initiated by the resolutions of the Paris Photographic Congress of 1887. Eighteen observatories scattered north and south of the equator divided the sky among them; and the outcome of their combined operations aimed at the production of a catalogue of at least 2,000,000 strictly determined stars, together with a colossal map in 22,000 sheets, showing stars to the fourteenth magnitude, in numbers difficult to estimate. (*See* PHOTOGRAPHY, CELESTIAL.)

The investigation of double stars was carried on from 1819 to 1830 with singular persistence and ability at Dorpat and Pulkowa by F. G. W. Struve, and by his son and successor, O. W. Struve. The high excellence of the data collected by them was a combined result of their skill, and of the vast improvement in refracting telescopes due to the genius of Joseph Fraunhofer (1787–1826). Among the inheritors of his renown were Alvan Clark and Alvan G. Clark of Cambridgeport, Massachusetts; and the superb definition of their great achromatics rendered practicable the division of what might have been deemed impossibly close star-pairs. These facilities were remarkably illustrated by Professor S. W. Burnham's record of discovery, which roused fresh enthusiasm for this line of inquiry by compelling recognition of the extraordinary profusion throughout the heavens of compound objects. Discoveries with the spectroscope have ratified and extended this conclusion.

Stellar Proper Motions. — Only spurious star-parallaxes had claimed the attention of astronomers until F. W. Bessel announced, in December, 1838, the perspective yearly shifting of 61 Cygni in an ellipse with a mean radius of about one-third of a second. Thomas Henderson (1798–1844) had indeed measured the larger displacements of α Centauri at the Cape in 1832–33, but delayed until 1839 to publish his result.

The exhaustive ascertainment of stellar parallaxes, combined with the visible facts of stellar distribution, would enable us to build a perfect plan of the universe in three dimensions. Its perfection would, nevertheless, be undermined by the mobility of all its constituent parts. Their configuration at a given instant supplies no information as to their configuration hereafter unless the mode and laws of their movements have been determined. Hence, one of the leading inducements to the construction of exact and comprehensive catalogues has been to elicit, by comparisons of those for widely separated epochs, the proper motions of the stars enumerated in them. Little was known on the subject at the beginning of the 19th century. William Herschel founded his determination in 1783 of the sun's route in space upon the movements of thirteen stars; and he took into account those of only six in his second solution of the problem in 1805. But in 1837 Argelander employed 390 proper motions as materials for the treatment of the same subject; and L. Struve had at his disposal, in 1887, no fewer than 2,800.

Spectroscopy. — A beam of sunlight admitted into a darkened room through a narrow aperture, and there dispersed into a variotinted band by the interposition of a prism, is not absolutely continuous. Dr. W. H. Wollaston made the experiment in 1802, and perceived the spaces of colour to be interrupted by seven obscure gaps, which took the shape of lines owing to his use of a rectangular slit. He thus caught a preliminary glimpse of the "Fraunhofer lines," so called because Joseph Fraunhofer brought them into prominent notice by the diligence and insight of his labours upon them in 1814–15. He mapped 324, chose out nine, which

he designated by the letters of the alphabet, to be standards of measurement for the rest, and ascertained the coincidence in position between the double yellow ray derived from the flame of burning sodium and the pair of dark lines named by him "D" in the solar spectrum. There ensued 45 years of groping for a law which should clear up the enigma of the solar reversals. Partial anticipations abounded. The vital heart of the matter was barely missed by W. A. Miller in 1845, by L. Foucault in 1849, by A. J. Angstrom in 1853, by Balfour Stewart in 1858; while Sir George Stokes held the solution of the problem in the hollow of his hand from 1852 onward. But it was the synthetic genius of Gustav Kirchhoff which first gave unity to the scattered phenomena, and finally reconciled what was elicited in the laboratory with what was observed in the sun. On Dec. 15, 1859, he communicated to the Berlin Academy of Sciences the principle which bears his name. Its purport is that glowing vapours similarly circumstanced absorb the identical radiations which they emit. That is to say, they stop out just those sections of white light transmitted through them which form their own special luminous badges. Moreover, if the white light come from a source at a higher temperature than theirs, the sections, or lines, absorbed by them show dark against a continuous background. And this is precisely the case with the sun. Kirchhoff's principle, accordingly, not only afforded a simple explanation of the Fraunhofer lines, but availed to found a far-reaching science of celestial chemistry. Thousands of the dark lines in the solar spectrum agree absolutely in wavelength with the bright rays artificially obtained from known substances, and appertaining to them individually. These substances must then exist near the sun. They are in fact suspended in a state of vapour between our eyes and the photosphere, the dazzling prismatic radiance of which they, to a minute extent, intercept, thus writing their signatures on the coloured scroll of dispersed sunshine. Research has been powerfully aided by the photographic camera and by the concave gratings invented by H. A. Rowland (1848–1901) in 1882.

Solar Research. — Solar physics has profited enormously by the abolition of glare during total eclipses. That of July 8, 1842, was the first to be efficiently observed; and the luminous appendages to the sun disclosed by it were such as to excite startled attention. Their investigation has since been diligently prosecuted. The corona was photographed at Konigsberg during the totality of July 28, 1851; similar records of the red prominences, successively obtained by Father Angelo Secchi and Warren de la Rue, as the shadow-track crossed Spain on July 18, 1860, finally demonstrated their solar status. The Indian eclipse of Aug. 18, 1868, supplied knowledge of their spectrum, found to include the yellow ray of an exotic gas named by Sir Norman Lockyer "helium." It further suggested, to Lockyer and P. Janssen separately, the spectroscopic method of observing these objects in daylight. Under cover of an eclipse visible in North America on Aug. 7, 1869, the bright green line of the corona was discerned; and Professor C. A. Young caught the "flash spectrum" of the reversing layer, at the moment of second contact, at Xerez de la Frontera in Spain, on Dec. 22, 1870. This significant but evanescent phenomenon, which represents the direct emissions of a low-lying solar envelope, was photographed by William Shackleton on the occasion of an eclipse in Novaya Zemlya on Aug. 9, 1896; and it has been abundantly registered by exposures made during subsequent eclipses.

The photography of prominences in full sunlight was, after some preliminary trials by C. A. Young and others, fully realized in 1891 by Professor George E. Hale at Chicago, and independently by Henri Deslandres at Paris. The pictures were taken, in both cases, with only one quality of light, the violet ray of calcium, the remaining superfluous beams being eliminated by the agency of a double slit. The last-named expedient had been described by Janssen in 1867. Hale devised on the same principle the spectroheliograph (*q.v.*) an instrument by which the sun's disc can be photographed in calcium-light by imparting a rapid movement to its image relatively to the sensitive plate; and the method has proved in many ways fruitful.

Stellar Spectroscopy. — The likeness of the sun to the stars has been shown by the spectroscope to be profound and inherent. Yet the general agreement of solar and stellar chemistry does not exclude important diversities of detail. Fraunhofer was the pioneer in this branch. He observed, in 1823, dark lines in stellar spectra which Kirchhoff's discovery supplied the means of interpreting. The task, attempted by G. B. Donati in 1860, was effectively taken in hand, two years later, by Angelo Secchi, William Huggins and Lewis M. Rutherfurd. There ensued a general classification of the stars by Secchi into four leading types, distinguished by diversities of spectral pattern; and the recognition by Huggins of a considerable number of terrestrial elements as present in stellar atmospheres. Nebular chemistry was initiated by the same investigator when, on Aug. 29, 1864, he observed the bright-line spectrum of a planetary nebula in Draco. About seventy analogous objects, including that in the Sword of Orion, were found by him to give light of the same quality; and thus after seventy-three years, verification was brought to William Herschel's hypothesis of a "shining fluid" diffused through space, the possible raw material of stars. In 1874, Dr. H. C. Vogel published a modification of Secchi's scheme of stellar diversities, and gave it organic meaning by connecting spectral differences with advance in "age." And in 1895, he set apart, as in the earliest stage of growth, a new class of "helium stars," supposed to develop successively into Sirian, solar, Antarian, or alternatively into carbon stars. The classification which survives at the present time is that of the Draper Catalogue of stellar spectra observed at Harvard (1890) comprising 10,351 stars.

On Aug. 5, 1864, G. B. Donati analysed the light of a small comet into three bright bands. Sir William Huggins repeated the experiment on Winnecke's comet in 1868, obtained the same bands, and traced them to their origin from glowing carbon-vapour. A photograph of the spectrum of Tebbutt's comet, taken by him on June 24, 1881, showed radiations of shorter wavelengths but identical source, and in addition, a percentage of reflected solar light marked as such by the presence of some well-known Fraunhofer lines. Further experience has generalized these earlier results. The rule that comets yield carbon-spectra has scarcely any exceptions. The usual bands were, however, temporarily effaced in the two brilliant apparitions of 1882 by vivid rays of sodium and iron, emitted during the excitement of perihelion-passage.

An important contribution of the spectroscope to astronomy is the determination of velocities in the line of sight by measurement of the Doppler displacement of spectral lines. In 1868 William Huggins attempted these measurements; but no trustworthy results were obtained till much later. Probably the earliest results that can be counted successful were those of H. C. Vogel who in 1888 substituted photographic for eye observation. The first extensive catalogue of radial velocities of stars was published by W. W. Campbell in 1911.

Miscellaneous. — The first evening of the nineteenth century saw the discovery of the minor planet Ceres by Giuseppe Piazzi at Palermo. This was the forerunner of a host of similar discoveries now numbering more than a thousand. Progress was greatly accelerated when Max Wolf of Heidelberg in 1891 introduced the photographic method of searching for minor planets. Discovery of the satellites of planets continued during the nineteenth century. Between 1846 and 1851 William Lassell added Neptune's satellite, Hyperion attending Saturn, Ariel and Umbriel attending Uranus. The two satellites of Mars were found by Asaph Hall at Washington in 1877. The fifth (innermost) satellite of Jupiter was found by E. E. Barnard in 1892; and four more faint and remote Jovian satellites have been added in the present century. Saturn's outermost satellite Phoebe was found by W. H. Pickering in 1898.

In regard to the progress of astronomy since the latter part of the last century we can only refer here to the general tendencies; fuller information is given in the separate articles cn celestial objects and astronomical methods. One feature has been the development of statistical studies of the distribution, motions, and other characteristics of stars. Important work on the extension of the sidereal universe was done by H. von Seeliger who

must be counted the pioneer of modern statistical astronomy; but the subject received most impetus from the researches of J. C. Kapteyn. This was the main line of stellar investigation from about 1902–1912, but since then there has been something like a reaction to intensive study of individual stars. More recently the feature of stellar astronomy has been the application of atomic physics and the quantum theory to the conditions in the stars and nebulae. This closer linking of astronomy with physics (and in particular with thermodynamics) may be said to have originated in important pioneer investigations of the flow of radiation through a star's atmosphere by Arthur Schuster (1903) and Karl Schwarzschild (1908). The great possibilities in the interpretation of spectra were first made manifest by M. N. Saha (1920).

ASTROPALIA, an Aegean island (classical Astypalaea, mediaeval *Stampalia*), with good harbours, situated in 36·5° N. and immediately west of 26·5° E. It was colonized by Megara, and its constitution and buildings are known from numerous inscriptions. The Roman empire recognized it as a free state, and in the middle ages it belonged to the noble Venetian family of Quirini. It was taken by the Turks in the 16th century, and is now noted for its sponges. The dialect, customs and dress of the people are interesting, and the fortified town picturesque. Pop. (1936) 2,006.

ASTROPHYSICS, that branch of astronomy which deals with the physical constitution of the heavenly bodies or involves the use of instruments and methods specially dependent on physics. It is contrasted with "astrometry," which deals with the positions and motions of the heavenly bodies. There is no strict line of demarcation, but in a general way we can divide astronomical methods into those making use of general types of equipment (the telescope, camera, micrometer, etc.) and those involving distinctively physical apparatus (the spectroscope, photo-electric cell, thermo-couple, etc.). Similarly, on the theoretical side we distinguish between conclusions based on geometry or on the law of gravitation (spherical astronomy and celestial mechanics) and those depending on advanced knowledge of atomic physics and thermodynamics. But even if it were desirable to divide astronomy in this way into two separate branches, the attempt is frustrated by the fact that astrometrical data are commonly found by astrophysical methods, and astrophysical data by astrometrical methods.

Astrophysics came into prominence through the application of the spectroscope in the third quarter of the 19th century; and it is mainly in its limited meaning of celestial spectroscopy that we shall give an introduction to it here. The spectroscope, like a glorified prism, takes the light of a body, separates it into its different constituents (different wave lengths) and lays them out side by side for examination. Primarily this spectrum tells us what chemical elements are present in the source of light, each element having its own characteristic set of lines. (See SPECTROSCOPY.) The lines may appear either as bright emission lines, or as relatively dark lines on a background of continuous light. In either case they are a sign of the presence of the corresponding element, either shining on its own account or robbing the light that comes from lower down in the star of these particular constituents. In this way 57 terrestrial elements have been recognized in the sun certainly and nine doubtfully. But absence of the characteristic lines does not necessarily mean that the element is absent or scarce; it may often happen that the temperature and density of the source are not suitable for exciting the spectrum, so that the element, although abundant, does not disclose itself. In any case the spectroscope, like the telescope, reaches only the outermost layers or atmosphere of the star and cannot indicate the chemical composition of the interior.

The first results obtained with the spectroscope related to the chemistry of the stars and nebulae; but later a much wider field of application was found in relation to the physics of the heavenly bodies. It is just because it is an erratic tool for the chemist that the spectroscope is so valuable for the physicist. It will not show the spectrum of an element unless the physical conditions are suitable: conversely, if it does show the spectrum we can infer that the physical conditions in the star are suitable. For example, we see very prominently in the spectrum of Sirius a series of lines due to hydrogen, and very little besides. We have to ask ourselves, what are the physical conditions which would account for so great a stimulation of this hydrogen spectrum? The answer, given partly by laboratory experience and partly by general physical theory, goes a long way towards settling the temperature and density in the outer layers of Sirius.

At high temperature an atom may become ionized, that is to say one of the electrons in the system of the atom breaks loose. The element then emits an entirely different spectrum. Or two, three, four electrons may break loose; a different spectrum being shown in each case. Stars of fairly low temperature show the spectrum of the complete calcium atom; those of higher temperature show the spectrum of the atom deprived of one electron. At still higher temperature there is no indication of calcium and we infer that it has all become doubly ionized, the calcium atom with two electrons missing being known to give no lines in the part of the spectrum which astronomers can observe.

In the sun and stars, the lines of which we have been speaking appear as dark gaps in the band of light forming the spectrum. But in some of the nebulae they appear as isolated bright lines with little or no continuous background. It is commonly said that continuous spectrum indicates a solid or liquid or highly compressed gas; whilst a bright line spectrum indicates rarefied gas. This is not quite accurate, because a rarefied gas will show a continuous instead of bright line spectrum if we look at a sufficient thickness of it. It is a question of transparency. Light which is strongly emitted by any kind of atom is also strongly absorbed by it; and the internal absorption in a deep layer of material tends to even out the emission in different wave lengths. Thus, if the light is strongly emitted and absorbed, we receive only the emission from a few atoms in the forefront, these forming an opaque screen to the radiation behind; if the emission is weak we see down to a greater depth, and so the weakness is compensated by the greater number of atoms visible. For a deep layer at uniform temperature this compensation is so complete that the resulting spectrum is a continuous band independent of the nature of the material and depending only on the temperature; this is known as the "black-body" spectrum.

The continuous spectrum from a star is not very different from a black-body spectrum; in fact, it is much closer than we should expect, seeing that the observed layer of the star is by no means at a uniform temperature, the upper part being considerably cooler than the lower part. By measuring the distribution of energy in the spectrum we can determine the temperature; for, as the temperature of a black body rises, the radiation comes more and more from the blue end of the spectrum. This temperature is commonly called the "effective temperature" or sur-

face temperature of the star; it is strictly the mean temperature of the layers which we actually see. Deep down in the interior the temperature is, of course, far greater.

Bright line spectra are shown by the gaseous nebulae, by tails of comets, and by the uppermost layers (chromosphere and corona) of the sun when viewed transversely at the edge of the disc. We are then looking at extremely rarefied gas, and the layer, although enormously thick compared with terrestrial standards, is still thin enough to be transparent. Occasional bright lines are also found in the spectra of some stars superposed on the continuous spectrum. These probably indicate either specially disturbed conditions or that the star is surrounded by an extended nebulous envelope.

We commonly judge stars by their light, but it is quite practicable to measure the heat which they send to us across interstellar space. This is done by placing a thermo-couple at the focus of the telescope where the star's rays are concentrated. The chief difficulty is that a great deal of the heat is absorbed in our atmosphere, so that large and sometimes uncertain corrections must be applied in order to obtain the true output of heat by the star. (A. S. E.)

ASTRUC, JEAN (1684–1766), French physician and biblical critic, was born March 19 1684, at Sauve, in Languedoc, and died in Paris, where he was regius professor of medicine, May 5 1766. He published anonymously Conjectures *sur les mémoires originaux* dont *il paraît que* Moyse *s'est* servi *pour* composer *le livre* de la *Genèse* (1753), in which he laid the foundation of modern criticism of the Pentateuch by pointing out that two main sources can be traced in the book of Genesis.

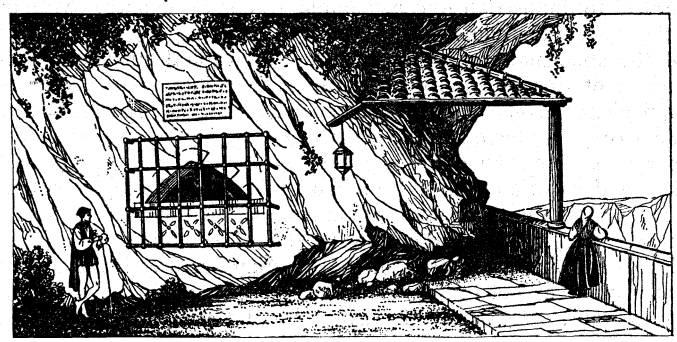
See Hauck, Realencyk. f. prot. *Theol.*, vol. ii. p. 162–170 (1897).

ASTURA, formerly an island, now a peninsula, coast of Latium, Italy, 7m. S.E. of Antium, at the south-eastern extremity of the bay of Antium. The name also belongs to the river which flowed into the sea at an anchorage immediately south-east. The mediaeval castle of the Frangipani, in which Conradin vainly sought refuge after the battle of Tagliacozzo in 1268, is built on the foundations of a large villa, with a series of tanks for pisciculture and a harbour for small boats. Along the coast, a mile to the north-west, a line of villas begins, which continues as far as Antium. To the south-east the coast seems to have been as sparsely populated in Roman times as it is now. Astura was the site of a favourite villa of Cicero, whither he retired on the death of his daughter Tullia in 45 B.C. It appears to have been unhealthy even in Roman times; according to Suetonius, both Augustus and Tiberius contracted here the illnesses which proved fatal to them.

ASTURES (ŭ), a warlike tribe occupying the mountains of the north-west of ancient Spain. They resisted the Roman conquest and were only reduced by Augustus; Asturica Augusta, Legio VII. Gemina and other strong places being planted to hold them down. Their name is preserved in the modern Spanish Asturias.

ASTURIAS, a principality of Spain, created (1388) by John I, of Lebn and Castile when his eldest son Henry married the daughter of the duke of Lancaster. The principality, now purely titular, belongs to the eldest son of the sovereign; administratively the principality is chiefly merged in the province of Oviedo, to describe which Asturias still survives in popular usage as a regional term. Clearly defined on three sides by mountain ranges which make the district a rough oval, and on the fourth side by a long straight coast-line, broken only by the projecting Cabo de Pefias, the Asturias are secluded from the rest of the peninsula and such outlook as they have is maritime. On the east the triple limestone massif of the Picos de Europa, reaching 2,6oom., leaves only a narrow strip for passage to the coast of old Castile; on the south the Cantabrian mountains shut off the central plateau to which no pass lower than 1,13om. gives access, the main road from Oviedo to León crossing by the Puerto de Pajares at 1,363m.; on the west the lower Sierras de Rafiadoiro and de Meira, running north-east to south-west, block the road to Galicia; between these sierras the bounddry-line of the Asturias runs without any special natural definition to the Ria de Rivadeo.

The abrupt descent from the Cantabrian crest, which reaches 2,3oom. in Peña Ubiña, brings down the rivers by steep courses set in deep valleys—in canyons, in the mountain limestone of the eastern Asturias—to the sea, nowhere more than 7okm. distant. A fan-shaped area drains to the Ria de Pravia by the converging rivers Narcea and Nalón; the town of Pravia stands at the apex of the fan. Besides these rivers and their tributaries, the Navia and Sella are the only important streams. To the east of this fan, behind the coast between Avilés and Caravia, lies the area of successive marine invasions in geological times. To one of these invasions is due the natural trench which forms the central



THE MOUNTAIN CLIFF TOMB IN ASTURIAS. OF PELAYO, THE ASTURIAN KING WHO ATTEMPTED TO RECONQUER CHRISTIAN SPAIN FROM THE MOORS IN THE 8TH CENTURY

valley of the Asturias east of Oviedo, and which continues along the line of the old sea-gulf narrowing out between the Picos de Europa and the Sierra de Cuera. This structural valley, neither the result of stream action nor occupied by any important stream, gives the principal interior line of communications in the Asturias. Along the coast the great Cantabrian platform, running from western Galicia to the mouth of the river Adour in France, is represented in the Asturias as elsewhere, by the gently rolling "downs," some 60 or 7om. in height and cut usually in sheer cliffs towards the sea, into which the platform, segmented by the rivers from the interior, has been moulded by the weather. To-day the platform is thickly populated, and one single coastal road connects the long line of small towns set on successive heights. The intervening rias are clogged with silt and afford no good harbours. The relief, of mountain, valley and coastal platform, the coal supply and the humidity of the climate determine jointly the character of the Asturias. The impenetrable Picos de Europa, in whose fastnesses the chamois still roams, sheltered the Christian nucleus of resistance to the Muslims, which developed into the kingdom of Oviedo and Asturias. In the early stages of this resistance the term Asturias (derived from the original inhabitants, the Astures, whose territory extended westwards from Ribudesella and as far as the Douro) covered loosely the Cantabrian territory held by the Christians; there were Asturias in the Liébana valley and as far east as Santander (Asturia de Sancto Anderio), and the name lingered long east of the Picos in the term Asturia de Santillana (Sancta *Illana*). But the important movement was westwards along the central valley, in which Cangas de Onís and Oviedo (alternating with Pravia) were successive headquarters or capitals of the small Christian State. After the capital of the enlarged State had been transferred to León by Ordono II. (914–924), the isolation of the Asturias and of Galicia, both from each other and from the repopulated territory on the central plateau, contributed to the weakness and lack of homogeneity of the kingdom of León. The mountain barrier between Léon and the Asturias made Oviedo at a later date a refuge for the Léonese king Bermudo II. during the raid of Almanzor.

The coal of the Asturias lies in distinct groups of small basins; the town of Tineo is the centre for the most westerly group, but the comparatively thick beds of anthracite coal have been little exploited there for lack of means of communication. The most important group at present is the central; here the coal lies in a series of folds of the mountain limestone, cut by the rivers Caudal and Nalon, on which Mieres and Langres are respectively

the centres of exploitation. The more northerly basins of Arnas and Ferroñes supply a soft coal with 45% of volatile substances, and, speaking generally, the coals of the Asturian basins form a descending scale of hardness from north to south. Iron ore is also extracted in the Asturias and blast furnaces have been erected at La Felguera to treat it. Zinc ores are mined in the Picos de Europa. The altitude at which the zinc is found, however, prevents operations in winter; the iron ores have a high percentage of silica; the coal seams are relatively thin and irregular and they dip steeply, so that the costs both of production and of transport are high. Thus the mineral resources of the Asturias have served to industrialize considerable tracts of country without bringing any high degree of prosperity. The temporary prosperity of the abnormal war years and the new capital sunk in consequence of this prosperity in improved machinery (calculated as equivalent to some eight millions of pounds sterling for the decennium 1915–25) have had the effect of raising in a more acute form in recent times the question of the protection by governmental decree of Asturian coal. With a humid climate and a high rainfall, nowhere less than 1,000mm. per annum, the Asturias are predominantly pastoral and the cow is the chief domestic animal. Horses and mules are bred on the Asturian pastures but they are not worked, except in the mines. The absence of a regular period of drought, together with favourable temperature conditions, makes maize the chief cereal cultivated; the soils do not, however. favour the cultivator and America and the mines attract labour more than the farm. The marked summer minimum of rainfall is sufficient to make ordinary summer irrigation desirable, but the typical Asturian irrigation is the winter flooding of lands by running water, partly to maintain the soil temperature and partly to secure the benefit of the fertilizing deposit of mud.

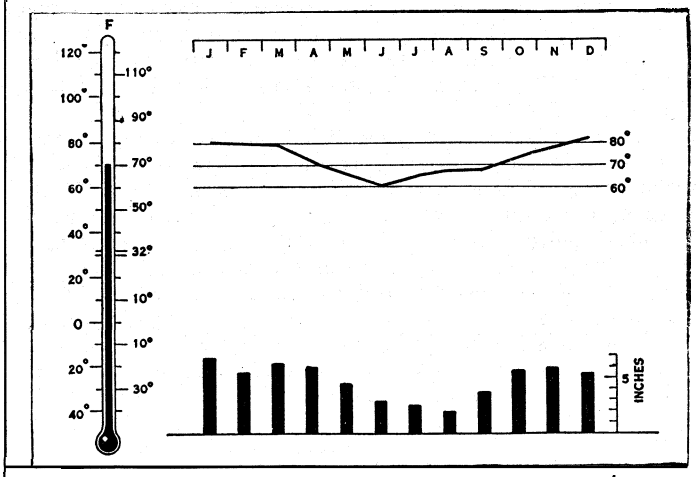
ASTYAGES, the last king of the Median empire. In the inscriptions of Nabonidos the name is written Ishtuvegu (cylinder from Abu Habba V R 64, col. 1, 32; Annals, published by Pinches, Tr. *Soc. Bibl.* Arch. vii. col. 2, 2). According to Herodotus, he was the son of Cyaxares and reigned 35 years (584–550 B.C.); his wife was Aryenis, the daughter of Alyattes of Lydia (Herod. i. 74). About his reign we know little, as the narrative of Herodotus, which makes Cyrus the grandson of Astyages by his daughter Mandane, is merely a legend; the figure of Harpagus, who as general of the Median army betrays the king to Cyrus, alone seems to contain any historical element, as Harpagus and his family afterwards obtained a high position in the Persian empire. From the inscriptions of Nabonidos we learn that Cyrus, king of Anshan (Susiana), began war against him in 553 B.C.; in 550, when Astyages marched against Cyrus, his troops rebelled, and he was taken prisoner. Then Cyrus occupied and plundered Ecbatana. The captive king was treated fairly by Cyrus (Herod. i. 130), and according to Ctesias (Pers., 5; cf. Justin i. 6) made satrap of Hyrcania, where he was afterwards slain by Oebares against the will of Cyrus, who gave him a splendid funeral. Alexander Polyhistor and Abydenus in their excerpts from Berossus, which Eusebius (*Chron.*, i. p. 29 and 37) and Syncellus (p. 396) have preserved, give the name Astyages to the Median king who reigned in the time of the fall of Nineveh (606 B.C.), and became father-in-law of Nebuchadrezzar. This is evidently a mistake; the name ought to be Cyaxares (in the fragments of the Jewish history of Alexander Polyhistor, in Euseb. Praep. *Ev.*, ix. 39, the name is converted into Astibaras, who according to the unhistorical list of Ctesias, was the father of Astyages), and there is no reason to invent an earlier King Astyages I., as some modern authors have done. The Armenian historians render the name Astyages by Ashdahak; *i.e.*, Azhi Dahaka (Zohak), the mythical king of the Iranian epics, who has nothing whatever to do with the historical king of the Medes.

(ED. M.)

ASUNCION (Nuestra Señora de la Asunción), capital of the republic of Paraguay, stands on the eastern bank of the Paraguay river in 25° 16′ 04″ S., 57° 42′ 40″ W., 935 mi. N of Buenos Aires. Pop. (1939) 109,426.

The city is connected with Buenos Aires and Montevideo by regular steamers. There is rail connection with Buenos Aires through cars being ferried over the Alto Paraná river betneen Posadas and Encarnación, time 52 hours; and a weekly air service is maintained between Asunción and the capitals of Argentina and Brazil. A spur of the Pan American highway branches north at Rosario, Argentina, to Asunción.



GRAPH OF THE TEMPERATURE AND RAINFALL OF ASUNCIÓN
The thermometer shows the annual mean temperature; the curve illustrates the monthly mean temperature. Columns indicate the normal rainfall for each month

Asunción is built opposite a wide stretch of the Paraguay, often called the Bay of Asunción. Its site is only 250 ft. above sea level but the hills rising gently back from the river furnish a healthier site for future growth. The city's streets are laid out in rectangular form and in the larger division or older city run northwest to southeast and are crossed by others at right angles. Many blocks are 240 ft. square and a number of streets are 45 ft. wide. Close to the river stands the famous palace built by Lopez II, now used for government offices. Barrio Cachingo is a new part of the city where streets run with cardinal points Dwelling houses of Asunción are largely one-story structures; recently taller buildings have become numerous. Prominent buildings are the House of Congress, National theatre, post and telegraph office, city hospital, Encarnación church, national library with many rare books, a new market and a college opened in 1928. The port of Asunción is one of the busiest parts of the city; here transshipment is made from small ocean-going vessels to those of lighter draught which handle upriver cargo (as far as Corumbá). Mean temperature at Asunción is about 72° F.; maximum, 105° F. December, January and February are the hottest months; the remaining months are cool or cold and occasionally frosts occur. The heaviest precipitation occurs about March and the lightest in August. The city is governed by a municipal junta consisting of six councilmen and an *intendente* or mayor who is appointed by the president of the republic; councilmen are elected by popular vote.

Among city improvements are some newly paved streets, sidewalks, extension of electric light and power service, installation of modern sewerage in certain districts, motor cars and a movement for extension of highways, new hotels, modern shops with large varieties of foreign goods and an active chamber of commerce. The pleasure and health resort of San Bernardino on Lake Ypacarái, a short distance by railway or road, is frequented in summer.

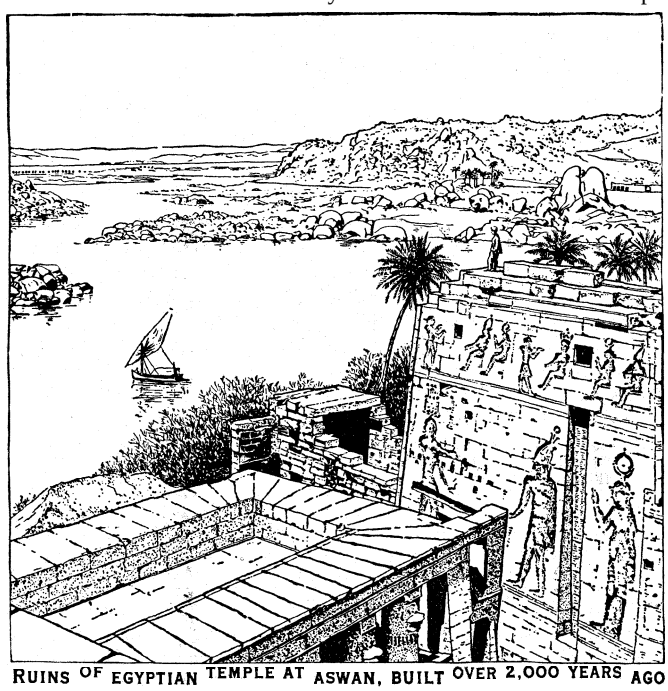
Sebastian Cabot, after his explorations in North America. turned to South America, and with a band of wanderers sailed up the Paraguay to the region where Asunción now stands. This event was about 1526–27. Subsequently Ayolas and Irala with other Europeans visited the spot where Asunción is situated and began a stockade in order to protect themselves from the Guaranís. These Indians, however, are said to have offered little resistance and ultimately assisted in laying out and building a

settlement. Ayolas sailed farther up the Paraguay river and never returned. In 1617 a seat of government was established at Buenos Aires, and Asunción was almost abandoned. Later other explorers came and Asunción for many years was the scene of cruelty, oppression, adventure, romance and bloodshed. Paraguay declared independence from Spain on Aug. 14, 1811, and Velasco, the Spanish governor, being in sympathy with the movement, was chosen a member of the Junta. Asunción still bears many marks of the terrible fighting that from time to time has made its streets run red with blood. In recent years, however, peace has reigned and considerable progress is recorded. (W. A. R.; X.)

ASVINS, in Vedic Hindu mythology, twir gods of light, and after Indra, Agni and Soma the most prominent in the *Rig Veda*, invoked in more than 50 hymns. As spirits of the Dawn they prepare her path in the sky. Called sons of the sun, offspring of the ocean, the youngest of the gods, "honey-hued," they are inseparable. The Boghaz-Keui inscription (c. 1400 B.C.) in Asia Minor mentions them with Indra and Varuna and they are unquestionably Zoroastrian, though they seem to be the Nasatya demons of the *Avesta*, and their resemblances to the Dioscuri are manifest. In the Epic era they survived chiefly as physicians and dentists and so rather lost caste. In modern Hinduism they have all but ceased to function.

See E. W. Hopkins, *Epic* Mythology (Strasbourg, 1915).

ASWAN or **ASSUAN,** a town of Upper Egypt on the east bank of the Nile, facing Elephantine island below the first cataract, and 590m. S. of Cairo by rail. It is the capital of a province of the same name—the southernmost province of Egypt. The principal buildings are along the river front, where a broad embankment has been built. Popular among Europeans as a winter health resort and tourist centre, Assuan is provided with large modern hotels (one situated on Elephantine island), and there is an English church. South-east of the railway station are the ruins of a temple



RUINS OF EGYPTIAN TEMPLE AT ASWAN, BUILT OVER 2,000 YEARS AGO
In the left background is Aswan dam, an engineering project responsible for the complete flooding of the island of Philae except from July to October. The boat with its one sail is characteristic of native craft navigating the Nile

built by Ptolemy Euergetes, and still farther south are the famous granite quarries of Syene. On Elephantine island are an ancient nilometer and other remains, including a granite gateway built under Alexander the Great at the temple of the local ram-headed god Chnubis or Chnumis (Eg. Khnum), perhaps on account of his connection with Amon (*q.v.*); two small but very beautiful temples of the 18th dynasty were destroyed there about 1820. In the hill on the opposite side of the river are tombs of the 6th to 12th dynasties, opened by Lord Grenfell in 1885–1886. The inscriptions show that they belonged to frontier-prefects whose expeditions into Nubia, etc., are recorded in them. Three and a half miles above the town, at the beginning of the cataract, the Assuan Dam stretches across the Nile and converts the river above it into a vast lake. Consequent on the rise of the water-level several islands have been wholly and others partly submerged, among the latter Philae (*q.v.*). On the east bank opposite Philae is the village of Shellal, southern terminus of the Egyptian railway system and the startingpoint of steamers for the Sudan.

In ancient times the chief city, called Yēb, capital of the frontier nome, the first of the Upper Country, was on the island of Elephantine, guarding the entrance to Egypt. Near the granite quarries on the eastern bank whence was obtained the material for many magnificent monuments—there grew up another city, at first dependent on, and afterwards successor to, the island town. This city was called *Swan*, the Mart, whence came the Greek *Syene* and Arabic *Aswân*. Syene is twice mentioned (as Seveneh) in the prophecies of Ezekiel, and papyri, discovered on the island, and dated in the reigns of Artaxerxes and Darius II. (464–404 B.C.), reveal the existence of a colony of Jews, with a temple to Yahu (Yahweh, Jehovah), which had been founded at some time before the conquest of Egypt by Cambyses in 523 B.C. In Roman times Syene was strongly garrisoned to resist the attacks of the desert tribes. Thither, in virtual banishment, Juvenal was sent as prefect by Domitian. In the early days of Christianity the town became the seat of a bishopric, and numerous ruins of Coptic convents are in the neighbourhood. On the conquest of Egypt by the Turks in the 16th century, Selim I. placed a garrison here, from whom, in part, the present townsmen descend. As the southern frontier town of Egypt proper, Assuan in times of peace was the entrepôt of a considerable trade with the Sudan and Abyssinia, and during the Mahdia (1884–99) it was occupied in force by British and Egyptian troops.

ASYLUM, a place of refuge. The derivation is of interest. In classical Greek, *ἡ σύλη* or *τὸ σῦλον* was the right of seizing the ship or cargo of a foreign merchant to cover losses incurred through him, and so came generally to mean the right of seizure or reprisal. The *ἀ* is privative: *τὸ ἄσυλον* means "the right of sanctuary." In ancient Greece an asylum was an "inviolable" refuge for persons in search of protection. All Greek temples and altars were inviolable, that is, it was a religious crime to remove by force any person or thing once under the protection of a deity. But this protecting right of a deity was recognized by common consent only in the case of a small number of temples. The right of sanctuary appears to have become limited to a few temples in consequence of abuses of it. Asylums in this sense were peculiar to the Greeks. The asylum of Romulus (Livy i. 8) cannot be considered as such. Under Roman dominion the rights of existing Greek sanctuaries were at first confirmed, but their number was considerably reduced by Tiberius. Under the empire the statues of the emperors and the eagles of the legions were made refuges against acts of violence. Generally speaking, the classes of persons who claimed the rights of asylum were slaves who had been maltreated by their masters, soldiers defeated and pursued by the enemy, and criminals who feared a trial or who had escaped before sentence was passed. (*See* classical dictionaries *s.v.*)

With the establishment of Christianity, the custom of asylum or sanctuary (*q.v.*) became attached to the church or churchyard. In modern times the word asylum has come to mean an institution providing shelter or refuge for any class of afflicted or destitute persons, such as the blind, deaf and dumb, etc., but more particularly the insane. (*See* INSANITY.)

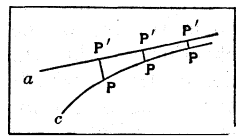
ASYLUM, RIGHT OF. This does not mean the right of a fugitive to demand protection but the right of a state to grant it. This latter flows from the principle of sovereignty (*q.v.*), but it is a right less and less insisted on with the progress of civilization. Asylum may be considered as equivalent to the exceptions to extradition (*q.v.*). Most nations reserve, or claim, a right of asylum for their own nationals. Portugal goes so far as to grant asylum for a fugitive who might, if delivered up, be put to death.

The right of neutral Powers to grant asylum to belligerent land forces is governed by articles 11, 12, 13, and 14 of The Hague

Convention V., 1907. The presence of belligerent warships in neutral ports is governed by The Hague Convention XIII., 1907 Generally such ships are not permitted to remain in neutral ports, roadsteads, or territorial waters for more than 24 hours.

Asylum in civil war is often claimed in South America for insurgents taking refuge in legations and consulates.

ASYMPTOTE, a line which approaches continually nearer to a given curve, but which does not meet it within a finite distance. More precisely speaking, if a curve (*c*) has an infinite branch and if there be a straight line (*a*) such that the distance *PP′* to a from a point *P* on *c* approaches zero as a limit, as *P* moves toward infinity, then a is called an asymptote to this curve. Geminus, writing in the first century B.C., remarked that: "Some lines exist which approach indefinitely and yet remain ἀσύμπτωτοι [literally, not-together-falling]." Elsewhere he gives the cases of the hyperbola and conchoid, each with its asymptote. The asymptote is often spoken of as a tangent to a curve at a point infinitely distant.



ASYUT, capital of a province of the same name in Upper Egypt, and the largest and best-built town in the Nile valley south of Cairo, from which it is distant 248 mi. by rail. The population rose from 32.000 in 1882 to 60,338 in 1937. Asyut stands near the west bank of the Nile across which, just below the town, is a barrage, completed in 1902, consisting of an open weir, 2,691ft. long and 111 bays or sluices, each 16½ft. wide, which can be opened or closed at will. At the western end of the barrage begins the Ibrahimia canal, nearly 200m. long, which supplies Middle Egypt and the Fayûm. The canal is skirted by a magnificent embankment, planted with shade trees, leading from the river to the town.

The town is famous for red and black pottery and for ornamental wood and ivory work, which find a ready market all over Egypt. It is one of the chief centres of the Copts. Here also is the northern terminus of the caravan route across the desert, which, passing through the Kharga oasis, goes south-west to Darfur. Asyut is the successor of the ancient Lycopolis (Eg. Sioout), capital of the 17th nome of Upper Egypt, and probably so called from the worship here of the jackal-headed Anubis. No ruins are visible, the mounds of the old city being for the most part hidden under modern buildings; but the slopes of the limestone hills behind it are pierced with an infinity of rock-cut tombs, some of which were large and decorated with sculptures, paintings and long inscriptions.

ATACAMA, a province of northern Chile, bounded north and south respectively by the provinces of Antofagasta and Coquimbo, and extending from the Pacific coast east to the Argentine boundary line. It has an area of 30,835 sq mi. lying in great part within the Atacama desert region, and a population (1902) of 71,446; (1940) 84,312. The silver and copper mines of the province are numerous, some of them ranking among the most productive known, but the majority are worked with limited capital and on a small scale. The silver ore was first discovered in 1832 by a shepherd at a place which bears his name, Juan Godoi. The nitrate and borax deposits are extensive and productive, and common salt is a natural product of large areas in the elevated desert regions of the Andes. The exports include copper and silver and their ores, nitrate of soda, borax and guano. The capital, Copiapó (pop. in 1940, 21,731), is situated on a small river of the same name 37m. from the coast and 51m. south-east by rail from Caldera, the principal port of this great mining district.

ATACAMA, DESERT OF, an arid, barren and saline region of western South America, covering the greater part of the Chilean provinces of Atacama and Antofagasta, the Argentine territory of Los Andes, and the south-western corner of the Bolivian department of Potosi. The higher elevations are known as the Puna de Atacama, which is practically a continuation southward of the great *puna* region of Peru and Bolivia. It is a broken, mountainous region, volcanic in places, saline in others, and ranges from 7,000 to 13,500ft. in general elevation. Its culminating ridges are marked by an irregular line of peaks and extinct volcanoes extending north by east from about 28° S. into southern Bolivia. On the eastern side, occasional rainfalls occur and streams from the snow-clad peaks produce some slight displays of fertility, but the general aspect of the plateaus, which are dry and cold in winter and in summer are swept by rainstorms and covered by occasional tufts of coarse grass, is barren and forbidding. They are also broken by great saline lagoons and dry salt basins. This region forms the Argentine territory of Los Andes and is habitable in places. On the western slope the land descends gradually to the Pacific, being broken into great basins, or terraces, by mountainous ridges in its higher elevations, widening out into gently sloping sandy plains below, famous for their nitrate deposits, and terminating on the coast with sharply-sloping bluffs, having an elevation of 800 to 1,500ft. and looking from the sea like a range of flat-topped hills. This desolate region, which is rainless and absolutely barren, and was considered worthless for three and a half centuries, is now a treasure-house of mineral wealth, abounding in copper, silver, lead, nickel, cobalt, iron, nitrates and borax. It is occupied by many mining settlements, and includes some of the most productive copper and silver mines of the world.

(A. J. L.)

ATACAMENAN, an independent linguistic stock of South American Indians, formerly occupying the coastal region and western slope of the Andes in the Chilean provinces of Tarapacá and Antofagasta. Some authorities believe that in the latter province they extended eastwards into the Puna de Atacama. The culture of the Atacameiias was relatively simple, but apparently had some similarities with that of the adjacent high plateaus of southern Bolivia. Except for a small remnant in the vicinity of S. Pedro de Atacama, the Atacameiias appear to be practically extinct. Uhle's excavations in the region just north of Tarapaca reveal sites regarded by him as Atacameiian, deep pit graves containing flexed burials associated with coiled basketry, textiles and rather coarse red pottery with decorations derived largely from the older cultures of the Bolivian plateau.

See G. de Créqui-Montfort, *Fouilles dans la nécropole préhispanique de Calama; Les anciens Atacamas* (*xiv. Congress of Americanists,* pp. 551–565; M. Uhle, *La arqueologia de Arica y Tacna (Bol. Soc. Ecuatoriana de Historia,* vol. iii., pp. 1–48).

ATACAMITE, a mineral found originally in the desert of Atacama, and named by D. de Gallizen in 1801. It is a cupric oxychloride, having the formula $CuCl_2{\cdot}3Cu(OH)_2$, and crystallizing in the orthbrhombic system. Its hardness is about 3 and its specific gravity 3.7, while its colour presents various shades of green. Some of the finest crystals have been yielded by the copper-mines of South Australia, especially at Wallaroo. It occurs also, with malachite, at Bembe, near Ambriz, in West Africa. From one of its localities in Chile, Los Remolinos, it was termed Remolinite by Brooke and Miller. Small quantities of atacamite and of the very similar mineral footeite have been found in Arizona.

ATAMUALLPA or **ATABALIPA** (*atahu,* virile, and *allpa,* sweet) (c. 1502–1533), "the last of the Incas" (or Yncas) of Peru, was the favourite son of the Inca Huayna Capac, by Pacchas, the daughter of the conquered sovereign of Quito. His half-brother, Huascar, succeeded Huayna Capac in 1525, for, as Atahuallpa was not descended on both sides from the line of the Incas, Peruvian law considered him illegitimate. His father left him, however, the kingdom of Quito. In 1530 a quarrel arose between them over the suzerainty of an interjacent province. Civil war broke out, and in 1532, about the time that the Spanish

conqueror, Pizarro, was beginning his march inland from the coast, Huascar had been defeated and thrown into prison, and Atahuallpa had become Inca. Pizarro set out from San Miguel in Sept. 1532 enroute to Caxamarca, a favourite resort of the Incas, where Atahuallpa had his headquarters. Messengers passed frequently between them, and the Spaniards on their march were hospitably received by the inhabitants. On Nov. 15 Pizarro entered Caxamarca and sent his brother Hernando and Hernando de Soto to request an interview with the Inca. On the evening of the following day Atahuallpa entered the great square of Caxamarca, escorted by 3,000 or 4,000 of his followers, who were either unarmed or carried only short clubs and slings concealed under their garments. Pizarro's artillery and soldiers were strategically arranged in the buildings and streets opening on to the square. The interview was carried on by the priest, Vicente de Valerde, through an interpreter. He stated briefly and dogmatically the history and tenets of the Christian faith and the Roman Catholic policy, and called upon Atahuallpa to become a Christian and to acknowledge Charles V. as his master. To this extraordinary harangue the Inca pointed out to him vehemently certain difficulties in the Christian religion, acknowledged the obvious greatness of the emperor, and declined to accept either Christianity or Spanish sovereignty. He then took the Bible from the priest's hands, looked at it, and flung it resentfully to the ground. The priest retired to give an account of the interview to Pizarro, and Pizarro immediately gave the prearranged signal for attack. The Spaniards rushed out from all sides, and the Peruvians, astonished and defenceless, were cut down in hundreds. Pizarro himself seized the Inca, and in endeavouring to preserve his life, received the only wound inflicted that day on a Spaniard. Atahuallpa, thus treacherously captured, offered in ransom the famous roomful of gold and silver. He fulfilled his engagement, the Spaniards received $4,000,000 of bullion; but Pizarro still detained him until reinforcements should arrive. While in captivity Atahuallpa was accused of giving secret orders for the assassination of his brother, Huascar, and also of plotting the overthrow of the Spaniards. In the spring of 1533 (February) Almagro arrived from the coast with more than 150 Spaniards; rumours soon spread through the camp of a vast invasion from Quito; and Pizarro ordered the Inca to be brought to trial on the charges of murder, sedition and idolatry. He was condemned to death, and, as an idolator, to death by fire, an act of treachery which called forth the protest of the most influential of Pizarro's advisers — except the priest Valerde. But Pizarro feared the anger of his soldiery if he retracted, and Atahuallpa, having professed himself a Christian and received baptism, died by strangulation on Aug. 29, 1533. With him died the Peruvian empire.

The standard authority for these events is still Prescott's History *of* the Conquest of *Peru*. Where there is a discrepancy of opinion, he offers comparisons in his voluminous footnotes. (W. B. P.)

ATALANTA, a heroine, probably a by-form of Artemis, variously said to be daughter of Schoeneus of Boeotia or of Iasus and Clymene, of Arcadia. She was a renowned and swift-footed huntress. From her complex legend the following incidents are of interest: (1) She was exposed at birth, as her father wanted a son, but suckled by a she-bear (a beast connected with Artemis). (2) She took part in the Calydonian boar-hunt (see MELEAGER). (3) She offered to marry any one who could outrun her; those who lost were to be killed. Hippomenes (or Meilanion) was given three of the apples of the Hesperides (*q.v.*) by Aphrodite; when he dropped them, Atalanta stopped to pick them up, and so lost the race. Their son was Parthenopaeus, one of the Seven against Thebes. (4) She and her husband, proving ungrateful to Aphrodite, were led to profane a shrine with their loves, for which Cybele turned them into lions.

See Roscher's Lexikon, s.v.

ATARGATIS, a Syrian deity, known to the Greeks by a shortened form of the name, Derketo, and as Dea Syria, or in one word Deasura (Lucian, de Dea *Syria).* She is generally described as the "fish-goddess." The name is a compound of two divine names; the first part is the equivalent of the Phoenician Astarte (*q.v.*), the second is a Palmyrene name *'Athe* (?*tempus opportunum*). The home of the goddess was unquestionably Syria, especially Hierapolis (*q.v.*), where she had a great temple. From Syria her worship extended to Greece, Italy and the farthest west. The wide extension of the cult is attributable largely to Syrian merchants; whence we find traces of it in the great seaport towns.

Atargatis appears generally as the wife of Hadad (*q.v.*). They are the protecting deities of the community. She becomes ultimately a great Nature-Goddess, analogous to Cybele and Rhea (see GREAT MOTHER OF THE GODS); in one aspect she typifies the function of water in producing life; in another, the universal mother-earth (Macrobius, Saturn, i. 23); in a third (influenced, no doubt, by Chaldaean astrology), the power of destiny. The legends are numerous and of an astrological character.

ATATURK, KEMAL: see MUSTAFA KEMAL.

ATAULPHUS (the Latinized form of the Gothic Ataulf, "Father-wolf," from atta, father, and *vulfs,* wolf; Mod. Ger. Adolf, Latinized as Adolphus, the form used by Gibbon for the subject of this article), king of the Goths (d. 415). On the death of Alaric (*q.v.*) his followers acclaimed his brother-in-law, Ataulphus, as king. In 412 he quitted Italy and led his army across the Alps into Gaul. Here he fought against some of the usurpers who threatened the throne of Honorius; he made some sort of compact with that emperor and, in 414, married his sister, Placidia, who had been since the siege of Rome a captive in the camp of the Goths. The ex-emperor Attalus danced at the marriage festival, which was celebrated with great pomp at Narbonne. In 415 Ataulphus crossed the Pyrenees into Spain and died at Barcelona, being assassinated by a groom. The most important fact in his history is his confession, recorded by Orosius, that he saw the inability of his countrymen to rear a civilized or abiding kingdom, and that consequently his aim should be to build on Roman foundations and blend the two nations into one.

ATAVISM, sometimes called reversion, the term given in biology to the reproduction in a living person or animal of characteristics of an ancestor more remote than its parents (see HEREDITY). Loosely used, it connotes a reversion to an earlier type. Individuals reproduce unexpectedly the traits of earlier ancestors, and ethnologists and criminologists frequently explain by "atavism" the occurrence of degenerate species of man; but the subject is complicated by other possible explanations of such phenomena. Many cases of atavism or reversion have been satisfactorily explained as due to recombination of Mendelian iactors; and others are undoubtedly the result of arrested development (see EMBRYOLOGY).

ATAXIA, LOCOMOTOR: see LOCOMOTOR ATAXIA.

ATBARA RIVER. The last tributary of the Nile is the Atbara, which joins it 40 km. upstream of Berber. after a total course of about 1,266 kilometres. It rises as the Takazze in the Lasta hills, close to the eastern escarpment of Abyssinia, and rapidly deepens its valley into a steep-sided ravine deeply cut into the basalt plateau until only 16 km. from its source it is flowing in a ravine 600 metres deep; at some 50 km. E. of the mountains of Debra Tabor it turns northwards, being joined by numerous tributaries, some of which are large streams carrying a considerable volume in the rainy season. In about lat. 13° 12′ N., where the road from Adua to Gondar crosses it, the Takazze turns westwards, and under the name of Setit, joins the Atbara river coming from the south-east to form the main stream of the Atbara at a point 502 km. from the Nile.

Like most of the rivers of Abyssinia, the Takazze is in flood in July and August, being fed by the summer rains of the Abyssinian plateau, but after October it falls rapidly, and from November to May the Takazze is of small depth, while the Atbara sinks to a number of separate pools which afford watering places for the Arabs.

The Takazze begins to rise with the early rains of Abyssinia in May, and early in June the middle reaches of the river are affected. Here at this time, owing to the deficient supply, the permanent water-surface is at most points below the surface of the river bed, except in the deep pools, but as the upper river rises, water flows down and raises this water surface till running water appears again

in the bed of the river. The Atbara is often described as being torrential in character, but this is more true of its tributaries in the upper reaches than of the river itself. Its slope is not excessively high, and when it has risen in flood it flows steadily, the sudden rises and falls which occur being due to its tributaries rising on the Abyssinian tableland, fed by the heavy rains of July and August.

The Atbara flood commences in July, when the average discharge does not exceed 700 cubic metres per second; in August it increases to 2,150 cubic metres per second and falls to about 1,190 cubic metres per second in September; afterwards the river falls rapidly.

The silt brought down to the Nile from Abyssinia by the Atbara during the annual flood may amount to from 10 to 15 million metric tons.

ATBARA, BATTLE OF, April 8, 1898. (See EGYPT: *Sudan Campaigns,* 1896–1900.)

ATCHISON, a city of Kan., U.S.A., 42m. N.W. of Kansas City, on the Missouri river; the county seat of Atchinson county. It is served by the Burlington, the Rock Island, the Santa Fe, and the Missouri Pacific railways. The population was 12,630 in 1920, 13,024 in 1930 and 12,648 in 1940. The surrounding territory is an exceedingly rich agricultural section, and it contains deposits of the loess soil which is especially favourable to fruit growing. The city has three large iron and steel foundries, three flour mills, a plumbing supply house, and garment manufacturing plants.

Atchison stands fifth in manufacturing among cities of Kansas. It is an important wholesale centre for hardware, drugs, groceries, athletic equipment, paint, paper, fruit and candy. At Atchison are St. Benedict's college and Mount Saint Scholastica, each college having an enrolment of about 350 students.

The Atchison Globe founded in 1878 by E.W. Howe and owned and edited by him until 1911, is one of the best known papers in the Middle West. Atchison was founded in 1854 by a group of pro-slavery settlers, and was named after their leader, David R. Atchison, U.S. senator. The town was chartered in 1858

ATCHISON, TOPEKA AND SANTA FE RAILWAY COMPANY. Chartered by the State of Kansas in 1859, to construct and operate a railroad from Atchison on the Missouri to Topeka and in the direction of Santa Fe, N.M., with a grant of land 100 ft. wide along the route, this railroad remained dormant until 1871, when 75 m. of track was built. By the end of 1872, it was completed to the border of the State of Kansas. Subsequently it was continued through Pueblo, Colo., and Santa Fe to the Pacific coast, and east to Chicago. In 1900 an extension to San Francisco was opened, and through trains were run from Chicago to San Francisco. Kansas was covered with a network of lines, which were extended through Oklahoma and Texas to Galveston on the Gulf of Mexico. At Dec. 31, 1939, the mileage operated was 13,444. Net corporate income which in 1875 was $800,000, was $8,502,732 in 1939. The capital account on the latter date was $1,232,087,716. Freight revenue for 1939 was $127,530,776, with a total of 31,053,547 tons of revenue freight carried during the year. Passenger revenue for 1939 was $18,277,823, with 2,595,556 passengers carried. There were on Dec. 31. 1939, 18,693 preferred and 35,110 common shareholders. (E. J. EN.)

ATE, in Greek mythology, the personification of criminal folly or infatuation, the daughter of Zeus or of Eris ("strife"). She even made Zeus take a hasty oath which resulted in Heracles becoming subject to Eurystheus. Zeus thereupon cast her by the hair out of Olympus, after which she remained on earth, working evil and mischief (Iliad, xix. 91). She is followed by the *Litai* ("prayers"), the old and crippled daughters of Zeus, who are able to repair the evil done by her (Iliad, ix. 502). In later times Ate is regarded as the avenger of sin.

ATELLA, ancient Oscan town, Campania. Italy, 9 mi. N. of Naples and 9 mi. S. of Capua. 4 member of the Campanian confederation, it shared the fortunes of Capua, but remained longer faithful to Hannibal, and he transferred the inhabitants to Thurii before the Romans took the town (211) and settled exiles from Nuceria there. The town is famous as the cradle of early Roman comedy, the Atellanae Fabulae (*q.v.*).

ATELLANAE FABULAE, a sort of farce, popular in Republican and early Imperial Rome. The ancients derived the name, probably with justice, from the town Atella in Campania. If this is so, then the farces were of Oscan origin, very likely influenced by the Greek farces of Tarentum and other cities. Strabo (v. 3, 6) even says that in his own day (time of Augustus), although Oscan had died out, farces for performance at religious festivals were still written in it; but this need mean no more than that their language was rustic Latin. According to Livy (vii. 2, 11) they were often acted by amateurs, and to be an actor of *Atellanae* did not, like ordinary acting, involve loss of civic status. In the last century B.C., when a taste arose for farces (exodia) to be played after tragedies, perhaps on the analogy of Greek satyr-plays, Atellanae became a literary genre, and we have some fragments of a writer of them, L. Pomponius of Bononia (Bologna); see Ribbeck, Scaenicae Romanorum *poesis fragmenta;* there are also a few remnants of two or three other authors. We learn, from these and other sources, that there mere four stock characters, Maccus the glutton, Bucco the simpleton, Pappus (Pantaloon), and Dossenus (Punch, a clever, rascally hunchback); that the actors wore masks; that the plot was generally taken from everyday Italian life, but was sometimes para-tragic; and that the language was Latin, with all manner of oddities and extravagances of diction. They finally disappeared, owing to the popularity of the *mimus,* about the time of Tiberius.

See Schanz-Hosius, *Gesch.* der *röm. Literatur,* i. 245–248 (bibl.).

A TEMPO (Ital., in time), in music, a direction to resume the original tempo of a piece after this has been temporarily modified by a *più* lento (more slowly), *più* allegro (faster) or some similar direction.

ATESTE: see ESTE.

ATH, an ancient town in the province of Hainaut, Belgium, on the left bank of the Dender. Pop. (1930) 10,606. The fortress was dismantled after 1858 and its ramparts superseded by boulevards. The fine church of St. Julien (14th century) was destroyed by fire in 1817 (since rebuilt). A tower (Tour Burbant) forming part of the *donjon* of the fortress erected by Baldwin IV., count of Hainaut, about 1150, is thus the sole mediaeval relic. Ath is famous for its gild of archers; and the town militia has the privilege of being armed with bows and crossbows. Ath is also well known for its annual fête called le jour de *ducasse*—ducasse being the Walloon word for kermesse (*fête*)—held on the fourth Sunday in August. A procession escorting figures of two giants—Goliath, called locally Goyasse, and Samson, forms the chief feature of the celebration.

ATHABASCA or **ELK,** a river and lake of the province of Alberta, Canada. The river rises in the Rocky mountains near the Yellowhead pass in 52° 10′ N. and 117° 10′ W., and flows northeast as far as Athabasca landing, and thence north into Lake Athabasca. It is 740m. long and has a number of important tributaries, including the McLeod, Pembina, Lesser Slave, which drains the lake of that name, and Clearwater. Athabasca lake is 195m. long, west to east, from 20 to 32m. wide, has an area of 3,085 sq.m., and is 690ft. above the sea. It discharges its waters northward by Slave river and the Mackenzie system to the Arctic ocean. The Athabasca is navigable, with minor rapids, to Grand Rapids, where navigation is interrupted as far as Fort McMurray; thence to Athabasca lake it flows slowly and is suitable for river steamers.

ATHABASCAN, a linguistic family of North American Indians, one of the most widely spread on the continent, and also known as Dene or Tinneh. The Athabascan languages are sharply characterized and seem fairly conservative; at any rate they differ relatively little from one another, even where widely separated and therefore presumably long divergent. The culture of the Athabascan groups, however, conforms rather closely to that of the non-Athabascan tribes of the same areas; and to some extent the same is true of physique, although the majority of divisions belong to a broad-headed, tall type widely spread in northwestern North America and sometimes called the Athabascan type. The Athabascan peoples fall into three geographical divisions—the northern, south-western and Pacific coast.

The northern division occupied the Yukon and Mackenzie drainages and the head of the basin of the Frazer; in other words, the whole interior of Canada and Alaska north-west of Churchill river. In this vast stretch fronting on Hudson bay and the Arctic and Pacific, the Athabascans were resident on salt water at only one point—Cook inlet in Alaska. The culture was relatively uniform over the area, being wholly without agriculture and primarily dependent on either caribou or moose and deer hunting. Huts and vessels were prevailingly of skins or bark. clothing of dressed skins or fur cut and pieced to fit the body, society mainly non-exogamic, ritual of the simplest, life carried on in small bands without political coherence. The principal tribal groups in this division were: Khotana on the lower Yukon and Cook inlet; Kutchin, including the Loucheux, on the middle Yukon and east toward the lower Mackenzie; Ahtena, on Copper river; the Yellowknife, Dogrib, Slavey, Chipewyan, Hare and Beaver in Mackenzie drainage and eastward; to the south, in the plains. the Sarsi, neighbours of the Blackfeet and culturally assimilated to them; Nahane, including Tahltan, upper Yukon; Sekani, upper Frazer and Peace rivers; thence south in British Columbia to latitude 51°, the Babine, Carrier or Takulli and Chilcotin. In southern British Columbia, Washington and Oregon were three small Athabascan tribes or bands, now extinct, leading on the map like stepping stones to the Pacific division. The total population of this area covering a sixth of the continent perhaps did not exceed 30,000.

The Pacific coast division extended not quite continuously from Umpqua river in Oregon to the head of the Eel in California, with sea frontage of about half the total stretch of 300m. occupied. The Oregon groups are not well known, but included the Umpqua, Coquille, Chastacosta, Tututni, Chetco; the California ones were, from north to south, the Tolowa, Chilula, Hupa, Whilkut, Nongatl, Mattole, Lassik, Sinkyone, Wailaki, Kato. These were groups each speaking a fairly uniform dialect, not politically organized tribes. The population has been estimated at 7,000 for the California groups, was probably about the same in Oregon, and did not exceed 20,000 for the division.

The South-western division comprised the Navaho and Apache (including Lipan) in Arizona, New Mexico, Texas, Chihuahua, and Coahuila. These tribes are separately described. They now number about 30,000 souls, largely due to an apparent increase of the Navaho in the last two generations as they have been at peace and pastoral. A few hundred Athabascans attached to the Kiowa of the plains and known as Kiowa Apache are said to be of northern origin, but may have been an Apache band in origin.

No Athabascan tribe is known to have attained a degree of cultural advancement equal to that of the most advanced tribes of its area, with the possible exception of the Hupa in north-west California. Nowhere have Athabascans achieved notable national or political solidarity. They are, however, in general, hardy, and some of the south-western bands were long the terrors of their white and Indian neighbours.

Sapir has united the Athabascan languages with Tlingit and Haida into a larger Na-Dene family, which is contested by others; and according to report, not yet substantiated by evidence, he connects the Na-Dene group genetically with the Sino-Tibetan languages.

See Samuel Hearne, *Journey* (1795); *E.* Petitot, several works (1876–93); A. G. Morice, *Trans. Can. Inst.* (1889 *seq.*, and elsewhere); P. E. Goddard, *Univ. Calif.* Pub. *Am. Arch. Ethn.* (1904 seq.), *Am. Mus. Nat. Hist. Anthr. Pap.*, vols. viii., x. (1911–17); W. Matthews, *Bur. Am. Ethn. Rep.*, ii., iii., v. (1883–87), *Navaho Legends* (1897), *Am. Mus. Nat. Hist.* Mem. (1902); Franciscan Fathers of St. Michaels, Ariz., *An Ethnologic Dictionary of the Navaho Language* (1910). (A. L. K.)

ATHALARIC (516–534), king of the Ostrogoths, grandson of Theodoric, became king of the Ostrogoths in Italy on his grandfather's death (526). As he was only ten years old, the regency was assumed by his mother, Amalasuntha (*q.v.*). He died on Oct. 2, 534.

ATHALIAH, the daughter of Ahab, and wife of Jehoram, king of Judah. After the death of Ahaziah, her son, she usurped the throne and reigned for six years. She massacred all the members of the royal house of Judah (2 Kings xi. 1–3). The sole survivor, Joash, was concealed in the temple by his aunt, Jehosheba, wife of the priest, Jehoida. These organized a successful revolution in favour of Joash (2 Kings xi., 2 Chron. xxii. 10–12, xxiii., xxiv. 7). The story of Athaliah forms the subject of one of Racine's best tragedies.

ATHAMAS in Greek mythology, king of the Minyae in Orchomenus. His first wife was Nephele (see ARGONAUTS). Athamas and his second wife Ino incurred the wrath of Hera, because Ino had nursed Dionysus. Athamas went mad, and slew one of his sons, Learchus; Ino, to escape, threw herself into the sea with her other son Melicertes. Both were afterwards worshipped as marine divinities, Ino as Leucothea, Melicertes as Palaemon. Athamas, with the guilt of his son's murder upon him, was obliged to flee from Boeotia. He was ordered by the oracle to settle in a place where he should receive hospitality from wild beasts. This he found at Phthiotis in Thessaly, where he surprised some wolves eating sheep; on his approach they fled, leaving him the bones. (Apollodorus i.. 80–84; Hyginus, Fab. 1–5; Ovid, *Metam.* iv. 416. *Fasti,* vi. 485; Valerius Flaccus, i. 277; Schol. on Apoll. Rhodius. ii. 513.) The legend is probably founded on a very old custom of human sacrifice amongst the Minyae.

ATHANAGILD became king of the Visigoths (in Spain) in 534, having invoked the aid of the emperor Justinian for his revolt against his predecessor Agila.

He is chiefly remembered for the tragic fortunes of his daughters Brunechildis and Gavleswintha, who married two Frankish brother kings, Sigebert and Chilperic. Athanagild died in 547.

ATHANARIC (d. 381), a ruler of the Visigoths from about 366 to 380. He bore the title not of king but of judge, a title which may be compared with that of ealdorman among the Anglo-Saxon invaders of Britain. Athanaric waged an unsuccessful war with the emperor Valens (367 to 369), and the peace by which the war was ended was ratified by the Roman and Gothic rulers meeting on a barge in mid-stream of the Danube. Athanaric was a harsh and obstinate heathen, and his short reign was chiefly famous for his brutal persecution of his Christian fellow-countrymen. In 376 he was utterly defeated by the Huns, who a few years before had burst into Europe. Athanaric seems to have fled into Transylvania. Being attacked there by two Ostrogothic chiefs he sought, in 381, the protection of Theodosius I. at Constantinople, where he died a fortnight later.

ATHANASIUS "THE GREAT," saint and bishop of Alexandria, was born about 298, probably at Alexandria. He received a liberal education. From early years he was instructed in the Scriptures, that is the Septuagint and New Testament. He knew no Hebrew. These studies, combined with Greek learning, moulded his later thought. In mind and outlook he was a thorough Greek. There was nothing of the native Egyptian about him. As a lad, he attracted the attention of the bishop, Alexander, and was taken into his household. At some period he also came under the influence of St. Antony. His first literary work, comprising the "Contra Gentes" and "De Incarnatione Verbi," two parts of what is really one treatise, may be dated with tolerable certainty before 318, since it is entirely silent on the Arian controversy. It is an amazing production for a youth barely out of his teens. It shows more of the influence of Origen and Alexandrine thought than his later works, but in asserting man's need of redemption and the meeting of that need through the Incarnation, establishes once and for all the gospel for which he battled throughout his life.

Alexander had inherited from his predecessor the disorders caused by the schismatic ordinations of Meletius (*q.v.*), bishop of Lycopolis, who had intruded himself during the persecution into the diocese. To these in 319 were added the dissensions caused by the teaching of Arius. Arius taught that the Son of God was a created being. There was a time when He did not exist. He was, indeed, the first born of all creatures and surpassed them in dignity. Through Him all other creatures were made. But He could only be called divine in a limited and secondary

sense. Arius also denied the full humanity of Christ. He held that this semi-divine being only took a body through which He acted. The Council of Nicaea were forced to employ some technical term, not in Scripture, to rule out such teaching which contradicted the sense of Scripture. Thus they added to the Creed the test word *homo-ousios* that is "of one essence" or "substance." There is nothing materialistic about it in Greek. All that it asserts is that whatever the essential being of God is, namely divinity, the Father and the Son possess it equally. They also affirmed that the Son was "of the *ousia* or 'essential being,' of the Father," that is, He was not created out of nothing, He existed eternally. The question of the full humanity of Christ came into full prominence only at a later stage. (See ARIUS.) In 321 Alexander sent out his first encyclical letter defending the deposition of Arius by an Egyptian Synod. In this it is reasonable to trace the hand of Athanasius, now a deacon and the bishop's secretary. As such, he accompanied Alexander to Nicaea. He states that he himself spoke in the council, perhaps at unofficial debates, but we must not assign to him too large a part in the proceedings. As a deacon, he was not a member of the council. But his influence was such that the Arians soon came to recognize in him their most formidable antagonist. Alexander returned to his see and, five months after concluding negotiations with the Meletians, died. He had nominated Athanasius as his successor. In June 328 he was canonically elected, in spite of opposition from Meletians and Arians. The cry of the people "Give us Athanasius, the good, one of the ascetics" attest his popularity.

For seven years he occupied his see, devoting himself to the work of his diocese and visiting the monks in the desert. He was rewarded by the solid loyalty shown to him in his later troubles. Meanwhile the reaction against Nicaea was being fostered. It was assisted by Constantine's attempt to enforce unity by persecution, against which Athanasius protested. The policy of Eusebius of Nicomedia was to attack first the Nicene leaders. Eustathius of Antioch and others were deposed on various charges. Trouble was stirred up in Egypt. The Meletians were encouraged to make common cause with the Arians. Athanasius himself was embroiled with the emperor by refusing to admit Arius to communion. A whole series of charges were brought against him, which he had no difficulty in refuting at an audience with Constantine. But the attack was not abandoned. Constantine forced him to attend a Synod at Tyre in 335, which was resolved to condemn him. A commission was sent to Egypt to collect more evidence. Meanwhile Athanasius fled and appealed to Constantine in person. The Synod deposed him, but Constantine summoned the leaders to court. A new charge was now preferred, that he had threatened to stop the export of corn from Alexandria to Constantinople. Possibly the emperor feared his great influence. If so, it must have been due to his dominating personality. The patriarch of Alexandria had not yet had time to acquire the political importance that he later enjoyed, though the development of this was doubtless forwarded by the prominence of Athanasius. More probably the emperor regarded him as intransigent, and as an obstacle to that peace in Church and State on which his heart was set. He was banished unheard to Trier.

Constantine died a year and a half later. At once Athanasius returned, ignoring, perhaps unwisely, the sentence of deposition passed at Tyre. This gave his enemies excuse for declaring the see vacant, and filling it with an Arianiser. Of the sons of Constantine, Constantine II. and Constans were on the side of the Nicenes, Constantius to whom was allotted the East was an Arianiser. After several efforts the enemies of Athanasius succeeded in installing an Arian Gregory in the see of Alexandria by force of arms, with the consent of Constantius. Athanasius fled to Rome, where in the autumn of 340 Pope Julius held a council of Western bishops which acquitted him. He followed it by a sharp remonstrance to the bishops of the East. In spite of this, at the Dedication Council of Antioch in 341 the deposition of Athanasius was confirmed. This council marks a change of policy. Not only are the Nicene leaders to be attacked, but an effort is to be made to find a new and vaguer formulary to be substituted for that of Nicaea.

In 343 a new general council was held at Sardica, at the instigation of Constans. Constantius was too embarrassed by the Persian wars to refuse. Athanasius was vindicated, but the general result was only, by emphasizing religious differences, to deepen the political breach between East and West. In 346 Constans compelled his brother Constantius to act on the decision and restore Athanasius. So began "the golden decade" of his episcopal rule. But the East was still critical of Nicaea. In 350 Constans was murdered by the troops of the usurper Magnentius, who sent officers to seek the support of Athanasius, a singular proof of his influence in Egypt. Athanasius refused to entertain such overtures, but they formed a ground of accusation against him after the defeat of Magnentius by Constantius. When in 351 Constantius became sole emperor, the Arianisers had their chance. A council at Sirmium issued a new creed, orthodox as far as it went, but in practical effect anti-Nicene. Under pressure from Constantius the West was compelled to condemn Athanasius. Synods at Arles in 353 and Milan in 355 were forced by the most violent methods to consent to his deposition. This mas clinched by the exile of his friends, including Pope Liberius. Finally, in 356 he himself was attacked by imperial troops, but escaped to the desert.

For six years he was lost to sight, but his influence was never greater. He produced a stream of anti-Arian writings, including the three orations against the Arians. He watched the anti-Nicene party fall to pieces in the hour of its triumph. At the one extreme were the Anomoeans, so called because they taught that the Son was unlike (ἀνόμοιος) the Father. This teaching was only the honest assertion of what Arius had really believed. In the middle came the Homoeans, who wished by using the vague phrase that the Son was like (ὅμοιος) the Father to evade the real issue and include as many as possible in a State Church. They were pre-eminently the court party, who were content to subordinate religion to the requirements of the State. At the other end were the so-called Semi-Arians, whose formula was *homoi-ousios,* of like essence or substance. They were for the most part really orthodox, but had scruples about the Nicene "of one substance." It must be admitted the Nicene word was of dubious meaning. The term *ousia* might mean either a particular entity, or the common element shared by a class of particulars. Thus to say that the Son was "of one *ousia*" with the Father might be held to mean they were both only modes or aspects of the one God, a heresy which is technically called Sabellianism, after Sabellius who taught it. It is probable that the heretic Paul of Samosata had used the term to assert that God was unipersonal and that the term itself had been condemned in this sense. Marcellus of Ancyra, the ally of Athanasius used it in his teaching that the Logos had no eternal personal existence. It is true that in the Creed of Nicaea the distinct existence of the Son was guarded by the further phrase "of the essence of the Father," but the hesitations of the more old-fashioned theologians of the school of Origen can be explained. The weakness of the phrase *homoi-ousios* was that it was equally unscriptural, and did not by itself safeguard the full divinity of the Son, but Athanasius was prepared to accept it as an alternative with certain additions to strengthen it and to show that it meant more than that the Son was vaguely like the Father. The popular idea that the controversy between Catholics and Arians was simply "over a diphthong" ignores the complexity of the problem and the variety of shades of opinion.

Athanasius grasped the situation. The Semi-Arians received a shock by a creed put out by the Anomoeans at Sirmium in 357, commonly called the "Blasphemy." They were out-manoeuvred by the Homoeans at the Synods of Ariminum and Seleucia in 359. Then Athanasius produced his "De Synodis" exposing the hollowness of the Homoean position and appealing to the Semi-Arians to support the *homo-ousion* as the one safeguard against Arianism. Though the appeal failed at the moment it bore fruit later.

Constantius died in 361. Julian recalled the exiles. Athanasius was able to return for eight months. He used his time well. In 362 he summoned a council at Alexandria which had results out

of all proportion to its size and advanced the cause of reunion with the Semi-Arians. As we saw, the term ousia was ambiguous. It might mean either a particular being or a common essence. The same ambiguity belonged to the term hypostasis, though it inclined to the meaning of a particular entity. In the anathemas appended to the Creed of Nicaea *ousia* and hypostasis were employed as synonyms. This increased the suspicion of the East that the term *homo-ousios* really excluded any real distinctions in the Godhead. On the other hand writers who used the term hypostasis in the sense of "Person," to mark the distinctions in the Godhead seemed to those who used it in the other sense to be speaking of three gods. Athanasius saw that the dispute was at bottom a matter of the use of terms. In the important *Tomus* ad *Antiochenos* which records the decisions of the council, both uses of hypostasis were recognized and explained, and the term *homo*-ousios was cleared of ambiguity. The way was prepared for the acceptance of the later terminology, "One *ousia*," "*Three Hypos*-tases," corresponding to the Western, "One Substance," "Three Persons."

Julian was acute enough to see in Athanasius the foremost representative of the religion that he hated. He singled him out for persecution, and, in spite of the protests of his flock, forced him to take refuge in the desert. On the accession of Jovian in 363, who treated him with great honour, he returned, but when Valens became emperor of the East in 364, and revived the policy of Constantius, Athanasius was again compelled to withdraw for his fifth exile. After a few months Valens restored him, and for the remaining seven years of his life he was left undisturbed. The welfare of the empire demanded peace in Egypt, and peace in Egypt demanded the presence of Athanasius. Outside Egypt Valens was persecuting Semi-Arians and Nicenes alike. The policy of Athanasius was succeeding. The majority of the Semi-Arians were adopting the formula of Nicaea. Athanasius died in 373, before his cause had conquered. When Valens died in 378, Arianism fell and the cause for which Athanasius had fought proved triumphant.

Athanasius was one of the greatest characters in early church history. He was in the best sense of the term a great ecclesiastic. His aim in life was the highest welfare of the Church. Thus we may see in him the first of the great protagonists of spiritual liberty against the encroachments of the State. Unlike many of his contemporaries, he was no Byzantine. He was a free Greek, with a Greek's loyalty to truth at all costs. Though he had the courage of a martyr, he never courted martyrdom. But under the new conditions that followed the so-called conversion of Constantine, he discerned the peril that threatened the life of the Church, and was prepared to defend its spiritual independence even at the cost of his own life, against the State that threatened to stifle it by its embraces as it had formerly threatened to destroy it by persecution. In the administration of his diocese he won the loyalty of his flock. Though his exegetical writings have almost entirely perished, his letters show the true pastoral spirit. His return from exile was followed by a conspicuous revival both of religion and morality. Nor is our estimate of his character seriously shaken by the papyri recently discovered, one of them a possible autograph of Athanasius. Several of them come from a Meletian source and represent him as instigating outrages by the mob on Meletians, and as tyrannical, shifty and nervous about his own safety. (See W. Idris Bell, Jews and Christians in Egypt.) Those familiar with religious partisan literature will discount much of their animosity. At most they show that Athanasius in his earlier years was at times hard and impatient to his opponents. It was the fault natural to his character, and he had much provocation. And after all he may well have felt that it was a bishop's duty to put down false doctrine and disorder.

From the religious point of view, his supreme achievement was that by his unflinching constancy to the truth, combined with his willingness to tolerate a variety of expression, by his personal holiness and devotion he saved Christianity from compromising its assertion of the two fundamental truths of the unity of God and the divinity of Christ. Arianisrn was but the working out to its logical conclusion of the tendency of much earlier theology to regard the pre-existent Logos as a separate being side by side with the Father, a second and a secondary God. That was polytheism. It is the great strength of Athanasius that he was never the mere theologian. His earliest work the *De Incarnatione* showed that he had grasped the truth that lies at the heart of the Gospel, that man needs redemption. He is not only weak and ignorant, but rebellious. His formal theology in this work may be vague and confused. For the moment he is concerned with an apology for the Christian faith as a whole, not with its details.

The Incarnation meets man's deepest needs because it brings not only illumination but redemption. Only power from outside could deliver him from sin and death. His refusal to accept the Arian Christ rested on the conviction that one who was not fully God could neither reveal God, nor impart Divine life. To worship the Arian Christ would be idolatry. If at Nicaea he supported the homo-ousios it was because there was no other phrase that ruled out the speculations that undermined the truth of redemption. Speaking generally, he has a claim to be placed in the first rank of the great religious reformers, because he recalled Christianity from the barren paths of speculation, into which it had strayed since the time of Origen, to a new sense of the reality of the Gospel. There was a danger that the church might have degenerated into a mere philosophical sect. The Logos doctrine was for him not merely an explanation of the order of the universe, but a principle of salvation. He placed at the centre of Christian life the idea of Christ as eternal Son rather than eternal Word. There is a new awareness in his writings of the underlying hostility between the world and the church. No one has suffered more than Athanasius by being judged from collections of dogmatic utterances, divorced from their context, such as are found in histories of dogma. They can only be rightly studied in conjunction with his pastoral and ascetic writings. At the same time it is wrong to depreciate Athanasius as a thinker. He is rightly styled "The Father of Greek orthodoxy." In his works, though they are all in the strictest sense of the term "occasional writings," we find laid down the lines on which later orthodoxy developed. If his theology lacks the precision and refinement of later Greek thought, it is at least open to discussion whether this may not, in many cases, be a merit rather than a defect. The so-called "Athanasian Creed" is universally admitted to be later than the time of Athanasius.

Much discussion has centred round his use of *homo-ousios*. In spite of his loyalty to Nicaea, he very rarely employs it in his own earlier writings. After his visit to Rome he is less shy of it. We saw the ambiguity of the term resulting from its use in pagan philosophy. The precise meaning that he attached to it can only be gained by a study of his writings. He explicitly disclaims any philosophical use of it. His interest is in the religion of the plain man. The Son is as divine as the Father and therefore can be worshipped without idolatry and bestow Divine life, because it is His to bestow. He was hampered by the fact that he possessed no term to express the distinction of the Persons. Though he did more than any one else to fix the later terminology, yet it is doubtful if the phrase "three *hypostases*" ever occurs in his own writings. His final service to the later theology of the Trinity was that when the question of the divinity of the Holy Spirit emerged towards the close of the Arian controversy, he asserted that the Holy Spirit was homo-ousios with the Father and the Son, and based his assertion on similar grounds. The Spirit could not sanctify, unless He were fully and truly divine. In this teaching he anticipates later theology.[1]

[1] If the above view is correct, the view first put forward by Zahn and accepted in some form by Gwatkin, Harnack and Seeburg that homo-ousios really triumphed in the end as having been silently transformed into *homoi-ousios,* is seen to start from a failure to appreciate its non-technical use by Athanasius. The theory is vigorously combated by Bethune-Baker, Texts and Studies, vol. vii., who, however, fails to recognize a certain development in the outlook of Athanasius. Duchesne's verdict The Early History of the Church (vol. ii. E.T. p. 281) is a fair statement of the case. "The Nicene term was in no way ousted. . . . But the idea which the *homoi-ousios* accentuated was admitted, under another formula—that of the three hypostaser—as a useiul and even necessary explanation of the *homo-ousios*."

So too in Christology Athanasius is the precursor of later Greek thought. The accusation that he was an Apollinarian has recently been brought against him. It is true that in his earlier writings he uses language that, if it is pressed, might be taken to support Apollinarianism.[1] But he is not using it in any technical sense. It is indeed doubtful against whom his letter to Epictetus, and his language in the De Synodis is directed, but his statements make plain that when teaching was brought to his notice that denied the possession of a human mind and soul by Christ, he immediately resisted it with vigour. It is true that he never worked out a theology of the person of Christ and that his interest was centred round His divinity rather than His humanity, but his writings were often quoted in later controversy, and are in full accord with the theology of Chalcedon.

Lastly, in the history of Christian monasticism Athanasius holds an important place. In the East as contrasted with the West monasticism developed in independence of ecclesiastical organization. Its attitude to the church was in large part that of detachment. Hence it is conceivable that in Egypt a schism might have arisen. Hence the friendship of Athanasius with Antony and Pachomius and his reputation for asceticism were of practical importance. He was the first episcopal promoter of monasticism, and was rewarded by the unfailing support of the monks in all his difficulties. He enabled the ascetic spirit to find a home in the Catholic Church. Further, his visit to Rome had an important effect on Western monasticism. Monasteries of some kind existed in Italy, but his arrival gave the first great impulse to monastic life. His life of St. Antony is addressed to the Western monks and had great influence. It is by no means accidental that the champion of the faith of Nicaea should also be the patron of monasticism. He was the enemy of pagan compromise in Christian life no less than in Christian belief.[2]

BIBLIOGRAPHY.—The primary source for the life and teaching of Athanasius is his own writings. They will be found collected in Migne, P. G. xxv–xxviii. These volumes however include much that is not genuine. *The Interpretatio in Symbolum, De Incarnatione Dei Verbi* and *Quod Unus Sit Christus* are universally recognized as Apollinarian works. The De *Trinitate* et *Spiritu Sancto* is also to be rejected. There is a growing consensus of opinion that the two books Against *Apollinarius* and the Fourth Oration against *the Arians* are not the work of Athanasius. The *De Incarnatione Dei Verbi et contra Arianos* is dubious. Several other writings are also either spurious or suspect. An English translation of the most important works together with a life of Athanasius, by Robertson, is published in the *Nicene and Post-Nicene Fathers.* This includes also the Festal Letters, extant mostly only in Syriac. There is a panegyric by Gregory Nazianzen. The ancient ecclesiastical historians add little of value. More important is the *Historia Acephala* translated in Robertson. The best modern account in English, with full references, is to be found in B. J. Kidd, History of the Church, vol. ii. It says, however, little about recent German criticism. For this *see* A. Stuelcken, "Athanasiana" in *Texte und Untersuchungen,* N.F. iv. 4; E. Schwartz Nachrichten *von* der Kgl. *Gesellschaft* der *Wissenschaften zu Göttingen,* 1904, 1905, 1908, 1911. H. M. Gwatkin's *Studies of Arianism* is still important. A full account of the writings of Athanasius will be found in Bardenhewer's *Patrology.* All histories of dogma contain an account of his doctrine, *see* especially those of Harnack, Loofs, Seeburg and Tixeront. (E. J. B.)

ATHARVA VEDA, the 4th and apocryphal Veda of the Aryans, mainly composed of incantations preserved in two recensions, a fifth of it reproduces spells from the *Rig Veda.* For a long period it was not accepted as a canonical Veda.

[1]The charge of Apollinarianism is in part due to the growing conviction that the two Letters against Apollinarianism are not the work of Athanasius. The best statement of the case against his orthodoxy is in Raven's Apollinarianism. But the unfairness of his criticism is rightly censured by P. E. More in Christ the Word, pp. 208 ff. His ally Eustathius of Antioch, explicitly defended the fullness of Christ's human nature. And the disciples of Apollinarius were in no doubt about relation of Athanasius to their master on this point. See Lietzmann, Apollinarius von Laodicea, p. 276. A full discussion of the Christology of Athanasius will be found in E. Weigl, "Untersuchenden zur Christologie des heiligen Athanasius." Forschungen *zur* Christlichen Literatur- *und Dogmengeschichte* vol. xii., though he fails to distinguish between his genuine and spurious writings.

