These wars were of special importance to the internal history of Denmark because they caused the Danish burghers' hatred of the nobles to break out anew more strongly than ever, without justification inasmuch as the Rigsraad had striven to the best of its ability to prevent the wars, but with justification inasmuch as the nobles had shown but little heroism and above all would not make, in common with the lower estates, the sacrifices required to remedy the poverty resulting from the wars. These differences were accentuated at the State assemblies which from 1638 onwards were now and again called together. All the proposals made, even those on behalf of the king, for the betterment of the condition of the country, were rejected by the Rigsraad, which was led by the high steward, Korfits Ulfeldt, the husband of Christian IV.'s daughter, Leonora Christina. As a condition of his accession the high steward compelled Frederick III. to sign a charter which considerably decreased the royal prerogative in nominating at his own pleasure lord lieutenants and members of the Rigsraad. With great shrewdness and firmness, Frederick III. began to work for a change in the constitution. He succeeded in overthrowing Korfits Ulfeldt, who had been found guilty of frauds; and when Charles X., vexed at not having completely conquered Denmark, recommenced the war in 1658 and soon invested Copenhagen, the burghers of the city were stimulated into a heroic defence by the offer of great privileges: Copenhagen became a free *Rigstad* (Crown city) whose assent was necessary for the settling of State affairs and whose burghers were to enjoy the same privileges as the nobles. The Dutch, who did not relish the idea of both shores of the Sound being in the hands of the Swedes any more than in the hands of the Danes, despatched a fleet to the relief of Copenhagen and on Feb. 11, 1659, the Swedish attack on the capital was repelled. Charles X.'s death was followed by the Peace of Copenhagen in 1660: Bornholm and Trondhjem, which in the meanwhile had freed themselves, were given back to Denmark, but in other respects the Treaty of Roskilde was confirmed because the Western Powers so willed it: Skaane, Halland, Blekinge and Bohuslan were forever lost to Denmark.

The Constitutional Revolution of 1660.—After peace had been declared the Estates Assembly met in Copenhagen in Sept. 1660. Measures of taxation were necessary but the nobles were as unwilling as ever to forego their exemption from taxes The church representatives under the leadership of the Bishop Hans Svane, together with the burghers, whose leader was Hans Nansen, the burgomaster of Copenhagen, then allied themselves to form an opposition party and forced the Rigsraad and the nobles to take on a share of the taxes and to enter into negotiations with the king for a change in the constitution. They constrained the Rigsraad and the nobles to confer on Frederick III. and his family the hereditary succession to the throne, and when the Rigsraad negatived this proposal the opposition submitted it on Oct. 10 direct to the king; under the pressure of threats the Rigsraad gave in on Oct. 13. The charter which had insisted on the elective nature of the monarchy was rendered void and handed over for cancellation to the king, who was acclaimed with great pomp as hereditary sovereign on Oct. 18. There were suggestions for a new constitution of the estates and when the assembly was dissolved (Dec.) it received the king's promise to institute a constitutional law for the kingdom. In Jan. 1661 the Government sent out an instrument or pragmatic sanction to be signed by all the more prominent citizens, landowners, bishops, professors, magistrates, etc., in which the king had conferred on him not merely the succession but also absolute sovereignty.

The constitution which Frederick III. had promised was at last drafted by the king's *Kabinetssekretär* (State secretary) Peder Schumacher. The king signed it on Nov. 14, 1665, but it was not made public until 1709. The king's law, as it was called, made the Danish sovereign absolute inasmuch as it imposed on him the sole duties of keeping the kingdom undivided and of maintaining the Christian religion in accordance with the Confession of Augsburg, while it further settled the succession on Frederick III.'s heirs both in the male and female lines. An absolute monarchy was, indeed, the necessary and only possible constitution for Denmark in 1660 if it was desired to deprive the nobles of their political power. For the burghers were clever enough to perceive that, however influential the nobles still were, a constitution would only have given them new power. The absolute monarchy meant that from now onwards every distinction of rank between the noble and de *ufri staender* (the unfree estates)—was done away with and from now onwards, as far as possible, all Danish citizens would be on a level under the absolute rule of the king.

The first task awaiting the monarchy was to bring about a new order in the kingdom. After the terrible misfortunes of the wars military affairs were completely separated from the civil administration. In the sphere of local government the country was divided anew into districts under superior magistrates who replaced the lord lieutenants. In the sphere of central government there were established administrative boards (*Kollegie-ordningen*); the two chanceries to which the name *kancelli* was applied and the office of the Exchequer were changed into administrative boards and other boards were instituted to deal with war and the admiralty, while yet another special board was set up apart as the supreme court of law of the kingdom. The boards laid proposals before the king, who gave his decisions soon after the matter had been dealt with by a secret council the members of which, selected chiefly from among the heads of the boards, were nominated by the king. While the old Danish nobility held aloof on their country estates their places in the administration were taken by burghers.

The Burgher Bureaucracy.—Thus there was formed a burgher bureaucracy in which the first and most significant figure was Peder Schumacher, a member of a rich and highly respected Copenhagen burgher family, who as early as Nov. 1673 was made State chancellor (rigskansler), because of his brilliant abilities, and at the same time created count of Griffenfeldt (*q.v.*). This was in accordance with a law formulated by Schumacher himself with reference to counts and barons (1671), whereby in the case of certain members of the burgher bureaucracy there might be created a nobility which should owe its existence to the king alone, to replace the old aristocracy. Griffenfeldt aimed at the removal of the old deep-rooted differences between the estates, and though he himself was overthrown in March 1676, the burgher bureaucracy remained to play an important rôle during the first period of the absolute monarchy. Not until about 1730

did there come a change; in this year once again the landowners, some of them of the old nobility, some of the new, came into power but only as servants of the absolute monarchy.

A joint code of laws for the entire kingdom was issued under the name of Christian V. (1670–99) in 1683; serfdom was abolished in 1702 and for a brief period the Zealand peasant became free; trade and industry were protected in accorddnce with mercantile principles; schools were opened in the provinces and thus a foundation was laid for a system of elementary education. But almost the most important reform of the whole period was the setting up in 1684 of a registration system throughout the kingdom whereby the land was classified in accordance with its value with the intention of attaining a more equitable distribution of taxes. For it was soon found that the absolute monarchy needed heavy taxes to cover the great expenditure involved in maintaining it. one item being the erection of a number of castles in North Zealand, another the great cost of the army and navy.

The absolute monarchy regarded it as an inherited responsibility to fight the traditional enemy Sweden and to reconquer Skaane. Hence the Skaane war of 1675–79 and the great Scandinavian wars of 1700 and 1709–20, which entailed terrible sacrifices. Skaane was not regained, but it was as a result of victories over Charles XII. and his ally, the duke of Holstein-Gottorp, that Frederick IV. (1699–1730) in 1721 was able to take possession of the ducal part of Schleswig and include it in the monarchial. In Sept. 1721 there took place in Schleswig a great ceremony in connection with the taking of an oath of fealty "in accordance with the king's law." The outcome naturally was a bitter hatred against Denmark on the part of the ducal family of Gottorp, and this grew the more dangerous in that the dukes became in 1743 heirs to the crown both in Sweden and in Russia.

When the duke himself in 1761 became emperor of Russia as Peter III., a war seemed inevitable and Denmark had to arm on a great scale. But the tsar was murdered at the instigation of his wife, who succeeded him as Catherine II., and Denmark's foreign policy, which since 1775 had been controlled by Johann Hartvig Bernstorff, took on a new aim, namely, to induce the empress to exchange the Gottorp portion of Holstein for Oldenburg which Griffenfeldt had won in 1673 for Denmark. This aim was achieved in 1773 and the Danish king once again held possession of both the dukedoms, Schleswig as a Danish, and Holstein as a German fief.

Economic and Social Conditions. — The weight of taxation was burdening the people, especially as the period preceding the year 1767 had been one of terrible depreciation for Danish agriculture. The price of corn had gone steadily down, for the Dutch could now buy wheat in England, which at this period supported her wheat exports with a premium. The exportation of bullocks had ceased, the Dutch about 1720 having instituted a heavy tax on Danish bullocks. The Danish peasant population was impoverished and Danish land sank lower and lower in value. To cover the expenditure which the war with Sweden had entailed, the Crown was obliged after 1660 to effect considerable sales of its property. Gifts from the king to ministers and favourites and continual sales resulted in a steady increase in the landowner's share of the soil. In order to collect taxes from the peasants the Crown had to make the landowner responsible for the taxes which their leasehold tenants had to pay. In return for this the owners were granted exemption for their principal estates; thus exemption for the landowners was restored, though upon a new basis of law. The new nobility of counts and barons which was created in 1671 not only acquired all the rights formerly enjoyed by the old Danish nobility, together with the exemption from taxation on a part of their peasant farms, but also the right to leave all their estates together in entail to the eldest son, although as a fief which on the extinction of the direct line should revert to the Crown. The harder the times the more the Crown had to accede to the demands of the landowners, which were, as before, that they should be able to compel occupation of their leasehold estates and obtain free labour from their tenants. One of the first acts of Christian VI. (1730–46) had been the abolition of the national militia, but in 1733 it was re-introduced, in combination with the so-called *Stavnsbaand,* which provided that all Danish farmers' sons from their 14th to their 36th year should be bound as villeins to the estates on which they were born; that is to say, any one of them, wherever he might be, might be forced by the landowners to come back either to take over a farm or else to be conscripted by the landowners as a soldier. In 1745 it was further decreed that even a soldier who had served his time was bound to return to the same estate and to take up a tenant farm. As soon as the landowners had obtained these rights over their leasehold tenants, they could screw their requirements in the matter of forced labour as high as they liked; they could have the refractory conscripted for the hated military service and could employ any bodily punishment including the so-called "timber-mare" (*traehesten*): the Government closed its eyes because it had to get the taxes.

In the middle of the 18th century, however, an economic advance became observable, when, under the leadership of France, colonial goods from the West Indies, and especially sugar, coffee and tobacco, began to find a European market. Denmark acquired three West Indian islands, of which the most important was St. Thomas. The eastern Asiatic trade also began to flourish under the leadership of England. Danish trade expanded and the new Asiatic and West Indian companies both prospered. In 1736 a Danish bank of issue was founded which supported these ventures and when the great colonial war broke out between France and England, the neutral trade of Denmark greatly benefited thereby. A. G. Moltke, the favourite of Frederick V. (1746–66), and a great landowner as the result of the king's generosity, was the first person to realize that this might also benefit Danish agriculture by opening up greater possibilities of production. But the landowners' government was thoroughly conservative and would not consider the economic freedom of the peasants. The landowners' rule was overthrown in 1770 by Struensee, an accomplished physician and a man of great gifts, who secured power through his close relation with Caroline Matilda, sister of King George III. of Britain, who had been united in an unhappy marriage with the degenerate and morbid Christian VII. (1766–1808). Struensee carried through a number of reforms, but Conservatism again revived under Høgh-Guldberg, who declared that the "yoke of the peasants could not be removed without Denmark shaking and quivering to its foundation."

Agricultural reforms were imminent, however, and when the Crown Prince Frederick in 1784 had acquired power by a *coup d'état,* he found a brilliant spokesman in a Danish landowner of old Danish stock, Christian Ditlev Reventlow, who had studied agriculture in England. Reventlow became the life and soul of a commission which brought about the liberation of the Danish peasant. The *Stavnsbaand* was ended on June 20, 1788; villeinage was stopped, compensation in money being given; the ancient agricultural associations were done away with, and the peasant was allotted his own plot of land. Many at once quitted the villages for the country. Transition to freehold ownership was the ultimate aim of this great land reform, which was carried through thoroughly and with excellent results in Denmark several years before any such reform had occurred to any other European nation.

The Napoleonic Wars. — The circumstances of the moment were helpful. By 1767 England as the result of its industrial awakening had changed from a corn-exporting to a corn-importing country. As a result Amsterdam once again had to purchase corn in the Scandinavian countries and the prices of corn and agricultural produce rose steadily during the period of the French Revolution and the Napoleonic wars. It was in this favourable period, which continued until 1807, that more than half the Danish peasants obtained ownership of their farms.

The period was favourable also for Danish trade, for the Danish foreign minister, A. G. Bernstorff, succeeded like his uncle before him in keeping Denmark out of the wars. After his death in 1797 there came, it is true, a clash with England, for Denmark together with Russia and other neutral powers was attempting to safeguard trading vessels by convoys of men-of-war. This displeased England, and Nelson was sent with a fleet

to break up the alliance of the Northern Powers. There followed the sea-fight off Copenhagen on April 2, 1801. After a gallant resistance the Danish fleet was destroyed, the capital bombarded and Denmark had to undertake to cease sending convoys. The period which followed brought great benefits to Danish agriculture and trade. Commerce had been facilitated by the toll law of 1797 which extended the principle of free trade. Wealthy businesses grew up in Copenhagen, and the bank of issue which had been founded in 1736 granted ever-increasing credit. After 1757 the bank was exempted from having to meet its notes with silver, and after it was taken over by the State in 1773 it had not only to emit as many notes as were required for the carrying on of business but also to meet in this respect the State's need of money.

In 1807 England called upon neutral Denmark to give up her considerable navy lest it should be used by Napoleon against England. Canning's demands had to be complied with, but not before an English fleet had laid large portions of Copenhagen in ruins. In anger over this, Frederick VI. (1808–39) from that time onwards attached himself politically to Napoleon. Seven burdensome war years followed, in the course of which relations between Denmark and Norway were completely broken off and Danish trade was gradually brought to a standstill. When at last victory fell to the coalition Denmark had to conclude a peace at Riel in 1814 by which Norway was handed over to Sweden and Heligoland to England; in exchange Denmark acquired Lauenburg.

1814-1914

The war had cost immense sums of money which, since neither taxes nor loans were available, the bank of issue had to meet by a limitless issue of notes. The consequence was a fall in their value to worthlessness; in 1813 the bank went bankrupt and a new National Bank was founded, which in 1818 became a private concern entirely independent of the State. Its notes first reached par in 1838 and in 1845 became payable on demand. The failure of the bank, the destruction of Danish trade and the fall of corn prices during the first ten years after the war left a period of poverty and stagnation during which, moreover, the land reforms came to a standstill.

The June Constitution. — This condition of things naturally called forth criticism of Frederick's absolute government and when he tried to keep down criticism by means of a censorship a Liberal Party came into existence which, in accordance with the growing Liberalism of other countries, set itself the task of substituting for the absolute Government a new constitutional Government representative of the people. Even Christian VIII. (1839–48), who as king of Norway in 1814 had co-operated in framing Norway's free constitution, did not seem disposed to perform the same service for Denmark. Immediately after his death on Jan. 20, 1848, came the revolution of February and the short-lived victory of Liberalism. In Copenhagen the movement had its outcome in a public procession on March 21 to the new King Frederick VII. (1848–63), who was able to reply that he intended to renounce the absolute rule and that he had already taken steps towards forming a Government responsible to the representatives of the people. This was appointed next day with A. V. Moltke as premier; among the ministers were leading National Liberals like Monrad, Tscherning and Lehmann. On Oct. 23 a national assembly met which, on the basis of a draft submitted by Monrad, prepared the constitution of the Danish kingdom of June 5, 1849. The legislature became a Rigsdag, with specified powers, consisting of a *Landsting* and a *Folketing;* the members of the former were to be elected for eight years by indirect vote and the latter for three years by direct vote.

The Schleswig-Holstein Question. — In the meantime even the question of the new constitution was thrown into the shade by the differences between Germans and Danes which was taking a more acute form. The Napoleonic wars had awakened the German national feeling and the ardent desire to see the entire German race united in one political entity. The political bonds which bad existed between Schleswig and Holstein ever since 1460 suggested that these two regions should form a single country which should be included in a united Germany. These efforts evoked a counter-movement among the Danish population in North Schleswig, and since 1838 in Denmark itself, where the Liberals especially had taken up the fight and after 1842 were insisting that Schleswig had belonged to Denmark for centuries and that the frontier between Germany and Denmark must in the future as in the past be the Eider. (See SCHLESWIG-HOLSTEIN QUESTION.) This difference between Eiderdanism, as it came to be called and Schleswig-Holsteinism led in March 1848 to an open Schleswig-Holstein revolution which was helped by the armed intervention of Prussia. The outcome of this was a three years' war (1848–50) which finished in a victory for Denmark. Great Britain, France, Russia, Norway-Sweden in 1850 recognized the integrity of the Danish monarchy and in the London Convention of 1852, together with Austria and Prussia recognized Prince Christian of Gliicksburg as heir to the whole monarchy after the death of the childless Frederick VII. In the agreement with Prussia, 1851–52, however, the Danish Government was obliged to undertake that in the ultimate framing of the constitution of the monarchy Schleswig should not be brought into closer relationship to Denmark than to Holstein. The impossibility of fulfilling this condition was soon to be seen.

In the Danish Rigsdag three parties had been formed: the Conservatives, comprising the landowners and all those who were against the free constitution, the National Liberal Burgher Party, which had carried through the June constitution, and the Left, including the Peasants and "Friends of the Peasants" (*bondevennerne*), whose chief desire was for a continuation of the land reforms. The Conservatives were in favour of restricting the June constitution as much as possible, being ready to fulfil their promise to Prussia by creating a conservative joint constitution for the whole kingdom, with a joint Rigsraad in which the Holstein landowners should also be represented. Such a constitution came into existence in 1855 but the Holsteiners promptly refused to meet in a joint Rigsraad. After 1857 the National Liberals returned to power with Carl Christian Hall (*q.v.*) as prime minister. He abolished the joint constitution for Holstein and on Nov. 18, 1863, prevailed upon the new king, Christian IX. (1863–1906) to sign a new joint constitution for Denmark and Schleswig which brought Schleswig into closer relationship to the kingdom than to Holstein. Bismarck was anxious for a popular war and desired the harbour of Kiel for Prussia; Austria agreed to join in and the two predominant Germanic Powers crushed down Denmark's heroic defence at Dybbol (Duppel) in 1864. By the Treaty of Vienna the three dukedoms were surrendered and also Danish North Schleswig; in 1866 after the Austro-Prussian War they became part of Prussia. Napoleon III. in the Treaty of Prague procured the insertion of an article (Art. V.) to the effect that North Schleswig should be reunited with Denmark when the majority of the population by a free vote should so desire; but it was in vain, for in 1878 Prussia and Austria agreed to the cancellation of the article.

The July Constitution. — The National Liberal Eider-Danish policy had brought about Denmark's defeat. The Conservatives took office and carried through in co-operation with the Peasants, who disliked the National Liberals, the new constitution of July 28, 1866, which was considerably more conservative than that of June: the general suffrage was indeed retained in the case of the Folketing, but in the composition of the *Landsting* the landowners and the most highly-taxed people were given an altogether overwhelming influence. This resulted in the two chambers entering into a state of permanent opposition to each other. In 1872 the Left severed their alliance with the Conservatives, who soon combined with the National Liberals to form a Right. This Right leaned on the Landsting and maintained the king's privilege of selecting his ministers without regard to the general voting.

In 1872 the Left secured a majority in the Folketing and insisted on the parliamentary system — the king's duty to choose his ministers from the party with a majority in the Folketing. The struggle persisted from 1873, when J. B. Estrup, the leader of the Right, became prime minister, until 1894 when he went out

of office; other and weaker ministries of the Right held power until 1901. The contest was bitter, for throughout all this period the Left had a growing majority in the *Folketing*. The election of 1884 gave them 81 seats out of 102, of which two were held by the first Social Democrats ever elected to the chamber. The Right demanded large grants for Denmark's military forces, for it always hankered after revenge against Germany in a great European war. The Left under the leadership of Hørup refused to make the grants for such a vain policy. Under the leadership of Berg the *Folketing* went so far as to negative the budget in 1876, in 1885 and again in 1894. But Estrup, like Bismarck, did not shrink from letting the king declare a "provisional budget," and by this means the Right mere able to provide for the fortifications of Copenhagen and to maintain themselves in power. Only when the election of 1901 had reduced the Government's strength in the second chamber to 8 members of the Right and 16 of the so-called Moderates, as against 76 of the Left and 14 Social Democrats, did King Christian IX request Professor Deuntzer to form the first Left ministry, of which J. C. Christensen, Hørup and Hage became members.

Economic Progress.—The period following 1848 was a period of great economic progress for Denmark as for the whole of Europe. The continual rise of prices down to 1873 had made possible a resumption of the land reforms which the "Friends of the Peasants" and the Left desired, and which were supported also by the National Liberal Government in the case of Monrad's Law of 1861 changing the leasehold tenancies into freehold land. By 1873 76% of the farms were freehold, which in 1905 had risen to 94%. The increasing exports of corn from America and Russia between 1873 and 1895 again brought Danish agriculture to a precarious state, but it bore up through this crisis and saved itself by making changes in its production. Instead of corn it produced butter and pork, and by its co-operative dairies and co-operative slaughterhouses made these goods standard commodities in the English market. Later there came co-operative export associations. When better times arrived these associations had a progressively good effect on Danish trade; the function of Danish commerce now came to be the exportation of the country's agricultural produce.

Estrup's policy had made Esbjerg an important centre for the English export trade. Tietgen founded the United Steamship Co. (whose Esbjerg-Harwich line took over the export to England) and the great Northern Telegraph Co., which acquired its greatest importance through its relations with China and Japan. New banks were founded, including the *Landmandsbank* (Agriculturists' Bank) in 1871 and the *Handelsbank* (Trade Bank) in 1873. The towns grew; in the course of the '70s Frederick III's old ramparts round Copenhagen were pulled down and new quarters arose on their site. A wage-earning class came into existence who were soon identified with the Social Democrats, which party in 1884 sent two representatives to the lower chamber. A labour conflict in 1899 led to the establishment of a court of arbitration for the settlement of labour disputes. The constitution of June had already acknowledged the full and unfettered right of association and this has never since been challenged in Denmark. During the period of development even the Government of the Right felt that its duties and responsibilities were not merely political but also social. In 1891 there was introduced an Old Age Pension Law, in 1892 an Health Insurance law, in 1899 an important law for the establishment of small farms with State help. Meanwhile the loss of Danish Northern Schleswig was a sore which the Prussian policy in that region made only more painful. Danish historians taught the Danish people to understand that the juridical question which the National Liberal party had wished to enforce was wrong, and that Denmark should no longer wish to recover Schleswig except those parts which declared themselves Danish and in a referendum would return under the principle of self-determination.

Ministries of the Left.—As a ministerial party the Left had great difficulties to overcome. It had to try to introduce universal suffrage in the election of parish councils *(sogneraad)*, county councils *(aintsraad)* and even the lower chamber itself, and for this a new fundamental law was required; it had to proceed with social legislation; the taxes—such as the tithe—which ever since the middle ages and from the period of absolute monarchy had remained upon the land of the peasants had to be changed into taxes upon the incomes and property of the citizens; it had to introduce regular budgets; and it had, generally speaking, to carry out an advanced policy. The Deuntzer ministry succeeded in carrying through the reform of the taxes in 1903; two years later J. C. Christensen became prime minister. He was anxious to demonstrate that the Left could rule, even with a hostile upper chamber, but he held that to this end it was necessary that the Left should break with the Social Democrats and declare themselves willing to carry through measures of defence adequate to the country's needs, even if it should prove impossible to effect a reduction in military expenses. The result was that a small section of the Left which would not admit the necessity of these two measures set up as an independent party, the Radical Party, under the leadership of Zahle. In the following year the military problem became the dominant issue; the prime minister endeavoured to solve it in conjunction with the Moderates, whose leaders were Klaus Berntsen and Niels Neergaard. But in 1908 the ministry was severely shaken when the minister of justice, A. Alberti, was forced to resign and subsequently confessed himself guilty of frauds. The Christensen cabinet was compelled to resign in the following October. Three short-lived cabinets followed namely, those of Neergaard, Count Holstein-Ledreborg and Zahle, whereupon Klaus Berntsen (July 5, 1910) formed a cabinet of the Left, including the Moderates, which listed until 1913. After violent conflicts on the defence problem, the Holstein cabinet carried an arrangement whereby, although the army and navy were enlarged, and Copenhagen's naval defences strengthened, the land defences of the capital were to be dismantled not later than March 31, 1922.

In 1910 the Left opened an agitation for a democratic amendment of the constitution. The Right, which was strong in the *Landsting*, opposed, and no solution had been reached when the elections were held in May 1913. The Radicals and Socialists now held 63 seats out of the 114 in the *Folketing*, and united to force the reform under a new Zahle cabinet containing Eric Scavenius (Foreign Affairs), Brandes, Rode and Munch. The Right answered by obstruction in the *Landsting* which the Government then dissolved. The new *Landsting* contained 38 supporters and 28 opponents of the constitutional amendment.

RECENT YEARS

The World War.—The European situation in 1914 caused Denmark great anxiety. On Aug. 1 the *Rigsdag* passed a number of emergency laws and the mobilization of the emergency army, numbering in all about 70,000 men, began on the same day. All political parties agreed in maintaining the neutrality of Denmark. A difficult situation arose on Aug. 5 in consequence of an inquiry from Germany whether the Danish Government intended to block the passage of Danish waters with mines, an inquiry which could only mean that if Denmark refused Germany would lay the mines. The Government had to consider Denmark's responsibility as a neutral Power, and after some hesitation decided to lay the mines. With this Germany was satisfied, and Britain sanctioned the action in view of Denmark's precarious position. It became apparent that the war situation might have serious effects upon Danish economic life and the Government was therefore granted emergency powers. It adhered to the policy of keeping the belligerent nations constantly informed of the measures which it had adopted, thus establishing with both sides confidence in Denmark's desire for a real neutrality and an understanding of the importance of maintaining its effective industries. This in time resulted in fixed agreements with Germany and England as to exports.

After the first anxiety caused by the war had been allayed the constitutional problem was again taken up. The opposition of the Right having weakened, on June 5, 1915, the king signed the new constitution. This introduced full equal suffrage in the elections for both Houses, men and women being entitled to vote under identical conditions; the privileged suffrage of the landlords and the wealthier classes came to an end; the voting age was fixed at 35 years for the *Landsting* and was lowered successively from 30 to 25 years for the *Folketing*. Of the members of the *Folketing*, 93 were elected in individual districts, 27 in greater Copenhagen according to proportional representation, while 23 supplementary seats were divided among the parties that had received too few representatives at the other polls in proportion to their number of votes. Of the members of the *Landsting* 54 were indirectly and proportionally elected in large districts, while 18 were elected by the retiring *Landsting* according to the same prin-

ciples. In the case of a constitutional amendment a referendum must take place, and 45% of the eligible voters must vote to give it validity. The constitution came into force on April 21, 1918.

Other important legislative enactments of the first years of the war, which the Zahle Government succeeded in passing without opposition, were the Reform of the Administration of Justice (April 11, 1916), which separated the administrative and judicial systems and introduced oral proceedings and publicity, with trial by jury in criminal and political cases, and the Accident Insurance law (July 6, 1916), which made it the duty of all employers to insure their employees. The privileged suffrage in respect of the elections to the *amtsraad* (county councils) was abolished with the consent of all parties.

In the late summer of 1916 a bitter opposition arose on the Government's announcement that it had concluded a treaty with the United States ceding the Danish West Indies to that country for $25,000,000. Finally the cabinet was supplemented by representatives of each political party and a plebiscite taken on the sale. At the polls (Dec. 14, 1916) 283,670 votes were cast in favour and 158,157 against, and shortly afterwards the Rigsdag ratified the cession. A similar but less far-reaching contest arose over the rearrangement of the relation of Iceland to Denmark. Iceland demanded political independence and integrity. Despite the opposition of the Conservatives, the support of the other three parties sufficed to pass an Act of Union (Nov. 1918) in which Denmark acknowledged the independence of Iceland. The king remained joint ruler of both countries, and Denmark had charge of Iceland's foreign relations. After the German occupation of Denmark, Iceland proclaimed her independence of action "for the present" April 10, 1940. (E. AP.; X.)

Even the early years of the War of 1914–18 were disturbing to Danish economy, which had become closely related through commerce to outside countries. Intensified submarine activity in 1917, along with the more stringent British blockade, created serious difficulties. Feed could not be obtained for livestock, exports declined, prices rose and unemployment spread. The government launched an extensive relief program and attempted to control prices. In the spring of 1918 women voted for the first time in the Folketing elections (68% voted to 84% of men), and the issue was closely drawn: the government coalition of Socialists and Radicals won 72 seats, to 68 for the total opposition. The Landstzng contained 17 Conservatives, 26 Left, 13 Radicals and 15 Socialists.

Reconstruction, 1918.—Denmark moved quickly and hopefully into the era of peace by demobilizing her forces, razing the special defence works, and, on March 17, 1920, abolishing the land defence and artillery of Copenhagen.

Most important direct result of the treaties of Paris for Denmark was the opportunity to regain at least a part of Schleswig, lost to Germany in 1864. Some hoped that the central portion of the province could be internationalized rather than go to Germany, but no provision had been made for such a settlement. The plebiscite, held in the spring of 1920, gave to Denmark the purely Danish part of North Schleswig (Nord Slesvig), but the size of the area rewon disappointed most Danes. (See SCHLESWIG.)

The nationalist agitation concerning Schleswig combined with other political controversies to create the "Easter crisis" of 1920. In view of the necessity for a new electoral law, the government refused to call a new election, so the king dismissed the ministers. The king was supported by a new cabinet of non-politicians formed at the end of March, headed by Liebe, but the Socialists called the dismissal unconstitutional and threatened a general strike. Conciliation brought a new ministry on April 5, composed mostly of State officials and charged with framing an electoral law and holding elections. Proportional representation in the county districts (*amtskredse*) and slight modifications in the supplementary seats system characterized the new law.

The Folketing elections of April 26, 1920, brought a Left cabinet under Niels Neergaard on May 5. Still another election had to be held in September on account of the incorporation of Nord Slesvig, and with the voting age 25 for the first time. In the enlarged Folketzng of 149 members the Left won 52 seats, the Socialists 48, Conservatives 27, Radicals 18, the Trades Party 3 and the Germans 1. The Neergaard Ministry continued with the support of the farmers of the Left and the mercantile Conservatives. The opposition was made up of labour and smallholder interests, plus a few "liberals."

The Social Democratic Regime.—The ten years after 1920 saw a gradual decline in the power of the Liberal Left. In 1924 the Social Democrats, with Th. A. M. Stauning as premier, took office. Then, in the 1926 elections, they lost two seats, and the Left group returned under the leadership of Madsen-Mygdal. In 1929 Stauning came in again, and his party increased its strength in succeeding elections, remaining in power up to the German occupation in 1940. Financial problems and unemployment were the chief difficulties during the first part of this period, and the defeat of the Social Democrats in 1926 was due to their desire to use State funds on a large scale to meet the crisis. The country gradually adjusted its economy to the tightening world conditions, and though the krone was thrown off the gold standard by the British action in 1931, the currency was later established in relation to the pound.

The Social Democrats are moderate socialists, representing small landholders and agrarian and industrial workers. The party has been closely associated with the co-operative movement, and advocates parcelling of large estates, universal suffrage on a 21-year-old basis, abolition of the upper chamber (Landsting), progressive taxation, and government control of industry and trade; in foreign policy it has stood for disarmament and co-operation with the League of Nations. The Liberal Left (Venstre) finds itself, by the early 20th century trend in politics, actually on the Right. It represents landowners and business and professional groups, and stands for economy in social legislation, tax reduction, an adequate defence system, the retention of the constitution and the League of Nations. The third group in importance is the Conservatives, representing a great variety of interests. It emphasizes private initiative, protection of property, Christian education in the public schools, and is nationalistic with a leaning toward inter-Scandinavian agreements. The party strength in the Rigsdag is shown in the table.

TABLE X—Parties in the Rigsdag

	Landsting		Folketing	
	1936	1939	1935	1939
Social Democratic	31	35	68	64
Conservative	22	18	29	30
Radical Left	15	13	26	26
Faroe Is.	7	8	14	14
Nat'l Socialist	1	1		1
Communist			..	3
Free Peoples (Farmers)			2	3
Justice League		1	5	4
Slesvig			4	3
			1	1

Agitation for constitutional revision culminated in 1938–39 with the elaboration of a new constitution, aimed to eliminate the still aristocratic Landsttng, and to create a new Rigsdag on a more popular basis. The document was approved by both houses in the spring of 1939, and sent to a plebiscite. Those who voted approved the change overwhelmingly, but the opposition (Liberal Left and the Farmers Party) stayed away from the polls. The law required approval by 45% of the electorate, which was missed by a slight margin. The change would have lowered the voting age to 23 for all purposes, and defined individual rights more positively. The Rzgsdag was to be composed of 210 members; 175 to be chosen by direct vote, of whom 140 were to constitute the Folketing, while the entire 175 would choose 35 to go to the other house, the Rigsting. An additional 35 members of the *Rigsting* were to be chosen by proportional representation from party lists. On the failure of the constitution the Conservative leader, Christmas Moller, resigned, but Stauning remained in office, not regarding the vote as one of lack of confidence.

A series of acts known collectively as "The Social Reform" were passed in 1933, placing Denmark among the more advanced states in this type of legislation. The Minister for Social Affairs, K. K. Steincke, worked out the bills on a scientific, carefully planned basis, building on ancient Danish experience and practice. The Public Assistance Act regulates medical aid, poor relief, child welfare, etc, and helped 206,000 persons in its first year. The Accident Insurance Act requires all employers to ensure workers with a company approved by the Ministry of Social Affairs. The Labour Exchanges and Unemployment Insurance Act sets up government control of a number of separate unemployment funds, to which individuals, communes and the State contribute. The National Insurance Act requires everyone aged 21 to 60 to belong to an approved sickness benefit society, as a passive "contributing" member if he is propertied, or as a participating full member otherwise; the State contributes to these clubs also, which enrol as regular members over 2,000,000.

Relations with her great neighbour to the south were so vital to the country that the Danes, alone among the Scandinavian states, signed the non-aggression pact with Germany (May 31, 1939). With Soviet Russia, Denmark had early reached an understanding on economic relations (1923). Acrimonious discussion with Norway over the question of Greenland led to a no-year agreement (1924) giving Norwegians certain rights, but leaving open the question of sovereignty. The matter was taken to the Permanent Court for International Justice, which in 1933 decided in favour of the Danish claims.

Foreign Affairs.—Denmark took an active and optimistic part in the early days of the League of Nations. When the small neutrals were given a meagre opportunity to make suggestions as the victorious Allies drew up the Covenant, Peter Munch and other Danes obtained a hearing and won some modifications. No political party opposed entrance into the League, though some individuals abstained from voting on the question, allowing the decision to be unanimous. Denmark feared the military sanctions clause, both the passage of League troops through her territory, and the furnishing of troops. She helped obtain the change in the Covenant from "indicating" what troops should be sent to "recommending" such forces. She joined with other neutrals in demanding that all European states be admitted—thinking especially of Germany. She was deeply interested in the early establishment of the World Court, the goal of long agitation in the country,

which favoured a neutralization scheme on an international juridical basis. Within the League she co-operated without pressing her own views, yet her treaties of arbitration and judicial settlement (1926) went further than the weak Locarno type of agreements; there was no "gap in justice" in them. She stood firmly for disarmament, and actually proceeded far on this road on her own initiative.

Danish co-operation with the "Oslo Group" was sincere, but increasingly hampered by fears of German displeasure. It was at Copenhagen on July 23, 1938, that the delegates of this group, disillusioned by the attitude of the great powers and the weakness of the League, announced themselves no longer to be bound by the sanctions agreements. From 1914 to 1940 her king or foreign minister met repeatedly with the kings and foreign ministers of Sweden and Norway to consult on problems of neutrality, armament and economic relationships. This type of conference steadily spread beyond the purely political realm, coming to include social legislation and a variety of cultural matters.

When in 1939 the German invasion of Poland flared into a general war, Denmark was again placed in a precarious position. Her non-aggression treaty with Germany, only a few months old, permitted her to carry on her normal trade with Great Britain, but circumstances and treaty did not coincide. Esbjerg was accidentally bombed by the British, the waters around Denmark were mined, and submarines, too, helped make these waters dangerous for either fishing or shipping. Britain and Germany were in a bitter struggle of annihilation, and the most painstaking Danish diplomacy could not solve the essential problem of Danish geography. Trade declined, and it became increasingly difficult to get the fodder necessary for livestock. In the early morning of April 9, 1940, the Germans entered the country with military forces at a number of points. Though a handful offered heroic resistance, the Danish Government immediately issued orders that the people should accept the occupation as a *fait accompli.* The Germans said they took control because otherwise Denmark would be made a hattleground by England; and they promised to restore Danish sovereignty when the war was over. To forestall German control of other territories associated with Denmark, the British at once took over the Faroe Islands "for the duration" and sent a small force to Iceland.