[2]*See* Hannay, *The Spirit and Origin of Christian Monasticism;* von der Goltz, in *Texte* und *Untersuchungen,* vol. xiv. N.F. who vindicates the authenticity of the De Virginitate and shows its importance for the understanding of Athanasius.

See R. C. Dutt, Civilisation of Ancient India (London, 1893); Farquhar, *Outline* of the Religious Literature of India (London, 1920).

ATHEISM is a term of varying application and significance (Gr. ἄθεος, "denying God," "godless," hence disbelief in or denial of God). Its meaning is dependent upon the particular type of "Theism" with which at the moment it is being contrasted.

Yet, as we should expect, there is some connecting link binding these various meanings together; and, for the most part, the connection is pretty easily shown. It is no mere accident that the same word "God" is used of the gods of Polytheism; of the god of Aristotle's *Metaphysics* (the unmoved hfover — not Creator— of the eternal heavens; a Being living, eternal, good; Who is Himself His own sole object of knowledge; Who produces motion passively by being loved, *Met.* 1072^a–3^a; 1074^b–5^a; cf. *Dante,* Paradiso xxiv., 130–2); of the Persons of the Christian Trinity; of the impersonal Absolute of modern philosophy (which unites within it all reality and all values). It is in the conception of "goodness" that the connecting link is found. Religion may in its origin be something very different from morality. It may be true (see R. Otto's The Idea of the Holy, Eng. trans., pp. 6, 14, 15) that "religious awe" "first begins to stir in the feeling of something uncanny, eerie or weird"; and the lines between "fear," "dread," "awe" and "reverence" may be hard to draw. Yet it dawns early upon the religious mind that the only worthy object of dread is that which is entitled to moral reverence (Isa. VIII. 13). The atheist therefore is conceived as the man who denies or despises what he ought not only to fear but to respect. It is intelligible, then, that the early Christians should be called "atheists" by their persecutors. The Christians denied, after all, many more gods than they acknowledged. The Pagan was morally offended at this wholesale rejection of familiar loyalties. It is equally intelligible that the Christians should retort the phrase (Martyrium *S.* Polycarpi, c. iii c. ix) on those who "blasphemed that worthy name by which they were called." For behind this sharp division of opinion lay a very real community of moral standard. Paganism had enough connection with morality to make it quite natural that Plato (*Politicus* 308 E) should speak of "godlessness" side by side with "insolence" and "injustice," and should contrast it with what leads to virtue (*cf.* Sophocles *Oed. Rex.,* 861; Xenophon *Mem.,* IV, 4).

Thus the profound saying of Feuerbach—"He alone is the true atheist to whom the *predicates* of the Divine Being, for example, love, wisdom and justice, are nothing; not he to whom merely the subject of these predicates is nothing" (Essence of Christianity trans., Evans, p. 21)—only brings to light what is implicit in the common usage. It is the explicit recognition of this truth which is characteristically modern. We are disposed to recognize today that a truly religious frame of mind (as the Kantian "awe of duty," such a "reverence" for the moral law as makes Kant "humble himself" before it) and further even an attitude of worship towards Christ, (as is implied when Baudelaire speaks of Jesus as Des *Dieux le plus* incontestable: *Les Fleurs* du *Mal* cxxviii), are compatible with a denial, or at least a doubt, of the ordinary theistic beliefs.

Yet even though we take Feuerbach's saying as giving the key to the true meaning of "Atheism" and so regard religion even in its humbler forms as a craving for the good (Odyssey III, 48), we must recognize that, side by side with the reverence for the Good as an Ideal—for the Divine "predicates"—there grows up in religion a belief in the realization of this ideal in the Universe, and commonly in its realization in a personal Being. So closely are these two elements connected that for many minds the rejection of the latter seems equivalent to a rejection of the former. In order to avoid this, and similar confusions, we must continue to recognize a variety of meanings for our term.

Thus Atheism might be defined (1) as a denial that there is any one supreme object of reverence; (2) as a denial that this object of reverence is also the all-inclusive reality ("Belief in a finite God," it has been said, "is not Theism"); (3) as a denial that there is any one all-inclusive reality at all. (For Hegel the atheist is the "pluralist" who acknowledges no ultimate unity. Spinoza, he says, is no atheist but an "acosmist." Of Hegel's principle, that "the Truth is the Whole" yet is also "essentially a result" to which the earlier stages of its development are vital, it is only the second half with which Spinoza seems to Hegel to be out of sympathy. See Logic of *Hegel,* Wallace's trans., pp. 275, 105, 106; Phenomenology, Baillie's trans, p. 17); (4) as a denial that the power which rules the world is worthy of our trust; (5) as a denial that this power is a Being with whom we may hold personal communion. (See C. C. J. Webb's *Gifford* Lectures.) Many modern philosophies might be described as atheistic in one or other of these senses; comparatively few as atheistic in all (*See* THEISM; PANTHEISM; TRINITY; ABSOLUTE). (C. J. SH.)

ATHEL, the name given to the tree *Tamarix aphylla* (*T. articulata*) of the Tamaricaceae. Originally a native of north-

eastern Africa and western Asia, it has since become naturalized in several other parts of the world. It was introduced into arid regions of southwestern United States where it became well established. The tree, which resembles certain conifers, will occasionally attain a height of 60 ft. and is readily distinguished by its jointed twigs with minute, ensheathing leaves and small sessile flowers borne in terminal panicles. J. S. Gamble records in his A *Manual* of Indian Timbers that the wood is used for many purposes including ploughs, ornaments, Persian uheels, fuel and charcoal. The bark is rich in tannin. Reproduction is accomplished equally as well by seeds, cuttings, or coppice. (E. S. Hr.)

ATHELM (d. 923), English churchman, is said to have been a monk of Glastonbury before his elevation in 909 to the see of Wells, of which he was the first occupant. In 914 he became archbishop of Canterbury.

ATHELNEY, a slight eminence of small extent in the low level tract about the junction of the rivers Tone and Parrett in Somersetshire, England. It was formerly isolated by marshes and accessible only by boat or artificial causeway, and under these conditions it gained its historical fame as the retreat of King Alfred in 878–879, when he was unable to withstand the incursion of the Danes. After regaining his throne he founded a monastery here in gratitude for the retreat afforded him by the island; no traces of it exist above ground, but remains have been excavated. There was also found here, in 1693, the celebrated Alfred jewel, bearing his name, and preserved in the Ashmolean museum at Oxford. An inscribed pillar commemorating the king was set up in 1801. The name of Athelney signifies the Isle of Princes (Ang. Sax. Aethelingaea). Athelney is a railway station on a branch of the Great Western railway.

ATHENA, the Attic (and Latin) form of the Homeric Athene, also called Pallas Athene, or simply Pallas, one of the most important goddesses in Greek mythology. No satisfactory derivation of the name Athena has been given; the name Pallas has been connected with the Greek *pallakē* ("maiden"). According to the legend, her father Zeus swallowed his wife Metis ("counsel") when she was pregnant with Athena, since he had been warned that his children by her might prove stronger than himself and dethrone him. Hephaestus (or Prometheus) subsequently split open his head with a hatchet, and Athena sprang forth fully armed. (Hesiod, Theogony, 886; Pindar, *Olymp.*, vii. 35.) According to Roscher, the manner of her birth represents the storm-cloud split by lightning; Farnell sees in it an indication that, as the daughter of Metis, Athena was already invested with a mental and moral character. It is probable that her epithet, *Tritogeneia,* originated in Boeotia, whence it was conveyed by colonists to Cyrene and thence to Libya, where there was a river Triton. Here some local divinity, connected with the water and also of a warlike character, was identified by the colonists with their own Athena. The legend of her birth was also associated with several other rivers and lakes of the same name. In any case, it is fairly certain that Tritogeneia means "water-born," although an old interpretation derived it from trifo, a supposed Boeotian word meaning "head."

In Homer Athena already appears as the goddess of .counsel, of war, of female arts and industries, and the protectress of Greek cities. Hence she is called Polias, *Poliouchos,* in many Greek states, and is frequently associated with *Zeus Polieus.* The most celebrated festival of the city-goddess was the Panathenaea at Athens and other places, and as *Panachais* she was protectress of the Achaean League (*q.v.*). At Athens she presided over the phratries or clans, and was known as *Apatouria* and *Phratria,* and sacrifice was offered to her at the festival Apaturia (*q.v.*). Her images, called Palladia (see Palladium), which guarded the heights, represented her with shield uplifted, brandishing her spear to keep off the foe. The cult of Athenia Itonia, whose earliest seat appears to have been among the Thessalians. made its way to Coronea in Boeotia, where her sanctuary was the seat of the Pan-Boeotian confederacy. Peculiar to Arcadia is the title Athena Alea, probably = "warder off of evil," although others explain it as = "warmth," and see in it an allusion to her physical nature as one of the powers of light. Farnell points out that she is certainly looked upon also as being in some way connected with the health-divinities, since in her temple she is grouped with Asclepius and Hygieia (see Hygieia).

She already appears as the goddess of counsel in the Iliad and in Hesiod. The Attic *bouleutai* took the oath by Xthena *Boulaia;* st Sparta she was Agoraia, presiding over the popular assemblies in the market-place; in Arcadia *Mēchanītis,* the discoverer of devices. Her connexion with the trial of Orestes (*q.v.*), the introduction of a milder form of punishment for justifiable homicide, and the institution of the court "at the Palladium" (Sanctuary of Pallas), show the important part played by her in the development of legal ideas.

The protectress of cities was naturally also a goddess of war. As such she appears in Homer and Hesiod and in post-Homeric legend as the slayer of the Gorgon and taking part in the battle of the giants. On numerous monuments she is represented as *Areia,* "the warlike," *Nikēphoros,* "bringer of victory," holding an image of Nikē (*q.v.*) in her outstretched hand. Martial music and the Pyrrhic dance, in which she herself is said to have taken part to commemorate the victory over the giants, and the building of warships were attributed to her. The epithets *Hippia, Chalinītis* ("the bridler"), and *Damasippos* ("horse-taming") usually referred to her as goddess of war-horses, may perhaps be reminiscences of an older religion in which the horse was sacred to her. As a war-goddess, she is the embodiment of prudent and intelligent tactics, entirely different from Ares (*q.v.*), the personification of brute force and rashness.

The goddess of war develops into the goddess of peace and the pursuits connected with it. She is prominent as the promoter of agriculture in Attic legend. The Athenian hero Erechtheus (Erichthonios), originally an earth-god, is her foster-son, with whom she was honoured in the Erechtheum on the Acropolis. Her oldest priestesses, the dew-sisters—Aglauros, *Herse,* Pandrosos—signify the fertilization of the earth by the dew and were probably at one time identified with Athena, who was also known as *Aglauros* and *Pandrosos.* Athena also gave the Athenians the olive-tree, which was supposed to have sprung from the bare soil of the Acropolis, when smitten by her spear, close to the horse (or spring of water) produced by the trident of Poseidon, to which he appealed in support of his claim to the lordship of Athens. She is also connected with Poseidon in the legend of Erechtheus, not as being in any way akin to the former in nature or character, but as indicating the contest between an old and a new religion. This god, whose worship was introduced into Athens at a later date by the Ionian immigrants, was identified with Erechtheus-Erichthonios, and thus was brought into connexion with the goddess, in order to effect a reconciliation of the two cults. Athena was said to have invented the plough, and to have taught men to tame horses and yoke oxen. Various arts were attributed to her—shipbuilding, the goldsmith's craft, fulling, shoemaking and other branches of industry. As early as Homer, she takes especial interest in the occupations of women, she makes Hera's and her own *peplos* (robe), and spinning and weaving are often called "the works of Athena." The custom of offering a beautifully woven *peplos* at the Panathenaic festival is connected with her character as *Ergane,* the goddess of industry. As patroness of the arts, she is associated with Hephaestus and Prometheus, and in Boeotia she was regarded as the inventress of the flute.

As in the case of Aphrodite and Apollo, Roscher deduces all the characteristics of Athena from a single conception—that of the goddess of the storm or the thunder-cloud. There seems, however, little reason for regarding her as a nature-goddess at all, but rather as the presiding divinity of states and cities, of the arts and industries—in short, as the goddess of the whole intellectual side of human life.

Little is known of the ceremonies or festivals which attended her worship, except those at Athens, where the following, among others, were celebrated: (1) the *Skirophoria,* with a procession from the Acropolis to the village of Skiron, in the height of summer, the priests who were to entreat her to keep off the

summer heat walking under a sunshade *(Skiron)* held over them; (2) The *Chalkeia* ("feast of smiths"), at which the birth of Erechtheus and the invention of the plough were celebrated; (3) The *Pluntēria* and *Kalluntēria* (feasts of washing and adorning), at which her ancient wooden image and *peplos* in the Erechtheum and the temple itself were cleaned, with a procession in which bunches of figs (frequently used in lustrations) were carried; (4) *Arrhēphoria,* or *Errēphoria,* perhaps = *Hersēphoria,* "dew-bearing," at which two maidens of noble birth, between seven and 11 years of age, carried certain unknown sacred objects from the temple of Athena on the Acropolis to that of Aphrodite "in the gardens," and returned with certain other objects to the Acropolis. Two other maidens began the weaving of the new *peplos* for the statue of Athena Polias, which was presented to the goddess every year; (5) the *Panathenaea* (*q.v.*) at which the new robes for the image of the goddess were carried through the city, spread like a sail on a mast; (6) Mention should also be made of the Argive ceremony, at which the *xoanon* (ancient wooden statue) of Athena was washed in the river Inachus, a symbol of her purification after the battle with the giants.

The usual attributes of Athena were the helmet, the aegis (*q.v.*), the round shield with the head of Medusa in the centre, the lance, an olive branch, the owl, the cock and the snake. Of these the aegis is probably intended as a battle-charm, like the Gorgon's head on the shield and the faces on the shields of Chinese soldiers; the owl probably represents the form under which she was worshipped in primitive times, and subsequently became her favourite bird (the epithet *Glaukōpis,* meaning "keen-eyed" in Homer, may have originally signified "owl-faced"); the snake, a common companion of the earth-deities, probably refers to her connexion with Erechtheus-Erichthonios. As to artistic representations of the goddess, we have first the rude figure which seems to be a copy of the Palladium; secondly, the still rude but otherwise more interesting figures of her on the early painted vases; and thirdly, the type of her as produced by Pheidias, from which little variation appears to have been made. Of his numerous statues of her, the three most celebrated were set up on the Acropolis. (1) Athena *Parthenos,* in the Parthenon. It was in ivory and gold, and 30 ft. high. She was represented standing, in a long tunic; on her head was a helmet, ornamented with sphinxes and griffins; on her breast was the aegis, fringed with serpents and the Gorgon's head in centre. In her right hand was a Nikē or winged victory, while her left held a spear, which rested on a shield on which were represented the battles of the Amazons with the giants; (2) A colossal statue said to have been formed from the spoils taken at Marathon, the so-called Athena *Promachos;* (3) Athena *Lemnia,* so called because it had been dedicated by the Athenian cleruchies in Lemnos. In this she was represented without arms, as a brilliant type of virgin beauty. The two last statues were of bronze. From the time of Pheidias calm earnestness, self-conscious might, and clearness of intellect, were the main characteristics of the goddess. The eyes, slightly cast down, betoken an attitude of thoughtfulness; the forehead is clear and open; the mouth indicates firmness and resolution. The whole suggests a masculine rather than a feminine form.

From Greece the worship of Athena extended to Magna Graecia, where a number of temples were erected to her in various places. In Italy proper she was identified with Minerva (*q.v.*).

ATHENAEUM, a name originally applied in ancient Greece to buildings dedicated to Athena, and specially used as the designation of a temple in Athens, where poets and men of learning were accustomed to meet and read their productions. The academy for the promotion of learning which the emperor Hadrian built (about *A.D.* 135) at Rome, near the Forum, was also called the Athenaeum. Poets and orators still met and discussed there, but regular courses of instruction were given by a staff of professors in rhetoric, jurisprudence, grammar and philosophy. The institution, later called Schola Romana, continued in high repute till the 5th century. Similar academies were founded in the provinces and at Constantinople by the emperor Theodosius II. In modern times the name has been applied to various academies, as those of Lyons and Marseilles and the Dutch high schools; and it has become a very general designation for literary and scientific clubs, the most famous club of the name being that which was founded in London by Sir Walter Scott and Thomas Moore in 1824. It is also familiar as the title of several literary periodicals, notably of the London literary weekly founded in 1828 by James Silk Buckingham and successfully established by C. W. Dilke. The *Athenaeum* was absorbed by the *Nation* in 1921.

ATHENAEUS, of Naucratis in Egypt, Greek rhetorician and grammarian flourished about the end of the 2nd and the beginning of the 3rd century *A.D.* Suidas only tells us that he lived "in the times of Marcus"; but the contempt with which he speaks of Commodus (died 192) shows that he survived that emperor. Athenaeus himself states that he was the author of a treatise on the *thratta* — *a* kind of fish mentioned by Archippus and other comic poets — and of a history of the Syrian kings, both of which works are lost. We still possess the *Deipnosophistae* ("dinner-table philosophers" or "authorities on banquets") in 15 books. The first two books, and parts of the 3rd, 11th and 15th, are extant only in epitome, but otherwise we seem to possess the work entire.

It is an immense store-house of miscellaneous information, chiefly on matters connected with the table, but also containing remarks on music, songs, dances, games, courtesans. It is full of quotations from writers whose works have not come down to us. It professes to be an account given by the author to his friend Timocrates of a banquet held at the house of Laurentius (or Larentius) a scholar and wealthy patron of art. It is thus a dialogue within a dialogue. The conversation ranges from the dishes before the guests to literary matters of every description, including points of grammar and criticism; and they are expected to bring with them extracts from the poets, which are read aloud and discussed at table. The plan is clumsy, but as a repertory of fragments and morsels of information the work is invaluable for Athenaeus refers to nearly 800 writers.

ATHENAGORAS, a Christian apologist of the 2nd century *A.D.,* was, according to an emendator of the Paris Codex 451 of the 11th century, a native of Athens. The only sources of information regarding him are a short notice by Philip of Side, in Pamphylia *(c.* 420 *A.D.),* and the inscription on his principal work, the *Apology.* The inscription describes the *Apology* as the "Embassy of Athenagoras, the Athenian, a philosopher and a Christian, concerning the Christians, to the Emperors Marcus Aurelius Antoninus and Lucius Aurelius Commodus, etc." The date of the *Apology* (Πρεσβεία περὶ Χριστιανῶν) may be fixed at about 177 *A.D.* Athenagoras also wrote a discourse on the resurrection of the body, which is not authenticated otherwise than by the titles on the various manuscripts. In the *Apology,* he refutes the accusations brought against the Christians of atheism, eating human flesh and licentiousness. The discourse on the resurrection attempts to prove the truth of the doctrine from consideration of God's purpose in the creation of man, His justice and the nature of man himself. Athenagoras is a powerful and clear writer, who strives to comprehend his opponents' views and is acquainted with the classical writers. He used the *Apology* of

Justin, but hardly the works of Aristeides or Tatian. His theology is strongly tinged with Platonism.

BIBLIOGRAPHY.—Editions: J. C. Th. Eg. de Otto, *Corpus Apol.* Christ. Saec., II. vol. vii. (Jena, 1857); E. Schwartz in Texte und Untersuchungen, iv. 2 (Leipzig, **1891**).

Literature: **A.** Harnack, Gesch. der altchr. Litt., pp. 526–58, and similar works by O. Bardenhewer and A. Ehrhard; Herzog-Hauck, Realencyk.; G. Kriiger, Early Chr. Lit., p. 130 (where additional literature is cited). In 1559 and **1612** appeared in French a work on True and Perfect Love, purporting to be a translation from the Greek of Athenagoras; it is a palpable forgery.

ATHENODORUS, the name of two Stoic philosophers of the 1st century B.C., who have frequently been confounded.

(1) ATHENODORUS CANANITES (*c.* 74 B.C.–A.D. 7), so called from his birthplace Canana, near Tarsus, was a friend of Strabo, from whom we derive our knowledge of his life. (See also Cic. Ep. ad. *Att.*, xvi. ii. 4, 14, 4.) He taught the young Octavian (afterwards Augustus) at Apollonia, and was a pupil of Poseidonius at Rhodes. Subsequently he appears to have lectured in the great cities of the Mediterranean. His influence over Augustus was strong and lasting. He followed him to Rome in 44. In later years he was allowed by Augustus to return to Tarsus in order to remodel the constitution of the city. He succeeded (c. 15–10 B.C.) in setting up a timocracy in the imperial interest. Sir W. M. Ramsay is inclined to attribute to the influence of Athenodorus the striking resemblances which can be established between Seneca and Paul, the latter of whom must certainly have been acquainted with his teachings. According to Eusebius and Strabo he was a learned scientist for his day. He helped Cicero in the composition of the De *Officiis.* His works are not certainly known, and none are extant. (See Sir W. M. Ramsay in the *Expositor*, Sept. 1906, p. 268 seq.)

(2) ATHENODORUS CORDYLION, also of Tarsus, was keeper of the library at Pergamum, and was an old man in 47 B.C. He settled in Rome, where he died in the house of the younger Cato.

Among others of the name may be mentioned:

(3) ATHENODORUS OF TEOS, who played the cithara at the wedding of Alexander the Great and Statira at Susa (324 B.C.); (4) a Greek physician of the 1st century A.D., who wrote on epidemic diseases; and two sculptors of whom (5) one executed the statues of Apollo and Zeus which the Spartans dedicated at Delphi after Aegospotami; and (6j the other was a son of Alexander of Rhodes, whom he helped in the Laocoon group.

ATHENRY, county Galway, Eire, 14 mi. inland from Galway on the Great Southern railway. Pop. (1936) 1,048. Its name is derived from the *Ath-na-riogh,* the ford of kings; and it grew to importance after the Anglo-Norman invasion as the first town of the Burgs and Berminghams. There are remains of walls erected in 1211 and a castle of 1238. A Dominican monastery was founded by Myler de Bermingham in 1241, and repaired by the Board of Works in 1893. Of the Franciscan monastery of 1464 little is left. The town returned two members to the Irish parliament from the time of Richard II. to the Union; but it never recovered from the wars of the Tudor period, culminating in a successful siege by Red Hugh O'Donnell in 1596.

ATHENS, the capital of the republic of Greece (Ἀθῆναι, *Athenae,* modern colloquial Greek Ἀθήνα), situated in 23° 44' E. and 37° 58' N., towards the southern end of the central and principal plain of Attica. There are various theories with regard to the origin of the name. It is now held that it is derived from the patron goddess Athene, whose name, like others ending in *-ηνη,* is thought to be pre-Hellenic.

I. TOPOGRAPHY AND ANTIQUITIES

The Attic plain, τὸ πεδίον, slopes gentiy towards the coast of the Saronic gulf on the south-west; on the east it is overlooked by Mt. Hymettus (3,370 ft.); on the northeast by Pentelicus (3,640 ft.) from which, in ancient and modern times, an immense quantity of the finest marble has been quarried; on the northwest by Parnes (4.600 ft.), and on the west by Aegaleus (1,534 ft.), which descends abruptly to the bay of Salamis. In the centre a ridge, perhaps the ancient Anchesmus, but now known as Turcovuni, runs from north-east to south-west and culminates in the sharply pointed Lycabettus (1,112ft.), now called Hagios Georgios from the monastery which crowns its summit. Lycabettus, the most prominent feature in the Athenian landscape, directly overhung the ancient city, but was not included in its walls. This range separates the valleys of the Cephissus and Ilissus. The former, rising in Pentelicus to the north-west, enters the sea at Phalerum, but in summer dwindles to an insignificant stream. The latter, coming from Hymettus, skirts the city on the south-west and is now usually dry owing to denudation caused by the destruction of the forests. This desiccation of Attica was first noticed by Plato. Separated from Lycabettus by a depression to the south-west, through which flows a brook, now a covered drain (probably the Eridanus), stands the remarkable oblong rocky mass of the Acropolis (512ft.), rising precipitously on all sides except the western; close to it on the west is the lower rock of the Areopagus, Ἄρειος πάγος (370 ft.), the seat of the famous council; the name (see also AREOPAGUS) has been connected with Ares, but is more probably derived from the Ἀραί or Eumenides. Farther west are three elevations; to the north-west the so-called "hill of the Nymphs" (341 ft.), on which the modern observatory stands; to the west the Pnyx (351 ft.), and to the south-west the loftier Museum hill (482 ft.). A cavity to the west of the observatory is supposed to be the ancient Barathron or place of execution. The distance from the Acropolis to the nearest point of the sea coast at Phalerum is a little over three miles.

Influence of the Geographical Position.— The situation of Athens naturally favours the growth of a powerful community. For the first requisites of a primitive settlement — food supply and defense — it afforded every advantage. The Attic plain, notwithstanding the lightness of the soil, furnished an adequate supply of cereals; olive and fig groves and vineyards were cultivated from the earliest times, and pasturage for sheep and goats was abundant. The surrounding mountains are broken towards the north-east by an opening between Hymettus and Pentelicus towards Marathon, and are traversed by the passes of Deceleia, Phylē and Daphne on the north and north-west, but the distance between these and the city was sufficient to obviate the danger of surprise by an invading land force. On the other hand Athens, like Corinth, Megara and Argos, was sufficiently far from the sea to enjoy security against the sudden descent of a hostile fleet. Yet the three natural harbours, Peiraeeus, Zea and Munychia, favoured maritime commerce and the sea power which formed the basis of Athenian hegemony. The climate is temperate, but liable to sudden changes; the mean temperature is 63°·1 F, the maximum (in July) 99°·01, the minimum (in January) 31°·55. The summer heat is moderated by the sea-breeze or by cool northerly winds from the mountains (especially in July and August). The clear, bracing air, according to ancient writers, fostered the intellectual and aesthetic character of the people and endowed them with mental and physical energy. For the architectural adornment of the city the finest building material was procurable in abundance; Pentelicus forms a mass of white, blue-veined marble; another variety, somewhat similar in appearance, but generally of a bluer hue, was obtained from Hymettus. For ordinary purposes grey limestone from Lycabettus and the adjoining hills, limestone from the promontory of Actē (the so-called "poros" stone), and conglomerate were largely employed. For the ceramic art admirable material was at hand in the district north-west of the Acropolis. The water supply then, as now, being insufficient for a large and growing city, was supplemented by an aqueduct constructed in the time of the Peisistratids and by others of the Roman period. A great number of wells were also sunk and rain-water was stored in cisterns.

Sources for Athenian Topography.— For the purposes of scientific topography observation of the natural features is followed by exact investigation of the architectural remains, a process demanding high technical competence, acute judgment and practical experience, as well as wide and accurate scholarship. The building material furnishes evidence no less important than the character of the masonry, the design and the modes of ornamentation. The testimony afforded by inscriptions is often of

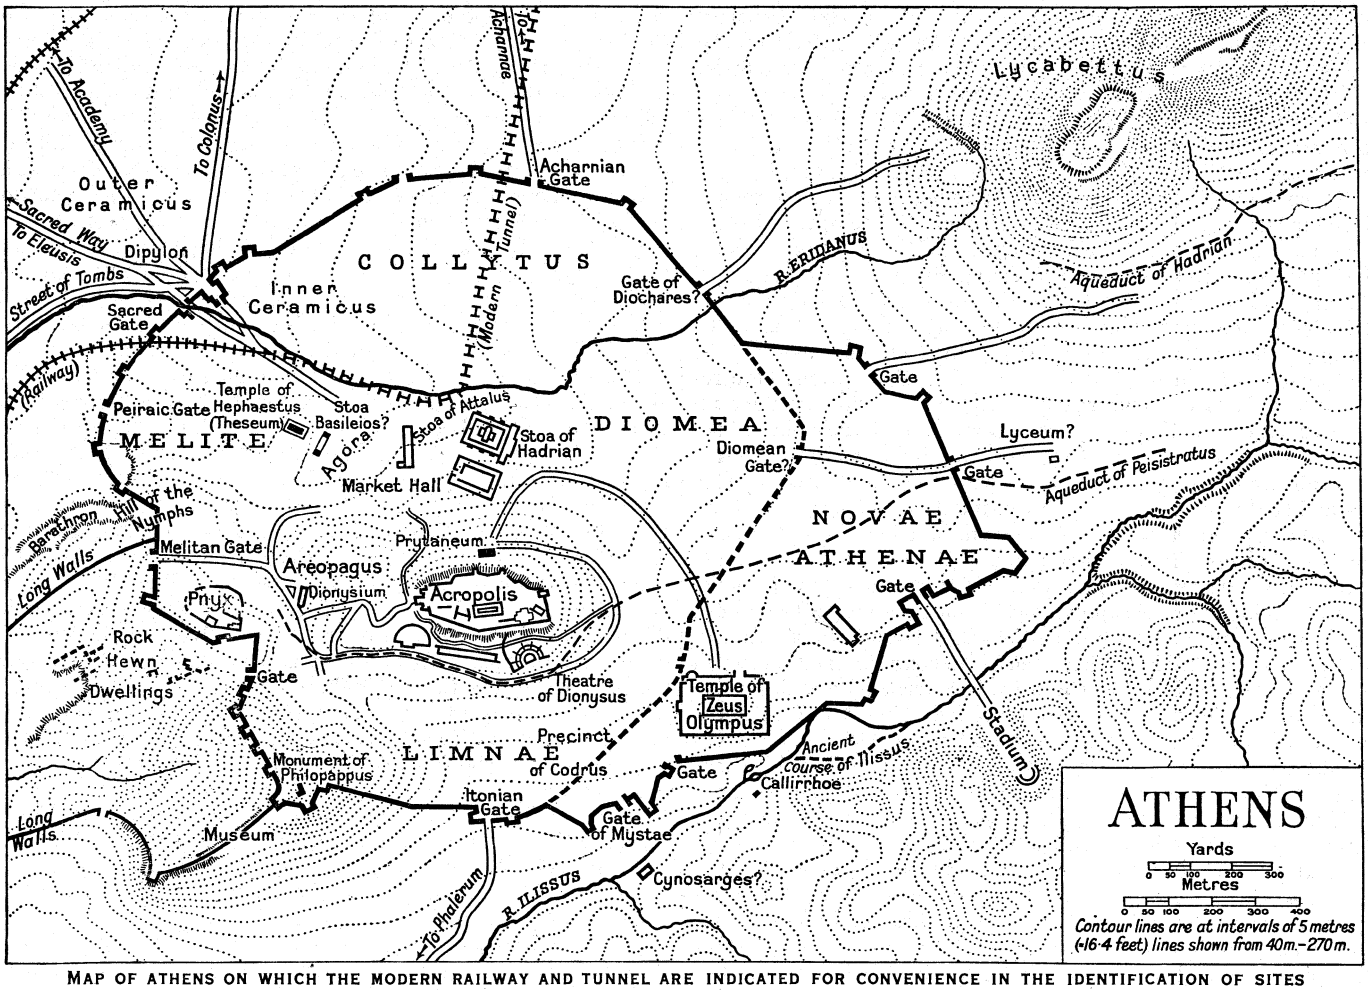
decisive importance. Next comes the evidence derived from ancient literature and specially from descriptions of the city or its different localities. The earliest known description of Athens was that of Diodorus, ὁ περιηγητής, who lived in the second half of the 4th century B.C. Among his successors were Polemon of Ilium (beginning of 2nd century B.C.) whose great κοσμικὴ περιήγησις gave a minute account of the votive offerings on the Acropolis and the tombs on the Sacred Way; and Heliodorus (second half of the 2nd century), who wrote 15 volumes on the monuments of Athens. Of these and other works of the earliest topographers only some fragments remain. In the period between A.D. 143 and 159 Pausaniss visited Athens at a time when the monuments of the great age were still in their perfection and the principal embellishments of the Roman period had already been completed. The first 30 chapters of his invaluable *Description* of *Greece* (περιήγησις τῆς Ἑλλάδος) are devoted to Athens, its ports and environs. His account, drawn up from notes taken in the main from personal observation, possesses an especial importance for topographical research, owing to his method of describing each object in the order in which he saw it during the course of his walks. His accuracy, which has been called in question by some scholars, has been remarkably vindicated by recent excavations at Athens and elsewhere. The literature of succeeding centuries furnishes only isolated references; the more important are found in the scholia on Aristophanes, the lexicons of Hesychius, Photius and others, and the *Etymologicum Magnum.* The notices of Athens during the earlier middle ages are scanty in the extreme. In 1395 Niccolo da Martoni, a pilgrim from the Holy Land, visited Athens and wrote a description of a portion of the city. Of the work of Cyriac of Ancona, written about 1450, only some fragments remain. which are well supplemented by the contemporaneous description of the capable observer known as the "Anonymus of Milan." Two treatises in Greek by unknown writers belong to the same period The Dutchman Johannes Meursius (1579–1639) wrote three disquisitions on Athenian topography. The conquest by Venice in 1687 led to the publication of several works in that city, including the descriptions of De La Rue and Fanelli and the maps of Coronelli and others. The systematic study of Athenian topography was begun in the 17th century by French residents at Athens, the consuls Giraud and Chataignier and the Capuchin monks. The visit of the French physician Jacques Spon and the Englishman, Sir George Wheler or Wheeler (16jo–1723), fortunately took place before the catastrophe of the Parthenon in 1687; Spon's *Voyage d'Italie, de Dalmatie, de Grèce et du Levant,* which contained the first scientific description of the ruins of Athens, appeared in 1678; Wheler's *Journey into Greece,* in 1682. A period of British activity in research followed in the 18th century. The monumental work of James Stuart and Nicholas Revett, who spent three years at Athens (1751–54), marked an epoch in Athenian topography and is still indispensable, owing to the demolition of ancient buildings which began about the middle of the 18th century. To this period also belong the labours of Richard Pococke and Richard Dalton, Richard Chandler, E. D. Clarke and Edward Dodwell. The great work of W. M. Leake (*Topography* of *Athens and the Demi,* 2nd ed., 1841) brought the descriptive literature to an end and inaugurated the period of modern scientific research.

Recent Research. — Recent investigation has thrown a new and unexpected light on the art, the monuments and the topography of the ancient city. Numerous and costly excavations have been carried out by the Greek Government and by native societies, and the six foreign archaeological schools, while accidental discoveries have been frequently made during the building of the modern town. The native archaeologists of the present day hold a recognized position in the scientific world; the patriotic sentiment of former times, which prompted their zeal but occasionally warped their judgment, has been merged in devotion to science for its own sake, and the supervision of excavations, as well as the control of the art-collections, is now in highly competent hands. The supreme importance of a study of Greek antiquities on the spot, long understood by scholars in Europe and in America, has gradually come to be recognized in England, where a close attention to ancient texts, not always adequately supplemented by a course of local study and observation, formerly fostered a peculiarly conservative attitude in regard to the problems of Greek archaeology. Since the foundation of the German Institute in 1874, Athenian topography has to a large extent become a specialty of German scholars, among whom Wilhelm Dorpfeld is distinguished by his architectural attainments and local knowledge. In recent years he has been succeeded by the American B. H. Hill, who has won fame by his researches on the Acropolis.

Prehistoric Athens. — The Acropolis is so well defended by nature and so accessible to the means of life and to the springs at its foot that it was occupied by man from the earliest times. Remains of the neolithic period similar to those from Thessaly and the Greek mainland have been found, and they are succeeded by plentiful traces of bronze age inhabitation. The first and second periods are represented, and in the third the rock was fortified like the citadels of Mycenae and Tiryns. A cyclopean wall runs round the natural edges of the rock and is best preserved at the south-west end behind the temple of *Nike* and at the north-east angle by the Erechtheum. Here there seems to have been an entrance leading perhaps to a "palace" of which traces are seen in two "Mycenaean" column bases in the foundations of the old Athena temple. Other walls assigned to the same date and many fragments of pottery, especially of the last phase of the bronze age, show that Athens, even in prehistoric times, was not insignificant. This is borne out by the Homeric reference to the "strong house of Erechtheus" (Od. vii. 81) and by the numerous traces of the same period throughout Attica. (*See* AEGEAN CIVILIZATION.) Remains of the early iron age are common on the Acropolis and also of the "Dipylon" or "Geometric" period which help to demonstrate that that phase of art was not suddenly introduced by invaders such as the Dorians, who never settled in Attica, but was merely one stage in the evolution of Greek culture, though probably affected by some external influence.

The **Pelasgicum.**—The early fortifications of the Acropolis, sometimes ascribed to the primitive non-Hellenic Pelasgi, must be distinguished from the Pelasgicum or Pelargicum, which was probably a wall, built around the base of the citadel and furnished with nine gates from which it derived the name of *Enneapulon.* Such a wall would protect the clusters of d ellings around the Acropolis as well as its springs, while the gates opening in various directions would give access to the surrounding country. This view, that of E. Curtius, alone harmonizes with the statement of Herodotus (vi. 137) that the wall was "around" (περί) the Acropolis, and that of Thucydides (ii. 17) that it was "beneath" (ὑπό) the fortress. Thus the citadel would have had an outer and an inner line of defense. The space enclosed by the outer wall was left unoccupied after the Persian wars in deference to an oracle. A portion of the outer wall has been recognized in a piece of primitive masonry discovered near the Odeum oi Atticus Herodes. Dorpfeld believes it to have extended from the grotto of Pan to the sacred precinct of Asclepius. It enclosed the spring Clepsydra, beneath the north-western corner of the Acropolis which is approached by a rock-cut staircase, and was once more included in the fortress during the War of Independence by the Greek chief Odysseus.

The **Pnyx.**—On the north-eastern slope of the Pnyx is an immense double terrace (395ft. by 212ft.), the upper part cut in the rock, the lower supported by a semicircular retaining wall of massive masonry. This has been thought to be prehistoric, but excavation has shown that it cannot be older than the 4th century, though there are traces of a yet older wall. The whole area seems to have formed a sanctuary, possibly of Zeus, but there is no reason to reject the opinion that this was the meeting-place of the Athenian assembly. The semicircular retaining wall was probably much higher and supported a large theatre-like structure which sloped down towards the rock-cut terrace. Here a cube of rock (11ft. square, jft. high) projects from the centre of the chord of the semicircle and is approached on each side by a flight of steps. This, which Curtius supposes to have been the primitive altar of Zeus Ὕψιστος may be safely identified with the orators' bema, ὁ λίθος ἐν τῇ Πυκνί (Aristoph. *Pax.* 680). Other cubes of



MAP OF ATHENS ON WHICH THE MODERN RAILWAY AND TUNNEL ARE INDICATED FOR CONVENIENCE IN THE IDENTIFICATION OF SITES

rock, apparently altars, exist in the neighbourhood. The Pnyx was clearly the seat of an ancient cult; the meetings of the Ecclesia were of a religious character and were preceded by a sacrifice to Zeus Ἀγοραῖος.

The Pnyx, the hill of the Nymphs and the Museum hill are covered with vestiges of supposed early settlements which extend towards the south-east in the direction of Phalerum. They consist of chambers, some of which were human habitations, cisterns, channels, seats, steps, terraces and tombs, all cut in the rock. This was held by Curtius to have been the site of the primaeval rock city, κραναὰ πόλις (Aristoph. *Ach.* 75), afterwards abandoned in favour of the Acropolis. This view is not generally accepted. Some of the rock tombs were afterwards converted, under pressure of necessity, into habitations, as in the case of the so-called "prison of Socrates," which consists of three chambers horizontally excavated and a small round apartment.

The **Areopagus.**—The Areopagus is now a bare rock possessing few architectural traces. The seat of the old oligarchical council and court for homicide was probably on its eastern height. Here were the altar of Athena Areia and two stones, the λίθος Ὕβρεως, on which the accuser, and the λίθος Ἀναιδείας, on which the accused, took their stand. Beneath, at the north-eastern corner, is the cleft which formed the sanctuary of the Σεμναί, or Erinyes. It is not certain whether this was the scene of St. Paul's address to the Athenians.

Hellenic Period.- he earliest settlement on the Acropolis was doubtless soon increased by dwellings at its base, which would naturally lie close to the western approach. After the building of the Pelargicum they seem to have extended beyond its walls towards the south and south-west—towards the sea and the Ilissus. The district occupied faced the sun and was sheltered by the Acropolis from northerly winds. The Thesean synoecism led to the foundation of new shrines partly on the Acropolis, partly in the inhabited district at its base both within and without the Pelargicum. Some are mentioned by Thucydides in a passage of capital importance for the topography of the city (ii. 15). By degrees the inhabited area took in the ground to the north-west, the nearer portion of the later Ceramicus, or "potters' field," and eventually extended north and east of the citadel, which, by the 5th century B.C., had become the centre of a circular or wheel-shaped city, πόλιος τροχοειδέος ἄκρα κάρηνα (oracle *apud* Herod. vii. 140). To this enlarged city was applied, about the second half of the 6th century, the special designation τὸ ἄστυ, which afterwards distinguished Athens from its port, Peiraeeus; the Acropolis was already ἡ πόλις (Thucyd. ii. 15). The city is supposed to have had a wall before the time of Solon, the existence of which may be deduced from Thucydides' account of the assassination of Hipparchus (vi. 57), but no certain traces have been discovered.

The Agora.—The centre of commercial and civic life was the agora or market. Here were the various public buildings which. when power was transferred to the archons, formed the offices of the administration. The site of the primitive agora (ἀρχαία hyoph) was perhaps in the hollow between the Acropolis and the Pnyx. Under the Peisistratids the agora was enlarged over the inner Ceramicus on the north-west, apparently reaching the northern declivities of the Areopagus and the Acropolis. After the Persian Wars the northern portion was used for commercial, the southern for political and ceremonial purposes. In the southern were the Orchestra, where the Dionysiac dances took place, and the famous statues of Harmodius and Aristogeiton by Antenor which were carried away by Xerxes; also the *Metroön,* or temple of the Mother of the Gods, the *Bouleuterion,* or council-chamber of the Five Hundred, the Prytaneum, the hearth of the combined communities, where the guests of the State dined, the temple of the Dioscuri, and the Tholos or *Skias,* a circular stone-domed building in which the Prytaneis were maintained at the public expense;

in the northern were the Leocorium, where Hipparchus was slain. the στοὰ βασιλική, the famous στοὰ ποικίλη, where Zeno taught, and other structures. Of all these buildings hardly a trace remains and their positions are largely conjectural.

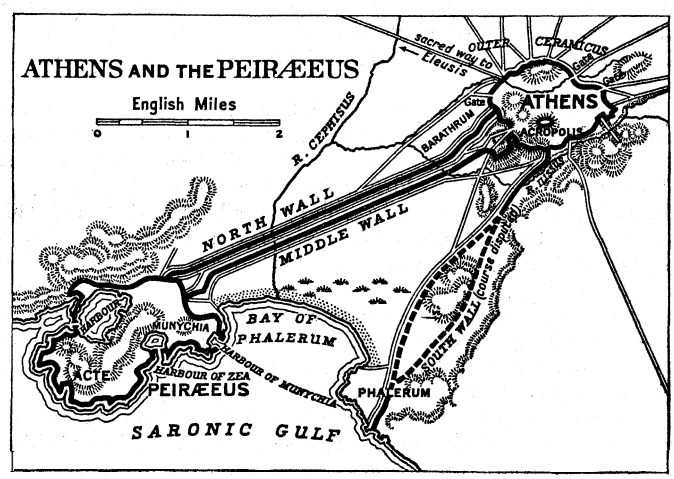
The **Enneacrunus.**—The Enneacrunus fountain has hitherto been generally identified with the spring Callirrhoe in the bed of the Ilissus, south-east of the Olympieum; it is apparently placed by Thucydides (ii. 15) close to that building, as well as the temple of Dionysus ἐν λίμναις and other shrines, the temples of Zeus Olympius and of Ge and the Pythium, which he mentions as situated mainly to the south of the Acropolis. On the other hand, Pausanias (i. 14. 1) mentions the Enneacrunus in his description of buildings undoubtedly in the region of the agora, and unless he is guilty of an unaccountable digression the Enneacrunus which he saw must have lain west of the Acropolis. Excavations here revealed a main road of surprisingly narrow dimensions winding up from the agora to the Acropolis. South-west of the point where the road turns towards the Propylaea was found a large rock-cut reservoir which Dorpfeld identifies with the Enneacrunus. This is supplied by a conduit of 6th-century tiles connected with an early stone aqueduct which runs beneath the Dionysiac theatre and the royal garden in the direction of the upper Ilissus. These waterworks were, according to Dorpfeld, constructed by the Peisistratids to increase the supply from the ancient spring Callirrhoe, which was furnished with nine jets and so known as Enneacrunus. This identification has been hotly contested and must still be regarded as undecided. Close by is a triangular enclosure of polygonal masonry, in which were found relics relating to the worship of Dionysus, a very ancient wine-press (ληνός) and a small temple. Built over this early precinct, which Dorpfeld identifies with the Dionysium ἐν λίμναις, or Lenaeum, is a basilica-shaped building of the Roman period, apparently sacred to Bacchus; in this was found an inscription containing the rules of the society of the Iobacchi. There is an obvious difficulty in assuming that λίμναι, in the sense of "marshes," existed in this area. So Dörpfeld's identification of the Dionysium, ἐν λίμναις cannot be regarded as proved; his view that another Pythium and another Olympieum existed here is still less probable; but this does not necessarily invalidate his identification of the Enneacrunus. The whole district was found to have been thickly built over; the mean dwelling-houses and crooked lanes confirm an ancient topographer's picture of the contrast between the modest private residences and the great public structures of the ancient city.

The Acropolis Before the Persian Wars.—The age of the Peisistratids (560–511 B.C.,) marked an era in the history of Athenian topography. In addition to the temple of Olympian Zeus and the Enneacrunus, they laid out the Academy and perhaps the Lyceum. The famous seat of the Platonic philosophy was a gymnasium enlarged as a public park by Cimon; it lay about a mile to the north-west of the Dipylon gate. The Lyceum, where Aristotle taught, was originally a sanctuary of Apollo Lyceius. It also contained a gymnasium and garden and lay to the east of the city beyond the Diocharean gate.

Little was known of the buildings on the Acropolis in the pre-Persian period till the Greek excavations under Kawadias from 1885 onwards. Then much of the débris of the sculpture and architecture ruined by the Persians was unearthed—a splendid series of archaic statues of maidens with the original colours still fresh, fragments of Attic vases from the ateliers of famous potters, bronzes and terra-cottas. Some fragmentary pedimental groups sculptured in soft limestone and highly painted are important as giving clues for the existence of early shrines. Attempts have been made to identify these as the Pandroseum, old Erechtheum and a small temple which would have stood on the site of the Parthenon, and have had one end apsidal like the old temple at Thermum, but none of the suggestions made are generally accepted. The most important discovery perhaps was that of the old Athena temple which stands on the supposed "House of Erechtheus," perhaps a palace shrine and the seat of the primitive cult of Athena.

This, the ancient Hecalompedon, is identified with an early temple, 100ft. long, the foundations of which immediately adjoin the south side of the Erechtheum. The foundations belong to the 7th century, except those of the colonnade, probably added by Peisistratus. According to Dorpfeld, this was the "old temple" of Athena Polias, mentioned in literature and inscriptions, in which was housed the most holy image (ξόανον) of the goddess which fell from heaven; it was burnt, but not completely destroyed, during the Persian War, and some of its entablature was built into the north wall of the Acropolis; it was subsequently restored, he thinks, with or without its colonnade—in the former case a portion of the peristyle must have been removed to make room for the caryatids porch of the Erechtheum; the building was burnt in 406 B.C. (Xen. Hell. i. 6. 1), and the fire is that mentioned by Demosthenes (In *Timocr.* xxiv. 155); its "opisthodomos" served as the Athenian treasury in the 5th and 4th centuries; the temple is the ἀρχαῖος νεὼς τῆς Πολιάδος of Strabo (ix. 16), and it was still standing in the time of Pausanias, who applies to it the same name (i. 27. 3). That the foundations are those of an old temple burnt by the Persians has been generally accepted, but other portions of Dorpfeld's theory—especially his assumption that the temple was restored after the Persian War—have been contested. Perhaps the temple was repaired to provide a temporary home for the venerated image; no traces of a restoration exist, but the walls probably remained standing after the Persian conflagration. The removal of the ancient temple was undoubtedly intended when the Erechtheum was built, but superstition may have prevented its demolition and the removal of the ξόανον. The temple consisted of an eastern cella with pronaos; behind this was the opisthodomos, divided into three chambers—possibly treasuries—with a portico at the western end. The peristyle, from the measurements of the stylobate and of the column drums built into the wall of the Acropolis, would have consisted of six Doric columns at the ends and 12 at the sides. A representation of the reception of Heracles to Olympus, sculptured in soft limestone and painted, occupied the pediment of the early temple. When Peisistratus added the colonnade it was replaced by a gigantomachy in marble. Fragments of both these groups exist and also some marble reliefs supposed to belong to its later frieze.

The Classical Period.—The almost complete destruction of the buildings on the Acropolis and in the city, among them many shrines which religious sentiment might have preserved, facilitated the magnificent architectural designs of Themistocles, Cimon and Pericles, while the rapid growth of the Athenian empire provided the necessary means for their execution. After the departure of the Persians the first necessity was the reconstruction of the defences. The walls, now built under the direction of Themistocles, embraced a larger area than the previous circuit, with which they coincided at the Dipylon gate on the north-west where the Sacred Way to Eleusis was joined by the carriage route to Peiraeeus and roads to the Academy and Colonus. The other important gates were the Peiraic and Melitan on the west; the Itonian on the south leading to Phalerum, the Diomeian and



MAP OF ANCIENT ATHENS AND ITS PORT TOWN. PEIRAEEUS, SHOWING LONG WALLS BUILT IN 460 B.C. CONNECTING THE PEIRAEEUS WITH THE CITY

Diocharean on the east, and the Acharnian on the north. The wall, strengthened with numerous towers, enclosed the quarters of Collytus on the north, Melite on the west, Limnae on the south-west and south, and Diomeia on the east. The remains have not been systematically excavated except by the Dipylon; sepulchral monuments built into the masonry illustrate the statement of Thucydides with regard to the employment of such material in the hasty construction. The circuit has been ascertained in its general lines; it is given by Thucydides (ii. 13. 7) as 43 stades (about 5½m.) exclusive of the portion between the points of junction with the long walls to Peiraeeus, but the whole circumference cannot have exceeded 37 stades.

The "Long Walls."—The design of connecting Athens with Peiraeeus by long parallel walls is ascribed by Plutarch to Themistocles. The "Long Walls" (*τὰ μακρὰ τείχη, τὰ σκέλη*) consisted of (*1*) the "North Wall" (*τὸ βόρειον τεῖχος*), (2) the "Middle" or "South Wall" (*τὸ δὶα μέσου τεῖχος*, Plato, *Gorg.* 555 E; *τὸ νότιον τεῖχος*); and (3) the "Phaleric Wall" (*τὸ Φαληρικὸν τεῖχος*). The north and Phaleric walls were perhaps founded by Cimon, and completed about 457 B.C. in the administration of Pericles; the middle wall was built about 44j B.C. The north wall, leaving the city near the modern observatory, ran from north-east to south-west near the present road to Peiraeeus, until it reached the Peiraeeus walls a little to the east of their northernmost bend. The middle wall, beginning south of the Pnyx near the Melitan gate, gradually approached the northern wall and, following a parallel course at an interval of 550ft., diverged to the east near the modern New Phalerum and joined the Peiraeeus walls on Munychia where they turn inland from the sea. The course of the Phaleric wall has been much disputed. The widely received view of Curtius that it ran to Cape Kolias (now Old Phalerum) on the east of the Phaleric bay is not now accepted. The wall proved indefensible and was abandoned towards the close of the Peloponnesian War; with the other two walls it was destroyed after the surrender of the city, and was not rebuilt by Conon in 393 B.C. The parallel walls fell into decay during the Hellenistic period and, according to Strabo (ix. 396), were demolished by Sulla.

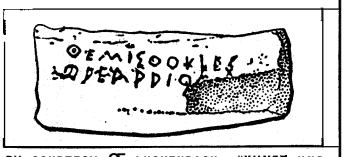
Peiraeeus.—The advantages Peiraeeus with its three harbours offered for defence and commerce were first recognized by Themistocles, in whose archonship (493 B.C.) its fortifications were begun. Before his time the Athenians used as a port the roadstead at the north-eastern corner of Phalerum bay partly sheltered by Cape Kolias. On the completion of the city walls, Themistocles resumed the construction of the Peiraeeus defences, which protected the larger harbour of Cantharus on the west and the smaller ports of Zea and Munychia, terminating in moles at their entrances and enclosing the promontory on the land and sea sides except a portion of the peninsula of Acte. The walls were about 10ft. in thickness and upwards of 60ft. in height, and were strengthened by towers. The town was laid out in straight, broad streets, intersecting at right angles, by the architect Hippodamus of Miletus under Pericles. In the centre was the agora of Hippodamus; on the western margin of the Cantharus harbour the emporium, or Deigma, the centre of commercial activity, flanked by porticoes; at its northern end, near the entrance to the inner harbour, was another agora, on the site of the modern market-place, and near it the *μακρὰ στοά*, the corn depot of the State. This inner and shallower harbour, perhaps the *κωφὸς λιμήν*, was excluded from the town precinct by the walls of Conon, which traversing its opening on an embankment (*τὸ δὶα μέσον χῶμα*) ran round the western promontory of Eetioneia, previously enclosed by the wider circuit of Themistocles. In the harbours of Zea and Munychia traces may be seen of the remarkable series of galley-slips in which the Athenian fleet was built and repaired. Those around Zea were roofed by a row of gables supported by stone columns, each gable sheltering two triremes. Among the other noteworthy buildings were the arsenal (*σκευοθήκη*) of Philon and the temples of Zeus Soter, the patron god of sailors, of the Cnidian Artemis, built by Cimon, and of Artemis Munychia situated near the fort on Munychia; traces of a temple of Asclepius, of two theatres and of a hippodrome remain. The fine marble lion which stood at the mouth of the Cantharus harbour gave Peiraeeus its mediaeval and modern names of Porto Leone and Porto Draco; it was carried to Venice by Morosini.

The Dipylon and Ceramicus.—The Ceramicus gives the best opportunities for studying both the cemeteries and walls of Athens. The latter divide the region into the inner and outer Ceramicus and three stages are clearly seen, the wall of Themistocles, the restoration by Conon in 393 B.C., and a reconstruction by Lycurgus some 60 years laters. The Dipylon gate belongs to the last stage and consists of an inner and outer double gate separated by a rectangular court and flanked by towers on either side. Just within it is a fountain house. South lies another gate by the side of the Eridanus and here issued the sacred way leading to Eleusis. Outside the city this is bordered by tombs, the marble reliefs of which stand in family groups above the level of the road and date mainly from the 4th century B.C. Two boundary stones inscribed *ὅρος Κεραμεικοῦ* have been found and tombs of all periods, classical, "Mycenaean" and "Geometric" which first yielded "Dipylon" ware. Monuments to some persons interred at the public expense suggest that this was the scene of Pericles' famous funeral speech. Excavations, not yet completed, have revealed the Pompeium, a shrine of the Tritopatreis, and sluices for diverting the waters of the Eridanus to irrigate gardens outside the city.

The Acropolis of the Classical Period.—The Acropolis ceased to be a fortress after the expulsion of Hippias; and was defended against the Persians by a wooden barricade. The fortifications were again demolished by the Persians, after whose departure the existing north wall was erected in the time of Themistocles; many fragments from the buildings destroyed by the Persians were built into it, possibly owing to haste, as in the case of the city walls. The fine walls on the south and east were built by Cimon after the victory of the Eurymedon, 468 B.C.; they extend considerably beyond the prehistoric circuit, the intervening space being filled up with the débris of the ruined buildings so as to increase the level space. On the north Cimon completed the wall of Themistocles at both ends and added to its height; the ground behind was levelled up on this side also, the platform of the Acropolis thus receiving its present shape and dimensions. The staircase leading down to the sanctuary of Aglaurus was enclosed in masonry. At the south-western corner, on the right of the old entrance, an early bastion was encased in a rectangular projection which formed a base for the temple of Nike.

The greater monuments of the classical epoch on the Acropolis are described in separate articles. (See PARTHENON; ERECHTHEUM; PROPYLAEA.) Next in interest to these is the beautiful little temple of Athena Nike, wrongly designated Nike *Apteros* (Wingless Victory), standing on the bastion mentioned; it was begun after 450 B.C. and was probably finished after the outbreak of the Peloponnesian War. The temple, which is entirely of Pentelic marble, is amphiprostyle tetrastyle, with fluted Ionic columns, resting on a stylobate of three steps; its length is 27ft., its breadth 18½ft., and its total height, from the apex of the pediment to the bottom of the steps, 23 feet. The frieze represents on the east a number of deities, on the north and south Greeks fighting with Persians, and on the west Greeks fighting with Greeks. Before the east front was the altar beneath which an earlier altar has been found. The irregularly shaped precinct was enclosed by a parapet about 3ft. 2in. in height, decorated on the outside with beautiful reliefs representing winged Victories engaged in the worship of Athena. The treatment of the drapery suggests that the parapet was added in the latter years of the Peloponnesian War. The temple was still standing in 1676; some eight years later it was demolished by the Turks, and its stones built into a bastion; on the removal of the bastion in 1835 the temple was reconstructed by Ross. At either corner of the Propylaea entrance were equestrian statues dedicated by the Athenian knights; the bases with inscriptions have beer, recovered. From the Propylaea a passage led eastwards along the north side of the Parthenon; facing the entrance was the colossal bronze statue of Athena Promachos by Pheidias, probably set up by Cimon in commemoration of the Persian defeat. The statue, 30ft. high, represented the goddess as fully armed; the gleam of her helmet and spear could be seen by the mariners approaching from Sunium (Pausanias i,

28). On both sides were numerous statues, one of Athena Hygeïa (whose altar lies at the south-east angle of the Propylaea), set up by Pericles to commemorate the recovery of a slave injured during the building of the Parthenon, a colossal bronze image of the wooden horse of Troy and Myron's group of Marsyas and Athena. Another statue by Myron, the Perseus, stood near the precinct of Artemis Brauronia, lying between the south-eastern corner of the Propylaea and the wall of Cimon. Adjoining it to the east was a large rectangular building, which was apparently fronted by a colonnade; this has been identified with the Χαλκοθήκη, a storehouse of bronze implements and arms. Beyond the Parthenon, a little to the north-east, was the great altar of Athena, and near it the statue and altar of Zeus Polieus. Immediately west of the Erechtheum is the Pandroseum or *temenos* of Pandrosos, the daughter of Cecrops, seen here by Pausanias (i. 27). This precinct, in which the sacred olive tree of Athena grew, has been fixed by an inscription. Between it and the Propylaea were a number of statues, among them the heifer of Myron, and perhaps his Erechtheus; the Lemnian Athena of Pheidias, and his effigy of his friend Pericles.



BY COURTESY OF LUCKENBACH, "KUNST UND GESCHICHTE"

OSTRACISM OF THEMISTOCLES

Sketch of *Ostrakon*, a piece of pottery on which an Athenian, about 471 B.C., wrote the name, "Themistocles of Phrearri," for whose expulsion he wished to vote

The Classical City, the **"Theseum."**—The reconstruction of the city after its demolition by the Persians was not carried out on the lines of a definite plan like that of the Peiraeeus. The houses were hastily repaired, and the narrow, crooked streets remained; the influence of Themistocles, who aimed at transferring the capital to Peiraeeus, was probably directed against any costly scheme of restoration, except on the Acropolis. The period of Cimon's administration, however, especially the interval between his victory on the Eurymedon and his ostracism 468–461 B.C., was marked by great architectural activity in the lower city as well as on the citadel. To his time may be referred many of the buildings around the agora (probably rebuilt on the former sites) and elsewhere, and the passage, or δρόμος, from the agora, to the Dipylon flanked by long porticoes. The Theseum proper, which lay to the east of the agora near the Acropolis, was built by Cimon: here he deposited the bones of the national hero which he brought from Scyros about 470 B.C.

The Hephaesteum, the so-called Theseum, is situated on a low hill, the Colonus Agoraeus, west of the agora. The best preserved Greek temple in the world, it possesses no record of its origin; the style of its sculptures and architecture suggests that it was built about the same time as the Parthenon, and finished by 421 B.C. It has been known as the Theseum since the middle ages, apparently because some of its sculptures represent the exploits of Theseus, but its identification with the temple of Hephaestus and Athena seen by Pausanias (i. 14. 6) is practically certain, notwithstanding the difficulty presented by the sculptures, which bear no relation to Hephaestus. The temple is a Doric peripteral hexastyle in *antis*, with 13 columns at the sides; its length is 104ft., its breadth 45½ft., its height, to the top of the pediment, 33 feet. The sculptures of the pediments have been lost, but their design has been ingeniously reconstructed by Sauer. The frieze contains sculptures only in the metopes of the east front and in those of the sides immediately adjoining it; the frontal metopes represent the labours of Heracles, the lateral the exploits of Theseus. As in the Parthenon, there is a sculptured frieze above the exterior of the cella walls; this, however, extends over the east and west fronts only and the east ends of the sides; the eastern represents a battle-scene with seated deities on either hand, the western a centauromachia. The temple is of Pentelic marble, except the foundations and lowest step of the stylobate, which are of Peiraic stone, and the frieze of the cella, which is in Parian marble. The preservation of the temple is due to its conversion into a church in the middle ages.

The Dionysiac Theatre and **Asclepieum.**—The Dionysiac theatre, situated beneath the south side of the Acropolis, was partly hollowed out from its declivity. The representation of plays was transferred here from the original Orchestra in the agora by the beginning of the jth century B.C.; it afterwards superseded the Pnyx as the meeting-place of the Ecclesia. Here the first structures were provisional and of wood, and traces have been found of the early orchestra and auditorium which had its seats in straight lines. This was replaced by a stone theatre during the administration of Lycurgus (337–323 B.C.), but the present arrangement of stage and orchestra date from Roman times. The stage-building consisted of a rectangular hall with square projections (παρασκήνια) on either side; in front of this was built in late Greek or early Roman times a stage with a row of columns which intruded upon the orchestra space; a later and larger stage, dating from the time of Nero, advanced still farther into the orchestra, and this was finally faced (probably in the 3rd century A.D.) by the "bema" of Phaedrus, a platform-wall decorated with earlier reliefs, cut down to suit their new position. The remains of two temples of Dionysus have been found adjoining the stoa of the theatre, and an altar of the same god adorned with masks and festoons; the smaller temple probably dates from the 6th century B.C., the larger from the end of the 5th or the beginning of the 4th century.

Immediately west of the theatre is the sacred precinct of Asclepius, where were discovered the foundations of the temple, together with several inscriptions and a great number of votive reliefs offered by grateful invalids. A Doric colonnade with a double row of columns extended along the base of the Acropolis for a distance of 54yd.; behind it in a chamber hewn in the rock is the sacred well mentioned by Pausanias. The colonnade was a place of resort for the patients; a large building close beneath the rock was probably the abode of the priests. East of the theatre and closely related to it was the Odeum of Pericles, the only building which can be assigned to him, though he may have designed the first plan of the theatre too. This was a large rectangular hypostyle hall with probably six rows of six marble columns, which would have replaced the original wooden columns at its restoration by Ariobarzanes of Cappadocia after its destruction by Sulla in 86 B.C. Plutarch says that the Odeum imitated the tent of Xerxes, but it is possible that he may be referring only to the roof of the building.

The Choragic Monument of **Lysicrates.**—The beautiful choragic monument, of Lysicrates, dedicated in the archonship of Euaenetus (335–334 B.C.), is the only survivor of a number of such structures which stood in the "Street of the Tripods" to the east of the Dionysiac theatre, bearing the tripods given to the successful choragi at the Dionysiac festival. It owes its preservation to its former inclusion in a Capuchin convent. The monument consists of a small circular temple of Pentelic marble, 21½ft. in height and gft. in diameter, with six engaged Corinthian columns and a sculptured frieze, standing on a rectangular base of Peiraic stone. The delicately carved convex roof, composed of a single block, was surmounted by the tripod. The frieze represents the transformation of the Tyrrhenian pirates by Dionysus into dolphins. Another choragic monument was that of Thrasyllus, which faced a cave in the Acropolis rock above the Dionysiac theatre. A portion of another, that of Nicias, was used to make the late Roman gate of the Acropolis. In one of these monuments was the famous Satyr of Praxiteles.

The Hellenistic Period.— After the age of Alexander, Athens was adorned with many new buildings, a tribute paid to her intellectual renown by foreign potentates or dilettanti, who desired to add their names to the list of its illustrious citizens and patrons. Among the first of these benefactions was the great gymnasium of Ptolemy, built in the neighbourhood of the agora about 250 B.C. Attalus I. set up a number of bronze statues on the Acropolis; Eumenes II. built the long portico west of the Dionysiac theatre; Attalus II. erected the magnificent Stoa near the agora, which has been identified by an inscription. The Stoa consisted of a series of 21 chambers, probably shops, faced by a double colonnade, the outer columns being of the Doric order, the inner unfluted, with lotus-leaf capitals, it possessed an upper storey fronted with Ionic columns.

The greatest monument, however, of the Hellenistic period, the colossal temple of Olympian Zeus, "unum in terris inchoatum pro magnitudine dei" (Livy xli. 20), stood by the Ilissus, south-east of the Acropolis. Its foundations were laid on the site of a small ancient shrine by Hippias, but the building in its ultimate form was for the greater part constructed under the auspices of Antiochus IV. Epiphanes, king of Syria, by the Roman architect Cossutius between 174 and 164 B.C., the date of the death of Antiochus. The work was apparently resumed under Augustus and, finally, in A.D. 129, completed and dedicated by Hadrian, who set up a chryselephantine statue of Zeus in the cella. The building was octostyle; its length was 318ft., its breadth 132ft. With the exception of the foundations and two lower steps of the stylobate, it was entirely of Pentelic marble, and possessed 104 Corinthian columns, 56ft. 7in. in height, of which 48 stood in triple rows under the pediments and 56 in double rows at the sides; of these, 16 remained standing in 1852, when one was blown down by a storm. The Olympieum of Hippias was to be of the Ionic order.

The **Roman** Period.—An earlier building of this period is the Horologium of Andronicus of Cyrrhus (the "Tower of the Winds"), still standing near the eastern end of the Roman agora. This may belong to the 2nd or 1st century B.C.; it is mentioned by Varro (*De re rust.* iii. 5. 1;), and therefore cannot be of later date than 35 B.C. It is an octagonal marble structure, 42ft. in height and 26ft. in diameter; the eight sides, which face the points of the compass, are furnished with a frieze containing inartistic figures in relief representing the winds; below it, on the sides facing the sun, are the lines of a sundial. It was surmounted by a weathercock in the form of a bronze Triton and contained a water-clock to record the time when the sun was not shining.

The new, or Roman, agora to the north of the Acropolis, perhaps mainly an oil market, was constructed after the year 27 B.C. It consisted of a large open rectangular space surrounded by an Ionic colonnade into which opened a number of shops or storehouses. The eastern gate was adorned with four Ionic columns on the outside and two on the inside, the western entrance being the well-known Doric portion of Athena Archegetis with an inscription recording its erection from donations of Julius Caesar and Augustus. The Agrippeum, a covered theatre, derived its name from Vipsanius Agrippa, whose statue was set up, about 27 B.C., beneath the north wing of the Acropolis propylaea, on the high rectangular base still remaining. At the eastern end of the Acropolis a charming circular temple of white marble with a peristyle of nine Ionic columns was dedicated to Rome and Augustus. The conspicuous monument which crowns the Museum hill was erected as the mausoleum of Antiochus Philopappus of Commagene, grandson of Antiochus Epiphanes, in A.D. 114–116. It was nearly square, but the only portion remaining is the slightly curved front with three niches between Corinthian pilasters; in the central niche is the statue of Philopappus.

The Emperor Hadrian was a lavish benefactor. He enlarged the circuit of the city walls to the east, enclosing the area now covered by the royal and Zappeion gardens and Constitution square. This was the City of Hadrian (Hadrianopolis) or New Athens (Novae Athenae); a handsome suburb with numerous villas, baths and gardens; its walls were fortified with rectangular towers. The Arch of Hadrian near the Olympieum marked the boundary between the new and the old cities. This is surmounted by a triple attic with Corinthian columns; the frieze above the keystone bears, on the north-westem side, the inscription αἵδ' εἶσ' Ἀθῆναι, Θησέως ἡ πρὶν πόλις and on the south-eastern, αἵδ' εἶσ' Ἀδριανοῦ καὶ οὐχὶ Θησέως πόλις. The library of Hadrian, mentioned by Pausanias, was probably in the vast rectangular enclosure, immediately north of the new agora. A portion of its western front, adorned with monolith unfluted Corinthian columns, is still standing—the familiar "Stoa of Hadrian"; another well preserved portion, with six pilasters, runs parallel to the west side of Aeolus street. The interior consisted of a spacious court surrounded by a colonnade of 100 columns, into which five chambers opened at the eastern end. A portico of four fluted Corinthian columns on the western side formed the entrance to the quadrangle. A Pantheon, a gymnasium and temples of Hera and Zeus Panhellenius were likewise built by Hadrian; the aqueduct, which he began, was completed by Antoninus Pius (A.D. 138–161); it is still in use.

The Stadium, in which the Panathenaic Games were held, was first laid out by the orator Lycurgus about 330 B.C. It was an oblong structure filling a depression, partly natural, partly artificial, near the left bank of the Ilissus beneath the eastern declivity of the Ardettus hill. The immense building, however, which was restored in 1896 and the following years, was that constructed in Pentelic marble about A.D. 143 by Tiberius Claudius Atticus Herodes, a wealthy Roman resident. The seats, rising in tiers, as in a theatre, accommodated about 44,000 spectators; the arena was 670 ft. in length and 109 ft. in breadth. The Odeum, built beneath the south-west slope of the Acropolis after A.D. 161 by Atticus Herodes in memory of his wife Regilla, is comparatively well preserved. The plan is that of the conventional Roman theatre; the semi-circular auditorium, which seated some 5,900 persons, is, like that of the Dionysiac theatre, partly hollowed from the rock. The orchestra is paved with marble squares. The facade, in Peiraic stone, displays three stories of arched windows. The whole building was covered with a cedar roof.

II. THE MODERN CITY

At the conclusion of the Greek War of Independence, Athens was little more than a village of the Turkish type, the poorly built houses clustering on the northern and eastern slopes of the Acropolis. The narrow crooked lanes of this quarter still contrast with the straight, regularly laid-out streets of the modern city, which extends to the north-west, north. south and east of the citadel. The greater commercial advantages offered by other cities were outweighed by the historic claims of Athens in the choice of a capital for the newly founded kingdom, and the seat of government was transferred hither from Nauplia in 1833. The new town was, for the most part, laid out by the German architect Schaubert. It contains several squares and boulevards, a large public garden and many handsome public and private edifices. A great number of the public institutions owe their origin to the munificence of patriotic Greeks, among whom Andreas Syngros and George Averoff may be especially mentioned. The old palace, designed by Friedrich von Gartner (1792–1847), is a tasteless structure; attached to it is a beautiful garden laid out by Queen Amalia. On the southeast is the newer palace.

The academy, built from designs by Theophil Hansen (1813–91), is constructed of Pentelic marble in the Ionic style: the colonnades and pediments are richly coloured and gilded. and may perhaps convey some idea of the ancient style of decoration. Close by is the university, with a colonnade adorned with paintings, and the National library with a handsome Doric portico of Pentelic marble. The observatory, connected with the university, stands on the summit of the hill of the Nymphs; like the academy, it was erected at the expense of a wealthy Greek, Baron Sina of Vienna. In the public garden is the Zappeion, a large building with a Corinthian portico, intended for the display of Greek industries; here also is a monument to Byron, erected in 1896. The Boulē, or parliament-house, possesses an excellent library. Other public buildings are the Polytechnic institute, built by contributions from Greeks of Epirus, the theatre, the Arsakeion (a school for girls), the Varvakeion (a high school), the military school (σχολὴ εὐελπίδων), the Gennadeion (a library attached to the American school), and several hospitals, schools and orphanages. The cathedral, a large modern structure, is devoid of architectural merit, but some of the smaller, ancient Byzantine churches are singularly interesting and beautiful. After the successive enlargements of the boundaries of Greece in 1881, 1912 and 1920 Athens increased rapidly as the focus of society, politics and trade. After 1922 whole new quarters sprang up to house the great influx of refugees from Asia Minor. especially in the Patēsia and Pangrati regions of the city, which now encircles Lycabettus. Neighbouring townships such as Marousi, Kēphisia, Psychiko, Ēraklion, Kallithea and Phalēron also grew correspondingly, particularly after the coming of the motor car and the improvements of the roads had made them popular resi-

dential suburbs. Athens and Peiraeeus are well served by electric tramways which run also to Phalēron. There is an electric railway to Peiraeeus and a suburban line to Kēphisia. There are motor omnibus services to all suburbs and to outlying towns in Attica such as Eleusis, Marathon and Laurium, and even to and from Thebes.

Museums.—The museums of Athens have steadily grown in importance, are well arranged, and the remnants of ancient art which they contain have fortunately escaped injudicious restoration. The National museum, founded in 1866, is especially rich in archaic sculptures and in sepulchral and votive reliefs. Among the most notable works of art are the bronze youths from Marathon and Cerigotto, the colossal archaic "Apollo" from Sunium, the Scopaic heads from Tegea, the Demeter relief from Eleusis and the sculptures of Damophon from Lycosura. Its unrivalled collection of prehistoric antiquities contains the treasures of Mycenae (found by Schliemann), Vaphio, Dendra and Tiryns, and rich series of vases and other objects from "Mycenaean" sites all over Greece and from Thessaly and from the Cyclades. There are also terra-cottas from Tanagra and Asia Minor; bronzes from Olympia, Delos and the Acropolis, and numerous painted vases, among them the unequalled white lecythi from Athens and Eretria. The Epigraphical museum contains an immense number of valuable historical inscriptions. The Acropolis museum (opened in 1878) possesses a singularly interesting collection of sculptures belonging to the "archaic" period of Greek art, all found on the Acropolis; here, too, are some fragments of the sculptures of the Parthenon and the reliefs from the parapet of the temple of Nike. In the Polytechnic there is a historical and ethnological museum, and the national gallery of paintings. The national collection of coins is accommodated in the Academy and the Byzantine museum is to be moved to a large villa on the Kēphisia road. In the old Turkish mosque near the library of Hadrian is the museum of decorative art which, though recently founded, is steadily increasing. There is a small museum of antiquities at Peiraeeus.

Scientific Institutions.--Owing to the numbers and activity of its institutions, both native and foreign, for the prosecution of research and the encouragement of classical studies, Athens had become once more an international seat of learning. The Greek Archaeological society, founded in 1837, numbered some distinguished scholars among its members, and displayed great activity in the conduct of excavations. There are also several Greek societies for encouraging the study of philology, Byzantine art, ethnology and other learned subjects. Of the foreign archaeological schools the French was founded in 1846, the German in 1874, the American in 1882, the British in 1886, the Austrian in 1898 and the Italian in 1909. (See GREEK ARCHAEOLOGY.)

Industry and Commerce.—In spite of some disadvantages from its situation and the resources of Attica, Athens prospered in industry and commerce until World War II. It is the centre of banking and of all mercantile business, export and import. With Peiraeeus it is, as the terminus of all the steamship and railway lines (the Peloponnesian, the Attic and the main line which connects with Salonika and the direct route to Paris or Berlin), the most important manufacturing town in Greece. There are cloth and cotton mills, distilleries, breweries, potteries, flour mills, soap factories, shipbuilding and engineering works, tanneries and chemical works and carpet factories, the last a new and rising industry established by the refugees from Asia Minor. Exports are normally wine, oil, tobacco, marble and cognac, and imports are coal, grain and manufactured articles of all kinds. Peiraeeus is also a great entrepôt for the Levant.

Peiraeeus.—Peiraeeus, which had never revived since its destruction by the Romans in 86 B.C., was, at the beginning of the 19th century, a small fishing village known as Porto Leone. When Athens became the capital in 1833 the ancient name of its port was revived, and after that time piers and quays were constructed, and spacious squares and broad regular streets were laid out. The town also acquired an exchange, a large theatre, a gymnasium, a naval school, municipal buildings and several hospitals and charitable institutions erected by private munificence. The harbour, in which ships of all nations may ordinarily be seen, as well as great numbers of the picturesque sailing craft engaged in the coasting trade, was improved by the construction of breakwaters and dry docks.

In 1932 a free zone was constituted, covering in 1937 an area of 217,067 sq.yd.

Population.—The population of Athens has rapidly increased. In 1834 it was below 5,000; in 1870 it was 44,510; in 1879, 63.374; in 1889, 107,251; in 1896, 111,486. Peiraeeus, which in 1834 possessed only a few hundred inhabitants, in 1879 possessed 21,618; in 1889, 34,327; in 1896, 43,848. The total population of Athens in 1907 was 167,479 and of Peiraeeus 67,982. In 1938 Athens had a population of 392,781 and Peiraeeus 284,079.

(J. D. B.; A. J. B. W.; X.)

III. HISTORY

1. The Prehistoric Period.—Archaeology gives the early history of Athens, for it is barely mentioned by Homer and the numerous legends have little historical value. Its neolithic inhabitants, of the race that occupied most of Greece and was related to that of the Danubian and Carpathian areas, were followed by a bronze-using folk akin to the islanders and Cretans, possibly a non-Hellenic people, Next came the mysterious makers of Minyan ware (see AEGEAN CIVILIZATION), and in the late bronze age Athens became a strong castle like Tiryns with traces of a "palace." Rich finds of "Geometric" vases indicate prosperity in the early iron age. Some try to associate this pottery with Dorians, though the Athenians always boasted they were children of the soil and free from admixture, that is to say Dorians. At the dawn of history proper the independent communities of Attica were absorbed into a central state of Athens under a monarchy (see THESEUS) of Ionian affinities, for the people were divided into four tribes whose names—Geleontes, Hopletes, Argadeis and Aegicoreis—recur in several true Ionian towns. The centralization (synoecism), to which many Greek peoples never attained, laid the foundations of Athenian greatness. But in other respects the new constitution tended to arrest development. When the monarchy was supplanted in the usual Greek fashion by a hereditary nobility, according to tradition, between about 1000 and 683 B.C., all power was appropriated by a privileged class of Eupatridae (*q.v.*), who owed their predominance to their control over legal procedure; the Geomoroi and Demiourgoi, who formed the bulk of the community, enjoyed no political rights. The aristocratic council of the Areopagus (*q.v.*) constituted the chief criminal court, and nominated the magistrates, among whom the chief archon (*q.v.*) passed judgment in family suits, controlled admission to the genos or clan, and consequently the acquisition of the franchise. This system was further supported by religious prescriptions which the nobles retained as a corporate secret. The Eupatridae also tended to become sole owners of the land, reducing the original freeholders or tenants to the position of serfs. During this period Athens seems to have made little use of her militia, commanded by the polemarch, or of her navy, which was raised in special local divisions known as naucraries; hence no military esprit de corps could arise to check the Eupatrid ascendancy. Nor did the commons obtain relief through any commercial or colonial enterprises as in many other Greek States. The first attack upon the aristocracy proceeded from a young noble named Cylon, who endeavoured to become tyrant about 630 B.C. The people helped to crush this movement; yet discontent must have been rife, for in 621 the Eupatrids commissioned Draco (*q.v.*), a junior magistrate, to draft and publish a code of criminal law. By this notable concession the nobles lost that exclusive legal knowledge which had formed one of their main instruments of oppression.

2. The Rise of **Athens.**—A still greater danger grew out of the widespread financial distress, which was steadily driving many of the agricultural population into slavery and threatened the entire state with ruin. After a protracted war with the neighbouring Megarians had accentuated the crisis, the Eupatridae gave to one of their number, the celebrated Solon (q v.), free power to remodel the whole state (594). By his economic legisla-

tion Solon placed agriculture once more upon a sound footing and encouraged commercial enterprise, thus laying the foundation of material prosperity. His constitutional reforms proved less successful, for, although he put into the hands of the people safeguards against oppression, he could not ensure their use in practice. After a period of party-feud among the nobles the new constitution was superseded by the autocratic rule of Peisistratus (*q.v.*), and his sons Hippias and Hipparchus. The age of despotism, which lasted, with interruptions, from 560 to 510, was a period of great prosperity. The rulers fostered agriculture, stimulated commerce and industry (notably the famous Attic ceramics), adorned the city with public works and temples, and rendered it a centre of culture. Their vigorous foreign policy first made Athens an Aegean Power and secured connections with mainland Powers. They also weakened the undue influence of the nobles and created a national Athenian spirit in place of the ancient clan-feeling.

The equalization of classes was already far advanced when, about 509, an Alcmaeonid named Cleisthenes (*q.v.*), who had taken the chief part in the final expulsion of the tyrants, acquired ascendancy as leader of the commons. His constitution (508–507) expressed the change of political feeling by providing a national basis of franchise and a new state organization. By making effective the powers of the Ecclesia (Popular Assembly) the Boulē (Council) and Heliaea, Cleisthenes became the true founder of Athenian democracy.

This revolution was accompanied by a conflict with Sparta and other powers, but in the ensuing wars Athens worsted powerful. enemies like Thebes and Chalcis (506). A bolder stroke followed in 500, when a force was sent to support the Ionians in revolt against Persia and helped to sack Sardis. After the failure of this expedition the Athenians became absorbed in a struggle with Aegina (*q.v.*). In 493 the prospect of a Persian invasion brought into power men like Themistocles and Miltiades (*qq.v.*), to whose firmness and insight the Athenians largely owed their triumph in the great campaign of 490 against Persia. After a second political reaction, the prospect of a second Persian war, and the naval superiority of Aegina, led to a strong policy. In 483 Themistocles overcame the opposition of Aristeides (*q.v.*), and passed his famous measure providing for a large increase of the Athenian fleet. In the great invasion of 480–479 the Athenians displayed a resolution which could not be shaken even by the evacuation and destruction of their native city. Though the traditional account exaggerates the services of Athens, the ultimate victory was chiefly due to the numbers and efficiency of her fleet and to the wise policy of Themistocles. (See SALAMIS; PLATAEA.)

3. Imperial Athens. — After the Persian retreat and the reoccupation of their city the Athenians continued the war with unabated vigour. Led by Aristeides and Cimon they rendered such prominent service as to receive in return the formal leadership of the Greek allies and the presidency of the newly formed Delian league (*q.v.*). The ascendancy acquired in these years eventually raised Athens to the rank of an imperial state. For the moment it tended to impair the good relations which had subsisted between Athens and Sparta since the first days of the Persian peril. But so long as Cimon's influence prevailed the ideal of "peace at home and the complete humiliation of Persia" was steadily upheld. Similarly the internal policy of Athens continued to be shaped by the conservatives. The only notable innovations since the days of Cleisthenes had been the reduction of the archonship to a routine magistracy appointed partly by lot (487), and the rise of the ten elective strategi (generals) as chief executive officers. (See STRATEGUS.) But the triumph of the navy in 480 and the great expansion of commerce and industry had shifted the political centre of gravity from the moderate democrats to the more radical party. Though Themistocles soon lost his influence, his party eventually found a new leader in Ephialtes, and after the failure of Cimon's foreign policy (see CIMON) triumphed over the conservatives. The year 461 marks the reversal of Athenian policy at home and abroad. By cancelling the political power of the Areopagus and multiplying the functions of the popular law-courts, Ephialtes abolished the last checks upon the sovereignty of the commons. His successor, Pericles, merely developed the full democracy so as to secure its effectual as well as its theoretical supremacy. The foreign policy of Athens was now directed towards an almost reckless expansion. (See PERICLES.) Besides securing her Aegean possessions and her commerce by the defeat of Corinth and Aegina, her last rivals on sea, Athens acquired an extensive dominion in central Greece and for a time quite overshadowed the Spartan land-power. The rapid loss of the new conquests after 447 proved that Athens lacked a sufficient land-army to defend permanently so extensive a frontier. Under the guidance of Pericles the Athenians renounced the unprofitable rivalry with Sparta and Persia, and devoted themselves to the consolidation and judicious extension of their maritime influence.

The years of the supremacy of Pericles (443–429) are the most glorious in Athenian history. In actual extent of territory the empire had receded somewhat, but in point of security and organization it now stood at its height. The Delian confederacy lay under Athenian control, and the points of strategic importance were largely held by cleruchies (*q.v.*; see also PERICLES) and garrisons. Out of a citizen body of over 50,000 freemen, reinforced by mercenaries and slaves, a superb fleet exceeding 300 sail and an army of 30,000 drilled soldiers could be mustered. The city, with its fortifications extending to the port of Peiraeeus, was impregnable to a land attack. Her commerce extended from Egypt and Colchis to Etruria and Carthage, and her manufactures, which attracted skilled operatives from many lands, found a ready sale all over the Mediterranean. With tolls, and the tribute of the Delian league (*q.v.*), a fund of 9,700 talents (£2,300,000) was amassed in the treasury.

Yet the material prosperity of Athens under Pericles was less notable than her brilliant attainments in every field of culture. No city ever adorned herself with such an array of temples, public buildings and works of art as the Athens of Pericles and Pheidias. Her achievements in literature are hardly less great. The Attic drama of the period produced many masterpieces, and the scientific thought of Europe in the departments of logic, ethics, rhetoric and history mainly owes its origin to a new movement of Greek thought which was largely fostered by the patronage of Pericles himself. Besides producing numerous men of genius herself Athens attracted all the great intellects of Greece. The brilliant summary of the historian Thucydides in the famous funeral speech of Pericles (delivered in 430), in which the social life, the institutions and the culture of his country are set forth as a model, gives an ideal picture of Athens in her greatest days.

The payment for public service which Pericles had introduced may have contributed to raise the general level of culture of the citizens, but it created a dangerous precedent and incurred the censure of notable Greek thinkers. Moreover, all this prosperity was obtained at the expense of the confederates, whom Athens exploited in a somewhat selfish and illiberal manner. The cry of "tyrant city" roused public opinion in Greece against Athens and brought on the Peloponnesian War (*q.v.*) which ruined the Athenian empire (431–404). The issue was determined less by any intrinsic superiority on the part of her enemies than by the blunders committed by a people unable to carry out a consistent foreign policy, and served since Pericles by none but selfish or short-sighted advisers. It speaks well for the patriotism of her commons that Athens, weakened by plague and military disasters, should have withstood for so long the blows of enemies from without, and the damage inflicted by traitors within her walls. (See ANTIPHON; THERAMENES.)

4. The Fourth Century. — After the complete defeat of Athens by land and sea, it was felt that her former services on behalf of Greece and her high culture should exempt her from total ruin. Though stripped of her empire, Athens obtained very tolerable terms from her enemies. The democratic constitution, which had been supplanted for a while by a government of oligarchs, was restored in 403 after the latter's misrule had brought about their own downfall. (See CRITIAS; THERAMENES; THRASYBULUS.) Indeed the spread of democracy elsewhere increased the prestige of the Athenian administration, which had now reached a high pitch of efficiency. Athenian art and literature in the 4th

century declined but slightly from their former standard; philosophy and oratory reached a standard which was never again equalled in antiquity. Athens took a prominent part with a view to upholding the balance of power, joining the Corinthian League in 395, and assisting Thebes against Sparta after 378, Sparta against Thebes after 369. Her generals and admirals, Conon, Iphicrates, Chabrias, Timotheus, distinguished themselves and partially recovered their country's predominance in the Aegean, with a teniporary renewal of the Delian league (*q.v.*). When Philip of Macedon began to grow formidable she seemed called upon once more to champion the liberties of Greece. This ideal, when put forward by Demosthenes and other orators, created great enthusiasm among the Athenians, who at times displayed their old vigour, notably in the decisive campaign of 338. But popular opicion repeatedly veered back in favour of the peace-party. With her diminished resources Athens could not indeed hope to cope with the great Macedonian king; however much we may sympathize with the patriots, we must admit that in the light of hard facts their conduct appears quixotic.

5. The Hellenistic Period.—Philip and Alexander, who sincerely admired Athenian culture and courted a zealous co-operation against Persia, treated the defeated city with marked favour. But the people would not resign themselves to playing a secondary part, and watched for every opportunity to revolt. For her outbreak after Alexander's death (323) the regent Antipater punished Athens by the loss of her remaining dependencies, the proscription of her chief patriots and the disfranchisement of 12,000 citizens. The Macedonian garrison prevented the city from taking a prominent part in the wars of the Diadochi. Cassander placed Athens under Demetrius of Phalerum (317–307), and after the temporary liberation by Demetrius Poliorcetes (306–300), under a dictator named Lachares, who lost the place again to Poliorcetes after a siege (295). The Athenians regained their liberty while Macedonia was thrown into confusion by the Celts, and in 279 rendered good service against the invaders with a fleet off Therinopylae. When Antigonus Gonatas threatened to restore Macedonian power in Greece, the Athenians, supported perhaps by Ptolemy, formed a defensive coalition; but in the ensuing "Chremonidean War" (266–263) a naval defeat off Andros led to the imposition of a Macedonian garrison. The latter was withdrawn in 229 by the good offices of Aratus of Sicyon (*q.v.*). At this period Athens was altogether overshadowed by the great Hellenistic monarchies and even by the new republican leagues of Greece; but the prestige of her past history now perhaps attained its zenith. Her democracy was respected by the Macedonian kings; the rulers of Egypt, Syria, and especially of Pergamum, courted her by gifts of buildings and works of art, to which the citizens replied by unbecoming flattery, even to the extent of creating new tribes named after their benefactors. If Athens lost her supremacy in the fields of science and scholarship to Alexandria, she became more than ever the home of philosophy, while Menander and the other poets of the New Comedy made Athenian life known throughout the civilized world.

6. Relations with the Roman Republic.—In 228 Athens entered into friendly intercourse with Rome, in whose interest she endured the desperate attacks of Philip V. of Macedonia (200–199). In return for help against King Perseus she acquired some new possessions, notably the great mart of Delos, which became an Athenian cleruchy (166). Athens indirectly brought about the conflict between Rome and the Achaean league which resulted in the loss of Greek independence, but remained herself a free town with rights secured by treaty. In spite of the favours of Rome, the more radical section began to chafe at the loss of their importance. This discontent was skilfully fanned by Mithridates the Great at the outset of his Roman campaigns. His emissary, the philosopher Aristion, induced the people to declare war against Rome and to place him in chief command. The town with its port stood a long siege against Sulla, but was stormed in 86. The conqueror allowed his soldiers to loot, but inflicted no permanent punishment upon the people. This war left Athens poverty-stricken and stripped of her commerce; her only importance now lay in the philosophical schools, which were frequented by many young Romans of note (Cicero, Atticus, Horace, etc.) as a sort of university (cf. Propeitius iv. 21). In the great civil wars Athens sided with Pompey, but received a free pardon "in consideration of her great dead." Similarly the triumvirs after Philippi condoned her enthusiasm for the cause of Brutus. Antony repeatedly made Athens his headquarters and granted her several new possessions, including Eretria and Aegina—grants which Octavian subsequently revoked.

7. The Roman Empire.—Under the new settlement Athens remained a free and sovereign city—a boon which she repaid by zealous Caesar-worship. Hadrian displayed his fondness for the city by raising new buildings and relieving financial distress. He amended the constitution and instituted a new national festival, the Panhellenica. Under the Antonines the endowment of professors out of the imperial treasury gave Athens a special status as a university. Her whole energies seem henceforth devoted to academic pursuits; the military training of her youth was superseded by courses in philosophy and rhetoric; the chief organs of administration, the revived Areopagus and the senior Strategus, became an education office. Save for an incursion by Goths in A.D. 267 and a temporary occupation by Alaric in 395, Athens spent the remaining centuries of the ancient world in quiet prosperity. The rhetorical schools experienced a revival under Constantine and his successors, when Athens became the *alma mater* of many notable men, including Julian, Libanius, Basil and Gregory of Nazianzus, and in her professors owned the last representatives of a humane and moralized paganism. The freedom of teaching was first curtailed by Theodosius I.; the edict of Justinian (529), forbidding the study of philosophy, dealt the death-blow to ancient Athens.

The authorities for the history of ancient Athens will mostly be found under GREECE: *History*, and the various biographies. The latest account of Athenian history will be found in the Cambridge Ancient History, vols. iii.–vi., which have full classified bibliographies. For general impressions, A. E. Zimmern, *The* Greek *Commonwealth* (Oxford, 1925) and W. S. Fergusson, *Hellenistic Athens* (London, 1911) should be consulted. (M. C.; A. J. B. W.)

8. Byzantine Period.—The city now sank into the position of a provincial Byzantine town, and is rarely mentioned in the chronicles. Already it had been robbed of many of its works of art, among them the Athena Promachos and the Parthenos of Pheidias, for the adornment of Constantinople, and further spoliation took place when the church of St. Sophia was built in A.D. 532. The Parthenon, the Erechtheum, the "Theseum" and other temples were converted into Christian churches and were thus preserved throughout the middle ages. The Emperor Constantine II. spent some months here in A.D. 662–663. In 869 the see of Athens became an archbishopric. In 995 Attica was ravaged by the Bulgarians under their Tsar Samuel, but Athens escaped; after the defeat of Samuel at Bēlasitza (1014) the Emperor Basil, who blinded 15,000 Bulgarian prisoners, came to Athens and celebrated his triumph by a thanksgiving service in the Parthenon (1018). From the Runic inscription on the marble lion from Peiraeeus it has been inferred that Harold Hardraada and the Norsemen in the service of the Byzantine emperors captured Peiraeeus in 1040. Like the rest of Greece, Athens suffered greatly from its Byzantine administrators. The letters of Acominatus, archbishop of Athens, towards the close of the 12th century, bewail the desolate condition of the city.

9. Period of Latin Rule: 1204–1458.—After the Latin conquest of Constantinople in 1204, Otho de la Roche was granted the lordship of Athens by Boniface of Montferrat, king of Thessalonica, with the title of Megaskyr (μέγας κύριος=great lord). His nephew and successor, Guy I, obtained the title duke of Athens from Louis IX. of France in 1258. On the death of Guy II., last duke of the house of la Roche, in 1305, the duchy passed to his cousin, Walter of Brienne. He was expelled in 1311 by his Catalonian mercenaries; the mutineers bestowed the duchy "of Athens and Neopatras" on their leader, Roger Deslaur, and, in the following year, on Frederick of Aragon, king of Sicily. The Sicilian kings ruled Athens by viceroys till 1385, when the Florentine Nerio Acciajuoli, lord of Corinth, defeated the Catalonians, seized the city and received the title of duke from the

king of Naples His palace was in the Propylaea; the lofty "tower of the Franks," which adjoined the south wing of that building, was possibly built in his time. The Acciajuoli dynasty lasted till June 1458, when the Acropolis was taken by the Turks under Omar, the general of the sultan Mohammed II., who had occupied the lower city in 1456. When the sultan entered Athens he was greatly struck by its ancient monuments and treated its inhabitants with comparative leniency.

10. *Period of Turkish Rule:* 1458–1833.—After the Turkish conquest Athens disappeared from the eyes of Western civilization. The Parthenon was transformed into a mosque; the existing minaret at its south-western corner was built after 1466. The Propylaea served as the residence of the Turkish commandant and the Erechtheum as his harem. In 1466 the Venetians succeeded in occupying the city, but failed to take the Acropolis. About 1645 a powder magazine in the Propylaea was ignited by lightning and the upper portion of the structure was destroyed. Under Francesco Morosini the Venetians again attacked Athens in Sept. 1687; a bomb fired during the bombardment of the Acropolis exploded a powder magazine in the Parthenon and the building was rent asunder. After capturing the Acropolis the Venetians employed material from its ancient edifices in repairing its walls. They withdrew in the following year, when the Turks set fire to the city. The central sculptures of the western pediment of the Parthenon, which Morosini intended to take to Venice, were unskilfully moved, and falling to the ground were broken to pieces. Several ancient monuments were sacrificed to provide material for a new wall with which the Turks surrounded the city in 1778.

In 1821 the Greek insurgents surprised the city, and in 1822 captured the Acropolis. Athens again fell into the hands of the Turks in 1826, who bombarded and took the Acropolis in the following year; the Erectheum suffered greatly, and the monument of Thrasyllus was destroyed. The Turks remained in possession of the Acropolis till 1838, when Athens was chosen as the capital of the newly established kingdom of Greece. On April 27, 1941, it was occupied by the Germans, who, however. had spared it from bombing. (For its modern history *see* GREECE.)

(J. D. B.; A. J. B. W.)

ATHENS, a city of Georgia, U.S.A.. 73 mi. E. by N. of Atlanta, on a hill overlooking the Oconee river; the county seat of Clarke county.

Athens is on federal highways 78, 29 and 129; the city is served by the Southern, the Seaboard Air Line, the Gainesville Midland, the Georgia, and the Central of Georgia railways. The population in 1920 was 16,748, of whom 6,595 were Negroes; and was 20,650 in 1940 by the federal census. Athens was founded in 1801 as the seat of the University of Georgia (chartered 1785) for which the State Legislature had in 1784 set aside 40,000 acres of land. The first department, Franklin college, was opened in 1801; the college of agriculture and mechanic arts in 1872. In 1867 the Lumpkin law school (incorporated 1859), in 1872 the North Georgia agricultural college at Dahlonega (established 1871), and in 1873 the Georgia medical college at Augusta (founded 1829) became departments of the university. The school of pharmacy was established in 1903; the summer school (authorized 1897) in 1904; the schools of forestry, commerce, and journalism. in 1906, 1912, and 1915 respectively. The Peabody College of Education is also a part of the University of Georgia. The following institutions elsewhere in the State were also established, under the State Constitution of 1877, as branches or departments of the university: the Georgia school of technology, Atlanta (1885); the Georgia normal and industrial college for girls, now the State college for women, Milledgeville (1889); the Georgia industrial college for coloured youth, near Savannah (1890); the South Georgia normal school, now the State woman's college, Valdosta (1906); the Bowdon State normal college, Bowdon (1919); and the South Georgia agricultural and mechanical college, Tifton (1924).

Athens has an extensive wholesale trade, and is growing in importance as a manufacturing centre. In 1937 there were 31 factories within the city and the value of their output was $5,763,572. The leading products are cotton goods, cottonseed oil, hardnood handles, sash, doors, lumber, fertilizer, bed-springs and mattresses, articles of marble and granite, and brick and tile. The city was chartered in 1872.

ATHENS, a city of Ohio, U.S.A., 72 mi. S.E. of Columbus, on the Hocking river; the county seat of Athens county. It is on federal highways 50 and 33, and is served by the Baltimore and Ohio, the New York Central and the Chesapeake and Ohio railways. The population in 1940 was 7.696. The city occupies a site 70 ft. above the river, which almost encircles it, and commands views of some of the most beautiful scenery in the state. There are several prehistoric mounds in the vicinity. South of the city is a state hospital for the insane. The principal manufactures are office equipment, files and parquetry flooring. Parts of the Jackson, Ironton, and Hocking coalfields lie within the county.

Athens is the seat of Ohio university (co-educational), the oldest college north-west of the Ohio. When the Ohio Company, in 1789, made its contract for the purchase of land in the North-west Territory, Manasseh Cutler secured from Congress the donation of two entire townships as a perpetual endowment for a university. In 1801 he was appointed by the Territorial Legislature, one of the trustees of the Ohio University, to bring the lands into available use, and he proceeded up the Hocking river with a fleet of canoes, and with compass and chain fixed the boundaries of the university campus in the virgin forest. A charter for "the Ameri-

can University" was granted by the Territorial legislature in 1802; and in 1804 the new State legislature passed a modified act establishing "Ohio University" in the town of Athens. The college was opened in 1809. A building erected in 1817 is still in use. In recent years the total net enrolment of resident students has been about 3,500, of whom about 42% were women. The appropriations by the legislature for 1939–40 were $1,371,124.

Athens was made the county seat in 1805; was incorporated as a village in 1811; and was chartered as a city in 1911.

See S. P. Hildreth, *Biographical and Historical Memoirs of fhe early Pioneer Settlers of Ohio,* **p.** *114.*

ATHERSTONE, WILLIAM GUYBON (1813–1898), British geologist, one of the pioneers in South African geology, was born in 1813 in the district of Uitenhage, Cape Colony, and died at Grahamstown, June 26, 1898. He devoted the leisure of a long and successful medical practice to the pursuit of geological science. Atherstone's identification as a diamond of a crystal found at De Kalk, near the junction of the Riet and Vaal rivers (1867), led indirectly to the establishment of the great diamond industry of South Africa. He encouraged the workings at Jagersfontein, and he also called attention to the diamantiferous neck at Kimberley. He was one of the founders of the Geological Society of South Africa at Johannesburg in 1895; and was for some years a member of the Cape Parliament.

See the obituary by T. Rupert Jones, *Natural Science,* vol. xiv. (Jan. 1899).

ATHERSTONE, market-town, Warwickshire, England, 102½ mi. N.W. from London by the L.M.S. railway. Pop. (1931) 6,245; of rural district (est. 1938) 22,000. It lies in the upper valley of the Anker and is on the Coventry canal.

Atherstone (Aderestone, Edridestone, Edrichestone) is mentioned in Domesday Book among the possessions of Countess Godiva, the widow of Leofric. In the reign of Henry III. it passed to the monks of Bec in Normandy, who in 1246 obtained the grant of an annual fair at the feast of the Nativity of the Virgin, and the next year of a market every Tuesday. This market became so much frequented that in 1319 a toll was levied upon all goods coming into the town, in order to repair the roads, and in 1332 a similar toll was levied on all goods passing over the bridge called Feldenbrigge, near Atherstone. The September fair and Tuesday markets are still continued.

ATHERTON or **CHOWBENT,** urban district, Lancashire, England, 13 mi. W.N.W. of Manchester on the L.M.S. railway. Population (1938) 20,590. The cotton facto ies account for the rapid industrialization of the district. The manor was held by the Athertons from John's reign to 1738, when it passed by marriage to Robert Gwillym and subsequently to Lord Lilford. It is an early Nonconformist centre, with a chapel built in 1645. During the rebellion of 1715 this Nonconformist church headed by its pastor marched against the Pretender, a typical attitude for a weaving population. Up to 1891 the lord of the manor held a court-leet and court-baron annually in November, but in that year Lord Lilford sold to the local board the market tolls, stallages and pickages, and since this sale the courts have lapsed. The earliest manufactures were iron and cotton. Silk-weaving, formerly an extensive industry, has now almost entirely decayed. At the present time textile works, mining (coal) and quarrying, as well as iron foundries, are the most important sources of employment.

ATHETOSIS, the medical term for certain slow, purposeless movements of the hands and feet. The fingers are separately flexed and extended, abducted and adducted in an entirely irregular way. The hands as a whole are also moved, and the arms, toes and feet may be affected. The condition is usually due to some lesion of the brain which has caused hemiplegia, and is especially common in childhood. It is occasionally due to injury of the brain during birth. Athetosis never develops where there is no recovery of voluntary power. The movements are one-sided and may or may not continue during sleep. They cannot be arrested for more than a moment by will power, and are aggravated by voluntary movements. The prognosis is unsatisfactory, as the condition usually continues unchanged for years, though improvement occasionally occurs in slight cases, or even complete recovery.

ATHIAS, JOSEPH (died May 12 1700), Jewish rabbi and printer, was born in Spain and settled in Amsterdam. His editions of the Hebrew Bible (1661, 1677) are noted for beauty of execution and the general correctness of the text. He also printed a Judaeo-German edition of the Bible in 1679.

ATHLETE, in Greek and Roman antiquities, one who contended for a prize (ἆθλον) in the games; now a general term for any one excelling in physical strength (Gr. ἀθλητής; Lat. *athleta).* Originally denoting one who took part in musical, equestrian, gymnastic or any other competitions, the name became restricted to the competitors in gymnastic contests, and, later, to the class of professional athletes. Whereas in earlier times, competitors, who were often persons of good birth and position, entered the lists for glory, without any idea of material gain, the professional class. which arose as early as the 5th century B.C., was chiefly recruited from the lower orders, with whom the better classes were unwilling to associate, and took up athletics entirely as a means of livelihood. Ancient philosophers, moralists and physicians were almost unanimous in condemning the profession of athletics as injurious not only to the mind but also to the body. The attack made upon it by Euripides in the fragment of the *Autolycus* is well known. The training for the contests was very rigorous. The matter of diet was of great importance, this was prescribed by the *aleiptes,* whose duty it also was to anoint the athlete's body. At one time the principal food consisted of fresh cheese, dried figs and wheaten bread. Afterwards meat was introduced, generally beef or pork; but the bread and meat were taken separately, the former at breakfast, the latter at dinner. Except in wine, the quantity was unlimited, and the capacity of some of the heavyweights must have been, if such stories as those about Milo are true, enormous. In addition to the ordinary gymnastic exercises of the palaestra, the athletes were instructed in carrying heavy loads, lifting weights, bending iron rods, striking at a suspended leather sack filled with sand or flour, taming bulls, etc. Boxers had to practise delving the ground, to strengthen their upper limbs. The competitions open to athletes were running, leaping, throwing the discus, wrestling, boxing and the pancratium, or combination of boxing and wrestling. Victory in this last was the highest achievement of an athlete, and was reserved only for men of extraordinary strength. The competitors were naked, having their bodies salved with oil. Boxers wore the *caestus* (*q.v.*), a strap of leather round the wrists and forearms, with a piece of metal in the fist, which was sometimes employed with great barbarity. An athlete could begin his career as a boy in the contests set apart for boys. He could appear again as a youth against his equals, and though always unsuccessful could go on competing till the age of 35, when he was debarred, it being assumed that after this period of life he could not improve.

Amongst the Romans, athletic contests had no doubt taken place from the earliest times, but according to Livy (xxxix. 22) professional Greek athletes were first introduced at Rome by M. Fulvius Nobilior in 186 B.C. After the institution of the Actian games by Augustus their popularity increased, until they finally supplanted the gladiators. In the time of the empire, guilds or unions of athletes were formed, each with a temple, treasury and exercise-ground of its own. The profession, although it ranked above that of a gladiator or an actor, was looked upon as derogatory to the dignity of a Roman, and it is a rare thing to find a Roman name among the athletes on inscriptions. The system was entirely. and the athletes themselves nearly always, Greek *(See* also GAMES. CLASSICAL, and ATHLETIC SPORTS)

ATHLETICS, WOMEN IN. During World War I women began to enter fields of sport which hitherto had been the private preserves of the male sex. Football, boxing, wrestling and field and track athletics, including the tug-of-war, became popular and were more or less efficiently practised by women. After the War France created a State department of sport, under the Ministry of Health and Education. The object of this department,

which has now become a ministry, was to provide every member of the republic with his or her game. It was early realized that to be included in the international team would be the aim and object of every athlete of either sex, and it was mainly due to the energetic promotion of international athletic matches for women by France, and their repeated invitations to England to take part therein, that the international and national governing bodies of women's athletics in many countries of the world have been brought into being.

France was responsible for the formation in 1921 of the *Fédération Sportive Féminine Internationale,* which is the supreme governing body of women's sport. At the inaugural meeting the countries represented were the United States, Czechoslovakia, France, Great Britain, Italy and Spain, but now the nations which send delegates to the F.S.F.I. congresses are: United States, France, Great Britain, Sweden, Czechoslovakia, Belgium. Italy, Japan, South Africa, Argentina, Australia, Austria, Brazil, Bulgaria, Canada, Chile, China, Denmark, Egypt, Spain, Estonia, Finland, Greece, Hungary, Latvia, Lithuania, Luxembourg, Norway, Holland. Peru, Poland, Portugal, Rumania, Switzerland, Turkey, Uruguay, Yugoslavia. In 1922 the English Women's Amateur Athletic Association was founded at the suggestion of the A A A. The English Association now legislates for more than 23,000 girls.

Some minor international meetings, in all of which Great Britain was successful, took place in the years immediately after the World War, but the first Olympic games for women were not held until 1922. The British women were once more successful, the general classification of points being: Great Britain 50, United States 31, France 29, Czechoslovakia 12 and Switzerland 6. At the first Olympiad the victors were as follows:—

Event	Winner	Country	Time or distance
			min. sec.
60 metres	Mejzlikova II.	Czecho-slovakia	$7\frac{3}{5}$
100 yards	Callebout	England	12
300 metres	M. Lines	England	$44\frac{4}{5}$
1000 metres	L. Bréard	France	3 12
100 yards hurdles	C. Sabie	U. S. A.	$14\frac{2}{5}$
440 yards relay	Great Britain		$51\frac{4}{5}$
			ft. in.
High jump (with run)	C. Hatt / N. Voorhees	England / U. S. A.	4 $9\frac{3}{16}$
Long jump (with run)	M. Lines	England	16 $6\frac{7}{8}$
Long jump (without run)	C. Sabie	U. S. A.	8 $2\frac{1}{8}$
Putting the weight (both hands)	L. Godbold	U. S. A.	66 $4\frac{3}{4}$
Javelin (both hands)	F. Pianzola	Switzerland	141 $10\frac{3}{8}$

The first Olympic games for women, held at Paris in 1922, were an attempt to revive the women's athletic festivals of classical antiquity. At that time athletics for women (apart from fencing) scarcely existed in Sweden. There was some interest in the schools and a few events at the schools annual sports at Stockholm. Meanwhile the propaganda committee of the Swedish National Athletic Association formulated special lines of work for the movement, resulting in women's competitions, but there were very few entries. In the summer of 1925 a strong team of English girl athletes visited Sweden, and, competing at Gothenburg and Falkenberg, aroused such interest that the *Sveriges Kvinnliga Idrottsförbund* (Women's Athletic Association) was at once formed and affiliated to the F.S F.I.

At the third congress of the F S.F.I. it was arranged that the second women's Olympiad should be held at Brussels in 1926, a venue later changed to Gothenburg in Sweden. The organizers had received entries from ten nations but, unfortunately, Italy and Yugoslavia were unable to send teams. The eight nations represented were Belgium, Czechoslovakia, France, Great Britain, Japan, Latvia, Poland and Sweden. The games lasted for three days of unbroken sunshine and the large attendance of spectators made it unnecessary for the organizers to call upon the Swedish sportsmen who had guaranteed the expenses of the games. When the contests were over and the final points assessed Great Britain came first with 50 points, then France 27, Sweden 20, Czechoslovakia 19, Japan 15, Poland 7 and Latvia 1. The results were as follows:—

Results at the Second Internatzonal Ladies' Games

Event	Performance	Winner	Nation
	min. sec.		
60 metres run	78	Radideau	France
100 yards run	$11\frac{4}{5}$	,,	,,
250 metres run	$33\frac{2}{5}$	Edwards	Gt. Britain
1000 ,, ,,	3 $8\frac{4}{5}$	Trickey	,, ,,
440 yards relay (4x110 yards)	495	Gt. Britain	,, ,,
rom metres walk	5 10	Crossley	,, ,,
100 yards hurdles	$14\frac{2}{5}$	Sychowa	Czecho-slovakia
	ft. in.		
Running high jump	4 $11\frac{1}{16}$	Bonze	France
,, long ,,	18 $0\frac{1}{2}$	Hitomi	Japan
Standing ,, ,,	8 $2\frac{1}{8}$	,,	,,
Discus (best hand)	124	Konopacka	Poland
Shot put (right hand 33 ft., $11\frac{1}{8}$ in.) (left hand 30 ft., $2\frac{1}{4}$ ins.)	64 $2\frac{11}{16}$	Vidalkowa	Czecho-slovakia
Javelin (right hand 97 ft, $3\frac{9}{16}$ in) (left hand 63 ft., $11\frac{7}{16}$ in.)	161 3	Adelskold	Sweden

The fourth congress of the F.S.F.I. took place in Gothenburg on Aug. 27–29, 1926; Belgium, Czechoslovakia, France, Germany, Great Britain, Italy, Japan, Lithuania, Luxembourg, Poland, Sweden and Switzerland were represented. At this congress it was decided to adopt and use the metric system only and to eliminate races at distances between 200 and 800 metres. The weight of the women's javelin was fixed at 600 grams (1·322lb.) and that of the shot and discus at 4 kilograms (8·8184lb.) and 1 kilogram (2·2046lb.) respectively. It was also agreed to take account only of best hand throws at the next games and to exclude walking contests from the list of records. The most important question dealt with was that of participation in the men's Olympic games, the I.O.C. having decided to include five events for women at the ninth Olympiad at Amsterdam in 1928. These resulted as follows:—

Event	Winner	Country	Time or Distance
			min. sec.
roo metres.	E. Robinson	U.S.A.	$12\frac{1}{5}$
800 metres.	L. Radke	Germany	2 $16\frac{4}{5}$
400 metres relay	Canadian Olympic Team	Canada	$49\frac{2}{5}$
High Jump	E. Catherwood	Canada	5 ft 3 in
Discus	H. Konopacka	Poland	129 ,, $11\frac{7}{8}$,,

Note. In each of the above events a new world's record was made.

It may be added that all the nations subsequently decided to take part, with the sole exception of Great Britain. At the fourth congress of the F.S.F.I. it was decided to hold the third international ladies' games at Prague in *1930.*

Each country has its own governing body and its annual national championships. Two important international matches have taken place in London, more than 25,000 spectators being present on each occasion. In 1924 Great Britain scored 56 points, France 24, Belgium 15, Czechoslovakia 13, Switzerland 7 and Italy 2. In 1925 there was a triangular match between Great Britain (56 points), Czechoslovakia (26 points) and Canada (23 points). Women's athletic sport is growing rapidly, and a high level of performance has been already reached, as may be seen from the table of world's records on pp. 614–6.

See F. A. M. Webster's *Athletics* of *To-day for Women* (Frederick Warne & Co., Ltd., London, 1930). (**F. A.** M. W.)

ATHLETIC SPORTS. Various sports were cultivated many hundreds of years before the Christian era by the Egyptians and several Asiatic races. The Irish, too. had a great festival known as the Lugnasad, or Tailtin games, which were celebrated several

centuries B.C. From such ancient festivals as these the early Greeks undoubtedly adopted the elements of their athletic exercises *(see* ATHLETE) which reached their highest development in the Olympic games and other periodical meetings of the time *(see* GAMES, CLASSICAL). After the Norman Conquest of England the nobles devoted themselves to the chase and the joust, but the people also had their sports. In the main these were in the nature of preparations for war. The chroniclers of the middle ages are, for the most part, silent concerning the purely recreational pastimes. We are told, however, that Henry V. "was so swift a runner that he and two of his lords, without bow or other engine, would take a wiid buck in a large park." Strutt *(Sports and Pastimes of the People of England)* chronicles the fact that young men of good family were taught to run, leap, wrestle and joust. Several ordinances of reigning sovereigns make it clear that the common people had their sports, but these, apparently, interfered with the practice of archery, and Edward III. prohibited weight-putting by statute. The popularity of feats of strength prevailed, however, and we find, later, that "casting of the barre" was a popular pastime with Henry VIII., who had also a penchant for throwing the hammer. In the reign of this monarch there appears to have been a great athletic revival. Opinion as to the value of athletics was sharply divided during the reign of Henry VIII. His secretary, Richard Pace, advised the sons of noblemen to practise sport and leave study and learning to the sons of meaner people. At about the same period Sir Thomas Elyot deprecated too much study and flogging for schoolboys and suggested that more satisfactory results might be obtained by a proper appreciation of athletic lore. On the other hand Roger Ascham, in his *Toxophilus,* declares that "running, leaping and quoiting be too vile for scholars." Up to the 16th century a great football match had been played annually at Chester, but in that century was abandoned in favour of a series of foot-races, which took place in the presence of the mayor. The Stuart kings were warm encouragers of sport, and James I. in the *Basilikon Doron,* written to his son, recommended all forms of manly exercise. During the Puritan rule and that of Charles II., however, athletic sport all but died out in England, only to be revived with renewed vigour in the early part of the 19th century.

An extraordinary variety of sports has been popular in the British Isles with people of all classes for the past 500 years, but so far as history and legend record Ireland boasts by far the most ancient organized sports, the Tailteann Games, or Lugnasad, traditionally established by Lugaid of the long arm, one of the gods of Dia and Anna, in honour of his foster-mother, Tailti, some 3,000 years ago. Cuchulain, the mythical Irish hero, is said to have taken part. For many centuries these games and others like them were kept up in Ireland, and though almost constant wars which harried the country finally destroyed their organization, yet the Irish were for many centuries a very important factor in British athletics, as well as in America and the British dominions overseas. The Tailteann Games were successfully revived at Dublin in 1924, following upon the eighth Olympiad at Paris in the same year.

The Scottish people have, like the Irish, ever delighted in feats of strength and skill, especially the Celtic Highlanders. Unfortunately many of the great Highland gatherings are still of a professional nature, which has prevented the Scottish athlete from attaining the truly world-wide prominence to which his performances justly entitle him.

The Briton does not lose his love of sport upon leaving his native soil, and the development of athletics in the United States and the British dominions has, in many events, forged far ahead of that of the Motherland. Since the institution of the modern Olympic Games at Athens in 1896, national championship meetings have been promoted annually on the Continent and throughout Scandinavia. In recent years America, Finland, France, Germany, Italy, Norway and Sweden have produced a number of extraordinary world's record-breakers.

The first regularly organized athletic meeting of modern times was that promoted by the Royal military academy, Woolwich, in 1849. A year later Exeter college, Oxford, inaugurated sports which have been continued annually down to the present day. The Exeter college meeting was undoubtedly the precursor of the Cambridge sports founded in 1857 and the Oxford sports which were first decided in 1860. The Oxford and Cambridge sports commenced in 1864 and the English championships in 1866.

In 1852 Kensington grammar school began to hold regular sports meetings, Harrow and Cheltenham and Durham university followed suit a year later, and from those days may be traced the growth of athletic sport in English schools which now has reached its climax in the public schools sports meeting promoted annually by the London Athletic Club. The London Athletic Club came into being in June, 1863, under the style of the Mincing Lane Athletic Club, the majority of the founders having their business in that centre of London trade. In the following year

two meetings were held at the West London grounds at Brompton. In the spring of 1866 the club changed its name to its present style of the London Athletic Club. The year 1864 marks a definite epoch in the history of modern athletics. On March 3 Cambridge visited Oxford for a match of eight events on the Christ Church cricket ground, the result being a draw, as each side won four events. The Oxford and Cambridge sports were not moved to London until 1867. In the same year, 1864, the Civil Service sports were started, and at the beginning of 1866 the Amateur Athletic Club was formed to "supply the want of an established ground upon which competitions in amateur athletic sports might take place between gentlemen amateurs." The first English championship meeting was promoted by the A A C. in 1866. Despite this fact active athletes continued to ally themselves more with the L.A.C. than the A.A.C. The year 1879 marked a point of cleavage and two championship meetings were held: one promoted by the A.A.C., which had up to that time been in the habit of holding the championships in the spring, immediately after the Oxford and Cambridge sports, the other being held later in the summer under the management of the L.A C. for the greater convenience of non-university athletes. In 1880 the English Amateur Athletic Association was founded, and British athletic sports, together with the promotion of the English championships, have remained under the jurisdiction of that body ever since.

Annual championship meetings are held in the dominions and all foreign countries, the programmes being based upon the list of events contested quadrennially at the Olympic games. Of late years in England a general tightening up of the rules has placed a period upon the time during which a man may represent his university. In 1927 the joint committees of the Oxford and Cambridge university athletic clubs adopted the following new regulations regarding the eligibility of competitors in inter-university contests:

"That the present eligibility rules governing the inter-university athletic sports be cancelled and the following substituted: The eligibility to compete in (1) the inter-university sports, relays and cross-country races shall be limited to members of the two universities who, on the date on which the meeting is held, have not exceeded four calendar years from the date of their matriculation in either university; (2) Any meeting in which the two universities compete as such, including those mentioned in (1). shall be limited to those who have not exceeded the age of 23 years on Oct. 1 preceding the meeting in question. These rules, (1) and (2) to take effect as from Oct. 1, 1927, but not to affect those who were resident members of the universities of Oxford and Cambridge before that date, to whom the old rules will apply." (For eligibility rules in U.S. universities, see ATHLETIC SPORTS: United *States.)*

Athletic sports are now usually understood to consist of those events recognized in the championship programmes of the different countries which, in their turn, are based upon the Olympic games schedule of events. This, however, does not apply so far as England is concerned. Apart from the numerous championship meetings and international, inter-county and inter-club matches, the majority of sports meetings in England are confined to flat race handicaps, the field events and hurdle racing are entirely ignored and it is true that only during the last few years the whole of the Olympic field events have been included in the A A A. open and district championships programmes, nor are the whole of these events even yet practised at Oxford and Cambridge, whereas in America nearly all of the items have been added to the A.A.U. and I C.A.A.A.A. championship programmes as soon as they were raised to Olympic status. The events included in the Oxford and Cambridge sports are 100yd., 440yd., 880yd., 1m., 3m., 120yd. high hurdles, 220yd. low hurdles, high and long jumps, pole vault and shot put. Of the above list the A.A A. Open English championships do not include the 3m. run and the 220yd. low hurdles, but add 4m. and 10m. walks, 440yd. low hurdles. 2m. steeplechase, throwing the hammer, discus and javelin, hop, step and jump. tug of war (catch weights), tug of war (100st.), 440yd. relay race (4 x 100), and 1m. relay race (4 x 440yd.). In 1920 there was instituted an annual relay meeting between Oxford and Cambridge. Up to 1927 no Blues had been awarded for this match, which now comprises 400yd., ½m., 1m., 2m., 4m., 480yd. high hurdles and 880yd. low hurdles, four runners, each covering an equal quarter of the distance, representing either university in each event.

(For the United States events, *see* the article TRACK AND FIELD SPORTS.)

Long before annual championship meetings were instituted in any country the desire to pit the athletes of one nation against those of another was clearly in evidence, and England was visited in 1844 by George Seward, an American professional runner, who achieved some signal successes, and in 1863 by Louis Bennett, called "Deerfoot," a full-blooded Seneca Indian, who established running records up to 12 miles. In 1884 a team of Irish athletes, among them the late Dr. W. J. M. Barry, a magnificent exponent of the heavy-weight field events, visited Canada and won several championships. In 1888 the Manhattan A.C., New York, sent to England a team and the Gaelic A.A. despatched a team to America. In 1890 the Salford Harriers were the guests of the Manhattan A.C. in New York, and the following year the Manhattan athletes went again to England. The first matches of a truly international character occurred, however, in 1894 and 1895, and were arranged by the famous Yale sprinter, C. H. Sherrill, who invented the crouch start. In 1894 the universities of Yale and Oxford met in London and the English blues proved successful by winning 5½ to 3½ events. The following year the London A.C. took to New York almost the strongest team that could be mustered in the British Isles. They competed against the New York A.C., but did not win a single event. Twelve thousand people witnessed this match on Manhattan Field. Fourteen events comprised the programme and three world's records were broken and one equalled. Two weeks later Cambridge was defeated by Yale in America by 8 events to 3. In 1899 Oxford and Cambridge combined forces for a match in London against Harvard and Yale, who were beaten by the odd event.

A summary of the most interesting meetings follows:—

1894	Oxford 5½	Yale 3½	in England
1895	Yale 8	Cambridge 3	in America

It is from the enterprise of such bodies as the Salford Harriers, Gaelic A.A., London A.C., Manhattan A.C. and New York A.C. and the early meetings between English and American universities that the present series of international matches between all countries throughout the world, apart from the Olympic Games, has grown, until no athletic season passes at the present time without each country engaging in several international matches with one or more other countries. The most important of all international festivals is, however, the revived Olympic Games. They were instituted by delegates from the different nations who met in Paris on June 16, 1894, principally at the instigation of Baron

Pierre de Coubertin, the result being the formation of an international Olympic Games committee with Baron de Coubertin at its head which resolved that games should be held every fourth year in a different country.

First Olympiad. — The first modern Olympiad took place at Athens, April 6–12, 1896, in the ancient stadium, which was rebuilt through the liberality of M. Averoff, a Greek merchant, and seated about 45,000 people. The programme of events included the usual field and track sports, gymnastics, wrestling, rope-climbing, lawn-tennis, fencing, rifle and revolver shooting, weight-lifting, swimming, the Marathon race and bicycle racing. Among the contestants were representatives of nearly every European nation, besides Americans and Australians. Great Britain took little direct interest in the occasion and was inadequately represented, but the United States sent five men from Boston and four from Princeton university, who, although none of them held American championships, succeeded in winning every event for which they were entered. The Marathon race of 42 kilometres (26m.), commemorative of the famous run of the Greek messenger to Athens with the news of the victory of Marathon (see MARATHON RACE), was won by a Greek peasant.

Second and Third Olympiads. — The second Olympiad was held in Paris in June, 1900. Again Great Britain was poorly represented, but American athletes won 18 of the 24 championship events. The third Olympiad was held at St. Louis, Mo., in the summer of 1904 in connection with the Louisiana Purchase Exposition, its success being due in great measure to the late James E. Sullivan, the physical director of the exposition, and Caspar Whitney, the president of the American Olympic Games committee. Although there were scarcely any entries except Americans, the programme contained far more events than those of the previous Olympiads, including sports of all kinds, handicaps, inter-club competitions and contests for aborigines. In the track and field competitions the American athletes won every championship except weight-throwing (56 lb.) and lifting the bar. The sports of the American Indians, Africans of several tribes, Moros, Patagonians, Syrians, Ainus and Filipinos were disappointing, their efforts in throwing the javelin, shooting with bow and arrow, weight-lifting, running and jumping proving to be feeble compared with those of the white races. The American Indians made the best showing.

Since that time, however, coloured athletes have attained to a remarkable prominence. At the Stockholm Olympiad, 1912, James Thorpe, an American Indian, won the pentathlon by a margin of 14 points and the decathlon with 8,412·955 points, which latter performance would have stood for many years as a world's record but that Thorpe was unfortunately declared a professional on the technicality of once, as a youth, having accepted a small payment for playing in a baseball game. At the same Olympiad, Louis Tewanami, another American Indian, finished second in the 10,000 metres world's championship. More recently France has produced one and America three negro long jumpers who have beaten 2 jft., while two of the best sprinters Great Britain has had since the war are H. F. V. Edward, a West Indian, and J. E. London, a native of British Guiana. A regular championship meeting is now held annually in Kenya Colony for East African natives, and there are also Egyptian championships.

The Greeks, however, were not altogether satisfied with the cosmopolitan character of the revival of the celebrated games of their ancestors, and resolved to give the revival a more definitely Hellenic stamp by intercalating an additional series to take place at Athens, in the middle of the quadrennial period. Their action was justified by the success which attended the first of this additional series at Athens in 1906. This success may have been partly due to the personal interest taken in the games by the king and royal family of Greece, and to the presence of King Edward VII., Queen Alexandra and the prince and princess of Wales; but to whatever cause it should be assigned it was generally acknowledged that neither in France nor in America had the games acquired the same prestige as those held on the classical soil of Greece. In 1906 the Governments of Germany, France and the United States made considerable grants of money to defray the expenses of the competitors from those countries. The 1906 intercalated games aroused much more interest in England than the earlier ones in the series, but although upwards of 50 British competitors took part in the contests, they were by no means representative in all cases of the best British athletes. The American representatives were slightly less numerous, but they were more successful. It was noteworthy that no British or Americans took part in the rowing races in the Bay of Phalerum, nor in the tennis, football or shooting competitions. The English fencing team (epée) was composed of Lord Desborough, Sir Cosmo Duff Gordon, Edgar Seligman, Charles Newton-Robinson, Lord Howard de Walden (spare man) and Theodore Cook (captain). They fought France to a dead heat in the final. The Marathon race, by far the most important event in the games. was won in 1906 by a British athlete, M. D. Sherring, a Canadian by birth. Nine hundred and one competitors, representing 19 countries, took part. In accordance with an unofficial method of scoring adopted by the special correspondents of the press, America finished first in the athletic section with $75\frac{1}{6}$ points, Britain second, 41 points, Sweden third, 28 points and Greece fourth, $27\frac{1}{2}$ points. The Greeks have never been able to repeat the intercalated series of games at Athens, partly owing to the expense, partly because the Athenian Stadium is not built for high speed round the corners.

Fourth Olympiad. — The games of the fourth Olympiad (1908) were held in London in connection with the Franco-British Exhibition of that year. An immense sensation was caused by the finish of the Marathon race from Windsor Castle to the stadium in the Exhibition grounds in London. The first competitor to arrive was the Italian, Dorando Pietri, whose condition of physical collapse was such that, appearing to be on the point of death, he had to be assisted over the last few yards of the course. He was, therefore, disqualified, and J. Hayes, an American, was adjudged the winner; a special prize was presented to the Italian by Queen Alexandra. In the whole series of contests the United Kingdom made 38 wins, the Americans 22 and the Swedes 7. In the Olympic Games proper (athletic track and field events section), British athletes, including two wins by colonials from Canada and South Africa, scored 25 successes and the Americans 18. In the track events eight wins fell to the British including two colonials and six to American athletes; but the latter gained complete supremacy in the field events, of which they won nine, while British competitors secured only two of minor importance.

The London Olympiad of 1908 may, however, well be regarded as marking the commencement of a fresh athletic era throughout the world. It is worthy of note that the United States, in pursuit of a progressive policy, has always at once included in the Amateur Athletic Union and inter-collegiate championship programme any new event which might be added to the Olympic syllabus. The English Amateur Athletic Association (A.A.A.), on the other hand, for many years ignored such events as throwing the javelin, discus and 56 lb. weight and the hop, step and jump, and allowed to fall into disuse, through lack of encouragement and facilities for competition, such excellent exercises as pole vaulting, shot putting and hammer throwing, and gave but little more attention to high and long jumping and hurdling.

In 1910 the English Amateur Field Events Association (A.F.E.A.) was formed and authorized by the A.A.A. to hold championships. The new championships instituted were standing high jump (J. E. Boyde, 4ft. 6in.), standing long jump (L. H. G. Stafford, 9ft. $11\frac{3}{4}$in.), hop, step and jump (M. D. Dineen, 41ft. 6in.), throwing the javelin (F. A. M. Webster, 118ft. 11in.), and 440yd. hurdle race (E. B. Grier, $63\frac{2}{5}$sec.). By 1914 the purpose of the A.F.E.A. had been fulfilled, for in that year the A.A.A. incorporated in its championship programme the javelin, discus, hop, step and jump, and the 440yd. low hurdles, but even then these events were not taken so seriously as the others.

Fifth Olympiad. — Meanwhile the holding of the fifth Olympiad (1912) had been allotted to Stockholm, and the Swedes had recalled from America that great athletic coach, Ernie Hjertberg, to make ready a national team. Finland, also, had produced a great distance runner in Hannes Kolehrnainen, and a set of magnificent heavy-weight field events men, such as Saaristo, Taipale and

Niklander, while France had come into prominence with the late Jean Bouin, a world's distance-running record holder, who was, however, beaten by Kolehmainen in both the 5,000 and 10,000 metres races. Germany, too, gained prominence with R. Rau, the sprinter, H. Braun, the middle-distance runner, and H. Leische, the high jumper. Great Britain did very badly and would have been completely disgraced but for the superb running of A. N. S. Jackson, Oxford university, who won the 1,500 metres from a number of American world's record breakers, and in so doing set up a new Olympic record for the distance; in the 400 metres relay race Great Britain was also successful.

It is significant that at the Stockholm Olympiad the United States finished first with a total of 85 points, Finland second with 29 points, Sweden third with 27 points and Great Britain fourth with 15 points. American athletes were again in the ascendant, but with their supremacy challenged by Finland and Sweden. Finland, Sweden, Norway and Denmark had now become definitely athletic countries; while France, Germany and the lesser European nations, such as Italy, Belgium and Holland, were all showing steady progress towards national athletic efficiency.

More International Matches. — About this time, too, the custom of holding international athletic matches became popular. Most notable of all these, perhaps, is the Scandinavian *Landskamp,* founded in 1917, in which Norway, Sweden and Denmark meet annually at Oslo, Copenhagen and Stockholm in rotation. France, too, entered the international arena with matches with Sweden and Belgium, and Great Britain began to hold a triangular international, in which England, Ireland and Scotland meet annually. The other European nations, in meeting each other, contest practically the whole of the Olympic programme, whereas from England's match with France are excluded such important events as javelin throwing, pole vaulting and the low hurdles, and in the case of the British triangular international the discus is also omitted. In any comparison of international prowess in field events it is only fair to note that neither discus nor javelin throwing is practised at Oxford and Cambridge, and that the hammer-throwing event has been abandoned, while these events are regular features at all American and foreign schools, colleges and universities. Examination of world, university and school records shows clearly that England has fallen far behind the other nations in athletics. This circumstance is directly traceable to the fact that no coaching, such as appertains in cricket, is given to English boys while they are still at school, whereas the youths of other nations enter the universities with their athletic education already far advanced.

The War Period. — After Stockholm came the World War, which prevented the Sixth Olympiad, although a vast stadium had been built to house it at the Griinewald, Berlin. Many doubtless thought that in those strenuous years all sports must come to an end. This was not to be. Alva Kranzlein, the American sprinter-hurdler-jumper, had returned to Germany, the land of his forefathers, to make ready the German Olympic team, and in Germany or Hblland he stayed throughout the war, laying the foundations of a great athletic future for those nations. He was probably the first person to discover, in the internment camp at Gravenhaag, Holland, the potentialities of H. F. V. Edward, the West Indian sprinter, who won so many A.A.A. championship titles.

In England championships were abandoned from 1914 to 1919. Athletic meetings of a sort continued to be held under an unofficial general amnesty, which allowed pure amateurs and those soldiers who had forfeited their amateur status to compete together. In Great Britain the London Athletic Club contrived to carry on the public schools sports meeting right through the war, thus assuring for Great Britain the nucleus of a fine supply of athletes of international standing when the days of war should be ended. This public schools sports meeting, which has done more than anything else to induce British boys, to pay more attention to athletics, commenced in 1890, in which year C. H. Mason presented a quarter-mile challenge cup to be competed for annually by public school boys at an L.A.C. meeting. In subsequent years other cups were given and in 1897 a number of L.A.C. members presented public schools challenge cups to commemorate the diamond jubilee of Queen Victoria. A public schools meeting was promoted that year and now the public schools sports meeting comprises 100, 440 and 880yd., 1m., 1m. walk, 120yd. hurdles, ¾m. steeplechase, high jump, long jump and pole vault, and junior competitions for boys between 14 and 16 years of age, at 100yd., 250yd. and high jump. This meeting is the most important fixture of the public schools athletic season.

Education of Athletes. — Here one may pause to draw attention to the splendid movement now in progress all over the world for the better athletic education of boys at school. In the United States the universities and colleges, as well as all schools of any standing, have their properly qualified athletic coaches. Inter-university, inter-collegiate and inter-school athletic meets are exceptionally popular, and the same may be said of the Scandinavian and many other European nations. France, in particular, has established a ministry of sport. In Scotland inter-scholastic championships have long been in vogue. In England the public schools sports meeting and also the public schools relay meeting, the latter under the auspices of the Achilles Club, are both established fixtures, and there is now an Inter-Schools Athletic Association (elementary schools) which, for the first time, held championships in 1925. But in no country, save possibly the United States, is there to be found anything approaching the Swedish schoolboys' athletic week, held annually in Stockholm, to which city school teams journey from every part of Sweden. (*See* the United *States* section of this article, and TRACK AND FIELD SPORTS.)

To revert, however, to the war period. The United States, unaffected by the struggle in its early stages, and Sweden, Norway and Denmark, which countries maintained their neutrality throughout this time of strife, forged rapidly ahead. In 1915 at Cambridge, Mass., Norman S. Taber (Brown university, U.S.A.), placed upon the books a new amateur mile world's record of 4mins. 12⅗secs., which, at last, eclipsed the professional mile time of W. G. George, who, in 1866, covered the distance in his match with W. Cummings at Lillie bridge, in 4mins. 12¾secs., a record which was broken only by Paavo Nurmi in 1925. Taber's race was the forerunner of a great many record-breaking performances.

In 1916 at Evanston, Ill., R. I. Simpson brought the 120yd. high hurdles record down to 14⅘secs., owing to certain modifications he made in the then accredited style of hurdling; and in 1920, a young Canadian, Earl Thomson, who had served in the Royal Air Force, still further reduced the record time to 14⅖secs. Two of the most noteworthy achievements of the war period were the performances accomplished in 1916 by J. E. Meredith (University of Pennsylvania, U.S.A.), who set up new world's records for the quarter-mile, which he ran in 47⅖secs., and the half-mile run in 1min. 52⅕secs. At Magdeburg, in 1913, A. R. Taipale (Finland) threw the discus 158ft. 11in. This performance is duly recognized as a record in Scandinavia, but has never been passed by the International Amateur Athletic Federation. Otherwise it would stand as the world's record.

Shortly after the signing of the Armistice, a great inter-allied military athletic meeting took place in the Pershing Stadium at Paris. Of signal importance at this time was the step taken by the authorities of the British services, who decided that the pre-war custom of rewarding athletic proficiency among soldiers and sailors by money prizes must forthwith cease. An inter-services athletic sports meeting was held in 1919, at which some of Great Britain's dominion soldiers, not yet demobilized, proved clearly that the dominions themselves would hold a strong hand at the next celebration of the Olympic Games. It is interesting to note that even after the United States had entered the World War, the national A.A.U. championships were not abandoned, whereas, in Great Britain, no championship meetings took place between 1914 and 1919.

Peace Conditions Return. — In the year of the restoration of the **A.A.A.** championships the governing body again elected to omit certain of the field events from the programme; nor have they since insisted upon the inclusion of these events, which score

equally with the track events at the Olympic Games, in such important contests as the triangular international between England, Scotland and Ireland, the annual match between England and France, and the inter-county championships. The governing body in 1925 decided to abandon the English national championships, after they had been held for only three years, and were just beginning to produce a really satisfactory crop of fine young English exponents of these field events. The A.A.A. championships are open to the whole world and hitherto Great Britain has always been outclassed at the A.A.A. championships proper in the majority of field events.

In Great Britain the sterling post-war work of the Oxonians, A. N. S. Jackson and B. G. D. Rudd, coupled with the exertions of the Cambridge men, P. J. Baker, G. M. Butler, R. S. Woods and W. R. Seagrove, was responsible for inducing university athletes to take a healthy interest in open competitions generally, and championship meetings in particular, outside the limited scope of their own university sports.

In 1919, the Inter-University Athletic Board of Great Britain and Ireland was constituted, comprising the universities and university colleges of Aberystwith, Bangor, Birmingham, Bristol, Cardiff, Durham, Leeds, Liverpool, Manchester, Nottingham and Sheffield; other universities, including London, have since joined the movement. At these provincial universities the whole of the Olympic events are practised, and year by year the records, especially in the field of events, improve.

The keen promotion of and competition in athletics at the provincial universities is hating a far-reaching effect upon British sport. Sidney Best, of Leeds university, has been one of the most prominent people in the movement, and it is largely due to his efforts that there has been laid out at Westwood, Leeds, a ground which caters for every form of sporting activity, and which has an athletic track and field that is the equal of any to be found in the world. Other provincial universities are rapidly acquiring their own grounds, and as these are made available at certain times for the use of the general public, it follows that the nation must derive the greatest benefit from the I.U.A.B. movement. Lack of suitable tracks, playing fields and pitches is a factor which is seriously handicapping the athletic development of England, but this state of things is being slowly remedied by the work of the National Playing Fields Association. Much remains to be done before Great Britain reaches the level of the Dominions in this respect.

The participation of the University of London in the championships of the Inter-University Athletic Board had the effect of raising the standard between the years 1925–27.

Seventh Olympiad. — It was decided to hold the seventh Olympiad at Antwerp in 1920, partly as a tribute to the Belgian people for the part they had played in the war, but principally in order that the true Olympic cycle might not be interrupted. There was a great outcry that the war-worn nations were not yet sufficiently recovered to participate in such a festival. P. J. Baker, Cambridge university, was appointed captain of Great Britain's athletic team; the whole Olympic side came under the control of Brig. Gen. R. J. Kentish, C.M.G., D.S.O., and the British team won golden opinions in Antwerp. Great Britain did better in actual competition at this Olympiad than she had ever done at any previous celebration of the games. Notable victories were gained by A. G. Hill in the 800 and 1,500 metres, by B. G. D. Rudd, the Oxonian, representing South Africa, who won the 400 metres, and by Percy Hodge, who broke the world's record in the 3.000 metres steeplechase. The British team succeeded also in winning the 1,600 metres relay race.

At the conclusion of the Antwerp games, the United States was first, Finland second, Sweden third and the British Isles fourth, the same order as obtained at the conclusion of the Stockholm games, but in the other positions there was a marked difference. France, for example, eighth at Stockholm, was now fifth, while Italy had moved up from the eleventh to the sixth place. America's strength lay in the sprints, hurdles, relay races and jumps. Finland gained honours across country, in the middle-distances races and the throwing events. Sweden scored heavily through the magnificent team work of her men, and Italy came into prominence by the fine walking of Ugo Frigerio.

Further proof of the taste which the public was acquiring for international competition was exemplified immediately after the games by the match between France, Sweden and the United States, which took place in Paris, and that even greater match at Queen's Club, London, between the United States and the British empire, which ended in a dead heat. This latter match has evidently come to stay; it was repeated in London in 1924, after the celebration of the eighth Olympiad at Paris. In 1921 the International Amateur Athletic Federation held an important congress at Geneva. New rules for international competitions were passed and the Olympic programme at last standardized. The years that followed the Antwerp Olympiad were years of wonderful progress. This is conclusively proved by the existing world's records.

Eighth Olympiad. — At the eighth Olympiad held in Paris in 1924, at which nearly 2,000 athletes, representing 45 different nations, took part in the track and field events the United States, in 27 events, scored 12 first places, made five of the nine new world's records, and established two of the five new Olympic records, while one of the two marks, equalling previous Olympic records, was also established by an American. Of the other countries Finland scored nine first places, Great Britain three. New Zealand one, and Italy one. The manner in which world's and Olympic records were broken or equalled at this Olympiad mas amazing. In the 400 metres trials record was broken successively by J. Imbach (Switzerland), H. M. Fitch (U.S.A.), and E. Liddell (Great Britain). In the final Liddell still further reduced the record to $47\frac{3}{5}$ seconds. In the 400 metres relay race the world's and Olympic record, $42\frac{1}{5}$secs., made by the United States, Antwerp 1920, was beaten, Great Britain, in the first trial heat, reducing the time to 42 seconds. This was equalled by Holland in the third heat, and in the sixth heat the United States further reduced it to $41\frac{1}{5}$ seconds. In the first heat of the semi-final the United States team set up a new world's record of 41secs., and duplicated this in the final.

Ninth Olympiad. — The ninth Olympiad, held at Amsterdam in 1928, with 47 countries contesting, was distinguished by the wide distribution of awards among the nations. Thus in the marathon an Algerian "with a face like the Pharaohs," El Ouafi, ran first, his victory counting for France; a Chilean ran second, a Finn third, with a Japanese fourth and an American fifth. The last with admirable candour explained his failure by saying "I ran too slow." In the same way association (soccer) football was won by Uruguay, with Argentina second, Italy third and Spain fourth. British India was first in field hockey. Douglas Lowe, winning the 800 metres for Britain, made an Olympic record, 1 $51\frac{4}{5}$ secs. In the broad jump E. B. Hamm made an Olympic record, 25 ft. $4\frac{3}{4}$ in., for the United States. Olympic records were also made for the United States in pole vaulting and discus throwing, while victory in the 16 lb. hammer throw went to Ireland. Counting by team achievements, Germany won the highest total, including greco-roman wrestling and weight lifting. Finland sent marvellous long distance runners. From Canada and the United States went excellent women athletes, a Canadian winning the high jump while an American won the 100 metre dash.

Tenth Olympiad, 1932. Eleventh Olympiad, 1936: For these, held at Los Angeles and Berlin respectively. see OLYMPIC GAMES.

Athletics in Great Britain. — In America, Scandinavia, on the European Continent and among the coloured races of the world, athletic progress of an amazing kind is taking place from year to year, but up to 1925 it seemed certain that Great Britain must fall so far behind as to be at last forced to abandon the struggle altogether. Prior to the World War the secret of Great Britain's failure in international contests generally, and at the Olympic Games in particular, was to be found in the circumstance that Oxford and Cambridge athletes took little or no part in athletic sport, outside the competitions confined to their own and each other's universities; whereas the ever-successful American Olympic teams have been composed of nearly 80% of university and collegiate athletes. On several occasions before the war tentative proposals had been put forward for the promotion of a joint Ox-

ford and Cambridge athletic club, similar in character to the Leander Club. It was proposed that membership should be open to all blues, and also to a limited number of other undergraduates from Oxford and Cambridge. With others, Kenneth Powell (King's college, Cambridge) and G. R. L. Anderson (Trinity college, Oxford) had planned a definite attempt to form such a club in the winter of 1914, but the outbreak of war frustrated their intentions. These two famous hurdlers fell on active service, and it was not until March 27, 1920, that the Achilles Club came into being. One of the reasons for its promotion was that for many years previously very few blues had taken any part in national athletics, and those who formed the club believed it to be most desirable that they should do so. They thought that the club, when properly established, would have great influence, and, although their chief purpose was the promotion of match (team and relay) athletics, they also hoped that such a club would help to improve the standard of athletics in Great Britain. The sponsors of the movement have every reason to be proud of their endeavours. Athletes wearing the gold trimmings of the Achilles Club have rendered Britain the most valuable services at the Olympic Games, in other international contests and in defending British national titles. The club is responsible for the public schools relay meeting, which is held annually, while other missionary work that has been done is magnificent. Achilles teams have toured abroad in Central Europe, America, France, Greece and Germany; and, at home, have competed in Ireland and Scotland against national and university teams and in England against county, regimental and public schools teams, with great educational benefit to their opponents.

A direct outcome of the influence of the Achilles Club is that British athletics have become less individual by the introduction of that team spirit which is so wholly in accord with British tradition and temperament. A cautious decentralization of authority recently embarked upon by the A.A.A. marks a further step in progress, since it has led to the formation of county amateur athletic associations, holding certain administrative and judicial powers within their own territories.

The essence of the county administrative scheme is found in the internal management of the sport by counties within their own areas, inter-county contests being an essential adjunct to the movement. At present Bedfordshire, which county instituted matches in 1925 with the London Athletic Club and the University of London A.C., has probably achieved the most signal progress. In this connection it may be stated that England has for years past been divided into northern, midland and southern areas for administrative purposes, and that the furtherance of the county scheme lay at first entirely in the hands of the south, a circumstance strongly resented by the northern and midland districts. The Midlands are now more strongly represented, but the north still holds aloof.

In 1925 the first English inter-county relay and team athletic championship, for the trophy presented by the Achilles Club, was held at Stamford Bridge, London; Middlesex proved the winners and have never since lost their championship title. The position, however, was an entirely unsatisfactory one. The fatal policy of booming certain events at the expense of others was once again fully in evidence, such events as hammer, discus and javelin throwing, the pole vault, hop, step and jump and the 440yd. low hurdles being excluded from the programme. The result was that Bedfordshire, exceptionally strong in the field events and hurdles, and several other counties, refused to take part in championships which were not considered fully representative of English athletic sport. A pronouncement was made subsequently that the championship programme would not be in any way augmented in 1926. Consequently the midland counties, comprising Bedfordshire, Gloucestershire, Leicestershire, Shropshire and Staffordshire, for the time being, abandoned all thought of taking part in the inter-county championships. The north also, although possibly from different motives, refused to have anything to do with the county scheme. In deference to the views of the counties, however, it was finally agreed to include in the 1926 programme the pole vault and throwing the discus, but this still leaves hammer and javelin throwing, the hop, step and jump and the 440yd. low hurdles outside the scheme.

The essential fact is that, up to 1906, the Amateur Athletic Association, which is the governing body of the sport in England, had been unable to establish any liaison with the English public schools, which should prove the great recruiting ground for future Olympic teams. On the other hand, the counties, by reason of their more personal local contact, have in a few years begun to till this field, as is witnessed by the number of schoolboys who gained their county athletic colours during 1927, and the far greater number of school authorities who sought the advice and assistance, for the coaching of schoolboys for the annual sports, of old champions and other county experts. Notable examples of the value of coaching promoted by county associations are found in the cases of H. A. Simmons, Taunton's school, Southampton, and G. M. Moll, Bedford, aged 15 (high jumpers) both capped for their counties in 1927, and F. R. Webster, Bedford school, who, at 12 years of age, achieved 7ft. $4\frac{3}{4}$in. in the pole vault and set up new junior records in Yorkshire, Norfolk and Bedfordshire. G. M. Moll's winning high jump of 5ft. 5in. in the public schools junior competition constitutes a world's record for a boy of under 16 years of age.

The year 1926 was notable in that it marked the readmission of Germany to international competition with the former Allied Powers. At Basle, Switzerland, in August of that year, a triangular international match took place, Germany winning with $127\frac{1}{2}$ points, France being second ($89\frac{1}{2}$) and Switzerland third (68). A month previously the first German athletes who had been allowed to compete in England since the war appeared at Stamford Bridge, London, to contest the English championships and were well received. That the German people had already made up their minds to signalize their readmission to the Olympic Games at the ninth Olympiad at Amsterdam in 1928 was at once evident. Five German sprinters and one single British representative qualified for the final of the English A.A.A. 100yds. sprint championship, which was won by R. Corts, Germany, in 10secs.; in the 880yd. race Dr. Otto Peltzer, Germany, not only defeated the 800 metres Olympic champion, D. G. A. Lowe, Great Britain, but, in doing so, set up a new world's record of 1min. $51\frac{3}{5}$secs. Later in the afternoon the German doctor was but narrowly defeated in the 440yd. race by J. W. J. Rinkel, of Cambridge university. In several other events German athletes placed prominently. In 1927 the Germans made an even more successful raid upon the English championship titles; H. Kornig won the 100yd. in $10\frac{1}{10}$secs., H. Houben, the 220yd. in $21\frac{4}{5}$secs., R. Dobermann, the long jump at 23ft. $11\frac{3}{4}$in. and G. Brechenmacher, the shot put at 46ft. $6\frac{1}{2}$in., while the Preussen Krefeld team took the 440yd. relay race (4 x 110yd.) in $42\frac{1}{5}$secs. In the case of the 1927 international match in which Germany defeated Switzerland, the German 400 metres relay team equalled the world's record of 41secs. France, also, was met and defeated, the result being Germany 89 points, France 62 points. In addition to his half-mile record, Dr. Peltzer set up a new world's record of 1min. $3\frac{3}{5}$secs. for 500 metres. J. Schlokat, after only two months' practice, made a new German javelin throwing record of 204ft. $11\frac{5}{8}$ in., H. Hoffmeister, a new discus record of over 154ft., while G. Brechenmacher is a shot putter of the 10ft. class and R. Dobermann a long jumper of the 21ft. class. Athletics have rapidly attained an amazing degree of popularity in Germany; the country is starred with new, well-equipped tracks and grounds, and there is no doubt that Germany is becoming an athletic force which even America will have to reckon with in the very near future. Meanwhile Great Britain and her dominions overseas are steadily improving, as is proved by the running of D. G. A. Lowe, J. W. J. Rinkel, R. Leigh-Wood and H. H. Hodge and the hurdling of Lord Burghley, F. R. Gaby, S. J. M. Atkinson (South Africa) and G. C. Weightman-Smith (South Africa), while the American development in such field events as throwing the discus and javelin, which, in the past, have been considered almost purely Scandinavian pastimes, is no less remarkable.

The general improvement throughout the world, and the resultant number of records which have been recently broken, is

due partly to more intensive competition, but even more largely to the direct application of science to athletic sport. Coaching, elsewhere than in Great Britain, is now a recognized and remarkably lucrative calling. This state of things obtains on the Continent. Capt. Helge Lovland, athletic director to Norway, won the decathlon at the 1920 Olympiad. In Great Britain alone is the profession of athletic coach regarded as an unfit means for a public schools or university man to earn his living, and, consequently, British athletes do not enjoy such efficient instruction as is obtainable in other countries.

The teaching of athletics has now become a highly specialized art, in which all the aids of science are being fully utilized. Medical men and dieticians play their part; massage is freely employed to improve the athletes' condition and cinematography, slow-motion films and fixed cameras are used in the study of technique, to record faults, and to make plain to the athlete himself his own shortcomings. Scientific exercises are designed by physical culturists, and questions of temperature, as affecting athletic performances, are well understood, as also are the stress and strain involved in certain athletic performances. Recently Prof. A. V. Hill, F.R.S., University of London, has perfected an electrical apparatus which enables him to calculate the rate of speed of a runner at any given point of a race or training run. This apparatus consists of a series of vertical plane coils set up at measured intervals beside a running track and connected in series electrically with a galvanometer. The man whose performances are to be studied wears a thin strap of magnetized steel round his waist and the exact instant at which he passes each coil is registered by a flick of the galvanometer and recorded as a sharp wave on photographic paper. The moving paper is furnished with accurate time marks to enable readings to a 100th of a second to be made By this means can be recorded:—

(1) The starting signal.
(2) Time over the whole distance.
(3) Time over every intermediate distance.
(4) Speed at any point.
(5) Acceleration at the beginning.
(6) Total time-lag in attaining full speed.
(7) Point of maximum speed.
(8) Gradual slowing down due to fatigue.

Other instruments are in process of perfection which will determine correct angles of departure and flight in the jumps and throwing events, and yet other apparatus which will enable the coach to see at a glance exactly where his pupils are going right and where they are going wrong.

Much has been done in the way of athletic research; but, even yet, the processes at work in the employment of the athletes' muscles are only beginning to be understood; science and its applications, however, are proceeding hand in hand and it is certain that performances still more remarkable than any that have preceded them will be produced by future generations of athletes.

For list of world's records, see OLYMPIC GAMES and RUNNING.

ALL-ROUND ATHLETICS

Up to 1927 England had no all-round athletic championship, such as almost every other country has instituted upon much the same basis as the modern Olympic games decathlon. In ancient times athletes were encouraged to excel in several branches of sport, often quite opposite in character. Thus the athlete held in highest honour at the Olympic games of ancient Greece (see GAMES, CLASSICAL) was the winner of the pentathlon, which consisted of running, jumping, throwing the javelin and the discus and wrestling.

An all-round championship was instituted in America in 1884, comprising 100yd., 440yd. and 1m. runs, 880yd walk, 120yd. hurdles, high and long jumps, pole vault, throwing the 16 lb hammer and the 56 lb. weight and the shot put. This contest has now been abandoned in favour of the orthodox pentathlon and decathlon run on Olympic lines.

The ancient athletic pentathlon was revived in modern times at the Hellenic Festival, Athens, 1906. The events comprised weight lifting, wrestling (team and individual), 1,500 metres walk, rope climbing and tug of war. At the Stockholm Olympiad, 1912, the pentathlon was revived, the events contested being long jump, javelin, 200 metres run, discus and 1,500 metres run. In that year was added to the Olympic programme the decathlon, comprising 100, 400 and 1.500 metres runs, 110 metres hurdles, long jump, high jump, shot put, discus, javelin and pole vault.

The conditions of the present pentathlon are such that all entrants compete in the first three events, in each of which the winner receives one point and the second man two points, and so on. The total points of the competitors are counted and the 12 men with the lowest scores qualify to compete in the discus throwing; after the discus throwing the best six compete in the 1,500 metres flat race. At the end of all five competitions the competitor having the lowest score is adjudged the winner.

The winner of the decathlon is the one who scores the highest number of points in the ten divisions. At the third congress of the International Amateur Athletic Federation, Geneva, 1921, it was decided that for a result similar to the best result obtained at the 1912, or previous, Olympic Games, 1,000 points should be awarded, other results to be valued in accordance with the decathlon table. If a result exceed the best "Olympic" result, correspondingly higher points to be awarded. The basis of scoring, therefore, works out as follows:—

OLYMPIC RECORD SCORES UP TO 1912, 1000 PTS.

Event.	Olympic record.	Additional pts.
100 metres	$10\frac{3}{5}$secs. (1912)	$\frac{1}{5}$sec.=47·6opts.
Long jump	760cm.=24·934ft	1cm.=2·45pts.
Shot put	15·34m.=50·394ft. (1912)	1cm.=1pt.
High jump	1·93m.=6·331ft. (1912)	1cm.=14pts.
400 metres	$48\frac{1}{5}$secs.=(1912)	$\frac{1}{5}$sec.=7·52pts.
110 metres hurdles	15secs. (1908)	$\frac{1}{5}$sec.=19pts.
Discus	45·21m.=148·326ft. (1912)	1cm.=0·38pts.
Pole vault	395cm.=12·959ft.(1912)	1cm.=5·4pts.
Javelin	61m.=200·131ft.(1912)	1cm.=0·27jpts.
1,500 metres	3mins. $56\frac{4}{5}$secs. (1912)	$\frac{1}{5}$sec.=1·20pts.
Pentathlon		
200 metres	$21\frac{3}{5}$secs. (1904)	$\frac{1}{5}$sec.=22pts.

Among the best decathlon performances so far returned are those of the Finns, P. Yrjöla and E. Jarvinen, 1st and and in the 1928 Olympiad, J Thorpe, the American-Indian who was disqualified after the 1912 games and H. M. Osborn, U S.A., the Olympic winner in 1924. The schedules of performances are as follows:—

Event	Yrjola (Finland)	Jarvinen (Finland)	Thorpe (America)	Osborn (America)
100 metres	$11\frac{4}{5}$ secs.	$11\frac{1}{5}$ secs.	$11\frac{1}{5}$ secs.	$11\frac{1}{5}$ secs.
	ft. in.	ft. in.	ft. in.	ft. in.
Long Jump	22 $1\frac{1}{2}$	22 $7\frac{1}{4}$	22 $3\frac{5}{16}$	22 $8\frac{7}{16}$
Shot Put	46 $3\frac{3}{4}$	44 $9\frac{1}{4}$	42 $1\frac{3}{16}$	37 $6\frac{3}{8}$
High Jump	6 $1\frac{3}{4}$	5 9	6 $2\frac{5}{16}$	6 $5\frac{5}{16}$
400 metres	$53\frac{1}{5}$ secs.	$51\frac{2}{5}$ secs.	$52\frac{1}{5}$ secs.	$53\frac{1}{5}$ secs.
110 m. hurdles	$16\frac{3}{5}$ "	$15\frac{3}{5}$ "	$15\frac{3}{5}$ "	16 "
	ft. in.	ft. in.	ft. in.	ft. in.
Discus	138 1	118 $3\frac{1}{4}$	121 $3\frac{15}{16}$	113 $2\frac{11}{16}$
Pole Vault	10 10	10 10	10 8	11 6
Javelin	182 9	182 $4\frac{1}{4}$	149 $11\frac{1}{4}$	153 $1\frac{15}{16}$
	min. secs.	min. secs.	min. secs.	min. secs.
1500 metres	4 44	4 $52\frac{2}{5}$	4 $40\frac{1}{10}$	4 50
Total Points Scored	8053.29	7931·50	7751·06	7710.895

In 1931 the official world's decathlon record was held by H. Sievert of Germany (established in Germany, July 7–8, 1934) whose score was 8,79046 points. At the Olympic Games of 1932, in Los Angeles, the decathlon was won by James Baush, of the United States, with a score of 8,462·235 points.

In addition to the above all-round athletic championships there is in the Olympic programme a modern pentathlon comprising:—

1. Revolver shooting, rapid at 25 metres (82ft. $0\frac{7}{16}$in.) with the competitor's best hand.
2. Swimming, 300 metres (328·09yd.) free style.
3. Epée fencing.
4. Riding, 5,000 metres (5,468·11yd.). (Horses provided and drawn for by competitors.)
5. Cross-country running 4,000 metres (4,374·61 yd.).

A modern pentathlon championship of Great Britain was instituted in 1924.

UNITED STATES

Whereas in England the tertn *athletic sports* usually denotes track and field athletics, in the United States this term and especially the term *athletics* include not only the track and field sports (*q.v.*) such as running, jumping, hurdling and throwing, but also team games, like football, baseball, basketball, ice hockey and, among women, field hockey, as well as such games as tennis, golf and polo. In America contests in running, jumping, throwing, weight-lifting, wrestling, boxing and shooting were popular throughout most of the colonial period and after the Civil War. It was, however, the inter-collegiate contests of the later 1860s and the 18 jos which gave to athletic sports stimulus that has continued to the present day. Thus, the American interest in athletics, beginning in earlier popular matches of skill and strength became, with the subsidence of pioneer conditions, intensified after 1870 by college contests, and since that time, fed not a little by college *alumni* and by immigration from the northern countries of Europe, especially England and Ireland, has developed and progressed until it has undoubtedly attained an important position in the national life.

National Athletic Bodies.—In the United States there are six bodies, national in their composition, which in function are either consultative and regulatory or executive, or both: the Amateur Athletic Union of the United States, the American Olympic Association, the Intercollegiate Association of Amateur Athletes of America, the National Amateur Athletic Federation, the National Collegiate Athletic Association and the National Federation of State High School Athletic Associations. The Amateur Athletic Union of the United States was founded in 1888. Through some 23 regional associations, covering the country on a geographical basis, the A.A.U. "recognizes all amateur sports and claims jurisdiction over" basketball, boxing, gymnastics, running, including hurdling, obstacle racing, steeple chasing, walking, jumping, pole vaulting, shot putting, throwing the hammer, weights, javelin and discus, swimming, tug-of-war, wrestling both catch-as-catch-can and greco-roman styles, weight-lifting, volley ball and indoor baseball and squash. In all of these sports the Union "has conducted national championships annually." It governs in matters of amateur status, national records and licensing of meetings to the extent that it requires all entrants in open meetings to be registered with it and to obtain its licence to compete therein. With the A.A U. are "allied" 23 other bodies, including two British and two Canadian, the rest being American organizations. Formal international relations for American athletes are maintained through the A.A.U., which is a certificating member of the International Amateur Athletic Federation, and the American Olympic Association of 79 member bodies which, through permanent representative organization, endeavours to perpetuate interest in the Olympic games and to exercise jurisdiction over all matters relating to American competition in them. Direct relations with American colleges and universities are maintained through membership of such institutions in various member associations and the Intercollegiate Association of Amateur Athletes of America (*see* below, and TRACK AND FIELD SPORTS).

The National Amateur Athletic Federation, founded in 1921, fosters amateur athletics, physical education and participation in the Olympic games, through its two divisions, for men and women. The men's division is made up of some 14 organizations, including the Army, Navy and Marine Corps of the United States, the Young Men's Christian Association, the Catholic boys brigade, and the National Collegiate Athletic Association, which provides contacts with the colleges. The women's division is composed on a different basis. Members include (1928) 21 national organizations, among which stand the American Child Health Association, the Girl Scouts, Inc., the Playground and Recreation Association of America and the Young Women's Christian Association national board, 14 schools of physical education, 101 colleges and universities attended by women, 43 normal colleges and schools, 92 private schools, 11 State departments of physical education, 25 city school systems, 45 individual public high schools, 48 local branches of the Young Women's Christian Association, 2 Young Women's Hebrew associations, 32 physical education and athletic groups, 17 women's clubs, corporations and commissions, and 98 individuals. This division "believes in the spirit of play for its own sake, and works for the promotion of physical activity for the largest possible proportion of persons in any given group, in forms suitable to individual needs and capacities, under leadership and environmental conditions that foster health, physical efficiency and the development of good citizenship."

As regards American college sport and certain phases of interscholastic relations, some 118 universities and colleges unite in the National Collegiate Athletic Association, whose principal functions are deliberative and advisory and which divides the country into eight athletic districts, each containing a number of universities under the leadership of a vice president. The N.C.A.A. promulgates rules for inter-collegiate competition in association football, baseball, basketball, boxing, gymnastics, ice hockey, lacrosse, swimming, track and field events, volley ball and wrestling, names committees to prepare such rules, and holds annually one national track and field meeting.

The Intercollegiate Association of Amateur Athletes of America, commonly called the "I.C.4A's" and organized in 1875, is a supervisory and executive body composed of 41 colleges and universities, about three-quarters of which are situated in the eastern States. Declaring its "absolute jurisdiction among its members over all forms of track and field athletics," it conducts under its own rules two annual competitions; a February indoor meeting, and a May track and field championship meeting. The I.C.4A. veterans division is composed of former college athletes and officers of the association. It occupies a position somewhat analogous to that of the Achilles club in England. In 1927 some 88 varsity track and field meetings, 17 freshman track and field meetings, and 70 cross-country runs were held under various auspices according to I.C.4A rules. Among national bodies the National Federation of State High School Athletic Associations endeavours to link together the athletic associations of the high schools in the several States for the improvement of competition in all sports and for freedom of action within the field of secondary school athletics. A total of 29 such associations are thus federated. In addition, the American Federation of Labor is doing much to bring sport into the leisure of its members.

Regional Athletic Bodies.—The most significant development in the field of inter-collegiate athletics during the past half century has been the athletic conference. Following upon such athletic organizations of the 1870s as the Rowing Association of American colleges and the competitive relation that sprang from inter-collegiate contests in more academic fields, the athletic conference may be defined as a group of collegiate institutions. from 4 to 22 in number, which band themselves together for competi-

tion in one or many sports under uniform standards and rules of eligibility. The Southern Intercollegiate Athletic Association was founded in 1894, followed by the Intercollegiate conference ("Western Conference" or "Big Ten") one year later, the Maine Intercollegiate Track and Field association in 1896, the Northwest conference in 1904, the Missouri Valley conference in 1907, the Rocky Mountain Faculty Athletic conference in 1909, the Southwest conference in 1914, the Pacific Coast Intercollegiate conference in 1926 and the Eastern Intercollegiate conference in 1928. There exist (1928) 40 definitely organized conferences besides several loosely associated groups. From deliberative assemblies, many conferences have developed into executive and supervisory bodies furthering increased standards of academic work and delegating to officers police powers to enforce regulations and investigate infractions. Some stipulate that the control of athletics in member institutions shall rest with the faculties, lay down stringent rules concerning eligibility (residence, attendance, scholastic standing, interchange of lists of eligibles, signed statements from athletes attesting their own amateur status), training periods and the employment and compensation of coaches, and not only supervise competition between their member institutions in football, baseball, basketball and other team games, but also arrange track and field, swimming, boxing and other meetings, whether conducted under conference or other rules. An estimate of the number of annual inter-collegiate contests for the year 1927 gives 5,000 in football, 8,000 in basketball and from 6,000 to 8,000 in baseball. Some 20 inter-collegiate intersectional track and field meetings, about the same number of collegiate State meetings, nearly 150 dual, 8 triangular and one or more quadrangular meetings, take place each year. At least 9 relay carnivals are held annually by universities, college conferences and other associations.

For high schools, each of the 48 States has its own interscholastic athletic association which, bearing many resemblances to the college conference, exercises an increasingly strict supervision over school competition in all sports. In Alabama, California, Delaware, Florida, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Missouri, New Jersey, New York, Ohio, Pennsylvania, Virginia and West Virginia, the State High School Athletic Association is allied with the State department of physical education, which is a part of the State department of public instruction. Each State high school athletic association holds annually at least one State-wide track and field meeting and many send representatives to compete in inter-scholastic meetings held by various national bodies. Attempts to estimate the number of inter-scholastic football, basketball and baseball games have proved futile, although one authority has given 80,000 as a possible annual minimum.

In each larger American city there exist one or more amateur athletic clubs, which possess houses often luxuriously appointed, with facilities for all forms of indoor athletic exercise (gymnasiums, swimming pools, running tracks, squash and tennis courts, etc.), as well as outdoor playing fields. Such clubs, usually affiliated with the A.A.U. through its regional associations, draw many of their more expert members from the ranks of former college athletes. Many industrial and commercial establishments make much of athletic sports and games, and some provide football and baseball fields for their employés as a branch of company personnel or welfare work. Besides the State and local associations that unite in the A.A.U., the Young Men's Christian Association and the Young Men's Hebrew Association are providing centres for all branches of sport.

College Athletics. — During the past 30 years, athletics in the American college and university have undergone a significant change, in both theory and practice. The middle of the 19th century saw the establishment of inter-collegiate competition. The first Harvard-Yale boat race was rowed on Lake Winnepesaukee in 1852; the first inter-collegiate baseball game, between Amherst and Williams, came seven years later, and the first inter-collegiate football contest was played by Princeton and Rutgers in 1869. three years before the first Oxford-Cambridge football match. In those days inter-collegiate athletic rivalry was informal and important principally to undergraduates. Later, with the increase in *alumni*, it became more and more the concern of the graduates. With the earlier years of the 20th century, however, the faculties of colleges and universities began to attempt to recover, especially as regards football, the authority which 60 years previously they had exercised over the administration of college sport. To these efforts and to the foresight of certain graduates, is due the division of college sport into two categories: inter-collegiate and intra-mural. Only in 1927 did consideration of problems of inter-collegiate athletics lead to a statement of their purposes, first for the Intercollegiate Conference ("Big Ten") and afterward for the N.C.A.A. The ideals of inter-collegiate competition are set as a series of "objectives," — that is, the theoretical ends which athletic competition between colleges should serve:

"General primary objectives of inter-collegiate athletics: (1) To supplement and broaden modern education. In order to take full advantage of opportunities of inter-collegiate sport to this end the entire inter-collegiate sport programme should be made a definite part of the general educational scheme. (2) To promote the all round welfare of an increased number of participants, — physical (health, motor skills), recreational (pleasure in sport), social (increased 'social insight,' good will), moral and spiritual (strengthening of essential attitudes and behaviour through illustration and practice). (3) To strengthen by illustration and example individual, university and public conceptions of sportsmanship (group, sectional, national, international: regard for player or adversary in victory or defeat, proper balance in victory, courage in defeat, fairness of attitude), team play, clean and healthful living, true winning spirit (tenacity, honesty of purpose), self-control, self-confidence, citizenship (respect for rules of game under stress, and for wise discipline and authority), fortitude. (4) To develop group consciousness, morale and spirit in the sense of loyalty to the institution, and to fellow members of the college community. (5) To reflect through representation the spirit of the institution (intellectual ability and achievement, moral tone and idealism, genuine sportsmanship through behaviour and conduct).

"Secondary objectives of intercollegiate athletics: (1) To serve as the peak of an all inclusive physical educational pyramid in opportunity for specialization and superior achievement. (2) To improve mental health for players and spectators by supplying wholesome absorbing interest. (3) To foster wholesome stimulating recreational opportunity for students, faculty, *alumni* and general public. (4) To provide opportunity to 'animal spirits' for legitimate physical expression. (5) To further the educational viewpoint and needs by securing and maintaining active interest of *alumni* and general public in the educational institutions through the field of greatest common interest and appeal."

With a view to diffusing more widely among student bodies the benefits to be gained from sport, most of the colleges and universities of the United States have initiated athletic competition between the groups into which undergraduates are divided by their daily associations and loyalties (fraternities, halls of residence, classes, etc.). The movement has owed much to the inter-college contests of Oxford and Cambridge, but little directly to the inter-house matches of English public schools. In these intra-mural programmes American colleges include all branches of sport, although football is less widely played by intra-mural teams than might be expected. The "objectives" of intra-mural sports, according to Prof. Mitchell, who has developed a remarkable interest in them at the University of Michigan, are recreation, the forming of social contacts, "group spirit" (solidarity through loyalty), better physical health, permanent interest in sports, the development of varsity material, bodily prowess (strength, endurance, neuro-muscular co-ordination), and mental alertness as expressed in improved academic achievement.

The endeavour of faculties to regain the administrative control of undergraduate athletics has led to the formulation of the doctrine of "faculty control," which provides that the teaching staffs shall be responsible for the administration and practice of athletic activities of all students. A corollary of the doctrine, to the effect that all teams, inter-collegiate and intra-mural, should be

coached not by seasonal coaches but by members of faculties, has led rather frequently to the elevation of coaches to academic status and full-year appointments, more rarely to American adaptation of the Oxford and Cambridge system of athletic mentors who assist in the development of college and university teams and crews. Especially at mid-western universities, no distinction appears to be held between, on the one hand, men who teach academic subjects for their livelihood and coach teams as an avocation, and on the other, men who as a career coach teams and teach physical education. In most of the American universities the administrative control of athletics is divided between representatives of interested groups: *alumni* and former students, faculties, trustees, who usually delegate their authority, and undergraduates, who are generally a minority upon committees, if indeed they sit with them at all. Townsmen, also, are beginning to exercise a direct influence upon college athletic administration. The influence and the practical nature of *alumni* interest are manifested through the offices of graduate treasurer, graduate manager of athletics and similar positions that, occupied by *alumni*, not infrequently dominate athletics in a college, and often in a salutary fashion. There is generally, however, an athletic association of undergraduates, somewhat resembling the amalgamated clubs of Oxford and Cambridge colleges and the athletic associations of certain newer English and Scottish universities, that still awards insignia and may name undergraduate managers and assistants, but has lost much of the power it possessed at the turn of the century through the encroachments of the *alumni* and the movement toward "faculty control" of college sport.