DENNERY or **D'ENNERY, ADOLPHE (PHILIPPE)** (1811–1899), French dramatist and novelist, was born in Paris on June 17, 1811. He obtained his first success in collaboration with Charles Desnoyer in *Émile, ou le fils d'un pair de France* (1831), a drama which was the first of a series of some 200 pieces written alone or in collaboration with other dramatists. *Les Deux Orphelines* (1875), perhaps his best piece, was written with Eugène Cormon. With Louis Gallet and Édouard Blan he composed the book of Massenet's *Cid* (1885); and, again in collaboration with Eugène Cormon, the books of Auber's operas, *Le Premier Jour de bonheur* (1868) and *Rêve d'amour* (1869). He died in Paris in 1899.

DENNEWITZ, a village of Germany, in the Prussian province of Brandenburg, near Jiiterbog, 40 m. S.W. from Berlin. It was the scene of a decisive battle on Sept. 6, 1813, in which Ney, with an army of 58,000 French, Saxons and Poles, was defeated with great loss by 50,000 Prussians under Bulow and Tauentzien.

DENNIS, JOHN (1657–1734), English critic and dramatist, was born in London, and educated at Harrow and Cambridge. After travelling for some time on the Continent he settled in London, and obtained, through the patronage of the duke of Marlborough, a small place in the customs, which he sold for a small charge covering a long period of years. His first successful plays were *A Plot and No Plot* (1697), *a* satire on the Jacobites, and *Rinaldo and Armida* (1699), and *Liberty Asserted* (1704). *Appius and Virginius* (written 1705 and produced at Drury Lane 1709) was satirized by Pope in the *Essay on Criticism:*

> Appius reddens at each word you speak,
> And stares tremendous, with a threatening eye,
> Like some fierce tyrant in old tapestry.

Dennis replied in 1712 with *Reflections . . .* on the *Essay,* and the quarrel was pursued in a series of pamphlets provoked by various incidents. He also quarrelled with Addison, and published *Remarks upon Cato* (1713), which drew from Pope the *Narrative of Dr. Robert Norris, concerning the strange and deplorable Frenzy* of *John Dennis* (1713). *In* the end Pope and Dennis were reconciled, and exchanged friendly letters. But Dennis's best claim to remembrance lies neither in his plays nor in his literary quarrels but in the body of his, on the whole, sane critical work. He had the prejudices of his time, and is tiresomely insistent on poetical justice.

The most important of his critical works are *The Advancement and Reformation of Modern Poetry* (1701); *The Grounds of Criticism in Poetry* (1704); and *An Essay on the Genius and Writings of Shakespeare* (1712).

Dennis's *Miscellanies in Prose and Verse* were collected in 1693. *See H.* G. Paul *John Dennis, His Life and Criticism* (New York, 1911); and Elwin and Courthope's *Works of Pope* (1871–79).

DENNISON, a village of Tuscarawas county, Ohio, U.S.A., 80 mi. S. by E. of Cleveland, on federal highways 36 and 250 and the Stone fork of the Tuscarawas river; served by the Pennsylvania railroad. The population was 4,413 in 1940. It has railroad shops, sewer-pipe factories and a steel casting foundry.

DENOMINATION, the giving of a specific name to anything, hence the name or designation of a person or thing (Lat. *denominare,* to give a specific name). In arithmetic it is applied to a unit in a system of weights and measures, currency or numbers. The most general use of "denomination" is for a body of persons holding specific opinions, usually religious, and having a common name, or for the various "sects" into which members of a common faith may be divided. "Denominationalism" is thus the principle of emphasizing the distinctions, rather than the common ground, in the faith held by different bodies professing one sort of religious belief. This use is particularly applied to that system of religious education by which children belonging to a particular religious sect are instructed in the tenets of their belief by members belonging to it and under the general control of the ministers of the denomination.

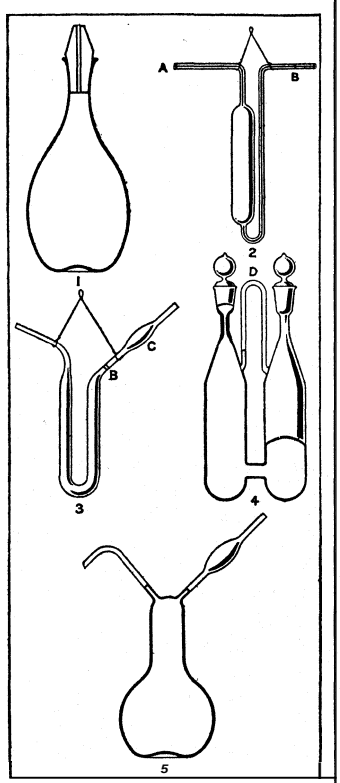
DENON, BOMINIQUE VIVANT, BARON DE (1747–1825), French artist and archaeologist, was born at Chalon-sur-Saône on Jan. 4, 1747. He studied law in Paris, and in his twenty-third year produced a comedy, *Le Bon Père,* which obtained a *succès d'estime.* Louis XV. entrusted him with the collection and arrangement of a cabinet of medals and antique gems for Madame de Pompadour, and appointed him attach6 to the French embassy at St. Petersburg. On the accession of Louis XVI. Denon was transferred to Sweden; but he returned, after a brief interval, to Paris with the ambassador de Vergennes, who had been appointed foreign minister. In 1775 Denon was sent on a special mission to Switzerland, and visited Voltaire at Ferney. He made a portrait of the philosopher, which was engraved and published on his return to Paris. He spent seven years (1780–87) at Naples, first as secretary to the embassy and afterwards as *charge' d'affaires.* After a brief interval spent in Paris he returned to Italy, living chiefly at Venice. During the Revolution he returned to Paris, where he was protected by his friend the painter David. At Bonaparte's invitation he joined the expedition to Egypt, and there made numerous sketches of the monuments of ancient art, sometimes under the very fire of the enemy. The results were published in his *Voyage dans la basse et la haute Égypte* (2 vols. fol., with 141 plates, Paris, 1802). From 1804 to 1815 he was director-general of museums. He accompanied Napoleon in his expeditions to Austria, Spain and Poland, advising the conqueror in his choice of spoils of art from the various cities pillaged. He died in Paris on April 27, 1825. He left unfinished a history of ancient and modern art, with admirable engravings, which was published posthumously, with an explanatory text by Amaury Duval, under the title *Monuments des arts du dessin chez les peuples tant anciens que modernes, recueillis par Vivant Denon* (4 vols. fol., Paris, 1829).

See J. Renouvier, *Histoire de Part pendant la Révolution;* A. de la Fizelière *L'Oeuvre originale de Vivant-Denon* (a vols., 1872–1873); Roger Portallis, *Les Dessinateurs d'illustrations au XVIIIe silcle:* D. H. Beraldi, *Les Graveurs d'illustrations au XVIIIe siècle.*

DENOTATION, in logic, a technical term used strictly as the correlative of connotation, to describe one of the two functions of a concrete term (from Lat. denotare, to mark out, specify). The concrete term "connotes" attributes and "denotes" all the individuals which, as possessing these attributes, constitute the genus or species described by the term. Thus "cricketer" denotes the individuals who play cricket, and connotes the qualities or characteristics by which these individuals are marked. In this sense, in which it was first used by J. S. Mill, denotation is equivalent to extension, and connotation to intension. It is clear that when the given term is qualified by a limiting adjective the denotation or extension diminishes, while the connotation or intension increases; *e.g.,* a generic term like "flower" has a larger extension, and a smaller intension than "rose"; "rose" than "moss-rose." In more general language denotation is used loosely for that which is meant or indicated by a word, phrase, sentence or even an action. Thus a proper name or even an abstract term is said to have denotation. (See CONNOTATION.) Some writers would confine the term denotation to real things (as distinguished from merely imaginary ones), and use "extension" in the wider sense. In that case the term "fairy" would have extension but not denotation.

DENSITY. The density of a substance is the mass of unit volume of the substance.

Density determinations are comparatively simple to carry out and a high degree of precision is often attainable. **A** knowledge of the density of a material is of considerable interest both from a theoretical and a practical standpoint. **A** few examples will indicate the wide range of problems and operations into which considerations of density enter. Accurate density determinations form a means of determining the molecular weight of gases. **A** knowledge of the density of the crystals examined is extremely valuable in the X-ray analysis of the structure of crystals. Density determinations have been used in the study of the constitution of liquids, of the dissociation of gases, and of the effects of cold work on metals. Lord Rayleigh's determination of the density of "atmospheric nitrogen" led to the discovery of argon. The very considerable revenue resulting from the duty on beer is assessed during the process of manufacture on the basis of determinations of the density of the worts. It is often specified in contracts for the supply of material that its density must be within prescribed limits, and density determinations are frequently necessary in industrial operations.



FIGS. 1–5.— FORMSOF PYKNOMETER

These examples suffice to show in how many directions a knowledge of the density of materials is of service. The widespread recurrence of density throughout the whole range of science and technology is not fortuitous, but a direct consequence of the fact that density is a fundamental physical property.

Different materials and conditions and the varying degrees of accuracy required for different purposes necessitate a number of different methods of determining density.

Units of Density.—Density, being simply mass per unit volume, may be expressed in terms of any units of mass and volume as, for example, lbs. per gallon, lbs. per cubic foot, grammes per cubic centimetre, or grammes per millilitre.

The most generally convenient unit is grammes per millilitre. The litre is defined as the volume at its temperature of maximum density (4° C) of one kilogram of pure water and the millilitre is the one-thousandth part of a litre or one cubic centimetre. It follows, therefore, that the density of water at 4° C expressed in terms of grammes per millimetre is unity.

Temperature and Pressure *Effects.*—In general, a rise in temperature causes a decrease in density and a rise in pressure causes an increase in density. With gases the changes are large and it is necessary to take both pressure and temperature into account when considering the density of gases. This is dealt with in detail later. Liquids are only slightly compressible but their density changes appreciably with change in temperature. It is therefore necessary, to secure precision, to specify the temperature at which a liquid has a stated density, but the pressure may usually be omitted. The variation in the density of solids with changes in temperature and pressure is comparatively small.

Determination of **the** Density of **Liquids.**—*Pyknometer Method.*—Given a vessel which requires a known volume of liquid to fill it, then simply by determining the weight of liquid required to fill the vessel the weight of a known volume of the liquid is determined. From this the density can be readily calculated.

A pyknometer is simply a vessel which can be filled with precision. In addition it should be easy to clean and weigh and suitable for allowing its contents to be brought to a uniform temperature.

There are numerous kinds of pyknometers, and five forms of interest in their relation to each other are shown in figs. 1 to 5.

Fig. 1 shows a small bottle having a well fitting ground glass stopper with a small hole drilled vertically through it, and in use the bottle is filled flush to the top of this hole. In fig. 2 is a type of pyknometer due to Sprengel which is finally filled by withdrawing liquid from the jet **A** with the aid of blotting paper until the liquid surface in the other horizontal tube is at a mark B. This form avoids errors which might arise in the preceding one if the stopper is not always pushed precisely the same amount inside the neck at each filling. Fig. 3 shows a more robust form of Sprengel tube which is provided with a small bulb above the graduation mark B. This bulb will accommodate any liquid which might expand from the main part of the pyknometer should the temperature rise after it has been filled, a happening which would be inconvenient in the two preceding forms. **A** pyknometer due to Bousfield (fig. 4) is still more robust, but retains all the advantages of the one shown in fig. **3** and has a glass hook D, by which it can be hung from a balance hook, thus getting rid of the wire suspensions, liable to alter in weight, required for the Sprengel type. The last pyknometer, due to Dr. C. Barr of the National Physical Laboratory, and not hitherto published, retains the advantages of the Sprengel method of filling but reverts to the bottle type of fig. 1 for the body of the instrument, and so secures the advantages of a pyknometer which will stand on its own base and not require suspension for weighing.

When using a pyknometer it is important to ensure that the contents of the pyknometer have attained a constant temperature before completing the filling, and to observe this temperature accurately. This is generally done by immersing the bulk of the pyknometer in liquid contained in a thermostat, keeping it there for a sufficient time to ensure uniformity of temperature, and then taking the temperature of the outer liquid at the time the final filling of the pyknometer is carried out as that of the liquid inside the pyknometer.

The operations in determining the density of a liquid by means of a pyknometer are to weigh the pyknometer (a) when empty (W, grammes), (b) when filled with water (W_w gms.), and (c) when filled with liquid (W_l gms.). We will assume that the same temperature $t°$ C obtains during each filling of the pyknometer and that the air density has the same value a gms./ml. during each weighing.

We must now consider how to determine the density mass per unit volume—of the liquid from the weights W_p, W_w, and W_l.

Weights are adjusted so that their mass is equal to the nominal value marked on them. When used on a balance they are subject to the buoyancy effect of the surrounding air, which is equivalent

to a reduction in mass equal to the mass of air displaced by the weights. The equilibrium obtained in the operation of weighing may therefore be represented by the equation:—(Mass of weights minus mass of air displaced by weights = Mass of body weighed *minus* mass of air displaced by body weighed).

Let M, gms. be the mass of the pyknometer and 6 gms./ml. the density at $t°$C of the glass from which it is made, M_w gms. the mass of water required to fill the pyknometer at t°C and ρ gms./ml. its density at $t°$C, M_l and d similarly refer to the liquid and finally let A gms./ml. be the density of the weights used. Then applying the equation to the weighing of the empty pyknometer we have:

$$W_p - \frac{W_p}{\Delta}\sigma = M_p - \frac{M_p}{\delta}\sigma \qquad (1)$$

for W_p/Δ is the volume of the weights and M_p/δ that of the pyknometer itself.

Equation (1) is more conveniently written

$$W_p\left(1-\frac{\sigma}{\Delta}\right) = M_p\left(1-\frac{\sigma}{\delta}\right) \qquad (2)$$

Similarly for the second weighing

$$W_w\left(1-\frac{\sigma}{\Delta}\right) = M_p\left(1-\frac{\sigma}{\delta}\right) + M_w\left(1-\frac{\sigma}{\rho}\right) \qquad (3)$$

and for the third weighing

$$W_l\left(1-\frac{\sigma}{\Delta}\right) = M_p\left(1-\frac{\sigma}{\delta}\right) + M_l\left(1-\frac{\sigma}{d}\right) \qquad (4)$$

The volume of liquid weighed is M_w/ρ millilitres and from (2) and (3)

$$\frac{M_w}{\rho} = \frac{W_w - W_p}{\rho - \sigma}\cdot\left(1-\frac{\sigma}{\Delta}\right) \qquad (5)$$

The mass of liquid weighed in M_l gms. and from (2) and (4)

$$M_l = \frac{d(W_l - W_p)}{(d-\sigma)}\left(1-\frac{\sigma}{\Delta}\right) \qquad (6)$$

The density of the liquid is

$$\frac{\text{Mass of liquid weighed}}{\text{Volume of liquid weighed}}$$

and so from (5) and (6)

$$d = \frac{W_l - W_p}{W_w - W_p}(\rho - \sigma) + \sigma \qquad (7)$$

If we write d' for $\frac{W_l - W_p}{W_w - W_p}\cdot p$ in equation (7) this becomes

$$d = d' - \sigma(d'/\rho - 1) \qquad (8)$$

For a mean value 0·0012 gms./ml. for σ the second term on the right of (8) is +0·0005 for a liquid of density of 0·6 gms./ml. and −0·0012 for a liquid of density 2 gms./ml. If errors of these magnitudes are negligible for any particular purpose it is permissible to use the simpler equation

$$d = \frac{W_l - W_p}{W_w - W_p}\cdot\rho \qquad (9)$$

for computing d.

If, contrary to our initial assumptions, the air density varied from weighing to weighing and the pyknometer was filled at different temperatures, the calculations are a little more complicated but involve no new principle. It is merely necessary to introduce individual values for the air density instead of a common value σ and to make due allowance for changes in the volume of the pyknometer with changes in temperature.

Sinker Method.—A hollow glass cylinder with closed hemispherical ends and provided with a glass ring by which it can be suspended, forms a convenient sinker for density determinations. It is necessary to load the sinker so that it will sink in any liquid whose density is to be determined by its aid.

When a sinker is weighed suspended in a liquid the buoyancy effect of the surrounding liquid is equivalent to an upward force on the sinker equal to the weight of liquid which it displaces. If this upward force is determined and the volume of the sinker is known, the weight of a known volume of the liquid is determined and hence its density also. To determine the density of a liquid the sinker is weighed (a) in air (W_a grns.), (b) suspended in water (W_w grns.), and (c) suspended in the liquid (W_l grns.). The first and second weighings serve to determine the volume of the sinker and the first and third the mass of an equal volume of liquid. By considering these weighings in precisely the same manner as the pyknometer weighings were considered it can be shown that if the water and liquid are at the same temperature

$$d = \frac{W_a - W_l}{W_a - W_w}(\rho - \sigma) + \sigma$$

which is of precisely the same form as equation (7) and may be simplified to

$$d = \frac{W_a - W_l}{W_a - W_w}\rho$$

an equation which is subject to the same limitations as equation (9).

The sinker method is much more convenient than the pyknometer method for determining the density of a liquid at a sequence of different temperatures, and if the sinker has not quite attained the temperature of the surrounding liquid, the resulting error is of much less consequence than if the liquid inside a pyknometer has not attained the temperature measured outside.

Osborne, McKelvy and Pearce carried out an extensive series of determinations of the densities of mixtures of ethyl alcohol and water, using both the pyknometer and sinker methods, and their work might be consulted for details of both methods.

The Westphal balance is an application of the sinker method in which the upward force on a sinker is directly measured on a balance of the steel-yard type. The balance is shown diagrammatically in fig. 6. With the sinker hanging in air the balance arm is adjusted so that the pointer P is at the middle of the scale S. If, now, a vessel containing a liquid of density 1 gm./ml. is placed so that the sinker hangs in the liquid there will be an upward force on the sinker amounting to 10 gms. weight, assuming the sinker to have a volume of 10 ml., and the balance arm will no longer be in equilibrium. A 10 gm. weight placed on the balance arm at the point on the scale marked 1·0, *i.e.*, immediately above the point from which the sinker is suspended, would restore the equilibrium of the balance arm and bring the pointer P back to the middle of the scale S. If the density of the liquid were 1·5 gms./ml. then a 10 gm. weight placed at 1·0 on the balance arm

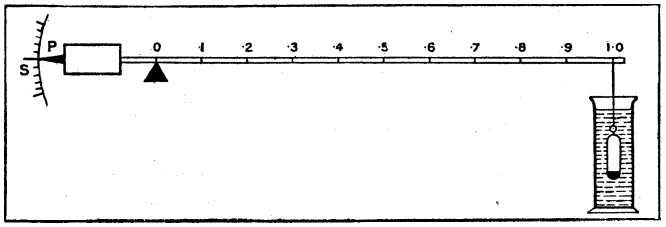


FIG. 6.—WESTPHAL BALANCE

and a second 10 gm. weight placed at 0·5 on the balance arm would counter-balance the 1j gms. weight upward force on the sinker. If the density of the liquid were 1·56 gms./ml. the second 10 gm. weight would have to be placed at a point corresponding to 0·56 on the balance arm to restore equilibrium. Alternatively the second 10 gm. weight could be placed at 0·j on the balance arm and 1 gm. weight at 0.6 on the scale, and the three weights together would then balance the 15·6 gms. buoyancy effect on the sinker. The balances are usually provided with three sizes of weights, the largest having a value in grammes numerically equal to the volume of the sinker in millilitres, the next size having one-

tenth this weight and the third one-hundredth. The positions of the heaviest weights on the balance arm give the units and first decimal place of the density, the position of the next smaller weight gives the second decimal place and that of the smallest the third decimal place.

Westphal balances are convenient when densities are required to an accuracy of about one part in a thousand, but a hydrometer *(see* HYDROMETERS) provides a more rapid and convenient means

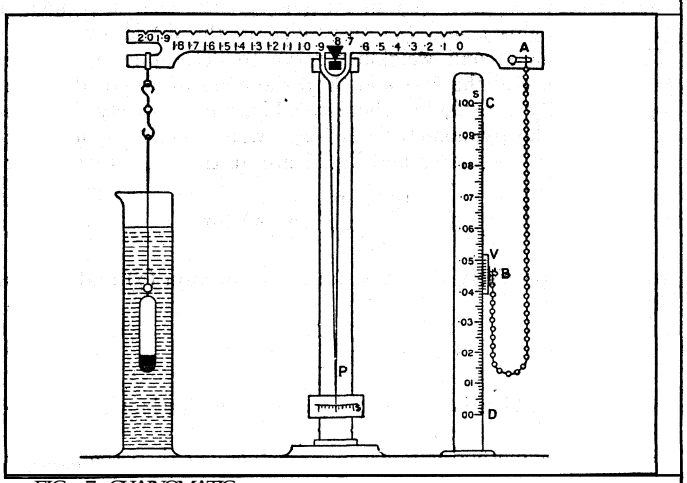

FIG. 7.—CHAINOMATIC BALANCE FOR DENSITY DETERMINATIONS

of attaining this degree of accuracy, and is replacing the Westphal balance in industry.

The principle of the Westphal balance has been applied to chainomatic balances, which can be obtained with scales indicating densities directly. In chainomatic balances the use of fractional weights is avoided by using a fine chain AB *(see* fig. 7) for the final adjustment. The end A of the chain is fixed to one end of the balance beam and the end B is attached to a hook on the Vernier V which slides along the scale CD. By lowering or raising V a greater or less fraction of the total weight of the chain is supported by the balance beam and this affords a delicate means of bringing the beam into its position of equilibrium, *i.e.,* with the pointer P central on the scale S. Such a balance obviously lends itself to adaptation for density determinations. A sinker is suspended from the end of the balance arm remote from A and hangs immersed in the liquid whose density is required. It is balanced by placing a movable weight in an appropriate notch on the beam and moving the vernier V to obtain the final adjustment. The notched beam is graduated from 0 to 2·0 and the position of the movable weight gives the unit and first decimal place of the density the subsequent decimal places being read off on the scale CD by means of the vernier V.

The sinker method is used as the basis of recording densimeters variations in the buoyancy effect on a sinker being used to operate recording mechanism.

If a sinker has precisely the same density as a liquid in which it is placed—no suspension wire being used, it will tend neither

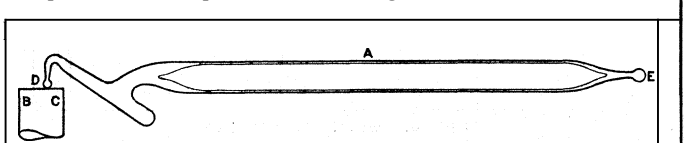

FIG. 8.—PROFESSOR A POLLARD'S TOTAL IMMERSION INDICATING HYDROMETER

to sink nor to float but will remain in suspension in the body of the liquid. The equilibrium is a very delicate one and has been made the basis of accurate density determinations.

Prof. A. Pollard has devised a total immersion instrument for density determinations, the essential portion of which is shown in fig. 8. This is a specially designed glass float A which is supported on a flat surface BC by a small sphere D fused on the float. When wnolly immersed in a liquid the float is free to rotate in a vertical plane about D and takes up a position of rest in which its inclination to the horizontal is dependent on the density of the liquid which is read off on a circular scale placed behind E.

Hare's Method. A long inverted U tube is held with one limb (A) dipping into a liquid and the other limb (B) dipping into a second liquid. By applying suction to a branch tube at the top of the U each of the limbs is partially filled with liquid. If d_1 is the density and h_1 the height of the liquid in A, d_2 and h_2 similarly referring to B, p is the pressure of the air enclosed in the U and P is the atmospheric pressure then

$$p = P - h_1 d_1 = P - h_2 d_2$$

and so

$$d_2 = d_1 \times \frac{h_1}{h_2}$$

Hence if d_1 is known the measurement of h_1 and h_2 suffices to determine d_2.

The method of balancing the pressure due to columns of liquids of different densities has been made use of in accurate density determinations.

Determination of the Density of **Solids.**—*Pyknometer Method.—In* the pyknometer method the volume of a known weight of solid is obtained by determining the diminution in the capacity of a pyknometer when the solid is placed inside it. Four weighings are involved to determine $W_p$gms. the weight of the empty pyknometer, $W_s$gms., the weight of the pyknometer and added solid, W_{sl}gms. the weight of the pyknometer, added solid, and liquid then required to fill the pyknometer, and W_l, the weight of liquid required completely to fill the pyknometer, no solid being present. If d gms./ml. is the density of the solid and gms./ml. that of the liquid then from the equations representing the equilibrium obtained in each weighing it readily follows that

$$d = \frac{W_s - W_p}{W_s + W_l - W_p - W_{sl}}(\rho - \sigma) + \sigma$$

or if the accuracy required in the determination permits it the simpler relation

$$d = \rho \cdot \frac{W_s - W_p}{W_s + W_l - W_p - W_{sl}}$$

may be used.

The method is convenient for solids available in small fragments or powders and a pyknometer such as that shown in fig. 1, into which such solids can be easily introduced is necessary. Powders are liable to entrap a quantity of air which remains in the pyknometer when filled with liquid. This is avoided by filling the pyknometer under reduced pressure.

By *Weighing the Solid in Air and also Suspended in a Liquid.* —If Ms. gms. is the mass of solid, Vs. ml. its volume, $W_a$gms. the observed weight in air and W gms. the observed weight when suspended in a liquid of density p gms./ml., then for the two weighings we have

$$W_a(1 - \sigma/\Delta) = Ms - Vs \cdot a$$

and

$$W_l(1 - \sigma/\Delta) = Ms - Vs \cdot \rho$$

the density of the solid d is given by

$$d = \frac{M_s}{V_s} = \frac{W_a}{W_a - W_l}(p - a) + \sigma \quad \text{or approximately} \quad d = \frac{W_a}{W_a - W_l}\cdot\rho.$$

If the solid has a density greater than that of the liquid in which it is weighed all that is necessary for the weighing is to suspend the solid by means of a fine wire from one arm of a balance so that it hangs suspended in a vessel of the liquid placed on a stand bridging the scale pan. The weight of the suspension wire is allowed for.

If the solid has a density less than the liquid then for the weighing in the liquid a heavier body is attached to the same suspension wire so that the two together sink in the liquid. The heavier body must also be weighed alone in the liquid and if W_3 gms. is this weight W_2 gms. the weight observed when both bodies are suspended in the liquid, and W_1 gms. the weight of the lighter solid in air then from the usual equations for each weighing it follows that—

$$d = \frac{W_1}{W_1 - W_2 + W_3} \cdot (\rho - \sigma) + \sigma$$

d gms./ml. being the required density of the solid, p gms./ml. that of the liquid in which it is weighed and a gms./ml. the density of the air.

Flotation Method.—The flotation method consists in adjusting the density of a liquid, *e.g.*, by mixing two liquids of different density in appropriate proportions, until it is equal to that of the solid. The criterion of equality is that the solid remains suspended in the liquid, neither sinking nor rising. The method is chiefly used for minerals available only in small fragments and in limited amounts. Methylene iodide (density 3·3 gms./ml.) and benzol (density 0·98 gms./ml) are convenient liquids for mixing together to obtain intermediate densities.

Direct Displacement Methods.—If a solid is added to a vessel partially filled with liquid the level of the liquid surface will be raised and the volume of liquid between the original and final levels of the liquid will be equal to the volume of the solid. This affords a means of obtaining the volume of a previously determined weight of solid, and so the density of the solid. Flasks with graduated necks having scales on which the volume corresponding to the rise in the liquid surface can be read directly are used for determining the density of fine materials such as sand and cement. Sometimes a flask with a single mark is used and the volumes required to fill it to the mark (a) when initially empty, (b) when containing a known weight of solid, are measured by means of a burette.

In Regnault's volumenometer the solid displaces air in a chamber connected to a manometer. By observing pressure changes on expanding or contracting the air by a definite amount (a) when the chamber contains air only, (b) when it contains the solid also, the volume of the solid can be determined.

Density of Gases.—Normal Temperature and Pressure.—The volume of a given mass of gas—and consequently the density of the gas—varies considerably with changes either of temperature or pressure. In order that results may be readily comparable it is desirable to quote as the density of a gas the value which it has under standard conditions of temperature and pressure. The standard temperature adopted is 0° C and the standard pressure 760 mm. of mercury. These conditions are referred to as "normal temperature and pressure" and by the corresponding abbreviation "N.T.P."

If the pressure and temperature of a given mass of gas are varied its volume alters in accordance with the relation

$$PV = RT$$

where P is the pressure, V the volume, R a constant and $T = (273 + t)$ where t is the temperature in degrees centigrade. If, therefore, V_1 is the volume of a mass m of gas at a pressure P, and temperature $t°$ C, it follows from the above relationship that its volume V_0 at N.T.P. is given by

$$V_0 = V_1 \cdot \frac{P_1}{760} \cdot \frac{273}{273 + t}$$

and the value of m/V_0 gives the density of the gas at N.T.P.

Methods of Determining the Density of Gases.—*By Weighing a Globe Filled with the Gas.*—The determination of the mass of gas required to fill a globe of known volume affords an accurate means of determining the density of gases. The method is the counterpart of the pyknometer method for determining the density of liquids, and in principle is equally simple. The volume of the globe is determined from its water content and then the globe is weighed first evacuated and secondly filled with gas at a measured temperature and pressure.

Owing, however, to the large volume occupied by a small mass of gas the mass of the globe must inevitably be large compared with that of the enclosed gas. Hence small percentage errors in the weighings involve large percentage errors in the mass of the gas. This coupled with the necessity for accurate control and measurement of both temperature and pressure render the accurate determination of the densities of gases by this method a matter calling for the utmost refinement of experimental procedure.

By Measuring the Volume of a Known Mass of Gas.—This method is the reverse of the preceding one and consists in using one or more globes, or other suitable measuring apparatus, merely to determine the volume of the gas whose mass is determined separately. For example, one of the methods used by Morley in his determination of the density of hydrogen was to weigh the hydrogen absorbed in palladium and to measure the volume of the hydrogen in three globes having a total capacity of 42 litres. Perman and Davies absorbed a measured volume of ammonia in concentrated sulphuric acid in order to obtain its mass.

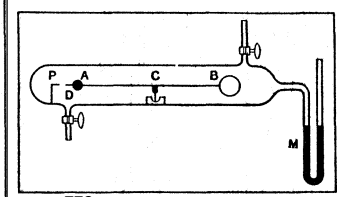

FIG. 9.— MICRO-BALANCE

By Means of the Micro-Balance.—The principle of the micro-balance may be readily seen from the diagrammatic representation in fig. 9. A very light quartz balance beam represented by AB is delicately pivoted at its centre C. At one end of the beam is a small solid sphere of quartz and at the other a larger hollow quartz sphere filled with air. The whole balance is enclosed in a vessel which can be filled with gas under any desired pressure and the pressure can be measured by a manometer M.

Suppose the balance beam is an equilibrium (*i.e.*, with the point D opposite the fixed point P) in one gas at a pressure p_1 and in a second gas at a pressure p_2, the temperature remaining constant. Since the beam is asymmetrical as regards volume, it follows that to produce equilibrium the first gas at the pressure p_1 must exert the same buoyancy effect on the beam as the second gas at the pressure p_2. The first gas must therefore have the same density at the pressure p_1 that the second gas has at the temperature p_2, and from this it follows directly that the density d of the second gas at N.T.P. is given by

$$d = \frac{p_1}{p_2} \cdot \rho$$

where p is the density of the first gas at N.T.P.

The micro-balance affords an extremely accurate means of comparing the densities of two gases and can be operated with exceedingly minute quantities of gas. It has been developed considerably in recent years and in addition to the delicate quartz micro-balances robust instruments based on the same principle have been designed for the commercial determination of gas densities.

Determination of Density of Vapours.—When a substance can exist at one and the same temperature in both a liquid and a gas-like form, the latter is termed the vapour of the liquid. By a sufficient increase in pressure all vapours can be liquefied.

In determining the density of a vapour one usually starts with the substance in its liquid form, and the vaporization of the liquid is an integral part of the density determination.

Dumas' Method.—This consists in vaporizing the liquid in a globe having a neck drawn down to a capillary. So long as any liquid remains in the globe, vapour may be seen issuing from the capillary, but ceases abruptly when the supply of liquid is exhausted. At this instant the capillary is sealed. By weighing the globe the mass of the contained vapour may be determined and its volume may be obtained by weighing the globe both when full of air and when filled with water. The resulting density is that of the vapour at the temperature and pressure prevailing when the bulb was sealed.

Schulze has recently introduced an ingenious modification of the method in which the vapour is liquefied into a small subsidiary bulb before weighing, and so the errors incident to weighing a large globe containing only a comparatively small mass of vapour are avoided.

Gay-Lussac's Method.—This consists in volatilizing a known mass of liquid over a mercury column and measuring the volume of vapour produced. By using a long vertical tube to contain the mercury the liquid can be volatilized under low pressure. A

number of modifications of the method have been introduced from time to time, two recent ones being those of Young and of Egerton.

Victor Meyer's Method.—A simple arrangement of apparatus for Victor Meyer's method of determining the density of a vapour is shown in fig. 10. The liquid in A is heated until air ceases to issue from the tube B. A jar C, filled with water, is then placed over B and a small bottle containing a known weight of liquid is dropped into the inner bulb B. The temperature in A is arranged to be high enough to ensure rapid volatilization of the liquid when introduced into D. The vapour so produced displaces air from the apparatus, and this is collected and measured in C. The volume of this air reduced to N.T.P. is equal to that of the vapour reduced to N.T.P. since before displacement from D the air was at the same temperature and pressure as the vapour.

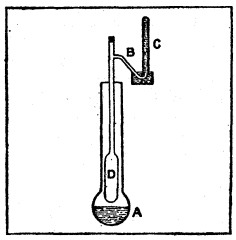

FIG. 10.—DIAGRAM OF VICTOR MEYER'S APPARATUS

The Victor Meyer method has been widely used, and details of a modern form of the apparatus having an improved method for introducing the liquid to be vaporized is described by McInnes and Kreiling.

DENT, JOHN CHARLES (1841–1887), Canadian journalist and historian, was born at Kendal, England. He was educated in Canada, being called to the bar in 1865. After writing for the English Daily Telegraph and then for certain Boston newspapers, he joined the editorial staff of the Toronto Globe in 1870. Later he turned to history, producing The Canadian Portrait Gallery (biographical studies, 1870), Canada since the Union of *1841* (1881), Rev. Henry *Scadding* (1884) and The Upper Canada Rebellion (1885).

DENTAL RUBBER, a form of vulcanite, coloured pink to simulate the human gums, and used extensively, strengthened with metal, to form the setting of artificial teeth, for which it is admirably suited. It is manufactured from over-vulcanized rubber, *i.e.*, pure rubber which is rolled with about 40% of sulphur, and in which a considerable amount of vermilion or other suitable pigment is incorporated. It takes a high polish, is tasteless and odourless, and is comfortable in wear.

DENTATUS, MANIUS CURIUS, Roman general, conqueror of the Samnites and Pyrrhus, king of Epirus, was born of humble parents, and was possibly of Sabine origin. In 290 B.C., when consul with P. Cornelius Rufinus, he gained a decisive victory over the Samnites, which put an end to a war that had lasted fifty years. He also reduced the revolted Sabines to submission; a large portion of their territory was distributed among the Roman citizens, and the most important towns received the citizenship without the right of voting for magistrates (*civitas sine suffragio*). With the proceeds of the spoils Dentatus cut a channel to carry off the waters of Lake Velinus, so as to drain the valley of Reate. In 275, after Pyrrhus had returned from Sicily to Italy, Dentatus (again consul) took the field against him and defeated him completely near Beneventum. Dentatus was consul for the third time in 274, when he finally crushed the Lucanians and Samnites. As censor in 272 he began to build an aqueduct to carry the waters of the Anio into the city, but died (270) before its completion. Dentatus was looked upon as a model of old Roman simplicity and frugality.

DENT DU MIDI, a conspicuous peak of the Swiss Alps 6 mi. S.W. of St. Maurice in the lower valley of the Rhône, with an altitude of 10,696 ft. See ALPS.