The central problem of athletic administration is generally considered to be financial. Athletic revenues range from as low as $4.300 at a small college of 229 undergraduates to $1,104,000 at a large university of 4,283 students. As at Oxford and Cambridge, gate receipts from varsity football games provide the great bulk of the support for all other branches of inter-collegiate athletics. At a few eastern institutions inter-collegiate football pays also for intramural sports. For example, although at the United States Military academy (West Point, N.Y.) intra-mural sports are considered to be of great value in the training of army officers, the current expense of all athletics is borne principally by sales of football tickets and not by appropriation from public funds. Most of the State and western universities make the cost of intra-mural programmes, except the use of facilities, a charge upon their instructional budgets. When the use of facilities is in question, preference is almost invariably given to candidates for inter-collegiate teams. The situation presents sharp contrasts with the practice at the older English universities of financing college sport from subscriptions to amalgamated clubs. American profits from football, after all expenses chargeable to that sport have been paid, have ranged (1925–27) to as high as $500,000 at a few larger universities, and football profits of from $200,000 to $300,000 from a season's schedule or fixture list are by no means uncommon at colleges of moderate size. Exceptions should, however, be noted in the case of a comparatively small number of institutions where because football has either not been sufficiently exploited, or in spite of exploitation has not yielded profits, the game shows a deficit and athletics are mainly supported by student fees. In most of the colleges of the United States, therefore, football is made to show a profit. When this consideration, respecting not alone football but any other sport, receives an emphasis that makes it paramount in the shaping of an institution's athletic policies, the result is a commercialism which no amount of "faculty control" appears powerful enough to abate. From the necessity of providing, out of football gate receipts, large sums of money, not alone for other inter-collegiate sports, but also equipment used in programmes of intra-mural athletics and of "physical education," has developed the need of accommodating huge numbers of spectators at even the less important football games and hence the building of great stadiums, or arenas, of reinforced concrete and in many cases of much architectural merit, owned by college athletic associations, in which matches take place. Statistics concerning the largest or most famous stadiums are as follows:—

Stadiums

Place and Name	Capacity
Chicago (Grant Park)	125,000
Philadelphia (Sesquicentennial)	125,000
Los Angeles (Coliseum)	105,000
Berkeley (University of California)	90,000
Palo Alto (Stanford University)	88,000
New York (Yankee Stadium)	82,000
New Haven (Yale University Bowl)	80,000
Pasadena, Cal. (Rose Bowl)	80,000
Philadelphia (U. of Pa., Franklin Field)	76,000
Columbus, O. (Ohio State University)	75,000
Ann Arbor (University of Michigan)	72,000
Urbana. Ill. (University of Illinois)	70,000
Cambridge (Harvard University)	55,000
Notre Dame (University of Notre Dame)	55,000

Prompted in part by large increases in funds made available from football gate receipts, many universities have embarked upon ambitious athletic building programmes, opened golf courses, erected "baseball cages" and "field houses" (huge barn-like structures of brick for practicing track and field events, basketball, certain features of baseball, etc.), enlarged gymnasiums and installed indoor tracks, basketball courts, swimming pools, tanks for indoor practice at the oar and other facilities, built training quarters, boat houses and locker accommodations, acquired increased acreage for playing fields, and generally augmented material facilities, indoor and outdoor, for all branches of athletics. Accommodations for women's sports have not kept pace with those for men except in a few instances.

The medical supervision of college athletics is receiving increased attention, and at a few institutions, notably Stanford university, the physiological health of the student is being closely interwoven with the athletic programmes. In figures collected for the Carnegie Foundation for the Advancement of Teaching, football exhibits the highest incidence of athletic injuries and accidents, with a total of 12 serious injuries (chronic sprains, fractures, concussions, exhaustion, internal injuries, *myositis ossificans*) among each 100 players,—17·7% among inter-collegiate contestants, 5·1% among intra-mural players; boxing, the next highest, 5·2%; lacrosse, 4.7%; association football, 4·0%; wrestling, 3·4%; baseball, 2·2%; cross-country running, 1.5%; ice hockey, 1·4%; basketball, 1·3%; track and field, 1·2%; rowing, 0·2%; and swimming and fencing, no serious injuries. The proportion of injuries for all sports is about 3%. Serious injuries are, of course, much more common in inter-collegiate than in intra-mural sport. Usually, injuries to varsity players are treated at the expense of the athletic association, which also provides, notably at Dartmouth. Harvard, Oberlin and the United States Military academy. facilities for team surgeons and trainers. Whatever the incidence of athletic injuries, the disadvantages that they imply should be judged, not absolutely, but in comparison with physical and moral values received by participants. Because no trustworthy method of measuring such values has been devised, they remain a matter of personal conviction.

With the growth of the notion of "faculty control" of college athletics, there has developed a tendency to exalt the position of the coach, not alone in respect of his status and tenure, but also as regards his relative importance as a member of the college family. Because it is widely recognized that the influence of the coach, whether salutary or debasing, among college students is very large, an increasing care is taken in the selection and appointment of men for such posts. Among Europeans the impression seems to be current that the widely known college coaches in the United States are men of some medical training, whereas they have come from all walks of life,—business, medicine, the law, teaching and the profession of arms,—and many have risen from the position of trainer or even of rubber and masseur. The leaders in the calling, including, for example, those most prominent in the councils of the American Association of Football Coaches, are men of university and in some instances of medical training, but the man of achievement in the field is as likely to be of more humble origin as he is to belong to a more select group. Recent

recruiting to the ranks of college coaches from among graduates of schools of physical education, like the Young Men's Christian Association Training colleges at Springfield, Mass., and Chicago, Ill., and the schools at the University of Illinois and Teachers college (Columbia university), Oberlin, Michigan, and most of the other State universities, is changing the situation. State universities are led to offer courses in physical education because State laws require that the subject shall be taught in public schools and teachers must be trained for the work. The number of coaches who with a hope of bettering their position have attended summer schools of coaching and physical education, no matter of what attainment such schools may be, is growing rapidly. Salaries of coaches vary over a wide range. On the whole, head coaches employed on a seasonal basis without appointment to faculties receive the highest pay. Of these, 12 have (1938) salaries running from $10,000 to $12,000, although one professor of physical education on permanent appointment as director and coach is paid $14,000. The maximum salary among college track and field coaches is $8,000. With faculty status, typical salaries ranged between $5,000 and $10,000, the majority being found at the lower levels, with a minimum of $2,400 or $2,500. Considering the unprecedented rise in salaries paid to college professors in the United States, the average of coaches' salaries is not alarmingly high, except when contrasted at individual institutions with the compensation of teachers of academic subjects. Most universities and colleges have from 3 to 20 coaches for all branches of athletics taken together. Coaching in intra-mural athletics, where less is at stake, being regarded as a less specialized task, is generally entrusted to assistants and to major students in graduate or undergraduate departments of physical education. Such departments and schools are providing an increasing supply of trained men for college coaching and for the teaching of physical education in schools, but the value of their training varies widely.

In the United States college sports are classified as major or minor. A major sport is a branch in which public appearance or distinguished service as a representative of a university or college on a team or crew is adjudged to be worthy of an award of a "letter" (the right to wear the initial of the college; *e.g.*, "C" for Columbia, "M" for Michigan, "P" for Purdue, etc.) upon a sweater or athletic uniform. For the minor sports there is the lesser award of "numerals" (of the class of the year in which graduation is anticipated), or second-string or other insignia. Major sports universally include football, basketball, rowing, track and field athletics sometimes embracing cross-country running, rowing, baseball (declining in college popularity in some sections), and occasionally fencing (Columbia), ice hockey (Dartmouth), and swimming (Yale). Minor sports usually are reckoned to include lacrosse, tennis, wrestling, boxing, swimming, association football, golf, polo, fencing and occasionally rifle shooting, gymnastics, water polo, trap shooting, and on the Pacific coast English "rugger." Programmes of intra-mural sports may include any or most of the major and minor sports and also volley ball, soft ball, touch football (a variant of American football without tackling), speedball, handball, any of the six varieties of indoor baseball, foul throwing or shooting adapted from basketball, horseshoe pitching and occasionally, squash, bowling and hiking. Awards for intra-mural sports take the form of "numerals," medals, cups, plaques or pennants. All awards in major and minor sports are generally made by committees of athletic associations on nomination by captains or coaches or both. The University of Iowa has abolished distinctions between major and minor sports. Sports for women, played under women's rules, include field hockey and basketball, in which most women's inter-collegiate matches take place, swimming, running, jumping and volley ball. Wellesley college (Mass.) rows. Certain colleges and universities (*e.g.*, Bowdoin, Dartmouth. Minnesota) especially favour winter sports, like skiing, snow-shoeing, ski-jumping, skating and ice hockey.

College sport is essentially amateur, and all conferences and practically all individual institutions have strict regulations to protect the amateur status of contestants. Rules of eligibility exhibit a tendency to uniformity: (1) an athlete must have completed one year's academic work before entering inter-collegiate competitions; (2) the playing of transferred students, migrants or "tramp" athletes is discouraged and has been in fact practically eliminated; (3) competition in inter-collegiate contests is generally limited to three years for each athlete; (4) a reasonable standard of academic work must be maintained; (5) an athlete must conform to the rule that "an amateur sportsman is one who engages in sport soieiy for the physical, mental or social benefits he derives therefrom, and to whom the sport is nothing more than an avocation" (part of the N.C.A.A. rule; the I.A.A.F., A.A.U., and I.C.4A. rule is not dissimilar). (See AMATEUR.) In spite of this amateur rule, athletes in the past have received money payments, scholarships and aids in the form of clothing or nominal jobs, generally in a covert and devious manner, and seldom with the open approval of college or university authorities. Such practices are decreasing, but there is still room for more common honesty in college sport, among the more rabidly partisan college alumni, and among needy young men who aspire through athletic subsidies to the advantages of a college education.

The part played by the undergraduate in college sport in the United States involves far less responsibility than at English universities and even at certain English public schools. The strategy and tactics of all branches are almost universally the affair of the trainer and the coach. The paternal attitude of the college, manifest for many years in the academic and disciplinary aspects of university life, extends even to athletics. Thus has been lost much of one of the greatest benefits that college sport can confer. As regards inter-collegiate contests, the proportion of students participating has not greatly changed since about 1900, about 20 to 25%. Owing, however, to the fostering of intra-mural athletics the country over, the total percentage of participation in all sports now lies between about 45% and 65% of all undergraduates, a proportion which is still rather below some estimates for Oxford and Cambridge. Much of the increased participation in intra-mural athletics is due to the fact that a student who takes part in them to the satisfaction of the department of physical education thereby satisfies one of the "credit" requirements for graduation.

Although the formal relationships of American college athletes with college athletes of other countries find expression through the A A.U. and the Olympic games, even more promising for international amity is the series of university track and field meetings inaugurated through the efforts of Dr. C. W. Kennedy, of Princeton, John T. McGovern, of Cornell, and Bevil Rudd, old Oxford blue, whereby in each year except Olympic years athletes from Oxford, Cambridge, Harvard and Yale compete alternately in England and the United States. The athletes lodge together, dine and train together, and exchange coaching suggestions where such assistance proves helpful. The plan, which provides a near approach to the ideals of amateur international competition, has led to further contacts between Oxford and Cambridge, and Cornell, Pennsylvania, Princeton and Syracuse universities in lacrosse, tennis, golf and other sports.

School Athletics. — In American tax-supported public schools and also in private schools, athletics bear many resemblances to college athletics. State departments of physical education, now parts of the educational systems of 17 States, generally exert a wholesome influence toward the uniting of physical education and athletics as regards both theory and practice. Playing field space has increased greatly, and few modern high school buildings are without gymnasiums, swimming pools, indoor running tracks and basketball courts. In the Middle West a number of well-appointed high school buildings have been erected from the proceeds of basketball games, a beneficent commercialism that parallels the situation in certain colleges. Much attention has been devoted to the selection of games and events suitable to school age, especially by the Playground and Recreation Association of America and the women's division of the N A A F. The results have proved salutary. Indeed, the whole programme of physical education and athletics in public high schools has been

revised, strengthened and better adapted to the tastes, capabilities and circumstances of boys and girls. Of especial significance are the tendency to have school teams coached by teachers, whether of physical education or of other subjects, somewhat after the method in English schools, the use of playgrounds and equipment by school athletes and teams after school hours under the supervision of qualified teachers, the work of the Sportsmanship Brotherhood, one of whose functions it is to hold the ideals of sportsmanship before school boys and girls, and the spread of school-boy athletic leagues, generally under wholesome and non-commercializing supervision. Indeed, the tone of high school athletics is in some respects relatively superior to the tone of athletics in American universities and colleges. In this field the Public School Athletic League, of New York city, organized in 1907, is the pioneer. It has equipped over 5,000,000 school boys and is supervising the play of 600,000 boys a year. Competitors in its meetings number from 7,000 to 8,000. Considered to be the most powerful single agency in the reduction of juvenile delinquency, the league has profoundly affected youthful athletic activities in the cities of the United States and Europe. As regards the salutary development of sport in high schools, much appears to depend upon the degree in which the authority of the principal is made to match his responsibilities. At American private schools, sport parallels closely in miniature the athletic activities of colleges and universities. On the whole, private school playing fields and other equipment tend to be better and more extensive than those of all but the more fortunate of public schools, and athletics are possibly a shade better supervised on the average. Teams representing private schools meet freely those representing public schools in most branches of sport. The future of school athletics in the United States would be the brighter if those responsible for it could assure its development independently of certain influences of college sport, which now tend to impair it.

Publicity and Sports Writers.—A study made for the American Society of Newspaper Editors (1927) indicates that, of 125 newspapers studied, one-third, published in cities of 50,000 population and over, devote to sport an average of more than 10 columns daily and from 10 to 30 columns on Sundays. A few publishers of metropolitan papers, all of which usually exceed this space, are adopting a policy of emphasizing amateur sports. The best of the sports coluinnists and special writers, some of whom syndicate widely, exert a commendable influence through their writings, but this is not the case with the more commercialized and sensational writers and newspapers. The undue attention lavished by sports writers, usually at the solicitation of university publicity agents, upon professional coaches and college athletes has been gravely detrimental to the best interests of amateur sport in the United States.

ATHLONE, urban district, County Westmeath. Eire. Pop. (1936) 7,257. It is 78 mi. W. of Dublin on the Great Southern railway. A castle and a bridge over the river were built by John de Grey, bishop of Norwich and justiciar of Ireland, in 1210. It became the seat of the presidency of Connaught under Elizabeth, and withstood a siege by the insurgents in 1641. In the war of 1688 the possession of Athlone was considered of the greatest importance, and it consequently sustained two sieges, the first by William III. in person, which failed, and the second by General Godart van Ginkel (*q.v.*). In 1797 the town was strongly fortified on the Roscominon side, but the works are now dismantled. Athlone was incorporated by James I., and returned two members to the Irish parliament, and afterwards one member to the imperial parliament till 1885.

The river Shannon divides the town into two portions, the Leinster side (east), and the Connaught side (west), which are connected by a bridge, opened in 1844. There is a swivel railway bridge. The rapids of the Shannon at this point are obviated by means of a lock communication with a basin, which renders the navigation of the river practicable above the town. Some trade by water is carried on with Limerick, and with Dublin by the river and the Grand and Royal canals. Athlone is an important agricultural centre and has a considerable cotton factory. The famous Athlone woollen mills burned in 1940, and many of its workers migrated to England. There are two parish churches, St. Mary and St. Peter, both erected early in the 19th century, of which the first has near it an isolated church tower of earlier date. There are three Roman Catholic chapels, a courthouse and other public offices. Early remains include portions of the castle, of the town walls (1576), of the abbey of St. Peter and of a Franciscan foundation. On several islands of Lough Ree, to the north, are ecclesiastical and other remains.

ATHOL, a town of Worcester county, in northern Massachusetts, U.S A. It lies in the valley of hfiller's river at a varying altitude of from 510 to 1.200 ft., and is served by the Boston and Maine railway. The area is 3j sq.mi. The population in 1940 Federal census was 11,180. The varied manufactures include fine tools, shoes and leather goods, toys, mill machinery, tables, crib.. cradles, towel racks, combs, sashes, doors, nindowpanes, blinds, gears, vises, drills, tents, celluloid goods, meat choppers, and popcorn products. A municipal Memorial building with an auditorium was completed in 1924, and in 1936 the high school building (erected in 1893) was remodeled.

Athol was settled in 1735 and incorporated as a township in 1762. It was named by its largest landowner, Col. John Murray, after the ancestral home of the Murrays, dukes of Atholl.

ATHOLL or **ATHOLE,** mountainous district in north Perthshire, Scotland, area about 450sq.m., bounded on the north by Badenoch, on the north-east by Braemar, on the east by Forfarshire, on the south by Breadalbane, on the west and north-west by Lochaber. It is watered by Tay, Tummel, Garry, Tilt, Bruar and other streams. Glen Garry and Glen Tilt are the chief glens, and Loch Rannoch and Loch Tummel the principal lakes. The population is mainly in Dunkeld, Pitlochry and Blair Atholl. The only cultivable soil is in the large valleys, but deer-forest and shootings on moor and mountain are very extensive. It is said to have been named Athfotla (Atholl) after Fotla, son of the Pictish king Cruithne, and was under the rule of a Celtic mormaer (thane or earl) until the union of the Picts and Scots under Kenneth Macalpine in 843.

ATHOLL, EARLS AND DUKES OF, the Stewart line of the Scottish earls of Atholl, which ended with the 5th Stewart earl in 1595, the earldom reverting to the crown, had originated with Sir John Stewart of Balveny (d. 1512), who was created earl of Atholl about 1457 (new charter 1481). The 5th earl's daughter Dorothea married William Murray, earl of Tullibardine (cr. 1606), who in 1626 resigned his earldom in favour of Sir Patrick Murray, on condition of the revival of the earldom of Atholl in his wife and her descendants. The earldom thus passed to the Murray line, and John Murray, their only son (d. 1642), was accordingly acknowledged as earl of Atholl (the 1st of the Murrays) in 1629.

JOHN STEWART, 4TH EARL OF ATHOLL, in the Stewart line (d. 1579), son of John, 3rd earl, succeeded his father in 1542. As one

of the principal Catholic nobles of Scotland, he was especially trusted by Mary, Queen of Scots, but after the murder of Darnley in 1567 he joined the Protestant lords against her, and was included in the regency of James VI. on her abdication. But in 1568 he was again advocating her cause. He had failed in 1572 to prevent Morton's appointment to the regency, but in 1578 he succeeded with the earl of Argyll in driving him from office. In March James dissolved the regency and Atholl was appointed lord chancellor. On May 24 Morton succeeded in regaining his guardianship of James. Atholl and Argyll, who were now corresponding with Spain in hopes of assistance from that quarter, then advanced to Stirling with a force of 7,000 men, when a compromise was arranged, the three earls being all included in the Government. While on his way from a banquet held on April 20 1579 to celebrate the reconciliation, Atholl was seized with sudden illness, and died April 25, not without strong suspicions of poison.

On the death, in 1595, of his son John, 5th earl of Atholl, the earldom in default of male heirs reverted to the crown.

JOHN MURRAY, 1ST EARL OF ATHOLL in the Murray line (see above), died in 1642. On the outbreak of the civil war he called out the men of Atholl for the king, and was imprisoned by the marquess of Argyll in Stirling Castle in 1640.

JOHN MURRAY, 2ND EARL and 1ST MARQUESS (cr. 1676) of Atholl (1631–1703), son of the 1st earl was born May 2, 1631. In 1653 he was the chief supporter of Glencairn's rising, but was obliged to surrender with his two regiments to Monk, Sept. 2, 1654. After the restoration Atholl received many high offices in Scotland. He at first supported Lauderdale's tyrannical policy, but after the raid of 1678, called the "Highland Host," in which Atholl was one of the chief leaders, he joined in the remonstrance to the King against the severities inflicted upon the Covenanters, and was deprived of his office of justice-general and passed over for the chancellorship in 1681. In 1679, however, he was present at the battle of Bothwell Brig; in July 1680 he was made vice-admiral of Scotland, and in 1681 president of Parliament. In 1684 he was appointed lord-lieutenant of Argyll, and invaded the country, capturing the earl of Argyll after his return from abroad in June 1685 at Inchinnan. The excessive severities with which he was charged in this campaign were repudiated with some success by him after the Revolution. (A. Lang, *Hist.* of Scotland, iii. 407.) At the Revolution he wavered, showing no settled purpose but waiting upon the event, but he took part in the proclamation of William and Mary as king and queen at Edinburgh. After Dundee's insurrection he was imprisoned for a few weeks. In 1690 he was implicated in the Montgomery plot and subsequently in further Jacobite intrigues. In June 1601 he received a pardon, and acted later for the Government in the pacification of the Highlands. He died on May 6 1703. He married Amelia, daughter of James Stanley, 7th earl of Derby (through whom the later dukes of Atholl acquired the sovereignty of the Isle of Man).

JOHN MURRAY, 2ND MARQUESS and 1ST DUKE OF ATHOLL (1660–1724), was born on Feb. 24, 1660. He was a supporter of William and the Revolution in 1688, taking the oaths in Sept. 1689, but was unable to prevent the majority of his clan, during his father's absence, from joining Dundee under the command of his brother James. In 1703–04 an unsuccessful attempt was made by Simon, Lord Lovat, who used the duke of Queensberry as a tool, to implicate him in a Jacobite plot against Queen Anne; but the intrigue was disclosed by Robert Ferguson, and Atholl sent a memorial to the Queen on the subject, which resulted in Queensberry's downfall. He vehemently opposed the Union during the years 1705–07, and according to Lockhart, he could have raised 6,000 of the best men in the kingdom for the Jacobites. On the occasion, however, of the invasion of 1708, he took no part, on the score of illness, and was placed under arrest at Blair Castle. On the downfall of the Whigs and the advent of the Tories to power, Atholl returned to office, and from 1712 to 1714 was high commissioner. On the accession of George I. he was again dismissed, but at the rebellion of 1715, while three of his sons joined the Jacobites, he remained faithful to the Government, whom he assisted in various ways, on June 4 1717 apprehending Robert Macgregor (Rob Roy), who, however, succeeded in escaping. He died Nov. 14 1724.

KATHERINE MARJORY, DUCHESS OF ATHOLL, wife of the 8th duke, entered the House of Commons for Kinross and West Perth in 1923, and in 1924 became parliamentary secretary to the Board of Education. She was a daughter of Sir J. H. Ramsay of Banff, the historian, and herself edited and contributed to a *Military* History of Perthshire (1660–1902).

The *Atholl Chronicles* have been privately printed by the 7th duke of Atholl (b. 1840). *See* also S. Cowan, *Three Celtic Earldoms* (1909).

ATHOS, the most eastern of the three peninsular promontories which extend, like the prongs of a, trident, southwards from the coast of Macedonia into the Aegean Sea. Before the 19th century the name Athos was usually confined to the terminal peak of the promontory, which was itself known by its ancient name, Acte. The peak rises like a pyramid, with a steep summit of white marble, to a height of 6,350ft., and can be seen at sunset from the plain of Troy on the east and the slopes of Olympus on the west. On the isthmus are distinct traces of the canal cut by Xerxes before his invasion of Greece in 480 B.C. The peninsula is remarkable for the beauty of its scenery, and derives a peculiar interest from its unique group of monastic communities with their mediaeval customs and institutions, their treasures of Byzantine art and rich collections of documents. It is about 40m. in length, with a breadth varying from 4 to 7m.; its whole area belongs to the various monasteries.

Owing to the timely submission of the monks to the Turks after the establishment of their empire in Europe and especially after the capture of Salonika (1430), their privileges were respected by successive sultans. Under the present constitution, which dates from 1783, the general affairs of the commonwealth are entrusted to an assembly (*σύναξις*) of 20 members, one from each monastery; a committee of four members, chosen in turn, styled *epistatae* (*ἐπιστάται*), forms the executive. The president of the committee (6 *πρῶτος*) is also the president of the assembly, which holds its sittings in the village of Karyes, the seat of government since the 10th century. The 20 monasteries, which all belong to the order of St. Basil, are: Laura (*ἡ Λαῦρα*), founded in 963; Vatopédi (*βατοπέδιον*), said to have been founded by the emperor Theodosius; Rossikón (*Ῥωσσικόν*), the Russian monastery of St. Pantelei'mon; Chiliándari (*Χιλιαντάριον*: supposed to be derived from *χίλιοι ἄνδρες* or *χίλια λεοντάρια*, founded by the Serbian prince Stephen Nemanya, 1159–95); Iveron (*ἡ μονὴ τῶν Ἰβήρων*), founded by Iberians, or Georgians; Esphigmenu (*τοῦ Ἐσφιγμένου*: the name is derived from the confined situation of the monastery); Kutlumush (*Κουτλουμούση*); I'andocratoros (*τοῦ Παντοκράτορος*); Philotheu (*Φιλοθέου*); Caracallu (*τοῦ Καρακάλλου*); St. Paul (*τοῦ* dyiov *Παύλου*); St. Denis (*τοῦ ἁγίου Διονυσίου*); St. Gregory (*τοῦ* dyiov *Γρηγορίου*); Simópetra (*Σιμόπετρα*); Xeropotámu (700 *Ξηροποτάμου*); St. Xenophon (*τοῦ* dyiov *Ξενοφῶντος*); Dochiaríu (*Δοχειαρείου*); Constamonitu (*Κωνσταμονίτου*), Zográphu (*τοῦ Ζωγράφου*); and Stavronikitu (*τοῦ Σταυρονικίτου*), the last built, founded in 1545. Dependent on the several monasteries are 12 sketae (*σκῆται*) or monastic settlements, some of considerable size, in which a still more ascetic mode of life prevails: there are, in addition, several farms (*μετοχία*), and many hundred sanctuaries with adjoining habitations (*κελλία*) and hermitages (*ἀσκητήρια*). The monasteries, with the exception of Rossikón (St. Pantelei'mon) and the Serbo-Bulgarian Chiliándari and Zográphu, are occupied exclusively by Greek monks.

The population of the holy mountain was 4,858 in 1928; about 3,000 are monks (*καλόγεροι*), the remainder being lay brothers (*κοσμικοί*). The monasteries, which are all fortified, generally consist of large quadrangles enclosing churches; standing amid rich foliage, they present a wonderfully picturesque appearance, especially when viewed from the sea. Their inmates, when not engaged in religious services, occupy themselves with husbandry, fishing and various handicrafts; the standard of intellectual culture is not high, A large academy, founded by the monks of Vatopédi in 1749 for a time attracted students from all parts of the East, but eventually proved a failure, and is now in ruins. The muniment rooms of the monasteries contain a marvellous series of documents, including chrysobulls of vari-

ous emperors and princes, *sigilla* of the patriarchs, *typica,* iradés and other documents, the study of which will throw an important light on the political and ecclesiastical history and social life of the East from the middle of the 10th century. Up to comparatively recent times a priceless collection of classical manuscripts was preserved in the libraries; many of them were destroyed during the War of Greek Independence (1821–29) by the Turks, who employed the parchments for the manufacture of cartridges; others fell a prey to the neglect or vandalism of the monks, who, it is said, used the material as bait in fishing; others have been sold to visitors, and a considerable number have been removed to Moscow and Paris.

See V. Langlois, *Le Mont Athos et ses monastères,* with a complete bibliography **(1867)**; Duchesne and Bayet, *Mémoire sur une mission en Macidoine et au Mont Athos* **(1876)**; Texier and Pullan, *Byzantine Architecture* **(1864)**; A. Riley, *Athos, or tlze Mountain of the Monks* (1887); P. Meyer, "Beiträge zur Kenntniss der neueren Geschichte und des gegenwärtigen Zustandes der Athosklöster," in *Zeitschrift* fur *Kirchengeschichte* (1890); G. Millet, J. Pargoire and L. Petit, *Recueil des inscriptions chrétiennes de l'Athos* (1904).

ATHY, urban district, County Kildare, Eire, 45 mi. S.W. of Dublin on a branch of the Great Southern railway. Pop. (1936) 3,628. It is intersected by the river Barrow, the crossing of which was disputed from earliest times, and the name of the town is derived from a king of Munster killed here in the 2nd century. There are remains of Woodstock castle of the 12th or 13th century. White castle, built in 1506 and rebuilt in 157j, is still occupied. Both defend the ford. There are also an old town gate and ancient cemetery with slight monastic remains. Previous to the Union, Athy returned two members to the Irish parliament. There are good water communications, by a branch of the Grand canal to Dublin, and by the river Barrow, navigable from here to Waterford harbour.

ATINA, the name of three ancient towns of Italy. (1) A town (mod. *Atena*) of Lucania, upon the Via Popillia, 7m. N. of Tegianum, towards which an ancient road leads, in the Diano valley. Walls of rough cyclopean work may have had a total extent of some two miles. There are remains of an amphitheatre and numerous inscriptions, including one carved upon the paving blocks of the ancient forum (or market place). (2) a town (mod. *Atina*) of the Volsci, 12m. N. of Casinum, and about 14m. E. of Arpinum; (3) a town of the Veneti, mentioned by Pliny.

ATITLAN or **SANTIAGO DE ATITLAN,** a town in the department of Sololb, Guatemala, on the southern shore of Lake Atitlán. The population in 1942 was about 5,000, almost all Indians. Cotton-spinning is the chief industry. Lake Atitlbn is 24 mi. long and 10 mi. broad, with 64 mi. circumference. It occupies a crater more than 1,000 ft. deep and about 4,700 ft. above sea-level. The peaks of the Guatemala Cordillera rise round it, culminating near its southern end in the volcanoes of San Pedro (7,000 ft.) and Atitlán (11,719 ft.). Although the lake is fed by many small mountain torrents, it has no visible outlet, but probably communicates by an underground channel with one of the rivers which drain the Cordillera. Mineral springs abound in the neighbourhood. The town of Sololb (*q.v.*) is near the north shore of the lake.

ATKARSK, a port and railway junction on the river Medvyeditsa, with a grain elevator, in the Saratov province of the U.S.S.R. Population 19,326. Lat. 51.52° N. Long. 44.58" E.

ATKINSON, EDWARD (1827–1905), American economist, was born at Brookline (Mass.) on Feb. 10, 1827. For many years he was engaged in managing various business enterprises, and became, in 1877, president of the Boston hlanufacturers' Mutual Fire Insurance Co., a post which he held till his death. He was a strong controversialist and a prolific writer on economic subjects. He was appointed in 1887 a special commissioner to report upon the status of bimetallism in Europe. He also made a special study of mill construction and fire prevention, and invented an improved cooking apparatus, called the "Aladdin oven." He died at Boston on Dec. 11, 1905. His principal works were *Right Methods of Preventing Fires in Mills* (1881); *Distribution of Products* (1885); *Industrial Progress of the Nation* (1889); *Taxation and Work* (1892); and *Margin of Profits* (1902).

ATKINSON, SIR HARRY ALBERT (1831–92), New Zealand statesman, was born at Chester, England, and migrated to New Zealand in 1855. He distinguished himself in the Waitara war of 1860–65, and entered parliament in 1863. As minister of defence in Sir Frederick Weld's ministry (1864–65) he was identified with the "self-reliance" policy of using colonial troops only against the Maori. In 1873 he re-entered parliament, and in 1874 became treasurer. Except during six months in 1876, he thenceforth held that post whenever his party was in power. From Oct. 1874 to Jan. 1891 Atkinson was only out of office for about five years. He was three times premier, and was always the most formidable debater and fighter in the ranks of the Conservative opponents of the growing Radical party.

He was mainly responsible for the abolition of the provinces into which the colony was divided from 1853 to 1876. He repealed the Ballance land tax in 1879, and substituted a property tax. In 1880 and again in 1888 he raised the customs duties, among other taxes, and gave them a quasi-protectionist character. In 1880 he struck 10% off all public salaries and wages; in 1887 he reduced the salary of the governor by one-third, and the pay and number of ministers and members of parliament. By these means revenue was increased, expenditure checked, and the colony's finance reinstated. Atkinson advocated compulsory national assurance, and the leasing as opposed to the selling of crown lands.

Defeated in the general election of Dec. 1890 he became speaker of the legislative council. While leaving the council chamber after the sitting of June 28, 1892, he died suddenly of heart disease. Though brusque in manner and never popular, he was esteemed as a vigorous, upright, and practical statesman.

ATKINSON, ROBERT (1839–1908), British philologist, was educated at Trinity college, Dublin. He became professor of Romance languages there in 1869, and in 1871 was professor of Sanskrit and comparative philology. In 1884 he became Todd professor of Celtic languages in the Irish academy. In Celtic studies Atkinson was a pioneer. He edited: *The Passions and Homilies from tlze Leabhar Breac* (1887); *Three Shafts of Death* (Tri Bior-gaoithe an Bhais, 1890), and also wrote introductions for many of the facsimiles issued by the Irish academy.

ATKYNS, CHARLOTTE, LADY (1758–1836), English actress, née Charlotte Walpole, who married Sir Edward Atkyns in 1779. She was in France during the Revolution, and was a faithful friend of the royal family.

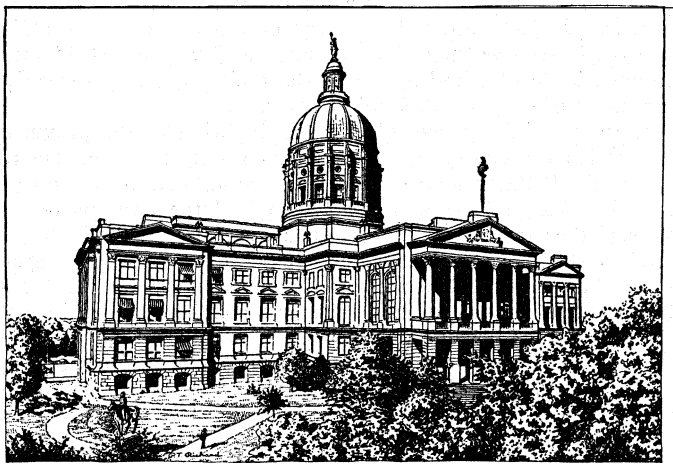
See F. Barbey, *A Friend of Marze Antoinette* **(1906)**.

ATLANTA, the capital of Georgia, U.S.A., and its largest city, in the north-central part of the State, 8 m. from the Chattahoochee river; lying mostly in Fulton county, of which it is the county seat, but partly also in De Kalb county. It is on the Dixie and the Bankhead highways, has a municipal airport, and is scrvcd by 15 lines of eight railways: the Atlanta, Birmingham and Coast, the Atlanta and West Point, the Central of Georgia, the Georgia, the Louisville and Nashville, the Nashville, Chattanooga and St. Louis, the Seaboard Air Line, and the Southern. It is the largest city between Washington and New Orleans, the commercial and financial capital of the south-east, and also an important manufacturing and educational centre. The population was 89,872 in 1900; 154,839 in 1910; 200,616 in 1920, of whom 62,796 were Negroes and 4.738 foreign born; and was 270,366 (after several annexations of territory) in 1930 by the federal census; and 302,388 in 1940.

The city lies on the Allegheny watershed, at an altitude of 1,000–1,17j ft., and is surrounded by the foothills of the Blue Ridge mountains. The rainfall is evenly distributed through the year, and the average mean monthly temperature ranges between 43·2° in January and 78·1° in July. The air is bracing, and deaths from sunstroke are unknown.

Atlanta owes its existence and development to the railroads. In 1836 the present site of the Union station was selected for the southern terminus of a projected State railway; and within a few decades, as one railway after another built from other directions to the same point, it became the principal transportation centre in the southern States The city was laid out in a circle nith a radius of 1¾ m, which had for its centre the old Union

station. The original area has been increased by successive annexations of territory in all directions until it is now 31·4 sq.mi., and the metropolitan area includes about 221 sq.mi. As the city was almost completely destroyed by Sherman's raid in 1864, it is nearly all of recent construction. In 1920 a city planning commission was established, and it secured the adoption of a zoning ordinance (1922) which helped promote the diffusion of population. There are beautiful streets and residence sections, among them Peachtree street, Ponce de Leon avenue, Pace's Ferry road, Druid Hills, Ansley Park, and Morningside Park. The business section has many large hotels and sky-scrapers; its principal oflice-buildings contain over 2,500,000 sq.ft. of floor space. The streets are over-crowded with traffic, and projects for widening some of them are under consideration. The principal railway station, the Terminal, is modern and well equipped. The old Union station is still used by three roads.



BY COURTESY OF THE ATLANTA CHAMBER OF COMMERCE

THE STATE CAPITOL BUILDING AT ATLANTA. COMPLETED IN 1889
Beside a collection of portraits of famous Georgians, the capitol building contains an extensive law library. The equestrian statue on the left represents General John Brown Gordon, distinguished in the American Civil War

The State Capitol, built in 1884–89, is designed after the National Capitol in Washington. The Federal Reserve Bank is a magnificent building of Georgia marble. The Fulton county court house, of granite and terra-cotta tile, the city auditorium-armoury, which has a hall seating 6,000, the Federal building and the Carnegie library (opened 1902) are other conspicuous public buildings. The Georgia training school for girls, a State reformatory institution, is about 7m. outside the city. On the southern boundary of the city are the State home for Confederate veterans; the Federal penitentiary, one of the three prisons maintained by the U.S. Government; and Ft. McPherson, a large army post of the 4th Corps Area, which has its headquarters in the city. There are many points of historic interest in and near the city, especially in connection with the Civil War. The home of Joel Chandler Harris, the author of "Uncle Remus," is kept as a memorial to him; and the old red brick building in which Woodrow Wilson began the practice of law still stands. There is a statue of Henry W. Grady in front of the city hall, and the memory of this beloved orator and editor, who did much to mitigate the bitterness between the North and the South after the Civil War, is further cherished in the names of the largest city hospital and one of the leading hotels.

There are 61 parks, squares, and open spaces in the city, with a total area of 1,200 acres. They include 24 playgrounds for children, 62 double tennis-courts, two nine-hole golf courses, 12 baseball diamonds, three football fields, six swimming pools, and two basketball courts—all maintained by the city for public use. The largest parks are Piedmont (185 ac.); Grant (144 ac.), which contains Ft. Walker, a part of the breastworks in the battle of Atlanta; and Lakewood (386 ac.), which is used as fair-grounds by the South-eastern Fair Association. There are several fine country clubs outside the city; and in all (public and private) there are ten golf courses here in the home of Bobby Jones.

The city pumps its water-supply from the Chattahoochee river, and the present equipment is sufficient to supply a population 50% larger than is now served. The sewerage system (a double system, with one set of pipes to carry off storm water, and another for the sewage) extends to 90% of the total street mileage, and additional mains are under construction. Coal comes from mines near by in Alabama, Tennessee, and Kentucky, and is cheap. Electrical energy is brought in by nine long-distance high-tension transmission lines, from various water-power developments.

Most of the industries use electric power.

The power company operates also a steam heating plant, which provides heat from underground mains for offices and other buildings in the central business district. The assessed valuation of property for purposes of taxation was $344,830,716 in 1940, representing an actual value of about $570,000,000. There were 97.200 telephones in use that year, and in 1940 the number of licences issued for privately owned passenger motor cars in the city and Fulton county was 92,684. The cost of living in Atlanta runs 7 or 8% below the average for American cities.

Atlanta's trade area embraces the entire southeastern quarter of the United States. In 1939 there were 809 wholesale houses and 3.833 retail establishments in the city, and 152 transport companies operating 2,000 motor trucks for commercial hauling exclusively; 500 cars of merchandise and package freight moved out daily over the various railways; and the post-office receipts were $3,628,823. While Atlanta ranks 28th in population (1940) among the cities of the United States, it ranks 21st in amount of postal receipts and 13th in bank clearings. It is the seat of the sixth federal reserve bank. Debits to individual accounts in the city's banks amounted to $2,449,500,000 in 1940 and clearing-house exchanges to $3,009,000,000. Retail sales for 1939 totalled $172,299,000, or $567 per capita; sales by the wholesale establishments, $465,115,000.

There were 902 manufacturing establishments within the city limits in 1939, and the aggregate value of their output was $172,000,000, about 19% of the total for the state. Many more are located outside the city, within the metropolitan area. Printing and publishing, especially of agricultural and trade journals, is an important industry. The leading manufactures include cotton goods, cottonseed oil, furniture and other lumber products, fertilizer, agricultural machinery and implements, and (as in all modern American cities) confectionery, ice-cream and bakery products; but there are no dominating industries, and more than 1,500 commodities are made within the metropolitan area. Many industries of national scope have established branches at Atlanta, either for production or for storage and distribution of their goods.

The public-school system comprises (1940) 76 elementary schools, four junior and four senior high schools, with a total enrolment of 69,000. In 1921–22 on the occasion of a special appropriation of $4,000,000 for the development of the school plant, a comprehensive survey of the system was made, and plans were mapped out to meet anticipated needs as far ahead as 1940. The free public library (organized 1899, when the city accepted a double offer from Andrew Carnegie and the Young Men's Library Association) has an annual circulation of over 630,000 volumes. It maintains eight branches, and conducts a school for training librarians, which since 1925 has been affiliated with Emory university. There are 586 churches within the metropolitan area (301 of them maintained by coloured people) representing 20 denominations. Charitable institutions and agencies, about 40 in number, are financed through a "community fund."

Atlanta has many institutions for the higher education of both white and coloured students. The Georgia institute of technology (opened 1888) is a part of the State university (see ATHENS). Oglethorpe university (originally conducted at Midway, destroyed during the Civil War, and reopened at Atlanta in 1916), the *alma mater* of Sidney Lanier, occupies beautiful blue granite buildings on a campus of 137ac. north of the city. Emory university (founded by the Methodist Episcopal Church South in 1914) incorporates Emory college, named after Bishop John Emory of Maryland (d. 1835), which was conducted 1837–1919

at Oxford, Georgia. It has endowments of $4,362,745, and its campus of 160ac. is just outside the city, in Druid Hills. Agnes Scott college for women is in the suburb of Decatur (*q.v.*) and the Georgia military academy is at College park, 7m. to the south-west. Besides the professional schools of the universities there are the Atlanta theological seminary (Congregational), the Atlanta law school, the Atlanta-Southern dental college, the Atlanta college of pharmacy and the Southern college of pharmacy. The institutions for coloured students include Atlanta university (founded 1865 by the American Missionary Association), the pioneer in advocating and furnishing opportunities for cultural education for negroes, with which W. E. Burghardt du Bois was associated for many years; Morehouse college, established in Augusta, in 1870, by the Baptist Home Missionary Society; Clark university, founded in 1870 by the Freedmen's Aid Society of the Methodist Episcopal Church; Morris Brown university, founded in 1882 by the African Methodist Episcopal Church; and Gammon theological seminary (Methodist Episcopal) established and endowed in 1883 by Dr. Elijah Gammon.

Three daily newspapers are published: the *Constitution* (established 1868), edited 1880–89 by Henry W. Grady (1850–89), and from 1889 to his death by Clark Howell (1863–1936), the *Journal* and the *Georgian*.

On Stone Mountain, a hill of naked granite 15m. E. of Atlanta, a magnificent memorial to the Southern Confederacy is under construction. When completed, a military procession of hundreds of figures chiselled in bold relief will sweep across the perpendicular cliff (800ft. high and 5,000ft. long) on the north side of the mountain, "reviewed" by a central group representing the Confederate High Command, including Jefferson Davis, Robert E. Lee, Stonewall Jackson and a colour-bearer. The work was begun by Gutzon Borglum and continued by Augustus Lukeman. A vast memorial hall will be quarried out, to serve as a depositary for records and relics of the Confederacy.

History.—In 1821 this region was ceded to the State of Georgia by the Creek Indians. In 1825 a lottery was held, and land lot no. 78, on which the greater part of the city stands, was drawn by Jane Doss, who sold it the following year for $50. The first cabin was built in 1833, by Hardy Ivy. Near his dwelling the railway engineers in 1836 drove their stake to mark the end of the proposed State railroad. The village was appropriately called Terminus at first, but in 1843, when a town charter was secured, the name was changed to Marthasville, in honour of the daughter of Gov. Wilson Lumpkin; and in 1847, when the city was incorporated, it was again changed to Atlanta, which was probably suggested by the name of the railroad (the Western and Atlantic). The population in 1850 was 2,572; in 1860, 9,554. During the Civil War the city was the seat of military factories and a depot of supplies. In 1864 it became the objective of Sherman's invasion of Georgia from Chattanooga. The battle of Atlanta was fought on July 22, and other severe engagements took place in the vicinity through July and August. On Sept. 2 the Union troops entered the city; the citizens were ordered to leave, and the place was turned into a military camp. When, on Nov. 15, Sherman started on his "march to the sea," the city was fired and a large part of it burned. The military government of Georgia was established here in 1865, and in 1868 Atlanta was made the capital of the State. The International Cotton Exposition was held here in 1881; the Piedmont Exposition in 1887; and in 1895 the Cotton States and International Exposition, which had exhibits from 37 states and 13 foreign countries.

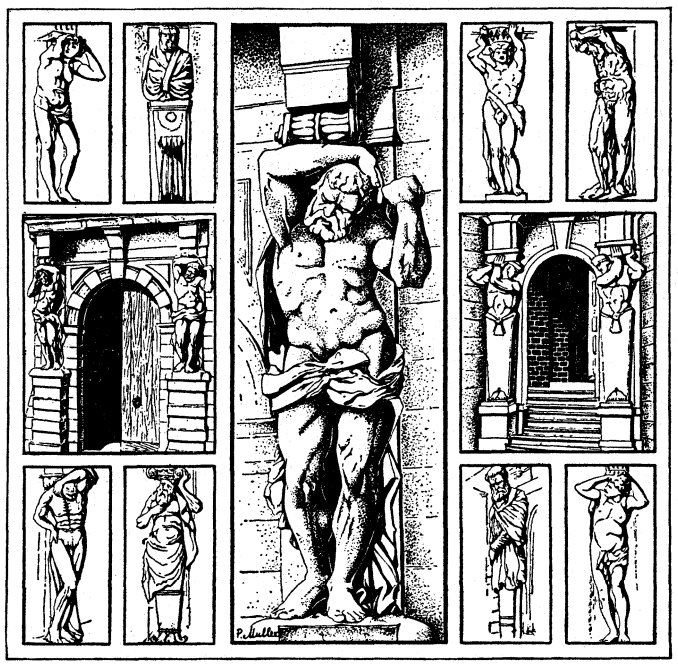
ATLANTA, BATTLES ROUND. The fighting round Atlanta (July 20–Sept. 2, 1864), the last phase of the Atlanta campaign (May–Sept.), ended with Sherman, the Federal general, forcing his opponent *Hood* to evacuate "the Gate City of the South." Having manoeuvred *Hood's* predecessor, *J. E. Johnston*, across the Chattahoochee (July 9), Sherman had before him a twofold objective, the capture of Atlanta and the destruction of the Confederate army. If the two ends could be compassed by a single stroke, so much the better; but Sherman had already decided that, if to take Atlanta he must let the enemy army escape, the capture of the city was the more important task. He believed that the fall of Atlanta would sound the death-knell of the Confederacy and to attain that he "was willing to meet the enemy in the open field but not behind well-constructed parapets" (Sherman). If Atlanta was, as *Johnston* wrote, "too strong to be taken by assault and too extensive to be invested," still the Confederate army could be forced to evacuate it by cutting off its sources of supply. Three railways fed Atlanta, viz., the Augusta, Montgomery and Macon lines. Sherman was warned by Grant that *Lee* might send reinforcements from Virginia, and these troops would probably follow the Augusta route, as *Longstreet* had done the previous year. Therefore Sherman decided to destroy the Augusta railway east of Decatur, hoping to put it out of action long enough to complete his operations against Atlanta and to close in upon the city from the north and east. His left wing, McPherson's Army of the Tennessee (XV., XVI. and XVII. Corps) was ordered to advance from Roswell and strike the railway between Decatur and Stone mountain, Schofield's Army of the Ohio (XXIII. Corps) to march straight upon Decatur, where it would be joined by McPherson, and Thomas with the Army of the Cumberland (IV., XIV. and XX. Corps) to advance upon Atlanta. *Johnston* meant to fight for Atlanta. He had prepared a line of defence behind Peach-tree Creek forming a semicircle round the north of the city, with its flanks resting on the Chattanooga and Augusta railways. The forces of the two combatants were now more nearly equal than they had ever been. For Sherman had to leave strong detachments north of the Chattahoochee to protect his communications against cavalry raids, and *Johnston* hoped to hold his fortified lines with the Georgia militia, which the State Governor was sending to Atlanta, and with his three corps attack the Federals in flank. But *Johnston* was superseded by *Hood*, one of his corps commanders (July 17). This step, generally regarded as one of *Davis's* worst mistakes, was forced upon the President by certain influential Georgians, who represented that *Johnston* was intending to abandon Atlanta without a battle. The Government could get no definite statement of his plans from *Johnston*, whose relations with the President had been strained since the autumn of 1861.

It was decided that a more aggressive policy must be adopted, and *Hood*, who had won a well-deserved reputation as a fighting general under *Lee*, was appointed in *Johnston's* place. *Johnston* on turning over the command had explained to his successor his plans for an offensive, and *Hood* decided to execute them forthwith. But he could only use two corps for his offensive, as only 2,500 militia had arrived. The disposition of Sherman's armies invited attack. The two flanks were 10m. apart and there was a big gap between Thomas's left and Schofield's right. *Hardee* was ordered with his own and *Stewart's* corps to attack Thomas's army, when crossing Peach-tree creek, and drive it down into the pocket between the creek and the river. But the Federals held their ground and beat off all the Confederate onslaughts (July 20). On the night of the 21st *Hood* withdrew his troops into an inner line of entrenchments and sent *Hardee's* corps round the east of Atlanta to fall upon the exposed flank and rear of McPherson's army, which seemed to be threatening a movement against the Macon railway. *Hood* intended, as soon as *Hardee's* attack threw the Federal left into confusion, to move out his other two corps from their entrenchments in succession and hoped to roll up the Federal line from left to right. After a 15m. night march *Hardee* reached a position in the thick woods where his right overlapped McPherson's left, which had just occupied the entrenchments vacated by the Confederates. The Federals were taken by surprise, as their cavalry was away tearing up the Augusta railway and Sherman himself imagined *Hood* to be evacuating Atlanta. But the unexpected appearance of the XVI. Corps in rear of McPherson's left prevented the Confederates from falling upon the enemy rear, and the onslaughts of *Hardee* on their left and of *Cheatham's* corps, which advancing from its lines took up the attack against the Federal front, were finally repulsed by the Army of the Tennessee, which fought this battle, known as the battle of Atlanta (July 22), the bloodiest of the whole campaign, practically unaided. It lost its commander, McPherson, who was killed at the outset. Logan took over the

temporary command, but Howard was formally appointed McPherson's successor (July 27). The railway bridge over the Chattahoochee was rebuilt (July 25), and for the greater security of his communications Sherman decided to advance against the Macon railway by his right flank instead of continuing the movement round the east of Atlanta. The Macon and Montgomery railways ran over the same line as far as Eastpoint, 3m. south of Atlanta. It was impossible for an army holding Atlanta to protect the latter railway, which crossed the Chattahoochee into Alabama. The safety of Atlanta therefore depended upon *Hood's* ability to keep the Macon railway intact. Sherman now transferred the Army of the Tennessee to the extreme right and sent his cavalry round both sides of Atlanta against this railway. As Howard was moving into position south-west of Atlanta (July 28) S. D. *Lee*, who had replaced *Cheatham* in command of *Hood's* old corps, attacked his right at Ezra Church with his own and part of *Stewart's* corps. *Hood's* third attempt to strike a heavy blow was repulsed with comparative ease, and *Davis*, alarmed at these costly failures, urged upon *Hood* a more cautious policy. Sherman continued to extend his lines to the right, moving Schofield (Aug. 1) with the XXIII. and XIV. Corps beyond Howard's army in the hope of capturing the railway above Eastpoint. But the insubordination of the XIV. Corps commander frustrated this attempt. Sherman now decided that he had stretched his lines as far as he could with safety. His cavalry raids failed to do any permanent damage to the railway. He therefore determined to cut loose from his base and throw his whole force (less one corps) against the Macon railway several miles south of Atlanta. He began the withdrawal of Thomas's and Howard's armies from their lines (Aug. 25), sending back the XX. Corps to entrench a position in front of the Chattahoochee railway bridge and leaving Schofield in his lines facing Eastpoint, where he kept up a series of demonstrations. By the night of the 27th the Federal forces were echeloned along the Atlanta-sandtown road and next day commenced a left wheel pivoting upon Schofield. Thomas struck the Montgomery railway at Red Oak, 7m. below Eastpoint, and Howard at Fairburn, 5m. farther south-west. The 29th was devoted to a thorough destruction of the railway track. On the 30th Howard reached the Flint river and pushed the XV. Corps across. Schofield had come up into line on Thomas's left the previous day and now moved up from Red Oak towards Eastpoint to cover the passage of the army trains, which carried 15 days' rations for the troops. *Hood* meanwhile was completely mystified by Sherman's withdrawal from before Atlanta. He had despatched *Wheeler* with over half his cavalry (Aug. 10) on an extensive raid against Sherman's communications, and on Aug. 27 he jumped to the conclusion that in consequence of *Wheeler's* raid Sherman was retreating across the Chattahoochee. On the 30th his cavalry brought him news that part of the Federal army was south of Atlanta, and he despatched *Hardee's* and *Lee's* corps under the former's command to Jonesboro to drive back the advancing enemy. *Hardee* attacked Howard (Aug. 31) but failed to drive him across the Flint river. Schofield and Thomas reached the Macon railway at and below Rough and Ready station and marched down towards Jonesboro, tearing up the track as they advanced.

Hood, when he learned that the enemy had reached the railway, ordered the return of *Lee's* corps to Atlanta. He inferred from his information that only the right wing of Sherman's army was on the railway and that a general attack upon Atlanta from the south was threatened. *Hardee* was left (Sept. 1) to defend Jonesboro. Sherman devoted his attention to the thorough destruction of the railway down to Jonesboro, until learning of *Lee's* departure he endeavoured too late to envelop *Hardee's* corps. *Lee* had been stopped half way on his return to Atlanta and ordered to cover the withdrawal of the remainder of *Hood's* army during the night from Atlanta. The XX. Corps occupied the city (Sept. 2). *Hood* marching round east of the railway effected a junction with *Hardee* at Lovejoy's station to interpose between Sherman and Andersonville, where 34,000 Federal prisoners were confined. Sherman did not push his advance farther south but rested content with the capture of Atlanta. *(See* AMERICAN CIVIL *WAR.)* (W, B. Wo.)

ATLANTES, in architecture, male figures used as supports for an entablature, a balcony or other architectural projection, especially when such figures are posed as though they were actually upholding great weights, like Atlas carrying the world. When male figures resemble the female caryatides (*q.v.*) they are more properly known as canephorae *(see* CANEPHORAE); when they are only half figures they are known as *gaines.* The earliest example



of true atlantes occurs on a colossal scale in the temple of Zeus at Agrigentum (c. 500 B.C.). They were favourite motifs in the later Renaissance, particularly in Italy, Germany and France.

ATLANTIC, a city in the south-west part of Iowa, U.S.A., 50m. E. by N. of Omaha; the attractive county seat of Cass county. It is at the intersection of highways 6 and 71 and is served by the Rock Island railway. It has an intermediate landing field for aeroplanes, lighted with beacons by the post office department. The population according to the federal census of 1940 was 5,802. Atlantic is the trade centre for a rich farming region, and has large corn-canning plants, flour mills and grain elevators, poultry-feeding yards and packing houses. It was chartered as a city in 1869.

ATLANTIC CITY, a city of Atlantic county, New Jersey, U.S.A.; a famous seaside resort, on the Atlantic ocean, 55 mi. S.E. of Philadelphia and 110 mi. S.-by-W. of New York. It is served by the Pennsylvania-Reading Seashore lines, by trolley (tram) and motor coach lines and by aeroplane service. It has had an airport since 1919. The residential population was 50,707 in 1920, of whom 10,946 were Negroes and 7,009 were foreign-born whites; according to the federal census residents numbered 64,094 in 1940. This population is increased by visitors to 300,000 in August, and the average daily population for the year is about 100,000. It is estimated that there are 15,000,000 visitors yearly.

The city lies on a low, sandy island (Absecon island), 10 mi. long with varying widths of from one-tenth of a mile to three-quarters of a mile, separated from the mainland by a narrow strait and 4 or 5 mi. of meadows, partly covered with water at high tide. In winter it is warmed by the Gulf stream and protected by the pine belt of New Jersey, and the heat of summer is moderated by the water on all sides. The percentage of sunshine is above the average, and there is little fog. These climatic advantages, added to its accessibility, have given it a unique position as an all-year-round playground, a resort for convalescents, and a favourite meeting place for conventions. There are about 1,000 hotels and several sanatoria. The assessed valuation of property in 1940 was $92,206,000.

The "Boardwalk," built of steel and concrete with a wooden flooring, 60 ft. wide in the central section and extending 8 mi.

along the ocean front, is the promenade of the nation. It is connected with six great recreation piers, which reach out over the ocean 1,000–2,500 ft. and on the other side is lined with sumptuous hotels, shops, restaurants and places of diversified amusements. For those who do not wish to walk, there are 2,500 licensed wheeled chairs. Surf bathing, horseback riding along the beach, fishing, yachting and wildfowl shooting are popular amusements. There are five country clubs with good golf courses, on which golf is played the year round.

Absecon lighthouse, on the north end of the beach, is 167 ft. high.

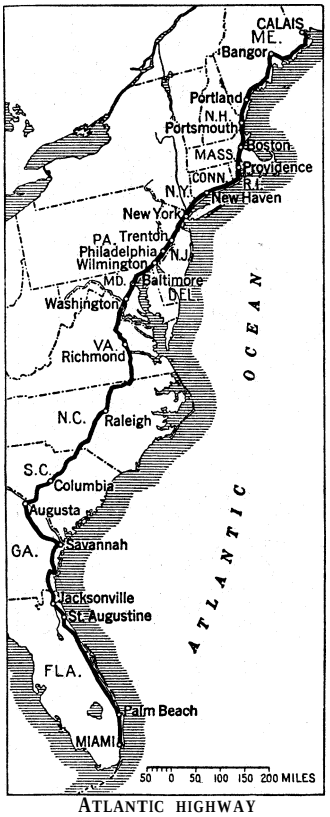
There was a settlement of fishermen on the island in the latter part of the 18th century. The movement to develop it as a seaside resort for Philadelphia began about 1845. and after the completion of the Camden and Atlantic City railway in 1854 the growth of the city was rapid. The first pier was opened in July 1882, and was destroyed by a storm in September of the same year. The city was incorporated in 1854 and adopted a commission form of government in 1912.

ATLANTIC COASTAL HIGHWAY runs from New York city to Miami, Florida. It is about 1,600m. in length and is for the most part hard surfaced or paved excepting between Wilmington, North Carolina, and Savannah, Georgia. This route follows the same general course as that of the Atlantic highway except between Petersburg, Va., and Savannah, Ga., and provides an excellent opportunity for viewing the coast lands of the intervening States. (See ATLANTIC HIGHWAY.)

ATLANTIC COAST LINE RAILROAD COMPANY, a Virginia corporation which operates in the States of Virginia, North Carolina, South Carolina, Georgia, Florida and Alabama. It is the outgrowth of the gradual consolidation of more than 80 separate railroad corporations and the construction and purchase of a large amount of additional mileage connecting therewith. The Richmond and Petersburg Railroad Company, chartered by the State of Virginia in 1836, was the basic or parent company, into which the other railroads were merged and consolidated. The first step was taken in 1898, when this company absorbed the property of the Petersburg Railroad Company, another Virginia corporation, chartered in 1830, and changed its name to Atlantic Coast Line Railroad Company of Virginia, with less than 100 m. total mileage. In 1900, the Company absorbed the property of the Wilmington and Weldon Railroad Company, chartered by the State of North Carolina in 1834, and of other companies, and again changed its name to Atlantic Coast Line Railroad Company. Upon this merger the railroad lines of the Atlantic Coast Line Railroad Company were extended from Richmond and Norfolk, in Virginia, to Charleston and Columbia, in South Carolina; with branch and feeder lines extending throughout eastern Virginia and eastern North Carolina and eastern South Carolina, with a total mileage of about 1,760 miles. In 1902 the Atlantic Coast Line Railroad Company acquired the Plant System, extending from Charleston, S.C., to Tampa, Fla., and Montgomery, Ala., with many branch lines. This purchase gave the Atlantic Coast Line a total of 4,138 miles. Additional track constructed and acquired had brought the total mileage up to 5,101·02 in 1940.

The territory served by the Atlantic Coast Line is one of the largest and most important producers in the United States of perishable fruits and vegetables, and this railway line ranks among the leading carriers of these commodities. Passenger travel is important also because of the large number of tourists that annually visit Florida and other points in the southeastern States. The Atlantic Coast Line operates a number of trains, both seasonal and year-long, designed to encourage this traffic. The capitalization of the Company on March 31, 1940 consisted of common stock 823,427 shares, with a par value of $82,342,700; preferred stock 1.967 shares, with a par value of $196,700; funded debt outstanding, $144,448,100; total $226,987,500. (G. B E.)

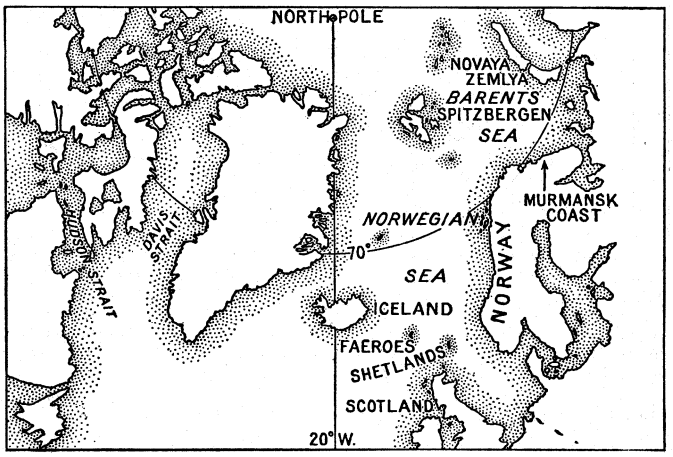
ATLANTIC HIGHWAY, one of the first great American thoroughfares to have a name, is notable for the fact that it passes through the greatest cities of the East and is surrounded by the historic points of interest of the 13 original States. Extending from Calais, Me., to Miami, Fla., it is all hard or paved roadway as far as South Carolina, and again in Florida. Bangor, Portland, Boston, Providence, New York, Trenton, Philadelphia, Wilmington, Baltimore, Washington, Richmond, Raleigh, Augusta, Jacksonville, St. Augustine and Palm Beach are some of the centres of population that lie along its route. Bordering upon the Atlantic ocean through much of its 2,240m., it affords scenes of great beauty, varying from the roaring surf and rock-bound cliffs of Maine to the coral reefs and opalescent blue of Florida's quiet waters.



ATLANTIC HIGHWAY

ATLANTIC OCEAN, the name given to the vast stretch of sea dividing the continents of Europe and Africa from the New World. The term is supposedly derived from Atlantis, presumed to be a submerged continent below the present ocean.

Extent.— The Arctic basin which stretches from Bering strait across the North Pole to Spitzbergen and Greenland belongs essentially to it, as in the south does the Weddell sea, south of South Georgia (fig. 1.). The utilization of the Arctic and Antarctic circles as boundaries has neither geographical nor physical justification. The Atlantic ocean has therefore a share in both the seas of ice. From a consideration of winds, currents and temperature it is best to count the equatorial boundary of the North Atlantic at about latitude 5° N. In contrast to the South Atlantic it is very rich in islands, in variety of coastline, and in land-locked seas. The latter include the Caribbean sea, the Gulf of Mexico, the Gulf of St. Lawrence, Hudson bay, Baffin bay on the west, and the Mediterranean sea, Black sea, North sea and Baltic sea on the east. Between



THE NARROW GATEWAY OF THE NORTH ATLANTIC

Spitzbergen and Novaya Zemlya on the one hand and the Murmansk coast on the other lies the Barents sea; between Spitzbergen, Iceland, the Faeroes, Shetlands and Norway lies the Norwegian sea. The southern outlets from the Arctic basin are relatively narrow. Hudson strait is 80km. broad, Davis strait 240km., Denmark strait between East Greenland and Iceland 260km., and the passage between Iceland and north Scotland 850km. The total of all this is only 1,430km. In the South Atlantic on the other hand, between Cape Horn and South Africa, Antarctic and Atlantic meet on a 6,500km. front, and the South Atlantic is therefore much

colder and rawer than the North Atlantic. The Atlantic is, broadly, **S**-shaped and narrow in relation to its length, with the result that writers have spoken of an Atlantic valley. From the Bering strait in the north to Coats land in the south the distance is 21,000km. The breadth from Newfoundland to Ireland is 3,375km. and from Cap San Roque (Brazil) to Cap Palmas only 2,900km. Southwards from these latter it becomes broader and

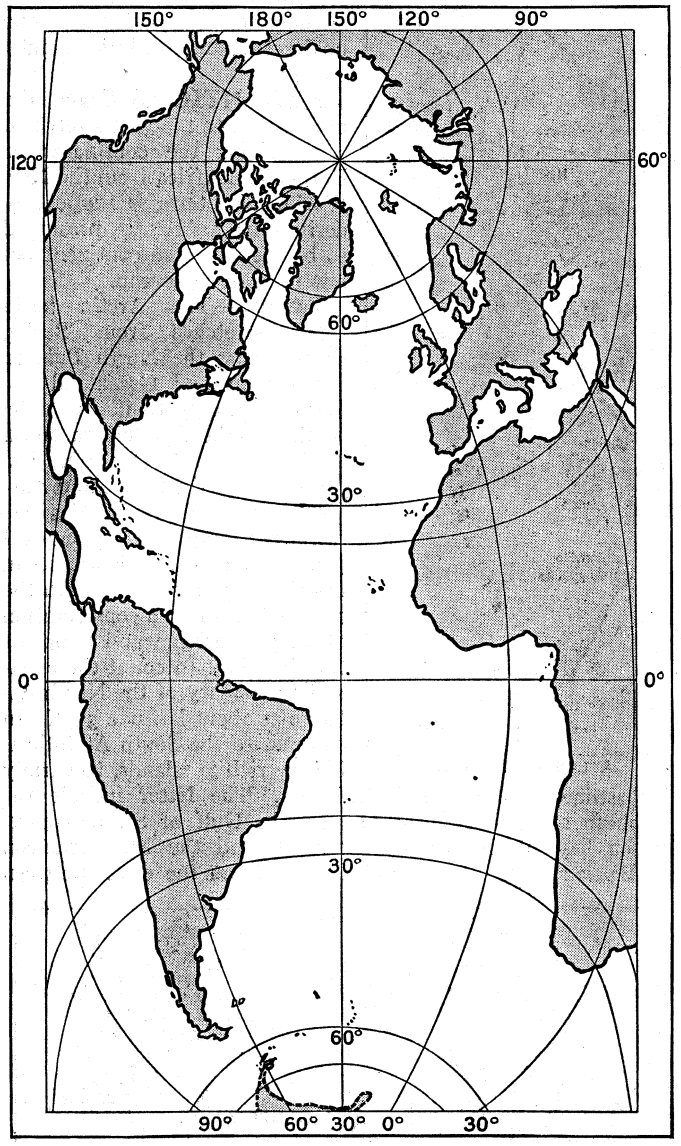


FIG. 1.— THE ATLANTIC OCEAN FROM BERING STRAIT TO WEDDELL SEA
Broadly S-shaped, and narrow in proportion to its length, the area of the Atlantic with its dependent seas is estimated at 106.4 million sq.km. It receives the waters of many of the great rivers of the world, including the St. Lawrence, Mississippi, Orinoco, Congo and Niger, as well as that of the rivers flowing into the Baltic and Mediterranean. The land area drained is nearly four times that drained by the Pacific ocean

is bordered by very simple coasts almost without islands. Drake straits, between Cape Horn and the South Shetlands, give a passage 900km. wide into the Pacific. Kossinna reckons the area of the Atlantic without its dependent seas at 82.4 million sq km. and with its dependent seas at 106.4 million sq.km. By way of comparison, one may mention that the North sea has an area of 0.6 million sq km. Although not the most extensive of the great oceans the Atlantic has by far the largest drainage area. The "long slopes" of the continents on both sides are directed towards the Atlantic, which accordingly receives the waters of a large proportion of the great rivers of the world, including the St. Lawrence, the Mississippi, the Orinoco, the Amazon, the rivers of the La Plata, the Congo, the Niger, the Loire, the Rhine, the Elbe and the great rivers of the Mediterranean and the Baltic. Sir J. Murray estimated the total area of land draining to the Atlantic to be 34,788,000sq.km., or, with the Arctic area, nearly 51,000,000 sq.km., nearly four times the area draining to the Pacific Ocean, and almost precisely four times the area draining to the Indian Ocean. (In this article m. represents metre.)

Islands.—Among purely oceanic islands without a foundation of continental rock, usually the result of volcanic action, we have Jan Mayen, Iceland (105,000sq.km.), Fernando Noronha (near Cap San Roque), Ascension, St. Helena (123sq.km.), Tristan da Cunha, and Bouvet islands (54° S. Lat.). Mainly volcanic, but with a sedimentary foundation are the Azores, Canaries, Madeira and Cape Verde islands. Purely continental are Spitzbergen and the Bear islands, the British isles, Newfoundland, the Great Antilles, the Falkland islands, South Georgia and the South Orkneys. The Bermudas (Lat. 30° N.) are the most northerly coral-reef islands of the world. All Atlantic islands of oceanic origin together have an area of 0.5 million sq.km. In this connection it seems best to consider Greenland as a part of the North American continent.

Relief of **the** Bed.—The foundations of our knowledge of the relief of the Atlantic bed may be said to have been laid by the work of H M S. "Challenger" (1873–1876), the German ship "Gazelle" (1874–1876) and the U.S. surveying vessel "Blake" (1877 and later). Large numbers of additional soundings have been made in later years by cable ships, by the expeditions of H.S H. the prince of Monaco, the German "Valdivia" expedition (1898), and the combined Antarctic expeditions (1903–1904), especially by the "Scotia." In the so-called Weddell sea, where the "Scotia" worked, the "Deutschland" in 1911–12 took many soundings towards the Antarctic continent. In 1925–27 the "Meteor" (German) took about 60,000 soundings by acoustic methods in the South Atlantic, thus rounding off our knowledge of the relief of the Atlantic bottom.

For the Arctic basin we have F. Nansen's maximum sounding of 3,850m., and we know that at the North Pole Peary failed to reach bottom with a sounding of 2,743m. In the Norwegian sea there are many depths of more than 3,000m., but the Barents sea is fairly shallow (300–400m.). The submarine ridge from East Greenland through Iceland and the Faeroes to North Scotland is such that a lowering of the water-level of 400m. would link Europe with Greenland. This ridge keeps the cold Polar bottom-water of the northern deeps away from the Atlantic. From this transverse ridge two branches stretch south-westwards, both probably of volcanic origin. The first projects from Iceland, the second, stretching from the Faeroes, includes the island of Rockall 500km. west of the Hebrides. The grand banks of Newfoundland are less than 200m. below sea level and between them and Iceland is the so-called "telegraph plateau," the level of which varies between depths of 500 and 4,000m. South of this plateau begins the dominant feature of the relief of the whole Atlantic, namely the central Atlantic rise. This keeps to the middle of the ocean as far south as Lat. 50° S., parallel to main curvings of the continental coasts on both sides; it stretches through over 100° of latitude. On this rise, the depths of water are usually less than 3,000m. and often less than 2,000m. On it lie the Azores, St. Paul's island, Ascension, Tristan da Cunha and Bouvet Island, and at the last of these the rise bends eastwards and goes to the Indian Ocean. On both sides of the rise are greater depths, of more than 5,000 or 6,000m. The greatest, those of over 6,000m. or approximately 3,000 fathoms, are called "Deeps" by Sir John Murray and he named them after famous marine explorers, *e.g.*, Nares Deep, north of Haiti and Porto Rico, with a depth of 8,526m., only 150km. from the coast, the deepest spot known in the Atlantic. More recently purely geographical names have been used, and we speak of a North American basin, a Brazilian basin and an Argentine basin. In the last, depths of 8,000m. have been found just North of the South Sandwich islands. East of the Central rise lie the deep Cape Verde depression, the West African depression and the Cape depression, always deeper than 5,000m., often than 6,000m. Some ridges branching out from the central rise in the South Atlantic influence greatly the water movements and temperatures of the depths.

Such are, to the West the Rio Grande ridge (30° S.), to the East the Walfish ridge, stretching S.W.–N.E. from Tristan da Cunha (35° S.) to the African coast near Walfish bay. On these two ridges depths of 900 or even only 700m. on some local pinnacles have been found, and the Walfish ridge is three times as long as the European Alps, with heights 4,000m. above the depths. The Atlantic thus possesses submarine mountains, of course with slopes less sharp than those of terrestrial ones.

Mean Depth and Bottom Deposits.—The average depth of the Atlantic according to Kossinna (1921) is 3,924m. without, or 3,332m. including the enclosed seas. This difference is due to the fact that the sea on large areas off many coasts is less than 100 fathoms or 200m. deep. This continental shelf occupies 13·3% of the area and the British isles lie upon a portion of it. The greater part of the bottom of the Atlantic is covered by a deposit of Globigerina ooze, roughly the area between 1,500 and 4,000m. deep, or about 53% of the whole. At a depth of about 5,000m., *i.e.*, in the "deeps," the Globigerina ooze gradually gives place to red clay. In the shallower tropical waters, especially on the central rise, considerable areas are covered by Pteropod ooze, a deposit consisting largely of the shells of pelagic molluscs. Diatom ooze is the characteristic deposit in higher southern latitudes. The terrigenous deposits consist of blue muds, red muds (abundant along the coast of Brazil, where the amount of organic matter present is insufficient to reduce the iron brought down by the great rivers so as to produce blue muds), green muds and sands, and volcanic and coral detritus. In the Arctic and Antarctic areas there are glacial muds, some from the Ice Age and some due to its survivals in modern glaciation. Even as far south as latitude 29" N. Murray found small stones of northern origin doubtless carried South by icebergs in the days when a great ice barrier stretched from South Greenland around to Scotland.

The origins and age of the Atlantic are unsettled. Neumayr (1885) thought that in Jurassic times there was a bridge-continent between North America and North Europe and one between South America and Africa, so that then the ocean lay only between the West Indies and south Europe. Wegener (1922) on the other hand thinks the Atlantic was formed in the Cretaceous period through a fracture between the Old and the New World, followed by the drift of America westward. J. Murray thought the Atlantic in the main extremely old, thus upholding a view of the permanence of this ocean basin.

Temperature Distribution.—The heat equator or line of highest average surface temperature of the water lies in all months north of the geographical equator, going from the Gulf of Guinea about 5° N. towards the coast of British Guiana and then northwest into the Caribbean sea to about 15° N. The yearly average of temperature on this line is about 27" C., and even far to the north, the isotherms keep a general direction E S E.–W.N.W., so the American side is warmer than the African. On the other hand north of 40° N. the European side is the warmer and the waters in the broad region from Newfoundland to Cape Hatteras are relatively cold. The Norwegian coast has a specially high temperature for its latitude and, even north of the Arctic circle, its fjords do not freeze. In the South Atlantic the Brazilian side is the warmer with an average temperature of 23" C. near Rio de Janeiro, while in the same latitude near Walfish bay, S.W. Africa, the temperature is 57°–59°. In higher southern latitudes the isotherms run nearly E. and W. save for local disturbances through the Cape current (Agulhas) and the Falkland current. Latitude for latitude, South Atlantic water is colder than that of the North. Near Bouvet island and South Georgia in lat. 54° S. we find the 0° C. isotherm, west of Ireland in 54° N. the 11° C. isotherm. Antarctic conditions thus reach into the temperate zone, and penguins have been seen even in the Great Fish bay, 16° S. The seasonal variation of the temperature of the surface waters is as little as 1°–4° C. in the tropics and in the colder regions, and may be 5°–8° C. in temperate latitudes.

Temperature decreases—save in the polar regions—from the surface to the depths; hut decreases in different places at different rates. In the inter-tropical regions at a depth of 400m. temperalures as low as 10° C. or even 8° C. and less have been noted. In middle latitudes, *e.g.*, in the Sargasso sea (*q.v.*) near the Bermuda islands the temperature may be as high as 17° C. at the same depth, and in latitude 30° S. we get 10°–12° C. and over at this depth. This striking fact can be explained only by supposing that in the equatorial region cold water rises nearly vertically from depths of 400–600m., whereas in middle latitudes warm surface water descends vertically to the depths.

In those parts of the Atlantic which are more than 1,000m. deep the temperature of the water depends mainly on the latitude at least south of the Tropic of Cancer. The Atlantic off Europe, helped by warm and very salt Mediterranean water flowing out through the Strait of Gibraltar, even at these great depths is warmer than the deep water of the inter-tropical region. The bottom temperatures are 2–2·5° C. in the North Atlantic, 0·5° C. in the Brazilian depression, 2·2° in the West African depression, zero and —0·4° C. in high southern latitudes. Differences of bottom temperatures are explained mainly by the form of the floor; transverse ridges stop the flow of the coldest water from higher latitudes, and the bottom temperature on their equatorial side is thus higher. In a similar manner the Greenland-Iceland-Shetland ridge with depth less than 500m. prevents the cold bottom water (temperature may be as low as —1·2° C.) of the Arctic and the Norwegian sea from entering the North Atlantic. This fact further helps the temperature of the European Atlantic waters, which are therefore of exceptionally high temperature for their latitude at every depth.

Salinity.—The Atlantic on the surface is by far the saltest of the great oceans. Its saltest waters arc found in the two trade-wind belts, one extending east and west in the North Atlantic between 20° and 30° N. lat., and another of almost equal salinity extending eastwards from the coast of South America in 10° to 20° S. lat. The average salinity in these two belts is 36·5–37·5‰. In the equatorial region between these belts the salinity is markedly less, especially in the eastern part, where only 34–30‰ is observed. North of the North Atlantic maximum the waters become steadily fresher as latitude increases until the channels opening into the Arctic basin are reached. In all of these, water of relatively high salinity usually appears for a long distance towards the north on the eastern side of the channel, while on the western side the water is comparatively fresh, especially in the vicinity of the Newfoundland Banks, but great variations occur at different seasons and in different years. In the higher latitudes of the South Atlantic the salinity diminishes steadily to 35‰ and tends to be uniform from east to west, except near the southern extremity of South America where the surface waters are very fresh (less than 34‰). In the true Polar sections of the Atlantic, *i.e.*, the Weddell sea in the south and the Arctic basin in the north, the surface water is relatively poor in salt, 34–30‰,

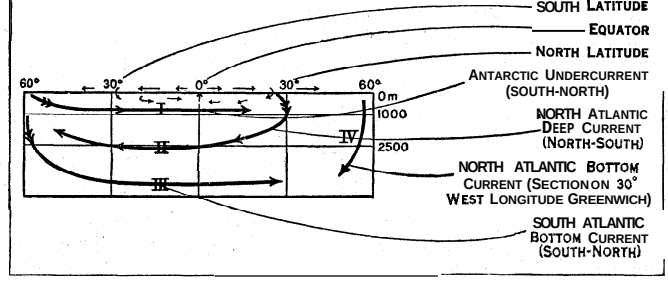

FIG. 2.—DIAGRAM OF THE DEEP WATER CURRENTS IN THE ATLANTIC OCEAN. SHOWING THE DEPTHS AND DIRECTION OF FLOW OF THE GREAT HORIZONTAL MOVEMENTS OF SEA WATER BENEATH THE SURFACE

especially where icebergs melt or the great Siberian rivers bring fresh water to the sea. Though this fresh water is very cold, its lack of salt makes it so light that it remains on the surface. Under this, one finds, however, warmer but salter water, a condition very different from that obtaining in the open ocean. In the Atlantic depths away from the ice regions the salt content of the water and its temperature both diminish with increasing depths, though this is strictly true only in the northern hemisphere. In the southern Atlantic depths, salt content and temperature decrease

only down to 800–1,000m. and then increase again slightly until a depth of 3,000m. is reached.

Circulation in the Atlantic Depths. — Modern chemical research on salt content at various depths has become very important and the observations made by the "Challenger" are now better understood. Fig. 2 shows a section through the Atlantic about longitude 30° W. with indications of the slow movements of great masses of water determined by very small, but distinct differences of salinity. The surface currents, important for climate and shipping, of course only affect the uppermost layers at the very most down to 300m., and are due to the winds; they have little relation to questions of salinity. In higher latitudes, at the ice-limit between the Falklands and Bouvet island, cold water poor in salt sinks to 800–1,000m. depth and moves thence northward as an Antarctic under-current (No. I. in fig. 2) beyond the equator to at least 20° N. In the Sargasso sea, on the other hand, warmer and very salt water sinks and moves, as an under-current at a depth of 1,500 to 3,000m., to the Antarctic zone; this is the North Atlantic under-current (No. II. in fig. 2). Affecting almost all the greater depths, we have a South Atlantic bottom current (No. III. in fig. 2) uniting with a weaker North Atlantic bottom current (No. IV. in fig. 2). There are thus in the Atlantic depths great horizontal movements, just as in the atmosphere there are layers with different characters and movements (trades, westerlies, etc.). But, whereas the equatorial belt divides the atmospheric circulatory system on its two sides, there are immense exchanges of water in the depths right across the equator.

Meteorology. — The difference between water-temperature and air-temperature just over the water is usually 1° C. or less in equatorial and temperate latitudes. Only in the region of the Gulf Stream near the American coast and towards the Polar regions is the air as much as 4°–6° C., colder than the water. North-westerly winter storms drive cold air (0°–5° C.) from North America eastwards into the Atlantic into regions where the water temperature may be 10°–15° C. On the other hand, on the Newfoundland banks with icebergs and cold water one finds in spring and summer that, if the wind is from the south, the air may be 10°–18° C. warmer than the water, and this is a main factor of the dangerous fogs there. On the whole, however, air temperatures over the Atlantic are distributed very much as are water temperatures at the surface. The wind circulation is much simpler than in the Indian ocean and is symmetrical about the meteorological equator which lies between lat. 2° N. and 10° N. Thus the two hemispheres have very similar and independent circulatory systems of air, though there are differences. The circulation in the South Atlantic is nearer than that of the North to a theoretical standard for a simple globe, as it is less influenced by land masses. Between latitudes 20° and 30° S. is a region of maximum pressure (anticyclone) and atmospheric pressure diminishes slowly northward and sharply southward. On the north side, the S.E. trade blows weakly in the southern summer but in the southern winter strongly, especially on the coast of North Brazil. On the African side, the S.E. trade always reaches beyond the equator and contributes to the rainy S.W. monsoon of the Gulf of Guinea (Cape Palmas to Gaboon). From the high pressure region towards the south there blow the N.W.–W. winds over a belt reaching from lat. 35° to 60° or 65° S. and they are felt around Cape Horn and Cape of Good Hope. They have been called "the roaring forties" because formerly ships sailing to India and Australia in lat. 40° to lat. 50° S. utilized these strong winds; storms are irequent here.

In the North Atlantic also there is a region of high pressure (anticyclone) across the ocean between lat. 20° and 30° N. The highest pressures are noted south of the Azores and west of Madeira. The northeast trade blowing thence southward is stronger in summer than in winter, especially near the Canaries and the Antilles; at this season it is felt as far north as the latitude of Gibraltar. On the north side of the high pressure region the conditions over the American continent cause considerable seasonal variations in the westerly winds. These blow relatively weakly towards North Europe in summer, but in winter, when North America has high pressure conditions, the barometric gradient towards the Atlantic is steep and the space between Labrador, Iceland, Jan Mayen and the North Cape is the great highway of a procession of cyclonic storms from the west; cyclonic storms also pass more or less parallel with them over the British isles towards the east.

Surface Currents. — In the "west wind zone," though this is the main direction, air movements are very varied as they are mostly movements in spirals of small diameter. The actual transport of air through space in these zones is therefore much less than in the zone of the almost constant if often more moderate trade wind. It thence follows that the trade winds have a far greater influence on the movement of surface water than have the westerlies of higher latitudes. The two Atlantic trade winds give rise to two great equatorial westward currents. On account of the earth's rotation the northern equatorial current turns into a N.W. direction, the southern into a S.W. one. As, further, the oceanographical and the meteorological equator lie north of the geographical equator, through the year a good deal of the water of the southern equatorial current passes north of Cape San Roque (N. Brazil) into the northern hemisphere and so reaches the north equatorial current on the coasts of Guiana and in the West Indies, and this current is thus much stronger than the south equatorial current on the coast of S. Brazil. Almost all water that streams westwards between latitudes 5° S. and 20° N. is eventually banked up in the Caribbean sea and just north of the Great Antilles with the result that there is a northern out-flow through the strait between Florida and the Bahamas. This is the origin of the Gulf Stream, though only a small fraction of the water of it comes from the Gulf of Mexico. This is one of the most important currents of the world, but it is markedly warm and rapid only in the uppermost layers. Even in Florida strait at a depth of 200m. the temperature is only 10° to 18° C. and the speed 0·4–0·8m. per second as contrasted with over 25° C. and 1·2 to 1·7m. per second at the surface. Generally speaking the suriace currents of the Atlantic and of all seas affect the sea to a depth less than 400–500m.

The Gulf Stream is separated by cold water (the cold wall) from the east coast of U.S A. as it flows northward to a region south of the Newfoundland banks. Here it mixes with the cold water of the Labrador current that comes from the west side of Baffin Bay; the interaction of these two currents causes powerful whirls near the southeast tail of the Newfoundland banks. Henceforth the Gulf Stream is so indefinite as to vary with the winds, and it is customary to speak of a Gulf Stream drift or an Atlantic drift, which moves towards and along the coast of Europe as far north as Norway and Spitzbergen. Here the sea temperatures on the S.W. coast remain above 0° C., and the sea water may have more than 35‰ of salts. In the Arctic this water sinks into the depths. A branch of the Gulf Stream drift, called the Irminger current, keeps the south and west coasts of Iceland free from ice. A third branch goes further north-westward and northward to the west coast of Greenland which is thus ice free for a large part of the year. Another branch reaches around Scotland into the North sea giving a mild and rainy climate. Not all the Gulf Stream drift goes north of lat. 50° N. An important part is deflected increasingly to the right near the Azores and forms a weak and variable Canaries current, which makes a small contribution to the northern equatorial current in the vicinity of the Cape Verde Islands. In the west centre of the mid-north Atlantic towards the Bermudas occurs the Sargasso sea with enormous masses of floating golden-yellow Gulf-weed (*Sargassum bacciferum*); this weed does not hinder ship movements. It is now thought that this Gulf-weed is a really pelagic plant and that only small amounts are torn from the coasts of the Antilles. Finally, in the north hemisphere, we must mention the Guinea current which can be discerned off the Liberia coast going south-eastwards but becomes far more marked from Cape Palmas eastward to the Gulf of the Cameroons. This is partly a re-action current compensating for the water driven west by the south equatorial current, but it is partly due to the south-west monsoon of this coast.

In the south Atlantic the Brazil current and south equatorial current have been mentioned. The Benguella current which contributes to the south equatorial current can be traced over a broad zone west of South Africa. In its path lie St. Helena and Ascension and it is composed of rather cool water flowing rapidly; this is specially marked near the coast of South West Africa. In the enormous stretches between lats. 30° and 60° S., under the influence of variable west winds. the surface current almost everywhere tends E.N.E. or N.E. (not E.S.E. or S.E. as we might perhaps expect from analogy with the Gulf stream); this fact is of enormous climatic importance, for cold water is thus brought to the neighbourhood of the Falkland islands, South Georgia, etc., and the eastern south Atlantic thus shows a large negative thermal anomaly being relatively 2°–5° C. too cold, whereas the eastern north Atlantic is abnormally warm.

Ice.—Pack ice from frozen sea water, and icebergs as fragments of the Antarctic ice-sheet and glaciers come especially from the gulf between Graham Land and Coats Land; *i.e.,* from the Weddell sea which stretches between lat. 60° S. and 78° S. The famous drift of Shackleton on the "Endurance" (1915) shows that there the ice moves clockwise and to the N.E. and attains open water near the South Orkneys and South Georgia. The average limit of large ice masses is thus near the South Shetlands in the west and near Bouvet island in the east. In some years one finds ice near Cape Horn and even north of the Falklands towards lat. 40° S. in such quantity as to be dangerous to ships. Such years were 1891–94 and 1906. This ice moves in the so-called Falkland current which sends cold water northwards parallel to the Patagonian shelf, and may be compared with the Labrador current; it is probable that this Falkland ice comes from the southernmost Pacific. In the north Atlantic the occurrence of ice fields and icebergs near the Newfoundland banks (about lat. 45° N.) is very important as this is near the most frequented of all ocean routes. It is the Labrador current that brings the ice southward, and the icebergs, especially, move along over the deep water outside; *i.e.,* east of the banks; thereafter they may swirl round for weeks between the Gulf stream and the Labrador current. This ice never reaches the coasts of Nova Scotia or U.S.A. and any ice sighted there comes from the Gulf of St. Lawrence. The ice of the Labrador current is seen between February and August and reaches farthest south (lat. 42° N.–43° N.) in May and June. From September to January the great seaway is practically free from ice. In some years the ice may reach as far south as lat. 40° N. or even 38° and the most dangerous zone is between long. 45° and 50° W. Collisions with icebergs have led to the southward deflection of the ocean route during the ice season and the presence of Newfoundland fogs in the same months has contributed to the same end. A vessel of the U.S. coast guard patrols the dangerous zone with signal apparatus during the critical periods. Polar ice is very important on the whole of the east side of Greenland, moving along the cold east Greenland current from the arctic basin. The east coast of Greenland therefore can rarely be reached without difficulty and it is almost uninhabited. The north and east coasts of Iceland are also blockaded for a large part of the year by ice that comes from the north and fills the bays. In the north of the Norwegian sea the boundary of ice floes stretches past Jan Mayen to the region west of Spitzbergen; in the Barents Sea it still remains far to the north of Norway and of the Russian coast.

Tides.—The vertical tidal differences and the direction of the tidal currents near the Atlantic coasts and harbours are well-known, but conditions over the open ocean are still very uncertain. The reasons for this are that one needs observations from a ship anchored over a period of *123* to 25 hr. and that we still lack instruments for measuring vertical changes in the conditions of the water in the open ocean. Probably the vertical tidal difference in the open Atlantic has a maximum of 0·5–1·0 m., as these values have been fixed for oceanic islands with sharp slopes down to the depths—Bermudas 1·0 m., Ascension 0·6 m., St. Helena 0·9 m. The tidal difference seems to be less between the tropics than in temperate and high latitudes. If the tidal waves from the great southern ocean between Cape Horn and the Cape of Good Hope are continued northward in the Atlantic deflection due to the earth's rotation. to the left in southern latitudes, to the right in northern ones, they must strengthen the tides on the coasts of South Brazil and the Argentine and on the coasts of Europe.

Large tidal differences have been observed in the harbours of Patagonia, moderate ones in the harbours of South and West Africa, large ones in the Spanish, French and West British harbours; they are quite small in the harbours of U.S.A. The funnel-shaped Bay of Fundy, Bristol Channel. Gulf of St. Malo all concentrate tides and give a local vertical tidal difference of more than 10 m.

Apparently the tidal currents are not restricted to coastal waters though as yet we have only a small number of observations; *e.g.,* south of the Azores, north of the Cape Verde Islands, the tidal current changes its direction from hour to hour and affects water to a great depth. Apparently this must be the same everywhere, as ebb and flow of the tide are cosmic phenomena.

ATLANTIC OCEAN, COMMAND OF THE. The voyages of exploration, dating from the later 15th century, shifted the maritime centre of gravity from the Mediterranean sea to the Atlantic ocean. Portuguese navigators crept southward along the African coast, rounded the Cape of Good Hope, and blazed an all-sea route to India. Columbus, sailing westward for the same destination, stumbled instead into the Americas. Succeeding explorers gradually filled in the map of the new world. After the explorers came traders, colonists and buccaneers—Portuguese, Spaniards, Frenchmen, Englishmen and others—who fought the elements, the natives and each other, in a long-drawn-out struggle for empire in the Americas, and for control of the sea routes connecting the new world with the old.

Transformation of the Atlantic from a deserted waste into a vast arena of commercial and military activity, profoundly altered power relationships in the old world. Lands fronting only on the Mediterranean lost in relation to those facing the Atlantic. In a long succession of wars (brilliantly analyzed in the historical works of Capt. Alfred Thayer Mahan), Britain successfully contested the sea power of Spain, Holland and France. As a result of this epic struggle, Great Britain became the dominant Atlantic power. By 1815, after the victorious close of the Napoleonic wars, British sea power had come literally to envelop the vast land mass of Eurasia-Africa from the North cape to the coast of China.

This far-flung *Pax Britannica,* as it was sometimes called, rested upon a remarkable combination of poiitical, military, and technological factors. For reasons beyond the scope of this article, England experienced the industrial revolution earlier than its continental rivals. British imports of foodstuffs and raw materials and exports of manufactures flowed in ever increasing volume along the ship lanes to and from the British Isles. The profits from this traffic were divided between further industrial development and support of the royal navy which guarded the life lines of Britain's global empire.

Geography facilitated this task of the royal navy. The British Isles interposed a great barrier between northern Europe and the Atlantic ocean. To reach the ocean all sea-borne commerce to or from that region had to pass through the English channel or round the stormy northern tip of Scotland. The Rock of Gibraltar, taken by British arms in 1704, guarded the narrow strait which afforded the only marine exit from the Mediterranean down to the opening of the Suez canal. In Gibraltar, moreover, Britain possessed a formidable military stronghold separating the Atlan-

tic and Mediterranean coasts both of France and of Spain. The island of Malta, which passed into British hands during the Napoleonic nars, somewhat similarly divided the eastern and western basins of the Mediterranean. Portugal was the only European country which suffered no strategical handicap that rendered it inherently vulnerable to the pressure of British sea power; but Portugal possessed neither the manpower nor the material resources necessary to remain a serious contender for the Atlantic trident after the onset of the industrial revolution.

Geography thus compelled most of the transatlantic, and much of the coastal, traffic of Europe to pass through narrow seas under the guns of the royal navy. British squadrons, patrolling the channel and the North sea within easy reach of their protected anchorages, afforded a constant reminder that British sea power had repeatedly in the past, and presumably could again, cut off northern Europe from sea-borne supplies. British squadrons in the Mediterranean afforded an equally impressive reminder of Britain's presumptive ability to halt the flow of traffic to and from the ports of southern Europe. British fleets could usually engage their continental foes without uncovering either the British Isles or a safe line of retreat to their own defended bases. British forces in the channel and North sea were favourably situated to interrupt communications between any hostile coalition of northern and western continental powers. By blockading the Strait of Gibraltar, Britain could divide the naval strength of Spain, and especially of France, the country generally regarded during the 19th century as Britain's most dangerous maritime rival.

Primitive overland communications prevailing in Europe well down through the 19th century enhanced the strategical advantage which Britain derived from geographical position and a strong navy. There were no motor vehicles, almost no all-weather highways, and only the rude beginnings of a railway system upon the European mainland. Large-scale movements of people or freight were next to impossible except by sea—and Great Britain commanded the sea right up to the coast of Europe. There was no escape from the paralyzing effects of sea blockade, and no way of countering the superior mobility which gave British sea power such a leverage on the continent.

Defensively, Britain's position was likewise secure. The fleets which stood ready to block the ocean portals of Europe, simultaneously barred hostile approach to the British Isles. The automotive torpedo did not appear until 1860, and did not pass into general use for several decades thereafter. There were no submarines to steal through the blockade and raid British merchant shipping on the high sea. There were no bombing planes to rain destruction upon the ships, docks and factories of Great Britain.

British sea power dominated not only the ocean portals of Europe, but all navigable passages leading from the Atlantic to the Indian and Pacific oceans as well. Acquisition of the Cape of Good Hope (1805) and of the Falkland Islands (1832) clinched the royal navy's hold on the only two sea routes to India and the far east down to the opening of the Suez canal. Occupation of a strategical site in the Gulf of Aden at the foot of the Red sea (1839), together with naval stations at Gibraltar and Malta, assured Britain a secure hold on that marine shortcut which connected the Mediterranean sea with the Indian ocean in 1869.

British sea power likewise dominated the western Atlantic down to the end of the 19th century. During the American Revolution, it is true, the French fleet of Admiral François J. P. de Grasse had wrested control of North American waters long enough to compel the surrender of Cornwallis at Yorktown in 1781. The resulting establishment of the United States raised a potential threat to Britain's permanent dominance in that region by laying the foundations for an independent, well-located, and ultimately formidable power centre in North America. But it was more than a century before the new republic developed into a serious contender for command of the American seas. Meanwhile, from its bases in Nova Scotia, Bermuda and the West Indies, the royal navy continued to exert strong influence on sea communications throughout the western Atlantic. Squadrons operating from these bases blockaded United States ports in the War of 1812; and repeatedly thereafter the pressure of British sea power made itself felt at critical stages in Anglo-American diplomacy.

This was especially the case during the long struggle for control of the Central American isthmus and of the Atlantic approaches thereto. Britain already possessed Jamaica, Trinidad and other strategical positions in this region. In addition, British leaders coveted the Spanish island of Cuba which screened the gulf coast of the United States in much the same manner as the British Isles covered the coast line of northern Europe. Another British objective was to control the various routes for a ship canal to the Pacific. Success in those aims would have strengthened British influence throughout the western hemisphere, and in particular would have given Britain a leverage on the United States comparable to that which it already held over Europe.

American statesmen were awake to this danger. In framing the Monroe Doctrine (1823), in which the United States warned the monarchies of continental Europe to keep their hands off the newly liberated Spanish colonies in the western hemisphere, Secretary of State John Quincy Adams rejected overtures for a joint Anglo-American declaration, lest such a move estop the United States later from turning the Monroe Doctrine against Great Britain itself. That contingency actually arose in the 1840s when Britain and the United States began a seesaw struggle for key positions in the Caribbean and in Central America, on the outcome of which depended the future command of the western Atlantic.

An uneasy truce was reached in the Clayton-Bulwer Treaty of 1850. British pressure in this region was further eased from time to time by the diversionary effects of the Crimean War and subsequent European developments involving British interests. The phenomenal rise of United States industrial and military potential during and after the Civil War (1861–65), culminating in rapid naval expansion toward the close of the century, confronted Britain with the choice either of steadily strengthening its naval establishments in the American seas, or of gradually losing command of those waters and therewith any possibility of controlling the future isthmian canal.

European complications again resolved this dilemma in favour of the United States. At the close of the Napoleonic wars, the royal navy was safely superior to all continental rivals. The long struggle had produced no radical changes in naval design. Technical stability meant slow obsolescence, a decided advantage to the leading naval power. By mid-century, however, a technical revolution was in full swing. The transition from sails to steam, from solid shot to explosive shells, from smooth bores to rifles, from wooden walls to armour—all these and other technical advances speeded obsolescence, and gave Britain's continental rivals a chance to compete on more nearly even terms. These technical developments also produced unsettling effects on political relations and behaviour, which in turn stimulated naval expansion. The resulting sense of insecurity was further aggravated by the growth of German power potential after the Franco-Prussian War (1870), and by the world-wide struggle for colonies, raw materials, protected markets and other imperialistic phenomena, which accompanied the later stages of the industrial revolution.

In the late 1870s, France, Russia, Italy and then Germany all began modernizing and expanding their navies. For a time the British government tended to regard France and Russia as the most dangerous rivals. With that combination in view, the British admiralty in 1889 publicly announced a "two-power standard" as the irreducible minimum to insure Britain's control of European waters and of the long sea routes to India and the far east. Gradually, however, British anxiety was transferred to Germany. The British watched German industrial and military growth with misgivings, heightened after 1890 by the aggressive overtones of German foreign policy. When Germany in 1900 launched a naval building program designed to break Britain's exclusive grip on the European seas, the effect was to bring about a fundamental reorientation of British policy.

To meet the rising German threat required the utmost concentration of British naval strength in European waters. Simultaneously to contest in the American seas the rapidly growing naval

power of the United States was out of the question. Britain had no choice but to recognize American primacy in the western Atlantic; and British statecraft proceeded with considerable finesse to derive from this necessity as much benefit as possible. A continuing and generally successful effort was made to settle outstanding disputes with the United States and to cultivate American good will in order that that country might safely be stricken from Britain's list of potential enemies. In the Hay-Pauncefote treaty of 1901, British statesmen even relinquished their long cherished ambition to share in the control of the future isthmian canal. And by 1904 the British admiralty had begun reducing its squadrons in American waters.

The first fruits of this reorientation were soon apparent. When European sympathies ranged almost solidly against Britain during the Boer War (1899–1902), American statesmen countered with quiet but unwavering diplomatic support. Thereafter, as crisis followed crisis in Europe, and as the German empire made increasingly menacing gestures toward the western hemisphere, the weight of the United States was ranged consistently on the side of Great Britain in a manner that strongly suggested the possibility of an Anglo-American naval coalition if such were necessary to hold the Atlantic against the steadily encroaching menace from the European continent.

The German menace had the further effect of suppressing at least temporarily the ancient rivalry between Great Britain and France. The Anglo-French entente of 1904 left Britain free to develop a fleet base at Alexandria near the Mediterranean terminus of the Suez canal; and recognized a French protectorate over Morocco except for a coastal strip facing Gibraltar. This understanding was accompanied by marked improvement in Anglo-French naval relations, permitting withdrawal of British fleet units from the Mediterranean. The entente thus brought about a further strengthening of the northern sea frontier; but, like the parallel if less formal understanding with the U.S., this step too represented a dissipation of that exclusive command of the Atlantic which had once been the cornerstone of British naval policy.

While bargaining for allies and simplifying their strategic commitments, British statesmen steadily enlarged and strengthened the royal navy. Despite Germany's utmost efforts, the royal navy held its lead. In first-class capital ships, then regarded as the true index of naval power, the British fleet outranked Germany's in 1914 by a ratio of three to two. And the Anglo-French coalition, to which was added the naval resources of Russia, Japan, later Italy, and eventually the United States, held an overwhelming preponderance of naval force measured in tons and guns.

Following the outbreak of war in 1914, the Allies, under the leadership of Great Britain, skilfully translated this mathematical primacy into an effective command of the Atlantic and adjoining narrow seas. Within a few days their naval forces drove the German merchant flag from the high seas. Within a few weeks the German oversea cruiser squadrons were run down and destroyed or driven to cover. The main British fleet screened the transport of the British army to France. while the German fleet lay at anchor or cruised near its home bases in the North sea, unwilling to risk a decisive battle and powerless to break up the blockade which the Allies drew tighter during the winter of 1914–15.

In Feb. 1915, the German command countered the Allied blockade with a submarine offensive against merchant shipping in a "war zone" surrounding the British Isles. Shortage of submarines, threats of American intervention, and other factors presently led to partial relaxation of this initial assault on Allied communications, but not until it had revealed the frightful commerce-destroying ability of the submarine, previously regarded with scepticism as a more or less useful auxiliary of the fighting fleets.

The temporary slackening of the submarine offensive was followed by increased activity on the part of the German High Sea Fleet. Late in May 1916 the German and British fleets met in the battle of Jutland. In this, the only major fleet action of the whole war, the fate of the Allies hung momentarily in the balance. A decisive defeat, shattering British sea power and transferring command of the Atlantic to Germany, would have constituted irretrievable disaster. No such catastrophe occurred. The German fleet, with skilful handling and exceptional luck, managed to inflict serious injury and then escape, though not without substantial casualties, from the annihilation that would certainly have been the outcome of a finish fight with Britain's Grand Fleet.

The battle of Jutland apparently convinced the German command of its inability in this way to smash the Anglo-French command of the Atlantic and thereby to raise the blockade. Only the submarine remained. U-boat construction was stepped up. The scope and area of submarine operations were gradually enlarged. Finally in Feb. 1917 the German command ordered a general submarine offensive against all merchant shipping, neutral as well as belligerent, in a desperate gambling attempt to starve Britain into surrender before an effective antisubmarine defense could be developed, and before the eventually certain intervention of the United States could turn the tide for the Allies.

This plan almost succeeded. When the United States entered the war in April 1917, the U-boats were sinking merchant ships at an appalling rate. Existing defensive measures—chiefly arming merchantmen and patrolling the ship lanes—were proving totally inadequate. The logical recourse was to convoy cargo ships in groups under armed escort, a device already tried and proved in the case of troopships. Now with American bases and naval reinforcements, a general convoy system became feasible and was successfully put into operation. In the intensified war against the U-boats, raids were carried out against the German submarine bases, mine fields were laid across the two Atlantic exits from the North sea, and acoustical devices were developed for detecting the presence of submerged U-boats. With the aid of these and other defensive measures, foodstuffs, raw materials and munitions continued to flow along the Atlantic sea lanes to the British Isles, across the channel to France, and through the Mediterranean to Italy and the near east. An American army, eventually 2,000,000 strong, was ferried safely across the Atlantic to the battlefields of Europe; and simultaneously the Allies drew steadily tighter the blockade of the Central Powers, which, starving their peoples and their war industries, prepared the way for their political and military collapse in 1918.

The victory of 1918 completely altered the balance of naval forces in the Atlantic. The destruction of German sea power removed the threat which had chained the royal navy to European waters; which had suppressed the ancient antagonism of France and Britain; which had driven Great Britain and America into something approaching an alliance; which had compelled the royal navy to relinquish without a struggle its primacy in the American seas. Temporarily at least, British sea power held exclusive and undisputed sway over the eastern Atlantic and adjoining narrow seas. And following the victory over Germany there were accumulating indications that British statesmen and their naval advisers looked forward to early restoration of their former global command of the seas.

This trend had disturbing repercussions on Anglo-American relations. The war had caused an upsurge of navalism within the United States. Congress in 1916 had voted a construction program designed to give the United States a "navy second to none." Late in 1918 the administration had thrown its weight behind a supplementary building program which, if and when carried out, would have given the United States incomparably the strongest navy in the world. These mutually conflicting aims caused the close wartime association of Britain and America to cool rapidly after the Armistice. Anglo-American relations began to show an alarming tendency to revert to their 19th-century pattern of mutual distrust and animosity.

One especially aggravating factor from the American point of view was the continued existence of the Anglo-Japanese alliance. The reason for that pact had disappeared with the defeat of Germany, but neither party seemed willing to terminate it while the United States went on expanding its navy. American statesmen, in turn, were just as unwilling to modify their naval plans as long as the Anglo-Japanese alliance remained in force, since its mere existence was felt to involve at least a theoretical possibility of simultaneous attack in two oceans.

The Washington conference for the limitation of armaments

(1921–22) broke this deadlock. The Anglo-Japanese alliance was abrogated; naval building programs were drastically curtailed; a large number of older capital ships were scrapped; and the British, American and Japanese battleship fleets were stabilized in the ratio of 5-5-3. The United States, in effect, recognized Britain's paramount strategic interest throughout the eastern Atlantic and European narrow seas. Britain, in turn, tacitly disavowed any intention of contesting United States control of the American seas.

The consequent improvement of Anglo-American relations opened the way for a mutually advantageous redisposition of naval forces. The United States gradually shifted almost all its major fleet units to the Pacific. Britain postponed indefinitely the planned re-establishment of a battleship fleet in that ocean and concentrated British naval strength in European waters. Whether or not these dispositions reflected some definite understanding between the two governments, it is certain that the United States fleet came widely to be regarded as a symbol of Anglo-American solidarity in the Pacific, and British sea power in European waters as America's first line of defense in the Atlantic.

The Washington conference achieved no such happy solution of European naval problems. Irreconcilable differences between France and Britain on the one hand, and France and Italy on the other, appeared early in the negotiations. These differences grew out of the general failure to establish a stable power equilibrium in Europe after the war. At the outset it was largely an Anglo-French controversy. The British did not wholly share French fears of future aggression from a resurgent vengeful Germany. They believed rigorous repression of that country would seriously retard economic recovery. The prospect of French military hegemony over the continent aroused deep-seated opposition. The British ideal was still avoidance of military guarantees, a balance of power on the continent, and a two-power naval standard for European waters.

No continental power was able, or even seriously disposed at that time, to contest Britain's two-power standard in the capital-ship category. But capital ships were no longer the only index of naval power. The late war had hastened the development of two new weapons which were to play an increasing role in the control of the seas, especially narrow seas such as the Mediterranean, the channel, and the North sea.

One of these new weapons, the submarine, had forced Britain to the brink of disaster, despite the royal navy's command of the ocean's surface. The other new weapon, the aeroplane, promised to develop into an even greater threat not only to shipping but also to the ports and industrial installations of the British Isles. The terms of peace prohibited Germany from possessing these newer weapons. But France suffered no such restriction and was geographically situated to use both submarines and planes against Britain with maximum effect. These weapons were consequently valuable diplomatic levers to be relinquished only in return for British guarantees to France. Moreover, if France were left to depend solely on its own defensive resources, a larger force of cruisers and destroyers would be required to insure safe passage across the Mediterranean for French colonial troops from Africa.

Another source of French intransigence was Italy's emergence as a serious contender for control of the Mediterranean. The Italian navy was decidedly inferior to that of France, but the Italian government insisted on the right to match France in every category of naval craft. Since Italy was exclusively a Mediterranean country, whereas France fronted on the Atlantic as well, to accept naval parity with Italy was equivalent, in French eyes, to surrendering control of the Mediterranean, and with it the assured flow of supply and reinforcements from Africa.

The French finally yielded with respect to capital ships and aircraft carriers, and in these two categories accepted parity with Italy and tonnage quotas low enough to preserve Britain's two-power standard for European waters. But every proposal to limit submarines and aircraft broke against the unsatisfied French demand for guarantees. Neither France nor Great Britain could agree on cruiser quotas acceptable to each other or to the other naval powers. The most that could be achieved was a qualitative restriction limiting individual cruisers to 10,000 tons displacement and 8-in. guns. Thus the way was left open for renewal of competitive warship construction.

The fascist revolution of 1922 provided just the stimulus needed to produce this result. To the fascists the Mediterranean was Italy's "mare nostrum." Mussolini boasted his determination to carve from its borderlands a modern counterpart of the classical Roman empire. Since control of the Mediterranean was an essential feature of his imperial pipe dream, Mussolini had no interest in naval limitation save as a means of cheaply improving Italy's naval position at the expense of France and Great Britain.

In 1927 the United States sponsored a second naval conference, called to deal specifically with the cruiser problem. Neither France nor Italy took any part in this conference which was thus foredoomed to failure. Its sessions, held at Geneva, quickly deteriorated into an Anglo-American wrangle in which technical arguments and considerations were allowed to revive the ancient feud over freedom of the seas, and to recast the two great Atlantic powers in their abandoned roles of naval rivals and potential enemies.

A change of government in both countries inspired a fresh start. A third conference was held at London in 1930. Here some of the damage to Anglo-American relations was repaired, and a provisional solution of the cruiser controversy was achieved. But the continued intransigence of France and Italy still prevented any stable adjustment of naval relations among the Atlantic and Mediterranean powers.

Likewise inimical to this end was the naval resurgence of Germany. Under the treaty of Versailles Germany was forbidden to acquire any modern armoured ship displacing over 10,000 tons. To circumvent this restriction, German naval architects created the so-called pocket-battleships, "Deutschland," "Admiral Scheer," and "Admiral Graf Spee." These ships, designed as commerce raiders, technically conformed to the Versailles limitation, but their 11-in. guns definitely outclassed the 8-in. weapons allowed on cruisers built by signatories of the Washington Naval treaty. These ships upset existing arrangements for the protection of commerce, compelled every Atlantic power to reconsider its naval program, and in conjunction with other developments started a fresh cycle of competitive building.

One of these contributing causes was the nazi revolution of 1933, followed by Hitler's denunciation of the Versailles treaty. Naval rearmament accelerated rapidly under the nazis. Profiting from past experience, they concentrated mainly on commerce-raiding weapons. Their battle cruisers, "Scharnhorst" and "Gneisenau" (laid down in 1934), and even their great battleships, "Bismarck" and "Tirpitz" (1937), were conceived less as components of a massed fleet than as superraiders for attacking convoys on the high sea. The same objective was implicit in Germany's resumption of submarine building on a large scale. Yet in the face of these preparations manifestly directed primarily against Great Britain, Hitler won London's consent in 1935 to further German naval expansion up to 35% of British strength, with the possibility of eventual parity in submarines!

The Ethiopian crisis, later in 1935, focused attention on the deterioration which was taking place in the strategical position of France and Britain in the Mediterranean. Both London and Paris showed the greatest reluctance to take any steps which might force hostilities with Italy, and doubts were expressed in many quarters regarding the royal navy's continued ability to hold the Mediterranean against the air and sea power of Italy.

Formation of the Rome-Berlin axis in 1936 formally linked the growing danger in northern and in southern waters, and inclined the naval balance still more strongly against the Atlantic powers. But this event, followed by rapid deterioration of world conditions, provided the necessary stimulus for strenuous if tardy counter measures which were well under way when war intervened in Sept. 1939.

The first phase of the ensuing battle for the Atlantic lasted until the fall of France in June 1940. During this period the Anglo-French coalition drove German merchant shipping from the Atlantic, and maintained a fairly effective long-range blockade on the general model of the previous war. The German-controlled zone in the North sea was somewhat broader than in 1914–18, mainly because of the maritime role now played by shore-based aviation. It was consequently more difficult to intercept German blockade-runners entering or leaving the North sea. The blockade in the Mediterranean also fell somewhat short, thanks to Italy's "nonbelligerent" help in forwarding seaborne supplies to Germany. But these handicaps were offset by the close co-operation of the United States and other oversea countries in the use of various devices—pre-emptive buying, "navicerts," etc.—designed to cut at the source all traffic with the axis.

On the defensive side, the initial nonbelligerency of Italy postponed a showdown in the Mediterranean with resulting advantage to the Allies. Also the exclusion of axis men-of-war from a western hemi-

sphere "safety zone," guarded by a "neutrality patrol" under United States leadership, afforded considerable protection to Allied shipping entering and leaving North and South American ports. On the other hand, the modern submarine proved to be a far more difficult weapon to combat than the primitive U-boats of 1918, and the Allies were dangerously short of antisubmarine equipment during the early months of the struggle. Early raids by the pocket-battleships, and threatened raids by the more formidable German battle cruisers, compelled the Allies to deplete their main fleets in order to provide battleship escort for their troop and cargo convoys. And the lengthening range of German air power, especially after the occupation of Norway, gradually curtailed British use of the North sea.

The battle for the Atlantic took a radically different turn following conquest of the Low Countries, the fall of France and Italy's entry into the war. Britain lost French naval support at the very moment when its own sea power was seriously crippled by losses incurred in the retreat from Narvik and evacuation from Dunkirk. The sea and air power of Italy, reinforced by German units, imperilled and eventually barred the direct route to Suez, forcing British shipping to use the long alternative route around the Cape of Good Hope. This cut the total cargo-carrying capacity of the British merchant marine almost in half at the very moment when German acquisition of naval and air bases on the channel and on the west coast of France foreshadowed more destructive attacks on shipping in northern waters.

At this critical juncture, the United States, though still technically a nonbelligerent, assumed a more positive role in the battle for the Atlantic. Fifty American destroyers were turned over to Great Britain to make good previous naval losses. In return, the United States received long-term leases for ship and plane bases in Newfoundland, Bermuda and numerous points in the Caribbean. Congress voted a 70% increase in the navy, and early in 1941 a separate Atlantic fleet was established. American units were sent to relieve the British garrison in Iceland, which had become a vital convoy depot and focus of antisubmarine activity. Greenland was occupied to provide additional facilities for the Anglo-American sea and air patrol rapidly spreading over the north Atlantic. Transatlantic air-ferry service was developed for the delivery of planes and for the rapid transportation of important freight and personnel.

Early in 1942, after the United States had become a full belligerent, the axis opened a large-scale submarine offensive against coastal shipping in American waters. German U-boats also operated in considerable force along the south Atlantic ship lanes to India and the middle east. The Allied campaign (1942–43) to reopen the Mediterranean depended almost entirely upon sea-borne supply shipped through submarine-infested waters. Allied convoys approaching the British Isles, and those bound for the Russian ports of Murmansk and Archangel, had to battle their way against savage air and undersea attacks. It was publicly estimated at the close of 1942 that Allied shipping losses, chiefly from planes and U-boats, still exceeded those suffered during the worst period of 1917. And a considerable weight of Allied naval power had to be kept constantly available in northern waters in case Germany's formidable surface raiders, especially the superbattleship "Tirpitz," should break into the Atlantic shipping lanes as the "Bismarck" did briefly in 1941.

On the other side of the ledger was the ever tightening Allied blockade of axis Europe, and perceptible, if slow, progress in combating the axis war on shipping. With more and better equipment, the convoy system was strengthened and extended. Unprecedented ship building, especially in American yards, caught up and began to forge ahead of losses, though the latter still remained dangerously high. Bombing raids on axis ports and industrial centres progressively impaired Germany's capacity to build and service submarines and aircraft. Transoceanic cargo planes provided for the United Nations an increasingly important alternative means of transport beyond the reach of enemy raiders. Brazil's entry into the war strengthened the Allied position in the south Atlantic. The occupation of virtually all west African ports, including the French naval bases at Casablanca and Dakar, denied to axis raiders their last possible havens in southern waters. All these and other developments foreshadowed ultimate failure of the axis sea strategy which aimed at halting the flow of American armies and materiel across the Atlantic to the battlefields of Europe and Africa; at starving Great Britain into submission; at preventing sea-borne supplies reaching soviet Russia; and at breaking the United Nations' blockade of axis Europe.

Victory in the Atlantic, when achieved, would represent the collective effort of the United Nations, but chiefly of Britain, Canada and the United States. The strength of this coalition was derived in no small degree from the successful reintegration of the fundamental components of sea power. These components are: (1) a secure primary base, (2) relatively superior resources, and (3) favourable strategical position. Britain formerly possessed all three vis-à-vis both Europe and America. The rise of United States power potential, coinciding with changing conditions in Europe, had compelled Great Britain to recognize American primacy in the western Atlantic. The tremendous industrial growth of Germany, coinciding with the development of submarines and later aircraft, undermined the security of England's island base off the coast of Europe, endangered the far-flung network of sea communications which supplied British industry, and thereby weakened the whole structure of British sea power. The United States lacked England's favourable strategical positions for offensive action vis-à-vis continental Europe. But the United States enjoyed a secure base thousands of miles from Europe and Asia. The United States also possessed resources and industrial potential surpassing those of any other country. Britain could no longer command the Atlantic singlehanded against a determined war on commerce backed up by the industrial resources of continental Europe. The United States could not play Great Britain's historic role singlehanded, without huge continuing outlays for armaments on a scale sufficient to compensate for the lack of key strategical positions bearing on the nerve centres of the old world. Together Britain and America possessed in large degree the fundamental requisites for continued command of the Atlantic and adjoining narrow seas. Still it was by no means conclusive that even an Anglo-American coalition could hold these waters indefinitely unless some means were devised to control the European development of submarines, aircraft and other new weapons. Thus the problem of command of the Atlantic was destined at the close of World War II to merge into the larger problem of future power relationships within Europe and between Europe and the other continents facing the Atlantic. In this region, Britain and the United States in concert presented the strongest single power combination. Depending on the terms of peace following World War II, and on the future trend of Anglo-American relations, the English-speaking countries facing the Atlantic might come to represent a coalition of sea power as formidable, as stable, and as useful in the future as British sea power was in the period following the Napoleonic wars.

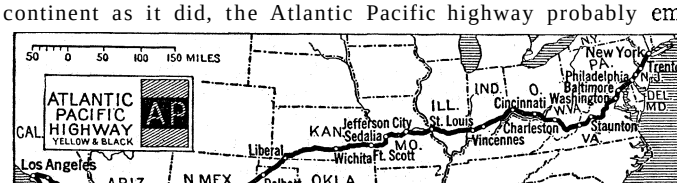
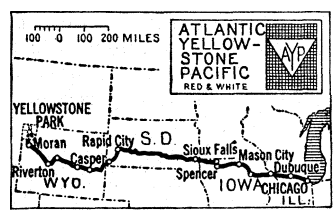
ATLANTIC PACIFIC HIGHWAY, the former name of a U.S. highway which extended from New York city to Los Angeles and San Diego, Calif., approximately 3,000 mi. in length. The name was discontinued with the adoption of state systems of numbering roads. and various parts of the highway were incorporated into–federal highways of different numbers. Spanning the continent as it did, the Atlantic Pacific highway probably em-



braced a greater variety of scenes and climate than any other American thoroughfare. Philadelphia, Wilmington, Baltimore, Washington. Covington, Charleston. Cincinnati. St. Louis. Wichita, Santa Rosa and Phoenix are among the cities which were included in its course.

ATLANTIC-YELLOWSTONE PACIFIC HIGHWAY running from Chicago, Ill., to Yellowstone park, about 1.562 mi. long. The name was gradually dropped, and sections of the highway became parts of various U.S. federal highways (18, 16, 20. etc.). Beginning close to the western shore of Lake Michigan, it passed through the low-lying farm country and touched upon the picturesque Black Hills of South Dakota, in which is situated Wind Cave National park. The Shoshone district, noted for its ranch resorts, and the Iowa lake region lay in its path, also the natural bridge of Wyoming and Jackson Hole, famous as a hunting resort.



Among the important cities along the route of the Atlantic-Yellowstone Pacific highway were Rockford, Dubuque, Mason City, Sioux Falls, Douglas and Casper.

ATLANTIS, ATALANTIS or **ATLANTICA,** a legendary island in the Atlantic ocean. Plato in the *Timaeus* describes how Egyptian priests, in conversation with Solon, represented the island as a country larger than Asia Minor with Libya, situated just beyond the Pillars of Hercules. Beyond it lay

an archipelago of lesser islands. Atlantis had been a powerful kingdom nine thousand years before the birth of Solon, and its armies had overrun the Mediterranean lands, when Athens alone had resisted. Finally the sea overwhelmed Atlantis, and shoals marked the spot. In the *Critias* Plato adds a history of the ideal commonwealth of Atlantis. It is impossible to decide how far this legend is due to Plato's invention, and how far it is based on facts of which no record remains. Mediaeval writers, receiving the tale from Arabian geographers, believed it true, and had other traditions of islands in the western sea, the Greek Isles of the Blest (q v.), or Fortunate Islands; the Welsh Avalon, the Portuguese Antilia (*q.v.*) or Isle of Seven Cities, and St. Brendan's island, the subject of many sagas in many languages. All except Avalon were marked in maps of the 14th and 15th centuries, and formed the object of voyages of discovery; St. Brendan's island until the 18th century. Somewhat similar legends are those of the island of the Phaeacians (Homer, Od.), the island of Brazil (*q.v.*), of Lyonnesse (*q.v.*), the sunken land off the Cornish coast, of the lost Breton city of Is, and of Mayda or Asmaide, the French Isle Verte and Portuguese *Ilha* Verde or "Green Island." The last appears in many folk-tales from Gibraltar to the Hebrides, and until 1853 was marked on English charts as a rock in 44° 48' N. and 26° 10' W. After the Renaissance attempts were made to rationalize the myth of Atlantis. It was identified with America, Scandinavia, the Canaries or Palestine. Ethnologists saw in its inhabitants ancestors of the Guanchos, the Basques or the ancient Italians. Even in the 17th and 18th centuries the credibility of the legend was seriously debated, and sometimes admitted, even by Montaigne, Buffon and Voltaire.

ATLAS, in Greek mythology, son of the Titan Iapetus and Clymene (or Asia), brother of Prometheus. Homer, in the Odyssey (i. 52) speaks of him as "one who knows the depths of fhe whole sea, and keeps the tall pillars which hold heaven and earth asunder." In the first instance he seems to have been a marine creation. The pillars which he supported were thought to rest in the sea, immediately beyond the most western horizon. But as the Greeks' knowledge of the west increased, the name of Atlas was transferred to a hill in the northwest of Africa. Later, he was represented as a king of that district, turned into a rocky mountain by Perseus, who, to punish him for his inhospitality, showed him the Gorgon's head (Ovid, *Metam.*, iv. 627). In works of art he is represented as carrying the heavens or the terrestrial globe. The Farnese statue of Atlas in the Naples Museum is famous.

The plural form ATLANTES is the classical term in architecture for the male sculptured figures supporting a superstructure, as in the baths at Pompeii, and in the temple at Agrigentum in Sicily. In 18th century architecture half-figures of men with strong muscular development were used to support balconies (see CARYATID). A figure of Atlas supporting the heavens is often found as a frontispiece in early collections of maps, and is said to have been first thus used by Mercator. The name is hence applied to a volume of maps (see MAP), and similarly to a volume which contains a tabular conspectus of a subject, such as an atlas of ethnographical subjects or anatomical plates. It is also used of a large size of drawing paper.

ATLAS MOUNTAINS, the name for the mountain chains more or less parallel to the coast of north-west Africa. They extend from Cape Nun (west) to the Gulf of Gabès (east), a distance of 1,500m., traversing Morocco, Algeria and Tunisia. They are bounded on the north by the Mediterranean sea and on the south by the Sahara desert. They can be roughly divided into two main chains: (1) the Maritime Atlas from Ceuta to Cape Bon; (2) the inner and more elevated ranges, which, starting from Cape Ghir, run south of the coast ranges and are separated from them by high plateaux. The western inner ranges, described here as the Moroccan ranges, are the most important of the whole system. The Maritime Atlas and the inner ranges in Algeria and Tunisia are treated under the heading Eastern Ranges.

The Moroccan Ranges.—This section, known to the inhabitants of Morocco by its Berber name, Idráren Dráren ("Mountains of Mountains"), consists of five distinct ranges, varying in length and height, more or less parallel to one another and with a trend from south-west to north-east.

1. The main range (the Great Atlas) occupies a central position and is by far the longest and loftiest chain. It has an average height of over 11,000ft. The slopes are precipitous toward the Atlantic but long and gradual toward the Dahra district of the north-east. Only one or two peaks reach the line of perpetual snow, but several summits are snowclad during most of the year. The northern sides and tops of the lower peaks are often covered with dense forests of oak, cork, pine, cedar and other trees, with walnuts up to the limit of irrigation. Their slopes enclose well-watered valleys of great fertility, in which the Berber tribes cultivate tiny irrigated fields, their houses clinging to the hillsides. The southern flanks, being exposed to the hot dry winds of the Sahara, are generally destitute of vegetation.

At several points the crest of the range has been deeply eroded, thus forming devious passes. The central section, culminating in Tizi n 'Tagharat or Tinzár, a peak estimated at 15,000ft. high, maintains a mean altitude of 11,600ft., and from this great mass of schists and sandstones a number of secondary ridges radiate in all directions.

For a distance of 100m. the central section nowhere presents any passes accessible to caravans, but in the south-west two gaps afford communication between the Tensift and Sus basins, those respectively of Gindáfi and Bíbáwan. A few summits in the extreme south-west in the neighbourhood of Cape Ghir still exceed 11,000ft., and although less majestic, the average height of this district is greater than that of the Alps. The most imposing view is to be obtained from the plain of Marrákesh, immediately north of the highest peaks. Besides huge masses of old schists and sandstones, the range contains extensive limestone, marble, diorite, basalt and porphyry formations, while granite prevails on its southern slopes. The presence of enormous glaciers in the ice age is attested by the moraines at the Atlantic end, and by other indications farther east. The best-known passes are: (1) The Bíbáwan in the upper Wad Sous basin (4,150ft.); (2) the Gindáfi, giving access from Marrákesh to Tároudánt, rugged and difficult, but low; (3) the Tagharat, difficult and little used, leading to the Dra'a valley (11,484ft.); (4) the Gláwi (7,600ft.); (5) Tilghemt (7,250ft.), leading to Tafilelt.

2. The lower portion of the Moroccan Atlas (the Middle Atlas), lying north of the Great Atlas, is crossed by the pass from Fez to Tafilelt. Both slopes are wooded, and here only in Morocco does the lion still survive. From the north this range, which is only partly explored, presents a regular series of snowy crests.

3. The Anti-Atlas (Jebel Sarro or Lesser Atlas) runs parallel to and south of the central range, and has a mean altitude of 5,000ft., although some peaks and even passes exceed 6,000ft. The relation of the Anti-Atlas to the Atlas proper at its western end is not clear. Two more or less parallel ranges of less importance complete the western system:—

4. The Jebel Bani, south of the Anti-Atlas, a low, narrow rocky ridge with a height of 3,000ft. in its central parts; and

5. The mountains of Ghaiáta, north of the Middle Atlas, a series of broken mountain masses from 3,000 to 3,500ft. high, to the south of Fez, Táza and Tlemsen.

The Eastern Ranges.—The lesser range (Maritime Atlas) nearer the sea, calls for little detailed notice. From Ceuta, above which towers Jebel Músa (2,800ft.) to Melilla, a distance of 150m., the Rif mountains face the Mediterranean, and here, as along the whole coast eastward to Cape Bon, many rugged rocks rise boldly above the general level. In Algeria the Maritime Atlas has five chief ranges, several mountains rising over 5,000ft. The Jurjura range, extending through Kabylie from Algiers to Bougie, contains the peaks of Lalla Kedija (7,542ft.), the highest point of the maritime chains, and Babor (6,447ft.). (See ALGERIA.) The Mejerda range, which extends into Tunisia, has no heights exceeding 3,700ft. It was in these coast mountains that the Romans quarried the celebrated Numidian marbles.

The southern or main range of the eastern division, the Saharan Atlas, is linked by secondary ranges to the mountains of Morocco. The Saharan Atlas is essentially one chain, though known under different names: Jebel K'Sour and Jebel Amour on the west, and Jebel Aurès on the east. The central part, the Záb mountains, is of lower elevation, the Saharan Atlas reaching its culminating point, Jebel Chelia (7,611ft. above the sea), in the Aurès. This range sends a branch northward which joins the Mejerda range of the Maritime Atlas, and another branch runs south by Gafsa to the Gulf of Gabès. Here Mt. Sidi Ali bu Musin reaches a height of 5,700ft., the highest point in Tunisia. In the Saharan Atlas the passes leading to or from the desert are numerous, and in most instances easy. Both in the east (at Batna) and the west (at Ain Sefra) the mountains are traversed by railways, which, starting from Mediterranean seaports, take the traveller into the Sahara.

Geology.—The Atlas mountains were uplifted during the Alpine earth-movements (see ALPS). The movement commenced here at the end of the Jurassic period, was renewed in the Upper Cretaceous and continued into the Miocene. There is also evidence of folding during earlier periods (Variscan in the Moroccan Meseta). The direction of movement throughout the greater part of the mountains is from north to south, and the trend from east-north-east to west-south-west. The trend is continued eastward through Sicily into the Apennines, and westward into the Canary islands. Nappe structures have been recognized here, but the detailed stratigraphy and tectonics are not fully known.

History and Exploration.—The name Atlas given to these mountains by Europeans—but never used by the native races—is derived from that of the mythical Greek god who was supposed to dwell in these mountains. The Atlas are the home of Berber races, and those in the least accessible regions have been independent throughout their recorded history. Some mountain districts of Kabylia had never been visited by Europeans until the French military expedition of 1857. In general the Maritime range was well known to the Romans. The Jebel Amour mas traversed by the column which seized El Aghuat in 1852, and from that time dates the survey of the mountains.

The ancient caravan route from Mauretania to the western Sudan crossed the lower Moroccan Atlas by the Pass of Tilghemt and passed through the Oasis of Tafilelt, formerly known as Sajilmása, on the east side of the Anti-Atlas. The Moroccan system was visited, and in some instances crossed, by various European travellers carried into slavery by the Salli rovers, and was traversed by René Caillé in 1828 on his journey from Timbuktu, but the first detailed exploration was made by Gerhard Rohlfs in 1861–62. Previous to that almost the only special report was the misleading one of Lieut. Washington, in 1837.

In 1871 the first scientific expedition, consisting of Dr. (afterwards Sir) J. D. Hooker, John Ball and G. Maw, explored the central part of the Great Atlas. They ascended by the Ait Mizan valley to the Tagharat pass (11,484ft.), and by the Amsmiz valley to the summit of Jebel Tezah (11,972ft.). Dr. Oskar Lenz in 1879–80 surveyed a part of the Great Atlas north of Tárudant, determined a pass south of Iligh in the Anti-Atlas, and penetrated thence across the Sahara to Timbuktu. He was followed in 1883–84 by Vicomte Ch. de Foucauld, whose itineraries included parts of the first and middle ranges; three routes over the Great Atlas, which was, moreover, followed along both flanks for nearly its whole length; and six journeys across the Anti-Atlas, with a general survey of the foot of this range and several passages over the Jebel Bani. Then came Joseph Thomson, who explored some of the central parts, and made the ascent of Mt. Likimt, 13,150ft. (1888); and Walter B. Harris, who explored some of the southern slopes and crossed the Atlas at two points during his expedition to Tafilelt in 1894, In 1901 and again in 1905 the marquis de Segonzac, *a* Frenchman, made extensive journeys in the Moroccan ranges. A member of his expeditions, de Flotte Rocquevaire, made a triangulation of part of the western portion of the main Atlas. Since that time numerous travellers and scientists have visited and explored the mountains. *(See* also MOROCCO; ALGERIA; TUNISIA and SAHARA.)

(J. I. P.)

ATLAS PORTLAND CEMENT COMPANY had its origin in the Mathey Cement company which was incorporated in New York State in 1885. This company underwent various corporate changes that in 1889 developed in embryo the present organization. In 1888 property at Coplay, Lehigh county, Pa., was acquired, and in 1889 *a* beginning for Atlas cement, was made with a mill turning out 200 barrels a day. In 1896 a second mill, in Northampton county, Pa., began operations with a capacity of 3,000 barrels a day. In 1900 a third mill started operation with a capacity of 10,000 barrels a day, and in 1905 a fourth mill, with a like capacity got under way at Northampton, Pa., 1905. The Company in 1905 opened two additional mills with *a* combined capacity of about 12,000 bbls. a day. Other acquisitions followed until, in 1930, it had plants producing 18,000,000 bbls. annually. On January 9, 1930 the Atlas Portland Cement Company was united with the Universal Portland Cement Company, under the name of the Universal Atlas Cement Company, a subsidiary of the United States Steel Corporation. The Universal Portland Cement Company had its beginning in 1896 as the Cement Department of the Illinois Steel Company, its original plant in Chicago producing 500 bbls. of cement daily. The Company continued to grow until in 1930, its total producing capacity was 17,300,000 bbls. annually. The capacity of the Universal Atlas Cement Co., largest cement producer in the world, is 33,590,000 bbls. annually. It manufactures Atlas and Universal (gray) Portland cements, Atlas White and Atlas Waterproofed White Portland cement, Atlas High-Early Strength, Unafine, Unaflo Oil Well cement, Atlas Lumnite cement and Gypsum Rock (B. F. A.)

ATMOLYSIS, a term invented by Thomas Graham to denote the separation of a mixture of gases by taking advantage of their different rates of diffusion through a porous septum or diaphragm. It is derived from Gr. *ἀτμός,* vapour: and *λύειν,* to loosen. (See DIFFUSION.)

ATMOSPHERE. The term "atmosphere" usually refers to the gaseous envelope covering the surface of the earth. The word is derived from the Greek words *ἀτμός,* smoke or vapour and *σφαῖρα,* globe or sphere. The early Greeks were probably the first to study the weather in a regular and systematic way and the wind was defined by Anaximander as "a flowing of the air." Hesiod in his treatise Works and *Days* discussed the origin of wind, and many observations of physical properties of the air were made by Ctesibus, Hero of Alexandria, and others. The material nature of air is clearly recognized in Hero's *Pneumatica.*

Anaximenes *(c.* 500 B.C.) regarded the air as the primordial substance from which all matter was condensed. During the time of Socrates meteorology was neglected, but Aristotle revived interest in the study of the atmosphere and wrote about the winds. He regarded the atmosphere as consisting of three regions; the lowest in which plants and animals exist he supposed to be immovable like the earth; the uppermost region adjoined the fiery heavens and moved with them; the division intermediate between the other two, he believed to be exceedingly cold. Meteors were considered by Aristotle to be exhalations from the earth, which became incandescent when they reached the hot upper layer.

Very little progress was made from this time until the early part of the 17th century, although it is said that during the 11th century the Arabs calculated the height of the atmosphere, from the duration of twilight, as 92 kilometres. In 1643, Torricelli, a student of Galileo, found that if a long glass tube sealed at one end was filled with mercury and the open end closed with the finger while the tube was inverted in a vessel containing mercury, the liquid sank only to a certain level. It thus became

possible to measure the pressure of the atmosphere, and the space above the mercury is still referred to as a Torricellian vacuum. This apparatus was called a barometer (*q.v.*) by Boyle and soon came into general use. Pascal demonstrated the decrease of the pressure of the air with altitude by measuring the height of the mercury column of a barometer at different points up a tower in Paris. In 1650 von Guericke (*q.v.*) found that he could pump air and was responsible for the famous experiment with the Magdeburg hemispheres.

That air consists chiefly of two gases was first recognized by Scheele (1772), but Cavendish (1781) was responsible for a large number of analyses of the air and found that 100 volumes contain 20·83 parts by volume of oxygen (*q.v.*) and 79·17 of nitrogen (*q.v.*). Similar experiments were carried out by Priestley (who thought the composition variable) and Lavoisier, but it was not until 1846 that it was definitely established by Bunsen that the composition of the atmosphere is not absolutely constant.

The Composition of the Atmosphere.— Air is a mixture of gases and is not a chemical compound. This is proved by the following:—(1) The composition of air is not constant, and the quantities present of the different components do not bear any simple relation to their atomic weights. (2) The constituents can be separated by diffusion and by the fractional distillation of liquid air. (3) Air dissolves in water in accordance with the law of partial pressures and hence air expelled from water contains an increased proportion of oxygen.

Below a height of 20km. (12½m.) the constituents of the atmosphere, with the exception of water vapour, are well mixed by winds and by diffusion. Slight changes in composition do occur, however, at the surface of the earth and these depend on latitude and the presence of large quantities of vegetation or sea-water. The permanent constituents of the air are generally present in the following proportions (according to Humphreys in the *Scientific Monthly,* 1927):—

Substance	Volume % in dry air
Total atmosphere	
Dry air	100·00
Nitrogen	78·03
Oxygen	20·99
Argon	0·9323
Water vapour	
Carbon dioxide	0·03
Hydrogen	0·01
Neon	0·0018
Krypton	0·0001
Helium	0·0005
Ozone	0·00006
Xenon	0·000009

The following table by Hann shows the variation with latitude.

	Nitrogen	Oxygen	Argon	Water vapour	Carbon dioxide
Equator	75.99	20·44	0·92	2.63	0·02
Latitude 50° N.	77·32	20·80	0·94	0·92	0·02
Latitude 70° N.	77·87	20·94	0·94	0·22	0·03

The composition also varies with altitude, but not to any very appreciable extent at heights at which respiration is still possible. The amount of water vapour present in the air is usually about 1·2% by volume, but in very cold weather this quantity falls almost to zero. At other times it may be as high as 5%.

The ozone (*q.v.*) of the atmosphere is produced by electrical discharges and is found over the sea and mountains. Probably it is never present in quantities greater than one part in ten millions and the amount varies with the seasons, being greatest in winter, and averaging 2·5 volumes per million of air. Large quantities of carbon dioxide, steam, nitrogen and hydrogen are constantly liberated from inside the earth by volcanoes; and carbon dioxide is the product of respiration of animals and plants. It is probable that when the earth was in the liquid state most of the nitrogen would remain free and would be retained by gravity rather than by chemical combination. The source of the oxygen presents difficulties: it may have been formed by the decomposition of volcanic carbon dioxide by plants; but this can only be effected by green plants in the presence of light, and, as most primitive plants are not green, it is more probable that there was an excess of oxygen in the first place and that it has been retained through the gravitational effect; however the balance of the quantity of oxygen in the air is maintained by the decomposition of carbon dioxide by plants. Lighter gases such as hydrogen and helium would tend to escape while the earth was still liquid, but would be retained when a solid crust had developed.

The Rare Gases.—During his experiments on the combination of nitrogen and oxygen by means of an electric spark, Cavendish, in 1785, observed that a small bubble of gas always remained after the absorption of the nitrogen oxides by potash and of the oxygen by "liver of sulphur." This was "certainly not more than $\frac{1}{120}$ of the bulk of the phlogisticated air (nitrogen) let up into the tube." Cavendish's observation was overlooked until in 1894 the late Lord Rayleigh noticed that atmospheric nitrogen is slightly denser than nitrogen prepared by chemical means (Atmospheric nitrogen, 1·25718; Chemical nitrogen, 1·25107). The difference could only be explained by the presence of an unknown gas in the air, and Lord Rayleigh and Sir William Ramsay used two methods to isolate this, one of which was a repetition of Cavendish's experiment on a large scale, while the other consisted in absorbing the nitrogen by heated magnesium. The new gas was found to be chemically inactive and hence was called argon (Gr. ἀργόν=lazy) (*q.v.*). During the course of the separation of argon from liquid air by fractional distillation, Ramsay and Travers (1898) discovered four more inert gases, which received the names helium, neon, krypton and xenon (*qq.v.*).

These five inactive gases are best characterized by their spectra, which are quite distinctive. They are all monatomic, *i.e.,* each molecule only contains one atom. Certain springs evolve these gases, and helium is found in some natural gas and also occluded in certain minerals, *e.g.,* broggerite.

Impurities.—Besides the normal constituents air always contains other substances which we can call "impurities." Organic and inorganic particles are always present to a certain extent, but are more plentiful over towns than elsewhere. The organic matter consists chiefly of plant spores and micro-organisms, and decreases in quantity when the temperature falls. Over the open sea the number of such particles is about one per cubic metre, while in crowded places it may rise to several thousand per cubic metre. Air may be sterilized by treatment with ozone if dry, by passing it through a hot tube, or partially by filtration through cotton wool. Inorganic dust is introduced into the atmosphere by the disintegration of meteors, volcanic eruptions, the combustion of fuel, and from the earth's surface by wind. The minute crystals of sodium chloride (common salt) found in the air owe their origin to ocean spray. The larger dust particles are visible as "motes" in a beam of light, but by far the greater number cannot be seen with the naked eye. In town air there are about 100,000 per cu. cm. but over the sea this number falls to some hundreds. The particles can be made to settle out by washing and scrubbing. Atmospheric dust is the chief cause of haze in dry weather. Very slight traces of radioactive substances are also found in the air.

A large number of gaseous impurities are present such as ammonia, oxides and acids of nitrogen, small quantities of hydrocarbons, sulphuretted hydrogen, carbon monoxide, sulphur dioxide and sulphurous and sulphuric acids, chlorine and hydrochloric acid. Nitrogen compounds (see NITROGEN) which are produced by electrical discharges, *e.g.,* during thunder-storms, and carried down by rain play an important part in the fertilization of the soil. Ammonia (*q.v.*) is also introduced by the decay of organic matter. Carbon monoxide is contained in the exhaust gases of petrol engines and is found in railway tunnels. Other impurities are released from various chemical works.

Height of the Atmosphere.— The height to which the atmosphere extends cannot be definitely stated, although at an altitude of 50m. the air cannot exert any measurable pressure. Three methods are available for the estimation of the height: (1) observation of meteors, (2) measurement of the duration of twilight, (3) observation of auroral displays. The first method gives results ranging from 1 jo to 300km., while the duration of twilight indicates a value of about 64km. at lat. 45°. It is difficult to make

reliable calculations from auroral displays, but it is claimed that these occur up to a height of 500km. If the density of the atmosphere remained uniform throughout with the same value as at the earth's surface, the air would form a layer only 8km. thick and this is sometimes called the "height of the homogeneous atmosphere." Half of the air is below a height of 5·8km. At low levels temperature is usually considered to decrease 0·56°C per 100 metres increase in altitude, but the rate is extremely variable. Above 2km. the temperature is on an average below 0°C and continues to fall up to 10km. (6m.) when it is about −55° C. At 37km. the temperature is practically the same as at 10km. The lower region of the atmosphere is known as the *troposphere* and extends up to 10km., beyond which clouds are not generally found, except in tropical latitudes.

The Outer Atmosphere. — The upper region of the atmosphere, above 10km., is called the *stratosphere* and is separated from the *troposphere* or lower region, by a boundary region known as the *tropopause*. In the stratosphere the temperature gradient runs parallel to the earth's surface, whereas at lower altitudes it is vertical, *i.e.,* in the former case the air is arranged in columns each with a given temperature, while in the troposphere there are layers of air at different temperatures. Knowledge of the upper atmosphere, its constitution and physical properties, is by no means complete, although sounding balloons have been used up to about 25km. Lindemann and Dobson have deduced from observations on meteors, that the stratosphere does not extend beyond about 60km. and they also conclude that above this level the temperature rises to about 30° C. This high temperature region they believe to extend up to 150km. at which height meteors become luminous. Evidence for such a warm region has also been brought forward by F. J. Whipple from a study of the abnormal audibility of explosions, but its existence has been questioned by Sparrow.

The behaviour of long wave-length electromagnetic radiation (wireless waves) points to the existence of a conducting layer of ionized gas (the Kennelly-Heaviside layer) at a level of 40km – 50km. during the day and rising to about 90km. at night. In the daytime this ionization could be caused by the ultra-violet (short wave-length) radiation from the sun, but its existence at night can only be explained if it is assumed that some substance is present which is capable of dissociation in the dark. It is believed that this substance is ozone. Various workers (Fabry and Buisson, 1921; Harrison and Dobson, 1925) have shown by studies of the absorption of solar radiation that there is a considerable quantity of ozone in the upper atmosphere and that it is probably formed by radiation of wave-lengths shorter than $\lambda = 2.000$ Å.U. ($2/10^5$ cm.). The region in which this ozone occurs would be expected to have an abnormally high temperature and electrical conductivity, because it absorbs strongly radiation of certain wave-lengths. This region may therefore be considered to be identical with that where meteors become luminous and wireless waves are reflected back to the earth's surface. Its upper boundary is probably at a level of about 150km. and since it contains ozone, oxygen must also be present. Moreover, as oxygen is less dense than ozone, it will tend to rise to even greater heights. At a height of 3,200km. according to Jeans, there can only be about 300,000 gas molecules per cubic centimetre.

Much information concerning the upper atmosphere may be derived from studies of spectrum photographs obtained from the displays of the Aurora Borealis. These displays take place at levels varying from about 80km. to 500km., but are most frequent at 106km. The auroral spectrum always contains a well-defined, strong, green line of wave-length $X = 5,577·35$ A.U., the origin of which remained a mystery for a long time. In 1925 M'Lennan and Shrum examined the radiation emitted by a mixture of oxygen and either helium or neon in excess, under the influence of an electrical discharge, and found a green line, $\lambda = 5,577·35$ Å.U., which was also shown with pure oxygen under low pressure. That nitrogen, in the same form as we know it, must exist at these great altitudes was shown by spectroscopic work carried out by Lord Rayleigh in 1921. Ozone, hydrogen and helium are also inferred. (*See* also AURORA POLARIS.)

Absorption of Radiation by the Atmosphere. — The blue colour of the sky is due to the fact that the air is not perfectly transparent and its particles reflect and scatter light, that from the blue end of the spectrum being most widely scattered. This effect also obscures the light of the stars. Very little of the sun's thermal radiation is absorbed by the air, which derives most of its heat from the earth by conduction and convection. A layer of air one metre thick absorbs about 0·007% of the radiant heat passing through it. Of the radiation incident on the outer atmosphere about 37% is lost by reflection and scattering. The fraction of the radiant energy from the sun which reaches the earth is termed the coefficient of transparency of the atmosphere. The absorption is chiefly dependent on the amount of water vapour, carbon dioxide and solid impurities present and consequently is much greater in the neighbourhood of towns. The following coefficients of transparency are given by Wild for one metre of air: — Dry, dust-free air, 0·99718, Dry air, containing dust, from a room, 0·99520, Dust-free air saturated with water vapour 0.99328. The ozone, which appears to be present at very high altitudes, is responsible for the removal of practically all the ultraviolet radiation of wave-length shorter than $\lambda = 2,885$ Å.U.

Since the temperature of the upper atmosphere is practically constant and no convection or condensation takes place there, it is important to consider what would be the effect of dust particles which might be forced into the stratosphere by volcanic eruption. After certain eruptions, *e.g.,* Krakatoa 1883, Mont Pele and Santa Maria 1902, Katmai 1912, a reddish halo was observed round the sun owing to the dust ejected to very great altitudes, and it was possible to calculate the size of the particles. It has been estimated that a quantity of dust of volume less than $\frac{1}{174}$ cu. km. distributed in the upper layers of the air, would reduce the intensity of solar radiation by 20%. It is possible to explain the occurrence of ice ages in this way. (*See* also SPECTROSCOPY; METEOROLOGY; CLIMATE AND CLIMATOLOGY.)

ATMOSPHERIC ABSORPTION is a loss of power in transmission of radio waves due to a dissipation in the atmosphere. The "fading" of radio waves as often observed in broadcast reception over long distances may be, in part, the result of variations in the atmospheric absorption to which the waves are subject.

ATMOSPHERIC RAILWAY. About 1840–45 great interest was excited by a method of propelling railway trains through the agency of atmospheric pressure. Various inventors worked at the realization of this idea. On the system worked out in England by Jacob Samuda and S. Clegg a continuous pipe or main was laid between the rails, and in it a partial vacuum was maintained by means of air pumps. A piston fitting closely in it was connected to the leading vehicle of the train by an iron plate which passed through a longitudinal groove or aperture running the whole length of the pipe. This aperture was covered by a valve consisting of a continuous strip of leather, strengthened on each side with iron plates; one edge was fastened while the other was free to rise. Connected behind the piston was a frame carrying four wheels which lifted and sustained the continuous valve for a distance of about 15 feet. Thus the piston, having atmospheric pressure on one side of it and a vacuum equal to 15 or 16in. of mercury on the other, was forced along the tube, taking the train with it. It was installed on about two miles of line between Kingstown and Dalkey (Ireland) in 1843 and worked till 1855; it was also tried on the London and Croydon and on the South

Devon lines, but was soon abandoned. (See PNEUMATIC DISPATCH.)

ATMOSPHERICS are electrical disturbances occasioned by lightning or other electrical changes in the atmosphere. They become manifest in radio reception as disturbing "crackling" sounds and are variously known as "static," "strays," "x's" or "noise."

ATOLL (native name *atollon* in the Maldive Islands), a horse-shoe or ring-shaped reef of coral enclosing a lagoon. It is found in low latitudes. Its form may be likened to that of a partly submerged dish with pieces broken from its edge, the ring of islands standing upon a conical pedestal. The dish is formed of hard coral and the shells of various reef-dwelling mollusca, covered, especially at the seaward periphery, with a film of living coral polyps that continually extend the fringe, and enlarge the diameter of the atoll. The lagoon tends to deepen when the land is stationary on account of the death of the coral animals in the still water, and the disintegration of the "hard" coral of the inner ring. while waves and storms tear off blocks of rock and pile them up at the margin, increasing the height of the islands, which in course of time usually become covered by vegetation. The lagoon entrance in the open part of the horse-shoe is always to leeward of prevailing winds. *See* CORAL REEFS.

ATOM, when ordinarily used in chemistry and physics, refers to the smallest particle of an element which can exist either alone or in combination with similar particles of the same or of a different element. The atom also refers to a quantity proportional to the atomic weight of an element. According to the theory of atomism, which dates from pre-Socratic times, the atom is one of the minute indivisible particles of which the whole universe is composed. (X.)

Through the important experimental discoveries of the second half of the 19th century it became gradually clear that the atoms of the elements, far from being indivisible entities, had to be thought of as aggregates built up of separate particles. Thus from experiments on electrical discharges in rarefied gases, and especially from a closer study of the so-called cathode rays, the existence of small negatively charged particles—the mass of which was found to be about 2,000 times as small as the mass of the lightest atom, the hydrogen atom—was recognized. These small particles, which may be regarded as atoms of negative electricity, are now, following Johnstone Stoney, generally called electrons. Through the investigations of J. J. Thomson and others convincing evidence was obtained that these electrons are a constituent of every atom. On this basis a number of the general properties of matter, especially as regards the interaction between matter and radiation, receive a probable explanation.

In fact, the assumption that electrons are vibrating around positions of stable equilibrium in the atom offered a simple picture of the origin of spectral lines, which allowed the phenomena of selective absorption and dispersion to be accounted for in a natural way. Even the characteristic effect of magnetic fields on spectral lines discovered by Zeeman could, as was shown by Lorentz, be simply understood on this assumption. The origin of the forces which kept the electrons in their positions remained for a time unknown, as well as the way in which the positive electrification was distributed within the atom. From experiments on the passage through matter of the high speed particles expelled from radioactive substances, however, Rutherford was in 1911 led to the so-called nuclear model of the atom. According to this the positive electricity is concentrated within a nucleus of dimensions very small compared with the total space occupied by an atom. This nucleus is also responsible for practically the whole of the atomic mass.

Properties of the Elements.— The nuclear theory of the atom has afforded a new insight into the origin of the properties of the elements. These properties can be divided into two sharply distinguished classes.

1. To the first class belong most of the ordinary physical and chemical properties. These depend on the constitution of the electron cluster round the nucleus and on the way in which it is influenced by external agencies. This, however, will depend on the attractive force due to the nucleus which keeps the cluster together. On account of the small size of the nucleus compared with the distance apart of the electrons in the cluster, this force will to a high approximation be determined solely by the total electric charge of the nucleus. The mass of the nucleus and the way in which the charges and masses are distributed among the particles making up the nucleus itself will only have an exceedingly small influence on the behaviour of the electronic cluster.

2. To the second class belong such properties as the radioactivity of the substance. These are determined by the actual internal structure of the nucleus. In the radioactive processes we witness, in fact, explosions of the nucleus in which positive or negative particles, the so-called α and β particles, are expelled with very great velocities.

The complete independence of the two classes of properties is most strikingly shown by the existence of substances which are indistinguishable from one another by any of the ordinary physical and chemical tests, but of which the atomic weights are not the same, and whose radioactive properties are completely different. Any group of two or more such substances are called isotopes (*q.v.*), since they occupy the same position in the classification of the elements according to ordinary physical and chemical properties. The first evidence of their existence was found in the work of Soddy and other investigators on the chemical properties of the radioactive elements. It has been shown that isotopes are found not only among the radioactive elements, but that many of the ordinary stable elements consist of isotopes, for a large number of the latter that were previously supposed to consist of atoms all alike have been shown by Aston's investigations to be a mixture of isotopes with different atomic weights. Moreover the atomic weights of these isotopes are whole numbers, and it is because the so-called chemically pure substances are really mixtures of isotopes, that the atomic weights are not integers.

The inner structure of the nucleus is still but little understood, although a method of attack is afforded by Rutherford's experiments on the disintegration of atomic nuclei by bombardment with α particles. Indeed, these experiments may be said to have started a new epoch in natural philosophy in that for the first time the artificial transformation of one element into another has been accomplished (*see* TRANSMUTATION OF THE ELEMENTS). In what follows, however. we shall confine ourselves to a consideration of the ordinary physical and chemical properties of the elements and the attempts which have been made to explain them on the basis of the concepts just outlined.

THE RELATIONSHIPS BETWEEN THE ELEMENTS

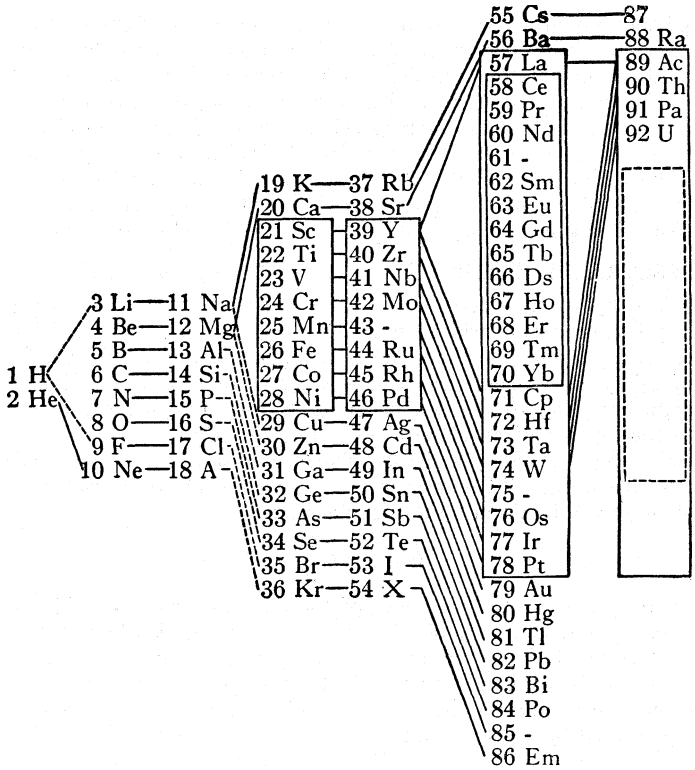
It was recognized by Mendelejeff that when the elements are arranged in an order which is practically that of their atomic weights, their chemical and physical properties show a pronounced periodicity. A diagrammatic representation of this so-called periodic table is given in Table I., which represents in a slightly modified form an arrangement first proposed by Julius Thomsen. In the table the elements are denoted by their usual chemical symbols, and the different vertical columns indicate the so-called periods. The elements in successive columns which possess homologous chemical and physical properties are connected by lines. The meaning of the square brackets around certain series of elements in the later periods, the properties of which exhibit typical deviations from the simple periodicity in the first periods, will be mentioned below.

Radiation.— The discovery of the relationship between the elements was primarily based on a study of their chemical properties. Later it was recognised that this relationship appears also very clearly in the constitution of the radiation which the elements emit or absorb in suitable circumstances. In 1883 Balmer showed that the spectrum of hydrogen, the first element in the table, could be expressed by an extremely simple mathematical law. This so-called Balmer formula states that the frequencies ν of the lines in the spectrum are given to a close approximation by

$$\nu = R\left(\frac{1}{(n')^2} - \frac{1}{(n')^2}\right) \qquad (1)$$

where R is a constant, and where n' and n'' are whole numbers. If n'' is put equal to 2 and n' is given successively the values 3, 4, . . . the formula gives the frequencies of the series of lines in the visible part of the hydrogen spectrum. If n'' is put equal to 1 and n' equal to 2, 3, 4, . . . a series of ultra-violet lines is obtained which was discovered by Lyman in 1914. To $n''=3$, 4, . . . correspond series of infra-red hydrogen lines which also have been observed.

TABLE I. *Periodic Table of the Elements*



Rydberg in his famous investigation of line spectra more than 30 years ago was able to analyse in a similar way many spectra of other elements. Just as in the case of hydrogen he found that the frequencies of a line-spectrum (such as that of sodium) could be represented by a formula of the type

$$\nu = T'' - T' \qquad (2)$$

where T''. T' can be approximately represented by

$$T = \frac{R}{(n - a_K)}, \qquad (3)$$

a_K is a constant for any one series, but takes different values a_1, a_2 . . . for the different series, while n takes a set of successive integral values. R is constant throughout for all spectra, and is the same constant as that appearing in (1); it is generally called the "Rydberg number." In many spectra the terms of most series are multiple, *i.e.,* the terms which we consider as forming a series do actually form two, three or more series corresponding to two, three or more slightly different values of a_K. Rydberg also discovered that the spectra of elements occupying homologous positions in the periodic table were very similar to each other, a similarity which is especially pronounced as regards the multiplicity of the terms.

Moseley's Discovery. — The study of X-ray spectra made possible by the work of Laue and Bragg brought out relations of a still simpler kind between different elements. Thus Moseley (*q.v.*) in 1913 made the fundamental discovery that the X-ray spectra of all elements show a striking similarity in their structure, and that the frequencies of corresponding lines depend in a very simple way on the ordinal number of the element in the periodic table. Moreover the structure of these spectra was very like that of the hydrogen spectrum. The frequency of one of the strongest X-ray lines for the various elements could, for instance, be given approximately by

$$\nu = N^2 R \left(\frac{1}{1^2} - \frac{1}{2^2}\right) \qquad (4)$$

and that of another line by

$$\nu = N^2 R \left(\frac{1}{2^2} - \frac{1}{3^2}\right) \qquad (5)$$

where R is again the Rydberg constant and N the ordinal number of the element in the periodic table. The extreme simplicity of these iormulae enabled Moseley to settle any previous uncertainty as to the order of the elements in the periodic table, and also to state definitely the empty places in the table to be filled up by elements not yet discovered.

In the nuclear model of the atom, the ordinal number of an element in the periodic table receives an extraordinarily simple interpretation. In fact, if the numerical value of the charge on an electron is taken as unity, this ordinal number, which is often called the "atomic number" (*q.v.*), can simply be identified with the magnitude of the nuclear charge. This law which was foreshadowed by J. J. Thomson's investigations of the number of electrons in the atom, as well as by Rutherford's original estimate of the charge on the atomic nucleus, was first suggested by van den Broek. It has since been established by refined measurements of the nuclear charge, and it has proved itself an unerring guide in the study of the relationship between the physical and chemical properties of the elements. This law also oifers an immediate explanation of the simple rules governing the changes in the chemical properties of radioactive elements following the expulsion of a or β particles.

THE QUANTUM THEORY

The discovery of the electron and of the nucleus was based on experiments, the interpretation of which rested on applications of the classical laws of electrodynamics. As soon, however, as an attempt is made to apply these laws to the interaction of the particles within the atom, in order to account for the physical and chemical properties of the elements, we are confronted with serious difficulties. Consider the case of an atom containing one electron: it is evident that an electrodynamical system consisting of a positive nucleus and a single electron will not exhibit the peculiar stability of an actual atom. Even if the electron might be assumed to describe an elliptical orbit with the nucleus in one of the foci, there would be nothing to fix the dimensions of the orbit, so that the magnitude of the atom would be an undetermined quantity. Moreover, according to the classical theory the revolving electron would continually radiate energy in the form of electromagnetic waves of changing frequency and the electron would finally fall into the nucleus. In short, all the promising results of the classical electronic theory of matter would seem at first sight to have become illusory. It has nevertheless been possible to develop a coherent atomic theory based on this picture of the atom by the introduction of the concepts which formed the basis of the famous theory of temperature radiation developed by Planck in 1goo.

This theory marked a complete departure from the ideas which had hitherto been applied to the explanation of natural phenomena, in that it ascribed to the atomic processes a certain element of discontinuity of a kind quite foreign to the laws of classical physics. One of its outstanding features is the appearance in the formulation of physical laws of a new universal constant, the so-called Planck's constant, which has the dimensions of energy multiplied by time, and which is often called the "elementary quantum of action." We shall not enter upon the form which the quantum theory exhibited in Planck's original investigations, or on the important theories developed by Einstein in 1905, in which the fertility of Planck's ideas in explaining various physical phenomena was shown in an ingenious way. We shall proceed at once to explain the form in which it has been possible to apply the quantum theory to the problem of atomic constitution. This rests upon the following two postulates: —

1. An atomic system is stable only in a certain set of states, the "stationary states," which in general corresponds to a discrete sequence of values of the energy of the atom. Every change

in this energy is associated with a complete "transition" of the atom from one stationary state to another.

2. The power of the atom to absorb and emit radiation is governed by the law that the radiation associated with a transition must be monochromatic and of frequency ν such that

$$h\nu = E_1 - E_2 \qquad (6)$$

where h is Planck's constant and E_1 and E_2 are the energies in the two stationary states concerned.

The first of these postulates aims at a definition of the inherent stability of atomic structures, manifested so clearly in a great number of chemical and physical phenomena. The second postulate, which is closely related to Einstein's law of the photoelectric effect, offers a basis for the interpretation of line spectra; it explains directly the fundamental spectral law expressed by relation (2). We see in fact that the spectral terms appearing in this relation can be identified with the energy values of the stationary states divided by h. This view of the origin of spectra has been found to agree with the experimental results obtained in the excitation of radiation. This is shown especially in the discovery of Franck and Hertz relating to impacts between free electrons and atoms. They found that an energy transfer from the electron to the atom can take place only in amounts which correspond with the energy differences of the stationary states as computed from the spectral terms.

The Hydrogen Spectrum. — From the Balmer formula (1) and the quantum theory postulates, it follows that the hydrogen atom has a single sequence of stationary states, the numerical value of the energy in the n^{th} state being Rh/n^2. Applying this result to the nuclear model of the hydrogen atom, we may assume that this expression represents the work necessary to remove the electron from the nth state to an infinite distance from the nucleus. If the interaction of the atomic particles is to be explained upon the laws of classical mechanics, the electron in any one of the stationary states must move in an elliptical orbit about the nucleus as focus, with a major axis whose length is proportional to n^2. The state for which n is equal to 1 may be considered as the normal state of the atom, the energy then being a minimum. For this state the major axis is found to be approximately 10^{-8} centimetres. It is satisfactory that this is of the same order of magnitude as the atomic dimensions derived from experiments of various kinds. It is clear, however, from the nature of the postulates, that such a mechanical picture of the stationary states can have only a symbolic character. This is perhaps most clearly manifested by the fact that the frequencies of the orbital revolution in these pictures have no direct connection with the frequencies of the radiation emitted by the atom. Nevertheless, the attempts at visualizing the stationary states by mechanical pictures have brought to light a far-reaching analogy between the quantum theory and the classical theory. This analogy was traced by examining the radiation processes in the limit where successive stationary states differ comparatively little from each other. Here it was found that the frequencies associated with the transition from any state to the next succeeding one tend to coincide with the frequencies of revolution in these states, if the Rydberg constant appearing in the Balmer formula (1) is given by the following expression:

$$R = \frac{2\pi^2 e^4 m}{h^3} \qquad (7)$$

where e and m are the charge and mass of the electron and h is Planck's constant. This relation is actually found to be fulfilled within the limits of the experimental errors involved in the measurements of e, m and h, and seems to establish a definite relation between the spectrum and the atomic model of hydrogen.

Correspondence Principle. — The considerations just mentioned constitute an example of the application of the so-called "correspondence principle" which has played an important part in the development of the theory. This principle gives expression to the endeavour, in the laws of the atom, to trace the analogy with classical electrodynamics as far as the peculiar character of the quantum theory postulates permits. On this line much work has been done in the last few years, and quite recently in the hands of Heisenberg has resulted in the formulation of a rational quantum kinematics and mechanics. In this theory the concepts of the classical theories are from the outset transcribed in a way appropriate to the fundamental postulates and every direct reference to mechanical pictures is discarded. Heisenberg's theory constitutes a bold departure from the classical way of describing natural phenomena but may count as a merit that it deals only with quantities open to direct observation. This theory has already given rise to various interesting and important results, and it has in particular allowed the Balmer formula to be derived without any arbitrary assumptions as to the nature of the stationary states. However, the methods of quantum mechanics have not yet been applied to the problem of the constitution of atoms containing several electrons, and in what follows we are reduced to a discussion of results which have been derived by using mechanical pictures of the stationary states. Although in this way a rigorous quantitative treatment is not obtainable it has nevertheless been possible, with the guidance of the correspondence principle. to obtain a general insight into the problem of atomic constitution.

SPECTRA OF ELEMENTS OF HIGHER ATOMIC NUMBER

The hydrogen spectrum may be considered as evidence of a step-like process in which an electron is captured and bound increasingly strongly in the field surrounding the nucleus, the stages of this process being the stationary states of the atom. Simple arguments lead to the conclusion that the stages corresponding to the binding of an electron by a nucleus of any given charge will be represented by a similar sequence of stationary states and that the energy W_n necessary to remove the electron from the n^{th} state will be given by the expression:

$$W_n = N^2 \frac{Rh}{n^2} \qquad (8)$$

where N is the atomic number of the elements under consideration. These states may be visualized as mechanical orbits of the electron in which the major axis is N times as small as the major axis in the corresponding orbit in the hydrogen atom. The spectrum associated with the binding process under consideration is represented by the formula:

$$\nu = N^2 R \left(\frac{1}{(n'')^2} - \frac{1}{(n')^2} \right) \qquad (9)$$

For $N=2$, this formula actually represents the spectrum which is emitted by a singly ionized helium atom, *i.e.*, a helium atom, which has lost one of its electrons. Spectra of this type have not yet been observed for values of N larger than 2, but it will be seen that formula (9) includes the approximate formulae (4) and (5) representing the frequencies of the strongest lines in the X-ray spectra of the elements. This may be understood if we assume that an X-ray spectrum is associated which changes in the state of binding of one of the electrons in the inner region of the atom, where, at least when the atomic number is large, the force on the electron due to the nucleus will far outweigh the forces due to the other electrons, and where consequently the presence of these electrons will have a comparatively small influence on the strength of the binding.

Influence of Electrons. — In general the mutual influence of the electrons is very considerable. Consider the stages by which an electron is captured by an atom of which the nucleus already has s electrons circulating round it. In the initial stages of this process while the orbits may be supposed to have dimensions which are large compared with the orbital dimensions of the electrons previously bound, the repulsive forces from these latter electrons may be assumed to neutralise s units of the nuclear charge, and the resultant force will be approximately the same as when an electron is circulating round a nucleus of atomic number N-S. In the later stages, when the dimensions of the orbit of the new electron are smaller, the other electrons can no longer be considered to act as a single central charge, and their repulsion cannot be easily determined. Thus the conditions become more complicated, and the stationary states can no longer be treated by picturing the motion of the new electron as following a Keplerian ellipse.

It has been found, however, that many features of the resulting spectra would be explained by assuming the added electron to move in a plane central orbit consisting of a sequence of quasi-elliptic loops. In contrast to a Keplerian orbit the single loops are not closed, but the successive maximum radii will be placed at constant angular intervals on a circle with the nucleus at the centre. For such central orbits it is possible, as was first shown by Sommerfeld, to select from the continuous multitude of possible orbits a set of orbits which may be taken as representing stationary states in the sense of the quantum theory. These states are labelled with two integral numbers; the one, denoted by n, corresponds to the integer appearing in the Balmer formula and is called the principal quantum number. The other, denoted by k, may be called the subordinate quantum number. For any given value of n, the number k can take the values 1, 2, 3 . . . n_n, corresponding to a set of orbits with increasing minimum distance from the nucleus. For a given value of k increasing values of n correspond to orbits which exhibit an increasing maximum distance from the nucleus, but which are similar in size and shape in the region where the electron comes nearest to the nucleus. For the work necessary to remove an electron in an n_k orbit completely from the nucleus, the theory leads to the following approximate expression

$$W_{n,k} = (N-s)^2 \frac{Rh}{(n-a_k)^2} \qquad (10)$$

where a depends only on the subordinate quantum number k, and approaches zero for increasing k.

If s is equal to N-1, we see that the $W_{n,k}$ when divided by h coincides exactly with Rydberg's expressions (3) for the spectral terms of the ordinary series spectra of the elements. These spectra may therefore be considered as evidence of processes, representing the last stage in the formation of a neutral atom, in which a nucleus of charge Ne, which holds already N-I electrons bound in its field, is capturing an N^{th} electron. In recent years it has been found that many elements under suitable conditions besides their ordinary spectra also emit spectra for which the terms can be represented by

$$T = p^2 \frac{R}{(n-a_k)^2} \qquad (11)$$

where p may take the integral values 2, 3, 4. . . . Comparing (11) with formula (10) we see that these spectra must be ascribed to atoms, which after having lost p electrons are rebinding an electron in the field of the remaining atomic ion.

This interpretation of series spectra, allows also the rules governing the possible combinations of spectral terms to be explained. In fact, it has been found that only those lines appear in the spectrum for which the k-values of the spectral terms involved differ by one unit. From an investigation of the constitution of the radiation which on classical electrodynamics would be emitted from an electron performing a central motion, this rule can be shown to be a simple consequence of the correspondence principle.

Multiplex Structure. — The multiplex structure exhibited by the terms of most series spectra makes it necessary to assume that the motion of the electron involved in the emission of these spectra is somewhat more complicated than the simple central motion described above. An analysis based on the correspondence principle indicates that this motion may be described as a central motion on which is superposed a uniform precession of the orbital plane round an invariable axis in space. For a time, however, it seemed very difficult to obtain any closer connection between the observed structures and the above hypothesis of the constitution of the atom. In particular the remarkable analogy between the finer structures of the optical spectra and the X-ray spectra, which had been brought out by the experiments, was very puzzling. The study of the strange anomalies exhibited by the effect of a magnetic field on the components of the optical multiplets has, however, quite recently led to the view that the electron itself carries. besides its electric charge, also a magnetic moment which may be associated with a swift rotation round an axis through its centre. This new assumption allows not only the anomalous Zeeman eflect to be accounted for, but affords at the same time a natural explanation for the empirical rules governing the dependency of the widths of the multiplet structures on the atomic number.

ATOMIC CONSTITUTION AND THE PERIODIC TABLE

Soon after the discovery of the electron it was recognized that the relationships between the physical and chemical properties of the elements expressed in the periodic table point towards a group-structure of the electronic distribution in the atom. Fundamental work on these lines was done by J. J. Thomson in 1904. After the discovery of the nucleus and the simple interpretation of the atomic number given above, his work has been followed up with great success especially by Kossel and Lewis.