DENTIL, in architecture, a small, rectangular block, used in a row as a decoration for the bed-moulding of a cornice. It is undoubtedly a decorative interpretation in stone of projecting beam ends in earlier wooden construction, and many of the famous rock cut tombs of Lycia, in Asia Minor, which represent wooden structures, show similar forms. Moreover, the tomb of Darius at Nakshi Rustan (c. 485 B.C.), which represents the entire front of a Persian palace, plainly shows the beam ends appearing as a dentil band. In ordinary classic usage the dentil decorates the cornices of the Ionic and Corinthian orders (see ORDER). The Attic custom, followed generally by the Romans and the Renaissance architects, kept the dentil relatively small, and spaced the dentils with an inter-space of about half the width of the block itself. Occasionally, as in the Pantheon at Rome (c. 120), an unbroken band, known as a dentil band, replaces the separate dentils. In the Hellenistic temples of Asia Minor, such as the great temple of Athena Polias at Priene (c. 350 B.C.), a special type of heavy Ionic entablature is used, in which the dentils are much enlarged, more widely spaced, and resemble brackets. The Byzantine dentil was a specific type of band ornament, possibly with little relation to the classic dentil, and was used especially as a border for panels. It consists of an alternation of projecting blocks with splayed faces between, usually arranged in a double band, with the blocks on one side of the centre, in every case opposite the splays on the other. It is so found bordering the marble panels of S. Sophia at Constantinople (6th century), and became a favourite ornament in Venice, where it was used not only as a panel mould but also as a horizontal band and even around arches.

DENTISTRY, a special department of medicine, dealing with diseases of the teeth and their treatment. (For anatomy see TEETH.)

Until well into the 19th century apprenticeship afforded the only means of acquiring a knowledge of dentistry, but in Nov. 1840 was established the Baltimore College of Dental Surgery, the first college in the world for the systematic education of dentists. This, combined with the refusal of the medical schools to furnish the desired facilities for dental instruction, placed dentistry for the time being upon a footing entirely separate from general medicine. The British medical schools later revised their policy and special courses of instruction are arranged to meet the demands of the various examining bodies. Recently an official dental register corresponding to the medical register has been instituted in Great Britain.

The most important dental research of modern times is that carried out by W. D. Miller of Berlin (1884) upon the cause of caries of the teeth, a disease said to affect the human race more extensively than any other. Miller demonstrated that, as previous observers had suspected, caries is of bacterial origin, and that acids play an important rôle in the process. This work has been given greater precision by McIntosh, James and P. Lazarus-Barlow who isolated a group of bacilli (B. *acidophilus odontolyticus*) from carious teeth which was capable of producing the characteristic changes under experimental conditions. Dental caries and septic conditions of the gums bear highly important relations to more remote or systemic diseases, furnishing avenues of entrance for pathogenic bacteria, notably those of actinomycosis and pyaemia.

Operative Dentistry.—The art of dentistry is usually divided arbitrarily into operative dentistry, the purpose of which is to preserve as far as possible the teeth and associated tissues, and prosthetic dentistry, the purpose of which is to supply the loss of teeth by artificial substitutes. The filling of carious cavities was probably first performed with lead, and was sufficiently prevalent in France during the 17th century to bring into use the word *plombage*, which is still occasionally applied in that country to the operation of filling. Gold as a filling material came into general use about the beginning of the 19th century.[1] Tin foil was also used to a limited extent.

The dental engine in its several forms is the outgrowth of the simple drill worked by the hand of the operator. It is used in

[1] The filling of teeth with gold foil is recorded in the oldest known book on dentistry, *Artzney Buchlein*, published anonymously in 1530, in which the operation is quoted from Mesue (A.D. 857), physician to the caliph Haroun al-Raschid.

removing decayed structure, and for shaping the cavity for inserting the filling. The rubber dam invented by S. C. Barnum of New York (1864) provided a means for protecting the field of operations from the oral fluids, and extended the scope of operations even to the entire restoration of tooth-crowns with cohesive gold foil. Its value has been found to be even greater than was at first anticipated. In all operations involving the exposed dental pulp or the pulp-chamber and root-canals, it is the only efficient method of mechanically protecting the field of operation from invasion by disease-producing bacteria.

The difficulty and annoyance attending the insertion of gold, its high thermal conductivity. and its objectionable colour have led to an increasing use of amalgam, gutta-percha, and cements of zinc oxide mixed with zinc chloride or phosphoric acid. Attention has also been devoted to restorations with porcelain and porcelain-like cements.

Until recent times the exposure of the dental pulp inevitably led to its death and disintegration, and, by invasion of bacteria via the pulp canal, eventually caused the loss of the entire tooth. A rational system of therapeutics, in conjunction with proper antiseptic measures, has made possible in many cases a conservative treatment of the dental pulp when exposed, and successful treatment of pulp-canals when the pulp has been devitalized either by design or disease. The conservation of the exposed pulp is effected by the operation of capping. In capping a pulp, irritation is allayed by antiseptic and sedative treatment, and a metallic cap, lined with a non-irritant sedative paste, is applied under aseptic conditions immediately over the point of pulp exposure. A filling of cement is superimposed, and this, after it has hardened, is covered with a metallic or other suitable filling. The utility of arsenious acid for devitalizing the dental pulp was discovered by J. R. Spooner of Montreal, and first published in 1836. The painful action of arsenic upon the pulp was avoided by the addition of various sedative drugs — morphia, atropia, iodoform, etc.—and its use soon became universal. Of late years immediate surgical extirpation under novocaine is in use, and by novocaine also the pain incident to excavating and shaping of cavities in tooth structure may be controlled. To fill the pulp-chamber and canals of teeth after loss of the pulp, all organic remains of pulp tissue should be removed, and then, in order to prevent the entrance of bacteria, and consequent infection, the canals should be perfectly filled. Upon the exclusion of infection depends the future integrity and comfort of the tooth. Numerous methods have been invented for the operation. Pulpless teeth are thus preserved through long periods of usefulness, and even those remains of teeth in which the crowns have been lost are rendered comfortable and useful as supports for artificial crowns, and as abutments for assemblages of crowns, known as bridge-work.

Malposed teeth are not only unsightly but prone to disease, and may be the cause of disease in other teeth, or of the associated tissues. By the use of springs, screws, vulcanized caoutchouc bands, elastic ligatures, etc., as the case may require, practically all forms of dental irregularity may be corrected, even such protrusions and retrusions of the front teeth as cause great disfigurement of the facial contour.

The extraction of teeth, an operation which until quite recent times was one of the crudest procedures in minor surgery, has been reduced to exactitude by improved instruments, designed with reference to the anatomical relations of the teeth and their alveoli, and therefore adapted to the several classes of teeth. The operation has been rendered painless by the use of anaesthetics.

Dental Prosthesis. — The fastening of natural teeth or carved substitutes to adjoining sound teeth by means of thread or wire preceded their attachment to base-plates of carved wood, bone or ivory, which latter method was practised until the introduction of swaged metallic plates in the latter part of the 18th century. An impression of the gums was taken in wax, from which a cast was made in plaster of Paris. With this as a model, a metallic die of brass or zinc was prepared, upon which the plate of gold or silver was formed, and then swaged into contact with the die by means of a female die or counter-die of lead. The process is essentially the same to-day, with the addition of numerous improvements in detail, particularly that of using vulcanite in place of metal. The discovery, by Gardette of Philadelphia in 1800, of the utility of atmospheric pressure in keeping artificial dentures in place led to the abandonment of spiral springs. A later device for enhancing the stability is the vacuum chamber, a central depression in the upper surface of the plate, which, when exhausted of air by the wearer, materially increases the adhesion. The base-plate is used also for supporting one or more artificial teeth, being kept in place by metallic clasps fitting to, and partially surrounding, adjacent sound natural teeth, the plate merely covering the edentulous portion of the alveolar ridge. It may also be kept in place by atmospheric adhesion, in which case the palatal vault is included, and the vacuum chamber is utilized in the palatal portion to increase the adhesion.

Metallic bases were used exclusively as supports for artificial dentures until in 1855–56 Charles Goodyear, Jr., patented in England a process for constructing a denture upon vulcanized caoutchouc as a base. Several modifications followed, each the subject of patented improvements. Though the cheapness and simplicity of the vulcanite base has led to its abuse in incompetent hands, it has on the whole been productive of much benefit. It has been used with great success as a means of attaching porcelain teeth to metallic bases of gold, silver and aluminium. It is extensively used also in correcting irregular positions of the teeth, and for making interdental splints in the treatment of fractures of the jaws. For the mechanical correction of palatal defects causing imperfection of deglutition and speech, which comes distinctly within the province of the prosthetic dentist, the vulcanite base produces the best-known apparatus. Two classes of palatal mechanism are recognized — the obturator, a palatal plate, the function of which is to close perforations or clefts in the hard palate, and the artificial velum, a movable attachment to the obturator or palatal plate, which closes the opening in the divided natural velum and, moving with it, enables the wearer to close off the nasopharynx from the oral cavity in the production of the guttural sounds. Vulcanite is also used for extensive restorations of the jaws after surgical operations or loss by disease, and in the majority of instances wholly corrects the deformity.

The progress of dentistry since 1900 has been more rapid and more radical than in any previous period. The cause of this progress was the general advancement in knowledge due to the accumulation of data from scientific investigation and the application of the knowledge thus acquired to the prevention and treatment of disease.

Septic Foci. — In several communications on septic dentistry, notably in an address delivered in 1910 at McGill university, Montreal, Dr. William Hunter, of London, criticized badly conceived and unskilfully executed dental restorative operations, especially in crown and bridge work, and the treatment of pulpless teeth, which was performed without regard to surgical asepsis. He showed that operations so performed leave septic foci that cause septicaemic conditions, as well as infections in remote parts of the body.

Hunter's criticisms immediately bore fruit. Bacteriological and X-ray examination of teeth and jaws, particularly in so-called pyorrhoea alveolaris, quickly became the rule.

Change of Interest and Development. — The total effect of this evidence, both clinical and scientific, upon the development of dentistry has been little short of revolutionary. Hitherto, the major feature of dental interest, upon which the attention of the profession was concentrated, had been the development and perfection of manipulative procedure in restorative operations. The ingenuity expended and the excellence of the results attained became the outstanding characteristics of dental practice; and the restoration by prosthetic or operative means of the masticatory mechanism damaged by partial or total loss of teeth was its dominating ideal. There is now an enforced recognition in the professional, as well as in the lay mind, of the importance of the welfare of the tissues and organs of the mouth. In the dental

profession the consequent changes of technical procedure and objectives have been fundamental. The ideal of mechanical perfection in the methods and appliances by which the dental surgeon restores the patient's power to masticate, is now regarded as a remedial measure subservient to the larger ideal of normal mouth health.

Oral Hygiene in Schools.--One of the principal factors which extended and popularized this knowledge is the oral hygiene movement, an effort to demonstrate practically that school children, relieved of the disabilities arising from infected mouths and diseased teeth which handicap normal development, show improved physical and mental efficiency. The Cambridge experiment, inaugurated in 1907 by the late George Cunningham, of Cambridge, England, was perhaps the earliest practical test. The analogous work of Dr. Ernst Jessen, of Strasbourg, introduced oral hygiene into the public schools of a number of towns in Germany. In the United States the utility of the movement was tested in the Marion school of Cleveland, O., in 1910, and in 1919 there was completed, under conditions yielding accurate figures, a five years' test of applied mouth hygiene in the public schools of Bridgeport, under the direction of Dr. A. C. Fones.

In this test 20,000 children of the first five school grades were under observation and treatment. The average number of carious cavities was found to be over 7% per child; 30% claimed that they brushed their teeth occasionally; 60% stated that they did not use a tooth-brush and 10% had fistulous openings on the gums from abscesses at the roots of decayed teeth. Systematic application of oral hygiene, the intelligent and systematic use of the tooth-brush and the elimination of accretions, dental decay and suppurative conditions were followed by great improvement in general health and mental efficiency. Whatever may be the full explanation it is certain that deaths of Bridgeport children ffom diphtheria, measles and scarlet fever were fewer after oral hygiene had prevailed (1919) than they were before (1914). This is seen from the following table:—

Disease	1919.	1914.
	%	%
Diphtheria	18·7	36.6
Measles	4·1	20·0
Scarlet fever	0·5	14·1

(E. C. K.)

Under the direction of Supt. Willis A. Sutton, a dental clinic was installed in a school of 987 pupils in Atlanta and a hygienist, a dentist, a dietitian and a visiting teacher were selected. The number of days the children had been absent, in the past year, causes of the absences, the number of subject failures and the physical condition of each child as to weight and general appearance were all carefully noted. Each child's mouth was then put in good condition and after three weeks new records were kept. All other factors entering into improvement were as carefully eliminated as possible. Upon comparison of the two records many significant deductions were made. First, the 987 children had 3,364 less absences than the preceding year. Second, whereas the preceding year practically 20% had failed in one or more subjects, the year following the experiment less than 6% had failed. Third, every child in the entire group had gained in weight, ranging from 6 lbs. for the 9 months' period to 22 lbs., with an average of 11·2 pounds. Normally an average gain of about 8 lb. would have been expected. Fourth, the general appearance of the children had improved remarkably, and they were far more spontaneous and happy than before. The dental clinics were then installed in other schools, with the result that of the 60,000 children enrolled, 6,000 more per day attended school than formerly. The percentages of failures were reduced in the elementary schools by 8% and in the junior and senior high schools by 6%. The direct saving in money was $150,000–$200,000 per year in a budget of $3,000,000.

(W. A. S.)

Dental Disease and Mental Efficiency.—An improvement in mental efficiency is deduced from the reduction in the percentage of retarded children, *i.e.*, children who are not less than two years older than the normal age for the school grade to which they should belong. The percentage of retarded children before and after the introduction of mouth hygiene in the Bridgeport schools is shown in the following table:—

Grade.	Sept. 1912.	Nov. 1918.	Drop in retardation.
	%	%	%
I	16·5	8·1	51·0
II	37·0	15·3	58·0
III	53·0	24·7	53·0
IV	59'5	31·7	47·0
V	61·0	33·1	45·0
VI	54·0	30·4	44·0
VII	39·0	19·3	50·0
VIII	27·0	12·5	54·0
Average	43·3	21·1	50·2

Retardation represents inability of the child to advance with his class, necessitates repetition of his grade work, and becomes an economic question of serious importance to the ratepayer. The cost of re-education in Bridgeport in 1912 was 42% of the entire budget, and for 1918 only 17%. Among the 20,900 children under observation in the schools of Bridgeport, 98% had various forms and degrees of malocclusion of the dentures, a condition now generally recognized as associated with asymmetrical development of the bones of the face and the brain case. Many children with malocclusion owing to the arrested development of the facial and cranial bones suffer from impeded nasal respiration, and develop adenoids and tonsilar hypertrophy, leading to infection with its systemic sequelae and the interferences with bodily nutrition incident to insufficient oxidation of the blood. Orthodontic treatment for the correction of malocclusion in children is a therapeutic and prophylactic measure having an important health relation rather than a procedure for the relief of deformity.

During the World War bad teeth were so serious a bar to recruiting that the matter called for attention in all armies. Everywhere the dental service was increased. In 1921 Great Britain created a definite Army Dental Corps, but in the United States such a corps had been formed some years earlier.

National Dental Service.—Undoubtedly the most notable example of comprehensive planning for the national extension of dentistry and oral hygiene as a factor of the public health service is that proposed in the interim report on the Future Provision of Medical and Allied Services, made to the British Ministry of Health by the Consultative Council on Medical and Allied Services, May 1920. This report recognizes oral hygiene and dental service as factors of public health and as proper subjects for control and development by the State.

Personal Hygiene.—To establish the habit of personal care of the mouth in school children is a field of activity that has developed the specially trained dental nurse or hygienist as an adjuvant to dental service, whose calling is now legalized in the principal States of the United States. The work of the dental nurse is limited to the treatment of the exposed surfaces of the teeth, in the removal of deposits and accretions thereon, the training of school children in the systematic use of the tooth-brush and their education in the importance of mouth cleanliness.

War Surgery.—The many head, face and jaw wounds during the World War created a new field for oral surgery and surgical prosthesis. Surgical measures alone were insufficient for successful treatment, as the loss of tissue from gunshot wounds of the head and face, and scars resulting from extensive lesions left the patient in many instances with repulsive deformities. The resources of surgery and dentistry were called into co-operation and the aid of dental prosthetic technique was often necessary.

Oral Prophylaxis.—Oral prophylaxis, in so far as it has been instrumental in securing cleanliness of the mouth and teeth, has undoubtedly prevented dental disease to a considerable degree, but has not been wholly effective. As research has thrown light upon dental disease, attention has been increasingly focused upon means for its prevention. The factors of susceptibility and immunity are undergoing active investigation, with strong indica-

tions that nutritional errors and faulty metabolism play a role of primary importance in the causation of dental disease. Correction of faulty food habits and a rational hygiene should contribute materially toward the prevention of caries and periodontal necrosis, the most common and widely distributed of human disorders. Because of the recognition of the vital relations of the teeth, the dental educational system, through a rapid reorganization, is proceeding toward a more efficient adaptation of the knowledge of health relations of the teeth to the ends of dental practice.

A systematic survey of the whole field of dental education has been made by the Carnegie Foundation for the Advancement of Teaching, with a view to recommending such adjustments as will bring systematic dental education fully up to the standard of present requirements from a public health standpoint.

General Developments.— While the most conspicuous progress in dentistry since 1910 has been in the direction of its vital and hygienic relations, its technical and engineering features have shown a similar development. Until this period the construction of artificial dentures for the prosthetic restoration of lost teeth was almost wholly an empirical procedure depending on the judgment, manual skill and good taste of the operator. Scientific studies of the engineering principles underlying the mechanism of the human masticatory function, initiated about 1866 by F. H. Balkwill, have since then been prosecuted by numerous followers, who have brought the knowledge of masticatory movements and of the relations of the teeth and their morsal surfaces thereto to a state of completeness that enables the prosthetist, by the aid of mechanical articulating devices, to reproduce in the artificial denture a mechanism with possibilities approximating, both functionally and artistically, those of natural dentures.

The entire development of modern dentistry dates from the 19th century, and mainly from its latter half. Beginning with a few practitioners and no organized professional basis, educational system or literature, many thousands of its practitioners are, at the present time, to be found in all civilized communities. Its educational institutions are numerous and well equipped. It possesses a large periodical and standard literature in all languages. Its practice is regulated by legislative enactment in all countries in the same way as medical practice. The business of manufacturing and selling dentists' supplies represents an enormous industry, in which millions of capital are invested.

DENTON, urban district, Mossley parliamentary division, Lancashire, England, 4½ mi. N.E. from Stockport, on the L.M.S. railway. Pop. (1938), 21,700. In the township are reservoirs for Manchester's water supply. The leading industry is the manufacture of felt hats. Coal occurs in the district.

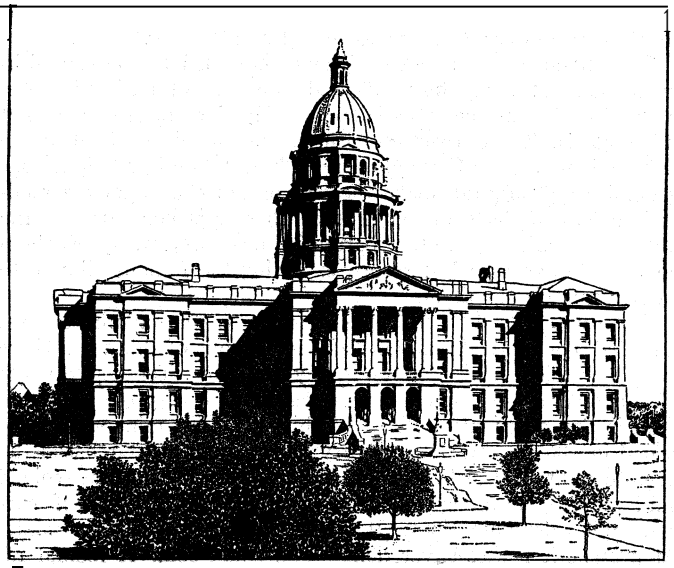
DENTON, a city of Texas, U.S.A., 35 mi. N.W. of Dallas and N.E. of Fort Worth; the county seat of Denton county. It is on federal highways 77 and 377, and is served by the Missouri-Kansas-Texas and the Texas and Pacific railways. Pop. (1940) 11,192. Wheat, oats, corn, cotton, peanuts, grain sorghums, fruit, truck are raised in this region. It is a livestock, dairy and poultry centre. Industries include flour mills, a brick plant, a food products plant, a cheese plant, a garment factory, bottling plants and a pottery plant. It is the seat of the North Texas State Teachers college and the Texas State college for women. Denton was settled in 1857 and incorporated in 1866.

D'ENTRECASTEAUX ISLANDS, a group of islands in the Pacific ocean about 2 mi. S.W. of New Guinea. They comprise three large islands, Ferguson, Goodenough and Formanby and a number of islets separated by narrow channels with a total area of 12,000 sq.mi. There are traces of extinct volcanoes, and gold has been discovered in certain parts. They were discovered by Bruni D'Entrecasteaux in 1792 and are now part of the dependency of New Guinea (*q.v.*).

DENVER, capital of Colorado, U.S.A., on the South Platte river, in the centre of "the west." Population in 1920 was 256,491 (84% native white); 287,861 in 1930; 322,412 in 1940 by the federal census.

It is on federal highways 40 and 85; is served by the Burlington, the Rock Island, the Santa Fe, the Union Pacific, the Denver and Rio Grande Western, the Colorado and Southern and the Denver and Salt Lake railways; and has airmail and commercial air service. There are five aviation fields. The Moffat tunnel of the Denver and Salt Lake railway through James peak in the continental divide, built by the city of Denver in co-operation with parts of several counties in northwestern Colorado (opened 1928), has eliminated 27 mi. of 4% grade and made possible shortening the distance to Salt Lake City and other points west by 173 miles.

The altitude of Denver, at the state capitol, is exactly one mile above the sea. Its area, coextensive with that of the county of Denver, is 58.75 square miles. It lies at the edge of the great plains, in the river valley running north and south, 12 mi. E. of the main range of the Rocky mountains, which stretches in a snow-capped background visible for 1jo mi. from Pikes peak on the south to Longs peak on the north. The climate, with a low degree of humidity throughout the year and a high percentage of sunshine, is favourable alike to health, industry and recreation. The city is well planned, with broad streets and a system of boulevards and parkways. Because of severe restrictions against wooden structures adopted in the early days, most of the residences, as well as the business and public buildings, are of brick, stone, tile or cement. All trains except those of the Denver and Salt Lake railway enter the Union station, a fine and commodious structure built in 1914 at a cost of over $3,000,000. There are 35 parks and 17 supervised playgrounds within the city limits,



THE COLORADO STATE CAPITOL, BUILT 1887–95, IN THE CENTRE OF DENVER. SHOWING THE DOME WHICH IS OVERLAID WITH NATIVE GOLD

comprising 1,563 ac.; and the city owns a chain of 30 mountain parks (in one of which is the grave of "Buffalo Bill"), aggregating 25,000 ac. in area, and connected with one another and with the city by 100 mi. of boulevard.

In the centre of the city is a stretch of half a mile (40 ac.) devoted to public buildings set in landscaped grounds. The massive state capitol of native granite (built in 1887–95, at a cost of $3,000,000), topped by a dome overlaid with gold from Colorado mines, stands on a terraced hill, flanked by the state office building, state capitol annex and the state historical museum, which

contains exhibits of prehistoric and Indian life and of pioneer days. Immediately west of the capitol grounds is the beautiful civic centre (due to the initiative of the late Robert W. Speer, who was mayor 1904–12 and 1916–18) including the public library, a Greek theatre and the new $5,000,000 city and county building; and beyond this group is the U.S. mint. In City park, a tract of 408 ac. set aside at an early date, is the Colorado museum of natural history. There is a municipal auditorium, seating 12,000, where the Democratic national convention which nominated William J. Bryan met in 1908. The water supply, taken from the river at a point 23 mi. above (*i.e.*, southwest of) the city, is supplemented by a system of reservoirs in the mountains and in, or adjacent to, the city, which have a capacity of 74,000,000,000 gal., enough to supply the city for three years without replenishing. The 8 ft. pioneer bore of the Moffat tunnel, paralleling the main bore, brings water from the western slope of the continental divide, supplementing the South Platte watershed supply. The assessed valuation of property for 1940 was $364,942,960.

Education. — The public-school system includes 66 elementary, g junior high, 5 senior high and several special schools, including one for deaf children, one for crippled children and the Emily Griffith Opportunity school. Illiteracy and child labour are low. Among the institutions for higher education are the University of Denver (Methodist), chartered in 1864 as Colorado seminary, Colorado Woman's college (1889), Regis college (1886), the Iliff School of Theology (Methodist Episcopal), the medical school of the University of Colorado, Loretto Heights college and the Westminster law school.

Tourist Amenities and Climate. — As a recreation centre Denver has so many attractions that providing for tourists is one of the leading industries. Motorbuses for sightseeing run in every direction. The tourist bureau lists 60 excursions to points of beauty and interest which can be made in a day or less each. Sports include glacier climbing, skiing, bathing in pools of hot mineral water, trout fishing and yachting on Grand lake (8,389 ft. above sea level), where an annual regatta is held in August. A mountain highway to the top of Mt. Evans, 14,260 ft., is the highest automobile road in the world. It is estimated that tourists spend over $15,000,000 annually in the city.

The climatic advantages of Denver have led to the establishment there of many hospitals and sanatoria of national scope, philanthropic and commercial, especially for the treatment of tuberculosis. These, together with the new medical school of the state university, the Colorado general hospital and the Fitzsimons general army hospital, make the city one of the important medical centres of the country. The death rate is kept high by the influx of invalids from other parts of the country, many of whom go to Colorado as a last resort, expecting the famous climate to work a miracle for them.

Commerce and Industry. — Denver is the administrative, financial, commercial and industrial metropolis of the west. There is no large city within 500 mi. in any direction. Ten departments of the federal government are represented by 145 offices — more than in any other city outside Washington. The mint was established in 1862, when the secretary of the treasury purchased the private mint of Clark, Gruber and company, which had coined gold pieces containing 1% more gold than U.S. coins of corresponding denominations. It is one of the three coinage mints. At present it makes silver dollars and small coin. A federal reserve branch bank is located in Denver. Bank clearings in 1940 amounted to $1,627,431,420, and deposits on Dec. 31 totalled $223,665,900.

Denver's trade territory embraces parts of 14 states, besides Colorado, and has a population of about 6,000,000. There are some 993 wholesalers in the city, who have agents and distributing warehouses at many points. Administrative headquarters of the beet sugar, metal-mining and coal industries of the state are located in Denver. It is the distributing centre of the automobile industry in the Rocky mountain region, and ranks fourth among the cities of the country as an administrative centre for the insurance business. The Denver stockyards is the largest cattle market in the west and it is the largest sheep market in the world. At the National Western stock show (held annually in January since 1907) pedigree breeding cattle are bought and sold in carload lots, feeder stock by the trainload. The annual value of wholesale transactions in 1939 was $340,989,000; of the city's retail trade, $177,963,000.

Distance from the manufacturing centres of the east forced Denver in its early days to develop industries to supply the needs of the mining and frontier population for wagons and harness, mining machinery, meat, flour and other necessities. On this foundation, utilizing the raw materials — mineral, animal and vegetable — at its doors, developing its specialties, but also diversifying its products, and gradually extending its markets, the manufactures of the city have grown until in 1939 there were 781 establishments within the city limits, employing a daily average of 16,239 wage earners, paying $20,910,625 in wages, and producing goods valued at $144,613,574. An estimate for 1937, including some plants in the suburbs, indicated an output valued at $115,847,646. A favourable factor is the abundant supply of coal and fuel oil from mines and refineries within a very short haul. In 1928 natural gas was piped in from the Amarillo district of Texas.

The leading industry, in point of value of product, is slaughtering and meat packing. Receipts at the stockyards in 1940 included 583,031 cattle, 568,231 hogs and 2,662.582 sheep. The average receipts for the five years 1936–40 were nearly $2\frac{1}{4}$ times as many cattle, $3\frac{1}{2}$ times as many hogs and $9\frac{1}{2}$ times as many sheep, as in 1900. Other manufactures of importance are mining machinery, which is marketed all over the world; sugar mill equipment, which goes as far as Hawaii and the Philippines; and luggage that is sold in every state of the union. A rubber manufacturer sells some 2,000 products in the domestic market as well as in all foreign countries. The manufacture of candy is favoured by the dry atmosphere. Because of its distance from the ports, Denver had no great volume of World War (1914–18) business, and consequently suffered less than most cities from the postwar deflation. Export business was (in 1940) estimated at $15,000,000 yearly.

History. — John Simpson Smith, trapper and trader, with his Sioux wife Wapoola, settled on the site of Denver in the autumn of 1857. The following summer, after traces of gold were found in the sands of Cherry creek by W. Green Russell of Georgia, rival settlements grew up on opposite sides of the creek, near its confluence with the South Platte river (at Fourteenth street in the present city plan): Auraria on the west bank, and on the east bank St. Charles, which was almost immediately renamed Denver, after the territorial governor, Gen. James W. Denver. The two settlements, with a population of about 1,000, were consolidated in 1860, and in 1861 received a charter from the first territorial legislature of Colorado. In 1868 Denver was made the capital of the territory, and in 1881, five years after Colorado became a state, the choice was confirmed by popular vote.

On Oct. 29, 1858, in a blinding snowstorm, two men drove in with a wagon train and opened the first "store." A second was opened on Christmas day, and a jewellery store a few days later. At the opening of 1859 lumber sold for $100 per 1,000 ft.; flour for $20 to $40 per 100 lb.; and sugar, coffee and tobacco, for almost their weight in gold dust, the currency of the region for some years. The first hotel ("The Eldorado") was opened in a large log house on Feb. 1, 1859. On April 23 the first number of the *Rocky Mountain* News was issued. On May 9, arrived the first coach of the Leavenworth and Pike's Peak Express company, which carried letters at 25 cents an ounce. News of Lincoln's election was brought from St. Joseph, Mo., nearly 700 mi. by the Pony express in 69 hours. Letter postage by Pony express was $5 per letter. Telegraph connection with the east ($9 for 10 words) was established in 1863. A private mint and a bank were opened in 1860. In 1863 there was a severe fire, and in 1864 a terrible flood came down Cherry creek and washed away many buildings. The first school teacher, dressed in a black broadcloth frock coat and a silk hat, drove into town late in the summer of 1859, behind a team of oxen which he apostrophized with Greek and Latin oaths that won him infinite respect from the local masters of profanity. In October he opened a school in a log cabin, after $250 had been

subscribed for its "endowment." In 1864 Colorado seminary was established, largely through the efforts of Gov. John Evans, who had been one of the founders of Northwestern university at Evanston, Illinois. When the Union Pacific passed through 106m. to the north of Denver, a local company was organized to connect the city with it by a line to Cheyenne, and on June 23, 1870, the first passenger train arrived. On Aug. 15, the Kansas Pacific was completed to Denver, and other transportation facilities soon followed.

By 1870 there were 1,500 buildings in the city, and the population was 4,759. In the next 20 years it grew to 106,713. All the facilities of a modern city were introduced in the '70s, and the '80s were a period of great activity in real estate. Since 1890 growth has been steady, though less spectacular. In the early days Denver had its problems with "squatters" and "land jumpers." There were the social conditions usually found in new mining communities, including crimes of violence and some exercise of extra-legal methods of administering justice. At the Palace gambling hall and variety theatre, celebrated the world over, fortunes were won and lost in a night. A flood in 1878 and the famous strike in Denver and Leadville in 1879–80 were temporary checks to prosperity. In 1880 there was a memorable election riot, under the guise of an anti-Chinese demonstration. A serious street-car strike in 1920 involved the loss of seven lives, the importation of armed strike-breakers, the intervention of Federal troops, and military rule for a month. Denver was the first city to undertake to finance its charitable agencies by a joint "community chest." Its juvenile court, under Judge Ben B. Lindsey (1869–1943), who served from 1901 to 1927, was a pioneer in its field. In 1902 a city-and-county of Denver was created, with power to frame its own charter, and the charter was adopted in 1904, but dual sets of officers served until 1912. A commission form of government was in force for four years from 1912, but in 1916 the mayor-and-council form was resumed.

DENVER AND RIO GRANDE WESTERN RAILROAD, incorporated in 1870, was conceived as a narrow gauge (3′0″) trunk line from Denver, Colo., to Mexico City, Mex., The route was projected along the Rio Grande del Norte; hence the first name, Denver and Rio Grande railway. Course of the railroad was turned westward through the Royal Gorge to tap the Leadville mining district; by 1883 the narrow gauge line was completed between Denver and Ogden, Utah, with branches reaching into the mountains wherever mining development demanded transportation. The Royal Gorge route, a through standard gauge (4′8½″) line, Denver to Ogden, via Tennessee Pass (10,240ft.), 782mi., supplanted the narrow gauge line in 1890, as the Rio Grande became an integral part of several transcontinental systems. Remaining narrow gauge are 686mi. of track, all in southwest Colorado; longest in the U.S., these lines are the model for all similar operations in the world. The Moffat Tunnel route, shortening Rio Grande's Denver-Salt Lake City distance to 57omi., in 1934 strengthened the road's position as a transcontinental route by utilizing the 6·2mi. bore through the Continental Divide 5omi. from Denver. The Rio Grande operates 2,566mi. in Colorado, Utah and New Mexico.

DEODAND, in English law, any personal chattel which. having moved ad *mortem* or been the immediate cause of the death of any reasonable creature, was forfeited to the king for pious uses. It was originally designed as an expiation for the souls of those suddenly snatched away by violent death, and was abolished by 9/10 Vict. C. 62. This imputation of homicidal guilt to inanimate objects or the lower animals is of great antiquity and led in the middle ages to the judicial trial of animals or things for manslaughter. In England, subsequent to the Reformation, deodands were distributed as alms by the king's high almoner, though more recently they were regarded as mere forfeitures.

If a horse or other animal in motion killed a person, whether infant or adult, or if a cart ran over him or a tree fell upon him, it was forfeited as a deodand and its value was appraised by the jury. It was at one time held that if death were caused by falling from a cart or a horse at rest, the law made the chattel a deodand only if the person killed were an adult, not if he were below years of discretion; but in later times this distinction was abolished. Blackstone says "where a thing not in motion is the occasion of a man's death, that part only which is the immediate cause is forfeited; as if a man be climbing up the wheel of a cart, and is killed by falling from it, the wheel alone is deodand." Whereas, if the cart were in motion, not only the wheel but all that moves along with it (as the cart and loading) are forfeited. On the other hand, if a man riding on the shafts of a wagon fall to the ground and break his neck, the horses and wagon only are forfeited, and not the loading, because it in no way contributed to his death. Where a man is killed by a vessel at rest, in fresh water, the cargo is not deodand; where the vessel is under sail, hull and cargo are both deodand. But accidents on the high seas, or on an arm of the sea, did not cause forfeiture "because mariners are continually exposed to so many perils that the law imputes misfortunes happening there rather to them than to the ship." The finding of a jury was necessary to constitute a deodand, and the death must take place within a year and a day of the accident. The investigation of the value of the instrument by which death was caused at one time occupied an important place among the provisions of English criminal law. More recently these forfeitures became extremely unpopular; and jurors, with the connivance of judges, found deodands of trifling value, so as to defeat what was regarded as an inequitable claim.

DEODAR. The deodar or "god tree" (Cedrus Deodara) is a species of coniferous evergreen tree closely allied to the cedar, the timber obtained therefrom being of considerable value. It forms extensive forests in the Himalayas at elevations of from 7,000 ft. and is also found in Afghanistan and north Baluchistan. The wood is durable and light-red in colour and is used particularly for cabinetwork as it can be highly polished. *See* also CEDAR.

DEODORIZER, a disinfectant which acts by oxidizing or otherwise changing the chemical constitution of volatile substances disseminated in the air. It also prevents noxious exhalations from organic substances, and in virtue of its properties is an effective disinfectant in certain diseases. See also DISINFECTANTS.

DEOGHAR (known in Bengal as Baidyanath, also called Baidyanath-Deoghar), a town in the Santal Parganas district of Behar and Orissa, India. Pop. (1921) 12,355. It has a famous temple dedicated to Baidyanath or Siva, the resort of numerous pilgrims. It also enjoys a reputation as a health resort among Bengalis, many of whom have country houses here.

DÉOLS, a suburb of the French town of Chbteauroux, in the department of Indre. Pop. (1936), 3,057. Déols lies to the north of Châteauroux, from which it is separated by the Indre. It preserves a fine Romanesque tower and other remains of the church of a famous Benedictine abbey, the most important in Berry, founded in 917 by Ebbes the Noble, lord of Déols. A gateway flanked by towers survives from the old ramparts of the town. The parish church of St. Stephen (15th and 16th centuries) has a Romanesque façade and a crypt containing the ancient Christian tomb of St. Ludre and his father St. Leocade, who according to tradition were lords of the town in the 4th century. The pilgrimage to the tomb of St. Ludre gave importance to Déols, which under the name of Vicus *Dolensis* was in existence in the Roman period. In 468 the Visigoths defeated the Gauls there, the victory carrying with it the supremacy over the district of Berry. In the middle ages the head of the family of Déols enjoyed the title of prince and held sway over nearly all Lower Berry, of which the town itself was the capital. In the 10th century Raoul of Déols gave his castle to the monks of the abbey and transferred his residence to Châteauroux. The abbey church was burnt by the Protestants during the religious wars and in 1622 the abbey was suppressed by the agency of Henry II., prince of Condé and of Déols.

DEONTOLOGY is the title of a book by Jeremy Bentham (*q.v.*), who introduced the term to denote a utilitarian system of ethics. The name has since then come to be applied to a system of ethics in which prominence is given to ideas of *duty* rather than to those of right or goodness.

DEPARTMENT, a division or part of a system; one of the branches of the Administration in a State or municipality. In Great Britain it is commonly applied to the subordinate divisions of the chief executive offices of State, such as the savings bank or other department of the Post Office, the mines department of the Board of Trade, etc.; in the United States these subordinate divisions are known as "bureaux," while "department" is used of the chief branches of the executive.

In France the word is also used for a territorial division corresponding loosely to an English county. Previous to the French Revolution the local unit in France was the military *gouvernement,* roughly corresponding to the old provinces, such as Franche Comté, Provence, Bourgogne, Bretagne, etc., but this division being too closely bound up with the administrative mismanagement of the old régime, at the suggestion of Mirabeau, the "provinces" were divided into departments, as nearly as possible equal to a certain average of size and population, and deriving their names principally from rivers, mountains or other prominent geographical features. In 1860 three new departments were created out of the newly annexed territory of Savoy and Nice. The three departments of Bas-Rhin, Haut-Rhin and Moselle, which were lost after the Franco-German war in 1871, were restored in 1919. Each department is presided over by an officer called a prefect (*q.v.*) and is subdivided into *arrondissements* each in charge of a sub-prefect. Arrondissements are again subdivided into *cantons* and these into *communes,* somewhat equivalent to the English parish. *(See* FRANCE: *Government and Administration.)*

DEPARTMENT STORE, the name given in the United States to a retail establishment which sells goods of all kinds and in which the merchandise is divided into classes, each one of which is handled as a department, distinct as to management and location within the store, and is carried in the accounts as a separate entity. The purpose of department store organization is to apply the principles of large-scale production to the problems of retail selling and to consolidate the ownership and management of many lines of merchandise under one roof. The original idea of this method was that the combining of overhead and service facilities would offer increased sales attraction and that such an enterprise could be carried on with many economies and efficiencies.

Of the total volume of sales by retail stores, which approximated in 1938 $35,719,000,000, department store sales represented 16%, or $5,715,040,000. The largest per cent of the total retail sales is done by small, independent specialty and neighbourhood stores, and next to the department store in percentage is the volume done in retail sales by chain and variety stores.

As compared with the unit or individual store, the most direct competitor, the department store offers important conveniences to its customers. It is pre-eminently the shopping store. It has secured so much of the shopping trade which involves the careful comparison of style, quality and price that the smaller unit dry goods stores have almost abandoned that trade and have confined themselves to a large extent to selling convenience goods. The department store is generally located in a central retail-shopping district with every provision for convenience and comfort. Within the store itself, two types of service are usually available: (1) services which assist the customer such as credits, deliveries, store directories, personal shopping services, etc.; and (2) services which attract trade to the store, such as restaurants, rest rooms, musical programs, classes in embroidery, etc.

The most serious problems with which the department store has to contend are the high operating expense as a retail outlet and susceptibility to losses through poor salesmanship. This difficulty is greater with the department store than with the chain store, which caters more largely to convenience goods, or the mail-order house, in which the personality of the employees is not in evidence. Although the total department store sales still show a trend to increase, the rate of increase is declining, since the department stores are losing ground to newer and different competitors such as the non-service chain stares and the numerous neighbourhood stores that have been developed in recent years in suburban communities.

The cost of operation of department stores in 1938 approached 36% of their sales. This is much higher than the cost of operating chain stores and neighbourhood stores. The primary causes for the increase in the operating expenses of department stores have been (1) a marked increase in wage rates, due in some localities to the unionization of stores, (2) a substantial increase in taxes, including Social Security and unemployment contributions, (3) the reduction in store hours, and (4) the drop in demand for merchandise in the higher brackets, due to a reduction in the consumers' buying power, which has tended to increase the cost of handling each transaction. Yet department store costs are divided over very large volumes of trade which tend to lessen the unit charge. Furthermore, even large unit costs are not a positive disadvantage if they are offset by, or are the means of securing, a rapid rate of turnover. (P. J. R.)

DE PERE, a city of Brown county, Wisconsin, 109m. N. of Milwaukee, on the Fox river, 6m. from its mouth. It is served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railways and by lake and river steamers. The population was 5,521 in 1930; in 1940 it was 6,373.

De Pere is a shipping and transfer point; has grain elevators, foundries and machine shops; manufactures boats, flour, paper, boilers and farm implements; and is the seat of St. Norbert college (Roman Catholic), established in 1902. The state reformatory is just north of the city. In 1634–5 Jean Nicolet found here, at the first rapids of the Fox river, a polyglot village of several thousand Indians, and here in 1670 Father Allouez established the mission of St. Francis Xavier, the second in the territory that is now Wisconsin. The French called the place *Rapides des Pères.* Nicolas Perrot, the first French commandant in the north-west, made it his headquarters, and here Father Marquette wrote the account of his journey to the Mississippi. A few miles south of the city lived for many years Eleazer Williams (*c.* 1787–1857), who claimed to be the "lost dauphin," Louis XVII. of France, and was an authority on Indians, especially the Iroquois. De Pere was incorporated as a village in 1857 and as a city in 1883.

DEPEW, CHAUNCEY MITCHELL (1834–1928), American lawyer and politician, was born in Peekskill, N.Y., on April 23, 1834, of a Huguenot family (originally Du Puis or De Puy). He graduated at Yale in 1856, entered politics as a Republican—his father had been a Democrat—was admitted to the bar in 1858, was a member of the New York Assembly (1861–62) and was secretary of State of New York (1864–65). Through his friendship with Cornelius and William H. Vanderbilt he became in 1866 attorney for the New York and Harlem railway, in 1869 was appointed attorney of the newly consolidated New York Central and Hudson River railway, of which he soon became a director, and in 1875 was made general counsel for the entire Vanderbilt system of railways. He became second vice president of the New York Central and Hudson River railway in 1869; president (1885–98), and chairman, in 1898, of the board of directors of the Vanderbilt system. In 1872 he joined the Liberal Republican movement and was nominated and defeated for the office of lieutenant governor of New York. In 1899 he was elected U.S. senator from New York State, and in 1904 was re-elected for the term ending in 1911. His orations and speeches have been compiled in 12 volumes; in 1922 he published *My Memories of Eighty Years.* He died on April 5, 1928.

See C. M. Depew, One *Hundred Years of American Progress;* "Leaves from my Autobiography," in *Scribner's Magazine,* lxx. (Nov.–Dec. 1921), 515–530, 664–676; *My Memories of Eighty Years* (1922).

DEPEW, a manufacturing village of Erie county, New York, U.S.A., 9 mi. E. of Buffalo on federal highway 20; served by the Erie, the Lackawanna, the Lehigh Valley and the New York Central railways. Pop. (1940) 6,084. Incorporated in 1894.

DEPHLOGISTICATED AIR, the name formerly given to air from which the oxygen has been extracted; this consists chiefly of nitrogen (*q.v.; see* also ARGON and CHEMISTRY, *History of).*

DEPLOY, a military term signifying to extend a force or unit of troops into a more open formation, *e.g.,* from column, the marching and approach (*q.v.*) formation, into line, whereby the

greatest number of its weapons can be brought to bear.

DEPORTATION or **TRANSPORTATION,** a system of punishment for crime, of which the essential factor is the removal of the criminal to a penal settlement outside his own country. It is to be distinguished from mere expulsion (*q.v.*) from a country, though the term "deportation" is now used in that sense in English law under the Aliens Act 1905 (see ALIEN). Strictly, the deportation or transportation system has ceased to exist in England, though the removal or exclusion of undesirable persons from British territory, under various Orders in Council, is possible in places subject to the Foreign Jurisdiction Acts, and in the case of criminals under the Extradition Acts.

English Practice.—At a time when the British statute-book bristled with capital felonies, when the pickpocket or sheep-stealer was hanged out of hand, when Sir Samuel Romilly, to whose strenuous exertions the amelioration of the penal code is in a great measure due, declared that the laws of England were written in blood, another and less sanguinary penalty came into great favour. The deportation of criminals beyond the seas grew naturally out of the laws which prescribed banishment for certain offences. The Vagrancy Act, 39 Eliz., c. 4, contained in it the germ of transportation, by empowering justices in quarter sessions to banish offenders and order them to be conveyed into such parts beyond the seas as should be assigned by the privy council. Full effect was given to this statute in the next reign, as is proved by a letter of James I., dated 1619, in which the king directs "a hundred dissolute persons" to be sent to Virginia. The statute, 18 Car. II., c. 3, gave power to transport to America notorious thieves in Cumberland and Northumberland. Transportation to the American colonies ceased with the achievement of their independence in 1776.

The British legislature, however, discovered that transportation to the colonies was bound to be attended by various inconveniences, particularly by depriving the kingdom of many subjects whose labour might be useful to the community; and an Act was accordingly passed which provides that convicts sentenced to transportation might be employed at hard labour at home. At the same time the consideration of some scheme for their disposal was entrusted to three eminent public men—Sir William Blackstone, Mr. Eden (afterwards Lord Auckland) and John Howard. The result of their labours was an act for the establishment of penitentiary houses, dated 1778. This act is of peculiar importance. It contains the first public enunciation of a general principle of prison treatment, and shows that even at that early date the system since nearly universally adopted was fully understood. The object in view was thus stated. It was hoped "by sobriety, cleanliness and medical assistance, by a regular series of labour, by solitary confinement during the intervals of work and by due religious instruction to preserve and amend the health of the unhappy offenders, to inure them to habits of industry, to guard them from pernicious company, to accustom them to serious reflection and to teach them both the principles and practice of every Christian and moral duty." However, the new and vast territories of Australasia promised an unlimited field for convict colonization, and for the moment the scheme for penitentiary houses fell to the ground. "There was general confidence," says Merivale in his work on colonization, "in the favourite theory that the best mode of punishing offenders was that which removed them from the scene of offence and temptation, cut them off by a great gulf of space from all their former connections, and gave them the opportunity of redeeming past crimes by becoming useful members of society." These views so far prevailed that an expedition consisting of nine transports and two men-of-war, the "first fleet" of Australian annals, sailed in March 1787 for New South Wales. A few free families also were encouraged to emigrate, but they were lost in the mass they were intended to leaven, swamped and outnumbered by the convicts, shiploads of whom continued to pour in year after year. When the influx increased, difficulties as to their employment arose. Free settlers were too few to give work to more than a small proportion. Moreover, a new policy was in the ascendant, initiated by Governor Macquarie, who considered the convicts and their rehabilitation his chief care, and steadily discouraged the immigration of any but those who "came out for their country's good." The great bulk of the convict labour thus remained in government hands.

Some change in system was inevitable, and the plan of "assignment" was introduced; in other words, that of freely lending the convicts to any who would relieve the authorities of the burdensome charge; but this system in its turn developed its own abuses. The story of effort and failure and scandal is too long to be told here. Sufficient to say that, chiefly owing to Australian protests, the system was abandoned in 1840 and finally abolished by the Penal Servitude Acts, 1855 and 1857. The measures taken to substitute other methods of secondary punishment are set forth in the article PRISON (*q.v.*).

French Practice.—France adopted deportation for criminals during the course of the eighteenth century. In 1797, during the French Revolution a small group of political prisoners, most of them priests, were deported from France to French Guiana by the revolutionary government. In the following year some 500 prisoners were likewise deported to French Guiana. In 1823 the philanthropist, Baron Milius, formed an expedition consisting of a company of military workers, some 50 orphan apprentices, and others, making a total of 164 people, who settled on the banks of the Mana. Disorders followed, necessitating the presence of a detachment of gendarmes. The principle of deportation was formally condemned by publicists and government until suddenly in 1854 it was reintroduced into the French penal code with many high-sounding phrases, but in practice the system again failed with deplorable results. Deportation to Guiana was not abandoned, but instead of native-born French exiles, convicts of subject races, Arabs, Annamites and Asiatic blacks, were sent exclusively, with no better success as regards colonization.

In 1864, however, it was possible to divert the stream elsewhere. New Caledonia in the Australian Pacific was annexed to France in 1853. Ten years later it became a new settlement for convict emigrants. A first shipload was disembarked in 1864 at Noumea, and the foundations of the city laid. Prison buildings were the first erected and were planted upon the island of Nou, a small breakwater to the Bay of Noumea. Outwardly all went well under the fostering care of the authorities. The population steadily increased; an average total of 600 in 1867 rose in the following year to 1,554. In 1874 the convict population exceeded 5,000; in 1880 it had risen to 8,000; the total reached 9,608 at the end of Dec. 1883. But from that time forward the numbers transported annually fell, for it was found that this South Pacific island, with its fertile soil and fairly temperate climate, by no means intimidated the dangerous classes; and the French administration therefore resumed deportation of French-born whites to Guiana, which was known as notoriously unhealthy and was likely to act as a more positive deterrent. The authorities divided their exiles between the two outlets, choosing New Caledonia for the convicts who gave some promise of regeneration, and sending criminals with the worst antecedents and presumably incorrigible to the settlements on the equator. This was in effect to hand over a fertile colony entirely to criminals. Free immigration to New Caledonia was checked, and the colony became almost exclusively penal. The natural growth of a prosperous colonial community made no advance, and convict labour did little to stimulate it, the public works, essential for development, and construction of roads were neglected; there was no extensive clearance of lands, no steady development of agriculture. From 1898 simple deportation practically ceased, but the islands were full of convicts already sent, and they still received the product of the latest invention in the criminal code known as "relegation," a punishment directed against the recidivist or incorrigible criminal whom no penal retribution had hitherto touched and whom the French law felt justified in banishing for ever to the "back of beyond." A certain period of time spent in a hard labour prison preceded relegation, but the convicts on arrival were generally unfitted to assist in colonization. They were for the most part decadent, morally and physically; their labour was of no substantial value to colonists or themselves, and there was small

hope of profitable result when they gained conditional liberation, with a concession of colonial land and a possibility of rehabilitation by their own efforts abroad. Thus, the punishment of relegation was not long in favour, and it has now been practically abandoned.

Russia.—Penal exile has been practised by some other countries as a method of secondary punishment. From 1823 onwards Russia directed a stream of offenders, mainly political, upon Siberia, and at one time the yearly average sent was 18,000. The Siberian exile system belongs only in part to penitentiary science, but it was punitive and aimed at regeneration of the individual and the development of the soil by new settlements. Although the journey was made mostly on foot and not by sea transport, the principle of deportation (or more exactly of removal) was the essence of the system. The later practice, however, has been exactly similar to transportation as originated by England and afterwards followed by France. The penal colonization of the island of Sakhalin reproduced the preceding methods, and the Russian convicts were conveyed by ships through the Suez canal to the Far East. Sakhalin was hopefully intended as an outlet for released convicts and their rehabilitation by their own efforts, precisely in the manner tried in Australia and New Caledonia. The result repeated previous experiences. There was land to reclaim, forests to cut down, marshes to drain, everything but a temperate climate and a good will of the felon labourers to create a prosperous colony. But the convicts would not work; a few sought to win the right to occupy a concession of soil, but the bulk were pure vagabonds, wandering to and fro in search of food. The agricultural enterprise was a complete failure. The wrong sites for cultivation were chosen, the labourers were unskilled and they handled very indifferent tools. Want amounting to starvation was a constant rule; the rations were insufficient and unwholesome—very little meat eked out with salt fish and with entire absence of vegetables. The general tone of morals was inconceivably low, and a universal passion for alcohol and card-playing prevailed According to one authority the life of the convicts at Sakhalin was a frightful nightmare, "a mixture of debauchery and innocence mixed with real sufferings and almost inconceivable privations, corrupt in every one of its phases." The prisons hopelessly ruined all who entered them, all classes being indiscriminatingly herded together. It is now generally allowed that deportation, as practiced, had utterly failed, the chief reasons being the unmanageable numbers sent and the absence of outlets for their employment, even at great cost.

Italy.—Italy has practised deportation in planting various agricultural colonies upon the islands to be found on her coast. They were meant to imitate the intermediate prisons of the Irish system, where prisoners might work out their redemption, when provisionally released. Two were established on the islands of Pianoso and Gorgona, and there were settlements made on Monte Cristo and Capraia. They were used also to give effect to the system of enforced residence or domicilio *coatto*.

Portugal.—Portugal also has tried deportation to the African colony of Angola on a small scale with some success, and combined it with free emigration. The settlers have been represented as well disposed towards the convicts, gladly obtaining their services or helping them in the matter of security. The convict element is orderly, and, although their treatment is *"peu repressive* et *relativement débonnaire,"* few commit offences.

India.—The Andaman islands have been utilized by the Indian government since the mutiny (1857) for the deportation of heinous criminals. (See ANDAMAN ISLANDS.)

DEPOSIT, anything laid down or separated; as in geology, any mass of material accumulated by a natural agency (see BED), and in chemistry, a precipitate or matter settling from a solution or suspension. Deposit is also used in the sense of earnest or security for the performance of a contract (see CONVEYANCING) in the law of contract, deposit or simple bailment is delivery or bailment of goods in trust to be kept without recompense, and re-delivered on demand (see BAILMENT). (For banking deposits, see BANK.)

DEPOT, a place where goods may be stored or deposited, such as a furniture or forage depot, the accumulation of military stores, especially in the theatre of operations (from the Fr. *Dépôt*, Lat. *depositum,* laid down). In America the word is used of a railway station, whether for passengers or goods; in Great Britain on railways the word, when in use, is applied to goods stations A particular military application is to a depot, situated as a rule, in the centre of the recruiting district of the regiment or other unit, where recruits are received and undergo the necessary preliminary training before joining the active troops. Such depots are maintained in peace time by all armies which have to supply distant or oversea garrisons; in an army raised by compulsory service and quartered in its own country, the regiments are usually stationed in their own districts, and on their taking the field for war leave behind a small nucleus for the formation and training of drafts to be sent out later. These nucleus troops are generally called depot troops.

DEPRECIATION. In accounting, the term "depreciation" is applied to that inevitable wastage in the value of assets due to some cause inherent in the thing itself, as distinct from fluctuations in value that arise from external causes. Depreciation may arise owing to the operation of (a) human, or (b) natural laws. Leaseholds and copyrights have, by the operation of the law, a limited duration of life, on the expiration of which no proprietory rights survive. Whatever may have been expended on such rights is accordingly expenditure to be recouped (if at all) out of the advantages derived from the use of the property during a definite known period. If due provision be made for depreciation it will take the form of charging against the profits of each successive year its due proportion of the total outlay, so that when the working life has expired the whole of the outlay will have been charged against profits. When depreciation takes place as the result of natural laws, it is caused by wear and tear, natural decay, or obsolescence. Its effect is very similar to that of depreciation from legal causes, save that the period of utility—the working life—is not precisely known, but has to be estimated. Moreover, in many cases, the effect of wear and tear is to impair the efficiency of the equipment gradually, with the result that its value as a profit-earner tends to diminish year by year. Nevertheless, the problem is essentially the same; the whole of the original outlay (minus its residual value, if the latter be worth considering) is a proper charge against the profits earned during the period that the article is in use. Due provision for depreciation during that extended period will involve each successive year's profits being charged with its due proportion of the total sum to be provided

As a matter of calculation, the total sum may be distributed over the required series of years by (*a*) equal, (*b*) gradually diminishing, (*c*) gradually increasing, or (d) irregular instalments. In practice all four methods are in use; they are often called respectively the straight-line, fixed percentage, annuity, and revaluation methods.

When expenditure upon renewals is more or less continual, there is ordinarily no difficulty about financing such expenditure out of revenue, but where relatively large sums have to be found infrequently, it is usually desirable to supplement the accounting provision for depreciation by a physical accumulation of funds available to meet the cost of renewals. This is done by investing year by year a sum equal to the amount charged against profits for depreciation and reinvesting any income derived from such investments, thus building up what is called a sinking fund.

Theoretically, provision for the depreciation of every wasting asset should be effected as the result of a separate calculation. In practice, however, assets are usually grouped into a comparatively small number of separate accounts, and the provision in

respect of each group is based upon the average life of the items composing it. The success of such a device as this depends entirely upon the adequacy of the grouping arrangements. Very often the grouping is overdone.

There should be no real difficulty about calculating in advance due provision for depreciation proper, but it is not, of course, possible to calculate with equal precision the effect of obsolescence. All that can be done is to keep the estimate of the working life low. Successful undertakings often deliberately underestimate the working life, as a sort of insurance against obsolescence. If this be over-done a secret reserve is created.

(L. R. D.)

DEPRETIS, AGOSTINO (1813–1887), Italian statesman, was born at Mezzana Corte, in the province of Stradella, on Jan. 31, 1813. He belonged to the *Giovane Italia*, and was nearly captured by the Austrians while smuggling arms into Milan. Elected deputy in 1848 he founded the journal *Il Diritto*. In 1860 he was sent on an abortive mission to Sicily to find a compromise between the Cavour and the Garibaldi policies. As a member of the Rattazzi cabinet of 1862 he arranged with Garibaldi the expedition which ended in disaster at Aspromonte. He was a member of the Ricasoli cabicet of 1866, and on the death of Rattazzi (1873) became the leader of the Left, and was premier in 1876–78, and for a brief period in 1879. Minister of the interior in the Cairoli cabinet of 1879, he was again prime minister from 1881 until his death on July 29, 1887. He reconstituted his cabinet four times alternately bestowing portfolios upon Ricotti, Robilant and other Conservatives, so as to complete the political process known as *trasformismo*. A few weeks before his death he repented of his transformist policy, and again included Crispi and Zanardelli in his cabinet. During his long term of office he abolished the grist tax, extended the suffrage, completed the railway system, aided Mancini in forming the Triple Alliance, and initiated colonial policy by the occupation of Massawa; but, at the same time, he vastly increased indirect taxation, corrupted and destroyed the fibre of the several parliamentary parties, and, by his uttter extravagance in public works, impaired the stability of Italian finance.

See Breganze, *Agostino Depretis e suoi tempi* (1894).

DEPTFORD, a south-eastern metropolitan borough of London, England, bounded by Bermondsey, the river Thames, Greenwich, Lewisham and Camberwell. The name is connected with a ford over the Ravensbourne, a stream entering the Thames through Deptford creek. The borough (pop. 1938, 95,460) comprises only the parish of Deptford St. Paul, that of Deptford St. Nicholas being included under Greenwich. All the northern part of Deptford adjoining the Thames is low-lying, but the southern, on a low gravel terrace, rises to 154 ft. in Telegraph hill. It is a district of poor streets inhabited by a large industrial population employed chiefly in railway, engineering and other riverside works. On the river front is the royal victualling yard which supplies the navy with provisions, medicines, furniture, etc., manufactured there or stored in the large warehouses. Henry VIII. established a royal naval dockyard at Deptford, and the shipbuilding industry flourished for a long time, persisting when wooden ships gave place to iron, and is still carried on. The old dockyard, however, ceased to be used in 1869, and was filled up and converted into a foreign cattle market by the City corporation. At the present time engineering and boiler-making are among the more important industries of Deptford.

Deptford shares in the great timber import of the adjoining district of Rotherhithe and the New Baltic and other timber wharves front the Surrey canal. In connection with this timber trade furniture, casks and packing cases are made. There are also works for tar, chemicals, asphalt, oil and whiting, a tea warehouse, cocoa and coffee works, bronze, brass and copper, galvanized iron and zinc works. Deptford creek, with coal and timber wharves, is 1,560 yd. long, and is crossed by a road bridge near the entrance. Of public buildings the chief are St. Paul's church, the Municipal buildings and the hospital for master mariners, maintained by the Corporation of the Trinity house. Other institutions are the Goldsmith's college, New Cross; and the South-eastern fever hospital. Sayes Court, demolished 1729, was the residence of the duke of Sussex in the reign of Elizabeth, was occupied in the next century by John Evelyn, and in 1698 by Peter the Great during his stay in Deptford. The site of its gardens is occupied by Deptford park, 11 ac. in extent, and Sayes Court gardens. Other open spaces are on Telegraph hill.

DEPTH, in military language, the space over which a body of troops is distributed from front to rear. In a tactical sense it is used to express the idea of, and need for, so distributing a force or unit as to have adequate reserves behind the fighting line to exploit initial success or to meet an emergency. In World War 1 the tendency was for the distribution of a force or unit to attain an ever-increasing depth in proportion to, and with a proportionate reduction of, its frontage.

DEPTH CHARGE: *see* MINES, MINELAYING AND MINESWEEPING.

DEPUTY, one appointed to act or govern instead of another; one who exercises an office in another man's right, a substitute; in representative government a member of an elected chamber. Various officials are empowered by statute to appoint deputies. Thus, a clerk of the peace, in case of illness, incapacity or absence, may appoint a fit person to act as his deputy. While judges of the supreme court cannot act by deputy, county court judges and recorders can, in cases of illness or unavoidable absence, appoint deputies. So can registrars of county courts and returning officers at elections. In many countries, *e.g.*, France and Spain, members of the lower house of parliament are called deputies.

DE QUINCEY, THOMAS[1] (1785–1859), English author, was born at Greenheys, Manchester, the fifth child in a family of eight (four sons and four daughters). His father left his wife and six children a clear income of £1,600 a year. Thomas was from infancy a shy, sensitive child, with a constitutional tendency to dreaming by night and by day; and, under the influence of an elder brother, a lad "whose genius for mischief amounted to inspirations," who died in his 16th year, he spent much of his boyhood in imaginary worlds of their own creating. The amusements and occupations of the whole family, indeed, seem to have been mainly intellectual; and in De Quincey's case, emphatically, "the child was father to the man." "My life has been," he affirms in the *Confessions*, "on the whole the life of a philosopher; from my birth I was made an intellectual creature, and intellectual in the highest sense my pursuits and pleasures have been." He received a rather desultory education, though at 15 he could speak Greek fluently. He ran away from his last school, Manchester Grammar school, and was sent into the country in Wales. Then he again ran away, this time to London, where, he says, commenced "that episode, or impassioned parenthesis of my life, which is comprehended in *The Confessions* of *an English Opium Eater.*" This London episode extended over a year or more; his money soon vanished, and he was in the utmost poverty; he obtained shelter for the night in Greek street, Soho, from a moneylender's agent, and spent his days wandering in the streets and parks; finally the lad was reconciled to his guardians, and in 1803 was sent to Worcester college, Oxford, being by this time about 19. It was in the course of his second year at Oxford that he first tasted opium—having taken it to allay neuralgic pains. De Quincey's mother had settled at Weston Lea, near Bath, and on one of his visits to Bath, De Quincey made the acquaintance of Coleridge; he took Mrs. Coleridge to Grasmere, where he became personally acquainted with Wordsworth.

After finishing his career of five years at college in 1808 he kept terms at the Middle Temple; but in 1809 visited the Wordsworths at Grasmere, and in the autumn returned to Dove cottage, which he had taken on a lease. His choice was of course influenced partly by neighbourhood to Wordsworth, whom he early appreciated, having been, he says, the only man in all Europe who quoted Wordsworth so early as 1802. His friendship with

[1]The following account has been abbreviated for this ed. Its original author, John Ritchie Findlay (1824–1898), proprietor of The *Scotsman* newspaper, and the donor of the Scottish National Portrait gallery in Edinburgh, had been intimate with De Quincey, and in 1886 published his *Personal Recollections* of him.

Wordsworth decreased within a few years, and when in 1834 De Quincey published in *Tait's Magazine* his reminiscences of the Grasmere circle, the indiscreet references to the Wordsworths contained in the article led to a complete cessation of intercourse. Here also he enjoyed the society and friendship of Coleridge, Southey, and especially of Prof. Wilson, as in London he had of Charles Lamb and his circle. He continued his classical and other studies, especially exploring the, at that time, almost unknown region of German literature, and indicating its riches to English readers. Here also, in 1816, he married Margaret Simpson, the "dear M———" of whom a charming glimpse is accorded to the reader of the Confessions; his family came to be five sons and three daughters.

For about a year and a half he edited the *Westmorland* Gazette. He left Grasmere for London in the early part of 1820. The Lambs received him with great kindness and introduced him to the proprietors of the London Magazine. It was in this journal in 1821 that the Confessions appeared. De Quincey also contributed to Blackwood, to Knight's Quarterly Magazine, and later to *Tait's* Magazine. His connection with Blackwood took him to Edinburgh in 1828, and he lived there for 12 years, contributing from time to time to the Edinburgh Literary Gazette. His wife died in 1837, and the family eventually settled at Lasswade, but from this time De Quincey spent his time in lodgings in various places, staying at one place until the accumulation of papers filled the rooms, when he left them in charge of the landlady and wandered elsewhere. After his wife's death he gave way for the fourth time in his life to the opium habit, but in 1844 he reduced his daily quantity by a tremendous effort to six grains, and never again yielded. He died in Edinburgh on Dec. 8, 1859, and is buried in the West Churchyard.

During nearly 50 years De Quincey lived mainly by his pen. His patrimony seems never to have been entirely exhausted, and his habits and tastes were simple and inexpensive; but he was reckless in the use of money, and had debts and pecuniary difficulties of all sorts. The famous Confessions of an English Opium Eater was published in a small volume in 1822, and attracted attention, not simply by its personal disclosures, but by the extraordinary power of its dream-painting. No other literary man of his time, it has been remarked, achieved so high and universal a reputation from such merely fugitive efforts. The only works published separately (not in periodicals) were a novel Klosterheim (1832), and The Logic of Political Economy (1844). After his works were brought together, De Quincey's reputation was not merely maintained, but extended. For range of thought and topic, within the limits of pure literature, no like amount of material of such equality of merit proceeded from any eminent writer of the day. However profuse and discursive, De Quincey is always polished, and generally exact—a scholar, a wit, a man of the world and a philosopher, as well as a genius. He looked upon letters as a noble and responsible calling; in his essay on Oliver Goldsmith he claims for literature the rank not only of a fine art, but of the highest and most potent of fine arts; and as such he himself regarded and practised it. He drew a broad distinction between "the literature of knowledge and the literature of power," asserting that the function of the first is to teach, the function of the second to move—maintaining that the meanest of authors who moves has pre-eminence over all who merely teach, that the literature of knowledge must perish by supersession, while the literature of power is "triumphant for ever as long as the language exists in which it speaks." It is to this class of motive literature that De Quincey's own works essentially belong; it is by virtue of that vital element of power that they have emerged from the rapid oblivion of periodicalism, and live in the minds of later generations. But their power is weakened by their volume.

De Quincey fully defined his own position and claim to distinction in the preface to his collected works. These he divides into three classes: "*first,* that class which proposes primarily to amuse the reader," such as the Narratives, Autobiographic Sketches, *etc.;* second, "papers which address themselves purely to the understanding as an insulated faculty, or do so primarily," such as the essays on Essenism, the Caesars, Cicero, etc.; and finally, as a third class, "and, in virtue of their aim, as a far higher class of compositions," he ranks those "modes of impassioned prose ranging under no precedents that I am aware of in any literature," such as the Confessions and *Suspiria* de Profundis. The high claim here asserted has been questioned; and short and isolated examples of eloquent apostrophe, and highly wrought imaginative description, have been cited from Rousseau and other masters of style; but De Quincey's power of sustaining a fascinating and elevated strain of "impassioned prose" is allowed to be entirely his own. Another obvious quality of all his genius is its overflowing fullness of allusion and illustration, recalling his own description of a great philosopher or scholar—"Not one who depends simply on an infinite memory, but also on an infinite and electrical power of combination, bringing together from the four winds, like the angel of the resurrection, what else were dust from dead men's bones into the unity of breathing life."

In politics, in the party sense of that term, he would probably have been classed as a Liberal Conservative or Conservative Liberal—at one period of his life perhaps the former, and at a later the latter. As he advanced in years his views became more and more decidedly liberal, but he was always as far removed from Radicalism as from Toryism, and may be described as a philosophical politician, capable of classification under no definite party name or colour. Of political economy he had been an early and earnest student, and projected, if he did not so far proceed with, an elaborate and systematic treatise on the science, of which all that appears, however, are his fragmentary *Dialogues* on the system of Ricardo, published in the London Magazine in 1824, and *The* Logic of Political Economy (1844). How wide and varied was the region he traversed a glance at the titles of the papers which make up his collected (or more properly, selected) works (for there was much matter of evanescent interest not reprinted), sufficiently shows. Some things in his own line he has done perfectly; he has written many pages of magnificently mixed arguments, irony, humour and eloquence, which, for sustained brilliancy, richness, subtle force and purity of style and effect, have simply no parallels; and he is without peer the prince of dreamers. The use of opium no doubt stimulated this remarkable faculty of reproducing in skilfully selected phrase the grotesque and shifting forms of that "cloudland, gorgeous land," which opens to the sleep-closed eye.

It has been complained that, in spite of the apparently full confidences of the Confessions and Autobiographic Sketches, readers are left in comparative ignorance, biographically speaking, of the man De Quincey. Two passages in his Confessions afford sufficient clues to this mystery. In one he describes himself "as framed for love and all gentle affections," and in another confesses to the "besetting infirmity" of being "too much of an eudaemonist." "I hanker," he says, "too much after a state of happiness, both for myself and others; I cannot face misery, whether my own or not, with an eye of sufficient firmness, and am little capable of surmounting present pain for the sake of any recessionary benefit." His sensitive disposition dictated the ignoring in his writings of traits merely personal to himself, as well as his ever-recurrent resort to opium as a doorway of escape from present ill; and prompted those habits of seclusion, and that apparently capricious abstraction of himself from the society not only of his friends, but of his own family, in which he from time to time persisted. He confessed to occasional accesses of an almost irresistible impulse to flee to the labyrinthine shelter of some great city like London or Paris—there to dwell solitary amid a multitude, buried by day in the cloister-like recesses of mighty libraries, and stealing away by night to some obscure lodging. Long indulgence in seclusion, and in habits of study the most lawless possible in respect of regular hours or any considerations of health or comfort—the habit of working as pleased himself without regard to the divisions of night or day, of times of sleeping or waking, even of the slow procession of the seasons—had latterly so disinclined him to the restraints, however slight, of ordinary social intercourse, that he very seldom submitted to them. On such rare occasions, however, as he did appear, per-

haps at some simple meal with a favoured friend, or in later years in his own small but refined domestic circle, he was the most charming of guests, hosts or companions. A short and fragile, but well-proportioned frame; a shapely and compact head; a face beaming with intellectual light, with rare, almost feminine beauty of feature and complexion; a fascinating courtesy of manner; and a fullness, swiftness and elegance of silvery speech — such was the, irresistible "mortal mixture of earth's mould" that men named De Quincey. It was impossible to deal with or judge him by ordinary standards — not even his publishers did so. Much no doubt was forgiven him, but all that needed forgiveness is covered by the kindly veil of time, while his merits as a master in English literature are still gratefully acknowledged. (J. R. F.)

BIBLIOGRAPHY.—In 1853 De Quincey began to prepare an ed. of his works *Selections Grave and Gay. Writings Published and Unpublished* (1853–60), followed by a second ed. (1863–71) with notes by James Hogg and two additional vols.; a further supplementary vol. appeared in 1878. The first comprehensive ed., however, was printed in America (1850–55); and the "Riverside" ed. (1877) is still fuller. The standard English ed. is *The Collected Writings of Thomas De Quincey* (Edinburgh, 1889–90), edited by David Masson, who also wrote his biography (1881) for the "English Men of Letters" series. *The Uncollected Writings of Thomas De Quincey* (1890) contains a preface and annptations by James Hogg; *The Posthumous Writings of Thomas De Quincey* (1891–93) were edited by A. H. Japp ("H. A. Page"), who wrote the standard biography, *Thomas De Quincey: his Life and Writings* (2nd ed., 1870), and *De Quincey Memorials* (1891). *See* also Arvède Barine *Nevroses* (1898); Sir L. Stephen *Hours in a Library*; H. S. Salt *De Quincey* (1964); and *De Quincey and his Friends* (1895), a collection edited by James Hogg, which includes essays by Dr. Hill Burton and Shadworth Hodgson. *See* also editions of the *Confessions* (1927) by G. Saintsbury, and of the *Diary* (1927) by H. A. Eaton.