It is suggested that the electrons within the atom possess a tendency to form stable groups, each containing a definite number of electrons which, in the neutral state of the atom, surround the centre of the atom like successive shells or layers. An explanation of the simple valency properties holding for the second and third period of the periodic table was, for instance, obtained by assuming that there was a tendency to form completed shells each containing eight electrons. The single valency of sodium and the double valency of magnesium are ascribed to the facility with which the neutral atoms of these elements can lose one or two electrons respectively, as the atomic ions remaining would then contain completed shells only. On the other hand the double negative valency of sulphur and the single negative valency of chlorine are ascribed to the tendency of their outermost shells to take up two or one additional electrons respectively in order to form a complete shell of eight electrons, like that contained in the neutral atom of the inactive gas argon.

Spatial Arrangement **of** Electrons. — Attempts have been made to associate the existence of such groups with statical configurations of electrons possessing a high degree of symmetry. The presence of groups of eight electrons for instance has been explained as an arrangement of electrons at the corners of a cube. However suggestive these ideas have been in affording pictures of the constitution of chemical compounds, they do not allow a direct connection with other properties of the atom to be established; the main difficulty being that stable spatial arrangements of the electrons are incompatible with the nuclear theory of the atom. In the meantime, however, it has been possible to connect the group structure of the electronic cluster in the atom with the quantum-theory interpretation of spectra. Thus the constitution of the neutral atom in its normal state can be investigated by imagining a process by which N electrons one after one are captured and bound in the field of force surrounding a nucleus of charge Ne.

To each step there corresponds a multitude of stages, *i.e.*, stationary states, in which the electron is more and more firmly bound to the atom. The final state, in which binding is strongest, corresponds to the normal state of the atomic ion. A definite connection between the spectra and the group structure was now established by assuming that, in the normal atom only a limited number of electrons can be bound in states visualized as orbits characterized by definite values of the quantum numbers n and k. The electrons bound in orbits corresponding to a given value of n are said to form an n-quantum group, which in its finally completed stage will contain n subgroups, corresponding to the possible values 1, 2 . . . n which k may take. For a sufficiently large nuclear charge, the strength with which the electrons in the different subgroups belonging to one and the same group are bound will be nearly equal.

In the gradual building up of the groups in atoms with increasing nuclear charge, it is, however, to be noted that when an n_k orbit appears for the first time in the neutral atom, the strength of the binding will depend very considerably on the value of k. This is due to the circumstance that this quantum number fixes the closest distance to which the electron may approach the nucleus. The screening of the nuclear charge by the other electrons in the atom may therefore be very different for orbits corresponding to different values of k, and the effect on the strength

of the binding can be so large that an orbit characterized by certain values of n and k may correspond to a stronger binding than an orbit for which n is smaller but k larger. This offers a natural explanation of one feature of the periodic table, namely that the periods grow gradually larger, while there appear sequences of elements which differ comparatively little in their chemical and physical properties. Such a sequence marks a stage in the development of an n-quantum group, which consists in the addition of a subgroup corresponding to a value of k which was previously not yet represented in that group, and which takes place after the building up of a group corresponding to a higher value of n has already begun. In fact, during the addition of the subgroup a temporary standstill will occur in the development of the latter group, the constitution of which will primarily determine the chemical affinity of the atom, since it contains the most loosely bound electrons.

In the accompanying table (Table II.) is given a summary of the structure of the normal state of the neutral atoms of the elements. The figures before the different elements are the atomic numbers, which give the total ncmber of electrons in the neutral atom. The figures in the different columns give number of electrons in orbits correspocding to values of the principal and subordinate quantum numbers standing at the top. A comparison with the periodic table (Table I) will show that those elements which in chemical respect are homologous, will have the same number of electrons in the electronic groups most loosely bound, containing the so-called valence-electrons. The atoms of elements which in Table I. are enclosed in brackets possess electronic configurations in which a subgroup is being added to a group, whose principal number is less than the group containing the typical valence-electrons. An especially conspicuous example of such a completion of an inner group is offered by the elements forming the family of the rare earths. Here we witness the addition of the fourth subgroup to the 4-quantum group, which begins first in Ce (58) while the addition of the third subgroup was already finished in Ag (47).

Table II. is in general agreement not only with the optical spectral evidence but also with that in the region of X-rays. As mentioned earlier, we see in X-ray spectra a change in the binding of an electron in the interior of the atom. This takes place when, for instance, by the impact of a swiftly moving particle on the atom, an electron is removed from one of the electronic groups, and its place is taken by an electron belonging to a group for which the binding energy is smaller. As an example it may be stated that the strong X-ray whose frequency is approximately represented by formula (4) is emitted when an electron has been removed from the 1-quantum group, and one of the 2_2 electrons performs a transition so as to occupy the empty place. The line represented approximately by formula (5) originates from a

transition by which a 3_3 electron takes the place Ieft open upon the removal of a 2_2 electron.

The question how many electrons there are in the various groups and subgroups has been subject to much discussion in the last few years. Table II. is the temporary result of this discussion and seems to give an adequate description of the spectral as well as the chemical evidence. It is clear that a full theoretical treatment of the problem cannot be obtained from considerations based only on the simple picture of central orbits. Such a treatment will essentially involve an examination of those features of the binding of the electrons, which appear in the multiplet structure of spectral lines. Indeed it is very probable that the idea that the electron itself has magnetic properties may give the clue to the interpretation of the empirical rules governing the number of electrons in the group structure of the atom.

Recent Progress.—Such is the outline of the theory of the atom and its structure as it stood in 1925. Since then the subject of atomic structure has undergone a remarkable development due to the establishment of rational quantum theoretical methods which enable a quantitative treatment to be given to a large number of atomic problems that, earlier, were accessible only to considerations of a more qualitative character. These methods take their origin from two sources. On the one hand the symbolic procedure of "quantum mechanics" initiated by Heisenberg, and briefly referred to above, has, thanks to the collaboration of a number of eminent physicists, developed into a structure which, as regards generality and consistency, may be compared with the theory of classical mechanics. On the other hand a new method of "wave mechanics" of great power and fertility has been developed by Schrodinger having its starting point in the pioneer work of de Broglie. (See QUANTUM THEORY.) This method utilizes the analogy between mechanics and optics emphasized already long ago by Hamilton. According to de Broglie, the motion of a material particle may be compared with the propagation of a train of waves, the frequency of which is related to the kinetic energy of the particle, as calculated on the relativity theory, by the general quantum relation $E=h\nu$. Indeed, this view may be considered as an inversion of the considerations by which Einstein was led to the hypothesis that the carrier of light energy had to be considered not as waves but as corpuscles—the so-called light quanta—which concentrated within a small volume contained the energy $h\nu$. Notwithstanding the indispensability of the wave theory of light for the account of ordinary optical experience, Einstein's hypothesis has proved most fruitful in explaining a number of phenomena, notably the important discovery of Compton of the change in the frequency which X-rays suffer when scattered by electrons. Similarly the view of de Broglie, strange as it is from the classical point of view, has received a striking support from the recent discovery of Davisson and Germer about the selective reflection of electrons from metal crystals. Indeed, in these experiments the electrons were found to behave as waves possessing the wave length anticipated from quantum theory.

The first indication of the importance of the wave idea in the problem of atomic constitution was the suggestion of de Broglie that the stationary states of an atom might be interpreted as an interference effect of the waves associated with a bound electron. A real advance in this direction, however, was first achieved by Schrodinger, who succeeded in replacing the classical equations of motion for the particles in the atom by a certain differential equation of a type similar to that known from the theory of elastic vibrations of solid bodies. As is well known from acoustics any such vibration can be resolved into a number of purely harmonic components, representing the fundamental tones of a musical instrument. It was now found that the "characteristic solutions" of the Schrodinger wave equation, corresponding to such purely harmonic vibrations, offer a detailed interpretation of the properties of stationary states. First of all the energy values appearing in the quantum theory of spectra are obtained by multiplying the frequencies of the characteristic vibrations by Planck's constant. Next Schrodinger succeeded in associating with the solution of his wave equation a continuous distribution of electric charge and current, which, when applied to a characteristic vibration, represents the electrostatic and magnetic properties of an atom in the corresponding stationary state. Similarly the superposition of two characteristic solutions corresponds to a continuous vibrating distribution of electric charge, which on classical electrodynamics would give rise to an emission of radiation, fulfilling the requirement of the quantum postulate and the correspondence principle as regards frequency as well as intensity and polarization.

These remarkable results have given rise to a renewed discussion regarding the physical nature of the constituents of the atom. Indeed, the view has been advocated that the wave idea offers a real picture of the atom, allowing a direct application of the methods of classical physics. On this view the wave mechanics represent a natural generalization of classical mechanics of material particles, to which it is related in the same way as the modern theory of optics based on the fundamental equations of electrodynamics is related to the more primitive theory of geometrical optics, which makes use of the idea of light rays. It would appear, however, that the situation is more complicated. Due to the very contrast between the ideas of quantum theory and the fundamental principles of classical physics, we cannot expect to be able to visualize atomic phenomena by means of our classical ideas. In the dilemma regarding the nature of light and the ultimate constituents of matter we witness a general feature of a dualism inherent in the quantum theory description. Indeed, the wave and particle ideas are both indispensable if we attempt to get a full description of experience. This situation is brought out very clearly by the recent development of the symbolic method of quantum mechanics, through which an intimate connection between the correspondence argument and Schrodinger's work is established. Just when due regard is given to the feature of dualism in question, the quantum theory can, unfamiliar as it is, still be regarded as a natural development of the ordinary description of physical phenomena.

In the problem of atomic constitution we meet with a very striking example of the dualism mentioned. Notwithstanding the wonderful power of the Schrodinger wave functions of illustrating properties of stationary states, the wave theory fails to account for the peculiar stability of these states, on which the interpretation of atomic phenomena rests so essentially. Indeed, we have here to do with the very feature of discontinuity or rather "individuality," by which the quantum theory departs from the ideas of classical physics, and of which we perhaps have the most striking example in the existence of the individual particles themselves. For the rest, the dualism of the quantum theory brings with it the conclusion that the use of the idea of stationary states excludes the possibility of following at the same time the behaviour of the single particles in the atom. Just this situation finds its adequate representation in the characteristic vibrations of the Schrodinger wave problem. This problem. in fact, is not a 3-dimensional one, as that of ordinary spatial description, but one which operates with a number of dimensions equal to the number of degrees of freedom of the whole atom. This fact has recently found an important application in the interpretation of a certain peculiar duplexity in the structure of spectra especially marked in the helium spectrum. This duplexity, which for a long time eluded explanation, has recently been explained by Heisenberg, who pointed out that we have here to do with an effect of the mutual interaction of the electrons in the atom, which exhibits a close correspondence with a classical resonance problem, but cannot be accounted for on the simple procedure of characterizing the behaviour of the individual electrons by quantum numbers. The justification of this procedure in a large number of applications rests on the circuinstance that in general the resonance effect is very small, the mutual influence of the various electrons on each other being, as already described, to a close approximation to that of a conservative central field of force.

It is impossible here to give anything but a vague idea of the abundance of details regarding the physical and chemical properties of the elements which have been explained by means of the new methods of quantum theory. It may still be mentioned that

the important contributions of Main Smith and Stoner to the interpretation of the periodic table—embodied already in the scheme of electron orbits given in the article—have been brought into most convincing connection with the so-called exclusion principle of Pauli and with the idea of the magnetic electron referred to already. Moreover a study of the fine structure of band spectra has led to the conclusion that the proton, or the nucleus of the hydrogen atom, also possesses an angular momentum and a magnetic moment. Quite recently even a successful attack on the fundamental problem of the origin of the so-called electron spin has been made by Dirac, whose work has opened new prospects. ATOMIC NUMBER, in chemistry, is the ordinal number of an element in the series of the elements arranged in accordance with the periodic law (*q.v.*).

The chemical elements were formerly arranged in the periodic classification in ascending order of their atomic weights, but this arrangement led to three pairs of anomalies, *viz.,* argon and potassium, cobalt and nickel, and tellurium and iodine, in which the order of the atomic weight obviously disagreed with the position of the elements as shown by their chemical properties. This discrepancy was completely cleared up in 1913 by H. G. J. Moseley, who measured the wave-length of X-rays given off by elements when bombarded with cathode rays and showed that the frequencies of these X-rays were characteristic for each element. The square root of the frequency of the principal rays increased proportionately with the rise in atomic number, and when this relationship is traced out with a group of elements including iron, cobalt, nickel and copper, it is found that cobalt precedes nickel although of higher atomic weight, and X-ray spectra reveal a similar inversion in the case of tellurium and iodine. Similarly, potassium (atomic weight 39·1) is placed next but one after chlorine (atomic weight 35·46), thus leaving the intermediate position for argon (atomic weight 40). In Moseley's own words these results show that "there is in the atom a fundamental quantity which increases by regular steps as we pass from one atom to the next. This quantity can only be the charge on the central positive nucleus." (Moseley in Philosophical *Magazine,* 1913 and 1914.) Chemical atoms are composed of positive units of electricity (protons) and of an equal number of negative units (electrons), the charge on any one of such units being $\pm 4{\cdot}77 \times 10^{-10}$ electrostatic units. The protons are concentrated in the nucleus which also contains a portion of the electrons, the remaining electrons being extra-nuclear or planetary. Thus an element of atomic weight *W* and atomic number N will have a nucleus consisting of *W* protons and W—N electrons surrounded by N planetary electrons. Accordingly the atomic number is (1) the ordinal number of the element, (2) the positive electrical charge on the nucleus, and (3) the number of planetary electrons surrounding the nucleus. (G. T. M.)

ATOMIC WEIGHTS. Atomic weights have been defined as "the relative weights of the atoms of chemical elements referred to a common standard." This statement still serves as the simplest indication of the fundamental idea involved, although it now needs amplification. The concrete development of the idea was first effected in 1803 by John Dalton, an English chemist, when he converted the vague atomistic theory of the ancient Greeks into a highly valuable scientific asset by means of the concept of atomic weights. The chemical atomic theory thus initiated has been strengthened by modern investigation, and is to-day entrenched in a well-nigh impregnable position.

Practical and Scientific Interest.—Atomic weights are quantities of great practical and theoretical importance. They record the operation of the chemical law of definite combining proportions; hence they are the basis of quantitative chemical analysis, and are in everyday use throughout the world. Because of the parallelism between gravitational effect and inertia, they record also the relative masses of the atoms of the elements. They possess an extraordinary degree of definiteness, since the law of combining proportions is one of the few known precise laws of the universe. Far deeper in meaning than the accidental astronomical "constants," such as the length of the day or the length of the year, the atomic weights of the simple elements and of the individual isotopes (see ISOTOPES) stand out as among the peculiar and basic attributes of those 92 elementary substances of which everything is composed. Their interpretation is closely concerned with our inferences concerning the nature of matter.

Dalton's Views.—Simple as the original concept of atomic weights seems to be, it nevertheless presents problems which are rather complex. For example, 22·997 grammes of sodium combine with 126·932 grammes of iodine to form sodium iodide. This ratio of the combining weights of these elements appears to be invariable. As Dalton pointed out, these weights must depend on the relative weights of the respective atoms; no other simple explanation is conceivable. There is in the experimental result, however, nothing which shows whether the sodium and iodine combine atom for atom, or whether one atom of sodium combines (for example) with two of iodine. Dalton himself perceived that this latter happening might in many cases occur; indeed it is the essence of his Law of Multiple Proportions. There is now every reason to believe that in this particular case of sodium and iodine the atoms actually combine one to one and that the numbers given above represent really the relative weights of the atoms of sodium and iodine; but there are many less simple cases. For instance, 126.932 grammes of iodine combine with 20·035 grammes of calcium; here the latter number represents only half the atomic weight of calcium; because every molecule of calcium iodide is believed on excellent evidence to contain two atoms of iodine for every atom of calcium (see VALENCY). Such a decision was beyond the reach of Dalton. It is based chiefly upon three subsequent discoveries to be briefly described.

Avogadro's Hypothesis.—In 1811 Count Amedeo Avogadro di Quaregna advanced the hypothesis, based upon Gay Lussac's Law of Volumes, that equal volumes of gases under like conditions of temperature and pressure contain the same number of molecules, a molecule being defined as consisting usually of two or more atoms. This hypothesis (which has since been so amply confirmed as to become, in many minds, a statement of fact) furnishes the most important means of deciding between the multiples or sub-multiples of the combining proportions which are to be taken as the atomic weights, because it fixes the molecular weights and formulas of volatile elements and compounds (see CHEMISTRY).

Dulong and Petit's Constant.—The second important means of deciding between possible multiples and sub-multiples of atomic weights was the discovery of Dulong and Petit (1818) that the atomic weight of an element is about equal to a constant number (6.3) divided by the specific heat. To be sure, this rule is not exact; but its inexactness is not usually great enough to affect it in its office of deciding the multiple or sub-multiple of the chemical combining proportion to be taken as the atomic weight. For example, the specific heat of calcium is about 0·16; therefore its atomic weight is shown to be about 39.4, whereas the exact value found by chemical means is 40·07.

Crystalline Similarity.—A third method of answering the question exists in the similarity of the crystal forms of similar salts of allied elements, discovered by E. Mitscherlich in 1821. If the atomic weight of one element entering into such isomorphous crystals is unknown, that multiple of the combining proportion of this element which corresponds to the formula indicated by the known salt will be the true atomic weight. (See ISOMORPHISM.)

The full significance and essential consistency of these three methods of solving Dalton's unsolved problem were not realized until 1858, when a table of atomic weights identical in principle with that used to-day was published by S. Cannizzaro. Previous doubts concerning the criteria just described had caused many

chemists to reject wholly the term "atomic weights," and to call the arbitrarily selected multiples merely by some such name as "proportion numbers" or "chemical equivalents." But the numbers now used (as regards the multiples chosen) inevitably involve the atomic theory, hence the adjective "atomic" is fitting. "Weight" also is fitting, since the values are determined by means of the gravitational balance. The term "atomic mass" applies consistently only when inertia is the basis of measurement. The term "chemical equivalent" is now used to signify the atomic weight divided by the valency (*q.v.*).

Standard of Atomic Weights. — The choice of the standard of atomic weights has varied. Dalton chose the smallest atomic weight, that of hydrogen, as his standard. Berzelius temporarily selected Oxygen=100 as the standard of his system. Later the chemical world returned to Dalton's practice, especially because (according to early work) it was believed that the atomic weight of oxygen is nearly the whole number 16, if hydrogen is taken as 1. Finally, after it had been shown by E. W. Morley and others that the ratio of the atomic weights of oxygen and hydrogen is in fact 15·878 to 1, it was decided, by general consent, in 1905, to abandon the standard H=1·000, retaining the standard O=16·000. The decision was based upon convenience. The permanent choice of O=15·878 would have changed by nearly one per cent. almost every other accepted value, and would have caused much confusion in previous quantitative statements. Besides, more atomic weights approach whole numbers when oxygen is taken as exactly 16·000 than when any other usual standard is chosen.

A more weighty reason lay in the fact that most of the values are experimentally determined by relation to oxygen, and are referred to hydrogen only through that element. Hence any subsequent change in the accepted ratio H:O (one of the most difficult to determine of all such ratios) would affect all the atomic weights, if hydrogen were chosen as the standard substance. The present unit of the system of atomic weights is therefore exactly the sixteenth part of the atomic weight of oxygen. The atomic weight of hydrogen thus becomes 1·0077. The choice, on the whole, was a wise one; it has been justified by modern research, and has proved to be peculiarly fortunate, because probably all atoms of oxygen are alike in weight (see ISOTOPES).

Atomic Numbers and Actual Weights. — Atomic weights are numbers; that is to say, they represent ratios and are therefore devoid of physical dimensions. They are, however, very different from the quantities designated by J. A. R. Newlands and H. G. J. Moseley "atomic numbers" (*q.v.*), which record the serial order of the places in the periodic classification of the chemical elements. No immediate knowledge of the actual weights of individual atoms is afforded by "atomic weights," unless the number of atoms in a given gross weight of some elementary substance is known. Various researches have shown that 16 grammes of oxygen contain about 606×10^{21} atoms; hence a single atom of oxygen must weigh 0·000,000,000,000,000,000,000,026,4 gramme. The actual weights of other kinds of atoms must be in due proportion.

Experimental Determination. — The exact values of the chemical combining proportions which form the basis of the table of atomic weights are found only by experimental work. Therefore, before the table is given, the necessary experimental methods may well be briefly described. The first and most generally useful method employed for the purpose has as its object the determination of the precise amount of one element which is necessary exactly to combine with a given amount of some other element of known atomic weight. The experimental technique is of the most refined quantitative chemical analysis. Early extensive and careful investigations of this kind were conducted by J. Berzelius, C. de Marignac, J. B. A. Dumas, J. S. Stas and many others. Recently most of the work in this direction has been conducted in the United States (E. W. Morley, W. A. Noyes, T. W. Richards, G. P. Baxter and others), although European investigators (especially B. Brauner and 0. Honigschmid) have made important contributions.

Experimental work of this kind naturally involves the observance of a number of essential conditions. Comparatively few compounds of any given element are fit to serve as a means of determining its atomic weight, for the reason that comparatively few substances may be prepared in a perfectly pure state. The choice of the compounds to be employed is in some ways the most crucial part of the whole process, for with some compounds no result worthy of consideration could be obtained, even using the greatest care possible.

Having chosen wisely, the experimenter must prepare the needful substances, whatever they may be, in a state of very great purity. He must never forget that every precipitate carries down with it contaminating impurities absorbed or included by the substance as it separates from the solution. He must remember always that no receptacle necessary to contain the substance is free from the possibility of being attacked or dissolved, thus affecting the result. Moreover, precipitates are never wholly insoluble; and most substances will volatilise if heated to an excessive temperature. These complicating circumstances combine often in unexpected ways to introduce impurity, and the experimenter must not only guard against these dangers, but must prove by adequate tests that no such complication has occurred. Moreover, above all, he must not forget that oxygen, nitrogen and water are almost omnipresent; and continual care must be exercised lest in some way one of these impurities may affect the substance which is serving as the basis of the work. For further statement of these and other precautions and for a brief description of apparatus suitable for avoiding many pitfalls, together with the details of an especially instructive complex case, the reader is referred to Carnegie Institution of Washington, Publication No. ***125.*** A critical summary by F. W. Clarke of all investigations up to 1920 is to be found in the third Memoir of vol. xvi. of the *Memoirs* of the *National* Academy of Sciences (Washington).

A Typical Experiment. — A simple case may best exemplify the method. In one of many experiments, 7·59712 grammes of ferric oxide (Fe_2O_3) prepared with the greatest care, were found to yield on reduction (by means of hydrogen at a high temperature) 5.31364 grammes of metallic iron. The loss of weight (2.28348 grammes) represents the oxygen present in the oxide. Hence, from the proportion $(2{\cdot}28348):(5{\cdot}31364)=O_3:Fe_2=3(16{\cdot}000):2x$, the atomic weight of iron is found to be 55.848 (G. P. Baxter and C. R. Hoover). The analysis was repeated many times in order to eliminate accidental errors.

Alternative Method. — Another general method of determining atomic weights (applicable only to gases or vapours) depends upon Avogadro's Rule, and resolves itself into the weighing of like volumes of different gases under like conditions of temperature and pressure. This is the only gravimetric method applicable to the six inert gases (helium, etc.) which do not form chemical compounds. The method determines molecular weights, not atomic weights; but the number of atoms in a molecule may be inferred in other ways, and therefore the atomic weights may be calculated from the data. The method involves experimental difficulties. The globe containing a gas inevitably weighs much more than the gas itself and is peculiarly subject to changes of buoyancy of the air. The exact measurement of temperature and pressure is not always easy, nor is the perfect purity of the gas to be weighed a condition readily secured. Moreover, Avogadro's Rule holds only for perfect gases; no actual gas fulfils exactly its requirements, because of the bulk occupied by the molecules themselves and their mutual attraction. On the whole, making allowance for these difficulties (see STOICHEIOMETRY), the method of determining molecular (and therefore atomic weights) by comparison of the densities of gases agrees remarkably well with the results obtained from chemical analysis (Lord Rayleigh, E. W. Morley, P. A. Guye, **A.** Leduc, E. Moles, G. P. Baxter).

Third Method. — A third method of determining atomic weights (like the last, a purely physical method) is that which determines the mass (or rather the ratio of mass to electric charge) of rapidly moving charged atoms or molecules by means of the deflection by electric and magnetic fields. It appraises (by means of impressions on a photographic plate of the positions of impact of the deflected particles) the relative atomic masses pertaining

to selected groups of atoms. In its original form it furnished the first experimental evidence not only that in some elements the atoms are all alike in weight, but also that in other elements this is not the case (Sir J. J. Thomson, 1912). Different varieties of a single chemical element, similar in every respect except as regards the weights and masses of their atoms, and apparently inseparable by natural agencies when once mixed, are called isotopes (F. Soddy). Under that head will be found a full description of this method of evaluating them, which was greatly improved by F. W. Aston, in his "mass-spectrograph."

Isotopes.—Many but not all of the elementary substances have been found by this third method to be isotopic or "complex." Hence elements may be divided into two classes: simple elements, probably possessing only one variety of atom, and isotopic elements, containing two or more varieties. The relative proportions of the several isotopes in a given elementary substance are shown roughly by the relative intensities of the "photographic" records; they can be shown exactly only by quantitative analysis, and then only when no more than two isotopes are present. Thus ordinary terrestrial chlorine (Cl=35·46) must consist of a mixture of about 30 atoms of Cl=37 to every 100 atoms of Cl=35.

Although the term "atomic weight" referred originally to the elementary substances (whether simple or isotopic) which actually occur on the earth's surface, it is applicable with even greater fitness to each isotope alone. Of all the isotopic elements only one, namely lead, has had the atomic weight of any individual isotope accurately determined by chemical analysis (Richards, Soddy, Honigschmid). The individual isotopes of this metal are unique because, so far as we can tell, they are end-products of the spontaneous disintegration of uranium, and other radioactive elements, in which the atoms of lead were segregated at the moment of their terrestrial birth and confined in the minerals producing them. Their abnormal atomic weights (determined by chemical methods of unquestioned trustworthiness) constituted at first the most convincing evidence of the existence of isotopes.

Table of Atomic Weights.—The following table of atomic weights of the chemical elementary substances as they exist on the surface of the earth is essentially the table issued in 1925 by the International Committee on Elements and Atomic Weights, but includes the newly discovered element hafnium, as well as two of the individual isotopes of lead which have been experimentally investigated by chemical methods. "Atomic numbers" are also given. Usually, the larger the atomic weight the larger the atomic number; but all isotopes of a given element have the same atomic number. Except for hydrogen, the atomic number is never more and usually less than half of the atomic weight.

Redefinition of Term.—The discovery of the spontaneous disintegration of radioactive elements and the finding of isotopes have modified our theoretical interpretation of the atomic weights. Because of these discoveries, two *a priori* premises (of a more or less philosophical nature), namely, first, the assumption that the atoms are indivisible (the elementary substances being absolutely permanent) and, second, the assumption that the atoms of a given chemical element are all alike in weight, must to-day be abandoned, but the premises are seen on close scrutiny to be by no means an essential part of the chemical atomic theory. Nevertheless, the old definition of atomic weights must be altered in order to correspond exactly to modern knowledge. A more complete and precise definition may be worded as follows: "Primarily, atomic weights are appropriate simple multiples (decided by theory) of the relative combining proportions or relative gas-densities of elementary substances calculated on a consistent basis. They represent the relative average weights of the atoms of given specimens of elementary substances referred to a common stand-

TABLE OF ATOMIC WEIGHTS OF THE CHEMICAL ELEMENTS

	Symbol.	At. No.	At. Wt.		Symbol.	At. No.	At. Wt.
Aluminium	Al	13	26·97	Manganese	Mn	25	54·93

ard." Any such definition involves other definitions. An elementary substance is a substance which is not further disintegrated by ordinary chemical reactions. This definition avoids the implication that such a substance is incapable of disintegration by extra-chemical means. "Element" and "chemical elements" are sometimes used synonymously. "Atoms" are postulated as the smallest particles of such a substance under ordinary conditions. They are not necessarily incapable of disintegration under extreme conditions. Hence their name (from ἄ privative and τομός "divided, cut") is not now appropriate, but it will doubtless be retained; the term "chemical atom" would perhaps be better. The qualification involved in the word "average" above is necessary because of the discovery of isotopes. The weighted average of the atomic weights of the isotopes in any particular isotopic or "complex" elementary substance is that which is recorded as its atomic weight.

Constancy of Atomic Weights.— That the atomic weights are constant in different compounds is shown by the analysis of many pure substances containing the same element and also by H. Landolt's experiments (1907), which proved that there is no loss or gain of gravitational effect in ordinary chemical reactions within one part in ten million. Moreover, specimens of various elementary substances (*e.g.*, sodium, calcium, copper, silver, iron, nickel, cobalt, etc.) found in different parts of the earth or even in meteorites, have been found by careful research to have constant atomic weights independent of geographical occurrence. All the samples of terrestrial lead even, except those found in uranium or thorium minerals, show similar uniformity. That each native terrestrial mixture of isotopes is thus unvarying seems to show that each was commingled when the earth was still fluid, or else that some unknown law determines the proportion in which the isotopes are formed. If it were not for the consistency indicated in this paragraph, the table of atomic weights would be much less useful than it is. The atomic weights are precisely consistent also with the electro-chemical equivalents indicated by Faraday's Law (Faraday, Rayleigh, Richards), affording thus further evidence of their fundamental nature.

Hydrogen and Other Elements.— The hypothesis of Prout (1815) that all elements are aggregates of hydrogen has been greatly strengthened by the discovery of isotopes; for it appears that the fractions in the table above are due chiefly to isotopic' mixtures, in which each isotope taken separately has nearly a whole number for its individual atomic weight. The atomic weights of uranium, radium, thorium, the isotopes of lead, and helium furnish an argument in favour of the theory of the atomic disintegration in which they are concerned, and therefore support the postulate maintaining the composite nature of the elements. Nevertheless, all the simple elements and individual isotopes have atomic weights somewhat less than the appropriate multiples of that of hydrogen, as has been shown in the case of oxygen. Many theorists believe that this common deficiency is due to the actual loss of mass during the atomic coalescence of hydrogen nuclei, the expelled mass being transformed into energy. If this is true, the exact values of the simple atomic weights (and those of individual isotopes) even to the third decimal place, possess great theoretical interest, since they must furnish an essential clue to the amount of energy expended. Modern hypotheses concerning the structure of the atom (Sir E. Rutherford, Sir J. J. Thomson, N. Bohr, G. N. Lewis, I. Langmuir) assume that practically all the weight and mass of the atom (fixing, of course, its atomic weight) are concentrated in an exceedingly small nucleus in its centre.

Concord with Atomic Numbers.— For 50 years the atomic weights decided the arrangement of the periodic system of the elements. Recently x-ray spectra have more certainly evaluated the atomic numbers which place the elements in this system (Moseley); but the agreement between the two methods is close enough to indicate a fundamental if sometimes complex relation between them.

Atomic Weights and Cosmogony.— The sun and stars appear spectroscopically to be made largely of the elements existing on earth. It is therefore no mere flight of fancy to infer that the vast gravitational forces which regulate the motions of the heavenly bodies are due to the collective action of countless myriads of atoms, whose individual shares in the process are recorded in the table of atomic weights. The foregoing considerations concerning atomic weights suggest many other cosmological inferences, which are, however, beyond the scope of this article (see "Atomic Weights and Isotopes," *Chemical* Review, **I.** I., [1924]). It is not too much to say that these unique numbers, the atomic weights, probably bear a very close relation to the unknown fundamental processes which determined the nature and evolution of the universe. (T. W. R.)

ATOMIZATION, ELECTRICAL, a process for the production of stable colloidal solutions of metals. An electric arc is passed between electrodes of pure metal in distilled water contained in a vessel made of practically insoluble material. Faraday probably was the first to employ the electric arc to produce finely dispersed gold, but Bredig developed the method here described. Svedberg used the oscillating discharge from an induction coil and greatly reduced the current density, producing some hydrosols and olganosols. (See COLLOIDS.)

ATONALITY, a modern musical term which has been adopted in connection with that class of composition which is not written in any definite key and hence has no defined tonality (See HARMONY.)

ATONEMENT. To "atone" is to make "at one," and this is the actual derivation of the word. A doctrine of atonement makes the following assumptions. (a) There is a natural relation of communion between man and God. (b) This communion has been broken through man's fault. Early conceptions of this breach as due to the non-observance of taboos and rituals become, in the higher religions, a sense of sin, as an ethical offence against God's holiness and love. (c) Communion can be restored, *i.e.*, sin can be forgiven.

The Religious Doctrine.— Atonement is the means or condition of the restoration of communion between man and God. This has been variously found (a) in the endurance of punishment; (b) in the payment of compensation for wrong done, in the form of sacrifices or other offerings; (c) in the performance of some special ritual, the efficacy of which consists in its being pleasing to or appointed by God, or even in its having a coercive power over God; (d) in repentance and amendment of life. In most theories two or more of these are combined. Some or all of the conditions of atonement may be fulfilled, according to various views, either by the sinner or vicariously on his behalf by some kinsman; or by his family, clan or nation; or by someone else.

Old Testament.— In the Old Testament to "atone" represents the Heb. Kipper, a word originally meaning to "cover" or "wipe out," but probably used simply as a technical term. There is no harmonious system of teaching on the subject. In some cases there is no suggestion of forgiveness; sinners are "cut off" from the chosen people (Josh. vii. 24), nations perish in their iniquity (Jer. li. 62). Some passages make punishment the condition of pardon (II. Sam. xii. 13, 14; Is. xl. 2), though here repentance is assumed as following the punishment. Sometimes penitence and amendment are the sole conditions (Ezek. xviii.; Mic. vi.).

Sacrifice and other rites are also spoken of in this connection. The Priestly Code (Leviticus and allied passages) seems to confine the efficacy of sacrifice to ritual, venial and involuntary sins (Lev. iv. 2), and requires that the sacrifices should be offered at Jerusalem by the Aaronic priests; but these limitations did not belong to the older religion. Some writers (Ps. li.; Mic. vi. 6–8; Is. i. 11) protest against the ascription of great importance to sacrifice. The Old Testament has no theory of sacrifice; in connection with sin the sacrifice was popularly regarded as payment of penalty or compensation and this is specially connected with the offering of the blood (Lev. xvii. 11).

Jewish Day of Atonement.— The atoning ritual reached its climax on the Day of Atonement (in the Mishna simply "the Day" *Yōmā*), observed annually on the 10th day of the 7th month (Tisri), shortly before the Feast of Tabernacles or vintage festival. The laws of the Day of Atonement belong to the Priestly Code. There is no trace of this function before the exile (see Ezek. xlv. 18–20 LXX.) but the ritual of the '(scapegoat" was

doubtless derived from earlier times. The object of the observances was to cleanse the sanctuary, the priesthood and the people from all their sins and to renew and maintain favourable relations between Yahweh and Israel. The ritual includes certain unique acts. The Day of Atonement is the only fast provided in the Law; it is only on this occasion that (a) the Jews are required to "afflict their souls"; (b) the High Priest enters the Holy of Holies; (c) the High Priest offers incense before the mercy seat and sprinkles it with blood; and (d) the scapegoat or goat for Azazel is sent away into the wilderness, bearing upon him all the iniquities of the people. In later Judaism, especially from about 100 B.C., great stress was laid on the Day of Atonement, and it is now the most important religious function of the Jews.

The idea of vicarious atonement appears in the Old Testament in different forms. The nation suffers for the sin of the individual (Josh. vii., 10–15); and the individual for the sin of his kinsfolk (2 Sam. xxi., 1–9; Deut. v. g, 10); or of the nation (Ezek. xxxi. 3, 4). Above all the Servant of Yahweh appears as atoning for sinners by his sufferings and death (Is. liii.). But the Servant is nowhere identified with the Messiah.

New Testament. — In the New Testament, the English version uses "atonement" once, Rom. v. 11, for καταλλαγή (R.V. here and elsewhere "reconciliation"). This Greek word corresponds to the idea suggested by the etymology of at-one-ment, the reuniting in amity of those at variance, a sense which the word had in the 17th century but has since lost. But the idea which has usually been expressed by "atonement" is rather represented in the New Testament by ἱλασμός and its cognates, *e.g.*, I. John ii. 2, R.V., "He (Jesus) is the propitiation (ἱλασμός) for our sins." But these words are rare, and we read more often of "salvation" σωτηρία) and "being saved," which includes or involves restoration to communion with God. The leading varieties of teaching, the sayings of Jesus, St. Paul, the Johannine writings, the Epistle to the Hebrews, connect the Atonement with Christ especially with His death, and associate it with faith in Him and with repentance and amendment of life. It is quite clear that such teaching goes back to Jesus Himself. Attempts to dispute the authenticity of Mark x. 45 ("to give His life a ransom for many") and xiv. 24 (This is My blood of the covenant which is shed for many") have not been successful.

These ideas are also common to Christian teaching generally. The New Testament, however, does not indicate that its writers were agreed as to any formal dogma of the atonement, but various suggestions are made. St. Paul's teaching connects with the doctrine of Is. liii., and less directly with the ritual sacrifices (I. Cor. v. 7). It is developed mainly on legalistic lines. (Christ's righteousness makes possible the acquittal [δικαίωσις] of the sinner who has identified himself with Christ by faith [Rom. vi. 3–9, etc.]. His work is an expression of God's love to man (Rorn, v. 8). The redeeming power of Christ's death is also explained by his solidarity with humanity as the second Adam — the redeemed sinner has "died with Christ" (Rom. v. 15–19; vi. 8). Some atoning virtue seems also attributed to the Resurrection (Rom. iv. 25). In I. John, Christ is a "propitiation" (ἱλασμός) provided by the love of God that man may be cleansed from sin; He is also their advocate (Παράκλητος) with God that they may be forgiven, for His name's sake. Hebrews speaks of Christ as transcending the rites and officials of the law; He accomplishes the realities which they could only foreshadow; in relation to the perfect sacrifice which has atoned for sin, He is both priest and victim (Heb. ii. 17; ix. 14).

Later Interpretation. — The subsequent development of the Christian doctrine has chiefly shaped itself according to the Pauline formulae; the demands of divine righteousness were met on man's behalf, or in man's stead, by Christ, a formula, however, which left much room for controversy. The creeds and confessions are usually vague. Thus the Apostles' Creed, "I believe in the forgiveness of sins"; the Nicene Creed, "I believe in one Lord Jesus Christ . . . who for us men and for our salvation came down from heaven . . . I acknowledge one baptism for the remission of sins"; the Athanasian Creed, "Who (Christ) suffered for our salvation." In the Thirty-nine Articles of the Church of England we have (ii.) "Christ suffered . . . to reconcile His Father to us, and to be a sacrifice. not only for original guilt, but also for all actual sins of men" (so, verbally, the Augsburg Confession); and (xxxi.) "The offering of Christ once made is that perfect redemption, propitiation and satisfaction, for all the sins of the whole world." The Council of Trent declared that "*Christus . . . nobis sua sanctissima passione ligno crucis justificationem meruit et pro nobis deo patri satisfecit,*" "Christ earned our justification by His most holy passion and satisfied God the Father for us." The Westminster Confession declares: "The Lord Jesus Christ, by His perfect obedience and sacrifice of Himself, which He through the Eternal Spirit once offered up to God, hath fully satisfied the justice of His Father, and purchased not only reconciliation but an everlasting inheritance in the kingdom of heaven, for all those whom the Father hath given unto Him."

Individual theologians have sought to define more exactly the points on which the standards are vague. For instance, how was justice satisfied by Christ? The early Fathers, from the 3rd to the 11th century held, *inter alia,* that Christ paid a ransom to Satan to induce him to release men from his power. Anselm and the scholastics regarded the Atonement as a satisfaction to God's honour, rather than a ransom or a penalty, a satisfaction of such worth that the outrage of man's sin is made good. Hence this view is often called the *Satisfaction* Theory. The leading reformers emphasized the idea that Christ bore the punishment of sin, sufferings equivalent to the punishments deserved by men, a view especially characteristic of the later Calvinism, and known as the *Penal* Theory. But the intellectual activity of the Reformation also developed other views; the Socinians, with their humanitarian theory of the Person of Christ, taught that He died only to assure men of God's forgiving love and to afford them an example of obedience — "Forgiveness is granted upon the ground of repentance and obedience." Grotius put forward what has been called the *Governmental* Theory, viz., that the atonement took place not to satisfy the wrath of God, but in the practical interests of the divine government of the world, "The sufferings and death of the Son of God are an exemplary exhibition of God's hatred of moral evil, in connection with which it is safe and prudent to remit that penalty, which so far as God and the divine attributes are concerned, might have been remitted without it."

Modern Views. — The formal legal view continued to be widely held, though it was modified in many ways by various theologians. For instance, it has been held that Christ atoned for mankind not by enduring the penalty of sin, but by identifying Himself with the sinner in perfect sympathy, and feeling for him an "equivalent repentance" for his sin. Thus McLeod Campbell held that Christ atoned by offering up to God a perfect confession of the sins of mankind and an adequate repentance for them, with which divine justice is satisfied, and a full expiation is made for human guilt. A similar view was held by F. D. Maurice. Others hold that the effect of the atoning death of Christ is not to propitiate God, but to reconcile man to God; it manifests righteousness and thus reveals the heinousness of sin; it also reveals the love of God, and conveys the assurance of His willingness to forgive or receive the sinner; thus it moves men to repentance and faith, and effects their salvation; so substantially Ritschl. This view, which is found as early as Abélard, is commonly called the *Moral* Theory. In England much influence has been exerted by Dr. R. W. Dale's *Atonement,* the special point of which is that the death of Christ is not required by the personal demand of God to be propitiated, but by the necessity of honouring an ideal law of righteousness. This view, however, leads to a dilemma; if the law of righteousness is simply an expression of the divine will, satisfaction to law is equivalent to propitiation offered to God; if the law has an independent position, the view is inconsistent with pure monotheism.

Dale's attempt to restate the Penal Theory in a form free from objection on ethical grounds was followed on rather less definite lines by J. Denney in his *Death of Christ* and *Atonement and the Modern Mind.* The general trend of recent thought has been, however, in the direction (a) of much more strongly modified

transactional statements and (b) of a moral theory, stated as objectively as possible. Of the first of these types a good example is J. Scott Lidgett's *Spiritual Principle of the Atonement,* in which it is insisted that God should be regarded as a loving Father rather than a Judge, and the work of atonement is restated in the light of this principle. An even more influential book is R. C. Moberly's *Atonement and Personality.* Here an attempt is made to work out the implications of McLeod Campbell's suggestion that vicarious penitence, rather than vicarious suffering, is the key to atonement. Moberly retains the conception of an objective transaction, but interprets this along the lines of the Moral Theory, as an expression of love. This combination of views is made possible by emphasis upon the mystical self-identification of Christ with the sinner. More recently H. Rashdall (*The* Idea *of Atonement in Christian Theology*) has devoted a long and careful historical discussion to a defence of the Moral Theory in its simpler and less objective form, and his work has given a considerable impetus in Modernist circles to views of this type. There is, however, an undoubted reaction from such extreme treatments of the subject and both Rashdall's historical data and his reconstruction have been widely criticized. Meanwhile modified forms of Anselm's Satisfaction Theory, often expressed in terms of sacrifice, still hold the field in popular theology of a Catholic type and in devotional literature.

AT OR BETTER, a term used in instructions to brokers in the securities or commodities markets which means, if it is in a selling order, to sell at the price specified or higher; or if it is in a purchase order, to buy at the price specified or lower.

ATOUTS, the 22 emblematic cards, numbered from 1 to 21, and including one unnumbered card, used in the ancient game of tarrochino or tarots. (*See* CARDS, PLAYING.) Atouts is also the regular modern French word for trumps at Auction and Contract Bridge.

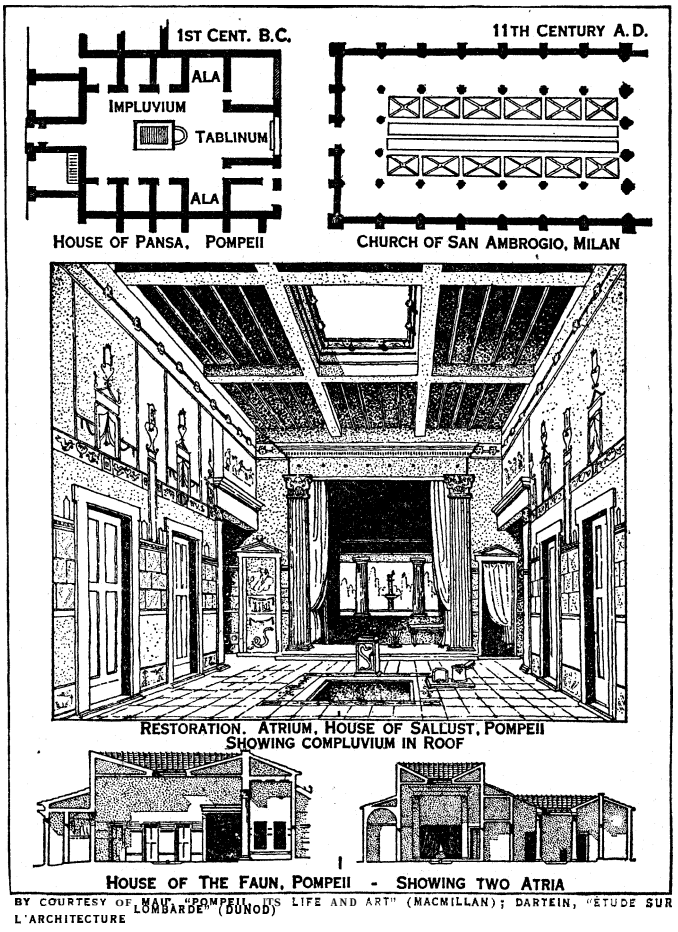
ATRATO, a river of western Colombia, South America, rising on the slopes of the Western Cordilleras, in 5° 36' N. lat., and flowing almost due north to the gulf of Uraba, or Darien, where it forms a large delta. Its length is about 400m., but owing to the heavy rainfall of this region it discharges no less than 175,000cu.ft. of water per second, together with a very large quantity of sediment, which is rapidly filling the gulf. The river is navigable to Quibdo (250m.), and for the greater part of its course for large vessels, but the bars at its mouth prevent the entrance of sea-going steamers. Flowing through the narrow valley between the Cordillera and coast range, it has only short tributaries, the principal ones being the Truando, Sucio and Murri. The gold and platinum mines of Choco were on some of its affluents, and the river sands are auriferous. The Atrato at one time attracted considerable attention as a feasible route for a trans-isthmian canal, which, it was estimated, could be excavated at a cost of £11,000,000.

ATREK, (ATRAK) a river which rises in lat. 37° 10′ N., long. 59° E., in the mountains of the north-east of the Persian province of Khorasan, and flows west along the borders of Persia and the Turkmen S.S.R. (*q.v.*). After a course of 350 mi., it enters the south-eastern corner of the Caspian sea, its mouth being in the Turkmen S.S.R., a little north-north-west of the Persian town of Astarabad.

ATREUS, in Greek legend, son of Pelops and Hippodameia, elder brother of Thyestes and king of Mycenae. His wife Aerope was seduced by Thyestes, who was driven from Mycenae. To avenge himself, Thyestes sent Pleisthenes (Atreus's son whom Thyestes had brought up as his own) to kill Atreus, but Pleisthenes was himself slain by his own father. After this Atreus, apparently reconciled to his brother, recalled him to Mycenae and set before him the flesh of his son whom Atreus had slain. Thyestes fled in horror. Subsequently Atreus married the daughter of Thyestes, Pelopia, mother of Aegisthus (*q.v.*). Thyestes was found by Agamemnon and Menelaus, the sons of Atreus, and imprisoned at Mycenae. Aegisthus being sent to murder Thyestes, mutual recognition took place, and Atreus was slain by the father and son, who seized the throne, and drove Agamemnon and Menelaus out of the country. Atreus is generally identified with the Attarissiyas of the Boghaz-Keui tablets.

ATRI, Abruzzi, Italy, province of Teramo, 18m. W. of Teramo station on the railway from Ancona to Foggia, and 18m. due E.S.E. of Teramo, on the site of the ancient Hadria (*q.v.*). Pop. (1936), 3,837 (town); 12,735 (commune). Its Romanesque-Gothic cathedral (1285–1305) is remarkably fine, though the interior was spoilt by restoration in 1657. The crypt was originally a Roman cistern. The palace of the Acquaviva family, dukes of Atri from the 14th century to 1775, stands on the principal square.

ATRIUM, originally the central room of a Roman house in which was placed the hearth. As this room had a hole in the roof to let out the smoke the atrium was in essence a small court, and when with the developing complexity of the Roman house the kitchen and hearth were removed to other positions the atrium remained as a court serving as a formal reception room and as the official centre of family life. By the end of the republic the addition of one or more colonnaded courts in the larger houses removed from the atrium the last vestiges of family life and in the empire it became practically the office of the owner of the



BY COURTESY OF MAU, "POMPEII, ITS LIFE AND ART" (MACMILLAN); DARTEIN, "ÉTUDE SUR L'ARCHITECTURE LOMBARDE" (DUNOD)

house. The atrium might be either with or without columns; it had. universally, a marble basin which was known as the *impluvium.* This was situated in the centre under the opening in the roof called the *compluvium.*

The term atrium is used in a generic sense (like the English "hall") as in the Atrium Vestae, the house of the vestal virgins. The word was later used for any open court, especially that around a temple or in front of a Christian church as in San Clemente at

Rome and San Ambrogio at Milan. Occasionally the word is incorrectly used for narthex (*q.v.*). (T. F. H.)

ATROPATENE or **MEDIA ATROPATEME,** anciently the district now occupied by the Azerbaijan republic and the Persian province of the same name. It formed part of the ancient Persian empire and the empire of Alexander, but in the confusion following the latter's death, secured for a considerable time the rank of an independent State. (See PERSIA: Ancient History, and PARTHIA.)

ATROPHY, a medical term implying wasting from some interference with healthy nutrition. Waste and repair are constant processes in the animal body; when they balance, the volume of the body and of its constituent parts remains constant; when repair is greater than waste there is growth or hypertrophy; when waste is greater than repair there is atrophy. The chief causes of atrophy are (1) disuse, (2) pressure, (3) interference with nervous supply. Thus the diminution in size of the pregnant uterus after child birth, the shrivelling of thymus and umbilical vessels in the infant, are atrophies from disuse; the disappearance of soft tissues and even bone in the neighbourhood of tumours, or an aneurysm, is an example of pressure-atrophy; the wasting of limbs in disease affecting the large motor ganglia of the ventral horns of the spinal cord, or the anterior nerve roots or efferent nerves, is atrophy from interference with nervous supply.

These causes may act singly or in conjunction, and may themselves be dependent upon antecedent conditions. A limb may atrophy from disuse because disease of bone, or of joint, renders movement painful, and pressure-atrophy depends upon interference of blood supply which the pressure induces. For interference with nervous supply to cause atrophy of muscle—other than disuse-atrophy—it is necessary for the efferent nerve to be disorganized in some part of its course. Hence in paralysis affecting the leg, when the lesion is in the brain, such atrophy as occurs is due to disuse, whereas in infantile paralysis and progressive muscular atrophy, the lesion is in the large multipolar cells of the ventral horns of the spinal cord, and the atrophy of muscle is truly of nervous origin and far more conspicuous. Interference with afferent or sensory nerves causes atrophy of skin and subcutaneous tissue. This is seen in certain injuries to nerves. Thus, severance of the radial nerve (or musculo-spinal from which it arises) occasions a glossy condition of the skin covering the thumb, index, middle and contiguous half of the ring finger, and the skin becomes as thin as paper.

The intimate structure of an atrophied part may be little or greatly altered. In the natural atrophy accompanying old age the microscope shows little difference from normal adult conditions. The biceps of a man aged 80 is visibly smaller than that of a pugilist aged 21, but the two could not easily be distinguished microscopically. The same is true of the muscle of an undersized and ill-developed factory worker. For this reason it is customary in pathology to distinguish between true atrophy and hypoplasia, the former signifying that the part regressed after having reached a normal size, the latter that it never reached the normal size. It is clear, too, that a part may be hypoplastic either because it is composed of fewer elements each of which is normal size, or because it contains a normal number of elements each of which is smaller than usual. Unknown factors of inheritance may control these two conditions.

In cases of true atrophy, particularly those moderately rapid in onset, the diminution in size is accompanied by other changes, such as fatty degeneration and fibrosis, which are recognizable microscopically. Even in the atrophy of muscle in the aged the muscle nuclei are packed more closely and appear somewhat shrivelled, but in the atrophy of muscle caused by pressure of an aneurysm these changes are well marked, and in the region where atrophy is greatest the muscle fibres contain numerous minute fat globules due to fatty degeneration of the protein substance. In the renal atrophy characteristic of chronic granular kidney, fatty changes and fibrosis co-exist with actual disappearance of true renal elements, but it is uncertain which is the primary change.

Sometimes these associated changes are so pronounced that their bulk more than counterbalances the diminished bulk due to atrophy itself, with the result that the part, though atrophied in respect of its essential elements, is actually larger than normal. Thus a fatty heart is atrophied so far as concerns its muscular elements, but may measure, and even weigh, more than the normal organ. In hypertrophic muscular paralysis, too, the muscles of calf and buttock are so large and firm that they give the impression of magnificent development, and yet they are totally inefficient for their function, and the microscope shows that their bulk is composed of fat and fibrous tissue almost to the exclusion of muscular fibres. In spite of appearances the condition is essentially atrophic. This disease does not come into the classes of atrophy mentioned above, for the cause is unknown; it seems to depend upon a hereditary factor and more than one member of a family may suffer from it.

Atrophy may be very rapid in onset. In acute yellow atrophy of the liver, and in allied conditions caused by some poisons, the organ may diminish in size to one-third or half within a few days. Under these circumstances the destructive changes are so intense that it may be impossible to recognize hepatic substance in the fatty, blood-impregnated and pigmented material revealed by the microscope. But as a rule atrophy is a gradual and slow process.

Since an atrophied part is abnormal and depends upon abnormal nutrition, it is sensitive to conditions which the normal part can resist. The small injuries and adverse circumstances of life produce disproportionately great results in the first instance, and reparative processes are correspondingly slow and unsatisfactory. Sometimes it becomes necessary to consider surgical removal of the affected part. In cases due to severance of a nerve, suture of the divided ends may effect great improvement or even a cure. In the case of muscles and skin suffering from disuse-atrophy, massage and surgical treatment of any underlying condition are indicated. But in many forms no treatment modifies the atrophy itself and treatment of symptoms as they arise alone is possible.

(W. S. L.-B.)

ATROPINE, a poisonous, crystalline alkaloid (see ALKALOIDS) widely used in medicine. It does not normally occur in nature, but is derived from laevo-hyoscyamine and laevo-hyoscine (see HYOSCYAMINE and HYOSCINE), found in various plants of the nightshade family, as belladonna (Atropa), henbane (*Hyoscyamus*), thorn-apple (Datura) and *Scopolia.* Pure atropine, $C_{17}H_{23}O_3N$, crystallizes from alcohol on addition of water in colourless prisms, which melt at 118° C It is readily soluble in alcohol or chloroform, less so in ether, and almost insoluble in water. When atropine was first prepared in 1833 the processes in use for the extraction of alkaloids were too crude to avoid racemization of laevo-hyoscyamine, and so the racemic isomeride, atropine, was obtained, and partially racemic mixtures were later on mistaken for new alkaloids, of which "daturine," "duboisine," etc., are examples. Atropine is now made by racemization, with small quantities of alkali, of crude *l*-hyoscyamine, the best source of which is Egyptian henbane (*Hyoscyamus* muticus). The alkaloid may be extracted by the process described in the article ALKALOIDS, and is generally purified after racemization by conversion into, and re-crystallization of, the neutral oxalate. Atropine forms a series of well-crystallized salts, of which the sulphate $(C_{17}H_{23}O_3N)_2,H_2SO_4,H_2O$ is that principally used in medicine. This salt crystallizes in long, slender, colourless needles (which break up on exposure to air to a crystalline powder) and melts at 194° C. Both atropine and hyoscyamine have been synthesized and are known to be respectively the racemic and laevo-tropic esters of tropine (*q.v.*) and many attempts have been made to improve on them. The most successful attempt of this kind is *homatropine,* which is a phenylglycollic ester of tropine, and is a powerful mydriatic, more rapid but also more transient in its action than atropine.

MEDICAL USES

Medicine — The official doses of atropine or its sulphate are from $\frac{1}{200}$ to $\frac{1}{100}$ grain. The most valuable preparations of this drug are the liquor atropinae *sulphatis,* which is a 1% solution, and the lamella—for insertion within the conjunctival sac—which contains $\frac{1}{5,000}$ grain of atropine.

Pharmacology.—When rubbed into the skin with such substances as alcohol or glycerine, which are absorbed, atropine paralyses the terminals of the pain-conducting sensory nerves. It acts similarly, though less markedly, upon the nerves governing the secretion of sweat and is therefore a local anaesthetic or anodyne and an anhidrotic. Being rapidly absorbed into the blood, it acts on nearly every part and function of the nervous system. Its most remarkable action is that upon the terminals of nearly all the secretory nerves in the body. Sweating and secretion of saliva and mucus in the mouth and throat are arrested. But certain nerve fibres from the sympathetic nervous system, which can also cause the secretion of a (specially viscous) saliva, are entirely unaffected by atropine. A curious parallel to this occurs in its action on the eye. The secretions of stomach, intestines, liver, pancreas and kidneys are reduced, though not arrested, as in the other cases. The secretion of mucus by the bronchi and trachea is greatly reduced and their muscular tissue is paralysed. The secretion of milk is much diminished or entirely arrested. Given internally, atropine does not exert any appreciable sedative action upon the sensory nerves.

The action of atropine on the motor nerves is equally important. Those that go to the voluntary muscles are depressed only by very large and dangerous doses. But moderate doses of atropine paralyse the terminals of the nerves of involuntary muscles, whether motor or inhibitory. In the intestine, for instance, are layers of muscle-fibre which are constantly being inhibited by the splanchnic nerves. These are paralysed by atropine, and intestinal peristalsis becomes more active, the muscles being released from nervous control. The motor nerves of the arteries, of the bladder and rectal sphincters, and of the bronchi, are also paralysed by atropine. The action upon the vaso-motor system is fairly clear. Whether affected entirely by action on the nerve terminals, or by an additional influence upon the vaso-motor centre in the medulla oblongata, atropine causes extreme dilatation of the blood-vessels, the skin becomes flushed and there may appear, after large doses, an erythematous rash, which must be carefully distinguished, in cases of supposed belladonna poisoning, from that of scarlet fever: especially as the temperature may be raised and the pulse is very rapid in both conditions. But the first action of atropine is to stimulate the vaso-motor centre — thereby causing temporary contraction of the vessels — and to increase the rapidity of the heart's action, so that the blood-pressure rapidly rises. Though transient, this action is so certain, marked and rapid, as to make the subcutaneous injection of atropine invaluable in certain conditions. Since the respiratory centre is similarly stimulated, atropine must be regarded as a temporary but efficient respiratory and cardiac stimulant.

Toxic doses of atropine — and therefore of belladonna — raise the temperature several degrees. The action is probably nervous. In small therapeutic and in small toxic doses it stimulates the motor apparatus of the spinal cord, just as it stimulates the centres in the medulla oblongata. In large toxic and in lethal doses the activity of the spinal cord is lowered.

No less important than any of the above is the action of atropine on the cerebrum, a state closely resembling that of delirium tremens being induced. In cases of poisoning the delirium may last for many hours or even days. Thereafter a more or less sleepy state supervenes due to exhaustion after the long period of cerebral excitement. It is to be noted that children who are particularly susceptible to the influence of certain of the other potent alkaloids, such as morphine and strychnine, will take relatively large doses of atropine without ill-effect.

The action of atropine on the eye is of high theoretical dnd practical importance. The drug affects only the involuntary muscles of the eye, just as it affects only the involuntary or non-striated portion of the oesophagus. The result of its instillation into the eye — and the same occurs when the atropine has been absorbed elsewhere — is rapidly to cause wide dilatation of the pupil. As a result, the tension of the eyeball is greatly raised. The sight of many an eye has been destroyed by the use of atropine — in ignorance of this action on the intra-ocular tension — in cases of incipient glaucoma. The use of atropine is absolutely contra-indicated in any case where the intra-ocular tension already is, or threatens to become, unduly high. The fourth ocular effect of atropine is the production of a slight but definite degree of local anaesthesia of the eyeball. It follows from the above that a patient who is definitely under the influence of atropine will display rapid pulse, dilated pupils, a dry skin and a sense of discomfort, due to dryness of the mouth and throat.

Therapeutics. — The external uses of the drug are mainly analgesic. The liniment or plaster of belladonna will relieve many forms of local pain; but totally to be reprobated is the use, in order to relieve pain, of belladonna or any other application which affects the skin, in cases where the surgeon may later be required to operate. In such cases, it is necessary to use such anodyne measures as will not interfere with the subsequent demands that may be made of the skin, *i.e.*, that it be aseptic and in a condition so sound that it is able to undertake the process of healing itself after the operation has been performed. Atropine is universally and constantly used in ophthalmic practice in order to dilate the pupil for examination of the retina by the ophthalmoscope, or in cases where the inflamed iris threatens to form adhesions to neighbouring parts. The drug is often replaced in ophthalmology by homatropine (*vide* supra). The anhidrotic action of atropine is largely employed in controlling the night-sweats characteristic of pulmonary tuberculosis.

Atropine, used as a plaster or internally, often relieves cardiac pain. Professor Schäfer recommended the use of atropine prior to the administration of a general anaesthetic, in cases where the action of the vagus nerve upon the heart is to be dreaded. It is of value as an antidote in poisoning by pilocarpine, muscarine (mushroom poisoning), etc.

In cases of whooping-cough or any other condition in which there is spasmodic action of the muscular fibre in the bronchi — a definition which includes nearly every form of asthma and many cases of bronchitis — atropine is an almost invaluable drug. Not only does it relieve the spasm, but it lessens the amount of secretion — often dangerously excessive — which is often associated with it. The relief of symptoms in whooping-cough is sharply to be distinguished from any influence on the course of the disease, since the drug does not abbreviate its duration by a single day. In treating an actual and present attack of asthma, it is advisable to give the standardized tincture of belladonna — unless expense is no consideration, in which case atropine may itself be used — in doses of twenty minims every quarter of an hour as long as no evil effects appear. The nocturnal urinary incontinence of children and of adults is frequently relieved by this drug.

Toxicology. — The symptoms of poisoning by belladonna or atropine are dealt with above. The essential point here to be added is that death takes place from combined cardiac and respiratory failure. This fact, is, of course, the key to treatment. This consists in the use of emetics or the stomach-pump, with lime-water, which decomposes the alkaloid. These measures are, however, usually rendered nugatory by the very rapid absorption of the alkaloid. Death is to be averted by such measures as will keep the heart and lungs in action until the drug has been excreted by the kidneys. Inject stimulants subcutaneously; give coffee — hot and strong — by the mouth and rectum, or use large doses of caffeine citrate; and employ artificial respiration. Do not employ such physiological antagonists as pilocarpine or morphine, for the lethal actions of all these drugs exhibit not mutual antagonism but coincidence.

ATROPOS, in Greek mythology, the eldest of the three Fates. Her name, the "Unalterable," indicates her function, that of rendering the decisions of her sisters irreversible or immutable. Atropos is most frequently represented with scales, a sun-dial or a cutting instrument, the "abhorred shears" with which she "slits the thin-spun life." Of the two other Fates (Moirai), Clotho is she who spins the thread of life, represented with a spindle, and Lachesis, she who casts lots as to its length, drawing a lot or pointing to the globe (see also FATE).

ATROSCINE: see HYOSCINE.

AT SIGHT, a term used on bills of exchange and drafts meaning that they are payable upon presentation or demand. Such

instruments are ordinarily known as sight drafts (*q.v.*), or sight bills of exchange (*q.v.*).

ATTA, TITUS QUINTIUS (QUINTICIUS) (d. 77 B.C.), Roman comedy writer, was distinguished as a writer of national comedies.

See Aulus Gellius vii. 9; Ribbeck, Comicorum Latinorum *reliquiae* (1855).

ATTACHMENT, in law, a process from a court of record, awarded by the justices at their discretion, on a bare suggestion, or on their own knowledge, and properly grantable in cases of contempt. It differs from arrest (*q.v.*), in that he who arrests a man carries him to a person of higher power to be forthwith disposed of; but he that attaches keeps the party attached, and presents him in court at the day assigned, as appears by the words of the writ. Another difference is, that arrest is only upon the body of a man, whereas an attachment is often upon his goods. It is distinguished from distress in not extending to lands, as the latter does; nor does a distress touch the body, as an attachment does. See PRACTICE AND PROCEDURE.

ATTACK is a word used in various senses in musical terminology. Thus in the form attncca (Ital.) it is a direction to proceed without pause to the next movement or section of a composition. "Good attack" applied to a performance signifies a performance characterized by spirit, decision and good ensemble; a use of the term allied with the French chef *d'attaque* as a designation for the leader of an orchestra. Attacco (Ital.), in turn, is a term applied to a short phrase or episodic subject in a fugue.

ATTAINDER, in English law, was the immediate and inseparable consequence from the common law upon the sentence of death. When it was clear beyond all dispute that the criminal was no longer fit to live he was called *attaint,* and could not, before the Evidence Act 1843, be a witness in any court. This attainder took place after judgment of death, or upon such circumstances as were equivalent to judgment of death, such as judgment of outlawry on a capital crime, pronounced for absconding from justice. Conviction without judgment was not followed by attainder. The consequences of attainder were (1) forfeiture, (2) corruption of blood. On attainder for treason, the criminal forfeited to the Crown his lands, rights of entry on lands, and any interest he might have in lands for his own life or a term of years. For murder, the offender forfeited to the Crown the profit of his freeholds during life, and in the case of lands held in fee-simple, the lands themselves for a year and a day; subject to this, the lands escheated to the lord of the fee. These forfeitures related back to the time of the offence committed. Forfeitures of goods and chattels ensued not only on attainder, but on conviction for a felony of any kind, or on flight from justice, and had no relation backwards to the time of the offence committed. By *corruption* of blood, "both upwards and downwards," the attainted person could neither inherit nor transmit lands. The lands escheated to the lord of the fee, subject to the Crown's right of forfeiture. The doctrine of attainder has, however, ceased to be of much importance. The Forfeiture Act 1870 enacted that henceforth no confession, verdict, inquest, conviction or judgment of or for any treason or felony, or *felo* de se, should cause any attainder or corruption of blood, or any forfeiture or escheat.

Bills of Attainder, in English legal procedure, were formerly a parliamentary method of exercising judicial authority. They were ordinarily initiated in the House of Lords and the proceedings were the same as on other bills, but the parties against whom they were brought might appear by counsel and produce witnesses in both Houses. In the case of an impeachment (*q.v.*), the House of Commons was prosecutor and the House of Lords judge; but such bills being legislative in form, the consent of Crown, lords, and commons was necessary to pass them. Bishops, who do not exercise but who claim the right to vote in cases of impeachment (*q.v.*), have a right to vote upon bills of attainder, but their vote is not conclusive in passing judgment upon the accused. First passed in 1459, such bills were employed, more particularly during the reigns of the Tudor kings, as a species of extrajudicial procedure, for the direct punishment of political offences. Dispensing with the ordinary judicial forms and precedents, they took away from the accused whatever advantages he might have gained in the courts of law; such evidence only was admitted as might be necessary to secure conviction; indeed, in many cases bills of attainder were passed without any evidence being produced at all. In the reign of Henry VIII. they were much used, through a subservient parliament, to punish those who had incurred the king's displeasure; many distinguished victims who could not have been charged with any offence under the existing laws being by this means disposed of. In the 17th century, during the disputes with Charles I., the Long Parliament made effective use of the same procedure, forcing the sovereign to give his consent. The most famous cases were those of Strafford and Laud. After the Restoration it became less frequent, though the Jacobite movement in Scotland produced several instances of attainder, without, however, the infliction of the extreme penalty of death. The last bill of attainder passed in England was in the case of Lord Edward Fitzgerald, one of the Irish rebel leaders of 1798.

A bill for reversing attainder takes a form contrary to the usual rule. It is first signed by the Sovereign and presented by a peer to the House of Lords by command of the Crown, or, in other words, it is entirely within the Crown's grace and favour. Such bills for reversal are not obsolete as they are the first step necessary by a claimant to a peerage which has fallen into abeyance (see PEERAGE) when the ancestor was attainted. The House of Lords has recently (1928) adopted a report recommending that such attainders be not reversed "where the attainder has been in existence for several centuries."

The Constitution of the United States forbids Congress to pass any bill of attainder or ex post facto law. Most of the State constitutions contain similar prohibitions.

ATTAINT, WRIT OF, an obsolete method of procedure in English law, for inquiring by a jury of 24 whether a false verdict had been given in a trial before an ordinary jury of 12. It originated in the days when jurors were regarded as witnesses as well as judges and a false verdict was regarded as perjury. If it were found that an erroneous judgment had been given, the wrong was redressed and the original jury incurred infamy, with imprisonment and forfeiture of their goods, which punishments were, however, commuted later for a pecuniary penalty. In criminal cases a writ of attaint was issued at suit of the king, and in civil cases at the suit of either party. In criminal cases it appears to have become obsolete by the end of the 15th century, although juries were sometimes fined by the Star Chamber for acquittal. Procedure by attaint in civil cases had also been gradually giving place to the practice of granting new trials, and after the decision in Bushell's case in 1670 (see PRACTICE AND PROCEDURE) it became obsolete, and was finally abolished by the Juries Act 1825, except as regards jurors guilty of embracery (*q.v.*).

ATTALEIA, an ancient city of Pamphylia, which derived its name from Attalus II., king of Pergamum; the modern Adalia (*q.v.*). It was important as the nearest seaport to the rich districts of south-west Phrygia. A much-frequented "half-sea" route led through it to the Lycus and Meander valleys, and so to Ephesus and Smyrna. This was the natural way from any part of central Asia Minor to Syria and Egypt, and accordingly we hear of Paul and Barnabas taking ship at Attaleia for Antioch. Originally the port of Perga, Attaleia eclipsed the old Pamphylian capital in early Christian times and became the metropolis. There are extensive remains of the ancient walls. The most conspicuous monument is the triple Gate of Hadrian, flanked by a tower built by the empress Julia.

ATTALUS, the name of three kings of ancient Pergamum.

Attalus I., Soter, king of Pergamum, succeeded Eumenes I. at Pergamum in 241 B.C. Soon after his accession (perhaps 235) he defeated the Galatians in a great battle, as a result of which he took the title of king, and by defeating Antiochus Hierax extended his boundaries over a large area in Asia Minor. Most of the rest of his life was occupied with wars against Philip V. of Macedon. He fought with Rome and the Aetolians against Philip and the Achaeans in 211, and joined in the general peace made in 204. In 201 war again broke out between Philip and Rhodes,

and Attalus joined the Rhodians. He died at Pergamum in 197. During his reign the court of Pergamum was one of the centres of Hellenistic culture. A Pergamese school of sculpture arose, stimulated by the dedication of votive figures to the great shrines after the victory over the Galatians, of which the so-called "Dying Gladiator" is one. There was equal activity on the literary side; there were a great library and a Stoic Academy.

Attalus II., king of Pergamum, was born in 200 B.C. He served as a general under his brother Eumenes II. and commanded the Pergamene contingent that served the Romans in their expeditions in Galatia (189) and Greece (171). He visited Rome frequently as an ambassador, and succeeded his brother in 159. Secure in his alliance with Rome, he played a successful part in the wars and diplomacy of the East, though Rome had to intervene actively when he was besieged in his capital by Prusias II. of Bithynia in 154. Under Attalus II. Pergamum retained its rank as a centre of Hellenistic culture, and is especially notable for Crates, the Homeric critic. He died in 138.

Attalus III., Philometor, succeeded his uncle Attalus II. in 138 B.C. A very different type of ruler from his predecessors, he introduced the Pergamese to the methods of Asiatic tyranny, from which they had previously been secure. After pursuing an eccentric career, largely devoted to gardening and sculpture, he died in 133. The sole importance of his reign lies in his will. As the last of the Attalic house he could dispose of the sovereignty, and he bequeathed it to Rome. Rome accepted it and became involved in a struggle with the pretender Aristonicus (*q.v.*).

BIBLIOGRAPHY.—Ancient authorities are: Polybius xvi., Livy, xxxviii. *et* seq. Modern: M. H. E. Meier, "Pergamenisches Reich," in d. allg. Encyc. d. *Wiss. u. Künste,* xvi, pp. 356 ff. (1842); E. Thraemer, Pergamos (Leipzig, 1888); J. Mahaffy, Alexander's Empire (1887).

ATTAR OF ROSES, a perfume prepared by macerating or distilling roses, mainly the Rosa damascena. The essential oil obtained is a beautiful, precious and very costly material, costing as much as £50 a pound. Some 250 lbs. of roses are needed to make a single ounce of the attar, which means that several ac. of land yield only that small quantity of the perfume. The word attar, sometimes corrupted as "otto," is from the Persian 'attar, essence. The manufacture is chiefly oriental, in India and Persia, but it is also carried on in France and the Balkans.

ATTEMPT, in law, an act done with intent to commit a crime, and forming one of a series of acts which would constitute its actual commission if it were not interrupted. Mere intention to commit a crime is not sufficient, and an attempt must proceed to an overt act, but at the same time it must fall short of the ultimate purpose in any part of it. A person may be guilty of an attempt to commit a crime, even if its commission in the manner proposed was impossible. Every attempt to commit a felony or misdemeanour is in itself a common law misdemeanour, punishable by fine or imprisonment, unless the attempt to commit is specifically punishable by statute as a felony, as in the case of attempted murder, or in a defined manner as a misdemeanour; and a person who has been indicted for a felony or misdemeanour may, if the evidence so warrants, be found guilty only of the attempt.

ATTENTION. The term is employed in psychology sometimes in a wider, and sometimes in a narrower sense. In the narrower sense, which coincides more or less with the popular use of the term, attention means that mental process by which some object comes to be apprehended more clearly or distinctly than before it was attended to, or by which one object occupies the focus of consciousness while others (to which attention is not directed) are in the margin or periphery of consciousness. In the wider sense of the term attention denotes the mental process in virtue of which anything becomes an object of consciousness at all, as compared with the multitude of stimuli which never find entry into consciousness, although they are within reach of the observer. The wider sense is the more convenient, provided it is recognized that there are many degrees of attention varying from what is commonly called inattention (that is, a very low degree of attention) to the highest concentration. Attention in all its forms, and especially in its higher forms, is a process of selection, a form of preferential treatment — some things are admitted into consciousness whereas others are not, or some are placed in the very centre of consciousness whereas others are relegated to the margin. It is largely by the exercise and distribution of attention that the human mind may be said to assert itself against becoming the passive target of external stimulations.

The general effect of attention is that a certain object is admitted into consciousness while others are excluded, or that an object which receives more attention is apprehended more clearly. The resulting difference is not a difference in intensity but a difference in clearness. When, *e.g.,* special attention is concentrated on the first violin in a trio its notes do not become louder but clearer. One rarely mistakes an increase in clearness for an increase in intensity. Only some people confuse the two merely because both changes have the same kind of effectin so far as the object in question is helped to occupy a more central place in consciousness. For, as will be pointed out presently, the intensity of a stimulus, and therefore an increase in intensity, is one of the conditions which help to determine attention or to attract attention to the stimulus, and so give it a prominent place in consciousness. A negative result of attention directed to any object is that other objects receive either no attention or less attention than they would otherwise receive, that is to say they are either excluded from the field of consciousness or are relegated to a back place.

The conditions which influence the direction of attention to some objects rather than to others are of two principal kinds. The direction of attention is determined partly by the nature of the objects claiming attention, and partly by the disposition and character of the individual mind or subject exercising attention. The two sets of conditions may accordingly be described as the objective and the subjective conditions respectively.

Objective Conditions. — The objective conditions of attention are to be sought mainly in the intensity, volume, duration, and novelty of the objective stimulus claiming attention. A brilliant light or a shrill noise is more likely to attract attention than a feeble light or a soft sound. Again, within certain limits, a stimulus of longer duration is more likely to attract attention than a momentary one. Similarly a large object is more likely to be noticed than a small one. But most important of all the objective conditions is novelty, or change from preceding stimulation. Though the duration of a stimulus is favourable to its being noticed, yet a point is soon reached when its very sameness leads to its being ignored in favour of some new stimulus or some change in an existing stimulus. Change as such tends to attract attention. The sudden cessation in the motion of a mill or in the ticking of a clock will be noticed when the preceding uniform sound of either has ceased to attract attention. The importance of change of stimulus (including movement or apparent movement) in attracting attention is realized and exploited by the purveyors of luminous advertisements.

Subjective Conditions. — The subjective conditions of attention turn mainly on the momentary pre-occupations or the permanent interests of the individual mind. We may distinguish several forms in which such pre-occupations or interests may influence the direction of attention. First, there is the influence of the idea or experience which happens to occupy our attention at the moment, or did so shortly before. If we happen to be thinking of an object, it will attract our attention even under conditions in which it would otherwise have escaped our notice. Similarly a distant aeroplane though difficult to locate at first may be easily followed once it has been observed or spotted. Secondly, there is the mental *attitude* of the individual at the moment. A mental attitude is a kind of limited orientation. It favours whatever appears relevant to it, and resists everything else. In its simplest and most obvious form the general nature of a mental attitude is exemplified when a question occurs to one spontaneously, or is put to us by somebody else. The effect is a certain kind of expectancy and preparedness for anything that may help to answer the question or to solve the problem. If one is asked, or asks himself, about the architectural character of a clock-tower in front of him, he will attend to its architectural character, and

probably fail to note the time indicated by the clock; if he is asked the time, he will note this, and probably fail to observe the architectural form of the tower, or even the character of the numerals on the face of the clock, until he is asked whether they are Roman or Arabic, etc. On the whole it is remarkable how little most people really notice for which their mental attitude is not set. This is not altogether to be regretted, for it means a certain economy of mental effort. Lastly, there is the influence of one's entire previous training, that is, one's general mental outlook or orientation, or his dominant disposition or permanent interests, as determined by his whole previous education, in the widest sense of the term. In a miscellaneous exhibition different people will direct their attention to different exhibits according to their knowledge of the different fields of interest to which the objects belong. Of the miscellaneous contents of a newspaper different parts will similarly attract the attention of different people according to their previous training. Even if they all read the major portion of the newspaper, they will read the several parts each in a different order.

Various Kinds of Attention. — Psychologists usually distinguish various kinds of attention, and the classification is based on various grounds. Sometimes the classification is based on the differences in the kind of objects to which attention is directed. In this case we get the distinction between *sensorial attention* and *ideational attention,* according as the object attended to is a sensible object or an idea. More important are the distinctions based on the effort exerted. This distinction, however, is intimately bound up with that of interest. And the otherwise laudable attempt to combine both these bases in one scheme of classification has led to a somewhat inconsistent use of terms in this connection, the trouble being mainly due to the ambiguity of the epithet "voluntary," which is sometimes used in the sense of "involving volition" or effort, and sometimes in the sense of "free" or "willing" or "spontaneous," "not constrained." The most important distinctions may be indicated as follows: It is a familiar experience that we sometimes pay attention to something because it interests us, whereas at other times we attend to things by an effort of will. The former is called *attention from interest,* the latter is called *attention from effort.* The former is usually spontaneous and easy, the latter is often unpleasant and a strain. The former, again, is frequently called *spontaneous attention,* the latter *volitional or voluntary attention.* Again, attention is sometimes attracted by the mere intensity of some external stimulus such as a loud noise or a flash of light. The attention in this case involves no effort at all, and the object may or may not prove interesting. Such attention is often called *involuntary attention,* because it is often exercised in spite of our wish to attend to something else.

The Duration of Attention. — The concentration of attention upon some object or thought may continue for a considerable time among normal people. But what is commonly called an object or a thought is something very complex having many parts or aspects, and our attention really passes from part to part, backwards and forwards all the time. Our attention to what can be seriously called a single thing, affording no opportunities for the movement of attention from part to part, say a small patch of colour, cannot be held for more than about a second without serious risk of falling into a hypnotic trance or some similar pathological condition.

The Span of Attention. — How many objects can be attended to at one time? Many people have the impression that they can attend to a number of things at the same time. What really happens in such cases is that their attention alternates from one object to another, so that they really do attend to a multiplicity of things within a given time, only successively. But if the expression "at one time" is taken strictly, then it seems very doubtful whether more than one object (or at most a group of four or five things forming one object) can be attended to at once. When, in experiments on attention, objects are exposed for a small fraction of a second, then as a rule only one object is apprehended. Even when with somewhat longer exposures four or five objects appear to be apprehended by the subject there is some ground for supposing that most of them are really observed in the form of after-images rather than as direct percepts.

Abnormalities of Attention. — In normal life one does not always concentrate one's attention on anything special, but scatters it somewhat diffusely over a number of objects, passing more or less rapidly from one thing to another. This is healthy up to a point — it is a form of mental relaxation. But when such a state of comparative inattention becomes chronic, it is a symptom of a pathological mental condition. There are so-called "scatter-brained" people who are constitutionally incapable of concentrating attention on anything for long. If they enquire about anything their interest in it seems exhausted by the time they have put the question, and they proceed to put another question before the first has been answered. This condition is sometimes a passing phase with children, but chronic with the feeble-minded, or the mentally unstable. The opposite abnormality to such instability of attention is seen in people suffering from "fixed ideas." Even in normal life people sometimes concentrate attention on some one object or problem to such an extent that, for the time being, they are absorbed in it, and oblivious of everything else. This state of mind often betrays itself in what is called absent-mindedness, that is, inattention to most things because of special concentration on others. Up to a point this state, too, is healthy and effective. But when it becomes chronic and excessive it ends in a variety of abnormalities ranging from the harmless crank, to the fanatic, and the person suffering from fixed ideas and illusions from which he cannot divert his attention.

ATTENUATION, in radio communication, is the reduction in power of a wave or a current with increasing distance from the source of transmission. Attenuation of an electric current or wave is ordinarily the result of the absorption or loss of power in certain elements of the circuit or transmission path. In some electrical circuits, particularly for currents of audio-frequencies, it is possible to make substantially equal the total attenuation for all frequencies within a certain range. A device used for this purpose is called an attenuation equalizer.

ATTERBOM, PER DANIEL AMADEUS (1790–1855), Swedish poet, son of a country parson, was born in the province of Östergötland. He studied in the university of Uppsala (1805–15) and became professor of philosophy there in 1828, and of aesthetics and literature in 1835. He was the first great poet of the romantic movement which was to revolutionize Swedish literature.

In 1807 he founded at Uppsala an artistic society, the Aurora League, whose first newspaper, *Polyfem,* was a crude effort, soon abandoned; but in 1810 there began to appear a journal, *Fosforos,* edited by Atterbom, which lasted for three years and found a place in classic Swedish literature. It consisted of poetry and aesthetico-polemical essays; it introduced the study of the new Romantic school of Germany, and formed a vehicle for the early works, not of Atterbom only, but of Hammerskold, Dahlgren, Palmblad and others. Later, the members of the Aurora League established the *Poetisk Kalender* (1812–22), in which their poems appeared, and a new critical organ, *Svensk Litteraturtidning* (1813–24).

Of Atterbom's independent works, the most celebrated is *Lycksalighetens O (The Fortunate Island),* a romantic drama published in 1824. Previously he had published a cycle of lyrics, *Blommorna (The Flowers),* of a mystical character somewhat in the manner of Novalis. Of a dramatized fairy tale, *Fagel bla (The Blue Bird),* only a fragment, which is among the most exquisite of his writings, is preserved. His *Svenska Siare och skalder* (1841–55, supplement, 1864), a series of biographies of Swedish poets and men of letters, forms a history of Swedish letters down to the end of the "classical" period. Atterbom's works were collected (13 vols., Örebro) in 1854–70.

ATTERBURY, FRANCIS (1662–1732), English man of letters, politician and bishop, was born at Milton, Bucks, the son of a clergyman. Educated at Westminster School and Christ Church, Oxford, he became a tutor of his college. He took holy orders in 1687, and was appointed one of the royal chaplains, but most of his time was spent in Oxford, where he was the chief

adviser of Dean Aldrich under whom Christ Church had become a centre of Toryism. He stood behind Charles Boyle in his attack on Richard Bentley, and in the *Rattle of the Books* S ift calls him the Apollo who directed the fight. In the high and low church controversy he was a witty and audacious champion of the high church clergy against what they regarded as the oligarchy of Erastian prelates. He was rewarded by the archdeaconry of Totnes, a prebend in Exeter Cathedral, and, after Queen Anne's accession, the deanery of Carlisle. In 1710 the prosecution of Sacheverell gave Atterbury another opportunity for the use of his powers of sarcasm and invective. He helped to frame the brilliant speech which the accused delivered at the bar of the House of Lords. With the fall of the Whigs his triumph came.

As prolocutor of the lower house of convocation, he drew up in 1711 the famous *Representation of the State of Religion,* and in August of that year Queen Anne, who had come to rely on Atterbury for advice in ecclesiastical matters, appointed him dean of Christ Church. He was not a good college administrator, and in 1713 was removed from Oxford to be bishop of Rochester.

Probably Atterbury was one of those who hoped to arrange matters so that at Queen Anne's death the act of succession could be easily set aside in favour of James Stuart, but on the accession of George I. he took the oath of allegiance and sought to ingratiate himself with the new court, though without success. He then violently opposed the new Government by his brilliant speeches in the House, and anonymously by pamphlets against the Hanoverians. When the rebellion of 1715 broke out in favour of the Pretender he refused to sign the address in which the bishops of the Province of Canterbury declared their attachment to the royal house, and in 1717 he began to correspond directly with the Pretender.

Atterbury was implicated in a plot in 1721 for the restoration of the Stuarts, and spent some months in the Tower in 1722. The evidence against him was insufficient for legal conviction, and recourse was had to a special bill in Parliament by which he was deprived of his ecclesiastical dignities and banished for life. For some years he was principal adviser to James, but, finding that his counsels were disregarded, he retired to Montpelier. For a brief period before his death on Feb. 22 1732, he was again in the Pretender's service. His remains were brought to England and secretly buried in Westminster Abbey.

In private life Atterbury was gentle and forbearing, and showed none of the acerbity and violence of the pamphleteer. Between him and his daughter, Mrs. Morice, there was tender affection; when he was ill in France she went over at the risk of her life to see him, and died immediately on her arrival. He was a close friend of Addison, and was on excellent terms with Pope, Swift, Arbuthnot and Gay.

See F. Williams, *Memoirs and Correspondence of Atterbury witlz Notes,* etc. (1869); *Stuart Papers,* vol. i.: *Letters of Atterbury to the Chevalier St. George,* etc. (1847); J. Nichols, *Epistolary Correspondence,* etc. (1783–96); and H. C. Beechmg, *Francis Atterbury* (1909).