DERA GHAZI KHAN, a town and district of British India, in the Punjab. The original town was founded at the close of the 15th century and named after Ghazi Khan, son of Haji Khan, a Baluch chieftain, who after holding the country for the Langah sultans of Multan had made himself independent. The greater part of this town was washed away by the Indus in 1908–09 and the new town, built near by, is now the headquarters of the District.

The district, which consists of an area of 5,325 sq.m., is a long narrow strip of country, 198 m. in length, sloping gradually from its western boundary hills to the river Indus on the east. Although liable to great extremes of temperature, and to a very scanty rainfall, the district is not unhealthy. The population in 1931 was 491,044, the great majority being Baluch Mohammedans. The principal exports are wheat and indigo. The only manufactures are for domestic use. There is no railway in the district. In the hills beyond the limit of the district is an area occupied by Biloch tribes which is administered by the deputy commissioner of Dera Ghazi Khan. The frontier tribes here include the Kasranis, Bozdars, Khosas, Lagharis, Khetrans, Gurchanis, Mazaris, Marris and Bugtis. The chief of these are described under their separate names.

DERAIL, a device used mainly on the sidings of railways to prevent a car that has been moved by wind, gravity or by the error of trainmen from running foul of the main track. It is also frequently used to protect men at work under a car. The derail is variously designed, but generally acts by providing a surface on which the flange of one wheel mounts and crosses over the head of the rail, dragging the wheel at the other end of the axle off its rail. Each pair of wheels follows in turn and, being forced over the irregularities of the road-bed, soon bring the car to a full stop. Some derails are portable, but most are fixed definitely in place and are operated by hand, in unison with a switch or mechanically from a central point. The illustration shows a manual derail with signal target, in operating position.

DERAIN, ANDRE (1880–), French painter, was born at Chatou (France), on June 10, 1880. For a considerable time he shared a studio with the landscape painter Vlaminck; he then made the acquaintance of Picasso, Georges Braque and the poet Guillaume Apollinaire. It was from this small group that Cubism developed. Yet Derain cannot be considered as a representative of the Cubist school; his best works adhere to the great traditions of the classic landscapes, and are formal in character and restrained in colour, while his figures exhibit a grandeur and serenity, which reveal an admirer of the great masters.

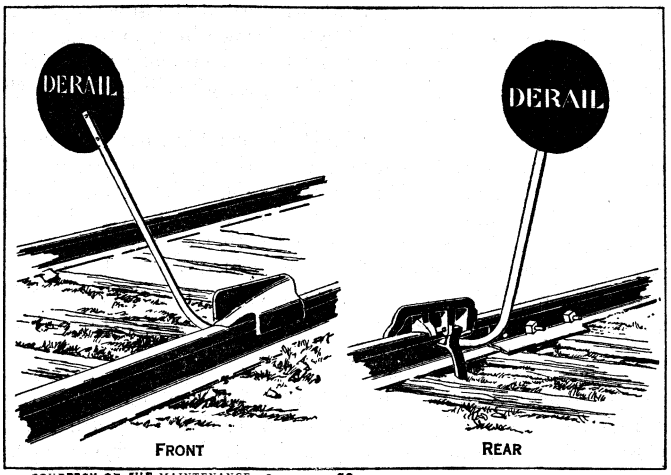
DERA ISMAIL KHAN, a town, cantonment and district in the Derajat division of the North-West Frontier Province of India. The town is situated near the right bank of the Indus, here crossed by a bridge of boats during half the year. Pop. (1921) 39,341. It takes its name from Ismail Khan, a Baluch chief who settled here towards the end of the 15th century, and whose descendants ruled for 300 years. The old town was swept away by a flood in 1823. The main channel of the Indus which often changes, was in 1927 2 m. from the town. The town contains a large bazaar for Afghan traders and is the residence of many Mohammedan gentry. Since the occupation of Waziristan the garrison has been reduced to half a brigade. There is considerable through trade with Afghanistan by the Gomal pass.

The district—area 3,403 sq.m., pop. (1921) 260,767—was formerly divided by the Indus, which intersected it from north to south. To the west of the Indus the country resembles Dera Ghazi Khan. To the east of the present bed of the river a wide tract, the Kachi, is exposed to river action. Beyond this, the country rises abruptly, and a barren, almost desert plain stretches eastwards, sparsely cultivated, and inhabited only by nomadic tribes In 1901 the trans-Indus tract was allotted to the newly formed North-West Frontier Province, the cis-Indus tract remaining in the Punjab jurisdiction. The former cis-Indus portions of the Dera Ismail Khan and Bannu districts is now the Punjab district of Mianwali.

The district is the junction of Pathan and Baluch tribes, the Pathan element predominating. The chief frontier tribes are the Sheranis and Ustaranas and Bhittanis.

DERAIYEH or **DERAYAH.** A city of Arabia formerly the capital of the Wahhabis and of considerable importance prior to 1819 when it was captured by Ibrahim Pasha. It now consists of five walled villages amongst the ruins, with a population of about 1,500 inhabitants, the Wahhabi capital is now Riad.

DERBENT or **DERBEND,** a town in the A.S.S.R. of Daghestan, on the western shore of the Caspian, 42° 4′ N., 48° 15′ E. Pop. (1926) 23,111. It occupies a narrow strip of land beside the sea, from which it climbs up the steep heights inland. The environs are occupied by vineyards, gardens and orchards, in which madder, saffron and tobacco, as well as figs, peaches, pears and other fruits, are cultivated. Earthenware, weapons and silk and



BY COURTESY OF THE MAINTENANCE EQUIPMENT CO

FRONT AND REAR VIEWS OF THE "BLUE FLAG" PORTABLE DERAIL

cotton fabrics are the principal products of the manufacturing industry. Recently a wool spinning factory has been built; and steamers call at the port, which has a lighthouse and cold storage accommodation for the fruit and fish industry. To the north of the town is the monument of the *Kirk-lar*, or "forty heroes," who fell defending Daghestan against the Arabs in 728; and to the south lies the seaward extremity of the Caucasian wall (50 m. long), otherwise known as Alexander's wall, blocking the narrow

pass of the Iron Gate or Caspian Gates (Portae Albanae or Portae *Caspiae*). This, when entire, had a height of 29 ft. and a thickness of about 10 ft., and with its iron gates and numerous watch-towers formed a valuable defence of the Persian frontier. Derbent is usually identified with Albana, the capital of the ancient Albania. The modern name, a Persian word meaning "iron gates," came into use when the city was refounded by Kavadh of the Sassanian dynasty of Persia. The walls and the citadel are believed to belong to the time of Kavadh's son, Khosrau (Chosroes) Anosharvan. In 728 the Arabs entered into possession, and established a principality in the city, which they called Bab-el-Abwab ("the principal gate"), Bab-el-Khadid ("the iron gate"), and Seraill-el-Dagab ("the golden throne"). The celebrated caliph, Harun-al-Rashid, lived in Derbent at different times, and brought it into great repute as a seat of the arts and commerce. In 1220 it was captured by the Mongols, and in the course of the succeeding centuries it frequently changed masters. In 1722 Peter the Great of Russia wrested the town from the Persians, but in 1736 the supremacy of Nadir Shah was again recognized. In 1796 Derbent was besieged by the Russians, and in 1813 incorporated in the Russian empire. During the Civil War 1917 to 1921, the greater part of the town was destroyed.

DERBY, EARLS OF. The 1st earl of Derby was probably Robert de Ferrers (d. 1139), who is said by John of Hexham to have been made an earl by King Stephen after the battle of the Standard in 1138. Robert and his descendants retained the earldom until 1266, when Robert (c. 1240–*c.* 1279), probably the 6th earl, having taken a prominent part in the baronial rising against Henry III., was deprived of his lands and practically of his title. These earlier earls of Derby were also known as Earls Ferrers, or de Ferrers, from their surname; as earls of Tutbury from their residence; and as earls of Nottingham because this county was a lordship under their rule. The large estates which were taken from Earl Robert in 1266 were given by Henry III. in the same year to his son, Edmund, earl of Lancaster; and Edmund's son, Thomas, earl of Lancaster, called himself Earl Ferrers. In 1337 Edmund's grandson, Henry (c. 1299–1361), afterwards duke of Lancaster, was created earl of Derby, and this title was taken by Edward III.'s son, John of Gaunt, who had married Henry's daughter, Blanche. John of Gaunt's son and successor was Henry, earl of Derby, who became king as Henry IV. in 1399.

In October 1485 Thomas, Lord Stanley, was created earl of Derby, and the title has since been retained by the Stanleys. It is derived, not from Derbyshire, but from the hundred of West Derby in Lancashire. Thomas also inherited the sovereign lordship of the Isle of Man, granted by the crown in 1406 to his great-grandfather, Sir John Stanley; and this sovereignty remained in possession of the earls of Derby till 1736, when it passed to the duke of Atholl.

The earl of Derby is one of the three "catskin earls," the others being the earls of Shrewsbury and Huntingdon. The term "catskin" is possibly a corruption of quatre-skin, derived from the fact that in ancient times the robes of an earl (as depicted in some early representations) were decorated with four rows of ermine, as in the robes of a modern duke, instead of the three rows to which they were restricted in later centuries. The three "catskin" earldoms are the only earldoms now in existence which date from creations prior to the 17th century.

THOMAS STANLEY, 1st earl of Derby (c. 1435–1504), was the son of Thomas Stanley, who was created Baron Stanley in 1456 and died in 1459. His grandfather, Sir John Stanley (d. 1414), had founded the fortunes of his family by marrying Isabel Lathom, the heiress of a great estate in the hundred of West Derby in Lancashire; he was lieutenant of Ireland in 1389–1391, and again in 1399–1401, and in 1405 received a grant of the lordship of Man from Henry IV. The future earl of Derby was a squire to Henry VI. in 1454, but not long afterwards married Eleanor, daughter of the Yorkist leader, Richard Neville, earl of Salisbury. At the battle of Blore Heath in Aug. 1459 Stanley, though close at hand with a large force, did not join the royal army, whilst his brother William fought openly for York. In 1461 Stanley was made chief justice of Cheshire by Edward IV., but ten years later he sided with his brother-in-law Warwick in the Lancastrian restoration. Nevertheless, after Warwick's fall, Edward made Stanley steward of his household. Stanley served with the king in the French expedition of 1475, and with Richard of Gloucester in Scotland in 1482. About the latter date he married, as his second wife, Margaret Beaufort, mother of the exiled Henry Tudor. Stanley was one of the executors of Edward IV., and was at first loyal to the young king Edward V. But he acquiesced in Richard's usurpation, and retaining his office as steward avoided any entanglement through his wife's share in Buckingham's rebellion. He was made constable of England in succession to Buckingham, and was granted possession of his wife's estates with a charge to keep her in some secret place at home. Richard could not well afford to quarrel with so powerful a noble, but early in 1485 Stanley asked leave to retire to his estates in Lancashire. After Henry of Richmond had landed, Stanley made excuses for not joining the king. On the morning of Bosworth (Aug. 22), Richard summoned Stanley to join him, and when he received an evasive reply ordered his son, George, Lord Strange, whom Stanley had given as a hostage, to be executed. In the battle it was William Stanley, his brother, who turned the scale in Henry's favour, but Thomas, who had taken no part in the fighting, was the first to salute the new king. Henry VII. confirmed Stanley in all his offices, and on Oct. 27, created him earl of Derby. As husband of the king's mother Derby held a great position, which was not affected by the treason of his brother William in Feb. 1495. In the following July the earl entertained the king and queen with much state at Knowsley. Derby died on July 29, 1504. Strange had escaped execution in 1485, but he died before his father in 1497, and his son Thomas succeeded as second earl. An old poem called The Song of the Lady *Bessy,* which was written by a retainer of the Stanleys, gives a romantic story of how Derby was enlisted by Elizabeth of York in the cause of his wife's son.

For fuller narratives *see* J. Gairdner's *Richard III.* and J. H. Ramsay's *Lancaster and York;* also Seacome's *Memoirs of the House of Stanley* (1741).

EDWARD STANLEY, 3rd earl of Derby (1508–1572), was a son of Thomas Stanley, 2nd earl and grandson of the 1st earl, and succeeded to the earldom on his father's death in May 1521. During his minority Cardinal Wolsey was his guardian, and as soon as he came of age he began to take part in public life. He helped to quell the rising known as the Pilgrimage of Grace in 1536; but remaining true to the Roman Catholic faith he disliked and opposed the religious changes made under Edward VI. Under Elizabeth his younger sons, Sir Thomas (d. 1576) and Sir Edward Stanley (d. 1609), were concerned in a plot to free Mary, queen of Scots, and he himself was suspected of disloyalty. He died at Lathom House, near Ormskirk, on Oct. 24, 1572

Derby's first wife was Katherine, daughter of Thomas Howard, duke of Norfolk, by whom he had, with other issue, a son Henry, the 4th earl (c. 1531–1593), who was a member of the council of the North, and like his father was lord-lieutenant of Lancashire. Henry was one of the commissioners who tried Mary, queen of Scots, and was employed by Elizabeth on other high undertakings both at home and abroad. He died on Sept. 25, 1593. His wife Margaret (d. 1596), daughter of Henry Clifford, 2nd earl of Cumberland, was descended through the Brandons from King Henry VII. Two of his sons, Ferdinando (c. 1559–1594), and William (c. 1561–1642), became in turn the 5th and 6th earls of Derby. Ferdinando, the 5th earl (d. 1594), wrote verses, and is eulogized by Spenser under the name of Amyntas.

JAMES STANLEY, 7th earl of Derby (1607–1651), sometimes styled the Great Earl of Derby, eldest son of William, 6th earl, and Elizabeth de Vere, daughter of Edward, 17th earl of Oxford, was born at Knowsley on Jan. 31, 1607. During his father's life he was known as Lord Strange. He was elected M.P. for Liverpool in 1625, received high officesin the North of England, and on March 7, 1628, entered the House of Lords as Baron Strange. When the Civil War broke out in 1642, Lord Strange devoted himself to the king's cause. His plan of securing Lancashire at the beginning and raising troops there, which promised success, was however dis-

couraged by Charles, who was said to be jealous of his power and royal lineage and who commanded his presence at Nottingham. His subsequent attempts to recover the county were unsuccessful. After several defeats he left for the Isle of Man in June 1643 to attend to affairs there, and in the summer of 1644 he took part in Prince Rupert's successful campaign in the north, when Lathom House, where Lady Derby had heroically resisted the attacks of the besiegers, was relieved, and Bolton Castle taken. He followed Rupert to Marston Moor, and after the complete defeat of Charles's cause in the north withdrew to the Isle of Man, where he held out for the king and offered an asylum to royalist fugitives. His administration of the island imitated that of Strafford in Ireland. It was strong rather than just. In July 1649 he refused scornfully terms offered to him by Ireton. By the death of his father on Sept. 29, 1642 he had succeeded to the earldom, and on Jan. 12, 1650, he obtained the Garter. On Aug. 1j, 1651, he landed at Wyre Water in Lancashire in support of Charles's invasion, and met him on the 17th. Proceeding to Warrington he failed to obtain the support of the Presbyterians through his refusal to take the Covenant, and on the 25th was totally defeated at Wigan, being severely wounded and escaping with difficulty. He joined Charles at Worcester; after the battle he accompanied him to Boscobel, and while on his way north alone was captured near Nantwich and given quarter. He was tried by court-martial at Chester on Sept. 29, his quarter was disallowed and he was condemned to death. When his appeal for pardon to parliament was rejected, though supported by Cromwell, he endeavoured to escape; but was recaptured and executed at Bolton on Oct. 15, 1651. He was buried in Ormskirk church. According to Clarendon Derby was "a man of great honour and clear courage," and his defects the result of too little knowledge of the world. Lord Derby left in ms. "A Discourse concerning the Government of the Isle of Man" (printed in the *Stanley Papers* and in F. Peck's *Desiderata Curiosa,* vol. ii.) and several volumes of historical collections, observations, devotions *(Stanley Papers)* and a commonplace book. He married on the 26th of June 1626 Charlotte de la Trémoille (1599–1664), daughter of Claude, duc de Thouars, and granddaughter of William the Silent, prince of Orange, by whom besides four daughters he had five sons, of whom the eldest, Charles (1628–1672), succeeded him as 8th earl.

Charles's two sons, William, the 9th earl (c. 1655–1702), and James, the 10th earl (1664–1736), both died without sons, and consequently, when James died in February 1736, his titles and estates passed to Sir Edward Stanley (1689–1776), a descendant of the 1st earl. From him the later earls were descended, the 12th earl (d. 1834) being his grandson.

The 14th earl is noticed separately *(see* below).

EDWARD HENRY STANLEY, 15th earl of Derby (1826–1893), eldest son of the 14th earl, was educated at Rugby and Trinity college, Cambridge, where he took a high degree and became a member of the society known as the Apostles. In March 1848 he unsuccessfully contested the borough of Lancaster and then made a long tour in the West Indies, Canada and the United States. During his absence he was elected member for Ring's Lynn, which he represented till October 1869, when he succeeded to the peerage. He delivered his maiden speech in May 1850 on the sugar duties. Just before, he had made a very brief tour in Jamaica and South America. In 1852 he went to India, and while traveling in that country he was appointed under-secretary for foreign affairs in his father's first administration. From the outset of his career he was known to be a most Liberal Conservative, and in 1855 Lord Palmerston offered him the post of colonial secretary. He was much tempted by the proposal, and hurried down to Knowsley to consult his father, who called out when he entered the room, "Hallo, Stanley! what brings you here?—Has Dizzy cut his throat, or are you going to be married?" The offer was declined. In his father's second administration Lord Stanley held, at first, the office of secretary for the colonies, but became president of the Board of Control on the resignation of Lord Ellenborough. He had the charge of the India Bill of 1858 in the House of Commons, became the first secretary of state for India, and left behind him in the India Office an excellent reputation. When the Greeks were looking round for a king after the death of King Otho, and the crown was refused by Queen Victoria for her son Alfred, there was some idea of inviting Stanley to take the vacant throne, but the offer was never formally made. After the fall of the Russell government in 1866 he became foreign secretary in his father's third administration. He compared his conduct in that great post to that of a man floating down a river and fending off from his vessel, as well as he could, the various obstacles it encountered. He thought that that should be the normal attitude of an English foreign minister, and probably under the circumstances of the years 1866–1868 it was the right one. He arranged the collective guarantee of the neutrality of Luxemburg in 1867, negotiated a convention about the "Alabama," which, however, was not ratified, and refused to take any part in the Cretan troubles. In 1874 he again became foreign secretary in Disraeli's government. He acquiesced in the purchase of the Suez canal shares; he accepted the Andrássy Note, but declined to accede to the Berlin Memorandum. His part in the later phases of the Russo-Turkish struggle has never been fully explained, for he declined to gratify public curiosity at the cost of some of his colleagues. He resigned, and was prepared to explain in the House of Lords the course he had taken if those whom he had left challenged him to do so, but from that course they consistently refrained. By Oct. 1879 it was clear enough that he had thrown in his lot with the Liberal party, but it was not till March 1880 that he publicly announced this change of allegiance. He did not at first take office in the second Gladstone government, but became secretary for the colonies in Dec. 1882, holding this position till the fall of that government in the summer of 1885. In 1886 Derby joined the Liberal Unionists, and took an active part in the general management of that party, leading it in the House of Lords till 1891, when Lord Hartington became duke of Devonshire. In 1892 he presided over the labour commission. He died at Knowsley on April 21, 1893.

During a great part of Derby's life he was deflected from his natural course by the accident of his position as the son of the leading Conservative statesman of the day. From first to last he was at heart a moderate Liberal. In one of the highest qualities of a statesman, "aptness to be right," he was surpassed by none of his contemporaries, or—if by anybody—by Sir George Cornewall Lewis alone. His chief defect as a statesman was that in his anxiety to arrive at the right conclusions he sometimes turned and turned and turned a subject over till the time for action had passed. Although he cared but little for what is commonly known as society—the society of crowded rooms and fragments of sentences—he very much liked conversation. During the many years in which he was a member of "The Club" he was one of its most assiduous frequenters, and his loss was acknowledged by a formal resolution. His talk was generally grave, but every now and then was lit up by dry humour. The late Lord Arthur Russell once said to him, after he had been buying some property in southern England: "So you still believe in land, Lord Derby." "Hang it," he replied, "a fellow must believe in something!" He did much work outside politics. He was lord rector of the University of Glasgow from 1868 to 1871, and later held the same office in that of Edinburgh. From 1875 to 1893 he was president of the Royal Literary Fund, and attended most closely to his duties there. He succeeded Lord Granville as chancellor of the University of London in 1891, and remained in that position till his death. He lived much in Lancashire, managed his enormous estates with great skill, and did a great amount of work as a local magnate. He married in 1870 Maria Catharine, daughter of the 5th earl de la Warr, and widow of the and marquess of Salisbury.

The best account of the 15th Lord Derby is that which was prefixed by W. E. H. Lecky, who knew him very intimately, to the edition of his speeches outside parliament, published in 1894.

The earl left no children and he was succeeded as 16th earl by his brother FREDERICK ARTHUR STANLEY (1841–1908), who had been made a peer as Baron Stanley of Preston in 1886. He was secretary of state for war and for the colonies and president of the board of trade; and was governor-general of Canada from 1888 to 1893. He died on June 14, 1908.

EDWARD GEORGE VILLIERS STANLEY, 17th earl of Derby (1865–), was educated at Wellington college, and served in the Grenadier Guards from 1885 to 1895. During the South African War he acted first as press-censor, then as A.D.C. to Lord Roberts. He sat in the House of Commons for West-Houghton, was a Lord of the treasury (1895–1900), financial secretary to the War Office (1900–03) and postmaster general (1903–05). He was the recipient of many honours, including the Garter (1914). In Oct. 1915 he became director of recruiting for the army, and as such was responsible for a new scheme for a final effort on behalf of voluntary service known as the Derby scheme. In Feb. 1916 Lord Derby became chairman of the naval and military air service joint committee, but resigned in April, becoming under-secretary for war in July. On the formation of D. Lloyd George's Government in Dec. 1916 he became secretary for war, and in April 1918 was appointed British ambassador to France. He retired from the latter office in Nov. 1920. In Oct. 1922 he became secretary for war in Bonar Law's cabinet, retaining this position under Baldwin until Jan. 1924.

DERBY, EDWARD GEOFFREY SMITH STANLEY, 14th earl of Derby (1799–1869), the "Rupert of debate," born at Knowsley in Lancashire on March 29, 1799, grandson of the 12th earl and eldest son of Lord Stanley, subsequently (1834) 13th earl of Derby (1775–1851). He was educated at Eton and at Christ Church, Oxford, and in 1819 he obtained the chancellor's prize for Latin verse, the subject being "Syracuse." As a boy he practised elocution under the instruction of Lady Derby, his grandfather's second wife, the actress, Elizabeth Farren. In 1820 he was returned for Stockbridge in Hampshire, one of the nomination boroughs whose electoral rights were swept away by the Reform Bill of 1832, Stanley being a warm advocate of their destruction.

His maiden speech was delivered early in the session of 1824 in the debate on a private bill for lighting Manchester with gas. On May 6, 1824 he delivered a vehement and eloquent speech against Joseph Hume's motion for a reduction of the Irish Church establishment, maintaining in its most conservative form the doctrine that church property is as sacred as private property. From this time he was acknowledged to be one of the most powerful speakers in the House. In the autumn of 1824 Stanley went on an extended tour through Canada and the United States with Henry Labouchere, afterwards Lord Taunton, and Evelyn Denison, afterwards Lord Ossington. In 1825 he married the second daughter of Edward Bootle-Wilbraham, created Baron Skelmersdale in 1828, by whom he had a family of two sons and one daughter who survived.

At the general election of 1826 Stanley was returned for borough of Preston, where the Derby influence was paramount. The change of seats left him free to speak against the system of rotten boroughs with great force during the Reform Bill debates, without laying himself open to the charge of personal inconsistency as the representative of a place where, according to Gay, cobblers used to "feast three years upon one vote." In 1827 Derby and other Whigs made a coalition with Canning on the defection of the more unyielding Tories, and he became under-secretary for the colonies. The coalition was broken up by Canning's death in August. During the administration of the duke of Wellington (1828–1830), Stanley and those with whom he acted were in opposition. His robust and assertive Liberalism about this period seemed curious afterwards to a younger generation who knew him only as the very embodiment of Conservatism.

On the advent of Lord Grey to power in Nov. 1830, Stanley was appointed to the chief secretaryship of Ireland. On accepting office he had to vacate his seat for Preston and seek re-election: and he had the mortification of being defeated by the Radical, "Orator" Hunt. The contest was a peculiarly keen one, and turned upon the question of the ballot, which Stanley refused to support. He re-entered the House as one of the members for Windsor, Sir Hussey Vivian having resigned in his favour. In 1832 he again changed his seat, being returned for North Lancashire.

Stanley was one of the most ardent supporters of the Reform Bill. Reference may be made especially to his eloquent speech on March 4, 1831 on the adjourned debate on the second reading of the bill. Apart from his connection with the general policy of the government, Stanley had a difficult task in his own office. Ireland was in a very unsettled state. The concession of Catholic emancipation had excited the people to make all sorts of demands, reasonable and unreasonable. "Scorpion Stanley," as O'Connell called him, discharged with determination the ungrateful task of carrying a coercion bill through the House. It was generally felt that O'Connell, powerful though he was, had fairly met his match in Stanley, who, with invective scarcely inferior to his own, evaded no challenge, ignored no argument, and left no taunt unanswered. The title "Rupert of debate" is peculiarly applicable to him in connection with the fearless if also often reckless method of attack he showed in his parliamentary war with O'Connell. It was first applied to him, however, 13 years later by Sir Edward Bulwer Lytton in *The New Timon:*—

> One after one the lords of time advance;
> Here Stanley meets—here Stanley scorns the glance!
> The brilliant chief, irregularly great,
> Frank, haughty, rash,—the Rupert of debate.

The best answer, however, to the attacks of the great agitator was the beneficial legislation which Derby secured for Ireland. He introduced and carried the first national education act for Ireland, one result of which was the remarkable and to many almost incredible phenomenon of a board composed of Catholics, Episcopalians and Presbyterians harmoniously administering an efficient education scheme. In 1833, just before the introduction of the Irish Church Temporalities Bill, Stanley had been appointed secretary for the colonies, with a seat in the cabinet. In this capacity he introduced the bill for freeing the slaves in the West Indies, on May 14, 1833, in one of his most eloquent speeches.

The Irish Church question determined more than one turning-point in his political career. In 1834 the proposal of the government to appropriate the surplus revenues of the church to educational purposes led to his secession from the cabinet, and, as it proved, his complete and final separation from the Liberals. Sir James Graham, the earl of Ripon and the duke of Richmond, also left the cabinet on the same issue. O'Connell, speaking in the House, described the secession in a couplet from Canning's *Loves of the Triangles:*—

> Still down thy steep, romantic Ashbourne, glides
> The Derby dilly carrying six insides.

Stanley spoke against the bill and against its authors with a bitterness that he himself is understood to have afterwards admitted to have been unseemly towards those who had so recently been his celleagues. The course followed by the government was "marked with all that timidity, that want of dexterity, which led to the failure of the unpractised shoplifter." His late colleagues were compared to "thimble-riggers at a country fair," and their plan was "petty larceny, for it had not the redeeming qualities of bold and open robbery."

In the end of 1834, Lord Stanley, as he was now styled by courtesy, his father having succeeded to the earldom in October, was invited by Peel to join the short-lived Conservative ministry which he formed after the resignation of Melbourne. Though he declined the offer for reasons stated in a letter published in the Peel memoirs, he acted from that date with the Conservative party, and on its next accession to power, in 1841, he accepted the office of colonial secretary, which he had held under Lord Grey. His position and his temperament alike, however, made him a thoroughly independent supporter of any party to which he attached himself. When, therefore, consideration of health

arising from the late hours in the Commons led him in 1844 to seek elevation to the Upper House in the right of his father's barony, Peel was rid of a too candid friend in the Commons and was assured of strong debating power in the Lords. But when Peel accepted the policy of free trade in 1846, the breach between him and Stanley was, as might have been anticipated, instant and irreparable. Stanley at once became the recognized leader of the Protectionist party, having Lord George Bentinck and Disraeli for his lieutenants in the Commons. They did all that could be done when the logic of events was against them, though Protection was never to become more than their watchword.

Lord Derby, who had succeeded to the earldom on the death of his father in June 1851, was called upon to form his first administration in Feb. 1852. He was in a minority, but the circumstances were such that no other than a minority government was possible, and he resolved to dissolve parliament and appeal to the country at the earliest opportunity. The election did not materially alter the position of parties. Parliament met in November, and in December the ministry had resigned in consequence of their defeat on Disraeli's budget. For the next six years, during Lord Aberdeen's "ministry of all the talents" and Lord Palmerston's premiership, Lord Derby led the opposition, whose policy gradually became more generally Conservative and less distinctively Protectionist as the hopelessness of reversing the measures adopted in 1846 made itself apparent. In 1855 he was asked to form an administration after the resignation of Lord Aberdeen, but failing to obtain sufficient support he declined the task. After the defeat of Lord Palmerston on the Conspiracy Bill in Feb. 1858, he formed his second ministry. Though he still could not count upon a working majority, defeat was avoided for a whole session, owing chiefly to the dexterous management of the Commons by Disraeli. During the session of 1858 the government carried two important measures, one a bill to remove Jewish disabilities, and the other a bill to transfer the government of India from the East India Company to the crown. Next year the question of parliamentary reform had to be faced, and the government introduced a bill at the opening of the session, which was rejected by the House, and, on a dissolution, rejected also by the country. After a vote of no confidence (June 10) in the new parliament Derby at once resigned.

He now devoted much of the leisure the position afforded him to congenial classical studies. It was his reputation for scholarship as well as his social position that had led in 1852 to his appointment to the chancellorship of the university of Oxford, in succession to the duke of Wellington. His Translations of Poems *Ancient* and Modern (1862) was privately printed. Its reception by those to whom it was circulated encouraged him to proceed with his magnum opus, the translation of the whole of the Iliad, which appeared in 1864.

During the seven years that elapsed between Lord Derby's second and third administrations the terrible industrial crisis in Lancashire caused by the stoppage of the cotton supply in consequence of the American Civil War, absorbed much of his time and thought. Derby worked unceasingly for its relief. His personal subscription, munificent though it was, represented the least part of his service. His noble speech at the meeting in Manchester in Dec. 1862, where the movement was initiated, and his advice at the subsequent meetings of the committee, were of the very highest value in stimulating and directing public sympathy. His relations with Lancashire had always been cordial; after the cotton famine period the cordiality passed into a warmer and deeper feeling among the factory operatives.

On the rejection of Russell's Reform Bill in 1866, Derby formed his third cabinet. It was destined to be short-lived, but lasted long enough to settle on a permanent basis the question that had proved fatal to its predecessor. The passing of the Reform Bill was the main business of the session 1867. The chief debates were, of course, in the Commons, and Derby's failing powers prevented him from taking any large share in those which took place in the Lords. His description of the measure as a "leap in the dark" was eagerly caught up, because it exactly represented the common opinion at the time,—the most experienced statesmen, while they admitted the granting of household suffrage to be a political necessity, being utterly unable to foresee its effect on the constitution and government of the country.

Declining health compelled Derby to resign office in Feb. 1868. He yielded the entire leadership of the party as well as the premiership to Disraeli. His subsequent appearances in public were few and unimportant. His last speech in the House of Lords, denunciation of Gladstone's Irish Church Bill, was marked by much of his early fire and vehemence. A few months later, on Oct. 23, 1869, he died at Knowsley.

Lord Aberdeen was reported by The Times to have said that no one of the giants he had listened to in his youth, Pitt, Fox, Burke or Sheridan, "as a speaker, is to be compared with our own Lord Derby, when Lord Derby is at his best." (G. Saintsbury, Lord Derby, 1906.)

DERBY (dar'bi), a county and parliamentary borough and the county town of Derbyshire, England, 60 mi. S.E. of Manchester on the L.M.S.R. and L.N.E.R. Pop. (1938) 139,000. Area 12.7 sq.mi. Occupying a position almost in the centre of England, the town is situated on the Derwent, at the southern end of the Pennines. It is the centre of an important network of routes since early times and more especially since the Industrial revolution. A little to the N.E. is Littlechester which was the site of a Roman fort or village. Under the heptarchy Derby was known as Northworthig, receiving its present name from Deoraby as it was known to the Danes after the Treaty of Wedmore. It was reconquered by Aethelflaed in 917, and prospered during the 10th century, but much of the land was waste at the time of Domesday. The first charter was granted in 1206 giving it all the privileges which Nottingham had in the time of Henry I and Henry II. The charter provides that no one shall dye cloth within ten leagues of Derby except in the borough. A charter of Henry III in 1260 granted that no Jew should be allowed to live in the town. Edward III granted the petition of the burgesses for two bailiffs, In 1745 the young pretender marched as far south as Derby, where it was decided that he should return to Scotland instead of going on to London.

Among interesting buildings are St. Peter's church, a fine building of Perpendicular date but with earlier portions; St. Alkmund's and St. Andrew's, in the Decorated style; and All Saints' with a beautiful choir screen and good stained glass. The church tower was built 1509–27, and is one of the finest in the midland counties. Derby grammar school was placed in 1159 under the administration of the chapter of Darley abbey. It now occupies St. Helen's house. Derby possesses a municipal technical college, schools of science and art, a public library, museum and art gallery, an agricultural institute, and Liversage's almshouses, a foundation inaugurated by Robert Liversage in 1529. A town planning scheme was adopted in 1929, while under a central improvement plan a covered market, a bus station, police buildings and riverside gardens were constructed. Further improvements to the river were also carried out.

Derby is celebrated for its porcelain. This manufacture was introduced about 1750, and although partially abandoned, it has been revived. The manufacture of silk, hosiery, lace and cotton formerly employed large numbers, and there are still numerous silk mills and elastic webworks. Silk "throwing" or spinning was introduced into England from Piedmont in 1717 by John Lombe, who set up machinery in Derby. In the 19th century the principal centre of the Midland railway was established at Derby. It is still a leading centre under L.M.S. control. Other industries include the manufacture of aircraft, motor cars, especially the Rolls-Royce car, as well as of electrical apparatus, paint, shot, white and red lead and varnish; and there are sawmills and tanneries. The manufacture of hosiery profited greatly by the inventions of Jedediah Strutt about 1750. In Littlechester there are chemical and steam boiler works. Derby was a bishopric suffragan in the diocese of Southwell but in 1927 became a separate bishopric. The parliamentary borough returns two members.

DERBY, a city of New Haven county, Connecticut, U.S.A., 10 mi. W. of New Haven, on the Housatonic river at the mouth of the Naugatuck, just below Ansonia and opposite the borough

of Shelton. The population was 11,238 in 1920 (32% foreign-born white), and was 10,287 in 1940 by the federal census. Derby was settled in 1643 as an Indian trading post called Paugasset, and received its present name in 1675. It was chartered as a city in 1893. In the 18th century it had a thriving commerce with the West Indies. It was the birthplace of David Humphreys (1752–1818), Washington's aide and military secretary from 1780 to the end of the war, first minister of the United States to Portugal (1790–97) and minister to Spain (1797–1802), and one of the "Hartford Wits"; and of Commodore Isaac Hull (1773–1843), commander of the U.S. frigate "Constitution ("Old Ironsides") during the War of 1812.

DERBYSHIRE, a north midland county of England, bounded north and northeast by Yorkshire, east by Nottinghamshire, southeast and south by Leicestershire, south and southwest by Staffordshire, and west and northwest by Cheshire. The area of the geographical county is 1,006 sq.mi. with a population estimated in 1938 at 766,800.

The county may be divided into two sections — the northern upland region culminating in the High Peak, and the southern lowland area around Derby.

The north is made up of Carboniferous limestone, millstone grit and the coal measures, while the lowland south is mainly underlain by red Triassic rocks.

Geology. — The Carboniferous or "Mountain" limestone in the northwest of the county is the oldest formation; its thickness is over 2,000 ft. It is well exposed in the numerous narrow gorges cut by the Derwent and its tributaries and by the Dove on the Staffordshire border.

The limestone uplands are bleak and dry generally with smooth outlines cut by deep ravines. Many of these glens are richly wooded. Volcanic rocks, locally known as "Toadstone" are represented in the limestones by intrusive sills and flows of dolerite and by necks of agglomerate notably near Tideswell, Millersdale and Matlock.

The highest ground in the extreme north of the county is capped by shales and sometimes by the millstone grit. In this region are Bleaklow hill (2,060 ft.), Shelf Moss (2,046 ft.), Kinder Scout (2,088 ft.) and other summits of the Peak itself. A series of black shales with nodular limestones, the Pendleside series rests upon the mountain limestone on the east, south and northwest; much of the upper course of the Derwent has been cut through these soft beds. Main tor (1,700 ft.) is made of these shales. Then follows a thick mass of sandstones, grits and shales — the millstone grit series. On the west side these extend from Blacklow hill to Axe Edge; on the east, from Derwent Edge to near Derby. A patch of millstone grit and limestone occurs in the south of the county about Melbourne and Tickvale.

The coal measures rest upon the millstone grit; the largest area of these rocks lies on the east, where they are coterminous with the coalfields of Yorkshire and Nottingham. A small tract, part of the Leicestershire coalfield, lies in the south of the county, and in the northwest corner a portion of the Lancashire coalfield appears about New Mills and Whaley Bridge. The coal measure country is gently moulded. East of Bolsover the coal measures are covered unconformably by the Permian breccias and magnesian limestone. South of a line through Ashbourne, Quarndon and Stanford, the land is at a much lower level. Flanking the hills between the former towns are red beds of Bunter, sandstone and conglomerate; they also appear at Morley, east of the Derwent, and again round the small southern coalfield. Most of the south part of the county is covered superficially by glacial drift and alluvium of the Trent. Local boulders as well as northern erratics are found in the valley of the Derwent. The bones of Pleistocene mammals — the rhinoceros, mammoth bison, hyaena, etc., have been found at numerous places, often in caves and fissures in the limestones, *e.g.*, at Castleton, Wirksworth and Cresswell. At Doveholes the Pleiocene Mastodon has been reported.

The rivers of the county radiate from the northern hills. Those of the northwest belong to the Mersey and those of the northeast to the Don, but all the others to the middle Trent which forms part of the southern county boundary with Leicestershire. The tributary streams of the Trent, of which the Derwent, Dove and Erewash are the most important, flow from north-north est to south-southeast over the Carboniferous, but turn almost west-northwest to east-southeast on the newer rocks before they enter the middle Trent, flowing roughly east-northeastwards. The Dove flows as the boundary between Derbyshire and Staffordshire for nearly its entire course. The Derwent rising in the High Peak flows southward, almost bisecting the county. The Erewash is the boundary stream between Nottinghamshire and Derbyshire. The Goyt rises a little farther north than the junction of the three counties — Staffordshire, Cheshire and Derbyshire, and flows north-northeastward dividing Derbyshire from Cheshire and finally falls into the Mersey.

Climate. — The winters in the uplands are generally severe, and the rainfall heavy. At Buxton (1,000 ft.) the mean temperature in January is 34.9° F., and in July 57.5"; at Derby, in the southern lowland, the figures are respectively 37.5° and 61.2°; intermediate conditions are found at Belper where the figures are 36.3° and 59.9°.

The contrasts shown by the mean annual rainfall are similarly marked, ranging from 52.03 in. at Woodhead in the north of the county through 35.2 in. at Matlock and 24.35 in. at Derby in the south.

History. — Important traces of the cultures of the late Palaeolithic age in Cresswell crags have been discovered.

The early settlement of Derbyshire was confined almost entirely to the well-drained Carboniferous limestone lands of the Peak. The marked Derbyshire group of Beaker pots indicates an important settlement of the dawn of the age of metals around the Peak district. It is thought that the Beaker folk came from the continent via the east coast, and groups apparently from the East Riding of Yorkshire reached the Derbyshire Peak district; others penetrated from the East Anglian coasts inland over the English plain. There are numerous Megalithic remains in the same area, the stone circle being much in evidence. The largest circles are those of Arbor Low, near Hartington, which retains most of its stones, and the "Bull Ring," at Dove Holes, near Chapel-on-le-Frith. Finds of bronze age weapons and implements are not so numerous as in the neighbouring counties. Many defensible sites, especially in the north of the country, are capped by ancient camps. Main tor, near Castleton, and Carl's Wark, near Hathersage, are good examples. It is impossible to assign a date to these structures as they were probably in use over a great length of time. Structures of this type were important in Romano-British and post-Roman times. The Romans were the first to utilize the lowlands to any great extent. At this period Littlechester, a camp to the northeast of Derby, became a focus of ways, receiving Ryknield street in particular. Aquae (Buxton), Anavio (near Castleton) and Melandra (west of Glossop) were sites in the north of the county.

The post-Roman centuries revived interest in the north until the conquests of the West Angles in the 6th century brought them up the valleys of the Derwent and the Dove.

Later the district formed the northern division of Mercia, and in 848 the Mercian witenagemot assembled at Repton. In the 9th century the district suffered frequently from the ravages of the Danes, who in 874 wintered at Repton and destroyed its famous monastery. Derby under Guthrum was one of the five Danish burghs, but in 918 was recovered by Aethelflaed. In 924 Edward the Elder fortified Bakewell, and in 941–942 Edmund regained Derby from the Danes. Saxon barrows are numerous in Wirksworth hundred and the Bakewell district, among them being White-low near Winster and Bower's-low near Tissington. There are Saxon cemeteries at Stapenhill and Foremark Hall.

Derbyshire probably originated as a shire in the time of Aethelstan, but for long it maintained a close connection with Nottinghamshire, and Domesday gives a list of customs affecting the two counties alike. The two shire-courts sat together for the Domesday inquest, and the counties were under one sheriff until the time of Elizabeth. The villages of Appleby, Oakthorpe, Donisthorpe, Stretton-en-le-Field, Willesley, Chilcote and Measham were reckoned as part of Derbyshire in 1086, although separated from it by the Leicestershire parishes of Over and Nether

Seat. Early divisions of the county were known as wapentakes, five being mentioned in Domesday, while 13th century documents mention seven corresponding with the six present hundreds, except that Repton and Gresley were then reckoned as separate divisions In the 14th century the divisions were described as hundreds, and Wirksworth alone retained the designation wapentake until modern times. Ecclesiastically the county constituted an archdeaconry in the diocese of Lichfield, comprising the six deaneries of Derby, Ashbourne, High Peak, Castillar, Chesterfield and Repington In 1884 it was transferred to the newly formed diocese of Southwell, but in 1927 was created a separate diocese of Derby, which includes the whole county except three parishes in the diocese of Peterborough The assizes for Nottinghamshire and Derbyshire were held at Nottingham until the reign of Henry III, when they were held alternately at Nottingham and Derby until 1566, after which the Derbyshire assizes were held at Derby. The miners of Derbyshire formed an independent community under the jurisdiction of a steward and barmasters, who held two Barmote courts (*q.v.*) every year The forests of Peak and Duffield had their separate courts and officers.

At the time of Domesday Henry de Ferrers owned almost the whole of the modern hundred of Appletree. The Ferrers estates were forfeited by Robert. earl of Derby, in the reign of Henry III. Another Domesday landholder was William Peverel, the founder of Peak castle, whose possessions were known as the honour of Peverel In 1155 the estates were forfeited to the crown. During the reigns of John and Henry III discontent was rife in Derbyshire and attacks were made on the central power. Riots occurred in 1443. In the 17th century the county first supported the king, but by 1643 Sir John Gell of Hopton had secured almost the whole county for the parliament Derby, however, was always royalist and Romanist in sympathy, and in 1745 entertained the young pretender.

Agriculture and Industries. — Slightly over 67% of the total area of 639,120 ac. was devoted to agriculture in 1939, but of this only 16% was arable land. Among the higher altitudes of north Derbyshire, where the soil is poor and the climate harsh, grain is unable to flourish, while even in the more sheltered parts of this region the harvest is usually late. Such districts have heath pasture with sheep farming. Farther south are heavy crops of wheat and oats, while turnips and swedes and green crops are not uncommon. Some barley is cultivated about Repton and Gresley. Wheat (19,321 ac. in 1939) is the most important crop in the county. A large part of the Trent valley is under permanent pasture, being devoted to cattle feeding and dairy farming. The National Trust owned 2,565 ac. in the county in 1942.

Derbyshire has always been mainly a mining and manufacturing county, though the rich land in the south formerly produced large quantities of corn. The lead mines were worked by the Romans, and Domesday mentions lead mines at Wirksworth, Matlock, Bakemell, Ashford and Crich. Iron has also been produced in Derbyshire from an early date, and coal mines were worked at Norton and Xlfreton in the beginning of the 14th century. The woollen industry flourished in the county before the reign of John, when an exclusive privilege of dyeing cloth was conceded to the burgesses of Derby. Thomas Fuller in 1662 mentions lead, malt and ale as the chief products of the county, and the Buxton waters were already famous in his day. The 18th century saw the rise of numerous manufactures. In 1718 Sir Thomas and John Lombe set up an improved silk-throwing machine at Derby, and in 1758 Jedediah Strutt introduced a machine for making stockings. In 1771 Sir Richard Arkwright set up one of his first cotton mills in Cromford, and in 1787 there were 22 cotton mills in the county. The Derby porcelain or china manufactory was started about 1750. The industrial districts, based on the coalfield, are in the east and extreme southwest. Silk, cotton, iron, papermaking, woollens, lace, malting and brewing are important. Derby, Belper and Duffield are the silk centres, while Derby has also its china, lace, braids, cords, chemical and motor (Rolls-Royce) manufactures Belper, Glossop, Ilkeston and Cromford specialize in cotton-spinning and hosiery. The iron smelting focuses on Alfreton, Chesterfield, Derby, Dronfield and Eckington. Lead, gypsum, zinc, iron ore, manganese and barytes are raised to some extent. The county is famous for its limestone and marble quarries, whilr the fluorspar of the limestone caverns is made into ornaments. The warm mineral springs at Buxton, Matlock and Bakewell are well known.

The chief railway serving the county is the L.M.S., which ha.; one of its chief works at Derby, while a branch of the L.N.E. serves Derby and other places in the south. The Trent and Mersey canal crosses the southern part of the county, and there is a branch canal (the Derby) connecting Derby with this and with the Erewash canal, which runs north from the Trent up the Erewash valley. From it there is a little-used branch (the Cromford canal) to Matlock. There were 2,395 mi. of roads in the county in 1942.

Population and Administration. — The area of the administrative county, which contains six hundreds, is 992.9 sq.mi.; pop. (1938) 627,800. Wartime movements had little effect in Derby the population rising only 1% between Sept 1939 and Feb. 1941. Derby is a county borough; the municipal boroughs are Buxton, Chesterfield. Glossop and Ilkeston. The urban districts are Alfreton, Ashbourne, Bakewell, Belper, Bolsover, Clay Cross, Dronfield, Heanor, Long Eaton, Matlock, New Mills, Ripley, Staveley, Swadlincote District, Whaley Bridge and Wirksworth. The county is in the Midland circuit, and assizes are held at Derby. It has one court of quarter sessions and is divided into 15 petty sessional divisions. The boroughs of Derby, Chesterfield and Glossop have separate commissions of the peace, and that of Derby has also a separate court of quarter sessions. The total number of civil parishes is 310. The county returned two members to parliament from 1295 until 1832, after which it returned four members in two divisions until 1868 when six members were returned for three divisions. After 1918 the county returned eight members, one each for the following divisions: Belper, Chesterfield, Clay Cross, High Peak, Ilkeston, Northeastern, Southern and Western, while the county borough of Derby returned two members after 1275.

DERBYSHIRE NECK: see GOITRE.

DEREHAM, (properly East Dereham), market town and urban district in Norfolk, England, 122 mi. N.N.E. from London. Pop (est. 1938) 5,730. Area, 8.9 sq.mi. The church of St. Nicholas is a cruciform Perpendicular structure with a beautiful central tower and some portions of earlier date. It contains a monument to William Cowper, who came to live here in 1796, and the Congregational chapel stands on the site of the house where the poet spent his last days. Dereham is an important agricultural centre, and has a large Friday market. There is an annual harvest fair in September. The manufactures are agricultural steam engines and threshing machines; there is also a coach works.

DERELICT, in law, property thrown away or abandoned by the owner in such a manner as to indicate that he intends to make no further claim to it. The word is used more particularly with respect to property abandoned at sea (see WRECK). Land gained gradually and slowly from the sea belongs to the owner of the adjoining land by *dereliction,* but in England in the case of sudden or considerable recession, the land belongs to the crown.

DERENBOURG, HARTWIG (1844–1908), French orientalist, son of the following, was born in Paris on June 17, 1844. He studied at Göttingen, Leipzig and at the École des Langues Orientales, Paris. In 1879 he was appointed professor of Arabic

at the École des Hautes Études in Paris. He collaborated with his father in the great edition of Seadiah (1893 etc) and the edition of Abu-'l-Walîd, and also prepared a number of important editions of other Arabic writers and a catalogue of the Arabic mss. in the Escorial (2 vols 1884–93).

DERENBOURG, JOSEPH (1811–1895), Franco-German orientalist, was born at Mainz on Aug. 21, 1811, and settled in Paris in 1839. He was a considerable force in the revival of Jewish education in France. He made great contributions to the knowledge of Seadiah (*q.v.*), and planned a complete edition of Seadiah's works in Arabic and French. Among his numerous works is an *Essai sur l'histoire et la géographie de la Palestine* (Paris, 1867). This was an original contribution to the history of the Jews and Judaism in the time of Christ, and has been much used by later writers on the subject (*e.g.*, Schurer). He became professor of Hebrew and rabbinical theology at the École des Hautes Études, Paris, in 1877. Derenbourg died on July 29, 1895, at Ems.

DERG, LOUGH, a lake of Ireland, on the boundary of the counties Galway, Clare and Tipperary. It is an expansion of the Shannon channel, 23 m. long and from 1 to 3 m. broad. The water appears to be dammed, as the Shannon flowing over the low lying central plain breaks through the narrow gorge between Slieve Bernagh and the Arra mountains. Ruined churches and fortresses are numerous on the eastern shore, and on Iniscaltra island are a round tower and the remains of five churches.

Another LOUGH DERG, near Pettigo in Donegal, is famous as the traditional scene of St. Patrick's purgatory. In the middle ages its pilgrimages had a European reputation, and they are still observed. The hospice, chapels, etc., are on Station island, and there is a ruined monastery on Saints' island.

DE RIDDER, a city of south-western Louisiana, U.S.A., on the watershed between the Sabine and the Calcasieu rivers; the capital of Beauregard parish. It is on Federal highway 171, and is served by the Santa Fe, the Kansas City Southern and the Southern Pacific railways. The population was 3,535 in 1920 (22% negro) and was 3,750 in 1940 by the Federal census. It was founded in 1900 as a pine-milling centre, and with the decline of that industry (about 1920) a study of the agricultural possibilities of the region was made, and the cultivation of satsuma oranges, grapefruit and lemons was introduced. By 1927 there were 400,000 citrus trees growing in the vicinity, of which 25,000 were already bearing full crops. De Ridder was organized as a city in 1912. It has a commission form of government.

D'ERLON, JEAN BAPTISTE DROUET, COUNT (1765–1844), marshal of France, was born at Reims on July 29, 1765. He entered the army as a private soldier in 1782, did good service in the campaigns of the revolutionary wars, and in 1799 attained the rank of general of brigade. He served in Switzerland under Masséna (1799), at Hohenlinden under Moreau (1800), at Jena (1806), and at Friedland (1807). After this last battle he was created count d'Erlon and received a pension. For the next six years d'Erlon was almost continuously engaged as commander of an army corps in the Peninsular War. At the pass of Maya in the Pyrenees he defeated (1814) Lord Hill's troops. After the first Restoration he was named commander of the 16th military division, but was arrested for conspiring with the Orléans party. He escaped, and joined Napoleon on his return from Elba. The emperor made him a peer of France, and gave him command of the I. army corps. In the Waterloo campaign d'Erlon's corps formed part of Ney's command on June 16, but, in consequence of an extraordinary series of misunderstandings, took part neither at Ligny nor at Quatre Bras *(see* WATERLOO CAMPAIGN).

He was in command of the right wing of the French army throughout the great battle of June 18 and fought in the closing operations around Paris. At the second Restoration D'Erlon fled into Germany, only returning to France after the amnesty of 1825. He was reinstated on the accession of Louis Philippe. As commander of the 12th military division (Nantes), he suppressed the legitimist agitation in his district and caused the arrest of the duchess of Berry (1832). He was governor of Algeria from 1834 to 1836. D'Erlon was made marshal of France shortly before his death in Paris on Jan 25, 1844.

DERMAPTERA, an order of insects (*q.v.*), which includes the earwigs (*q.v.*).

DERMATOLOGY: *see* SKIN DISEASES.

DERMOT MAC MURROUGH (d. 1171), Irish king of Leinster, succeeded his father in the principality of the Hui Cinsellaigk (1115) and eventually in the kingship of Leinster. About 1152 we find him engaged in a feud with O Ruairc, the lord of Breifne (Leitrim and Cavan). Dermot abducted the wife of O Ruairc more with the object of injuring his rival than from any love of the lady. The injured husband called to his aid Roderic, the high king (airdrigh) of Connaught; and in 1166 Dermot fled before this powerful coalition to invoke the aid of England. Obtaining from Henry II. a license to enlist allies among the Welsh marchers, Dermot secured the aid of the Clares and Geraldines. To Richard Strongbow, earl of Pembroke and head of the house of Clare, Dermot gave his daughter Eva in marriage; and on his death was succeeded by the earl in Leinster. The historical importance of Dermot lies in the fact that he was the means of introducing the English into Ireland. Through his aid the towns of Waterford, Wexford and Dublin had already become English colonies before the arrival of Henry II. in the island. To the credit of Derrnot Mac Murrough must be put the compilation of the *Book* of *Leinster,* a valuable collection of early Gaelic tradition.

See *The Song of Dermot and the Earl, an old French Poem* (by *M.* Regan?), edit. with trans. by G. H. Orpen (1892); Kate Norgate, *England under the Angevin Kings,* vol. ii.

DERNA, a town on the north coast of Cyrenaica, Africa (anc. *Darnis-Zarine*), 224 m. E. of Bengasi by road (railway as far as El Merg). Population (1938) 21,547. Situated below the eastern butt of Jebel Akhdar on a small but rich deltaic plain, watered by fine perennial springs, it has a growing population and trades in fruits grown in its extensive palm gardens, and in hides and wool brought down by the nomads from the interior. The bay is open from north-west round to south-east and often inaccessible in winter and spring. A portion of the people is of Moorish stock, of Andalusian origin, which emigrated in 1493; the descendants preserve a fine facial type. It was the easternmost city of the Pentapolis of Cyrenaica. There is a lighthouse west of the bay. The names Darnis and Zarine are philologically identical and probably refer to the same place. No traces are left of the ancient town except some rock tombs. Darnis continued to be of some importance in early Muslim times as a station on the Alexandria-Kairouan road, and has served on more than one occasion as a base for Egyptian attacks on Cyrenaica and Tripolitan'a. In 1805 the government of the United States, in dispute with the dey of Tripoli on account of piracies on American shipping, landed a force under William Eaton (*q.v.*) to co-operate in the attack on Derna then being made by Sidi Ahmet, an elder brother of the dey. After 1835 Derna passed under direct Ottoman control, and subsequently served as the point whence the sultan exerted a precarious but increasing control over eastern Cyrenaica and Marmarica. It passed to Italy in 1912. There is a caravan route to Tobruk (115 m.).

DERNBURG, HEINRICH (1829–1907), German legal scholar, was born on March 3, 1829, at Mainz, and died at Berlin on Nov. 23, 1907. He was made professor at Zurich (1854), at Halle (1862), at Berlin (1873) and from 1866 was in the Prussian Upper House. His chief publications are *Die Kompensation* (1854); *Das Pfandrecht* (2 vols., 1860); *Die Institutionen des Cajus* (1869); *Lehrbuch des preuss. Privatrechts* (3 vols., 1871–96); *Pandekton* (3 vols., 1884) and *Das burgerliche Recht des Deutschen Reichs u. Preussens* (5 vols., 1898).

DEROULEDE, PAUL (1846–1914), French author and politician, was born in Paris. His first published verses appeared in the *Revue nationale,* under the pseudonym of Jean Rebel, and in 1869 he produced at the Théâtre Français a one-act drama in verse entitled *Juan Strenner.* On the outbreak of the Franco-Prussian War he enlisted as a private, was wounded and taken prisoner at Sedan, and sent to Breslau, but effected his escape. He then served under Chanzy and Bourbaki, took part in the latter's disastrous retreat to Switzerland, and fought against the Commune in Paris. After attaining the rank of lieutenant, he

was forced by an accident to retire from the army. He published in 1872 a number of patriotic poems *(Chants du soldat)*, which enjoyed unbounded popularity. This was followed in 1875 by another collection, *Nouveaux Chants du soldat*. In 1877 he produced a drama in verse called *L'Hetman,* which derived a passing success from the patriotic fervour of its sentiments. For the exhibition of 1878 he wrote a hymn, *Vive la France,* which was set to music by Gounod. In 1880 his drama in verse, La *Moiibite,* which had been accepted by the Théâtre Français, was forbidden by the censor on religious grounds.

In 1882 M. Déroulède founded the *Ligue des patriotes,* with the object of furthering France's "revanche" against Germany. He was one of the first advocates of a Franco-Russian alliance, and as early as 1883 undertook a journey to Russia for the furtherance of that object. On the rise of General Boulanger, M. Déroulède attempted to use the *Ligue des patriotes,* hitherto *a* non-political organization, to assist his cause, but was deserted by a great part of the league and forced to resign his presidency. Nevertheless he used the section that remained faithful to him with such effect that the Government found it necessary in 1889 to decree its suppression. In the same year he was elected to the chamber as member for Angoulême. He was expelled from the chamber in 1890 for his disorderly interruptions during debate. He did not stand at the elections of 1893, but was re-elected in 1898. After the funeral of President Faure, on Feb. 23, 1899, he endeavoured to persuade Gen. Roget to lead his troops upon the Elysée. For this he was arrested, but on being tried for treason was acquitted (May 31). On Aug. 12 he was again arrested and accused, together with André Buffet, Jules Guérin and others, of conspiracy against the republic. After a long trial before the high court, he was sentenced, on Jan. 4, 1900, to ten years' banishment from France, and retired to San Sebastian. In Nov. 1905, however, the law of amnesty enabled him to return to France. He died near Nice on Jan. 30, 1914.

Besides the works already mentioned, he published *Le Sergent,* in the *Théâtre de campagne* (1880); *De l'éducation nationale* (1882); *Monsieur le Uhlan et les trois couleurs* (1884); *Le Premier grenadier de France; La Tour d'Auvergne* (1886); *Le Livre de la ligue des patriotes* (1887); *Refrains militaires* (1888); *Histoire d'amour* (1890); a pamphlet entitled *Désarmement?* (1891); *Chants du paysan* (1894); *Poésies Militaires* (1896) and *Messire du Guesclin, drame en vers* (1895); *La mort de Hoche. Cinq actes en prose* (1897); *La Plus belle fille du monde, conte dialogué en vers libres* (1898); *1870, Feuilles de route* (1905), a volume of reminiscences.

DERRICK, a type of crane; the name is derived from that of a famous early 17th-century Tybum hangman, and was originally applied as a synonym *(see* CRANES). The derrick of the petroleum industry is a skeleton framework or tower for hoisting or lowering from a fixed point.

DERRING-DO, valour, chivalrous conduct or "desperate courage." The word is a misconstruction of the verbal substantive *dorryng* or *durring,* daring, and the present infinitive of "do." Spenser first adapted *derring-do* as a substantive meaning "manhood and chevalrie," and this use was revived by Scott.

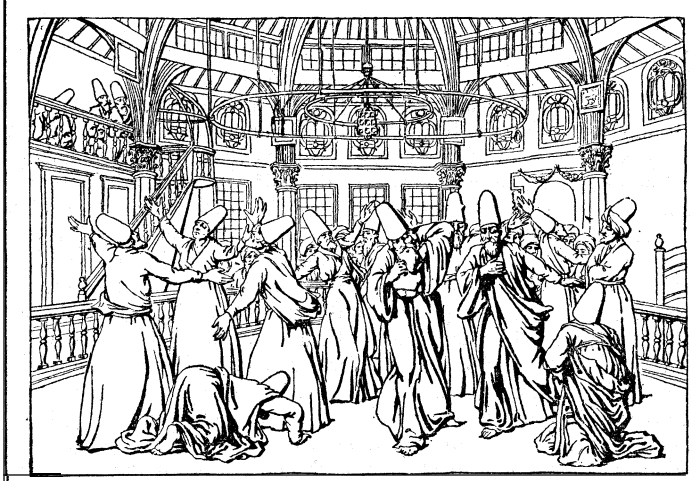
DERRY, a town of Rockingham county, New Hampshire, on Beaver Brook, 10 mi. S E. of Manchester; served by the Boston and Maine railroad. The population was 5.382 in 1920; 1940 it was 5,400. It is a summer resort; ships large quantities of milk to the Boston market; and manufactures shoes. wooden heels, tree labels, plant stakes, tags and witch hazel.

DE RUYTER, MICHAEL ADRIANZOON (1607–1676), Dutch naval officer, was born at Flushing on March 24. 1607. In 1636 he was entrusted by the merchants of Flushing with the command of a cruiser against the French pirates. In 1640 he entered the service of the United Provinces, and. being appointed rear-admiral of a fleet fitted out to assist Portugal against Spain, specially distinguished himself at Cape St. Vincent. Nov. 3, 1641. In the following year he left the service of the United Provinces to command a merchant vessel. In 1652 a squadron of seventy vessels was despatched against the English, under the command of Admiral Tromp. De Ruyter, who accompanied the admiral in this expedition. seconded him with great skill and bravery in the three battles which were fought with the English off Plymouth, the Kentish Knock, and Dungeness. He was afterwards stationed in the Mediterranean, where he captured several Turkish vessels. In 1659 he received a commission to join the king of Denmark in his war with the Swedes. As a reward for his services, the king of Denmark ennobled him and gave him a pension. In 1661 he grounded a vessel belonging to Tunis, released forty Christian slaves, made a treaty with the Tunisians, and reduced the Algerine corsairs to submission. He recaptured English settlements on the west coast of Africa but was repulsed at Barkad and failed to recover New Amsterdam. He returned to take command of a large fleet which had been organized against England, and in May of the following year, after a long contest off the North Foreland, he compelled the English to take refuge in the Thames and burnt the "King Charles" and other warships in the Medway. On June 7, 1672, he fought a drawn battle with the combined fleets of England and France, in Southwold bay, and convoyed saiely a fleet of merchantmen. In 1676 he assisted Spain against France in the Mediterranean, and, receiving a mortal wound in the battle on April 22, off Messina, died on the 29th at Syracuse. His body was carried to Amsterdam, where a magnificent monument to his memory was erected by command of the States-General. *(See* also DUTCH WARS.)

See Life of De Ruyter by Brandt (Amsterdam, 1687), and by Klopp (2nd ed., Hanover, 1858).

DERVISH, a Persian word, meaning "beggar"; generally in Islam a member of a religious fraternity, whether mendicant or not; but in Turkey and Persia more exactly a wandering, begging religious, called, in Arabic-speaking countries, a *faqir.* With important differences, the dervish fraternities may be compared to the regular religious orders of Roman Christendom, while the Ulama (*q.v.*) are, also with important differences, like the secular clergy. For the origin and history of the mystical life in Islam, which led to the growth of the order of dervishes *see* ṢŪFI'ISM; here an account is given of (1) the dervish fraternities, and (2) the Siifi hierarchy.

1. The Dervish Fraternities.— In the earlier times, the relation between devotees was that of master and pupil. Those inclined to the spiritual life gathered round the revered shaykh (*murshid,* "guide," *ustādh, pīr,* "teacher"), lived with him, shared his religious practices and were instructed by him. In time of war against the unbelievers, they might accompany him to the threatened frontier, and fight under his eye. Thus *murābit,* "one who pickets his horse on a hostile frontier," has become the *marabout* (*q.v.*) or dervish of Algeria; and *ribāt,* "a frontier fort," has come to mean a monastery. The relation, also, might be for a time only. The pupil might at any time return to the world, when his reli-



GROUP OF DANCING DERVISHES TAKING PART IN THE ZIKR CEREMONY
The zikr is the main devotional exercise of all orders of dervishes. Among the Mawlawis or "Dancing Dervishes," it consists of a monotonous chant accompanied with a slow whirling movement around the floor, with eyes closed and arms extended. The ceremony continues until the participants fall into a cataleptic state

gious education and training were complete. Continuous corporations began to be formed in the 12th century. Many existing orders trace their origin to saints of the 3rd, 2nd and even 1st Muslim centuries, *e.g.*, to either 'Ali or Abii Bakr, and in Egypt all are under the rule of a direct descendant of the latter, but such ascription is purely legendary.

Of these orders, 32 are commonly reckoned, but many have vanished or have been suppressed, and there are sub-orders innumerable. Each has a "rule" dating back to its founder, and a ritual which the members perform when they meet together in their convent (*khānqāh, zāwiya,* takiya). This may consist simply in the repetition of sacred phrases, or it may be an elaborate performance, such as the whirlings of the dancing dervishes, the Mawlawīs, an order founded by Jalāl ud-Din ar-Riimi, the most broad-minded and tolerant of all. There are also the performances of the Rifā'īs or "howling dervishes." In ecstasy they cut themselves with knives, eat live coals and glass, handle red-hot iron and devour serpents. They profess miraculous healing powers, and the head of the Sa'dis, a sub-order, used, in Cairo, to ride over the bodies of his dervishes without hurting them, the so-called Dōseh (dausa). Another division is made by their attitude to the law of Islam. Some neglect in general the ceremonial and ritual law, to such an extent that in Persia, India and Turkey dervish orders are classified as *bā-shar'*, "with law," and *bī-shar'*, "without law." The latter are really antinomians, and the best example of them is the Baktāshī order, widely spread and influential in Turkey and Albania and connected by legend with the origin of the Janissarics. The Sanūsī was the last order to appear, and is distinguished from the others by a severely puritanic and reforming attitude and strict orthodoxy, without any admixture of mystical slackness in faith or conduct. Each order is distinguished by a peculiar garb. Candidates for admission have to pass through a noviciate, more or less lengthy. First comes the *'ahd,* or initial covenant, in which the neophyte or *murīd,* "seeker," repents of his past sins and takes the shaykh of the order he enters as his guide (murskid) for the future. He then enters upon a course of instruction and discipline, called a "path" (*tarīqa*), on which he advances through diverse "stations" (*maqāmāt*) or "passes" ('aqabdt) of the spiritual life. The Mawlawīs have the most severe noviciate. Their aspirant has to labour as a lay servitor of the lowest rank for 1,001 days before he can be received. For one day's failure he must begin again from the beginning.

But besides these full members there is an enormous number of lay adherents, like the tertiaries of the Franciscans. Thus, nearly every religious man of the Turkish Muslim world is a lay member of one order or another, under the duty of saying certain prayers daily. Certain trades, too, affect certain orders. Most of the Egyptian Qādirīs, for example, are fishermen and, on festival days, carry as banners nets of various colours. On this side, the orders bear a striking resemblance to lodges of Freemasons and other friendly societies, and points of direct contact have even been alleged between the more pantheistic and antinomian orders, such as the Baktāshī, and European Freemasonry. They are the only ecclesiastical organization that Islam has ever known, but it is a multiform organization, unclassified internally or externally. They differ thus from the Roman monastic orders, in that they are independent and self-developing, each going its own way in faith and practice, limited only by the universal conscience (*ijmā,* "agreement": see ISLAMIC LAW) of Islam.

2. Saints and the **Sūfī** Hierarchy.— That an elaborate doctrine of wonder-working saints should have grown up in Islam may, at first sight, appear an extreme paradox. It, can, however, be conditioned and explained. First, Muhammad left undoubted loop-holes for a minor inspiration, legitimate and illegitimate. Secondly, the Siifis, under various foreigh influences, developed these to the fullest. Thirdly, just as the Christian church has absorbed much of the mythology of the supposed exterminated heathen religions into its cult of local saints, so Islam, to an even higher degree, has been overlaid and almost buried by the superstitions of the peoples to which it has gone. Their religious and legal customs have completely overcome the direct commands of the Qur'ān, the traditions from Muhammad and even the "Agreement" of the rest of the Muslim world (see ISLAMIC LAW). The worship of saints, therefore, has appeared everywhere in Islam, with an absolute belief in their miracles and in the value of their intercession, living or dead.

Further, there appeared very early in Islam a belief that there was always in existence some individual in direct intercourse with God and having the right and duty of teaching and ruling all mankind. This individual might be visible or invisible; his right to rule continued. This is the basis of the Ismā'īlī and Shi'i positions (see the article ISLAMIC INSTITUTIONS). The Siifis applied this idea of divine right to the doctrine of saints, and developed it into the Siifi hierarchy. This is a single, great, invisible organization, forming a saintly board of administration, by which the invisible government of the world is supposed to be carried on. Its head is called the *Quṭb* (Axis); he is presumably the greatest saint of the time, is chosen by God for the office and given greater miraculous powers and rights of intercession than any other saint enjoys. He wanders through the world, often invisible and always unknown, performing the duties of his office. Under him there is an elaborate organization of walis, of different ranks and powers, according to their sanctity and faith. The term wali is applied to a saint because of Kor. x. 63, "Ho! the walis of God; there is no fear upon them, nor do they grieve," where wali means "one who is near," friend or favourite.

In the fraternities, then, all are dervishes, cloistered or lay; those whose faith is so great that God has given them miraculous powers—and there are many—are walis; begging friars are fakirs. All forms of life—solitary, monastic, secular, celibate, married, wandering, stationary, ascetic, free—are open. Their theology is some form of Siifi'ism.

DERWENT, the name of several English rivers (Celtic *Dwrgent,* clear water). (1) The Yorkshire Derwent drains North Yorkshire moors, rising in their eastern part. A southern headstream, however, rises in the Yorkshire wolds near Filey, about a mile from the North Sea, but it flows inland owing to a coast morainic deposit. The early course of the Derwent lies through the flat open vale of Pickering between the Yorkshire moors and the Yorkshire wolds, the upper part of which is known as the Carrs, when the river follows an artificial drainage cut. It receives many tributaries from the moors, then breaches the low hills below Malton, and reaches the central plain of Yorkshire. Its direction, hitherto westerly, now becomes southerly, roughly parallel to the Ouse, which it joins near Barmby-on-the-Marsh, after a course, of about 70 m. As a tributary of the Ouse it is included in the Humber basin. It is tidal up to Sutton-upon-Derwent, 15 m. from the junction with the Ouse, and is locked up to Malton, but the navigation is little used. A canal leads east from the tidal water to the market town of Pocklington.

(2) The Derbyshire Derwent rises in Bleaklow hill north of the Peak and traverses a narrow dale, which, with the tributaries, the Noe, watering Hope valley, and the Wye, is famous for its beauty (see DERBYSHIRE). The Derwent flows south past Chatsworth, Matlock and Belper and then, passing Derby, debouches upon a low plain, and turns south-eastward, to join the Trent, after flowing 60 in, near Sawley. It falls in all some 1,700 ft. (from Matlock 200 ft), and no part is navigable, save certain reaches at Matlock and elsewhere for pleasure boats.

(3) The Cumberland Derwent rises below Great End in the Lake District, draining Spinkling and Sty Head tarns, and flows through Borrowdale, receiving a tributary from Lang Strath. It then drains the lakes of Derwentwater and Bassenthwaite, after

which its course, hitherto northerly becomes westerly past Cockermouth to the Irish Sea at Workington. The length is about 34 m., and the fall about 2,000 ft. (from Derwentwater 244 ft.); the waters are beautifully clear, and the river is not navigable. At a former period Derwentwater and Bassenthwaite formed one lake, but they have been separated by lacustrine deltas at the mouths of the river Greta, which now joins the Derwent immediately below Derwentwater, and the Newlands Beck, which enters Bassenthwaite.

(4) A river Derwent rises in the Pennines near the borders of Northumberland and Durham, and forming a large part of the boundary between these counties, takes a north-easterly course of 30 m. to the Tyne, which it joins 3 m. above Newcastle.

DERWENT, the principal river of Tasmania, with a length of 130 miles. It rises in Lake St. Clair and flows south-west, entering Storm bay at Hobart by an estuary four miles wide. See TASMANIA.