ATTESTATION, the verification of a deed, will, or other instrument by the signature to it of a witness or witnesses, who subscribe to a memorandum, to the effect that it was signed or executed in their presence, showing that at the execution of the document there was present some disinterested person capable of giving evidence as to what took place. In Scots law, the corresponding clause is called the tecting-clause [*see* DEED; WILL (TESTAMENT); WITNESS].

AT THE MARKET, a term used in instructions to brokers in securities or commodities authorizing them to buy or sell at the most favourable price as promptly as possible after the order is given. Brokers receiving orders on such terms convey them to the exchange floor at once, where the floor trader will attempt to put through the trade upon the best possible terms for his customer. While no price is named and no price limit is set, the broker is expected to make the purchase or sale within a fraction of the price set by the last transaction in the same security or commodity.

ATTHIS (an adjective meaning "Attic"), the name given to a monograph or special treatise on the religious and political history, antiquities and topography of Attica and Athens. During the 4th and 3rd centuries B.C., a class of writers arose, who, making these subjects their particular study, were called atthidographi, or compilers of atthides. The first of these was Clidemus or Clitodemus (about 378 B.C.); the last, Ister of Cyrcne (d. 212 B.C.); the most important was Philochorus (first half of the 3rd century B.C.), of whose work considerable fragments have been preserved.

Fragments in Müller, *Fragmenta Historicorum Graecorum,* i.

ATTIC, in architecture, any portion of wall raised above the main cornice, utilized by the Romans principally for decorative purposes, inscriptions, etc., as in triumphal arches. It was developed in the Renaissance as an important part of a façade, frequently enclosing an additional storey, the windows of which were treated as part of the decoration. In modern usage the word is also employed to designate a storey immediately under the roof, especially when the roof is of steep pitch.

ATTICA, a triangular district of ancient Greece, with the chain of Mts. Cithaeron and Parnes as its base and Sunium as its apex. It is washed on two sides by the Aegean sea, and the coast is broken up into small bays and harbours, exposed to the south wind. Attica is very mountainous, and between the mountain chains lie several small plains open to the sea. On the west its natural boundary is the Corinthian gulf, so that it would include Megaris; indeed, before the Dorian invasion, which resulted in the foundation of Megara, the whole country was politically one, in the hands of the Ionian race. This is proved by the column which, as we learn from Strabo, once stood on the Isthmus of Corinth, bearing on one side in Greek the inscription, "This land is Peloponnesus, not Ionia," and on the other, "This land is not Peloponnesus, but Ionia."

Mountains.—The mountains of Attica continue the chain from Tymphrestus at the south end of Pindus, through Phocis and Boeotia (Parnassus and Helicon); from this proceeds the range which, as Cithaeron (4,600ft.) in the west and Parnes

FROM MURRAY, HANDY CLASSICAL MAPS

MAP OF ANCIENT ATTICA AND SOME OF ITS COASTAL ISLANDS. INCLUDING AEGINA

(4,600ft.) in the east, separates Attica from Boeotia, throwing off spurs southward towards the Saronic gulf in Aegaleos (1,534ft.) and Hymettus (3,370ft.), which bound the plain of Athens. The east end of Parnes is joined by another line of hills, which, separating from Mt. Oeta, skirts the Euboic gulf, and, after entering Attica, throws up the lofty pyramid of Pentelicus (3,635ft.), overlooking the plain of Marathon, and then sinks towards the sea at Sunium to rise once more in the outlying islands, Finally, in the extreme west, Cithaeron bends round at

right angles in the direction of the isthmus, at the northern approach to which it abuts against the mighty mass of Mt. Geraneia, between the Corinthian and the Saronic gulf.

Soil.—The soil is light and thin, and requires very careiul agriculture on the rocky mountain sides and in the maritime plains. This enforced industrious habits on the inhabitants and encouraged seafaring. The level ground was sufficiently fertile to form a marked contrast to the rest of the district. Thucydides attributes to the unattractive nature of the soil (i. 2 τὸ λεπτόγεων), the permanence of the same inhabitants in the country, whence arose the claim to indigenousness on which the Athenians prided themselves; while at the same time the richer ground fostered that fondness for country life spoken of by Aristophanes. The fact that out of the 182 demes (*see* CLEISTHENES) into which Attica was divided, one-tenth were named from trees or plants points to less aridity in ancient times.

Climate.—In approaching Attica from Boeotia a change of temperature is felt as soon as a person descends from Cithaeron or Parnes, and the sea breeze moderates the heat in summer. So Euripides describes the inhabitants as "ever walking gracefully through the most luminous ether" (*Med.* 829).

Again Xenophon says "one would not err in thinking that this city is placed near the centre of Greece—nay, of the civilized world—because, the farther removed persons are from it, the severer is the cold or heat they meet with" (Vectigal. 1. 6). The air is so clear that one can see from the Acropolis the lines of white marble that streak the sides of Pentelicus. The brilliant colouring of the Athenian sunsets is due to the same cause. The epithet "violet-crowned," used of Athens by Pindar, is due either to the blue haze on the surrounding hills, or to the use of violets (or irises) for festal wreaths. The prevalence of the north wind is expressed on the Horologium of Andronicus Cyrrhestes, called the Temple or Tower of the Winds, at Athens.

Vegetation.—Sophocles (Oed. Col. 700) shows that the olive flourished specially in Attica (see also Herodotus v. 82). In the legend of the struggle between Poseidon and Athena, for the patronage of the country, the sea-god is represented as having to retire vanquished before the giver of the olive; and the evidences of this contention were an ancient olive tree in the Acropolis, together with three holes in the rock, said to have been made by the trident of Poseidon. The fig also throve and Demeter was said to have bestowed it as a gift on the Eleusinian Phytalus, *i.e.*, "the gardener." Cithaeron and Parnes were formerly wooded; for on the former are laid the picturesque sylvan scenes in the Bacchae of Euripides, and it was from the latter that the wood came which caused the neighbouring deme of Acharnae to be famous for its charcoal—the ἄνθρακες Παρνήσιοι of the *Acharnians* of Aristophanes (348). From the thymy slopes of Hymettus came the famous Hymettian honey.

Minerals.—The pure white marble of Pentelicus used for the Athenian temples, and the blue marble of Hymettus—the trabes *Hymettiae* of Horace, used for Roman palaces, were famous. The silver mines of Laurium rendered silver the principal medium of exchange in Greece, so that "a silver piece (ἀργύριον) was the Greek name for money. Aeschylus speaks of the Athenians as possessing a "fountain of silver" (Pers. 235), and Aristophanes makes his chorus of birds promise the audience that, if they show him favour, owls from Laurium (*i.e.*, silver pieces with the emblem of Athens) shall never fail them (Birds, 1106). The purity and accurate weight of the Laurium coins gave them a wide circulation. (See further NUMISMATICS: Greek, § Athens.) In Strabo's time the mines had almost ceased to yield, but silver was obtained from the scoriae; and at the present day lead is got in the same way, chiefly by two companies, one of which is French and the other Greek. Two thousand shafts and galleries of the ancient mines remain.

Plain of **Megara.**—The plain of Megara was geographically linked with Attica. It commanded the three passes into the Peloponnese, one a long detour along the shores of the Corinthian gulf; the other two starting from Megara, and passing, the one over the ridge of Geraneia, the other along the Saronic gulf, under the dangerous precipices of the Scironian rocks.

Plain of **Eleusis.**—To the east of Megara lies Eleusis, bounded on the one side by the chain of Kerata, and on the other by that of Aegaleos, through a depression in which was the line of the sacred way, where the torchlight processions from Athens used to descend to the coast, the "brightly gleaming shores" (λαμπάδες ἀκταί) of Sophocles (Oed. Col. 1,049). The deep bay which here runs into the land is bounded on its southern side by the rocky island of Salamis. The winding channel which separates that island from the mainland in the direction of the Peiraeeus was the scene of the battle of Salamis. The east of the plain of Eleusis was called the Thriasian plain, and the city itself was situated in the recesses of the bay just mentioned.

Plain of Athens.—Next in order to the plain of Eleusis came that of Athens, the most extensive, reaching from the foot of Parnes to the sea, and bounded on the west by Aegaleos, and on the east by Hymettus. Its most conspicuous feature is the broad line of dark green along its western side, formed by the olive-groves of Colonus and the gardens of the Academy, watered by the Cephisus. This river, unlike the other rivers of Attica, has a constant supply of water, from its sources on Mt. Parnes, which was diverted in classical times, as it still is, into the neighbouring plantations (cf. Sophocles, Oed. *Col.* 685). The two bare knolls of light-coloured earth caused the poet in the same chorus to apply the epithet "white" (ἀργῆτα) to Colonus. The Ilissus river, rising in Mt. Hymettus and skirting the east of Athens, is a mere brook, which disappears in summer. Three roads lead to Athens from the Boeotian frontier over the mountain barrier—the easternmost over Parnes, from Delium and Oropus by Decelea, the usual route of the invading Lacedaemonians during the Peloponnesian war; the westernmost over Cithaeron, by the pass of Dryocephalae, or the "Oakheads," from Thebes by Plataea to Eleusis, and so to Athens, along which the Plataeans escaped during the siege of Plataea in the Peloponnesian war. The third, midway between the two, by the pass of Phyle, near the summit of which, overlooking the Athenian plain, is the fort occupied by Thrasybulus in the days of the Thirty Tyrants. On the sea-coast to the south-west of Athens rises the hill of Munychia, a mass of rocky ground, forming the acropolis of the town of Peiraeeus. The ground which joins it to the mainland is low and swampy, alluvial soil brought down by the Cephisus and according to Strabo was at one time an island. On one side of this, towards Hymettus, lay the open roadstead of Phalerum, on the other the harbour of Peiraeeus, a completely land-locked inlet, safe, deep and spacious, the approach to which was still further narrowed by moles. On the east are the small harbours of Zea and Munychia.

Eastern Attics.-The north-eastern boundary of the plain of Athens is formed by the graceful pyramid of Pentelicus, commonly known as Brilessus in ancient times. Between it and Hymettus intervenes a level space of ground zm. wide, which formed the entrance to the Mesogaea, an elevated undulating plain in the midst of the mountains, reaching nearly to Sunium. At the extremity of Hymettus, where it projects into the Saronic gulf, was the promontory of Zoster ("the Girdle"), so called because it girdles and protects the neighbouring harbour. From this promontory to Sunium there runs a lower line of mountains, and between these and the sea is the fertile strip of land called the Paralia. Beyond Sunium, on the eastern coast, were two safe ports, Thoricus, defended by the island of Helene, forming a natural breakwater in front of it, and Prasiae, now called Porto Raphti ("the Tailor"), from a statue at the entrance. In the north-east corner between Parnes, Pentelicus and the sea is the little plain of Marathon (*q.v.*), the scene of the battle against the Persians (490 B.C.). The bay in front is sheltered by Euboea, and on the north by a projecting tongue of land, called Cynosura.

One district of Attica, the territory of Oropus, belonged to Boeotia, as it was situated to the north of Parnes; but the Athenians always endeavoured to retain it, because it facilitated their communications with Euboea, which was of the utmost importance to them; for, if Aegina should rightly be called "the eyesore of the Peiraeeus," Euboea was quite as truly a thorn in the side of Attica; Demosthenes (De *Cor.*, p. 307) records the ravages of the Euboean pirates.

ATTIC BASE, the term given in architecture to any column base (*q.v.*) consisting of an upper and lower torus separated by a scotia. Used first by the Greeks in connection with the Ionic order, it became the favourite base of the Romans and is common in Byzantine, Romanesque and early Gothic work.

ATTICISM. (1) Taking the side of Athens in the Peloponnesian war, a word formed similarly to *medism* (taking the side of Persia in the Persian war); (2) the artificial imitation of Attic Greek in Hellenistic literature. (*See* GREEK LITERATURE.)

ATTICUS, TITUS POMPONIUS (109–32 B.C.), Roman patron of letters, was born at Rome three years before Cicero, with whom he was educated. His name was Titus Pomponius, that of Atticus being given him afterwards from his long residence in Athens (86–65) and his intimate acquaintance with the Greek literature and language. When Pomponius was still a young man his father died, and he prudently transferred himself and his fortune to Athens, in order to escape the civil war, in which he might have been involved through his connection with the murdered tribune, Sulpicius Rufus. Here he lived in retirement, devoting himself entirely to study. On his return to Rome, he assumed the name of Quintus Caecilius Pomponianus. From this time he kept aloof from political strife, attaching himself to no particular party, and continuing on intimate terms with men so opposed as Caesar and Pompey, Antony and Octavian. His most intimate friend, however, was Cicero, whose correspondence with him extended over many years. His private life was tranquil and happy. He did not marry till he was 53 years of age, and his only child became the wife of Marcus Vipsanius Agrippa, the distinguished minister of Augustus. In 32, being seized with an illness believed to be incurable, he starved himself to death. Of his writings none is extant, but mention is made of two: a Greek history of Cicero's consulship, and some annals forming an epitome of Roman history down to the year 54. His most important work was his edition of the letters addressed to him by Cicero. He formed a large library at Athens, and engaged a staff of slaves to make copies of valuable works.

See Life by Cornelius Nepos; Berwick, *Lives of Messalla Corvinus and T.P.A.* (1813); Fialon, *Thesis in T.P.A.* (1861); Boissier, *Cicéron et ses amis* (1888; Eng. trans. A. D. Jones, 1897); W. H. How, *Cicero: Select Letters* (Oxford, 1926) vol. ii. Appendix ii. A translation of Cicero's Letters to Atticus by E. O. Winstadt is published in the Loeb Classical Library (1912).

ATTICUS HERODES, TIBERIUS CLAUDIUS (*c.* A.D. 101–177), Greek rhetorician, celebrated among his contemporaries. In 125 Hadrian appointed him prefect of the free towns of Asia, and in 140 he was summoned by Antoninus Pius to undertake the education of Marcus Aurelius and Lucius Verus, and received many marks of favour, amongst them the consulship (143). He is principally celebrated, however, for the vast sums he expended on public purposes. He built at Athens a race-course of Pentelic marble, and a music theatre, called the Odeum, which still exists. At Corinth he built a theatre, at Delphi a stadium, at Thermopylae hot baths, at Canusium, in Italy, an aqueduct. He even contemplated cutting a canal through the Isthmus of Corinth. Many of the partially ruined cities of Greece were restored by Atticus, and numerous inscriptions testify their gratitude. Of his many works, the only one extant is a speech "On the Constitution" (ed. Hass, 1880).

ATTILA (d. 453), king of the Huns, became king in 433 on the death of his uncle Roua. In the first eight years of his reign Attila was chiefly occupied in the wars with other barbarian tribes, by which he made himself virtually supreme in Central Europe. His own special kingdom comprised the countries which are now called Hungary and Transylvania, his capital being possibly near the modern city of Buda-Pest; but having made the Ostrogoths, the Gepidae and many other Teutonic tribes his subject-allies, and having also sent his invading armies into Media, he seems for nearly 20 years to have ruled practically without a rival from the Caspian to the Rhine.

Early in his reign, Honoria, grand-daughter of the Emperor Theodosius II., being subjected to severe restraint on account of an amorous intrigue with one of the chamberlains of the palace, sent her ring to the king of the Huns, and called on him to be her husband and her deliverer. Nothing came of the proposed engagement, but the wrongs of Honoria, his affianced wife, served as a pretext for some of the constantly recurring embassies with which Attila worried the two courts of Constantinople and Ravenna.

One of the return embassies from Constantinople (448) had the advantage of being accompanied by a rhetorician named Priscus, whose minute account of the negotiations, including a vivid picture of the great Hun in his banquet-hall, is by far the most valuable source of information as to Attila's court and camp. In the ambassador's suite there was an interpreter named Vigilas, who for 50 pounds of gold had promised to assassinate Attila. This design was discovered by the Hunnish king, but had not been revealed to the head of the embassy or to his secretary.

The new Emperor Marcian answered the insulting message of Attila in a manlier tone than his predecessor. Accordingly the Hun now turned upon Valentinian III., the trembling emperor of the west, and demanded redress for the wrongs of Honoria, and one-half of Valentinian's dominions as her dowry. Allying himself with the Franks and Vandals, he led his vast many-nationed army to the Rhine in the spring of 451, crossed that river, and sacked, apparently, most of the cities of Belgic Gaul, finally reached the Loire and laid siege to the strong city of Orléans. The citizens, under the leadership of their bishop, Anianus, made a heroic defence, but the place was on the point of being taken when, on June 24, the allied Romano-Gothic army of Aëtius and Theodoric, king of the Visigoths, was seen on the horizon. Attila turned again to the north-east, halted near Troyes, in the Catalaunian plains, and offered battle to his pursuers.

The battle (Chalons) which followed—one of the decisive battles of the world—has been well described by the Gothic historian, Jordanes, as "ruthless, manifold, immense, obstinate." It lasted for the whole day, and the carnage was terrible. The Visigothic king was slain, but the victory, though hardly earned, remained with his people and his allies. Attila retreated, apparently in good order, on the Rhine, recrossed that river and returned to his Pannonian home. Thence in the spring of 452 he again set forth to ravage or to conquer Italy. After a stubborn contest, he took and utterly destroyed Aquileia, the chief city of Venetia, and burned the cities at the head of the Adriatic, Concordia, Altinum and Patavium (Padua). The fugitives, seeking shelter in the lagoons of the Adriatic, laid the foundations of the future city of Venice. Upon Milan and the cities of western Lombardy the hand of Attila seems to have weighed more lightly, plundering rather than utterly destroying; and he yielded to the entreaty of Pope Leo I. and consented to cross the Alps, with a menace, however, of future return, should the wrongs of Honoria remain unredressed. But no further expeditions to Italy were undertaken by Attila, who died suddenly in 453, in the night following a great banquet which celebrated his marriage with a damsel named Ildico.

Under his name Etzel, Attila plays a great part in Teutonic legend (see NIBELUNGENLIED) and under that of Atli in Scandinavian Saga, but his historic lineaments are greatly obscured in both. He was short of stature, swarthy and broad-chested, with a large head and hair which early turned grey, snub nose and deep-set eyes. He walked with a proud step, darting a haughty glance this way and that as if he felt himself lord of all.

See Priscus, Jordanes, the *Historia Miscella,* Apollonius Sidonius and Gregory of Tours, who are the chief authorities for Attila's life.

ATTIS or **ATYS,** a deity worshipped in Phrygia, and later throughout the Roman empire, in conjunction with the Great Mother of the Gods. Their worship included the celebration of

mysteries annually on the return of the spring season. Attis was confused with Pan, Sabazius (*q.v.*), Mēn and Adonis, and there were resemblances between the orgiastic features of his worship and that of Dionysus. His resemblance to Adonis has led to the theory that the names of the two are identical, and that Attis is only the Semitic companion of Syrian Aphrodite grafted on to the Phrygian Great Mother worship. It is likely, however, that Attis, like the Great Mother, was indigenous to Asia Minor, adopted by the invading Phrygians, and blended by them with a deity of their own.

Legends.—According to Pausanias (vii. 17), Attis was a beautiful youth born of the daughter of the river Sangarius, who was descended from the hermaphroditic Agdistis, a monster sprung from the earth by the seed of Zeus. Having become enamoured of Attis, Agdistis struck him with frenzy as he was about to wed the king's daughter, with the result that he deprived himself of manhood and died. Agdistis in repentance prevailed upon Zeus to grant that the body of the youth should never decay or waste. In Arnobius (v. 5–8) Attis emasculates himself under a pine tree, at the foot of which violets sprang from his blood, like the flower called after him from that of Hyacinthus (*q.v.*). The Great Mother and Agdistis carry the pine-tree to her cave, where they wildly lament the death of the youth. Zeus grants the petition as in the version of Pausanias, but permits the hair of Attis to grow, and his little finger (which has been interpreted as the phallus) to move. In Diodorus (iii. 58–59) the Mother is the carnal lover of Attis, and when her father the king discovers her fault and kills her lover, roams the earth in wild grief. In Ovid, (*Fasti,* iv. 223 *et seq.)* she is inspired with chaste love for him, which he pledges himself to reciprocate. On his proving unfaithful, the Great Mother slays the nymph with whom he has sinned, whereupon in madness he mutilates himself as a penalty. Another form of the legend (Paus. vii. 17), showing the influence of the Aphrodite-Adonis myth, relates that Attis, the impotent son of the Phrygian Caläus, went into Lydia to institute the worship of the Great Mother, and was there slain by a boar sent by Zeus.

Attis was originally a god of vegetation, or tree-spirit, as is indicated by his association with the pine-tree, into which he was said to have been afterwards changed. In his self-mutilation, death and resurrection he represents the fruits of the earth, which die in winter only to rise again in spring.

See GREAT MOTHER OF THE GODS; J. G. Frazer, *Adonis, Attis, Osiris* (1906) and *The Golden Bough* (abridged edition, 1922).

(G. S.)

ATTITUDE. The term is mostly used in psychology to denote a certain disposition or preparedness to attend to certain objects or certain parts of objects rather than others. This is one of the most important subjective conditions of attention (*q.v.*) Its influence manifests itself not only in waking life but even in sleep. A mother's attitude is "set" for her child, and she will hear the child's movements though deaf to other, louder noises. The term is also used sometimes in a physical or physiological sense to denote a certain condition of partial stimulation or nascent excitation of nerve centres, which may help to explain the phenomena of habit (*q.v.*).

ATTLEBORO, a city of Bristol county in southeast Massachusetts, U.S.A., 12 mi. N.E. of Providence. It is served by the New York, New Haven and Hartford railroad. The area is 28 sq. miles. The population was 21,769 in 1930, of whom 4,765 were foreign born; and 22,071 in 1940.

There were 708 employed in retail selling, and retail sales were $7,551,000 in 1939. The 121 manufacturing establishments, with 6,732 employees, produced goods valued at $35,108,952 in 1939. Attleboro manufactures mainly jewellery and silverware but also makes optical goods, wrenches, tools, building paper, cotton goods and boxes, and has a large dyeing and bleaching plant. The jewellery industry was established there in 1780.

The first settlement within the present bounds of the city was made in 1669 by John Woodcock. The name commemorates the market town of Attleborough, Norfolk, England, the home of some of the early settlers. There is a glacial rock ledge in fine preservation in Attleboro; and an old powder house where ammunition was stored in the days of the Revolution. Some old houses are still standing in the city. The Angle Tree monument was erected in 1790. The town was incorporated in 1694. In 1887 it was divided by the creation of the township of North Attleborough, which is also a manufacturing centre, and which had a population of 10,359 in 1940. The city mas incorporatedin 1914.

See J. Dagget, *A Sketch of History of Attleborough to 1887* (Boston, *1894).*

ATTOCK, a town and fort in British India, in the Punjab, 47m. by rail from Peshawar, and on the east bank of the Indus. The Indus is here crossed by the military and trade route through the Khyber Pass into Afghanistan. The river runs past Attock in a deep, rapid channel about 200yd. broad. The rocky gorges through which it flows, with a distant view of the Hindu Kush, form some of the finest scenery in the world. Since 1883 an iron girder bridge of five spans carries the North-Western railway to Peshawar, and has also a subway for wheeled traffic and foot passengers. The fort of Attock was built by the emperor Akbar in 1581, on a low hillock beside the river.

ATTORNEY, in English law, in its widest sense, any substitute or agent appointed to act in "the turn, stead or place of another." Attorneys are of two kinds, attorneys-in-fact and attorneys-at-law. The former is simply an agent, the extent of whose capacity to act is bounded only by the powers embodied in his authority, his power of attorney. The latter was a public officer, conducting legal proceedings on behalf of others, known as his clients, and attached to the supreme courts of common law at Restminster. Attorneys-at-law corresponded to the solicitors of the courts of chancery and the proctors of the admiralty, ecclesiastical, probate and divorce courts. Since the passing of the Judicature Act of 1873, however, the designation "attorney" has become obsolete in England, all persons admitted as solicitors, attorneys or proctors of an English court being henceforth called "solicitors of the supreme court" *(see* SOLICITOR).

In the United States an attorney-at-law exercises all the functions distributed in England between barristers, attorneys and solicitors, and his full title is "attorney and counsellor-at-law." When acting in a court of admiralty he is styled "proctor" or "advocate." In courts of equity or chancery in many States he is styled "solicitor." Formerly, in some States, there existed a grade among lawyers of attorneys-at-law, which was inferior to that of counsellor-at-law, and in colonial times New Jersey established a higher rank still—that of sergeant-at-law. Now the term of attorney-at-law is precisely equivalent to that of lawyer, yet many consider a lawyer to be an attorney, particularly proficient in his profession. Attorneys are licensed to practice as the result of acts of the State legislatures, or by the rules of the highest court of the state. This is done ordinarily by examination by state or local boards, named by the court. In all States but Indiana, a preliminary education in a law school or under the direction of a practising attorney, or both, is required. In most States a preliminary high school education is required, and in a few of the States, part or all of a college education is required. New Jersey has a later separate examination for counsellor. Attorneys from other States may do a limited practice under comity in most States, and similarly one may be admitted to practice in most States if he has previously practiced for a required number of years in another State under what is known as "comity." In the courts of the United States, admission is governed by particular rules, the Supreme Court of the United States requiring practice of three years in a State, and admission for the same length of time at the bar of the highest court of that State. In almost all States aliens are not admitted, most requiring actual residence in the State as well as American citizenship. Women may practise in the United States Supreme Court, having been given this privilege in 1879, and in substantially all of the State courts.

An attorney is an officer of the court which admits him to practice, and he is subject to its discipline. He is liable to his client in damages for failure to exercise ordinary care and skill, and he can bring action for the value of his services. He has a lien on

his client's papers, and usually on any judgment in favour of his client to secure the payment of his fees. (See BAR.)

ATTORNEY-GENERAL, in England, the chief law officer appointed to manage all the legal affairs and suits in which the Crown is interested. He is appointed by letters-patent authorizing him to hold office during the sovereign's pleasure. He is ex *officio* the leader of the bar. Although we do not meet with the title *attornatus regis* until 1253, we may be sure that the office had already been long in existence. We are told by Bracton that the king had his serjeants-at-law in every county to prosecute pleas of the Crown in his name. These king's serjeants may be identified with the attornati *regis,* the number of whom varied from time to time. Eventually, in 1472, William Husee was appointed attorney-general of England with power to appoint deputies to act for him in any court of record. Henceforth the office is held singly. He has precedence in all the courts, and in the House of Lords he has precedence of the lord advocate, even in Scottish appeals. He is a necessary party to all proceedings affecting the Crown. The attorney-general and the solicitor-general (*q.v.*) are always members of the House of Commons (except for temporary difficulties in obtaining a seat) and of the Ministry, being selected from the Party in power, and their advice is at the disposal of the Government, and of each department of the Government, while in the House of Commons they defend the legality of ministerial action if it is called in question. Prior to 1895 no restriction was placed on the private practice of the law officers, but since that date this privilege has been withdrawn, and the salary of the attorney-general fixed at £7,000 a year with such fees as he may receive for litigious business on behalf of the Crown. During recent administrations he has had a seat in the cabinet and been made a privy councillor. The Crown has also as a legal adviser an attorney-general in Northern Ireland. In Scotland he is called lord advocate (*q.v.*). There are attorneys-general for the duchies of Cornwall and Lancaster. There is also an attorney-general or his equivalent in almost all the British colonies, and his duties are very similar to those of the same officer in England. In the self-governing colonies he is appointed by the administration of the colony, and in the Crown colonies by royal warrant under the signet and sign-manual.

The functions of the attorney-general are to-day of great constitutional importance and a number of recent statutes, casting upon him new duties, have invested his office with a continually increasing responsibility. He is not only the legal representative of the Crown in the courts but the *parens patriae* or guardian of public interests. In English law "the public" as a juristic conception does not exist, the Government of the country is not a corporation, the term "State" is merely a political expression, and even the term "Crown" is only a convenient impersonal expression for the king. The rights of the public in general are therefore protected by the attorney-general as the representative of the king in whom the "public" rights are vested. The result is that whenever acts are done tending to the injury of the public in general, and to the injury of no one in particular, the only person who can set the law in motion is the attorney-general. If a plaintiff wishes to put in suit a public wrong, he can only do so at the instance of the attorney-general. Our law here goes on the principle that "what is everybody's business is nobody's business" —it is the business only of the attorney-general. A plaintiff can only sue by himself in respect of a public tort where the interference with the public is such that some private right of his is, at the same time, interfered with, *e.g.,* where the obstruction of a highway by a local authority is such that the owner of premises abutting upon the highway is specially affected by the interference with his private right of access. But so far as the public is wronged by such obstruction of the highway, the wrong can only be redressed at the instance of the attorney-general who in such a case would apply for an injunction. The attorney-general has an absolute discretion as to whether he will intervene or not (see *L.C.C.* v. *Attorney-General,* 1902, A C. 165, which may be regarded as the leading case on the subject). On the other hand, the attorney-general, once he intervenes, is just as much subject to the control of the courts as every other suitor (R. v. *Prosser* 18 L. J. Ch. 35) and the courts are not bound to grant what he asks; they can prevent him from prosecuting a proceeding which is simply vexatious and has no legal object. He enjoys prerogatives as the representative of the Crown when he appears in the courts, such as the right to reply, trial at bar, change of venue (see PREROGATIVE, also PETITION OF RIGHT), but it is characteristic of the independence of the British courts towards the Executive that a law officer's opinion has no more force than the opinion of any other counsel.

Just as a public wrong, affecting no one in particular, can only be restrained at the instance of the attorney-general, so a public duty, the performance of which affects no one in particular, can only be enforced at the instance of the attorney-general, who in such cases is the proper party to apply for a writ of mandamus. Proceedings by criminal information, opposed as they are to the usual criminal procedure of indictment, are reserved for cases of public importance and are therefore regarded as at the suit of the attorney-general, even when the initiative is taken by a private individual, *i.e.,* a "relator" or "informer." The most familiar example of such proceedings is the publication of a seditious libel; in such a case the attorney-general himself files an *ex officio* information. So also, in the case of charities of a public character, the attorney-general represents all the persons who are an object of the charity, and they are thus plaintiffs through him.

In all civil proceedings by or against the Crown the attorney-general, or the solicitor-general, is the proper legal representative of the Crown in court. In actions for the recovery of any debt due to the Crown, whether by way of penalty or of tax, the attorney-general proceeds by information of debt. In proceedings against the Crown (see PETITION OF RIGHT) the Crown itself is the nominal defendant, but one or other of the law officers represents it. Furthermore, although it rests nominally with the Home Secretary, under the Petition of Right Act, to decide whether a suppliant shall be allowed to sue the Crown, in practice the Home Secretary always refers the petition to the attorney-general for his decision whether his leave ("fiat") shall be granted, and this discretion is absolute and cannot be questioned by the suppliant. In such cases the interests of the Crown are, of course, directly concerned. Where they are only indirectly concerned, the attorney-general himself is, and must be, made a defendant in order that the interests of the Crown may be protected. In a recent case of considerable constitutional importance (*Esquimault* Railway v. Wilson, 1925, A.C. 358) the power of the courts to insist on the attorney-general being joined as a defendant was based on wider ground, namely the right of a subject, when plaintiff in such an action, to claim that the attorney-general be made a party. This decision was a natural sequel to the great case of Dyson v. the Attorney-General, 1911, 1 K. B., 410, where the courts held, following ancient Exchequer precedents, that a subject might sue the attorney-general, as representative of the Crown. directly in an action for a declaration as to the subject's rights (see PETITION OF RIGHT).

To enumerate all the cases—such as peerage claims, lunacy proceedings, legitimacy declarations—in which the attorney-general may or must be a party would be beyond the limits of this article. It is enough to say that in all such cases the explanation of his participation is the same: the Crown is regarded as an interested party.

Of late years duties of great public importance have been cast upon the attorney-general by statute. The most recent example, and in some ways the most important, is the Trade Disputes and Trade Unions Act of 1927, by s. 7 of which the attorney-general is empowered to apply for an injunction to restrain the application of trade union funds in contravention of that section of the act which declares a "general strike" illegal. This, in effect, is to enable the attorney-general to interfere in such a case for the protection of the State. Certain Acts—such as the Official Secrets Act of 1911 (see SECRET)—provide that no prosecution for offences thereunder shall be initiated except by or with the consent of the attorney-general. Such provisions may be regarded as interposing the shield of the attorney-general between the police authorities and persons against whom they might institute

proceedings, and it is regrettable that the protection thus afforded by the Act of 1911 has been cut down by the Official Secrets Act of 1920 which only requires the consent of the attorney-general to proceedings in cases under the Act where they are dealt with "summarily," in other words without a jury. The consent of the attorney-general is also required before an appellant whose conviction and sentence has been affirmed by the court of criminal appeal (*q.v.*) can appeal further to the House of Lords, and such consent will only be granted where some important point of law is involved. Here also the attorney-general has an absolute discretion in the grant, or refusal, of his certificate.

The office of attorney-general is therefore unique in character. He is a minister of the Crown but he also exercises, particularly in the consideration of Petitions of Right, a judicial discretion. He is the representative of the interests of the Crown and at the same time the guardian of the rights of the public, and the two may not always coincide. It is easy to conceive a conflict of duties and on this ground it has been contended that the recent innovation of giving him cabinet rank is a bad one as calculated to impair his independence as the guardian of the public rights.

See Holdsworth, *Hist. Eng. Law* vi. 457; J. H. Morgan, "Remedies v. the Crown"; Bellot, "The Origin of the Attorney-General," *Law Quarterly Review* xxviii. p. 400. There is an admirable exposition of the attorney-general's duties by Sir Douglas Hogg, now Lord Hailsham, in Hansard's *Parliamentary Debates (Commons)* vol. 207 (No. 75) cols. 427–434. (J. H. Mo.)

UNITED STATES

The attorney-general of the United States is the chief law officer of the Government and head of the Department of Justice, one of the executive departments. He is appointed by the president, and, like the heads of the other executive departments, is a member of the cabinet. Since 1886, in case of death, resignation, removal or disability of both the president and the vice-president, he is in line of succession to the Presidency, after the secretary of State, secretary of the Treasury and secretary of War.

The office of attorney-general has existed since 1789, when the Government, under the Constitution, was organized. It was created by the Judiciary Act of 1789. That Act divided the United States into 13 judicial districts, established courts therein, defined their jurisdiction, and also the appellate jurisdiction of the Supreme Court. It provided that in each district there should be an attorney for the United States, who should have charge of civil and criminal actions in his district, and finally that there should be appointed an attorney-general of the United States who was to be "a meet person learned in the law," whose duty it should be to represent the United States in the Supreme Court and who should be the legal adviser of the president and of the heads of the departments "touching any matters that may concern their Departments." The attorney-general, under that act, was not an executive officer of the Government. His duties, as defined by the statute, made him merely an adviser of the executive branch and an advocate in the Supreme Court, and the measure of his compensation, $1,500 a year, was based upon the belief that his duties would take but little of his time, leaving him free to enjoy the professional emoluments which it was thought the prestige of his position would bring him. Until about the year 1814, the attorney-general did not reside at the seat of Government. In that year, Attorney-General Pinckney, one of the great lawyers of his day, resigned because President Madison insisted that he take up his residence in Washington. From the beginning, however, the office was regarded as one of great dignity and importance, and with the growth of the United States and the development of its governmental functions statutes were enacted from time to time which increased its duties and responsibilities, and gradually brought it to a parity with the heads of the executive departments. In 1870 it was organized by law as the Department of Justice.

The Department of Justice is an executive department and the attorney-general as its head has plenary control over the law business of the Government, all its other law officers being responsible to him, though some of the bureaux and commissions, such as the Bureau of Internal Revenue, the Federal Trade Commission and the Interstate Commerce Commission have lawyers on their staffs who are not officers or employés of the Department of Justice and who, in the performance of their duties within their respective departments, are not under the direction of the attorney-general. In the language of the U.S. Supreme Court he "has charge of the institution and conduct of the pleas of the United States and of the litigation which is necessary to establish the rights of the Government." The duties of the attorney-general are primarily those of a lawyer, but as head of the department much of his time and energy must now be devoted to administration. The personnel of his immediate staff at the seat of Government numbers between 700 and 800. His chief assistant is the solicitor-general, who by law exercises the powers of the attorney-general in the latter's absence and to whom is assigned charge of the Government's litigation in the Supreme Court, being about one-third of the entire business of that court. The solicitor-general also decides whether review in the higher courts shall be sought in cases which the Government has lost in courts below. This duty of passing upon questions of appeal and therein seeing to it that the Government's interests are protected, and all reasonable effort made to procure a correct construction of the law, at the same time avoiding imposing unwarranted burdens upon the appellate courts and unnecessary expense to litigants, is one of grave responsibility, calling for the exercise of sound, discriminating judgment.

There are an assistant to the attorney-general and seven assistant attorneys-general, among whom supervision of the work of the department is apportioned; one assistant, in charge of cases arising under the customs laws, has his office in the city of New York. There are several departmental solicitors who, as members of the attorney-general's staff, deal with legal matters arising in their respective departments. The Federal district attorneys, appointed by the executive for the ninety-one United States district courts, are in effect deputies of the attorney-general.

Through the superintendent of prisons the attorney-general controls all Federal prisons and prisoners. The number of such prisoners in Federal and State prisons in 1928 was about 16,000

The judicial districts have increased from the original 13 to 91 with 91 U.S. district courts and 136 U.S. district judges. There are nine judicial circuits with nine circuit courts of appeals and 34 U.S. circuit judges. There is a court of general jurisdiction and a court of appeals in the District of Columbia. In 1855 there was established a court of claims, a tribunal in which claims against the United States could be judicially heard and determined. It would not be within the scope of this article to set forth this jurisdiction in detail, but it may be said to include all causes of action based upon contract, express or implied, with the Government. As a result of the World War the number of cases of this kind has greatly increased and one of the heavy duties of the attorney-general and his staff is the defence of these suits. At the present time there are pending in that court over 2,200 suits involving claims against the Government in amount exceeding $1,800,000,000. At the close of the last fiscal year there were pending in the district courts over 16,000 civil suits in which the U.S. Government was directly interested and more than 35,000 criminal prosecutions, although during that year more than 19,000 civil suits and 67,000 criminal cases had been terminated.

The administrative control and supervision of the offices of U.S. marshals, and in some respects, of the offices of clerks of U.S. courts, is in the attorney-general. The entire personnel of the Department of Justice is about 5,100. All petitions to the president for pardon, commutation of sentence, or other form of executive clemency are investigated by an official of the department called the pardon attorney and the facts relating to each application are ascertained for the guidance of the attorney-general in making his recommendation to the president. About 1,200 petitions of this kind are considered each year. All petitions of Federal prisoners for release on parole are considered and approved or disapproved by the attorney-general. About 4,300 applications of this kind are considered each year. The attorney-general also makes recommendations to the president respecting appointments to all Federal judicial positions including the U S. Supreme Court.

As already pointed out, from the beginning the attorney-general has been the legal adviser of the president and of the heads of the

executive departments with respect to the questions arising in the administration of their departments. For many years pursuant to statute his formal opinions have been published from time to time in book-form, and are now contained in 34 volumes. They are binding upon and control the action of the executive officers of the Government, are frequently cited by the courts, and regarded as of high authority. Prepared under statutory sanction by the chief law officer of the Government for the guidance of the heads of departments charged with the administration of the statutes enacted by Congress, they have the status of important State papers entitled to the highest respect upon all questions of the powers and duties of the executive branch of the Government.

There is also under each State Government an officer usually called the attorney-general, whose relation to the Government of his State is similar to that of the U.S. attorney-general to the Federal Government. He is usually elected by the people at the same time and for the same term as the governor. For an accurate description of the duties of the attorney-general of any particular State an examination of the Constitution and laws of that State is necessary. (J. G. S.)

ATTORNMENT, in English real property law, the acknowledgment of a new lord by the tenant on the alienation of land. Under the feudal system it was always considered unreasonable to the tenant to subject him to a new lord without his own approval, and it thus came about that alienation could not take place without the consent of the tenant. Attornment was also extended to all cases of lessees for life or for years. The necessity for attornment was abolished by an act of 1705 (*see* now s. 151 of the Law of Property Act 1925). The term is now used to indicate an acknowledgment of the existence of the relationship of landlord and tenant. An attornment-clause, in mortgages, is a clause whereby the mortgagor attorns tenant to the mortgagee, thus giving the mortgagee the right to distrain, as an additional security.

ATTRIBUTES: *see* CATEGORY; SPINOZA; SUBSTANCE.

ATTRITION, a rubbing away; a term used in pathology and geology (Lat. *attritio,* from *attero,* "rub away"). Theologians have also distinguished "attrition" from "contrition" in the matter of sin, as an imperfect stage in the process of repentance; attrition being due to servile fear of the consequences of sin, contrition to filial fear of God and hatred of sin for His sake.

ATTWOOD, THOMAS (1765–1838), English composer, was a chorister of the Chapel Royal and a pupil of Mozart in Vienna. In 1796 he became organist of St. Paul's. One or two of his songs, such as "The Soldier's Dream," and of his glees such as "In peace love tunes the shepherd's reed" and "To all that breathe the air of Heaven," are still occasionally heard.

ATTWOOD, THOMAS (1783–1856), English political reformer, was born at Halesowen, Worcestershire, Oct. 6 1783. He was one of the founders, in Jan. 1830, of the Political Union, formed to agitate for a reform of the franchise. Under his leadership vast crowds of working men met periodically in the neighbourhood of Birmingham to demonstrate in favour of reform of the franchise, and Attwood used his power to prevent illegal methods of agitation. After the passing of the Reform act in 1832 he was elected one of the members for the new borough of Birmingham, for which he sat till 1839.

In the House of Commons he was persistent in advocating his monetary theory, that the existing currency should be rectified in favour of State-regulated and inconvertible paper money and the adoption of a system for altering the standard of value as prices fluctuated. He retired from Parliament in 1837, and died at Great Malvern, March 6 1856.

His grandson, C. M. Wakefield, wrote his life "for private circulation" (there is a copy in the British Museum), and his economic theories are set forth in a little book, *Gemini,* by T. *B.* Wright and J. Harlow, published in *1844.*

ATWOOD, GEORGE (1746–1807), English mathematician, was educated at Westminster school and Trinity college, Cambridge. He received from William Pitt an office in the customs which was practically a sinecure and left him leisure for his studies. He was the inventor of Atwood's machine.

Atwood's most important works are: *Treatise on the Rectilinear Motion and Rotation of Bodies* (1784), which describes the machine, since called by Atwood's name, for verifying experimentally the laws of simple acceleration of motion and *Dissertation on the Construction and Properties of Arches* (1801–04).

ATWOOD, WALLACE WALTER (1872–), American geographer and geologist, was born in Chicago, Ill., on Oct. 1, 1872. He graduated in 1897 and received the degree of doctor of philosophy in 1903 from the University of Chicago, in which from 1903 to 1913 he was successively instructor, assistant professor, associate professor and professor of physiography and general geology. He was professor of physiography at Harvard university from 1913 until 1920 when he became president of Clark university. In 1901–09 he was assistant geologist with the U.S. Geological Survey and in 1904 became geologist of the Illinois Geological Survey. He made extensive field researches in structural and economic geology, notably on the coal resources of Alaska. He also made studies of glaciation, especially in the Rocky mountains, and of the physical geography of various parts of the United States. In 1925 he founded and became editor of *Economic Geology.*

Besides numerous scientific and educational papers, he published *Physical Geography of the Devils Lake Region* (1899), *Physical Geography of the Evanston-Waukegan Region of Illinois* (1908), *Interpretation of Topographical Maps* (1908), *Glaciation of the Uinta and Wasatch Mountains* (1909), *Mineral Resources of South-western Alaska* (1910), *Geology and Mineral Resources of the Alaska Peninsula* (1911) and *New Geography, Book II.* (1920).

ATYPICAL CHILDREN. Atypical means irregular, or not conformable to type. Applied to children, it usually indicates those who are below normal mentally, or who are suffering from more or less abnormal conditions of the mind. (*See* MENTAL DEFICIENCY.) "Atypical schools" are maintained in Washington, D.C., and other American cities, for children of this class. No attempt is made to maintain the ordinary school curriculum. The atypical children are taught as individual peculiarities require. They are not able, usually, to profit by any considerable amount of mental training, but frequently receive much benefit from various sorts of manual training, rug and basket weaving and other types of physical work.

AUBADE (a French word from *aube,* the dawn), the dawn-song of the troubadours of Provence, developed by the Minnesingers (*q.v.*) of Germany into the *Tagelied,* the song of the parting at dawn of lovers at the warning of the watchman, and now applied, analogously with its counterpart "serenade," to musical compositions in general of a suitable type. In France the term is applied also to the performance of a military band in the early morning in honour of some distinguished person.

AUBAGNE, a town of south-eastern France, in the department of Bouches-du-Rhône, 11 mi. E. of Marseille on the river Huveaune. Pop. (1936), 7,294. The railway to Toulon here turns south and reaches the coast through two tunnels. Earthenware is made and fruit and vines are cultivated. A fountain commemorates the statesman The Marquis de Barthélemy (1750[?]–1830).

AUBE, department, France, S.E. of Paris, including the courses of the Seine and Aube from near the edge of the Jurassic rocks of Côte d'Or to the lowland in which Aube, Seine, Yonne and Loing unite. Area 2,327 sq.mi.; pop. (1936) 239.563. Its north boundary is an old frontier zone, *e.g.,* between Remi and Senones of early Gallo-Roman times, between the archbishoprics of Sens and Reims, between France and Burgundy till the days of Hugh Capet. The two main rivers traverse the *Champagne Humide* and the *Champagne Pouilleuse,* the clay and the chalk, in succession. Much of the department is a sterile plain with habitations near the *Sommes* or springs coming from the chalk, but a large outlier of Tertiary rocks covering the chalk in the south-west, the Forêt d'Othe, is shared between Aube and Yonne. On the Jurassic rocks in the south-east a height of 1,200ft. is reached and thence the general slope is down to the north-west. As an unforested region of early times it seems to have had some prehistoric importance, and as the unforested lowland north-east of the highland ways through CBte d'Or to Paris it was long a traders' route and had great fairs at Troyes and Arcis-sur-Aube. The transition in the north-west from chalk to Tertiary deposits gives a broken sur-

face. The climate is fairly mild and the rainfall mostly between 600 and 700 mm. per annum, but greater along the edge of the highland in the south-east, where porous Jurassic rocks give slopes useful for the vine. The river zones have good natural pasture and are famed for cattle and cheese, helped by good forage crops.

The capital of the department is Troyes, and that city, Bar-sur-Aube, and Nogent-sur-Seine give their names to arrondissements. The department is in the military circumscription of the XXth Army Corps, its courts refer to the Court of Appeal at Paris, its educational area *(acade'mie)* is that of Dijon. The archbishopric of Sens includes a bishopric of Troyes, and that cathedral's famed collection of painted (16th century) glass is the crowning example of a remarkable feature of the churches of the department. Within the department is the historic abbey of Clairvaux.

AUBENAS, south-east France, department of Ardèche, 19 mi. S.W. of Privas by road. Pop. (1936) 5,338 Situated on the slope of a hill, on the right bank of the Ardeche, its streets are crooked and narrow. It has a castle of the 13th and 16th centuries. Institutions include a tribunal and chamber of commerce, and a conditioning-house for silk. Iron and coal mines are worked in the vicinity. Aubenas is an important silk depôt and has a large silk-spinning and weaving industry. The district is rich in plantations of mulberries and olives.

AUBER, DANIEL FRANCOIS ESPRIT (1782–1871), French musical composer, the son of a Paris printseller, was born at Caen in Normandy. He learnt to play at an early age on several instruments, his first teacher being the Tirolean composer, I. A. Ladurner. Eventually he studied under Cherubini, and in 1813 made his début as a composer with a one-act opera, the *Séjour militaire,* which was a failure. In 1822 began his long association with **A.** E. Scribe, who shared with him, as librettist, the success and growing popularity of his compositions. The opera *Leicester,* in which they first worked together (1823) showed evidences of the influence of Rossini. But in general his style was wholly individual being marked by all the lightness and facility, sparkling vivacity, grace, elegance, and clear and piquant melody characteristic of the French School. *La Muette de Portici* familiarly known as *Masaniello* (1828), became a European favourite, and its overture, songs and choruses were everywhere heard. The duet, "Amour sacré de la patrie," was welcomed like a new "Marseillaise," and sung by Nourrit at Brussels in 1830, it became the signal for the revolution. Of Auber's remaining operas (about 50 in all) the more important are: *Le Maçon* (1825), *La Fiancée* (1829), *Fra Diavolo* (1830), *Lestocq* (1834), *Le Cheval de bronze* (1835), *L'Ambassadrice* (1836), *Le Domino noir* (1837), *Le Lac des fées* (1839), *Les Diamants de la couronne* (1841), *Hayde'e* (1847), *Marco Spada* (1853), *Manon Lescaut* (1856), and *La Fiancée du roi des Garbes* (1864).

In 1829 Auber was elected member of the Institute, in 1830 he was named director of the court concerts, and in 1842, at the wish of Louis Phillippe, he succeeded Cherubini as director at the Conservatoire. Napoleon III. made Auber his Imperial Maître de Chapelle in 1857. Auber's attractive manners, his witty sayings, and his ever-ready kindness won for him a secure place in the respect and love of his fellow-citizens. He remained in his old home during the German siege of Paris, 1870–71, but the miseries of the Commune profoundly affected him and probably hastened his death.

AUBERGINE: *see* EGG-PLANT.

AUBERLEN, KARL AUGUST (1824–1864), German Protestant theologian, was born at Fellbach, Germany, Nov. 19, 1824. He was educated at Tiibingen, and in 1851 was made professor of theology at Basel, where he soon earned attention by his success both as a teacher and as an author. As a young man he was influenced by the ideas of Hegel, Goethe and Baur; but as he grew older, he became more conservative. He was the author of a number of theological works, including *Der Prophet Daniel und die Offenbarung Johannis* and *Die gottliche Offenbarung,* both of which were translated into English. He died at Basel in 1864

AUBERVILLIERS, town of northern France, in the department of Seine, on the canal St. Denis, 2m. from the right bank of the Seine and 1m. north of the fortifications of Paris. Pop. (1936) 55,871. It manufactures cardboard, colours, chemical products, perfumery, etc. During the middle ages and till modern times Aubervilliers was the resort of numerous pilgrims to *Notre Dame des Vertus.*

AUBIGNAC, FRANCOIS HEDELIN, ABBÉ D' (1604–1676), French author, was born in Paris. His father practised at the Paris bar, and his mother was a daughter of the great surgeon Ambroise Paré. François Hédelin took holy orders, was appointed tutor to one of Richelieu's nephews, and received through his pupil's influence the abbeys of Aubignac and of Mainac. In 1646 he retired to Nemours, occupying himself with literature till his death. He took an energetic share in the literary controversies of his time. Against Gilles Ménage he wrote a *Térence justifié* (1656); he laid claim to having originated the idea of the "Carte de tendre" of Mlle. de Scudéry's *Clélie;* and after being a professed admirer of Corneille he turned against him because he had neglected to mention the abbé in his *Discours sur le poème dramatique.* He was the author of four mediocre tragedies: *La Cyminde* (1642), *La Pucelle d'Orléans* (1642), *Zénobie* (1647) and *Le Martyre de Sainte Catherine* (1650). *Zénobie* was written with the intention of affording a model in which the strict rules of the drama, as understood by the theorists, were observed. In the choice of subjects for his plays, he seems to have been guided by a desire to illustrate the various kinds of tragedy — patriotic, antique and religious. It is as a theorist that d'Aubignac still arrests attention. Jean Chapelain was the first to establish the convention of the unities ihat plays so large a part in the history of the French stage; but the laws of dramatic method and construction generally were codified by d'Aubignac in his *Pratique du théâtre.* The book was only published in 1657, but had been begun at the desire of Richelieu as early as 1640. His *Conjectures académiques sur l'Iliade d'Homère,* published nearly forty years after his death, threw doubts on the existence of Homer, and anticipated to some extent the conclusions of Friedrich August Wolf in his *Prolegomena ad Homerum* (1795).

BIBLIOGRAPHY.—See G. Saintsbury, *Hist. of Criticism,* bk. v., and H. Rigault, *Hist. de la querelle des anciens et modernes* (1859). The contents of the *Pratique du Théâtre* are summarized by F. Brunetière in his notice of Aubignac in the *Grande Encyclopédie.*

AUBIGNE, CONSTANT D' (BARON DE SURINEAU) (*c.* 1584–1647), French adventurer, was the son of Théodore Agrippa d'Aubigné, and the father of Madame de Maintenon. Born a Protestant, he became in turn Catholic or Protestant as it suited his interests. He betrayed the Protestants in 1626, revealing to the court, after a voyage to England, the projects of the English upon La Rochelle. He was renounced by his father; then imprisoned by Richelieu's orders at Niort, where he was detained ten years. After having tried his fortunes in the Antilles, he died in Provence. He had two children, Charles, father of the duchess of Noailles, and Françoise, known in history as Madame de Maintenon.

See T. Lavallée, *La Famille d'Aubigné et l'enfance de Madame de Maintenon* (Paris, 1863).

AUBIGNE, JEAN HENRI MERLE D' (1794–1872), Swiss Protestant divine and historian of the Reformation, was born on Aug. 6, 1794, at Eaux Vives, Geneva. The ancestors of his father, Aimé Robert Merle d'Aubigné (1751–1799), were French Protestant refugees. Educated in Germany, he was pastor of the French Protestant Church in Hamburg for some years, and in 1823 a pastor in Brussels. He was at this time president of the consistory of French Protestant Churches, and subsequently professor of Church history in a Swiss institution maintained by the Evangelical Alliance. He died in Switzerland in 1872.

His principal works *are:* — *Discours sur l'étude de l'histoire de Christianisme* (Geneva, 1832); *Le Luthéranisme et la Réforme* (Paris, 1844); *Germany, England and Scotland, or Recollections of a Swiss Pastor* (London, 1848); *Trois siècles de lutte en Écosse, ou deux rois et deux royaumes* (1850); *Le Protecteur ou la répu-*

blique d'Angleterre aux jours de Cromwell (Paris, 1848); *Le Concile et l'infaillibilité* (1870); *Histoire de la Re'formation aux XVI^ième siècle* (Paris, 1835–53; new ed. 1861–62, in 5 vols.); and *Histoire de la Re'formation en Europe au temps de Calvin* (8 vols. 1862–77).

The first portion of his *Histoire de la Re'formation,* which was devoted to the earlier period of the movement in Germany, was translated into most European languages. The second portion, dealing with reform in the time of Calvin, dealt with a subject hitherto less exhaustively treated, but it did not meet with the same success. This part was all but completed at the time of his death. Among his minor treatises, the most important are the vindication of the character and aims of Oliver Cromwell, and a sketch of the struggles in the Church of Scotland.

Aubigné had amassed a wealth of well-documented information; but his desire to give in all cases a full and graphic picture, assisted by a vivid imagination, betrayed him now and then into filling up a narrative by inference from later conditions. Moreover, in his profound sympathy with the Reformers, he is often an apologist rather than an impartial historian. But his work is a monument of painstaking sincerity, and brings us into direct contact with the spirit of the period.

AUBIGNÉ, THEODORE AGRIBPA D' (1552–1630), French poet and historian of his own time, was born at St. Maury, Saintonge, the son of a Huguenot gentleman, one of the conspirators of Amboise. He was sent, at the age of 14, to Geneva, but in a year's time had joined the Huguenot army in France. He served Henry IV. both in the field and in the council chamber, though his rough manners and habit of outspoken criticism made his career at court rather a chequered one. In 1620 he was compelled to leave France in consequence of the publication of his *Histoire universelle depuis 1550 jusqu'à l'an 1601.* The first two volumes appeared in 1616 and 1618, and the third, which was ordered to be burned by the common hangman, in 1619. The book is a lively account of the camp and court life of the time, valuable because of the author's first-hand knowledge of the events described. Aubigné found a secure retreat at Geneva for the last ten years of his life.

BIBLIOGRAPHY.—A complete edition of Aubignk's works according to the original mss. was begun by E. Réaume and F. de Caussade (1879). It contains all the literary works, the *Aventures du baron de Faeneste* (1617), and the *Mémoires* (1873–92). The best edition of the *Histoire universelle* is by A. de Ruble. The *Mémoires* were edited by L. Lalanne (1854).

AUBM, a town of southern France, in the department of Aveyron on the Enne, 30 mi. N.W. of Rodez Pop. (1936) 3,961. Aubin is the centre of important coal mines worked in the middle ages. and also has iron-mines and marble quarries. Sheep breeding is important in the vicinity.

AUBREY, JOHN (1626–1697), English antiquary, was born at Easton Pierse or Percy, near Malmesbury, Wiltshire. his father being a country gentleman. In 1667 he made the acquaintance of Anthony à Wood at Oxford, and when Wood began to gather materials for his invaluable *Athenae Oxonienses,* Aubrey offered to collect information for him. From time to time he forwarded memoranda to him, and in 1680 he began the "Minutes for Lives," which Wood was to use at his discretion. He left the task of verification largely to Wood. As a hanger-on in great houses he had little time for systematic work, and he wrote the "Lives" in the early morning while his hosts were sleeping off the effects of the dissipation of the night before. The principal charm of his "Minutes" lies in the amusing details he has to recount about his personages, and in the truthfulness that he permits himself in face of established reputations. In 1692 he complained bitterly that Wood had destroyed 40 pages of his ms., probably because of the dangerous freedom of Aubrey's pen. Wood was prosecuted eventually for insinuations against the judicial integrity of the earl of Clarendon. One of the two statements called in question was certainly founded on information provided by Aubrey. This perhaps explains the estrangement between the two antiquaries and the ungrateful account that Wood gives of the elder man's character. "He was a shiftless person, roving and magotie-headed, and sometimes little better than crased. And being exceedingly credulous, would stuff his many letters sent to A. W. with follies and misinformations, which sometimes would guide him into the paths of errour."[1]

In 1673 Aubrey began his "Perambulation" or "Survey" of the county of Surrey, and a "History of his Native District of Northern Wiltshire." In the next year he published his only completed, though certainly not his most valuable work, the *Miscellanies,* a collection of stories on ghosts and dreams. He died at Oxford and was buried in the church of St. Mary Magdalene.

Beside the works already mentioned, his papers included: "Architectonics Sacra," notes on ecclesiastical antiquities; and "Life of Thomas Hobbes of Malmesbury," which served as the basis of Dr. Blackburn's Latin Life, and also of Wood's account. His survey of Surrey was incorporated in R. Rawlinson's *Natural History and Antiquities of Surrey* (1719); his antiquarian notes on Wiltshire were printed in *Wiltshire; the Topographical Collections of John Aubrey,* corrected and enlarged by J. E. Jackson (Devizes, 1862); part of another ms. on "The Natural History of Wiltshire" was printed by John Britton in 1847 for the Wiltshire Topographical Scciety; the *Miscellanies* were edited in 1890 for the *Library of Old Authors;* the "Minutes for Lives" were partially edited in 1813. A complete transcript, *Brief Lives chiefly of Contemporaries set down by John Aubrey between the Years 1669 and 1696,* was edited for the Clarendon Press in 1898 by the Rev. Andrew Clark from the mss. in the Bodleian library, Oxford.

See also John Britton, *Memoir of John Aubrey* (1845); David Masson, in the *British Quarterly Review* (July 1856); Émile Montégut, *Heures de lecture d'un critique* (1891); and a catalogue of Aubrey's collections in *The Life and Times of Anthony Wood . . .,* by Andrew Clark (1891–1900, vol. iv. pp. 191–193), which contains many other references to Aubrey.

AUBRIETIA, a genus of small perennial herbs of the family Cruciferae, *A. deltoides,* the purple rock-cress, is frequently cultivated in rock-gardens. The flowers are purple or violet. They are natives of the mountainous regions of Greece, Italy, etc.

AUBURN, a city of northeastern Indiana, U.S.A., on federal highway 27 and state roads 427 and 8, 23 mi. N. by E. of Ft. Wayne; the county seat of DeKalb county and the centre of a great variety of manufacturing industries. It is served by the Baltimore and Ohio, the Indiana Service corporation, the New York Central and the Pennsylvania railways.

The population of Auburn in 1930 was 5,088 and 5,415 in 1940. Auburn was settled about 1800 and was selected as the county seat in 1836.

AUBURN, a city in the southwest part of Maine, U.S.A., on the Androscoggin river, opposite Lewiston, 32 mi. N. by E. of Portland; the shire town of Androscoggin county. It is on federal highway 202 and is served by the Grand Trunk and the Maine Central railways and by bus line to Portland. The population was 16,985 in 1920; 18,571 in 1930 (14·3% foreign-born white); and 19,817 in 1940 by federal census. With its neighbouring city across the river, Auburn forms an important industrial centre, favoured by abundant water power. A hydroelectric development, providing 27,000 h.p., is at Gulf island, four miles above the cities. Within the boundaries of Auburn there were 60 manufacturing establishments in 1937, which had an output valued at $14,551,370. The assessed valuation of property in 1938 was $17,044,570. There are two city parks covering about 200 ac. Auburn was settled in 1783; incorporated in 1842: rechartered in 1869; and adopted a commission-manager form of government in 1917.

AUBURN, the county seat and the only city of Cayuga county (N.Y.), U.S.A., 2j mi. S.W. of Syracuse, on an outlet of Owasco lake, which lies two miles to the southeast. It is on the Yellowstone trail, and is served by the Lehigh Valley and the New York Central railways. Its area is 8·4 sq.mi. The population was 36,652 in 1930 (about 20% foreign-born, chiefly from Italy, Poland and Russia); 35,753 in 1940 by the federal census.

The city occupies an undulating site. over 700 ft. above sea level, in the heart of the Finger Lakes district. The wide streets are shaded with arching elms and other beautiful trees. The fertile surrounding country produces milk, corn, oats, barley, buckwheat,

[1] "Life of Anthony à Wood written by Himself" (*Athen. Oxon.,* ed. Bliss).

potatoes, hay and fine fruits; and there are quarries of water lime, quicklime, gypsum and sandstone along the shores of Lake Cayuga. Auburn has 20 to 2j wholesale houses and over 700 retail stores. The principal manufactures are cordage and twine, agricultural implements and wagons, shoes and shoe patterns and shoe racks, shoe forms, fishhooks and lures, carpets and rugs, rubber stamps and inking pads, diesel engines and oiling devices, forgings and castings, caps and hats, buttons and surgical instruments. Printing is also an important industry. It has 24 classifications of industry with more than $32,000,000 in products turned out annually. The assessed valuation of property in 1940 was $51,222,33j.

On the summit of Fort Hill, in the southwestern part of the city, is a grass-grown earthwork which was an ancient stronghold of the Cayugas; and in its centre stands a monument to the Cayuga chief Logan (b. 1725) who was an unswerving friend of the early settlers of this region. The home of William H. Seward, Lincoln's secretary of state, still stands in the heart of the city. The Auburn theological seminary merged with Union theological seminary at New York city. A NYA resident centre is now housed in the seminary buildings. The Seymour (public) library of 50,539 volumes is housed in the beautiful Case Memorial building. The Auburn state prison, when it was built in 1816, embodied advanced ideas of prison construction, and the "Auburn system" (solitary confinement by night, combined with work in association during the day) received much attention from the penologists of Europe and America.

Auburn was founded in 1793 by Capt. John L. Hardenburgh, on the site of a Cayuga village called Wasco, near the place where the Genesee trail crossed the outlet of the lake, and at first it was called Hardenburgh Corners. In 1805 it was chosen as the county seat, and in 1815 it was incorporated. It was chartered as a city in 1848, and since 1920 has had the commission-manager form of government.

AUBURN, ruddy-brown; the meaning has changed from the original one of brownish-white or light yellow (Low Lat. *alburnus,* whitish, light-coloured), probably through the intensification of the idea of brown caused by the early spelling "abron" or "abrown."

AUBUSSON, PIERRE D' (1423–1503), grand master of the order of St. John of Jerusalem, was a scion of a noble French family, and was in early life a soldier of fortune under the emperor Sigismund. On his return to France he fought with the Armagnacs against the Swiss, distinguishing himself at the battle of St. Jacob (1444). He then joined the order of the Knights Hospitallers of St. John of Jerusalem, becoming grand master in 1476. The defence of Rhodes against the fleet of the sultan Mohammed II. in 1479 made Aubusson famous throughout Europe. His treacherous conduct toward Jem, brother of Mohammed's successor, the sultan Bayezid, is a stain on Aubusson's memory. After Jem's defeat by his brother he took refuge at Rhodes under a safe-conduct from the grand master; Aubusson nevertheless accepted a bribe from Bayezid, and after six years' imprisonment Jem was handed over to Pope Innocent VIII. Aubusson's reward was a cardinal's hat (1489), and the power to confer all benefices connected with the order without the sanction of the papacy; the order of St. John received the wealth of the suppressed orders of the Holy Sepulchre and St. Lazarus. The remaining years of his life Aubusson spent in the attempt to restore discipline and zeal in his order, and to organize a grand international crusade against the Turks. The death of Jem in 1495 had removed the most formidable weapon available against the sultan; and when in 1501 Aubusson led an expedition against Mytilene, dissensions among his motley host rendered it abortive. The old man's last years were embittered by chagrin at his failure, which was hardly compensated by his success in extirpating Judaism in Rhodes by expelling all adult Jews and forcibly baptizing their children.

See P. Bouhours, *Hist. de Pierre d'Aubusson* (Paris, 1676; Hague, 1793; abridged ed. Bruges, 1887); G. E. Streck, *Pierre d'Aubusson, Grossnzeister,* etc. (1873); J. B. Bury in *Cambridge Mod. Hist.* vol. i., p. 85, etc. (for relations with Jem).

AUBUSSON, a town of France, capital of an arrondissement in the department of Creuse, on the river Creuse, 24 mi. S E. of Guéret by rail. Pop. (1936) 5.464. It has celebrated manufactories of carpets, etc., employing over 2,000 workmen, the artistic standard of which is maintained by a national school of decorative arts, founded in 1869. The industry goes back at least as far as 1531. Beauvais tapestries and Gobelins are still made on hand-looms. From the 10th to the 13th century Aubusson was the centre of a viscounty. It was then incorporated in the countship of La Marche and shared in its fortunes. From the family of the old viscounts was descended Pierre d'Aubusson (*q.v.*).

AUCASSIN AND NICOLETTE, now considered the most charming of all mediaeval love romances, was not popular in its own day and has survived in a single manuscript in the Bibliothèque Nationale at Paris. The story resembles that of the far more popular *Floire et Blanchefleur* and, like it. was probably based on a Moorish original, though the scene is laid in Provence. Aucassin, son of the count of Beaucaire, is enamoured of a lovely slave-girl, Nicolette, daughter of the Saracen king of Carthage. To keep them apart both are imprisoned, but she escapes to the forest, where she is found by her lover. After spending three years together in the kingdom of Torelore (a name given to the barren district of Aiguesmortes), they are captured by Saracens. The ship in which Aucassin is carried off is wrecked at Beaucaire, where he is joyfully received as count, his parents being dead. The other ship brings Nicolette to Carthage, where she is recognized by her father, the king; but as he wishes her to marry a paynim lord, she escapes in the disguise of a minstrel and makes her way to Beaucaire, where all ends happily.

Not only is Aucassin the Arabic name Alcazin or al-Kâsim, and Carthage evidently Carthagena, but the form in which the tale is told is oriental; it is a chante-fable, told in alternating sections of prose and verse, or rather song, for the verses were unquestionably chanted. But, in spite of its Arabic origin and Provençal setting, it was composed in northern France in the 12th century by a skilful but unknown poet.

The unique ms. of *Aucassin and Nicolette* was first published by Méon in 1808. The best edition is that by F. W. Bourdillon (Manchester University Press, 1919), which includes a bibliography. The first translation, into modern French, was that by M. de Sainte-Palaye in 1752, and it has been translated into English by Andrew Lang, Laurence Housman and many others. (L. F. S.)

AUCH, south-west France, capital of the department of Gers, on the Southern railway, south of Agen. Pop. (1936) 11,850. It consists of a lower and upper quarter united by several flights of steps. The streets are steep and narrow, but there is an 18th century promenade in the upper town. Three bridges cross the Gers to the suburb of Patte d'Oie.

Auch (*Elimberris*) was the capital of a Celtiberian tribe, the Ausci, and became one of the most important cities of Roman Gaul. In the 4th century its bishopric was founded and after the destruction of Eauze it became the metropolis of Novempopulana. Till 732, Auch stood on the right bank of the Gers, but in that year the Saracen ravages drove the inhabitants to the left bank. The Benedictine abbey of St. Orrens was founded by Count Bernard of Armagnac in the 10th century. The city was the capital of Armagnac in the middle ages. Its importance may be related to the use of the valley-road through a rather difficult region of deeply-cut streams — the Plateau de Gers. During the Religious Wars of the 16th century Auch remained Catholic, except for a short occupation in 1569 by Huguenots under Gabriel, count of Montgomery. In the 18th century it was the capital of Gascony and the seat of a generality. Antoine Mégret d'Étigny, *intendant* from 1751 to 1767, did much to improve the city and its commerce. The most interesting part of the town is the old quarter around the Place Salinis, a spacious terrace with an extensive view. On its north side rises the cathedral of Sainte-Marie, built from 1489–1662. It is one of the finest Gothic buildings in south France. The Greco-Roman façade, however, dates from the 17th century. The chief treasures of the cathedral are the magnificent Renaissance stained-glass windows and the 113 choir-stalls of carved oak, also of Renaissance workmanship. The archbishop's palace, an 18th century building with a Romanesque

hall and tower (14th century), adjoins the cathedral. Little remains of the abbey of St. Orrens. The ecclesiastical seminary contains an important library with a collection of manuscripts. The former palace of the intendants of Gascony is now the prefecture. Auch is the seat of an archbishop, a prefect, and a court of assizes, and has tribunals of first instance and of commerce and a chamber of commerce. Trade is in Armagnac brandy, wine, cereals, poultry, and "pâté de foie." Other industries are the making of hosiery, horse-rearing, brick-making, flour-milling, and tanning.

AUCHMUTY, SIR SAMUEL (1756–1822), British general, was born in New York, and served in the American War of Independence. At the conclusion of peace he exchanged into a regiment going to India. He served in the campaign against Tippoo Sahib, returning to England in 1797. Auchmuty became adjutant-general to Sir David Baird in Egypt in 1801; he was one of the few officers who came out with distinction from the Buenos Ayres expedition of 1806–07.

In 1810 he was sent out to India as commander-in-chief in Madras, and in the following year commanded the expedition to Java. The storming of the fortified position of Meester Cornelis (Aug. 28 1811), stubbornly defended by General Janssens, practically achieved the conquest of the island, and after the action at Samarang (Sept. 8), Janssens surrendered. In 1822 Auchmuty, who had received a G.C.B. in 1815, became commander-in-chief in Ireland. He died Aug. 11 1822.

AUCHTERARDER, police burgh, Perthshire, Scotland, 13¾m. S.W. of Perth by the L.M.S. Railway, on Ruthven water, a right-hand tributary of the Earn. Pop. (1931) 2,254 The chief manufactures are those of tartans and other woollens. It obtained a charter from the earl of Strathearn (early 13th century), afterwards became a royal burgh for a period, and was represented in the Scottish parliament. Its castle, now ruinous, was built as a hunting-lodge for Malcolm Canmore, but of the abbey it possessed as early as the reign of Alexander II. (1198–1249) no remains exist. The Norman church of St. Mungo is in ruins. The town was almost entirely burned down by the earl of Mar in 1716 during the abortive Jacobite rising. It was here that the dispute arose which led to the disruption in the Church of Scotland in 1843. The estate of Kincardine, 1m. S., gives the title of earl of Kincardine to the duke of Montrose. The castle was dismantled in 1645 by the marquis of Argyll in retaliation for the destruction of Castle Campbell in Dollar Glen south of the Ochils. The ruined castle of Tullibardine, 2m. W. of the burgh, once belonged to the Murrays of Tullibardine, ancestors of the duke of Atholl, who derives the title of marquis of Tullibardine from the estate.

AUCHTERMUCHTY, royal and municipal burgh and market town of Fifeshire, Scotland, about 9m. W. by S. of Cupar. Pop. (1931), 1,253. (*See* also FIFE.)

AUCKLAND, GEORGE EDEN, EARL OF (1784–1849) a governor-general of India, was second son of the first Baron Auckland. He was educated at Oxford, succeeding to the peerage in 1814. He was a consistent supporter of the Whigs and was selected by Lord Grey as president of the Board of Trade and master of the Mint in the famous Reform ministry of 1830. He occupied these two posts until Lord Grey's retirement in 1834, when Lord Melbourne made him first lord of the Admiralty, a post which he lost on the fall of the ministry the same year. On his return to office in 1835, Lord Melbourne sent Auckland out as governor-general to India. He devoted his attention to the improvement of native schools, to the economic development of India and especially to construction of famine relief works in the north-west; and he would no doubt have been remembered only as a painstaking and successful administrator but for his appalling error in interfering in the affairs of Afghanistan. Yielding to unwise advice, he proclaimed in Oct. 1838 the dethronement of the Afghan usurper, Dost Mohammed, and sent an expedition to Kabul under Sir John Keane, who victoriously entered the city and placed the rival Shah Shuja on the throne in Aug. 1839. For this victory he was created Lord Eden of Norwood and Earl of Auckland. But at the end of 1841 the insufficient garrison left in Kabul was surprised and defeated by a native insurrection. A series of disasters followed, as a result of which very few of the white troops reached India alive. Lord Auckland left India, recalled by Peel, in Feb. 1842, when affairs were at their worst. He re-entered politics and was again made first lord of the Admiralty in 1846 by Lord John Russell. He died suddenly on Jan. 1, 1840.

See Forbes, The *Afghan* Wars (1892); S. J. Trotter, *The* Earl of *Auckland* (1893).

AUCKLAND, WILLIAM EDEN, 1ST BARON, cr. 1793 (1745–1814), English statesman, was educated at Eton and at Christ Church, Oxford, and was called to the bar in 1768. He was under secretary of State (1772), commissioner of the board of trade (1776), commissioner to North America in connexion with the dispute with the American colonists (1778), and chief secretary for Ireland (1780). He resigned the chief-secretaryship in 1782, but next year took office as vice treasurer of Ireland under the coalition ministry, resigning with the Government in December. He opposed strongly Pitt's propositions for free trade between England and Ireland in 1785, but took office with Pitt as a member of the committee on trade and plantations, and negotiated in 1786 and 1787 Pitt's important commercial treaty with France, and agreements concerning the East India companies and Holland. In 1788 he was sent as ambassador to Spain. The same year he was sent on a mission to Holland, and represented English interests there with great zeal and prudence during the critical years of 1790 to 1793, obtaining the assistance of the Dutch fleet in 1790 on the menace of a war with Spain, signing the convention relating to the Netherlands the same year, and in 1793 attending the congress at Antwerp. He did not again hold office until 1798, when he joined Pitt's Government as joint postmaster general. He severely criticized Pitt's resignation in 1801, from which he had endeavoured to dissuade him, and retained office under Addington. This terminated his friendship with Pitt, who excluded him from his Administration in 1804 though he increased his pension. Auckland was included in Granville's ministry of "All the Talents" as president of the board of trade in 1806. He held the appointments of auditor and director of Greenwich hospital, recorder of Grantham, and chancellor of the Marischal College in Aberdeen. He died on May 28 1814.

He had married in 1776 Eleanor, sister of the first Lord Minto, and had a large family. Emily Eden (1797–1869), the novelist, was one of his daughters. On the death of his son George, 2nd baron and earl of Auckland (*q.v.*), the barony passed to the 1st baron's younger son Robert John (1799–1870), bishop of Bath and Wells, from whom the later barons were descended, and who was also the father of Sir Ashley Eden (1831–87), lieutenant governor of Bengal.

Lord Auckland's *Journal* and Correspondence (published 1861–62) throws much light on the political history of the time.

AUCKLAND, the largest city of New Zealand, and a thriving sea-port, on the east coast of New Zealand; capital of the province of its name. Population (1927) 202,400. It is beautifully situated at the mouth of an arm of Hauraki Gulf, the Waitemata harbour, and only 6m. from the Manukau harbour on the western coast. Auckland harbour, one of the best in New Zealand, is approached by great vessels at the lowest tides, and has large up-to-date concrete wharves. In 1926 the cargo handled totalled 1,948,079 tons. The Calliope graving dock provides ample accommodation for all kinds of shipping. Queen street, the principal thoroughfare, leads directly inland from the central wharves, and contains the majority of the public buildings. The city has a university, an art gallery and free library containing excellent pictures, and valuable mss., including a collection by Sir G. Grey, and a museum containing fine collections of Maori art. There are many magnificent parks and public reserves, covering in all 9,509 acres, although a considerable proportion of this area is outside the actual city confines. The Zoo, which occupies 29 acres, is justly famous. Of the suburbs, Newton, Parnell and Newmarket are outlying parts of the city itself; Devonport, Birkenhead and Northcote are beautifully situated on the north shore of the harbour and are served

by steam ferries; other residential suburbs lie among the hills on the mainland, such as Mount Albert, Mount Eden and Epsom. Onehunga is a port on the Manukau harbour. Auckland's population increase has been greater in ratio in recent years than that of any other New Zealand city, owing to the rapid settlement of the magnificent dairying lands to the north and south, and to its growing popularity as a residential city. Auckland was founded as the original capital of New Zealand in 1840 by Governor Hobson, but the seat of government was removed in 1865 to Wellington. There are regular steamships to other parts of the dominion, the Pacific Islands, Australia, Vancouver and Eastern ports.

AUCKLAND ISLANDS, a group of islands in the southern Pacific Ocean in 50° 24' S., 166° 7 E., discovered in 1806 by Capt. Briscoe. The islands are of volcanic origin, with fertile soil and are forest clad. They were granted to a private company by the British Government as a whaling station, but the establishment was abandoned in 1852. The islands belong politically to New Zealand, which maintains there a depôt of food and clothing for shipwrecked sailors. They are uninhabited. Area of the largest about 330sq. miles.

AUCTION BRIDGE, this originated in India. Three members of the Indian civil service, Mr. F. Roe ("John Doe"), Mr. Hudson, and another, all keen bridge players, were staying at a far-away hill station, where it was quite impossible to find a fourth. They played "Cut Throat" for a time, but they soon got tired of that, and then they set their wits to work to invent some better three-handed form of bridge. They tried all sorts of variations, without success, until one of them hit on the idea (probably borrowed from Vint) of bidding for the declaration, and it caught on at once. On that basis a new game was formulated, and it was, then and there, christened "Auction Bridge." The exact date of its birth is uncertain. The first record which we have of it is a letter from the late Mr. Oswald Crawfurd, which appeared in the *Times* of Jan. 16, 1903. This letter gave a brief outline of the game, and described it as "the new game of Auction Bridge for three players." Mr. Crawfurd had just returned from India, and had, no doubt, seen the game played in that country.

The next thing that happened was the publication of a short treatise by "John Doe," entitled "Auction Bridge," which was published by the Pioneer Press at Allahabad in 1904. The game was still confined to three players, but it had grown considerably. A further, and much fuller, description of it appeared in the *Daily Mail* of April 24, 1906, again by Mr. Oswald Crawfurd who seems to have been the real pioneer of the game in Britain, but it was the card-playing members of the Bath club who converted it from a three-handed game into a four-handed one, and who put it on a sound basis. The Bath club was the original home of the game in Britain, and for some considerable time it spread no further. Then, in 1907, the Portland club took it up, and after that its circle widened very rapidly, so much so that in about a year's time ordinary bridge was a thing of the past. Whist still clung on, and still does in some few places, but straight bridge is practically dead.

Auction bridge is played on the same lines as ordinary bridge with one or two important variations. The point where auction bridge diverges most widely from its parent game is in the declaration, which is no longer confined to the dealer and his partner, but every player in turn has the right of making a declaration, or as it is now termed "a bid," by overcalling any previous bid which has been made. Another notable point of difference is that when the declarer fails to fulfil his contract, his adversaries do not score below the line as at ordinary bridge, but they score a penalty of 50 points, or 100 if doubled, above the line for each under-trick, whatever the call may have been. Under no circumstances can the adversaries of the declarer score anything towards game. Doubling may take place as in straight bridge, but no bid that has been redoubled may again be doubled.

When auction bridge was first introduced the old bridge values were used, but it was soon recognized that the game was spoilt by the overwhelming value of the no truinp call. The Americans introduced a variation by inventing a new suit, "Royal Spades," or "Royals," which gave spades an alternative value of 2 or 9 per trick. This was tried in Britain for a while, but it was so obviously bad that, when the laws were revised in 1914, the lower value of the spade was done away with altogether, leaving it at 9, and the suits were all brought closer together—clubs 6, diamonds 7, hearts 8, spades 9, no trumps 10. These are the values at the present time. The great advantage of this scale over the old one is that it is possible to win the game on any call. "Five clubs" will do it as effectively as "three no trumps." "No trumps" is still the most valuable call, but its power is not overwhelming.

The scoring at auction bridge runs much higher than at ordinary bridge, owing principally to the amounts scored above the line for penalties; also the bonus for winning the rubber is increased from 100 to 250 points. The average value of a rubber at ordinary bridge is 170 points, at auction bridge it is nearer 400.

The original laws of auction bridge were drawn up by a joint committee of the Portland and Bath clubs in 1909, and were revised in 1914 by a special committee consisting of members of the Portland, Bath, Turf, St. James's, Baldwin, and White's clubs. These laws governed the game in Britain for ten years, but after a time, and after further experience, a demand arose for fresh revisions, and the Portland club, in 1924, drew up a new code of laws for the use of its own members. The code was accepted and adopted by all the other clubs. In the meantime, the Americans, who had adopted the English laws in *toto* at first, began to make alterations here and there, until, in 1925, the Whist club of New York, in conjunction with the Whist League of America, drew up an entirely new code of their own.

The principal difference between the two systems is in the bidding. In Britain, the bidding is governed by value. A bid of two no trumps, counting 20 points, takes precedence of a bid of three clubs, counting only 18, and a bid of four spades, counting 36, is higher than five diamonds counting 35. In America a bid of a greater number of tricks takes precedence of a less number, irrespective of the value. Thus, three clubs is higher than two no trumps, and five diamonds beats four spades. This American system is known as "Majority calling." It is adopted almost universally on the Continent, and some British players were so strongly in favour of it that in the summer of 1927 a conference of representatives of all the principal card-playing clubs in London was called together to consider it. Such a wide difference of opinion was expressed, that, in order to ascertain the general feeling in the country, all British bridge players, both in London and in the provinces, were asked to give the majority calling four months' trial and to report to the conference at the end of that period. The conference met again on Nov. 7, 1927, the clubs represented being Almack's, Baldwin, Bath, Carlton, Conservative, Devonshire, National Liberal, Portland, St. James's, St. Stephen's, Turf, and White's. The reports received were fairly evenly divided. In London clubs there was a strong feeling against making any change, but a small balance of country clubs were in favour of majority calling. As there was no strong mandate for any change, the conference decided by 9 votes to 3, voting by clubs, to retain our old system of value caliing in the revised laws, but to describe the principles of majority calling in an appendix, so that anyone who liked could use it. The card committee of the Portland club had in the meantime carefully revised the laws, which were submitted to the conference, and passed with a few minor alterations, and they became law on March 1, 1928.

Apart from questions of law, auction bridge has been considerably influenced by American principles and American conventions. British players, as a rule, like a plain straightforward game, with as few conventions as possible. Americans, on the contrary, love conventions and are constantly inventing new ones, some of which have found their way to England. The most notable one is the "Informatory Double." When a player doubles an adverse bid of one no trump, his partner is bound to take the double out by bidding "Two" of his best suit, however, weak it may be, giving preference to the major suits over the minor ones. In the same way, if a player doubles a suit bid of "One" or "Two," it does not mean that he is strong in that suit, but just the opposite; it means that he is strong in the other three suits, but too weak in the suit declared to bid no trumps. His partner must make a bid in his own best suit, or bid no trumps if he has the declared suit stopped twice.

This convention met with strong opposition for many years in England, but it gradually crept in, and in 1925 became general.

On the completion of the deal, the dealer has first call. He can either pass or make a bid of some kind. If he elects to pass it is better to sny, "No bid" than "Pass," as the latter call is apt to be mistaken for "Hearts." Then each player in turn, commencing with the one on the dealer's left, can either pass or can overcall any previous bid that has been made either by the adversaries or by his own partner. When a bid has been passed by three players it becomes the declaration, and the player who made it, or in the case of the same suit having been bid by both partners, the player who made the first of such bids, plays the combined hands, and is termed "the declarer," his partner becoming "dummy."

When the declarer fulfils his contract, he scores, below the line, the value of as many odd tricks as he makes. When he fails to fulfil his contract his adversaries score 50 above the line, or 100 if doubled, for every under-trick. Honours are scored above the line by either side which holds them. A game consists of 30 points scored by tricks alone, that is, below the line. When either side has won two games, the total scores are added up, including scores for tricks, honours, and penalties, and the difference between the two scores is the amount won and lost.

The principle of bidding has undergone a considerable change since auction bridge was first introduced. In the early days players followed the lines of ordinary bridge and made their bids on numerical strength without top honours, but this has been entirely superseded. Players have learnt by experience that it is aces and kings that matter and that win games. An original bid, that is the first bid made on a hand, can always be depended upon to have top honours at the head of it, when it is made by a responsible player. Top honours mean ace, king; or ace, queen, knave; or king, queen, at least. Subsequent bids after the first original one are made on numerical strength with outside support to back them up, or an original bid of a partner can be supported on numerical strength, but the one outstanding principle of modern declaring is that an original suit bid must have top honours at the head of it. At ordinary bridge the dealer would always call "Hearts" on king, ten, to five or six, with little else in his hand, but no sound auction bridge player would call "one heart" on that hand as an original call. He might call "two hearts" on it on the second round, but that is quite a different thing from calling it originally.