DERWENTWATER, EARL OF, an English title borne by the family of Radclyffe or Radcliffe from 1688 to 1716, when the 3rd earl was attainted and beheaded, and claimed by his descendants, adherents of the exiled house of Stuart, from that date until the death of the last male heir in 1814. Sir Francis Radclyffe, 3rd baronet (1625–1697), was the lineal descendant of Sir Nicholas Radclyffe, who acquired the extensive Derwentwater estates in 1417 through his marriage with the heiress of John de Derwentwater, and of Sir Francis Radclyffe, who was made a baronet in 1619. In 1688 Sir Francis was created Viscount Radclyffe and earl of Derwentwater by James II., and dying in 1697 was succeeded as 2nd earl by his eldest son Edward (1655–1705), who had married Lady Mary Tudor (d. 1726), a natural daughter of Charles II. The 2nd earl died in 1705, and was succeeded by his eldest son James (1689–1716), who was born in London on June 28, 1689, and was brought up at the court of the Stuarts in France as companion to Prince James Edward, the old Pretender. In 1710 he came to reside on his English estates. Joining the Stuart rising of 1715, Derwentwater escaped arrest owing to the devotion of his tenantry, and in October, with about 70 followers, he joined Thomas Forster at Green-rig. When the rebels capitulated at Preston he was conveyed to London and impeached. Pleading guilty at his trial he was attainted, and was beheaded on Tower hill on Feb. 24, 1716, declaring on the scaffold his devotion to the Roman Catholic religion and to King James III.

On the death of the 3rd earl's son, John Radclyffe, in 1731 his uncle Charles (1693–1746), son of the 2nd earl, took the title of earl of Derwentwater. Charles Radclyffe had fought at Preston and was condemned to death for high treason; but, more fortunate than James, he escaped from prison and went to live in Rome. He was captured by an English ship in Nov. 1745 whilst proceeding to join Charles Edward, the young Pretender, in Scotland. He was beheaded on Dec. 8, 1746. His eldest son, James Bartholomew (1725–1786), who had shared his father's imprisonment, then claimed the title of earl of Derwentwater, and on his mother's death in 1755 became 3rd earl of Newburgh. His only son and successor, Anthony James (1757–1814), died without issue in 1814, when the title became extinct de facto as well as de jure. The present representative of the Radclyffe family is Lord Petre, and in 1874 the bodies of the first three earls of Derwentwater were reburied in the family vault of the Petres at Thorndon, Essex.

See R. Patten, *History of the Late Rebellion* (London, 1717); W. S. Gibson, *Dilston Hall, or Memoirs of James Radcliffe, earl of Derwentwater* (London, 1848–1850); G. E. C(okayne), *Complete Peerage* (Exeter, 1887–1898); and *Dictionary of National Biography*, vol. xlvii. (London, 1896).

DERWENTWATER, a lake of Cumberland, England, in the Lake District (*q.v.*). It is approximately oval in shape, about 3 m. long and from $\frac{1}{2}$ m. to $1\frac{1}{4}$ m. wide. The greatest depth is 70 feet. The lake is seen at one view, within an amphitheatre of mountains of varied outline, overlooked by others of greater height. Several elevations near the lake are famous view-points, *e.g.*, Castle Head. Walla Crag, Ladder Brow and Cat Bells. The shores are well wooded, and the lake is studded with several islands, of which Lord's Island, Derwent Isle and St. Herbert's are the principal. Lord's Island was the residence of the earls of Derwentwater. St. Herbert's Isle is so called because here lived St. Herbert, mentioned by Bede, in the 7th century. Derwent Isle (6 acres) contains a handsome residence surrounded by lawns, gardens and timber of large growth. The Falls of Lodore, at the upper end of the lake, consist of a series of cascades in the small Watendlath beck, which falls over crags from a height of nearly 200 feet. The "Floating Island" appears at intervals on the upper portion of the lake near the mouth of the beck, and is formed by the accumulation of decayed vegetable matter floating on the water. The river Derwent (*q.v.*) enters the lake from the south and leaves it on the north, draining it through Bassenthwaite lake, which is separated from Derwentwater by a lacustrine delta, to the Irish Sea. To the north-east of the lake lies the town of Keswick.

DERZHÁVIN, GAVRILA ROMÁNOVICH (1743–1816), Russian poet, was born at Kazán on July 14, 1743. He entered the army in 1762, was governor of Olónet (1784), Tambov (1785), and then secretary for petitions under Catherine II. to whom many of his odes are addressed. Under Alexander I. he was for a short time minister of justice, but in 1803 he retired to his estate at Zvanka, in the Novgorod Government, where he spent a serene and gay old age in the pursuit of letters. He died at Zvanka on July 21, 1816. Derzhbvin, says Prince Mirsky "for sheer imaginative power is one of the small number of Russia's greatest poets." His Ode to God (Eng. trans. Sir John Bowring, 1861), was one of his most famous poems and was translated into many European languages.

His works were edited by Grot (7 vols., 1864–73), who also wrote his biography (2 vols., 1880–83). His poems were translated into German by Kotzebue (1793). For translations of several of Derzhávin's poems into English *see* L. Wiener, *Anthology of Russian Literature* (1902) and Sir John Bowring, *Specimens of the Russian Poets* (1821).

DES ADRETS, FRANÇOIS DE BEAUMONT, BARON (*c.* 1512–1587), French Protestant leader, was born in 1512 or 1513 at the château of La Frette (Isère). In 1562, he joined the Huguenots, probably from motives of ambition and personal dislike of the house of Guise, and waged a successful campaign against the Catholics. In June of that year Des Adrets was master of the greater part of Dauphiné. The reprisals he exacted from the Catholics after their massacres of the Huguenots at Orange have left a dark stain upon his name. The garrisons that resisted him were brutally butchered, and at Montbrison, in Forez, he forced 18 prisoners to precipitate themselves from the top of the keep. Having alienated the Huguenots by his pride and violence, he entered into communication with the Catholics and declared himself openly in favour of conciliation. On Jan. 10, 1563, he was arrested on suspicion by some Huguenot officers and confined for a time in the citadel of Nimes. He died, a Catholic, on Feb. 2, 1587.

See J. Roman, *Documents inédits sur le baron des Adrets* (1878); and memoirs and histories of the time. *See* also Guy Allard, *Vie de François de Beaumont* (1675); l'abbé J. C. Martin, *Histoire politique et militaire de François de Beaumont* (1803); Eugene and Emile Haag, *La France protestante* (2nd ed., 1877 *seq.*).

DESAIX DE VEYGOUX, LOUIS CHARLES ANTOINE (1768–1800), French general, was born at Saint-Hilaire d'Ayat of noble parentage on Aug. 17, 1768, and was educated for the army. In 1789 he declared for the Revolution, and rose rapidly in the revolutionary army. By 1794 he had attained the rank of general of division. In the campaign of 1795 he commanded Jourdan's right wing, and in Moreau's invasion of Bavaria in 1796 he held an equally important command. In the retreat after the battles of Amberg and Wiirzburg (see FRENCH REVOLUTIONARY WARS) Desaix commanded Moreau's rearguard, and later the fortress of Kehl. He then obtained a mission to Italy, and met Bonaparte. Provisionally appointed commander of the "Army of England," Desaix was soon transferred by Ronaparte to the expeditionary force intended for Egypt. His division bore the brunt of the Mameluke attack at the battle of the Pyramids, and he defeated Murad Bey's army in Upper Egypt. Amongst the fellaheen he acquired the significant appellation of the "Just Sultan." Desaix was one of the small party selected to accompany Bonaparte on his return to France, but the campaign of 1800 was well on its

way to the climax when Desaix was able to report himself for duty in Italy. He was in command of a corps of two infantry divisions when (June 14) he heard the cannon of Marengo on his right. He marched at once towards the sound, meeting Bonaparte's staff officer, who had come to recall him, half way on the route. He arrived with Boudet's division at the moment when the Austrians were victorious all along the line. Exclaiming, "There is yet time to win another battle!" he led his three regiments straight against the enemy's centre. At the moment of victory Desaix was killed by a musket ball. Napoleon erected the monuments to his memory on the Place Dauphine and the Place des Victoires in Paris.

See F. Martha-Beker, Comte de Mons, *Le Général L. C. A. Desaix* (1852).

DESARGUES, GERARD (1593–1662), French mathematician, was born at Lyons. By profession he was an engineer and architect, and was an army officer in the engineering section at the siege of La Rochelle. Between 1626 and 1630 he gave a series of lectures on mathematics at Paris, and influenced Descartes and Pascal. He died at Lyons in 1662. Most of his mathematical work is on geometry, and the theory of involution and transversals is due to him. Desargues' most important writings are *Traitk de la section Perspective* (1636) and *Brouillon Project* (1639). The latter book deals with conics and embodies most of his researches.

DESAUGIERS, MARC ANTOINE MADELEINE (1772–1827), French dramatist and song-writer, son of Marc Antoine Désaugiers, musical composer, was born at Fréjus (Var). At the Revolution he emigrated to St. Domingo, and during the negro revolt he was made prisoner, barely escaping with his life. He took refuge in the United States, where he supported himself by teaching the piano. In 1797 he returned to his native country, and rapidly won fame as a writer of comedies, operas and vaudevilles, produced at the Théâtre des Variétés and the Vaudeville. He also wrote convivial and satirical songs, which, though different in character, can only worthily be compared with those of Béranger. He was at one time president of the *Caveau,* to which he introduced Béranger. In 1815 Désaugiers succeeded Pierre Yves Barré as manager of the Vaudeville. He died in Paris on Aug. 9, 1827.

An edition of Désaugiers' *Chansons et Poésies diverses* appeared in 1827 A new selection with a notice by Alfred de Bougy appeared in 1858. *See* also Sainte-Beuve's *Portraits contemporains,* vol. v.

DESAULT, PIERRE JOSEPH (1744–1795), French anatomist and surgeon, was born at Magny-Vernois (Haute Saône) on Feb. 6, 1744. He served as an apprentice in the military hospital of Belfort, and in 1782 he was appointed surgeon-major to the hospital *De la Charitk,* and in 1788 to the Hôtel Dieu. The clinical school of surgery which he instituted at the Hôtel Dieu attracted great numbers of students, not only from every part of France but also from other countries; and he frequently had an audienct of about 600. He died in Paris on June 1, 1795. Together with François Chopart (1743–95) he published a *Traitk des maladies chirurgicales* (1779), and Bichat published a digest of his surgical doctrines in *Oeuvres chirurgicales de Desault* (1798–99).

DESBOROUGH, JOHN (1608–1680), English soldier and politician, son of James Desborough of Eltisley, Cambs., married in 1636 Eltisley Jane, daughter of Robert Cromwell of Huntingdon, and sister of the future Protector. He fought on the parliamentary side in the Civil War, but avoided all participation in the trial of the king in Jan. 1649, being employed in the settlement of the west of England. He fought at Worcester as major-general and nearly captured Charles II. near Salisbury. During the Commonwealth he held many high offices and was a member of the parliaments of 1653, 1654 and 1656. In spite of his near relationship to the Protector's family, he violently opposed the assumption by Cromwell of the royal title, and after the Protector's death he was, with Fleetwood, the chief instigator and organizer of the hostility of the army towards Richard Cromwell's Administration, and forced him to dissolve his parliament in April 1659. He was chosen a member of the council of State by the restored Rump, but presenting with other officers a seditious petition from the army council, on Oct. 5, was dismissed. On the return of the Rump, Desborough was ordered to quit London. The reign of the new military Government was brief and inglorious, and after the Restoration he escaped to Holland where he engaged in republican intrigues. He was ordered home, in April 1666, on pain of incurring the charge of treason, and was imprisoned in the Tower till Feb. 1667. Desborough's rough person and manners are the constant theme of ridicule in the royalist ballads, and he is caricatured in Butler's *Hudibras* and in the *Parable of the Lion and Fox.*

DESCANT or **DISCANT,** a musical term much employed in earlier centuries, when it had various meanings. Thus it was at one time a term for any kind of polyphony and even for musical composition in general. In a more special sense it signified the addition of one part to another and-was thus the earliest term for counterpoint. In part music it meant the upper part or voice, especially the soprano or melody, while it also signified at a later period an instrumental piece consisting of what would be called nowadays a theme with variations. In modern usage, however, descant means primarily the early art of counterpoint, with its various rules and theories and successive forms, as practised from the 12th century onwards. What was known as the descant clef was the C, or treble, clef, with the sign placed on the lowest line of the staff. *(See* CLEF.)

DESCARTES, RENE (1596–1650), French philosopher and man of science. The name is sometimes given as Des Cartes, and sometimes in the Latinized form, Renatus Cartesius (whence the term *Cartesian).*

LIFE AND WRITINGS

Descartes was born at La Haye, in Touraine, on March 31, 1596. His grandfather, Pierre Descartes, was a doctor in Châtelleraut, in Poitou, who married the daughter of a medical colleague there, named Ferrand, who eventually became rector of the University of Poitiers. Pierre's son, Joachim, was councillor of the parliament of Rennes, and so a member of the lesser nobility. He married Jeanne Brochard, the daughter of a high law-officer of Poitiers. René was their third child. The house in which he was born at La Haye was his mother's property which she had inherited from her mother. She died in May 1597, when René was little more than a year old. About ten years later Joachim Descartes moved to Brittany, where he married a second time. Various members of the Descartes and Brochard families were men of learning, so that the scientific attainments of René Descartes were not really as exceptional as used to be supposed when it was thought that his ancestry was essentially military. The story of his military ancestry must be dismissed as a legend based on a confusion between his medical grandfather and an army officer of the same name.

Physically René Descartes was never robust. But already at an early age he displayed remarkable mental vigour, so that his father was wont to refer to him as his "little philosopher." In 1604, at the age of eight, he was sent to the Jesuit school at La Flhche, in Anjou. The school had only recently been founded and endowed by Henry IV. in the hope of ingratiating himself with the Jesuits, one of whom had tried to assassinate him in 1594. The rector of the school, during the latter part of Descartes' stay there, was Father Charlet, a kinsman of his, who naturally took a special interest in him. The teacher to whose special care he was entrusted was Father Dinet, who subsequently became confessor to Louis XIII. and Louis XIV. When Henry IV. was assassinated in 1610 Descartes was one of the pupils selected to receive the heart of the dead monarch for burial in the church of La Flhche.

The first five years of Descartes' school life were devoted to the then usual school subjects, especially to the classical languages. The last three years were devoted to the study of logic and ethics, mathematics and physics and metaphysics respectively. His health called for some special indulgence, and he was allowed to stay in bed as long as he liked. Then, as afterwards, a considerable part of his work appears to have been done in bed. But he had no difficulties with his studies. He mastered them with ease, distinguishing himself especially in mathematics. Many years afterwards he criticized rather severely the studies he had pursued at school.

But it is difficult to say to what extent, if any, those criticisms express his actual feelings while he was still at school. They were probably after-thoughts. In any case, they were not especially directed against his school, but rather (like Bacon's criticisms in the *Advancenzent of Learning)* against the general state of contemporary studies. Towards his school he always retained a feeling of warm attachment. Later, during his controversies with Bourdin and Voetius, he turned to his former school teacher, Father Dinet, for advice. And throughout his life Descartes showed a special regard for Jesuits. It seems to have been his greatest ambition in after years to get his own philosophy introduced at La Flèche and in other Jesuit colleges. But no details are available about his school life and friends. In later life he had among his intimate friends some former pupils of La Flbche, notably Marin Mersenne, who was about seven years his senior. But there is no evidence of their acquaintance prior to 1622.

Descartes left school in 1612, and appears to have studied from 1613–16 at the university of Poitiers, where he graduated in law in Nov. 1616. His older brother was already a lawyer, but he himself was not attracted by the legal profession, and seems to have been contemplating a military career. So he devoted himself to riding and fencing, and actually wrote an essay on the art of fencing. But next to nothing is known of his doings during 1613–17. In 1618 he left France apparently in search of military experience in Holland. He served as a gentleman volunteer in the army of the stadtholder, Prince Maurice of Nassau, at Breda. Of any real soldiering there is no evidence. His stay at Breda was only remarkable for his chance meeting with a brother mathematician, Isaac Beeckman, rector of the college at Dort. Mathematics was useful for military engineering, so there were a number of mathematicians in the stadtholder's entourage at Breda. In the absence of more urgent business some of them passed the time in propounding problems which they posted on the city walls with a challenge to others to solve them. One day Descartes was trying to get at the gist of such a challenge, which was written in Dutch. He turned to a bystander with the request to translate it for him into French or Latin. It happened to be Beeckman, who did as requested, and jestingly asked the French cadet to solve the problem. Descartes brought him the solution in a couple of days, and the chance acquaintances became friendly. Descartes gave Beeckman a manuscript *Essay on Algebra,* also a *Compendium of Music* (dated Breda, Dec. 31, 1618) which he dedicated to Beeckman. Some of the scant information about Descartes relating to this period consists of entries in the diary of Beeckman, which has fortunately been discovered in recent years.

In April 1619 Descartes left Holland. He had planned an extensive journey from Amsterdam to Copenhagen, and thence via Poland, Hungary and Bohemia to Bavaria. This very roundabout route to Bavaria seemed necessary because of the insecurity of the direct route from Holland to Bavaria owing to military conditions in the intervening area. But there is no evidence that Descartes carried out his plan. What is known is that he was in Frankfurt a.M. that summer, and there witnessed the festivities in connection with the coronation of the emperor Ferdinand. The following autumn and winter he seems to have passed in a village near Ulm on the Danube. Ostensibly he was taking part in the military campaigns which marked the opening of the Thirty Years' War. In reality he seems to have been occupied with problems of mathematics. Ulm was noted for its mathematicians, including Faulhaber (a reputed Rosicrucian) whom Descartes most probably met there. His stay near Ulm was chiefly remarkable for a certain illumination and certain dreams which he experienced there. He appears to have spent much of his time in solitary brooding over the problem of human knowledge. Moods of doubt and darkness assailed him, and he prayed for light. Of all his studies up to that point only one had really satisfied him, namely, mathematics. And he attributed the certainty of mathematics to the character of its method. On Nov. 10, 1619, the thought appears to have flashed upon him suddenly that the mathematical method, or, more precisely, the method of analytical geometry, might be extended to other studies. The thought dominated his mind like a divine revelation. Three dreams followed. In the first he appeared to be lame, and forced by a tempest to seek shelter in a church. In the second dream he heard the sound of thunder, and saw sparks of fire round about him. In the third he opened at random the poem of Ausonius, and his eyes fell on the words *Quid vitae sectabor iter?* (What way of life shall I follow?) The whole experience made such a deep impression on him that he vowed a pilgrimage to our Lady of Loretto. Whatever psychoanalytic interpretation one may put on the whole episode, there is no doubt of its profound effect on Descartes. He saw light. And it was probably at this period of his life that he arrived at his fundamental ideas relating to algebra, geometry and methodology. The years 1620–28 were no doubt devoted mainly to the elaboration and application of these ideas.

In 1620 Descartes visited Austria and Bohemia. He is reported to have served as a volunteer in the army of the duke of Bavaria against the protestant princes, and to have taken part in various battles, including that of the White Mountain, near Prague, which ended in the defeat of the Protestant princes and the downfall of Frederick V., father of the Princess Elizabeth of whom more will be said presently. But there is no reliable evidence for these dubious attempts to surround Descartes' head with a halo of military glory. Most probably he never smelled gunpowder. In April 1622 he was in France again, and stayed partly at Rennes and partly in Paris, until March 1623. He then went to Italy on certain family business. On May 16 (Ascension Day), 1624, he was in Venice and witnessed the symbolic ceremony of "the wedding of the sea" (the Adriatic). From Venice he went on his pilgrimage to our Lady of Loretto. Christmas 1624 saw him in Rome, where, in 1625, he witnessed the celebration of the Roman Catholic "Jubilee" (the Papal remission of the sins of the pilgrims). On his return he passed through Florence, but did not trouble to visit Galileo there. Indeed, in a subsequent letter, Descartes declared with emphasis that he had never learned anything from the writings of Galileo. The Loretto pilgrim could hardly have been expected to show sympathy for a semi-heretic like Galileo.

It appears that about this time Descartes was seriously thinking of settling in Italy, but the heat was too much for him. So he returned to France, passing the next three years partly in the country and partly in Paris. His contact with learned men in Paris stimulated his philosophic and scientific ambitions. Cardinal Bérulle, Mersenne and Mydorge were particularly encouraging to him. For a time he carried on research in optics with the help of Ferrier, a skilled maker of lenses. But the distractions of Paris were not conducive to fruitful work. Descartes consequently decided to move to some quiet place in Holland where he might devote his undivided attention to the problems of philosophy and science. He had seen enough of the bustle of the great world, and he longed for some quiet retreat where he might collect his thoughts and pursue his researches undisturbed by the claims of friends and acquaintances, or by other distractions. He had sold his estate and invested the proceeds to yield a comfortable income. His friends, Picot and Mersenne, undertook to look after his interests in France. So he felt free to settle where he liked.

In the autumn of 1628 Descartes went to Holland. He was in Dordrecht on Oct. 8. Nearly all the remaining years of his life were spent in Holland. He changed his place of residence many times for various reasons. But we know in what places he lived, and when, more or less accurately. It appears that in his choice of a locality he always considered the opportunities they afforded of practising catholicism. His first home in Holland was at Franeker (near Groningen), where he stayed from 1628–30, and it was here that he wrote his *Rules for the Direction of the Mind,* in 1628 or 1629, though it was not published till 1701. It may be recalled that his earliest known compositions, namely, the *Essay on Algebra* and the *Compendium of Music,* were written in Breda in 1618. In fact nearly all the works of Descartes were written in Holland. From 1630–32, and again from 1633–34, he lived in Amsterdam. Amsterdam was the London of that time in many ways. Another Frenchman who lived there in the 17th century described Amsterdam as "the most beautiful city of Europe." And Descartes evidently enjoyed his life there. In one of his letters to Balzac, dated Amsterdam, May 15, 1631, Descartes expressed

his deep satisfaction with his life there, and some of his reasons for it.

"In this great city where I now am," he wrote, "everybody but myself is in business and so engrossed with his profits that I could live here all my life without being noticed by anyone. I take my walk every day amid the Babel of a great thoroughfare with as much freedom and repose as you could find in your garden walks; and I observe the people whom I see just as I should the trees that you find in your forests or the animals that graze there; even the noise of their bustle does not disturb my reveries more than would the murmuring of a stream. When I consider their activities I derive the same pleasure which you have in watching the peasants till your fields, for I see that all their toil helps to adorn the place of my abode, and supplies all my wants. If there be pleasure in seeing the fruit grow in your orchard . . . think you there is not as much in seeing the vessels arrive which bring an abundance of all the produce of the Indies and all that is rare in Europe? What other place could you choose in all the world where all the comforts of life and all the curiosities that can be desired are so easy to find as here? What other country where you can enjoy such perfect liberty, where you can sleep with more security, where there are always armies afoot for our protection, where poisoning, treacheries, calumnies are less known, and where there has survived more of the innocence of our forefathers?"

In 1632 Descartes moved to Deventer. Here apparently he met a certain Hélène who, in 1635, bore him a child, which was christened Francine Descartes, and died at the age of five. It was during his stay in Deventer that Descartes heard of the Inquisition's condemnation of Galilei, in 1633, for supporting the Copernican hypothesis that the earth moves round the sun. Descartes had already written the greater part of a treatise, called The World, in which the Copernican hypothesis had been adopted. He at once abandoned the idea of completing and publishing the book, in the hope of discovering some more orthodox form of Copernicanism. This he eventually discovered in his vortex theory. Part of 1633 and 1634 was spent in Amsterdam. Descartes then moved to Utrecht in order to be near his first disciple, Reneri, who was professor at the university there.

From Utrecht Descartes went to Leyden, where he lived during 1636 and 1637, and again in 1640 and 1641. It was during his first stay here that he published, in 1636, the volume of essays containing the Discourse on Method, the *Dioptric,* Meteors and Geometry; and during his second stay here he published, in 1641, his Meditations on First Philosophy, together with Objections by Arnauld, Gassendi, Hobbes and others, and his Replies to them. From 1637–40 Descartes lived at Santpoort. After his second residence at Leyden he moved, in 1641, to Endgeest, near Leyden, where he remained till 1643. Here, in 1642, he was visited by Sorbikre, the French courtier, traveller and gossip, whose Voyage to England subsequently caused so much annoyance to the Royal Society of London. And we are indebted to Sorbikre for an interesting sketch of Descartes' life and surroundings at Endgeest. This is what he has written. "I was delighted with the civility of this *gentilhomme,* his retreat, and his household. He lived in a small château, beautifully situated, near a great and fine university (Leyden), three leagues from the court, and hardly two hours from the sea. He had a sufficient staff of servants, all well chosen and comely people; a nice garden with an orchard beyond it; and all around there were pastures from which stood out many steeples of various heights, until in the far horizon they appeared as mere points. He could go in a day by canal to Utrecht, Delft, Rotterdam, Dordrecht, Haarlem or Amsterdam. He could spend half his day at The Hague, and return in the evening, making this excursion by the most beautiful road in the world, through meadows and houses of pleasance, then through a great wood bordering this village, which is not inferior to the fairest towns of Europe, and boasted at that time the residence of three courts. That of the prince of Orange was quite military. . . . That of the States-General was composed of deputies from the united provinces and of burgomasters . . . the court of the queen of Bohemia, widow of King Frederick V., the elector-palatine, might be compared to that of the Graces, where all the fashionable world of The Hague went almost daily, to pay their homage to the talent, virtue and beauty of her four princesses, the eldest of whom (Elizabeth) had a fancy for the discourse of M. Descartes."

In the meantime Descartes was having his share of trouble too. His leading ideas were known to various scholars several years before they were published in book-form. Already in 1634 some of his doctrines were taught in the university of Utrecht by Reneri. It was in order to help Reneri in this work that Descartes had removed to Utrecht in 1635. The publication of the Discourse, etc., in 1636 soon involved Descartes in numerous controversies with mathematicians in Belgium, Holland and France, notably with Fermat. And for the rest of his life Descartes was frequently involved in controversies which sometimes embittered him, and which probably had something to do with his decision to go to Stockholm in 1649. Perhaps the most unpleasant of these controversies was that with G. Voetius, a Protestant divine and zealot, and rector of the university of Utrecht. When Reneri died in 1639, the funeral oration delivered by Emilius, lauded the dead scholar's friendship with Descartes, and incidentally Descartes himself. Voetius, a protagonist of ancient philosophy as allied with his theology, became alarmed and took an early opportunity to hint at the atheism of the new philosophy. In 1641 Regius, another Utrecht professor who for a time was an enthusiastic follower of Descartes, openly advocated certain Cartesian theses which so alarmed Voetius that he persuaded the magistrates of Utrecht, as well as the university, to pass judgment in favour of the old philosophy against the new. In 1642 Descartes brought out the second edition of his Meditations, with an introductory Lettre au P. Dinet, containing an attack on Voetius, who was so furious that he not only complained again to the magistrates, but also instigated the publication of a violent attack on Descartes in a pamphlet entitled Admiranda *Methodus* sive *Philosophia* Cartesian~ostensibly written by M. Schoock, who subsequently disowned it. Descartes replied in *Epistola* ad *Celeberrimum* Virum Gisbertum *Voetium* (May 1643). Thereupon the magistrates of Utrecht summoned Descartes to appear before them. Descartes did not appear, but sent them a letter. He was summoned a second time, and judgment was passed against him by default. Thanks to the intervention of influential friends at The Hague, the matter went no farther. The Utrecht magistrates simply decreed, in 1645, that nothing should be published either for or against the new philosophy. Descartes was also attacked by some of the professors at Leyden. And to crown it all he was soon involved also in a quarrel with Regius, whose aggressive advocacy of Cartesianism (as he understood or misunderstood it) had been the chief cause of the trouble with Voetius. The results of this quarrel were a Programma by Regius, and a reply by Descartes, Notae in Programma, in 1647.

However, if Descartes had some enemies in Holland among people like Gisbert Voetius, he also had many friends and admirers, and among these was the Princess Elizabeth to whom Sorbière referred in the passage cited above. As has already been mentioned above, Frederick V., the father of Elizabeth, had met with disaster at the battle of Prague (Nov. 1620). He lost the crowns of Bohemia and of the Palatinate, and was also deprived of his estates in Germany. He sought refuge in Holland, residing with his large family at The Hague, where he maintained a kind of court. His wife was Elizabeth Stuart, the sister of another unfortunate monarch, Charles I. Prince Rupert, who won and lost a great reputation as cavalry officer in the Civil War in England, was their third son. Another son, Charles Louis, was eventually reinstated in the palatinate, and showed his liberality of mind by inviting Spinoza, in 1673, to the chair of philosophy in the university of Heidelberg. Princess Elizabeth seems to have been the most bookish member of the family. She was about 19 when Descartes published his Discourse on Method (1637). She read it with great interest, as also subsequently his *Meditations* (1641), and made his personal acquaintance about 1640. Descartes dedicated to her his Principles of Philosophy, in 1644; and the dedicatory letter which he addressed to her shows what a deep impression she had made on him.

"The greatest advantage (Descartes wrote) I have derived

from my writings is the honour of becoming acquainted with your highness, and of being permitted at times to converse with you, and thus becoming a witness of your rare and estimable qualities; and I am sure that I shall render a service to posterity by holding them up as an example. It would be foolish of me to flatter, or to state what I am not convinced of, on the first page of a book in which I seek to expound the fundamental principles of knowledge. . . . I have met no one who has such a thorough and comprehensive understanding of my writings as you have. Even among the best and most cultivated minds, there are many who find them very obscure; and nearly always those who are familiar with mathematics cannot comprehend metaphysics, while those conversant with metaphysics cannot understand mathematics. The only mind, as far as my experience goes, to which both alike are easy, is yours; and so I am compelled to regard it as incomparable. And what increases my admiration is that it is not an aged man, who has given many years to study, in whom such wide and scientific knowledge is found, but a young princess whose charms resemble the Graces, as the poets describe them, rather than the Muses or the wise Minerva. I see in your highness all those excellences that are requisite to pure and sublime wisdom on the part, not only of the mind, but of the will and character; magnanimity and gentleness are united with a disposition which an unjust fortune with its persistent persecutions has not been able to embitter or discourage. It is this high-minded wisdom that I reverence in you; and I dedicate to it not only this work, because it treats of philosophy or the study of wisdom, but myself and my services." Apparently Descartes met the Princess Elizabeth fairly frequently during the years 1641 till 1643 when they lived near one another; but they do not seem to have met again after Elizabeth left The Hague in that year, though various letters passed between them almost to the time of his death, including one letter in which he condoled with her on the execution of her uncle, Charles I. Elizabeth lived for a time in Berlin, then in Heidelberg with her brother, and eventually she became abbess of the abbey of Herford (in Westphalia), where she died on the 30th anniversary of the death of Descartes (Feb. 11, 1680).

Descartes left Endgeest in 1643, and lived at Egmond-op-den-Hoef till 1644. His next, and last, place of residence in Holland was at Egmond-Binnen, near Alkmaar. Here he wrote his *Treatise on the Passions of the Soul* in 1649.

During the 21 years that Descartes lived in Holland (1628–49) he visited France on only three occasions, namely, in 1644, 1647 and 1648. The last of these visits was in connection with a royal pension, and in the hope of securing a congenial and important post in Paris. But he arrived in Paris at an unpropitious moment. It was on the eve of the civil war (the Fronde). So he hurried back to Holland empty handed.

In the meantime Chanut, the French resident at Stockholm, was trying to interest Christina, the queen of Sweden, in the philosophy of Descartes. Some correspondence followed, and in Feb. 1649, Descartes was invited to Stockholm. After his experience of royal patronage in Paris the year before, Descartes held back. A Swedish admiral was then sent to fetch him. But he hesitated still. Finally, however, he left Holland in Sept. 1649 for the Swedish court. Queen Christina received him in two audiences. He figured in various court functions, which did not appeal to him, and he regretted he had left Holland. Eventually it was arranged that Descartes should visit the queen three times a week at five in the morning in order to instruct her in his philosophy. But the severity of the northern winter and these unusually early hours were too much for Descartes. He became ill on Feb. 1, 1650, and died ten days afterwards.

THE PHILOSOPHY OF DESCARTES

Methodology. — Like Bacon, his older contemporary, and Spinoza, his younger contemporary, Descartes was deeply interested in the problem of method — the determination of the right method for obtaining real knowledge by the natural light of reason. Like numerous thinkers before him Descartes was thoroughly dissatisfied with the method of scholasticism then still in vogue. The scholastic method, on which Descartes had been nurtured at La Flèche, consisted mainly in attempting to solve problems by citing the views of more or less eminent writers or "authorities," instead of dealing with the problems themselves. It called for much book-learning, as well as much ingenuity in reconciling or harmonizing conflicting authorities, but it did not encourage independent research or thought. Now Descartes was not a bookworm by nature, and his early acquired habit of spending much time in bed was also more conducive to thinking than to much reading. Moreover, his genius was essentially mathematical; and in mathematics the question of "authority" did not arise even at his Jesuit school, where it counted in most other studies. Accordingly, we find Descartes engaged in questions of method already at an early stage in his career, and returning to them again and again subsequently. They are dealt with in his unfinished *Rules for the Direction of the Mind* (1628), in his fragmentary dialogue *The Search after Truth* (probably written either in 1628 or in 1641), in his *Discourse on the Method of Rightly Conducting the Reason* (published in 1637), in his *Meditations on First Philosophy* (published in 1641), and in *The Principles of Philosophy* (published in 1644).

In his autobiographical *Discourse*, Descartes relates how his dissatisfaction with book-learning came upon him. "I have been nourished on letters since my childhood, and since I was given to believe that by their means a clear and certain knowledge could be obtained of all that is useful in life, I had an extreme desire to acquire instruction. But so soon as I had achieved the entire course of study, at the close of which one is usually received into the ranks of the learned, I entirely changed my opinion. For I found myself embarrassed with so many doubts and errors that it seemed to me that the effort to instruct myself had no effect other than the increasing discovery of my own ignorance. And yet I was studying at one of the most celebrated schools in Europe. . . . I learned there all that others learned . . . and I did not feel that I was esteemed inferior to my fellow-students. . . . And this made me take the liberty of judging all others by myself and of coming to the conclusion that there was no learning in the world such as I was formerly led to believe it to be." And in his *Rules* he promptly demands that the investigation of any problem should not be dominated by what others have thought about, but by what we ourselves can see clearly or infer with certainty. "For" (he explains) "we shall not, for instance, become mathematicians, even if we know by heart all the proofs that others have elaborated, unless we have an intellectual talent that fits us to resolve difficulties of that kind. Neither, though we have mastered all the arguments of Plato and Aristotle, if we have not the capacity for forming a solid judgment on these matters, shall we become philosophers."

The one study which gave him real satisfaction was mathematics, "because of the certainty of its demonstrations and the evidence of its reasoning." He felt that there must be something about mathematics which made it a model for other studies. And he recalled with some satisfaction that "the earliest pioneers of philosophy in bygone ages refused to admit to the study of wisdom anyone who was not versed in mathematics, evidently believing that this was the easiest and most indispensable mental exercise and preparation for laying hold of other more important sciences." Now Descartes did not exaggerate the importance of mathematics after the manner of Pythagoras, as did even some of the most eminent astronomers of the 16th and 17th centuries. On the contrary, he speaks rather contemptuously of pure mathematics as such, remarking that "there is nothing more futile than to busy one's self with bare numbers and imaginary figures in such a way as to appear to rest content with such trifles." It was only the *method* of mathematics that appealed to him. And gradually the conviction grew on him that the method of mathematics could be extended to other sciences. Reference has already been made above to his experience on Nov. 10, 1619, for which he went on a pilgrimage to our Lady of Loretto. In course of time he formed the idea of "a species of mathematics," or a kind of "universal mathematics," that shall be applicable to all kinds of investigations. What he was thinking of was what may be called a Meth-

odology, or a study of scientific method, calling it a "species of mathematics" simply because "mathematics" literally means science. Methodical procedure in research was regarded by Descartes as of first-rate importance. Random search for knowledge and trust in some chance luck he condemned as at once fruitless and intellectually demoralizing.

Now the method of mathematics consists in beginning with the simplest notions and then proceeding cautiously to deduce inferences from them. Similarly in all scientific investigations one should begin with the simplest and surest notions, and advance logically to more complex truths by a progressive synthesis of the simpler factors; that is, by deduction. Descartes realized, of course, that knowledge is derived from experience as well as from deduction. But, in striking contrast with Bacon (whose *Novum Organum* he praised and commended to those who wished to follow the empirical path), he put more faith in deduction than in experience. Experience begins with very complex objects, and so our inferences from it are frequently fallacious, whereas deduction, according to Descartes, cannot be erroneous if carried out with moderate understanding. "This" (he says) "furnishes us with an evident explanation of the great superiority in certitude of arithmetic and geometry to other sciences. The former alone deal with an object so pure and uncomplicated, that they need make no assumptions at all which experience renders uncertain, but wholly consist in the rational deduction of consequences." The moral he draws is that "in our search for the direct road towards truth, we should busy ourselves with no object about which we cannot attain a certitude equal to that of the demonstrations of arithmetic and geometry."