There are two entirely diiferent departments of auction bridge—the declaration and the play of the cards. There is considerable difference of opinion as to the relative value of these two. Some players estimate the value of clever declaring as high as 80%, others, including Lenz of New Ycrk, think that they are nearly, if not quite, equal, and that scientific play of the cards is as important as clever declaring. Eoth are important, but correct declaring is easier to acquire. It is not given to everybody to have the card sense and to be able to play the cards well, but anyone of ordinary intelligence can be taught to declare correctly. The most valuable declaration which can be made is no trumps, because three by cards will win the game from a love score at no trumps, but it takes four or five by cards to win the game on a suit declaration, but nevertheless a really strong major suit call, that is spades or hearts, is safer and better than no trumps. Some players are so obsessed with the glamour of the no trump call, that they seem to think it is the only road to success at the bridge table, and they call it on every possible occasion, and sometimes on very inadequate material. This is a great mistake. A genuine no trump hand should be well guarded in at least three suits, and should have a queen over the average—nothing weaker than this is justifiable at the score of love. (See also BRIDGE; CONTRACT BRIDGE)

UNITED STATES

Auction bridge may be designated as the offspring of bridge, the grandchild of whist and the father of contract. The history of whist, bridge, auction bridge and contract bridge in America—meaning, in this instance, the United States and Canada—is a record of European importations and domestic modifications. "Contract" appears to have been derived directly from France; but the other three, whatever their original place of birth, undoubtedly came to America from England. To-day (1928) auction bridge is the prevailing game, with contract widely played and growing rapidly in popularity; bridge is virtually abandoned, and whist played enthusiastically at the annual sessions of the American Whist League, but rarely elsewhere.

The Whist Club (New York) promulgated the first American code of auction bridge laws in 1910; these laws were immediately adopted by all American players and since then that club has been recognized as the supreme legislative authority for auction bridge in America. The 1910 code was amended in 1911, and revised and rewritten in 1912. In 1911, the Racquet Club of Philadelphia adopted for its own use the count of 6 points per trick for the club suit, 7 for diamonds, 8 for hearts, 9 for "royal" spades and 10 for no trump; the count of 2 being retained for spades used defensively. This was the first change from the old bridge count of 12 for no trump, 8 for hearts, 6 for diamonds, 4 for clubs and 2 for spades. Early in 1912 the Whist Club adopted the Racquet Club count for club play, and in Nov. 1912, embodied that count in its official code.

In 1913 the American code was entirely rewritten. This code eliminated chicane, created new privileges for dummy and reduced the revoke penalty to 100 points. In 1915 another new code was issued; it increased the values of slams and abolished the dual value of spades, thus giving the single value of 9 to the spade suit. More radical than either of these was the substitution of "numerical overcalling" in place of the system under which the values of tricks determined the rank of a bid. Since this revision, a larger number of tricks bid for always overcalls a smaller number (e g., four clubs overcalls three no trumps); the declarations assuming rank only when an equal number of tricks is bid for—no trump highest and clubs lowest. This change proved popular.

Further revisions were made in 1917 and 1920, involving no radical changes; but in 1925–26, an exhaustive study was made by The Whist Club in collaboration with Knickerbocker Whist Club (New York) and the American Whist League. This resulted in March, 1926, in the promulgation, by the Whist Club, of the present (1928) American auction bridge code. Three features of this final code are radical departures from all that has gone before: (1) The rank of cards from ace down to deuce is made uniform for all purposes (formerly ace was low in drawing for deal and seats, and low won; now ace is high and high wins); (2) honour-values are made multiples of ten instead of being based on trick-values; (3) revoke penalties are payable in tricks, which are utilized and scored exactly as if they had been won in play.

The outstanding differences between the American and English games of auction bridge lie: first, in the laws relating to rank of cards in drawing for deal and choice of seats, rank of bids in overcalling, method of counting honours, and the revoke penalty; second, in the greater readiness in America to try and adopt new "conventions"; and third, in the greater popularity in America of duplicate contests, which tend to reduce the element of luck and make skill the important factor. Most of the special and conventional tactics of bidding and play, prominently the "informatory double," are of American origin; many of these conventions have been adopted in England.

The popularity of auction bridge in America has grown until it is played by all classes of intelligent people; the number of its devotees is impossible to estimate; but the demand for playing cards, score pads, text-books and all kinds of bridge literature proves it to be enormous.

Over 40 years ago the teaching of whist was inaugurated by Miss Kate Wheelock. She was successful but not until auction bridge becdme a popular fad did the demand for instruction become wide-spread. Of late. however, bridge players have furnished conclusive evidence of their desire to learn how to play scientifically; in 1928 there were over one thousand American teachers, many of whom were unable to meet the demands made upon them for lessons.

Bridge by radio was introduced in Nov. 1925 and continued weekly during the winter seasons of 1926–27 and 1927–28 (November to March inclusive). A bridge hand is widely advertised in advance and the correct bidding and play are described with expert comment from approximately one hundred broadcasting stations at a designated hour. It is estimated that ten million players listen in each week, in most cases actually playing the hand in concert with the announcement as it comes to them through the air.

The American Auction Bridge League was formed in 1927 with R. R. Richards of Detroit as its first president. It manages largely attended duplicate contests and awards national championships.

The *Auction* Bridge magazine, a monthly publication, which started its career in 1922 has steadily increased the number of its subscribers; it has a large and representative editorial board.

(M. C. W.)

AUCTION PITCH, a card game (a variation of All Fours, *q.v.*) for from four to seven players. A complete pack is used. All the players cut for deal, the highest winning. Ace is the highest card, deuce the lowest. The dealer shuffles, and his opponent at the right cuts. The deal passes to the left. The cards are dealt in rotation, three at a time, to the players, beginning at the dealer's left. Six cards are dealt to each player. If an exposed card or a wrong number be dealt to a player there must be a new deal. The choice of trump is auctioned. Each player has one chance to bid. The player at the dealer's left has the first chance; he may pass or bid from one to four. Each succeeding player must pass or exceed the preceding bid; in addition, the dealer may refuse to sell for four, by bidding four. The winner of the auction pitches *the* trump by leading a card; the suit of the card led becomes trump. If no bid is offered, the player at the dealer's left pitches the trump, without the obligation to fulfil any contract. The winner of one trick leads for the next. Each player who is able must follow suit or trump. A player unable to follow lead to a plain (non-trump) suit may discard or trump. A revoke penalizes the offender the amount bid. Other players score what they make. In addition, *the* pitcher cannot be penalized for failure to fulfil contract when another player revokes.

The highest card of the suit led or the highest trump played wins the trick. One point is scored by the player dealt the highest trump out; one point is scored by the player dealt the lowest trump out. The player of a trump may ask if it is high or low. Jack (Knave) counts one point for the player winning the trick containing the Jack of trumps. Cards count one point for the player scoring most, each 10 scoring 10, each Ace 4, each King 3, each Queen 2, and each Jack found in the tricks won by him scoring 1. The claimant of cards turns his tricks face up, so that all may count his score. A tie for cards is won by the non-pitcher of trumps; a tie between two other players cannot be scored. Should two players be able to score game, the pitcher has precedence; between two non-pitchers able to score game precedence is given; first, to the holder of *high,* second to low, third to Jack, last to cards. If the pitcher of trumps fails to fulfil his contract, the amount of his bid is deducted from his score. A minus score puts him "in the hole," his shortage being indicated by a circle about his score. Game is 7 or 10 points, as agreed. (E. V. S.)

AUCTIONS AND AUCTIONEERS. An auction (Lat. *auctio,* increase) is a proceeding at which people are invited to compete for the purchase of property by successive offers of advancing sums. The advantages of conducting a sale in this way are obvious, and we naturally find that auctions are of great antiquity. Herodotus describes a custom which prevailed in Babylonian villages of disposing of the maidens in marriage by delivering them to the highest bidders in an assembly annually held for the purpose (Book i. 196). So also among the Romans the quaestor sold military booty and captives in war by auction—sub *hasta*—the spear being the symbol of quiritarian ownership. The familiarity of such proceedings is forcibly suggested by the conduct of the Praetorian Guard when Sulpicianus was treating for the imperial dignity after the murder of Pertinax. Apprehending that they would not obtain a sufficient price by private contract, the Praetorians proclaimed from their ramparts that the Roman world was to be disposed of by public auction to the best bidder. Thereupon Julian proceeded to the foot of the ramparts and outbid his competitor (Gibbon, vol. i. ch. v.). Though, however, auctions were undoubtedly common among the Romans both in public and private transactions, the rules whereby they were governed are by no means clearly enunciated in the Corpus *Iuris Civilis.*

In England the method of conducting auctions has varied. In some places it has been usual to set up an inch of lighted candle, the person making the last bid before the fall of the wick becoming the purchaser. By an act of William III. (1698), this method of sale was prescribed for goods and merchandise imported from the East Indies. Lord Eldon speaks of "candle-stick biddings," where the several bidders did not know what the others had offered. A "dumb bidding" was the name given to a proceeding at which a price was put by the owner under a candlestick with a stipulation that no bidding should avail if not equal to it. In a "Dutch auction" property is offered at a certain price and then successively at lower prices until one is accepted.

According to the practice now usual in England, a proposed auction is duly advertised, and a printed catalogue in the case of chattels, or particulars of sale in the case of land, together with conditions of sale, are circulated, Sometimes, in sales of goods, the conditions are merely suspended in the auction room. At the appointed time and place, the auctioneer, standing on a desk or rostrum, "puts up" the several lots in turn by inviting biddings from the company present. He announces the acceptance of the last bid by a tap with his hammer and so "knocks down" the lot to the person who has made it. Sometimes property is offered on lease to the highest bidder. "Roup" is the Scottish term for an auction. A bid in itself is only an offer, and may accordingly be retracted at any time before its acceptance by the fall of the hammer or otherwise. Puffing is unlawful. Unless a right to bid is expressly reserved on behalf of the vendor, he must neither bid himself nor employ anyone else to bid. When a right to bid has been expressly reserved, the seller or any one person (but no more) on his behalf may bid at the auction. If it is simply announced that the sale is to be subject to a reserved or upset price, no bidding by or on behalf of the seller is permissible: it is only lawful to declare by some appropriate terms that the property is withdrawn. Where a sale is expressed to be without reserve, or where an upset price has been reached, the auctioneer must, after the lapse of a reasonable interval, accept the bid of the highest bona fide bidder. By not doing so he would render the vendor liable in damages. The auctioneer must not make a pretence of receiving bids which are not in fact made, as it would be fraudulent to run up the price by such an artifice. A "knock-out" is a combination of persons to prevent competition between themselves at an auction by an arrangement that only one of their number shall bid, and that anything obtained by him shall be afterwards disposed of privately among themselves. With a view to the suppression of such "rings," the Auctions (Bidding Agreements) act, 1927, was passed by the British parliament.

A "mock auction" is a proceeding at which persons conspire by artifice to make it appear, contrary to the fact, that a *bona* fide sale is being conducted, and so attempt to induce the public to purchase articles at prices far above their value. Those who invite the public to enter the room where the supposed auction is proceeding, or otherwise endeavour to attract bidders, are called "barkers." A conspiracy to defraud in this way is an indictable offence.

The Auctioneer's Licence.—By a charter of Henry VII., confirmed by Charles I., the business of selling by auction was confined to an officer called an *outroper,* and all other persons were prohibited from selling goods or merchandise by public claim or outcry (see Henry Blackstone's Reports, vol. ii. p. 557). The only qualification now required by an auctioneer is a licence on which a duty of £10 has to be paid, and which must be renewed before the 5th of July in each year. A liability to a penalty of £100 is incurred by acting as an auctioneer without being duly licensed. An auctioneer is bound under a penalty oi £20 to see that his full name and address, together with a copy of the

Auctions (Bidding Agreements) act, 1927, are displayed before the commencement of an auction and during its continuance in the place where he conducts it. He is the agent of the vendor only, except in so far that, after he has knocked down a lot to the highest bidder, he has authority to affix the name of the latter to a memorandum of the transaction. so as to render the contract of sale enforceable where written evidence is necessary. An auctioneer does not by merely announcing that a sale of certain articles will take place, render himself liable to those who, in consequence, attend at the time and place advertised, if the sale is not in fact proceeded with, provided he acts in good faith. One of the chief risks run by an auctioneer is that of being held liable for the conversion of goods which he has sold upon the instructions of a person whom he believed to be the owner, but who in fact had no right to dispose of them.

The number of auctioneers' licences issued during the year ended March 31, 1937 was 7,033. A central organization with headquarters in Lincoln's Inn Fields, London, the Auctioneers' and Estate Agents' Institute of the United Kingdom, was founded in 1886. The Incorporated Society of Auctioneers and Landed Property Agents was founded later. (H. H.)

In the United States the same general principles underlie the control of auctions as in Great Britain. Specifically, they are regulated by states. A survey conducted by the Better Business Bureau of Milwaukee, Wis. (1924) in 52 principal cities illustrates this. Eleven did not permit auctions after 6 P.M., the rest closed them from 6 to 12 P.M.; some required no license fee, a few demanded a percentage, others a fixed amount for a specified time, *i.e.,* Tacoma, Wash., $1,000 a year, $50 a day. A majority permitted more than one jewelry auction in a given store the same year, and allowed auctions to run any number of successive days; a few fixed 30, Pittsburgh, Pa., 7–10 days as the limit. About 50% demanded from short, indefinite periods to 1 year of residence from merchants of jewelry auctions. Control of fraud and switching varied from requiring bonds or stock permits, imposing fines or revoking licenses to applying false pretences laws or merely "watching." Several cities demanded $2,500 bonds to ensure auctioneer's good faith, some $100 annual license fee, others twice the amount sold. Street auctions are limited or barred entirely. Some cities enforce transient merchant laws; others have drafted ordinances The Mastick-Goodrich law of New York was passed in 1927 to regulate auctions. Efforts against fraud have centred especially on jewellery sales, the greatest breeders of fake and mock auctions.

AUCUBA, a small genus of the dogwood family (Cornaceae) containing the familiar Japanese laurel (*Aucuba japonica*), grown in frost-free places or in the cool greenhouse. It bears male and female flowers on distinct plants; the red berries often last till the next season's flowers appear. A variegated form is the gold-dust tree.

AUDAEUS or AUDIUS, a church reformer of the 4th century, by birth a Mesopotamian. He was banished into Scythia, where he worked successfully among the Goths. The Audaeans celebrated the feast of Easter on the same day as the Jewish Passover, and they were also charged with attributing to the Deity a human shape, an opinion which they appear to have founded on Genesis i. 26. Theodoret accuses them of Manichean tendencies.

The main source of information is Epiphanius (Haer. 70).

AUDE, department of south France formed in 1790 from part of the old province of Languedoc. Area 2,448 sq.mi. Pop. (1936) 285,115. It consists of the east side of the Carcassonne gap between the Montagne Noire as an outer rampart of the Plateau Central and the outer ramparts of the Pyrenees, and it includes portions of both as well as the north-eastward projection of the latter in the Corbières between the valley of the Aude and that of the much smaller Berre, the department's two chief rivers. Aude is bounded on the north-east by Hérault, north-west by Tarn, west by Haute-Garonne, south-west by Ariège, south by Pyrénées-Orientales and east by the Mediterranean, and it is formed mainly by the basin of the Aude which runs out at its north-east corner. The coast, like that of Hérault, has large lagoons (Bages et Sigean, Gruissan, Lapalme and Leucate) separated from the sea by spits. Climate and vegetation are Mediterranean, the average winter temperature 44°–45°, and summer temperature 70°–71°, the rainfall is less than 24in. save on the hills. The department is agricultural, growing maize and other grains, while, with Hérault, it produces most of the cheapest wines of France, though those of Limoux and Narbonne are highly esteemed. The olive and chestnut are also grown. There are salt-producing marshes, some mines of mispickel, iron and manganese, and stone quarries.

The Canal du Midi, coming from the west via the Carcassonne gap, follows the Fresquel tributary to the Aude and a branch, Canal de la Robine, passes out to sea through Narbonne. The Southern Railway (Midi) serves the department.

The three arrondissements are named from the chief towns, Carcassonne (capital of the department), Limoux and Narbonne, and they are divided into 31 cantons. Aude belongs to the 16th military region and to the *académie* (educational division) and court of appeal of Montpellier. It forms the diocese of Carcassonne under the archbishopric of Toulouse.

AUDE, river of south-west France, rising in the eastern Pyrenees near the P. Carlitte and flowing into the Gulf of Lions. The upper course, except near Axat, is through deep gorges. Below Carcassonne its course, from north, turns due east, skirting the Corbières, to enter the Mediterranean some 12m. E.N.E. of Narbonne. The Aude gap, between the Pyrenees and the Montagne Noire, is one of the great historic thoroughfares of western Europe. The Aude is 140 m. long, with a basin of 2,061 sq m.

AUDEBERT, JEAN BAPTISTE (1759–1800), French artist and naturalist, published in 1800 *L'Histoire* naturelle des singes, des makis et des *galéopithèques,* illustrated by 62 folio plates drawn and engraved by himself. Two posthumous works appeared in 1802 under the general title Oiseaux *dorés* ou *à reflets* me'talliques.

AUDEFROI LE BATARD, French *trouvère,* flourished at the beginning of the 13th century and was born at Arras. The seigneur de Nesles, to whom some of his songs are addressed, is probably the châtelain of Bruges who joined the crusade of 1200. Audefroi was the author of at least five lyric romances: Argentine, Belle Idoine, Belle Isabeau, Belle *Emmelos* and *Béatrix.* These romances are an attempt to put new life into the lyric romance which was already dying out.

See A. Jeanroy, *Les Origines* de *la poésie lyrique* en France *au* moyen *âge* (1889).

AUDIENCE. In a technical sense, the term is applied to the right of access to the sovereign enjoyed by the peers of the realm individually and by the House of Commons collectively. More particularly it means the ceremony of the admission of ambassadors, envoys, or others to an interview with a sovereign or an important official for the purpose of presenting their credentials. In France, azrdience is the term applied to the sitting of a law court for hearing actions. In Spain, azrdiencia is the name given to certain tribunals which try appeals from courts of first instance. The azidiencia *pretorial, i.e.,* of the praetor, was a court in Spanish America from which there was no appeal to the viceregent, but only to the council of the Indies in Spain.

In England the *Audience-court* was an ecclesiastical court, held by the archbishops of Canterbury and York, in which they once exercised a considerable part of their jurisdiction. It has been long disused and is now merged in the court of arches.

AUDIFFRET-PASQUIER, EDMÉ ARMAND GASTON, DUC D' (1823–1905), French statesman created duke in 1844, and became auditor at the council of State in 1846. After the revolution of 1848, he retired to private life. In Feb. 1871 he was elected to the National Assembly, and became president of the right centre in 1873.

After the fall of Thiers, he directed the negotiations between the different royalist parties to establish a king in France, but as he refused to give up the tricolour for the flag of the old régime, the project failed. Yet he retained the confidence of the chamber, and was its president in 1875 when the constitutional laws were being drawn up. He likewise was president of the senate from March 1876 until 1879, when his party lost the majority.

AUDIO FREQUENCIES, in radio communication, the frequencies corresponding to normally audible sound waves. The upper limit ordinarily lies between 10,000 and 20,000 cycles. The lower limit is about 16 cycles.

AUDIO-FREQUENCY TRANSFORMER, a transformer used with electric currents of audio-frequency. An example of such use is in the audio-frequency amplifier forming part of a radio receiving set.

AUDIT ALE, a special quality of strong ale brewed at certain colleges in the English universities of Oxford and Cambridge, so called because it was drunk at the feasts held on audit-day.

AUDIT AND AUDITOR. An audit is examination of the accounts kept by the financial officers of a state, public corporations and bodies, or private persons, and the certifying of their accuracy. In the British Isles the public accounts were audited from very early times, though until the reign of Queen Elizabeth in no very systematic way. Prior to 1559 this duty was carried out, sometimes by auditors specially appointed, at other times by the auditors of the land revenue, or by the auditor of the exchequer, an office established as early as 1314. But in 1559 an endeavour was made to systematize the auditing of the public accounts, by the appointment of two auditors of the imprests. These officers were paid by fee and did their work by deputy, but as the results were thoroughly unsatisfactory the offices were abolished in 1785. An audit board, consisting of five commissioners, was appointed in their place, but in order to concentrate under one authority the auditing of the accounts of the various departments, some of which had been audited separately, as the naval accounts, the Exchequer and Audit Act of 1866 was passed. This statute. which sets forth at length the duties of the audit office, empowered the sovereign to appoint a "comptroller and auditor-general," with the requisite staff to examine and verify the accounts prepared by the different departments of the public service. In examining accounts of the appropriation of the several supply grants, the comptroller and auditor-general "ascertains first whether the payments which the account department has charged to the grant are supported by vouchers or proofs of payments; and second, whether the money expended has been applied to the purpose or purposes for which such grant was intended to provide." The treasury may also submit certain other accounts to the audit of the comptroller-general. All public moneys payable to the exchequer (*q.v.*) are paid to the "account of His Majesty's exchequer" at the Bank of England, and daily returns of such payments are forwarded to the comptroller. Quarterly accounts of the income and charge of the consolidated fund are prepared and transmitted to him, and in case of any deficiency in the consolidated fund, he may certify to the bank to make advances.

In the United States the auditing of the federal accounts is in the charge of the office of the Comptroller General, who is the head of the General Accounting Office, an agency independent of the executive departments of the government and responsible directly to Congress. In the performance of this function, the Comptroller General operates through a technical unit or bureau called the Audit Division under which are the following subdivisions: (1) Contract Examining Unit; (2) Receiving and Computing Section; (3) Check Section; (4) Contract Voucher Section; (5) Miscellaneous Section; (6) Civil Pay and Travel Section; (7) Military Pay Section; (8) Receipts and Deposits Section; (9) Audit Review Section; (10) Accounting Section; (11) Indian Tribal Claims Section and (12) Veterans' Bureau Section. This covers all government activities except those of the Post Office which are audited by the Post Office Division, a co-ordinate bureau with the Audit Division under the Comptroller General.

Provision is made in all the state and local governments for the exercise of the audit function in some form.

In practically all European countries there is a department of the administration, charged with the auditing of the public accounts, as the *cour* des *comptes* in France, the *Rechnungshof* des *deutschen Reiches* in Germany, etc. All local boards, large cities, corporations and other bodies have official auditors for the purpose of examining and checking their accounts and looking after their expenditure. So far as regards the work which auditors discharge in connection with the accounts of joint-stock companies, building societies, friendly societies, industrial and provident societies, savings banks, etc, the word auditor is now almost synonymous with "skilled accountant," and his duties are discussed in the article ACCOUNTANCY AND ACCOUNTANTS.

In Scotland there is an "auditor" who is an official of the court of session, appointed to tax costs in litigation, and who corresponds to the English taxing-master. In France there are legal officers, called auditors, attached to the *Conseil d'État*, whose duties consist in drawing up briefs and preparing documents. On the continent of Europe, lawyers skilled in military law are called "auditors."

Auditores **Rotae.**—Auditor is also the designation of certain officials of the Roman curia. The auditores Rotae are the judges of the court of the Rota (so called, according to Hinschius, probably from the form of the panelling in the room where they originally met). These were originally ecclesiastics appointed to hear particular questions in dispute and report to the pope, who retained the decision in his own hands. In the Speculum *juris* of Durandus (published in 1272 and re-edited in 1287 and 1291) the auditores *palatii domini papae* are cited as permanent officials appointed to instruct the pope on questions as they arose. The court of the Rota appears for the first time under this name in the bull *Romani Pontificis* of Martin V. in 1422, and the auditores by this time had developed into a permanent tribunal to which the definite decision of certain disputes, hitherto relegated to a commission of cardinals or to the pope himself, was assigned. From this time the powers of the auditores increased until the reform of the curia by Sixtus V., when the creation of the congregations of cardinals for specific purposes tended gradually to withdraw from the Rota its most important functions. It still, however, ranks as the supreme court of justice in the papal curia, and, as members of it, the auditores enjoy special privileges. They are prelates, and, besides the rights enjoyed by these, have others conceded by successive popes, *e.g.,* that of holding benefices in plurality, of non-residence, etc. When the pope says mass pontifically the subdeacon is always an auditor. The auditores must be in priest's or deacon's orders, and have always been selected—nominally at least—after severe tests as to their moral and intellectual qualifications. They are 12 in number, and, by the constitution of Pius IV., four of them were to be foreigners: one French, one Spanish, one German and one Venetian; while the nomination of others was the privilege of certain cities. No bishop, unless in *partibus* (see BISHOP), may be an auditor. On the other hand, from the auditores, as the intellectual *élite* of the curia, the episcopate, the nunciature and the cardinalate are largely recruited. The auditor camerae (zrditore generale *della* reverenda camera apostolica) is an official formerly charged with important executive functions. In 1483, by a bull of Innocent VIII., he was given extensive jurisdiction over all civil and criminal causes arising in the curia, or appealed to it from the papal territories. In addition he received the function of watching over the execution of all sentences passed by the curia. This was extended later, by Pius IV., to a similar executive function in respect of all papal bulls and briefs, wherever no special executor was named. This right was confirmed by Gregory XVI. in 1834, and the auditor may still in principle issue letters monitory. In practice, however, this function was at all times but rarely exercised, and, since 1847, has fallen to a prelate *locum tenens,* who also took over the auditor's jurisdiction in the papal states (Hinschius, Kathol. *Kirchenrecht,* i. 409, etc.).

Auditores (listeners), in the early Church, was another name for catechumens (*q.v.*).

AUDIT BUREAU OF CIRCULATIONS, a co-operative organization of advertisers, advertising agencies, and publishers in the United States and Canada. Organized in 1914. Headquarters, Chicago, Illinois. The objects of the bureau are described in the by-laws as follows:

To issue standardized statements of the circulation of publisher members; to verify the figures shown in these statements by auditors' examinations of any and all records considered by the Bureau to be

necessary; and to disseminate circulation data only for the benefit of advertisers, advertising agencies and publishers.

Each Publisher's Statement and each Audit Report issued to members shall embrace figures and facts bearing on the quantity, quality, distribution of circulation and circulation methods; thereby enabling quality as well as quantity to be established. The figures in the Audit Report shall be those verified by Bureau auditors. Facts, without opinion, to be reported.

In 1939 the membership numbered over 2,000, including approximately 260 advertisers, 135 advertising agencies, 1,070 newspapers, 220 magazines, 60 farm papers, and 270 business papers.

Up to the time that the bureau was organized every publisher had his own conception of what constituted a paid subscriber so that one publisher who offered a circulation of 100,000 might have actually a very different total from another publisher who claimed the same figure. Advertisers recognized the need of a common denominator in measuring circulation and the need to have all publishers use the same standards of measurement. These needs have been supplied in the information that is contained in A.B.C. reports.

The operating procedure of the bureau is briefly as follows: Twice a year each publisher member submits to the bureau a statement answering questions that, in the group judgment of advertisers, have a bearing on circulation values. These reports, known as Publisher's Statements, are printed and distributed to members. Once a year trained auditors from the bureau make an audit of the circulation records of each publisher member. These official audits are also printed and distributed to members.

The cost of operating the bureau is largely covered by the dues of the publisher members. But it is controlled by the buyers of advertising — the advertising agency and advertiser members. The managing director of the bureau operates under the direction of a board of directors of 27 men elected by the members. The directors include the representatives of 12 advertisers, 3 advertising agencies, and 12 publishers.

These men meet frequently to hear the reports of the bureau's activities and to act as a court of review in cases where publishers have been found delinquent in meeting the requirements of the bureau or where any publisher has a complaint against the management's interpretation of the rules. The growth of publication advertising in the United States and Canada is due largely to the protection that advertisers are assured through the use of A B C. verified circulation (P. L. T.)

AUDITION, also known as auditory sensation, is the principle of the division of sensations of hearing, according to which two great groups are formed. The first is that of sensations of tone, which are musical and smooth; the second that of sensations of noise, which are abrupt, harsh and rough. The physical stimulus of audition is the vibration of some material body; this vibration is normally transmitted to the ear by a wave-movement of the air particles.

See ACOUSTICS OF BUILDINGS; Helmholtz. *On* the *Sensations* of Tone (Eng. trans. 1895); Titchener, Text-book of Psychology (1910).

AUDLEY or AUDELEY, **SIR JAMES** (c. 1316–1369), one of the original knights, or founders, of the Order of the Garter, was the eldest son of Sir James Audley of Stratton Audley in Oxfordshire. He served under the Black Prince in France, and was made governor of Aquitaine and great seneschal of Poitou.

BIBLIOGRAPHY.—*See* Jean Froissart, Chroniques, Tr. by T. Johnes (Hafod, 1810); G. F. Beltz, Memorials of the Most Noble Order of the Garter (1841).

AUDLEY, THOMAS AUDLEY, BARON (*c.* 1488–1544), lord chancellor of England, entered Parliament in 1523 for the county of Essex. In 1529 he was Speaker of the House of Commons, presiding over the famous Black Parliament which abolished papal jurisdiction in England. He supported Henry VIII. in seeking a divorce from Catherine of Aragon, and became lord chancellor on Jan. 26 1533. He presided at the trial of Bishop Fisher and Sir Thomas More in 1535, and in 1536 he tried Anne Boleyn. He was raised to the peerage in 1538, and received the garter in 1540. He presided at the trials of Henry Pole (Lord Montacute) and the marquess of Exeter, managed the attainder of Thomas Cromwell, and the dissolution of Henry's marriage with Anne of Cleves. He resigned the lord chancellorship on April 21 1544, and died on April 30. His subservience to Henry VIII. was rewarded by the gift of many monastic estates. He re-endowed Buckingham College, Cambridge, under the new name of St. Mary Magdalene.

AUDRAN, the name of a family of French artists and engravers. The first who devoted himself to the art of engraving was Claude Audran, born 1597, and the last was Benoit, Claude's great-grandson, who died in 1772. The two most distinguished members of the family are Gérard and Jean.

GÉRARD or GIRARD, AUDRAN, engraver, was the third son of Claude Audran, and was born at Lyons in 1640. He was taught the first principles of design and engraving by his father, and continued his studies in Paris. He there, in 1666, engraved for Le Brun "Constantine's Battle with Maxentius," his "Triumph" and the "Stoning of Stephen," which placed Audran in the very first rank of engravers at Paris. He spent the years 1667–70 in Rome, where he engraved several fine plates. J. B. Colbert was so struck with the beauty of Audran's works that he persuaded Louis XIV. to recall him to Paris. On his return he was appointed engraver to the king, from whom he received great encouragement. He died at Paris in 1703. His engravings of Le Brun's "Battles of Alexander" are regarded as the best of his numerous works.

JEAN AUDRAN, nephew of Gérard, was born at Lyons in 1667. He was 80 years of age before he quitted the graver, and nearly 90 when he died. The best prints of this artist are those in which the etching constitutes a great part; and he has finished them in a bold, rough style. The "Rape of the Sabines," after Poussin, is considered his masterpiece.

AUDRAN, EDMOND (1842–1901), French musical composer, was born at Lyons. He made his first appearance as a dramatic composer at Marseille with *L'Ours* et *le Pacha* (1862), a musical version of one of Scribe's vaudevilles. Later he made various attempts to win fame as a writer of sacred music but eventually became known almost entirely as a composer of the lighter kinds of opera. His first Parisian success was made with Les *Noces d'Olivette* (1879), a work which speedily found its way to London and (as *Olivette*) ran for more than a year at the Strand theatre (1880–81).

Later works from his fluent pen which enjoyed exceptional favour included Le Grand Mogol (Marseille, 1876; Paris, 1884; London, as *The Grand Mogul,* 1884), La Mascotte (Paris, 1880; London, as The Mascotte, 1881), Gillette de Narbonne (Paris, 1882; London, as Gillette, 1883), La Cigale et la *Fourmi* (Paris, 1886; London, as La Cigale, 1890), Miss *Hélyett* (Paris, 1890; London, as Miss Decima, 1891), La Poupde (Paris, 1896; London, 1897). Audran was one of the best of the successors of Offenbach. He had little of Offenbach's humour, but his music is distinguished by an elegance and a refinement of manner which lift it above the level of opéra bouffe to the confines of genuine opéra comique. He was a fertile if not a very original melodist, and his orchestration is full of variety, without being obtrusive or vulgar.

AUDREHEM, ARNOUL D' (c. 1305–70), French soldier, was born at Audrehem, in the present department of Pas de Calais, near St. Omer. In June 1351 he became marshal of France. In March 1352 he was appointed lieutenant for the King in the territory between the Loire and the Dordogne, in June 1353 in Normandy, and in 1355 in Artois, Picardy and the Boulonnais. At Poitiers he was one of those who advised King John to attack the English, and, charging in the front line of the French Army, was slightly wounded and taken prisoner. He took an active part in the negotiations for the treaty of Bretigny, recovering his liberty at the same time as King John.

In 1361, as the King's lieutenant in Languedoc, he prevented the free companies from seizing the castles, and negotiated the treaty with their chiefs under which they followed Henry, count of Trastamara (later Henry II. of Castile), into Spain. In 1365 he himself joined du Guesclin in the expedition to Spain, was taken prisoner with him by the Black Prince at the battle of Najera (1367), and was unable to pay his ransom until 1369. In 1368, on account of his age, he was relieved of the office of

marshal, but he was sent to Spain in 1370 by Charles V., to urge his friend du Guesclin to return to France, and in spite of his age he took part in the battle of Pontvallain (Dec. 1370).

See Émile Molinier, "Étude sur la vie d'Arnoul d'Audrehem, maréchal de France," in *Mémoires présentés par divers savants à l'académie des inscriptions et belles-lettres,* 2e série, iv. (1883).

AUDUBON, JOHN JAMES (1785–1851), American naturalist, was born at Les Cayes, Santo Domingo, now Haiti, April 26, 1785. By his father, Lieut. John Audubon, a French naval officer and planter, the boy was taken to the United States and then to France. Even in his petted boyhood he was fond of nature and began making collections. He attended a military school for a time, and for a brief period studied drawing in Paris. His chief preparation for his future work, however, came when he spent a year on his father's farm near Philadelphia, and some months after his return, in France, hunting and drawing birds. The loss of his father's property in the West Indies and the unsettled conditions in France caused Audubon to engage in business in the new world. After he had made various unsuccessful ventures in the west, his loyal wife, Lucy Bakewell Audubon, insisted that his avocation become a vocation and practically assumed the support of the family while Audubon devoted himself to his great work, *The Birds of America* (1827–38). This imposing series contained 435 hand-coloured plates with 1,065 life-sized figures of 489 supposedly distinct species of birds. In spite of the later criticisms of his drawing, Audubon's service in making known in so handsome a fashion the birds of the new world is of inestimable value. When his pictures were exhibited at the Royal Institution of Edinburgh, they became the talk of the town; and in many writers traces may be found of the deep influence the productions of the "American woodsman" exerted upon his contemporaries. Audubon was a pioneer in reproducing birds in their natural poses. His work, which was carried on by subscriptions, supplemented by his income from painting, teaching, etc., became in time a family affair, his son John assisting him in his collecting and drawing, and his son Victor taking charge of business affairs. While the volumes were going through the press, Audubon divided his time between England and America, gathering new specimens, making drawings, and supervising publication. After the publication of the descriptive matter, *Ornithological Biography* (1831–39), in which William Macgillivray assisted him, and of *A Synopsis of the Birds of North America* (1839), the naturalist returned permanently to his adopted country. Immediately after his settlement in New York he threw himself energetically into two new tasks—the revision in "miniature" or octavo form of *The Birds of America* (1840–44) and the production of *The Viviparous Quadrupeds of North America* on which he collaborated with his faithful friend, the Rev. John Bachman, the father-in-law of his two sons. The folio plates of the *Quadrupeds* appeared in parts from 1842 to 1846, but Audubon lived to see only one volume of the text finished. In spite of his wonderful vitality, both mind and health failed before his death, Jan. 27, 1851. The house which he built by the Hudson still stands in New York City, near Riverside Drive and 158th Street.

BIBLIOGRAPHY.—F. H. Herrick's *Audubon the Naturalist* (1917), contains a full bibliography. Robert Buchanan's *The Life and Adventures of John James Audubon, the Naturalist* (1868), published in Everyman's Library, although readable, is inaccurate. It is a condensation of Mrs. Audubon's manuscript. Unable to secure the return of this manuscript, she published in America (1869) the Buchanan life with some additions, omissions of objectionable passages, and a preface by J. G. Wilson. Although Audubon's facts are not always accurate, he gave some vivid pictures of the America of his day. For these see *Audubon and His Journals* (1897), edited by Maria R. Audubon and Elliott Coues; also *Delineations of American Scenery and Character* (1926), edited by F.H. Herrick. *See* also F. H. Herrick, *Audubonthe Naturalist* (1917); E.A. Muschamp, *Audacious Audubon* (1929).

AUDUBON, a residential borough of Camden county, New Jersey, U.S.A., 5 mi. S.E. of Camden, on federal highway 30. It is served by the Pennsylvania-Reading Seashore railway. The population was 4,740 in 1920 (90% native white); it was 8,904 in 1930 and 8,906 in 1940 by the federal census. Wire, cloth and concrete block are manufactured. The borough was incorporated in 1900.

AUE, town of Germany, in the *Land* of Saxony at the confluence of the Mulde and Schwarzwasser, 21 mi. S.W. of Chemnitz. Pop (1939) 25,512. It has the Erzgebirge in the background to the southward. It manufactures machinery and metal objects.

AUENBRUGGER, LEOPOLD (1722–1809), Viennese physician, was born at Graz, Steyermark, on Nov. 19, 1722. He studied at Vienna and was placed in charge of the Spanish military hospital and the hospital of the Holy Trinity. His *New Invention for Discovering Obscure Thoracic Diseases by Percussion of the Chest* (1762) first introduced percussion as a means of detecting chest diseases but his method was not taken up until after his death, being introduced largely by the influence of the physician Piorry (d. 1879).

See M. Neuburger, *Leopold Auenbrugger* (1922).

AUER, LEOPOLD (1845–1930), violinist and famous teacher, was born at Veszprim, Hungary, June 9, 1845. He was trained at the Vienna conservatoire and later studied with Joachim, making the acquaintance at the same period of Brahms and Liszt, with both of whom he played. His début he made at Leipzig at one of the Gewandhaus concerts. In London later he met Anton Rubinstein, who in 1862 had founded the Imperial Conservatoire of Music, St. Petersburg, and at his suggestion he succeeded Wienavski as professor of the violin there in 1868, becoming two years later solo violinist to the imperial court.

When the Russian Revolution occurred in 1917 he was in Scandinavia. At the age of 73, with two trunks, his Stradivarius violin and $1,000 as his total of possessions, he sought refuge in America in Feb. 1918. Among his more famous pupils are Jascha Heifetz, Efrem Zimbalist, Mischa Elman and Toscha Seidel, while the high esteem in which he is held was illustrated by a remarkable concert given in his honour at Carnegie Hall, New York, in 1925, in which Rachmaninoff, Josef Hofmann, Gabrilowitsch, Zimbalist and Heifetz all took part. He is the author of *Violin Playing as I teach it* (1921); *My Long Life in Music* (1923) and *Violin Master Works and their Interpretation* (1925).

AUERBACH, BERTHOLD (1812–1882), German novelist, whose fame rests on his tales of village life, was born on Feb. 28 1812, at Nordstetten in the Black forest, and died at Cannes on Feb. 8 1882. He was educated at Tiibingen, Munich and Heidelberg, and studied philosophy under Strauss and Schelling. His parents, who were Jews, intended him to enter the Jewish ministry, but he was estranged from Jewish orthodoxy by the study of Spinoza, and turned to literature. Spinoza's life formed the basis of his first novel, *Dichter und Kaufmann* followed in 1839, and a translation of Spinoza's works in 1841. In 1843 he published the *Schwarzwalder Dorfgeschichten,* stories of peasant life in the Black forest, and later on novels in the same genre, *Barfüssele* (1856), *Edelweiss* (1861), and others. These works found a wide public and many imitators. They are not realistic studies of rural life in the modern sense, and probably they owed some of their popularity to the philosophical reflections and romanticism which Auerbach lent to the subjects treated.

The first collected edition of Auerbach's *Schriften* appeared in 1863–64; the best edition is that of 1892–95. Auerbach's *Briefe an seinen Freund J. Auerbach* (preface by F. Spielhagen) were published in a vols. (1884). *See* E. Zabel, *B. Auerbach* (1882); *E.* Lasker, B. *Auerbach, ein Gedenkblutt* (1882).

AUERBACW, a town in the south-west of the *Land* of Saxony, lying 1,500 ft. above sea level under the Erzgebirge, east of Plauen. Pop. (1939) 18,226. It produces embroidery, carpets and textiles.

AUERSPERG, ANTON ALEXANDER, GRAF VON (1806–1876), Austrian poet, who wrote under the pseudonym of ANASTASIUS GRÜN, was born on April 11 1806 at Laibach, and died at Graz on Sept. 12, 1876, and was head of the Thurn-am-Hart branch of the Carniolan cadet line of the house of Auersperg. He studied law at Graz and Vienna. As a member of the estates of Carniola on the *Herrenbank* of the diet at Laibach, he was an outspoken critic of the Austrian Government, leading the opposition of the duchy to the exactions of the central power. After the revolution of 1848 at Vienna he represented for 2 short time the district of Laibach at the German national

assembly at Frankfurt, to which he tried in vain to persuade his Slovene compatriots to send representatives. In 1860 he was summoned to the remodelled reichsrat by the emperor, who next year nominated him a life member of the Austrian upper house (*Herrenhaus*).

Count Auersperg's first publication was a collection of lyrics, Blatter der *liebe* (1830). His second production, Der *letzte* Ritter (1830), celebrates the deeds and adventures of the Emperor Maximilian I. (1493–1519) in a cycle of poems written in the strophic form of the Nibelungenlied. But Auersperg's fame rests almost exclusively on his political poetry; two collections entitled *Spaziergänge* eines Wiener *Poeten* (1831) and *Schutt* (1836) created a sensation in Germany by their originality and bold liberalism. These two volumes of poems were the forerunners of the German "Freiheit" poetry of 1840–48. His Gedichte (1837), if anything, increased his reputation; his epics, Die *Nibelungen im* Frack (1843) and Der *Pfaff* vom *Kahlenberg* (1850), are characterized by a fine ironic humour. He also produced masterly translations of the popular Slovene songs current in Carniola (Volkslieder *aus* Krain, 1850), and of the English poems relating to "Robin Hood" (1864).

BIBLIOGRAPHY.—Anastasius Griin's Gesanzmelte Werke were published by L. A. Frankl (1877); his Briefwechsel *mit* L. *A. Frankl* (1897). A selection of his Politische *Reden* und Schriften has been published by S. Hock (1906). See P. von Radics, Anastasius *Grün* (2nd ed., Leipzig, 1879).

AUERSTADT, BATTLE OF, Oct. 13, 1806: see NAPOLEONIC CAMPAIGNS.

AUFFENBERG-KOMARÓW, MORITZ, RITTEW VON (1852–1928), Austrian general, was born May 22, 1852, at Troppau and died on May 18. 1928. A most able soldier, Auffenberg was one of the leaders of the Austrian military party which centred round the Archduke Franz Ferdinand. He was minister of war from Sept. 1911 until Dec. 1912. In the course of his reorganization of the army, especially of the supply department, he made many enemies who compelled his dismissal by the emperor. In 1914 he commanded the Austrian 4th Army and won a remarkable victory at Komarów, Aug. 26–Sept. 3, 1914.

After the victory Auffenberg succeeded in the difficult operation of completely changing the front of his entire army, with which he moved southward in time to take part in the second battle of Lemberg; but the superior strength of the Russians and the failure of his colleagues to maintain the front farther south made it impossible for him to avert defeat. He was then called on to resign his command, and in April 1915 was arrested for alleged irregularities during his tenure of the war ministry. There was no real evidence for the charges and he was acquitted; but he took no further part in public life. He wrote *Aus Oesterreichs* Hohe *und* Niedergang (1921); he also contributed to the Encyclopedia *Britannica* (12th ed.) an important article on the battles around Lemberg (Lwow) and some biographies.

AUFGESANG, a division of the verses or stanzas of the ancient German Minnelieder. The stanza was usually divided into three sections. The two first, which were similar in construction, formed the introduction or *Aufgesang*, and the third was known as the *Abgesang* or conclusion. The form is still in use for hymns.

AUFIDENA, ancient city of the Samnites Caraceni, just north of modern Alfedena, Italy, a station on the railway between Sulmona and Isernia, 37m. from the latter. Its remains are described by L. Mariani in *Monumenti* dei Lincei (1901), 225 seq.; *cf. Notizie* degli scavi (1901), 442 *seq.*; (1902), 516 seq. The ancient city occupied two hills, both over 3,800ft. above sea-level (in the valley between were found the supposed remains of the later forum), and the walls, of rough Cyclopean work, were over a mile in circuit. Fourteen hundred tombs have already been examined in the necropolis below the town, and this may be only a sixteenth of the whole. They are all inhumation burials, of the advanced iron age (7th to 4th century B.C), falling into three classes—those without coffin, those with a coffin formed of stone slabs, and those with a coffin formed of tiles. The objects discovered are preserved in a museum on the spot. Castel di Sangro, five miles to the north-east, was probably the post-station on the road between Sulmo and Aesernia in the Roman period.

AUGEAS, AUGEIAS or **AUGPAS,** in Greek legend, a son of Helios the sun-god, and king of the Epeians in Elis. He possessed an immense wealth of herds, including 12 white bulls, sacred to Helios. Eurystheus imposed upon Heracles the task of clearing out all his stalls unaided in one day. This Heracles did by turning the rivers Alpheus and Peneus through them. Augeas had promised him a tenth of the herd but refused this, alleging that Heracles had acted only in the service of Eurystheus. Heracles thereupon sent an army against him, and finally slew Augeas and his sons. (Pindar, *Olymp.*, xi. 24; Diodorus, iv. 13; Theocritus, Idyll, 25.)

AUGEREAU, PIERRE FRANÇOIS CHARLES, DUKE OF CASTIGLIONE (1757–1816), marshal of France, was born in Paris in a humble station of life. In his early manhood he was a soldier of fortune, serving in the Russian, Prussian, and Neapolitan armies; but the events of the French Revolution brought him back to his native land. He served against the Vendeans and then joined the troops opposing the Spaniards in the south. There he rose rapidly, becoming general of division on Dec. 23, 1793. His division distinguished itself in the Italian campaign, and under Bonaparte he had a share in the battle of Millesimo and in taking the castle of Cosseria and the camp of Ceva. At the battle of Lodi (May 10, 1796), the turning movement of Augereau and his division helped to decide the day, and at Castiglione he rendered signal services. Bonaparte thus summed up his military qualities: "Has plenty of character, courage, firmness, activity; is inured to war; is well liked by the soldiery; is fortunate in his operations"

In 1797 Bonaparte sent him to Paris to encourage the Directors, and it was Augereau and the troops led by him that coerced the "moderates" in the councils and carried through the coup *d'état* of 18 Fructidor (Sept. 4, 1797). He took no part in the coup *d'état* of Brumaire, 1799, and did not distinguish himself in the Rhenish campaign which ensued. Nevertheless, owing to his final adhesion to Bonaparte's fortunes, he received a marshal's baton at the beginning of the empire (May 19, 1804). In the campaign of 1805 he did good service around Constance and Bregenz, and at Jena (Oct. 14, 1806) his corps distinguished itself. Early in 1807 he fell ill of a fever, and at the battle of Eylau he had to be supported on his horse, but directed the movements of his corps with his wonted bravery. His corps was almost annihilated and the marshal himself received a wound from which he never quite recovered.

When transferred to Catalonia, he gained some successes but tarnished his name by cruelty. In the campaign of 1812 in Russia, and in the Saxon campaign of 1813, his conduct was little more than mediocre. Before the battle of Leipzig (Oct. 16 to 19, 1813), Napoleon reproached him with not being the Augereau of Castiglione, to which he replied, "Give me back the old soldiers of Italy, and I will show you that I am." In 1814 he had command of the army of Lyons, and his slackness exposed him to the charge of having come to an understanding with the Austrian invaders. Thereafter he served Louis XVIII., but after reviling Napoleon, went over to him during the Hundred Days. The emperor repulsed him and charged him with being a traitor to France in 1814. Louis XVIII., when restored to the throne, deprived him of his military title and pension. He died at his estate of La Houssaye on June 12 1816. In person he was tall and commanding, but his loud and vulgar behaviour frequently betrayed the soldier of fortune.

See Kock's *Mémoires* de *Masséna;* Bouvier, Bonaparte en *Italie;* Count A. F. Andréossi, La Campagne *sur le Mein, 1800–01;* Baron A. Ducasse, *Précis* de la *campagne* de *l'armée* de Lyon en 1814; and the Memoirs of Marbot.

AUGHRIM or **AGHRIM,** a small village in Co. Galway, Eire, 4 mi. W. by S. of Ballinasloe. It is rendered memorable by the decisive victory gained here on July 12, 1691, by the forces of William III under General Ginkel, over those of James II under the French general St. Ruth, who fell in the fight. The Irish, numbering 25,000 and strongly posted behind marshy ground, at first maintained a vigorous resistance; but Ginkel having penetrated their line of defense, and their general being

struck down by a cannon ball at this critical moment, they were at length overcome and routed with terrible slaughter. The loss of the English did not exceed 700 killed and 1,000 wounded; while the Irish, in their disastrous flight, lost about 7,000 men, besides the whole material of the army. This defeat rendered the adherents of James in Ireland incapable of further efforts, and was speedily followed by the complete submission of the country.

AUGIER, GUILLAUME VICTOR EMILE (1820–1889), French dramatist, was born at Valence, Drôme, on Sept. 17, 1820. He was the grandson of Pigault Lebrun, and belonged to the well-to-do *bourgeoisie* in principles and in thought as well as by actual birth. He received a good education and studied for the bar. In 1844 he wrote a play in two acts and in verse, *La Ciguë,* produced with considerable success at the Odéon. Thenceforward, at fairly regular intervals, either alone or in collaboration with other writers—Jules Sandeau, Eugène-Marie Labíche, Éd. Foussier—he produced plays which were in their way eventful His last comedy, *Les Fonrrchambault,* belongs to the year 1878. After that date he wrote no more, restrained by an honourable fear of producing inferior work. He died at Croissy on Oct. 25, 1889.

Augier, with Dumas *fils* and Sardou, may be said to have held the French stage during the Second Empire. The man respected himself and his art, and his art on its ethical side—for he did not disdain to be a teacher—has high qualities of rectitude and self-restraint. Uprightness of mind and of heart, generous honesty, as Jules Lemaitre well said, constituted the very soul of all his dramatic work. *L'Aventurière* (1848), in verse, the first of Augier's important worts, already shows a deviation from romantic models; and in the *Mariage d'Olympe* (185j) the courtesan is shown as she is, not glorified as in Dumas's *Dame aux Camélias.* In *Gabrielle* (1849), in verse, he declared war on romanticism; and in the comedies that followed he showed no sympathy for the nervous and melancholy types of character hitherto in favour. But it is difficult to comment on contemporary life in verse, and Augier found fuller expression for his criticism of the Paris of his day when he turned to prose-writing. *Le Gendre de M. Poirier* (1854), written in collaboration with Jules Sandeau, is still a classic. Others of his nine successful plays are *Le Fils de Giboyer* (1862), *Lions et renards* (1869), *Jean de Thommeray* (1874), *Madame Caverlet* (1876), and *Les Fourchambault* (1878). The two last-named are *pièces à thèse* on the strict Dumas model. Augier's first drama, *La Ciguë,* belongs to a time (1844) when the romantic drama was on the wane; and his almost exclusively domestic range of subject scarcely lends itself to lyric outbursts of pure poetry. His verse, if not that of a great poet, has excellent dramatic qualities, while the prose of his prose dramas is admirable for directness, alertness, sinew and a large and effective wit. René Doumic has said of his plays that in their ensemble they form the most complete expression of the bourgeois society of the time, and that they are one of the most important manifestations of the bourgeois spirit in the whole of French literature.

AUGITE, an important rock-forming mineral of the pyroxene (*q.v.*) group. The name is now applied to aluminous pyroxenes of the monoclinic series, which are dark-green, brown or black in colour. The habit of well-shaped crystals in lavas is simple and very characteristic, consisting of the forms a (100), b (010), *m* (110), and *s* (111). Twins with the orthopinacoid (100) as twin plane are common. Chemically, augite is an isomorphous mixture in which the compounds diopside ($CaMgSi_2O_6$) (*q.v.*) and hedenbergite ($CaFe'Si_2O_6$) preponderate, but containing also alumina and ferric oxide and variable amounts of the $(Mg,Fe'')SiO_3$ (clinoenstatite) molecule. The small amount of sodium usually present in the mineral occurs in solid solution as the acmite-jadeite molecule. The interpretation of augite analyses is not simple, and it is at present not possible to state the manner in which the sesquioxides $(Al,Fe''')_2O_3$ are disposed in the constitution of the mineral. According to G. Tschermak's view, these enter in the form of the hypothetical silicate $(Mg,Fe)O\,(Al,Fe)_2O_3SiO_2$ sometimes known as Tschermak silicate, but a study of superior analyses of augite shows that this view cannot be sustained. It is believed by some investigators that alumina and ferric oxide (above that needed for the acmite-jadeite molecules) enter as such in solid solution with diopside and hedenbergite. Thus interpreted an analysis of an augite from Hawaii and 6.82% Al_2O_3 and 3.36% Fe_2O_3, has the molecular composition as follows: $CaMgSi_2O_6$, 69·12%; $CaFeSi_2O_6$, 15·13%; $NaFeSi_2O_6$ (acmite), 5·08%; $MgSiO_3$, 1·90%; $FeSiO_3$, 0·40%; $(Al,Fe)_2O_3$,8·65%. Common augite is usually non-pleochroic, but varieties containing significant proportions of soda (aegirine-augite) or titania (titan-augite) are noticeably so, the former being characteristically green and the latter violet in thin section. Augite is a common mineral of igneous rocks of medium and low silicity such as porphyrites, gabbros and basalts while the varieties aegirine-augite and titan-augite are characteristic of alkaline igneous rocks, nepheline- and leucite-bearing lavas and intrusions, monchiquites, limburgites, etc. (C. E. T.)

AUGMENT, in Sanskrit and Greek grammar the vowel prefixed to indicate the past tenses of a verb; in Greek grammar it is called *syllabic,* when only the ε is prefixed; *temporal,* when it causes an initial vowel in the verb to become a diphthong or long vowel, (Lat. *augere,* to increase).

AUGMENTATION, or enlargement, a term in heraldry for an addition to a coat of arms; in biology, an addition to the normal number of parts; in Scots Law, an increase of a minister's stipend by an action called "Process of Augmentation." The "Court of Augmentation" in Henry VIII.'s time was established to try cases affecting the suppression of monasteries, and was dissolved in Mary's reign. In music, augmentation is a term signifying that the notes to which it applies are doubled in length, quavers becoming crotchets, crotchets minims, and so on.

AUGSBURG, a city and episcopal see, Bavaria, Germany, chief town of the district of Swabia. Pop. (1939) 185,704. Lying on a plateau 1,500ft. above sea, between the rivers Wertach and Lech, which unite below the city, it consists of an upper and a lower town, the old Jakob suburb and various modern suburbs.

Augsburg (*Augusta Vindelicorum*) is named after Augustus, who established a Roman colony here about 14 B.C. Sacked by the Huns in the 5th century it afterwards came under the power of the Frankish kings. It suffered in the war of Charlemagne against Tassilo III., duke of Bavaria; and later became part of the dukedom of Swabia, when it became important as a manufacturing and commercial town, becoming, after Niirnberg, the centre of the trade between Italy and North Europe; its merchant princes, the Fuggers and Welsers, rivalled the Medici of Florence; but with the discoveries of the 15th and 16th centuries trade declined. In 1276 it was made a free imperial city, until its annexation (1806) to the kingdom of Bavaria. It was besieged and taken by Gustavus Adolphus in 1632, and in 1635 surrendered to the imperial forces; in 1703 it was bombarded by the electoral prince of Bavaria, and also suffered severely in the war of 1803. The Augsburg confession (1530) and the Augsburg alliance (1686) were decided here. The Renaissance town hall (*1616–1620*) is one of the finest in Germany, and contains the "Golden Hall," 113 ft. long, 59 ft. broad and 53 ft. high. The cathedral, with two Romanesque towers, dates from the 10th century. The church of St. Ulrich is Late Gothic (1474–1500), finely proportioned, with a high tower (300 ft.). The newer buildings, in the west quarter of the city, include law courts, a theatre, and a municipal library. The "Fuggerei," built in 1519 by the brothers Fugger, is a miniature town, with six streets or alleys, three gates and a church, and consists of 106 small houses let to indigent Roman Catholic citizens.

Augsburg, the chief seat of the textile industry in south Germany, produces woollen, linen and cotton goods and has bleaching and dye works. Its production of agricultural and industrial machinery and its chemical works are important. Most important in World War II were the factories making Diesel engines for submarines and Messerschmitt planes. These factories were bombed by the British in Sept. 1940, and very heavily attacked from the air in April 1942 and in 1943

AUGSBURG, CONFESSION OF, the most important Protestant statement of belief drawn up at the Reformation,

presented in Latin and German to the emperor Charles V. at the Diet of Augsburg, June 25, 1530. It was compiled by Melanchthon, but based on articles previously drawn up by Luther, and in particular on those presented by him at the Marburg conference (see MARBURG, COLLOQUY OF); Melanchthon being in constant correspondence with Luther while compiling the Confession. It has become the classical statement of Lutheran doctrine, and is in effect the official creed of the Lutheran Churches. The 21 articles of its first part state the main doctrines held by Lutherans: (a) in common with Roman Catholicism, the doctrine of the creeds of the Catholic Church; (b) in common with Augustine and his followers, against Pelagianism and Donatism; (c) in opposition to Roman Catholicism, affirming justification by faith and the exclusive mediatorship of Christ; also on the Church, the ministry, and rites; (d) in opposition to Anabaptism, on the meaning and administration of sacraments, on confession, and on the millennium. The seven articles of the second part condemn what Luther and his followers believed to be the chief Roman abuses: (1) withholding the cup; (2) compulsory celibacy of the clergy; (3) the Mass a sacrifice; (4) compulsory confession; (5) festivals and fasts; (6) monastic vows; (7) secular authority exercised by bishops.

See Hastings, *Encyclopaedia of Religion and Ethics,* art. "Confessions," § 13, Confessions in the Lutheran Churches"; Lindsay, *History of the Reformation,* vol. i., bk. ii., ch. v.; Beard, *The Reformation in Relation to Modern Thought and Knowledge;* Herzog-Hauck, *Realencyklopadie,* art. "Augsburger Bekeantniss," with references to Continental writers. On the history of the text of the Coniession, *see* Müller, *Die symbolischen Bücher der evangelisch-lutherischen Kirche* (1907). The text presented at the Diet is known as the *Invariata,* and the edition revised by Melanchthon and issued in 1540 as the Variata—the former being authoritative for Lutheranism.

AUGSBURG, WAR OF THE LEAGUE OF (the name applied to the European War of 1688–97). The League of Augsburg was concluded on July 9, *1686,* by the emperor, the elector of Brandenburg and other princes, against the French. Spain, Sweden, England and other non-German states joined the league, and formed the Grand Alliance by the Treaty of Vienna (July 12, 1689). (*See* GRAND ALLIANCE, WAR OF THE.)

AUGURS, in ancient Rome, members of a religious college whose duty it was to observe and interpret the signs *(auspices)* of approval or disapproval sent by the gods in reference to any proposed undertaking. The *augures* were originally called *auspices,* but, while *auspex* fell into disuse and was replaced by *augur, auspicium* was retained as the scientific term for the observation of signs. *Auspex=avi-spex,* "observer of birds"; *augur* may perhaps=*avi-gur,* from *garrire,* to chatter (of birds), but is more probably to be referred to a lost verb *augo,* tell, so that the *augur* would be one who declares the will of the gods.

The early history of the college is obscure. Its institution has been attributed to Romulus or Numa. It probably consisted originally of three members, of whom the king himself was one. This number was doubled by Tarquinius Priscus, but in *300* B.C. it was only four, two places, according to Livy (x 6), being vacant. The Ogulnian law in the same year increased the number to nine, five plebeian being added to the four patrician members. In the time of Sulla the number was 1 j, which was increased to *16* by Julius Caesar. This number continued in imperial times; the college itself was certainly in existence as late as the 4th century A.D. The office of augur, which was bestowed only upon persons of distinguished merit and was much sought after by reason of its political importance, was held for life. Vacancies were originally filled by co-optation, but by the Domitian law (104) the selection was made, by 17 out of the 35 tribes chosen by lot, from candidates previously nominated by the college. The insignia of office were the *lituus,* a staff free from knots and bent at the top, and the *trabea,* a kind of toga with bright scarlet stripes and a purple border.

The science of augury was contained in various written works, including a manual of augural ritual, and a collection of answers given by the college to the senate. The natural region to look to for signs of the will of Jupiter was the sky, where lightning and the flight of birds seemed directed by him as counsel to men. It was the duty of the augur, before the auspices properly so called (those from the sky and from birds) were taken, to mark out with his staff the *templum* or consecrated space within which his observations were intended to be made. At midnight, when the sky was clear and there was an absence of wind, the augur, in the presence of a magistrate, took up his position on a hill which afforded a wide view. After prayer and sacrifice, he marked out the *templum* both in the sky and on the ground and dedicated it. Within its limit he then pitched a tent, in which he sat down with covered head, asked the gods for a sign, and waited for an answer. As the augur looked south he had the east, the lucky quarter, on his left, and therefore signs on the left side were considered favourable, those on the right unfavourable. The practice was the reverse in Greece; the observers of signs looked towards the north, so that signs on the right were regarded as the favourable ones, and this is frequently adopted in the Roman poets. The augur afterwards announced the result of his observations in a set form of words, by which the magistrate was bound.

Signs of the will of the gods were of two kinds, either in answer to a request (*auspicia impetrativa*), or incidental *(auspicia oblativa).* Of such signs there were five classes: (1) Signs in the sky *(caelestia auspicia),* consisting chiefly of thunder and lightning, but not excluding falling stars and other phenomena. Lightning from left to right was favourable, from right to left unfavourable; but on its mere appearance, in either direction, all business in the public assemblies was suspended for the day. Since the person charged to take the auspices for a certain day was constitutionally subject to no other authority who could test the truth or falsehood of his statement that he had observed lightning, this became a favourite device for putting off meetings of the public assembly. Restrictions were, however, imposed in later republican times. When a new consul, praetor or quaestor entered on his first day of office and prayed the gods for good omens, it was a matter of custom to report to him that lightning from the left had been seen. (2) Signs frorn birds *(signa ex avibus),* with reference to the direction of their flight, and also to their singing, or uttering other sounds. To the first class, called *alites,* belonged the eagle and the vulture; to the second, called *oscines,* the owl, the crow and the raven. The mere appearance of certain birds indicated good or ill luck, while others had a reference only to definite persons or events. In matters of ordinary life on which divine counsel was prayed for, it was usual to have recourse to this form of divination. For public affairs it was, by the time of Cicero, superseded by the fictitious observation of lightning. (3) Feeding of birds *(auspicia ex tripudiis),* which consisted in observing whether a bird—usually a fowl—on grain being thrown before it, let fall a particle from its mouth (*tripudium sollistimum*). If it did so, the will of the gods was in favour of the enterprise in question. The simplicity of this ceremony recommended it for very general use, particularly in the army when on service. (4) Signs from animals *(pedestria auspicia,* or *ex quadrupedibus), i.e.* observation of the course of, or sounds uttered by, quadrupeds and reptiles within a fixed space, corresponding to the observations of the flight of birds, but much less frequently employed. (5) Warnings *(signa ex diris),* consisting of all unusual phenomena, but chiefly such as boded ill. Such were various noises, the fall of a stick in a temple, the squeak of a mouse, stumbling, sneezing, or the seizure of anyone in the *comitia* by an epileptic fit (*morbus comitialis*). Being accidental in their occurrence, they belonged to the *auguria oblativa,* and their interpretation was rather a matter for the *pontifices* than for the augurs, when the incident wss not already provided for by a rule.

Among the other means of discovering the will of the gods were the casting of lots, oracles of Apollo (in the hands of the college *sacris faciundis*), but chiefly the examination of the entrails of animals slain for sacrifice. Anything abnormal found there was brought under the notice of the augurs, but usually the Etruscan *haruspices* (*q.v.*) were employed for this. The persons entitled to ask for an expression of the divine will on a public affair were the magistrates. To the highest offices, including all persons of consular and praetorian rank, belonged the right of taking *auspicia maxima;* to the inferior

offices of aedile and quaestor, the auspicia *minora;* the differences between these, however, must have been small. The subjects for which auspicia *publica* were always taken were the election of magistrates, their entering on office, the holding of a public assembly to pass decrees, the setting out of an army for war. They could only be taken in Rome itself; and in case of a commander having to renew his *auspicia,* he must either return to Rome or select a spot in the foreign country to represent the hearth of that city. The time for observing auspices was, as a rule, between midnight and dawn of the day fixed for any proposed undertaking. The founding of colonies, the beginning of a battle, the calling together of an army, sittings of the senate, decisions of peace or war, were frequently occasions for taking auspices. The place where the ceremony was performed was not fixed, but selected with a view to the matter in hand. A spot being selected, the official charged to make the observation pitched his tent there some days before. A matter postponed through adverse signs from the gods could on the following or some future day be again brought forward for the auspices. If an error (*vitium*) occurred in the auspices, the augurs could, of their own accord or at the request of the senate, inform themselves of the circumstances, and decree upon it. A consul could refuse to accept their decree while he remained in office, but on retiring he could be prosecuted. Auspicia oblativa referred mostly to the comitia. A magistrate was not bound to take notice of signs reported merely by a private person, but he could not overlook such a report from a brother magistrate. For example, if a quaestor on his entry to office observed lightning and announced it to the consul, the latter must delay the public assembly for the day.

BIBLIOGRAPHY.--On the subject generally, *see* A. Bouché-Leclercq, *Histozre de la divination dans l'antiquité* (1879), and his articles, with bibliography, in Daremberg and Saglio's *Dictionnaire des antiquitts;* J. Marquardt, *Ronzische Staatsverwaltung* (iii. 1885); articles "Augures," "Auspicium," in Pauly-Wissowa, *Realencyklopädie* (II. pt. ii., 1896); G. Purser (and others) in Smith's *Dictionary of Greek and Roman Antiquities* (3rd ed., 1890). *(See* also DIVINATION, OMEN, ASTROLOGY, etc.)

AUGUST (originally *Sextilis*), the sixth month in the pre-Julian Roman year, which received its present name from the Emperor Augustus. The preceding month, *Quintilis,* had been called "July" after Julius Caesar, and the emperor chose August to be renamed in his own honour because in that month he had been admitted to the consulate, had thrice celebrated a triumph, had received the allegiance of the soldiers stationed on the Janiculum, had concluded the civil wars, and had subdued Egypt.

AUGUSTA, a city of Georgia, U.S.A., 171 mi. E. by S. of Atlanta, at the head of navigation on the Savannah river; the county-seat of Richmond county. It is on federal highways 1, 25, and 78; is a pivoted point for other southeastern roads; and is served by the Southern, the Atlantic Coast Line, the Central of Georgia, the Georgia, the Charleston and Western Carolina, and the Georgia and Florida railways and by bus lines. It is an inland port on the Savannah river, 201 mi. from the seaport of Savannah, and in 1937 a lock and dam were constructed by the war department and an increase in water-borne commerce followed. The city is protected by an 11 mi. levee. The city has an airport, with air mail, air passenger and air express service. Population (1940) 65,919.

Augusta has an average monthly temperature ranging from 48° F. in January to 81° in July, and an average of 8 hrs. of sunshine daily throughout the year. This, combined with its accessibility, and with the natural beauties of pine forests, dogwood, jasmine, azaleas, and other characteristic flora, has given it an established reputation as a winter resort. There are hotels of charm and distinction, and many beautiful private winter homes.

The city extends along the river, from Lake Olmstead on the north, for more than 3 mi. On its outskirts are the residential suburbs of Lakemont and Forest Hills; the country club with two 18-hole golf courses; the aviation field; the U.S. Veterans' Psychiatric hospital No. 62; and Pendleton camp, a private benefaction for disabled veterans of World War I (100 ac. of virgin woodland, with cottages built as required), given and endowed (1919) by his parents as a memorial to Lieut. John Pendleton King. Across the river in South Carolina are the residential suburbs of North Augusta. Three miles down the river is the new Sand Bar Ferry bridge. The giant oaks which shade its approach mark the site of the most famous duelling ground of South Carolina and Georgia, where the last duel on record was fought in 1875.

The main business thoroughfare of the city (Broad street) is 170 ft. wide, and in it stands the Confederate monument, a shaft of marble surmounted by the figure of a private soldier. On beautiful Greene street are the city hall and the county court house, and several monuments of interest: to the poets of Georgia, who include Sidney Lanier; to Samuel Hammond, a revolutionary soldier and statesman; to the men of Richmond county who fell in the war between the states; and to the three Georgia signers of the Declaration of Independence. Over the canal is a bridge erected as a memorial to Archie Butt, who went down with the "Titanic." The city is famous for its beautiful private gardens.

There are many buildings of historic interest: *e.g.,* St. Paul's Episcopal church (founded 1750); the First Presbyterian church (1804) and the manse where Woodrow Wilson passed his boyhood; the United States arsenal, the only one in the southeast of the Mississippi, which was established in 1816, and has occupied its present site since 1826; the chimney of the Confederate powder mill, which was the principal source of supply for the Confederate army; and many homes of men who mere prominent in the history of state and nation. A Celtic cross in St. Paul's churchyard marks the site of Fort Augusta, built by Oglethorpe in 1735. It was near Augusta that Eli Whitney set up and operated his first cotton-gin.

The medical department of the University of Georgia (see ATHENS), founded in 1829 as the Georgia Medical college, occupies a campus of 45 ac., on which are located also the University hospital (built and maintained by the city) and the Wilhenford hospital for children, both of which are under the medical and surgical control of the university medical department. The state school for mentally defective children is 10 mi. from the city. The boys' high school occupies a building erected for the Academy of Richmond county (founded 1783). Paine college (incorporated as Paine institute, 1883) is an institution for Negroes supported by the Methodist Church.

Georgia's earliest textile mills were located near Augusta. Between 200,000 and 400,000 bales are the current annual cotton receipts. There are a press cloth manufacturing plant and four textile mills which consume 150,000 bales of cotton annually. One of the world's largest cotton waste mills is there. Augusta manufactures candy, fertilizer and cottonseed products. It handles hard and soft woods, and this enterprise, measured in lumber feet, amounts to 200,000,000 ft. a year. Augusta brick and tile manufacturers ship 650,000 tons of clay products annually. Contiguous to a rich kaolin belt, Augusta produces fire brick and manufactures refractory and insulating material.

Augusta was founded in 1735 by James Edward Oglethorpe, and was named after the contemporary princess of Wales. The Carolina colonists had a trading post in the vicinity before Oglethorpe, and earlier still it had been the chief trading centre of the seven Cherokee nations. During the colonial period it was the scene of several parleys and treaties with the Indians. At the most important of these, in 1763, the Choctaws, Creeks, Chicasaws, Cherokees, and Catawbas, meeting with the governors of North and South Carolina, Virginia, and Georgia, agreed to the terms of the Treaty of Paris. At the opening of the Revolution the prevailing temper of Augusta was loyalist. The town was held by the British for a month in 1779, and again from May 1780 to June 1781. Except for these periods it was the seat of the state government in 1779–80 and again from 1783–95. Here met the Land court which confiscated the property of the loyalists of Georgia; and also the convention which ratified the constitution af the United States.

The town was incorporated in 1798 and secured a city charter in 1817. A steam packet to Savannah was established in 1817, and this stimulated the commercial development. By 1860 the popu-

lation had grown to 12,493. Throughout the Civil War the city was an important centre for the manufacture of military supplies.

AUGUSTA, the capital of Maine, U.S.A., and the shire-town of Kennebec county, at the head of navigation on the Kennebec river, 60 mi. N.E. of Portland. It has an airport, is served by the Maine Central railroad and bus lines, and in every direction radiate hard-surfaced highways and historic trails.

The population in 1930 was 17,198 and 19,360 in 1940 by the federal census.

The state capitol is a fine building of native granite, which still keeps the original front designed by Charles Bulfinch in 1829. It houses the state museum, which contains many exhibits of Maine fauna. The executive mansion is the former home of James G. Blaine, who lived here during most of his public life. Fort Western (erected 1754) was restored in 1919 as a historic monument. Across the river on a farm of 500 ac. is a state hospital for the insane, which was established in 1834. Lake Cobbosseecontee, one of the best fishing waters in Maine, is about 4 mi. W. of the city. The bridge across the Kennebec is 1,100 ft. long. The Kennebec dam (first built in 1837) is head of tide, 40 mi. from the Atlantic ocean.

The principal industries are the manufacture of paper products, cotton goods and shoes. Printing and publishing are also important, including the publication of several national periodicals.

The post office is rated in the first class. There is a paper mill manufacturing tissues, towels and napkins; a cotton mill with 1,761 looms and 71,440 spindles; a lumber mill produces long lumber and house finishings; and two shoe factories. The output of the 39 establishments within the city limits in 1940 was valued at over $12,000,000.

Augusta occupies the site of an Indian village, Koussinoc, where the Plymouth colony established a trading-post about 1628. In 1754 a fort was erected. A post office was established in 1794. The town was incorporated under the name of Harrington in 1797, and became the shire-town in 1799. It was chosen as the capital of the state in 1827, and became the seat of government in 1831, on the completion of the state house. The city charter was obtained in 1849.

AUGUSTA, a seaport of Sicily, 19 mi. N. of Syracuse by rail. Pop. (1936) 17,716 (town); 19.690 (commune). It occupies a part of the former peninsula of Xiphonia, now a small island, connected with the mainland by a bridge. Founded by the Emperor Frederick II (1232), it was almost destroyed by earthquake (1693) after which it was rebuilt. The castle is now a large prison. There are considerable saltworks at Augusta. The port and vicinity were bombed by the Allies in World War II after the Tunisian victory.

AUGUSTA BAGIENNQRUM, chief town of Ligurian Bagienni, identical with modern Bene Vagienna, on the upper course of the Tanaro, about 3½ mi. S. of Turin, Italy. It remained a tribal centre in the reorganization and replanning under Augustus, whose name it bears. There are remains of public buildings, in concrete faced with small stones, with bands of brick at intervals, an amphitheatre with major axis 390 ft. and minor axis 305 ft., a theatre with stage 133 ft. in length, and near it the foundations of what was probably a basilica, an open space (no doubt the forum), an aqueduct, baths, also one of the city gates, flanked by two towers 22 ft. square.

AUGUSTAN HISTORY, the name given to a collection of the biographies of the Roman emperors from Hadrian to Carinus (A.D. 117–284). The work, which, as we have it, is mutilated, the preface and a few lines being lost, professes to have been written during the reigns of Diocletian and Constantine, and to be the composition of six authors — Aelius Spartianus, Julius Capitolinus, Aelius Lampridius, Vulcacius Gallicanus, Trebellius Pollio and Flavius Vopiscus. Who really wrote it is unknown; the date is perhaps the reign of Julian; the whole tone is interpreted by Baynes (see below) as one of disguised propaganda in his favour.

The importance of the Augustan history as a repertory of information is very considerable, because it is frequently our only authority for the period it covers. It is, however, a most wretched work, both as history and as literature. In form, the biographies are plainly modelled upon Suetonius; the sources are obscure, the authorities quoted mostly unknown, if not imaginary. Marius Maximus and Aelius Junius Cordus, to whose qualifications the *Historia* Augusta itself bears no favourable testimony, are oftenest cited, and are mere names for us. The earlier lives, however, contain a substratum of authentic historical fact, which recent critics have supposed to be derived from a lost work of an annalistic nature. Another and less good source was a series of biographies of the emperors. As to the alleged extracts from public records, private letters, etc., of the emperors, and so forth, they are to be received with the utmost caution, so many being palpable forgeries as to create a prejudice against them all. No biographical particulars are recorded respecting any of the writers. From their acquaintance with Latin and Greek literature they must have been men of letters by profession, and very probably secretaries or librarians to persons of distinction. There seems no reason to accept Gibbon's contemptuous estimate of their social position. They appear particularly versed in law. Spartianus's reference to himself as "Diocletian's own" seems to indicate that he was a domestic in the imperial household. They address their patrons with deference, acknowledging their own deficiencies, and seem painfully conscious of the profession of literature having fallen upon evil days.

BIBLIOGRAPHY.—Editio princeps (1475). Casaubon (1603) showed great critical ability in his notes, but for want of a good ms. left the restoration of the text to Salmasius (1620), whose notes are a most remarkable monument of erudition, combined with acuteness in verbal criticism and general vigour of intellect. Of recent years considerable attention has been devoted by German scholars to the *History*, especially by Peter, whose edition of the text in the Teubner series (1884) contains (praef. xxxv.–xxxvii.) a bibliography of works on the subject preceding the publication of his own special treatise. For the latest comment, *see* Norman Baynes, *The Historia Augusta, its Date and Purpose* (1926, contains bibliography of earlier works).

AUGUSTA PRAETORIA SALASSORUM (mod. Aosta, *q.v.*), ancient town of Italy, district of the Salassi, founded by Augustus about 24 B.C. on the site of the camp of Varro Murena, who subdued this tribe in 25 B.C., and settled with 3,000 praetorian~.Pliny calls it the last town of Italy on the northwest, and its position at the confluence of two rivers, at the end of the Great and Little St. Bernard, gave it much military importance, which is vouched for by considerable remains of Roman buildings. The ancient town walls, enclosing a rectangle 793 by 624 yd., are 21 ft. high, concrete faced with small blocks. There are towers at the angles of the *enceinte*, and others at intervals, and two at each of the four gates, making a total of 20 towers altogether. They are roughly 32 ft. square, and project 14 ft. from the wall. The east and south gates exist (the latter, a double gate with three arches flanked by two towers, is the Porta Praetoria, and is especially fine), while the rectangular Roman street scheme divides the town into 16 blocks (*insulae*). The main east to west road, 32 ft. wide, divides the city into two equal halves, showing that the city guarded the road. Some arcades of the amphitheatre (diameters 282 ft. and 239 ft.) and the south wall of the theatre are also preserved, the latter to a height of over 70 ft., and a market place some 300 ft. square, surrounded by storehouses on three sides with a temple in the centre, and two on the open (south) side, and the thermae, have been discovered. Outside the town is a handsome triumphal arch in honour of Augustus. About 5 mi. to the west is a single-arched Roman bridge, the Pondel, which has a closed passage, lighted by windows for foot passengers in winter, and above it an open footpath, both being about 33 ft. in width. There are considerable remains of the ancient road from Eporedia (mod. *Ivrea*) to Augusta Praetoria, up the Valle d'Aosta, which the modern railway follows.

Bérard in *Atti della Società di Archeologia di Torino*, iii. 119 *seq.*; *Notizie degli Scavi*, passim; A. d'Andrade, *Relazione dell'Ufficio Regionale per la conservazione dei Monumenti del Piemonte e della Liguria*, 146 *seq.* (Turin, 1899); F. Haverfield, *Ancient Town Planning* (Oxford, 1917).

AUGUSTINE, SAINT (AURELIUS AUGUSTINUS) (354–430), bishop of Hippo in proconsular Africa, A.D. 396–430, was born at Tagaste, a small town in the eastern part of the adjacent province of Numidia, in the year 354. His father Patricius

became Christian late in life; his mother Monica seems to have been Christian from her girlhood. Both were probably of pure Roman birth, but it is seldom possible to examine the racial antecedants of provincials at that date, and there may well have been some Numidian or Punic blood in the family. In any case they were Africans, and the climatic influences of the country are perceptible in the natural bent of Augustine's character. It may be noted that he wrote sympathetically of the last struggle of Carthage, and, addressing the Romans of his own day, called the conqueror "ille Scipio vester." (Civ. Dei. i. 30. iii. 18) He was acquainted with the Punic language, and aware of its affinity with Hebrew; when a bishop, he insisted on the appointment of priests who could speak it. At barely 12 years of age he was sent to a school of grammar at Madaura, an ancient colony of veterans where all was traditionally Roman. Five years later, steeped in Latin literature, but imperfectly acquainted with Greek and actively disliking it, he passed to Carthage, partly at the cost of his wealthy townsman Romanianus, for a course of rhetoric. Formally made a catechumen in childhood, he was not a Christian. He still retained enough of his mother's teaching to feel dissatisfied with the Hortensius of Cicero, for the strange reason that it contained no reference to Jesus Christ, but this was probably an interest of nothing more than curiosity. The self-reproaches of his maturity afforded no reason for attributing to him any plunge into gross licentiousness during his student days, and the constant temptations to such conduct seem rather to have disgusted him, though he experienced their full force; but his moral standards were those of the time and place, even if he were temperate in practice. Continence seemed to him out of the question; he formed at once one of those engagements of concubinage which were reckoned tolerable even for Christians, and found himself before he was 20 years old the father of a boy to whom he gave the pious name Adeodatus. Shortly afterwards he came under the influence of Manichaean teachers, and for nine years was a hearer, critical but not scornful, looking forward to the remotely possible asceticism of the elect. The attitude is significant, showing what was already the bent of his spirit. Intellectual difficulties, he was told, would be solved when he had heard Faustus, the great master Faustus came lo Carthage; Augustine thought him a poor, unscholarly creature, contemptuously cast aside the whole system, and fell back on the scepticism of the Academy.

AFTER A STATUETTE IN THE CHURCH OF S. MARIA DELLE GRAZIE, AT AREZZO
ST. AUGUSTINE, THE GREAT CHRISTIAN BISHOP AND PHILOSOPHER

Conversion. — In this mood he crossed the sea to Rome with his small family, hoping to find employment there as teacher of rhetoric. Failure and disappointment awaited him, and a year later he accepted an invitation to lecture at Milan. He arrived there in the autumn of 384, and was soon joined by his mother, now a widow. The crisis of his life was approaching. He soon came under the influence of Ambrose, the statesman-bishop of the city, who was engaged in a sharp struggle with Justina, the Arian mother of the young emperor Valentinian, but the influence seems to have been rather moral than intellectual. He was deep in the study of Cicero, who taught him to seek an escape from pyrrhonism in the practical certitude of moral judgments It is not easy to disentangle the events of the next two years, for the chronology of the memories written in his *Confessions* appears to be confused. It will be more serviceable to distinguish concurrent movements.

(1) Monica was determined, in a way which seems curiously modern, to settle him in marriage, and a suitable bride was found who was not quite of marriageable age The most unpleasant incident of his life follows As n preliminary his faithful companion the mother of Adeodatus was dismissed and sent back to Africa, where she joined a religious community. In reminiscence Augustine betrays some sympathy with her grief, but is much more occupied with his own loss. The result was a renewed conviction of the impossibility of continence, which he freely discussed with his pupil, the naturally chaste Alypius, doing the young man no little harm. To this period we may refer the ejaculatory prayer, branded on his memory, "Give me chastity, but not yet!" The struggle of flesh and spirit, which had driven him to Manichaeism, was again active. The issue was soon decided. He took another concubine for the time before his marriage, and was probably blamed by none but himself.

(2) Ponticinnus, an officer of the palace, called on Augustine and Alypius one day, and, a Christian himself, was surprised to find a volume of St. Paul's Epistles lying on their table. The ensuing conversation led him to speak of two officers of the imperial staff at Treveri who casually found in a house which they visited a copy of the Life of *St. Anthony,* the great Egyptian hermit; they read of his austerities, and were moved to embrace the same mode of life. Augustine was overwhelmed with shame. Those soldiers could make an act of renunciation which he, student and philosopher pledged to contempt of the world, could not compass.

(3) The weakness of the spirit against the flesh was enhanced by the intellectual weakness of scepticism. From this Augustine passed at a bound to Neoplatonism. A man whom he unkindly describes as inflated with conceit introduced him to the works of Plotinus, translated into Latin by Marius Victorinus, the eminent rhetorician practising at Rome. He read them with a personal interest when he heard from Simplicianus the story of the conversion of Victorinus to Christianity in his old age. His memory of the immediate effect, as narrated in the Confessions, may be coloured by later studies, for he says that he found in them a contact with the doctrine of the Word as taught in the fourth gospel; but the effect was certainly great, and he was, in a sense, Platonist from that time onward.

(4) The scene in the garden is one of the great loci *classici* of religious psychology. He was sitting one day with Alypius, who knew most of the trouble. his soul torn by the bitter conflict going on within him. A sudden gust of tears drove him from the presence of his friend; he went into the garden, and flung himself down, sobbing "How long! to-morrow and to-morrow!" He then heard the voice of a child singing in the next garden "Tolle lege, tolle lege." Curious, even at that moment, to know whether the words belonged to some childish game, he could remember nothing of the kind At once he applied them to himself as a divine command, calmly returned to the house, took up a volume of St. Paul's Epistles, opened it and read the words that first met his eyes: "Not in rioting and drunkenness, not in chambering and wantonness, not in strife and envying: but put ye on the Lord Jesus Christ, and make not provision for the flesh in the lusts thereof." He showed the passage to Alypius, who read further, pointed to the next words, "Him that is weak in the faith receive ye" and applied them to himself. Together they went to Monica and told her what had happened.

(5) This narrative, written by Augustine himself with extreme simplicity, and the whole story of his mental anguish, have been questioned as inconsistent with what followed. One of the few clear notes of chronology available shows that soon after these events Augustine, sick with the heat alike of summer and of his internal conflict, took a reading party to a pleasant country house at Cassiciacum, lent by his friend Verecundus This can be dated Aug. 386. Here they rend, and discussed what they had been reading with youthful high spirits and interludes of rustic labours. Monica, the only Christian of the party, occasionally intervened with modesty and good sense. A shorthand writer took notes of everything, which Augustine reduced to connected narratives modelled on Cicero's Tusculan Disputations. These are the Dialogues *Contra Academicos, De Beata* Vita, and De *Ordine.* They are purely philosophic, with occasional glances at Christian doctrines currently but imperfectly known in the world. Critics such as Gourdon and Alfaric ask what traces are here to be found of the stricken penitent soul which Augustine described in his

Confessions 13 years afterwards. If that picture had been true, it is urged, he must at once have renounced his chair of rhetoric, seeking the ascetic life which so strongly attracted him; nor indeed would his new friends within the Christian Church have tolerated the retention of so pagan a profession by a convert. The latter objection seems to imply that Christians in general shared the sentiments affected in open hostility by the emperor Julian; but Ausonius and Sulpicius Severus in recent years had not thought it necessary so to act. The former calls for examination. To understand the tone of the Dialogues we have to remember that not one of the young men of the party was an instructed Christian, and some had no thought of breaking with the old religion: Augustine the penitent would not wear his heart on his sleeve with them. It is even more important to bear in mind that from the moment of the incident in the garden he found himself, as frequently happens in such cases, wrapped in a profound peace. We have no reason to suppose that his gaiety at Cassiciacum was either forced or affected. When writing his Confessions he cared for nothing in that episode except his meditations on the Psalter in hours of solitude; the *Dialogues* he dismissed as mere academic exercises, which indeed they were, finished in the lingering darkness of his unregenerate days. Many years afterwards he noted in his Retractations their inevitable faults.