The first problem of method turns on the starting-point, the simple notions or principles which furnish the material for the subsequent deduction. If the initial premises are false even the soundest deduction cannot lead to knowledge. How then do we come by our simplest notions or principles? "The first principles," says Descartes, "are given by intuition alone." And by *intuition* he means "the undoubting conception of an unclouded and attentive mind, which springs from the light of reason." Such intuitions are not uncommon. "Thus each individual can have intuition of the fact that he exists, and that he thinks; that a triangle is bounded by three lines only; a sphere by a single superficies, and so on. Facts of such a kind are far more numerous than many people think who disdain to direct their attention to such simple matters." Intuition and deduction, then, "are the most certain routes to knowledge." If any complex problem presents itself, the proper course is to analyse it into its simplest elements or notions, enumerate these carefully (this enumeration Descartes calls *induction),* make sure of each of them by intuition, and reason from them by deduction.

In the *Rules* Descartes made no attempt to get behind *intuition* as described, and exemplified above. The *Discourse on Method,* however, is much more sophisticated. It begins with a methodical doubt which is intended to serve as a severe test for whatever may claim to serve as the sure starting-point of knowledge. Everything must be questioned (de *omnibus dubitandurn)* so that we may discover something that is beyond doubt. At first everything seems to succumb to it—traditional beliefs, commonly accepted ideas, the very facts of direct observation may all be but illusions and dreams. Eventually, however, something is discovered that is beyond cavil; namely, doubt itself. He who doubts cannot doubt the reality of his doubting. But what is doubt? It is an act of thinking. And thinking implies a thinker. And so, says Descartes triumphantly, *Cogito, ergo sum*—"I think, therefore, I am." This, then, is an ultimate certainty. But why is it accepted as certain? Because it is so clearly and distinctly realized—it is an ultimate intuition that cannot be denied. This, however, implies that whatever is apprehended as clearly and distinctly is true. In this way Descartes found a philosophical basis for the acceptance of intuitions; and deduction from intuitions must at each step be as clearly and distinctly apprehended as the initial intuitions, though the connection between the final stage of a series of deductions and the initial intuitions may be a matter of memory rather than of immediate apprehension. Among the ultimate intuitions Descartes evidently included the principle of universal causation, otherwise he could never have passed from *Cogito, ergo sum* to the existence of God, and from the existence of God to the reality of things that are clearly and distinctly apprehended. But these questions pertain to his metaphysics.

Metaphysics — Descartes once compared himself to Archimedes. This Greek founder of mechanics had said that if he could only find a fixed point in space to serve as a fulcrum for a suitable lever, he could lift the whole earth. Similarly, Descartes, in his stage of methodical doubt, said that if he could only discover something indubitable he would rear on it a whole system of real science. And, as was explained above, Descartes found the required bedrock in the activity of doubt itself, in thought—*Cogito, ergo sum.* By "thought" he meant not only what is commonly meant by that term (the reflective solution of difficulties), but almost every kind of mental experience. "By the word thought I understand all that of which we are conscious as operating in us. And that is why not only understanding, willing, imagining, but also feeling are here the same thing as thought." But, even if we substitute the term "consciousness" for Descartes' "thought," what exactly is the extent of the knowledge furnished by the certainty that "I think"? It seems to be extremely limited, and to amount to no more than "*I* think" or "I am a thinking (or conscious) being," or "I experience certain mental processes or ideas." It does not warrant the reality of the apparently material objects of our perceptions; it does not prove the reality even of the body of the thinker. For in dreams such experiences occur although admittedly there are no such material objects corresponding to them. And, adds Descartes, "the same thing, perhaps, might occur if *I* had not a body at all." If so, thought might be a purely subjective matter, and throw no light at all on the question of the reality of an external world. There would be little comfort in the certainty that "I think, therefore I am" if the world of which *I* am conscious is but my dream-world, and "I" am but a solitary dreamer. It seems evident that Descartes' line of thought might end in so-called subjective idealism, or even in solipsism. It would be no great exaggeration to say that modern idealism and solipsism are the direct offspring of Descartes' thought. This, no doubt, may be regarded as a measure of his influence on modern philosophy; it may also be regarded as a measure of the mischief which he has wrought. Descartes did not consider sufficiently the claims of our waking consciousness to a direct apprehension of real external objects; his argument about dreams is not convincing, for, after all, it is easy enough to distinguish between dreaming and waking consciousness, and people are sometimes mistaken about what they think that they really think. He was probably betrayed partly by a bias common among mathematicians from the days of Pythagoras and Plato onwards, and partly by the early Christian tendency (under Platonic and Neo-Platonic influence) to belittle the material world. The former was probably the more important influence. Mathematicians as a class are so preoccupied with ideal or mental constructions that they are apt to exaggerate the powers of pure thought. Descartes clearly betrays this tendency already at the very beginning of his *Rules for the Direction of the Mind,* where he speaks of knowledge as though it were a kind of illumination which streams forth from the mind in the same way, without regard to differences in the objects studied. "The sciences," he says, "are identical with human wisdom, which always remains one and the same, however applied to different subjects, and suffers no more differentiation proceeding from them than the light of the sun experiences from the variety of the things which it illumines."

Descartes himself, however, was not a solipsist or even an idealist; his religion and his science saved him from that. He had, therefore, to bridge the gulf between the mere *cogito* and the external world. This he endeavoured to do by making his "I think, therefore I am" an argument for the existence of God, and then making God's being the ground for his belief in the existence of an external world. Descartes offers three proofs for the existence of God, one of them is *a priori,* based on the implication of the very notion of God, the others are *a posteriori* and argue from effect to cause. The *a priori,* or ontological proof, adapted more

or less from St. Anselm, and most in accordance with Descartes' mathematical method, runs as follows: "When the mind considers the diverse conceptions which it has, it discovers the idea of a Being who is omniscient, omnipotent and absolutely perfect, which is far the most important of all; and in this idea it recognizes not merely a possible and contingent existence, as in all the other ideas it has of things which it clearly perceives, but one which is absolutely necessary and eternal. For just as when it perceives that it is necessarily involved in the idea of a triangle that it should have three angles equal to two right angles, it is absolutely persuaded that a triangle really has three angles equal to two right angles, so from the fact it perceives that necessary and eternal existence is comprised in the idea of an absolutely perfect Being, it must clearly conclude that this absolutely perfect Being exists." Of the a posteriori proofs the more important one is the so-called anthropological one based, not on the mere implication of the concept God, but on the existence of the idea in an existing but imperfect mind or minds. Descartes formulates it as follows. "As we find in ourselves the idea of a God, or a supremely perfect Being, we can investigate the cause which produces this idea in us. But considering the immensity of the perfection it possesses, we are constrained to admit that it can only emanate from an all-perfect Being, that is, from God who really exists. For it is not only made manifest by the natural light that nothing cannot be the cause of anything whatever, and that the more perfect cannot proceed from the less perfect as its efficient and total cause, but also that it is impossible for us to have any idea of anything whatever, if there is not within us or outside us an original which actually possesses all the perfections. But as we do not in any way possess all these absolute perfections of which we have the idea, we must conclude that they reside in some other nature different from ours, that is, in God." The other a posteriori argument infers the existence of God from the thinker's own existence, and his continued existence. These imply a Creator who has not only created the thinker, but maintains him in existence. For existence at one moment is itself no reason for existence at a subsequent moment, so that the conservation of whatever exists is really a continued creation.

The combined effect of all these arguments, taken in conjunction with his doctrine of innate ideas, of which the idea of God is one, may have been to give Descartes the conviction that he had in some way a direct intuition of God revealing Himself to Descartes through his innate idea of Him. But Descartes does not make himself clear on this point.

Having proved the existence of God as the supremely perfect Being, Descartes argues in the next place that God would not deceive the thinking beings He has created. So our sense-perceptions cannot be mere illusions, and there must exist an external world of Beings which we apprehend in perception. In this way, whereas his predecessors were wont to prove the existence of God from the existence of the world, Descartes inferred the existence of the world from the existence of God. But now he seems to have proved too much. Undoubtedly there are such experiences as illusions and errors. How shall we distinguish the real from the illusory? Descartes meets the difficulty by reverting to one of the main points in his methodology — we can only be sure of what we apprehend clearly and distinctly. Error is the result of the neglect of this precaution. It arises when our will goes beyond our understanding, as it often does. For our will has no limits, whereas our understanding is severely limited. And judgment, according to Descartes, is a decision of the will.

Clear and distinct apprehension must also be our guide in determining what these external material things essentially are. The sense-qualities, the so-called secondary qualities of things, such as colour, smell, etc., are not clearly and distinctly thinkable. Extension in three dimensions, and motion are the only features of material bodies that are clear and distinct to thought, and so they alone are the real essential features of material things, the so-called secondary qualities being but the subjective experiences of the percipient. In this way Descartes helped to lay the foundations of a mechanical interpretation of physical Nature. On the other hand the essential feature of minds is thought or consciousness. Minds are essentially thinking substances, just as bodies are essentially extended substances. For Descartes, accordingly, Reality consists of God, the perfect Being and Creator, and His Creations, namely, thinking substances, or minds, and extended substances, or bodies. And, prompted by his religious training, Descartes endeavours to set bodies and minds in extreme opposition to one another—whatever mind is, body is not. One result of this is that because mind is active, body is not, and so he conceives of motion, not as a property of bodies, but as something put into them by God. Another result is that there can be no interconnection between body and soul. Lower animals are consequently conceived by Descartes as mere automata, cleverly constructed mechanisms without soul. And the undeniable conjunction and apparent interaction of mind and body in human beings is in the last resort explained by the constant intervention of God.

The philosophy of Descartes has undoubtedly exercised a potent influence on modern thought, and to that extent the usual designation of Descartes as the father of modern philosophy is justified. But the intrinsic merits of his philosophy have been grossly exaggerated; and the exaggeration is itself due to a misinterpretation of Descartes' mentality. Descartes was a dual personality. Two tendencies struggled within him. On the one hand, there was the mathematical genius with a passion for clear and distinct ideas, and for logical deduction. On the other hand, there was the loyal Catholic, genuinely attached to a certain traditional theology. So long as he pursued problems of a purely scientific character, especially problems pertaining to pure or applied mathematics, he was in his element and showed his master mind. But the moment he attacked problems of general philosophic orientation, he was the traditional theologian rather than the revolutionary philosopher. Historians of philosophy have tried to save the philosophic reputation of Descartes by treating his theology as mere camouflage. But that is a mistake. Mersenne had a keen scent for heresy, yet he defended Descartes' orthodoxy; and Mersenne was well informed about Descartes. It is not very unusual even in the 20th century, it was certainly not unusual in the 17th century, for the same person to be a detached scientist when dealing with one set of problems, and a conservative theologian when dealing with another set of problems. And Descartes was of that type. In the same breath with which he asserted that the mind should admit no other methods than intuition and deduction, he also asserted "but this does not prevent us from believing matters that have been divinely revealed as being more certain than our surest knowledge, since belief in these things . . . is an act, not of our intelligence, but of our will." His abandonment of the idea of the earth's motion and his substitution of the vortex theory was probably due to his genuine regard for the authority of the Catholic Church, not to fear. Saumaise, who visited Descartes at Leyden in 1637, reports that he was a Catholic "des plus zélés." His whole orientation was essentially that of popular Christian theology, with its supernatural God, who created souls and bodies. And when he went the length of regarding distinctions between good and evil, between truth and falsehood as depending on the arbitrary decisions of the Divine Will, he really abandoned altogether the realm of rational philosophy for that of a particularly narrow mediaeval theology. Descartes' methodical doubt has misled people into supposing that he was a revolutionary philosopher. But in the history of human thought real "believers" have posed as sceptics almost as often as real sceptics have posed as believers.

DESCARTES' CONTRIBUTIONS TO SCIENCE

From what has already been said above about Descartes' Methodology, one almost expects that his endeavour would be to reduce all science to a kind of applied mathematics. And that is what he really did attempt. "I do not accept or desire," he wrote, "any other principle in physics than in geometry or abstract mathematics, because all the phenomena of nature may be explained by their means." Another way of expressing the same thing is to say that Descartes tried to reduce every science of natural phenomena to a branch of mechanics. But it must be remembered that for Descartes mechanics was essentially kinetics, not dynamics — a

calculus of changes of position, not a calculus of "forces." The progress of the physical sciences during the 17th and 18th centuries was due in large measure to the adoption of a mechanical interpretation of physical phenomena. This method of interpretation was initiated by Galilei and extended by Descartes. Its merits can only be appreciated when one recalls the "substantial forms," "hypostatical principles," "real accidents," and other mystifying conceptions of the pseudo-science which preceded the Cartesian attempt to interpret all natural phenomena by means of clear and distinct mechanical concepts. It was left to a later age to discover the inadequacy of an exclusively mechanical interpretation of natural phenomena. But this must not be allowed to detract from the merits of Descartes in the history of science.

Physics **and** Cosmology. — Descartes, by refusing to attribute to matter any sense-qualities, which are not reducible to clear and distinct ideas, reduced matter to extension in three dimensions. Matter thus coincided for him with space. One consequence of this was that he denied the existence of a vacuum. For the same reason he also rejected the existence of "atoms" in the literal sense of the term, for any minute part of space or extension remains theoretically divisible. But how does this apparently continuous extension come to assume the form of those detached material bodies with which we are familiar? Descartes explains this by reference to motion, which he regards as a separate creation of God, who also conserves its quantity. It is motion that leads us to distinguish separate bodies or parcels of matter. Any part of extension that moves together or simultaneously is regarded as such a body. Since, however, matter is extension and there is no vacuum, the motion of one body must be followed immediately by the motion of certain other bodies, so that the circle of extension may remain complete, without gaps. This idea of a circular motion of matter eventually suggested to him his theory of vortices. "All natural motions" (Descartes explains in Le Monde) "are in some way circular. When a body leaves its place, it enters that of another, and this enters that of yet another, and so on to the final one which occupies at the same instant the place left by the first. There is thus no vacuum between bodies when they move, any more than when they are at rest. To this end it is not at all necessary that all the moving parts should be arranged in a true circle, or be of like size or shape, for inequalities in these respects may be compensated for by other inequalities. We do not commonly observe these circular motions in the air, because we are accustomed to regard the air as an empty place. But if we observe fishes swimming in a basin we see that, if they do not approach too near it, they do not stir the surface, although they pass under it at a great speed. It is clear, therefore, that the water which they push before them does not push indifferently all the water in the basin, but only that which can best serve to complete the circle of their motion and enter the place which they have vacated."

Another consequence of Descartes' identification of matter with extension or space was his insistence on the unity of physical nature, which must be a *universe* because space is one and continuous. Both in his early work The *World* and in his *Principles* of Philosophy, Descartes attempted to give an account of the genesis or formation of the physical world. The account was intended to be purely hypothetical or speculative, not a rival theory to Genesis — just a flight of fancy based on Cartesian principles. "Give me extension and motion," he said in his earlier book, "and I will construct the world." Assuming that God has created a uniform matter (or extension) and endowed it with a fixed quantity of motion, which follows certain laws (namely, the laws of motion formulated by Descartes), how might a world (like the existing world) have come into being "by natural and gradual means"? Descartes answers the question somewhat as follows.

In a world closely packed with matter so that there is no vacuum in it the only kind of motion possible is that described above as circular motion or vortex (whirlpool) motion. Consequently when motion was imparted (by God) to matter, such vortices were set in motion — innumerable more or less circular eddies of material parts of all sorts of shapes, sizes and velocities. The friction set up by this vortex motion of closely packed material bodies results in the mutual rubbing off of their corners. And so we get, to begin with, two main kinds of material particles — the original particles rendered smooth and globular by the friction which rubbed their corners off, and the finer particles composed of the rubbings or filings. These fine particles Descartes calls "first matter"; the larger, globular particles he calls "second matter." There is yet a "third matter," namely, the most massive and heavy of the original particles that suffer no fracture or rubbing off in the vortex motion, and such other original particles as, thanks to their peculiar shapes, combined into larger, stronger combinations that similarly resisted all damage. The first kind of matter, the finest sort, tends towards the centre of each vortex, where it forms self-luminous suns and fixed stars. The second kind of matter, consisting of globular particles, tends to move away from the centre of the vortices in straight lines towards the circumference. It constitutes the transparent heavens, and transmits the light of the radiating stars. The third and grossest kind of matter is that of which the earth, the other planets, and the comets are composed — these are all opaque bodies.

In the Principles Descartes explains the formation of the comets and planets in this way. Sometimes as the smaller particles in a vortex pass through the interstices between the revolving globular particles, they get caught and become twisted and channelled, and when they finally reach the stellar matter at the centre of the vortex they form crusts or "sun-spots" on it. This may cause a diminution in the expansive force of the star, which is then caught up by a neighbouring vortex. If the velocity of the crusted star is greater than that of the encroaching vortex, the star will soon pass out of that vortex into another, and continue to wander from vortex to vortex. It is then known as a comet. But if the crusted star has a velocity equal to that of some part of the encroaching vortex, it will stay there and continue to revolve in that vortex. In that case it is known as a planet. The planets of the solar system are the crusted stars and their several vortices that have been swept up by the vortex of the sun.

The vortex theory enabled Descartes to reconcile Copernican with Biblical doctrine. In The World Descartes had embraced the Copernican theory of the earth's motion round the sun. The condemnation of Galilei, in 1633, made him drop the idea in the Copernican form. But by supposing the earth to be carried in its vortex round the sun, Descartes believed that he left the earth at rest in its vortex, and so satisfied the dogma of a stationary earth, while he also satisfied the Copernican theory inasmuch as he represented the earth's vortex as circling round the sun.

Descartes' Principles contains a detailed account of practically all the natural phenomena that had been investigated up to his time. It contains, of course, many errors. Even his fundamental laws of motion are mostly inaccurate. But it was an amazing attempt to reduce all natural phenomena to one system composed of one ultimate kind of matter and governed by the same laws of motion. One of its incidental results was the explanation of weight without recourse to gravitation. Bodies tend to fall towards the earth, according to Descartes, because the particles of the second kind of matter which move round the earth push those bodies towards the earth, and so give them what we call their weight. The popular conception of gravitation makes more or less an occult power of it. Newton's intention was merely to describe certain tendencies to movement without any attempt to explain them at all. Again, Descartes' rejection of the existence of a vacuum not only undermined the idea of Nature's abhorrence of a vacuum (horror vacui) which was wont to serve as an explanation of the action of water-pumps, but prepared the way to the correct explanation, namely the pressure of the air on the surface of the water. In fact Descartes claimed that he had anticipated Torricelli (the inventor of the barometer) and that, during his visit to Paris in 1647, he had suggested to Pascal the idea of the barometric experiment which the latter carried out on the Puy-de-Dôme on Sept. 19, 1648. Another important consequence of Descartes' rejection of a vacuum was that he was thereby led to give up the old corpuscular or emission theory of light, and to conceive of the transmission of light as a transmission of pressure from the luminous body through the intervening particles of secondary

matter to the sensitive eye. This view prepared the way for the undulatory theory of light which was soon afterwards formulated by Christiaan Huygens, the son of Descartes' friend and correspondent, Constantijn Huygens.

Descartes was deeply interested in optics, devoting to it not only his *Dioptric* (1636), but also parts 3 and 4 of his *Principles* (1644). He compares the transmission of light to the eye with the way in which a blind man feels his way with a stick. The resistances or pressures of the different objects (such as stones, trees, water, etc.) are transmitted along the stick to his hand and thence to his brain, so that he can distinguish them. Similarly no corpuscles actually pass from the visible objects to the eye, only a pressure through the fine particles which constitute the transparent medium. Rays of light are the line along which the pressure is transmitted. When they pass through a transparent medium they are straight, otherwise they are deflected or even stopped just like a moving ball when it encounters some obstruction. If the obstruction is hard, the ball rebounds in another direction; if soft, its movement will be arrested. Similarly, when a ray of light impinges obliquely on certain kinds of surfaces, it is reflected, and its angle of reflection is equal to the angle of incidence. But if the medium allows the ray to pass through with diminished speed, then it is refracted. In the *Dioptric* the law of refraction was published for the first time. Snell had discovered it in 1621, but did not publish it; and Descartes has sometimes been suspected of plagiarism. Most likely, however, Descartes discovered it independently.

Physiology. — The *World,* as originally planned by Descartes, was to have contained an hypothetical account of the development of the universe from chaos to man. Referring to this book, in June 1633, he said: "I shall treat of man to a greater extent than I proposed; I intend to explain the principal functions of his body, and I have already given an account of some of them, such as digestion, the beating of the pulse, the distribution of nutritious matter, the action of the five senses, etc. I have dissected the heads of various animals, in order to ascertain in what memory, imagination, etc., consist." The book was not published as it was then planned; but the results of Descartes' studies in this field are contained in his *L'Homme* (published in 1662), the first text-book on physiology. In accordance with the whole spirit of *The World,* of which the treatise on *Man* was originally meant to be the concluding part, the human body and its functions were treated by Descartes mechanically, like "an earthly machine." In this view he was greatly encouraged by the views of Vesalius (1515–64), the father of modern anatomy and physiology, and by Harvey's demonstration of the mechanical nature of the circulation of the blood (his *Exercitatio* was published in 1628), though Descartes did not entirely agree with Harvey. Descartes explains that blood is formed in the liver from the chyle of the food. This blood flows drop by drop into the right cavity of the heart which is so hot that the blood expands and is exhaled into the lung, whence it passes into the left cavity of the heart, and is thence distributed over the whole body. He describes the valves in the arteries which secure that the blood shall flow only drop by drop. Now of the blood which flows through the direct arteries from the heart to the brain, "the most agitated and vivified parts" are called "animal spirits." They are like "a very subtle air." By dilating the brain they enable it to receive impressions of external objects, and so give rise to sensation, imagination and retentive memory; by flowing from the brain through the nerves into the muscles, they enable the nerves to function as organs of the external senses; and by distending, and so contracting, the muscles, they effect the movements of the limbs. For Descartes the "animal spirits" were just a subtle fluid, the nerves were just tubes through which they flowed in a mechanical way.

He illustrates his strictly mechanical conception of the bodily machine as follows. "You may have seen in the grottoes and fountains which are in our royal gardens that the simple force with which the water moves when issuing from its source is enough to set in motion various machines, and to make various instruments play or utter words, according to the different arrangements of the tubes which convey the water. And so one may well compare the nerves of the machine which I am describing with the tubes of the machines of these fountains, the muscles and tendons with the other engines and springs which move the machines, and the animal spirits, the source of which is the heart and of which the cavities of the brain are the reservoirs, with the water which puts them in motion. Moreover, breathing and similar acts, which are natural and usual to the machine, and which depend on the flow of the spirits, are like the movements of a [water] clock or of a mill which the ordinary flow of water keeps going continually. External objects, which by their presence act on the sense-organs of the machine and so determine it to move in different ways according to the disposition of the parts of the brain, may be compared to strangers who, entering one of the grottoes containing many fountains, themselves cause unwittingly the movements they witness. For on entering they tread on certain tiles or plates which are so arranged that if they approach a bathing Diana they cause her to hide in the rose bushes, and if they try to follow her they cause a Neptune to come towards them threatening them with his trident. Or if they pass in another direction they make a sea-monster spring forward and spout water in their faces, or things of a like kind according to the caprice of the engineers who constructed them.

"In order to understand how the brain can be excited by external objects which affect the organs of sense, so that all the members can be moved in a thousand different ways, imagine that the delicate threads which arise from the inside of the brain and form the marrow of the nerves, are so disposed in all those parts which serve as the organs of any sense that they can be easily set in motion by the objects of the senses, and that whenever they are so set in motion, even ever so little, they pull upon the parts of the brain whence they originate, and so open certain pores on the internal surface of the brain. Through these pores the animal spirits in the ventricles pass into the nerves and then into the muscles which carry out movements like those to which we are incited when our senses are affected in that way. If, *e.g.,* fire comes near the foot, the minute particles of the fire . . . set in motion the skin of the foot, and by thus pulling the delicate thread attached to the skin there, they open the pore against which the thread ends, just as by pulling at one end of a rope one rings a bell at the other end."

In this way Descartes tried to explain physiological phenomena mechanically, and to banish from biology such conceptions as those of "vegetative" and "sensitive" souls, much in the same way as he and Boyle, and others, tried to banish from physics and chemistry such notions as those of "substantial forms," and occult qualities, etc. To this extent he rendered a service to biology in spite of his excessive proneness to follow the high a *priori* road, and to be satisfied with any fancies that seemed "clear and distinct" to him. He may be credited to some extent with the anticipation of the conception of "reflex movements," though these are not interpreted now in his purely mechanical fashion. He may also be regarded as the forerunner of modern "behaviourism," at all events as applied to the lower animals, for he would certainly have condemned a "soul-less" human psychology, as will be seen presently. His view of the lower animals as mere automata rather alarmed some people. But Descartes' main object was to vindicate the superiority of man over animals, even over his own animal body, in virtue of his "rational soul" or mind.

Body and Mind. — In Descartes' philosophy, as already explained, the human mind is "a thinking substance" *toto coelo* different from any "extended substances," including human bodies. Yet a human being seems to be an intimate association of a mind and a body, each influencing the other. How can the "extended substance" or "earthly machine" of the human body come into such intimate relation with unextended "thinking substance"? Descartes' ultimate solution of these, as of all other problems, lies in God, who graciously does all that Descartes thinks ought to be done. But as a more immediate, scientific solution of the problem, Descartes suggests that the mind comes into contact with the body in the conarion "whence it radiates through the rest of the body by means of the animal spirits, nerves and even the blood." The pineal gland "in the middle of the substance of the

brain" is the primary reservoir of animal spirits, the central cavity of the brain being the secondary reservoir. Reverting to the above-mentioned comparison with the mechanical inventions in the royal gardens, Descartes likens the function of the rational soul or mind presiding at the conarion to that of "the fountaineer who has to take his place in the reservoir whence all the different tubes of the machines proceed whenever he wants to start them, to stop them, or to change them in any way." Descartes thought he surmounted the difficulty of explaining the mutual influence of mind and body by supposing, on the one hand, that the conarion requires but a minimum of influence to incline it one way or another, and, on the other hand, that the "animal spirits" are such a subtle kind of air that they are on the verge of ceasing to be material. But according to his own philosophy the material remains material however fine it may be, and so remains entirely alien from the mental or spiritual.

Psychology.—The mind being, according to Descartes, a thinking substance entirely different from, and independent of, extended or material things, it "can work independently of the brain." This, at all events, is true of the most characteristic activities of the rational soul, "for clearly there can be no use of the brain for pure intelligence," says Descartes. Ideas in which pure intelligence expresses itself are innate, not derived from without, but from the rational soul itself. For Descartes, as for Plato, experience can only be the occasion for the recall of such ideas to consciousness. These ideas are not always explicit in our consciousness, rather they are latent in the "thinking substance," but they are not originated by experience, though experience may occasion their explicit recall. Among such innate ideas Descartes includes our "clear and distinct" ideas of God, of the self as a thinking thing, the axioms of mathematics and other so-called "common notions" like those of space, time and motion. Above all, perhaps, he finds the mind expressing itself most fully in acts of will, under which heading he includes all judgments and beliefs, as well as voluntary decisions. But then the mind is conjoined with a body, and they do somehow influence each other through the mediation of the conarion and the animal spirits, as already explained. One result of this is that in addition to the mind's own innate ideas, we have also "adventitious ideas" which come to us through the influence of external bodies, and also "factitious ideas" of merely imaginary objects which the mind puts together out of simpler "adventitious" and "innate" ideas. Descartes is not very clear or consistent in dealing with these problems. The idea of God, *e.g.*, is treated at once as "innate," and also as produced in us by God Himself, and therefore, in a sense, "adventitious." And his treatment of images is rather bewildering. Sometimes he treats images, in contrast with ideas, as something physical, and says: "no corporeal image is received in the mind; pure thinking is carried out without corporeal images; imagination, however, which can only arise in the case of corporeal things, needs an image, which is a truly corporeal thing; to this the mind applies itself, though the image is not received into the mind." At other times, however, he includes images, and even sensations and perceptions, under "thought," and distinguishes them from innate ideas, or pure thoughts, and volitions in so far as "imagination and sensation" need the brain as well as the mind; that is to say, in so far as they express not the pure *activity* of mind, but rather its *passivity*, the effect upon it of physical things, including the body with which it is mated. Hence he calls all such experiences "passions," under which heading he includes not only the feelings and emotions, but also sensation, retention, perception, and all adventitious ideas. The feelings are passions caused by the agitation of the animal spirits, but are not referred to any objects outside the body, whereas sensations are "passions" that are referred to external stimuli. Descartes' account of the emotions anticipates to some extent the James-Lange theory, inasmuch as it gives primary to the physical or physiological processes. Our perception of certain animals, *e.g.*, causes fear and flight immediately without the mediation of reason or volition, which only come into play afterwards. Since, however, the brain is the organ of the passions and also the seat of the rational soul, the passions can be brought under the control of the reason and the will. In fact, Descartes is quite Socratic in his insistence on the competence of right reason to conduce to right feeling and action.

The power which Descartes attributes to reason and will may seem to be little in harmony with his naturalistic, mechanical account of such large tracts of human experience. But, as already remarked, his great aim was really to vindicate the supremacy of the human mind or spirit. There was a marked tendency in his day, and long before him, to efface the sharp distinction between man and the lower animals by crediting the lower animals with human powers, including intelligence, which they were sometimes said to use more humanly than man. This tendency was mainly supported by the results of comparative anatomy, which showed essential similarity between the structures of human and animal bodies, including the central nervous system. Descartes tried to save the situation by regarding even the human body as a machine, and treating mechanically all such human experiences as might conceivably also be credited to lower animals, but claiming unique privileges for the rational soul, which he regarded as the *differentia* of man, and as absolutely independent of all that is material.

Mathematics.—Descartes has been described as the first modern mathematician. He was certainly one of the pioneers of modern mathematics. His only treatise on mathematics is the *Geometry* (1637) in which he laid the foundations of analytical or algebraic geometry. Descartes was not the first to apply algebra to geometry, or to conceive a line as generated by a moving point, or to solve geometrical problems by regarding them as solved and analysing the result ("analytic geometry" in the older sense). These things were already known to ancient and mediaeval mathematicians. But he applied these methods much more systematically and fruitfully.

He knew that a point in a plane can be fully determined if we know its distances from two given straight lines in the same plane (allowing for the sign-conventions relating to their different sides, and taking not perpendicular distances but distances parallel to given lines). If the distances be represented by x and y respectively, we can get an equation of the form $f(x,y)=o$. And although such an equation is indeterminate in the sense thst it can be satisfied by an infinite number of sets of values of x and y, yet these values determine the co-ordinates of a series of points which form a curve such that the equation in question is true of every point on it. He realized, moreover, that the properties of a curve can be ascertained by choosing as a definition any specific geometrical property, and expressing it as an equation by means of the co-ordinates of any point on the curve. Such an equation contains by implication all the properties of that curve. And any such property can be deduced from the equation by purely algebraic processes, and without direct reference to the geometry of the curve.

Descartes was the first to attempt a systematic classification of curves. First, he distinguished between "geometric" and "mechanical" curves, according as they could or could not be precisely expressed in equations. (These terms were subsequently displaced by Newton's terms "algebraic" and "transcendental.") Confining himself to "geometric" curves, Descartes classifies these into a series of classes of increasing complexity as follows. Class I. consists of curves (the circle, the parabola, the hyperbola and the ellipse) whose equations contain no term of higher degree than the multiple of two unknown quantities or the square of one. Class II. includes any curve whose equation contains one or more terms of the third or fourth degree in one or both of the two unknown quantities. Class III. contains curves whose equations include a term of the fifth or sixth degree in either or both of the unknown quantities, and so on. The curves are paired in each class in the way indicated because there are methods of reducing a curve of the fourth to one of the third degree, a curve of the sixth to one of the fifth degree, and so on. The straight line he regarded as an exceptional case of a curve of the second degree (Class I.).

In algebra Descartes' systematic application of it to geometrical measurement involved important consequences. It involved the geometric interpretation of negative quantities. It also led to the idea of continuity, which in its turn led to the theory of function

and to the theory of limits. Descartes, moreover, made important contributions to the theory of equations, to which the third and last book of his *Geometry* is devoted, and to which he appears to have been led by his (successful) efforts to solve the problems of doubling the cube and of trisecting an angle. It is also worth noting that we are indebted to Descartes for the convention of using the first letters of the alphabet to represent known quantities, and the last letters for unknown quantities. He also introduced our system of indices (although he frequently used xx instead of x^2). On the other hand, he used the sign ∞ instead of $=$ which Recorde had already introduced with its present meaning.

Descartes' general rule for solving equations is this. Write the equation in the zero form, and try to factorize the L.H.S. so as to reduce the equation to two or more equations of lower degree. If this is impossible, higher methods must be used. If the equation is of the third or fourth degree, the solution depends on the intersection of a circle with a conic. To solve equations of still higher degree, Descartes proposes the use of intersections of circles with the successive classes of geometric curves—conics being used to generate curves of Class II. and these again to generate curves of Class III., and so on. He thought that equations of any order could be solved in this way; but he was mistaken.

What is still known as *Descartes' Rule of Signs* is to the effect that an equation can have no more "true" (*i.e.*, positive) roots than its coefficients have changes of sign from + to −, and no more "false" (*i.e.*, negative) roots than the number of times two plus or two minus signs occur in succession.

Bibliography. — ***Oeuvres*** *de Descartes,* ed. by C. Adam and P. Tannery (13 vols., 4to, Paris, 1897–1911). This edition supersedes all other editions of Descartes' works. Since then some hitherto unpublished letters have been edited by L. Roth in *Correspondence of Descaries and Constantyn Huygens, 1635–47* (Oxford, 1926). The most reliable biography of Descartes is that by C. Adam, forming vol. xii. of the above-mentioned *Oeuvres de Descartes.* Of books for English readers the following are the most important: *The Philosophzcal Works of Descartes* rendered into English by E. S. Haldane and G. R. T. Ross (2 vols., 1911, 1912); Kuno Fischer, *Descartes and his School,* translated by *N.* Porter (1887); J. P. Mahaffy, *Descartes* (1902); E. S. Haldane, *Descartes, His Life and Times* (1905); *N.* Smith, *Studies in Cartesian Philosophy* (1902); L. Roth, *Spinoza, Descartes and Maimonides* (1924); The *Cambridge Modern History,* vol. iv., chap. 27, contains an account of "Descartes and Cartesianism" by E. Boutroux; *Science Progress* (No. 83, 1927) contains an account of "The Physical Work of Descartes" by F. Wootton; *The Geometry* of René Descartes, translated by D. E. Smith and M. L. Latham (1925); M. Foster's *History of Physiology* (1924) deals with Descartes' Physiology; and G. S. Brett's *History of Psychology* (vol. ii., 1921), treats of Descartes' *Psychology. See* also the Histories of Philosophy by J. E. Erdmann, H. Hoffding and W. Windelband; and articles CARTESIANS; PHILOSOPHY; PSYCHOLOGY, HISTORY OF. The best German translation is that by A. Buchenau, *Descartes' Philosophische Werke* (Leipzig, 1905–11). Of German books on Descartes the following are the most important: A. Hoffmann, *Rent Descartes* (Frommann's Klassiker der Phil., Stuttgart, 1922); K. Jungmann, *R. Descartes* (Leipzig, 1908); A. Kastil, *Descartes* (Halle, 1909); E. v. Aster, *Einfuhrung in die Phil. Descartes* (München, 1921); C. v. Brockdorff, *Descartes* (Munchen, 1923); E. Cassirer, *Descartes' Kritik der mathem. u. naturw. Erkenntnis* (Marburg, 1899), and *Das Erkenntnisproblem* (vol. i., book III. Berlin, 1911); P. Natorp, *Descartes' Erkenntnistheorie* (Marburg, 1882). Of recent French books the following may be mentioned: O. Hamelin, *Le Système de Descartes* (1911); G. Milhaud, *Descartes Savant* (1921); *E.* Gilson, *La Liberté chez Descartes et la Thtologie* (1913); H. Gouhier, *La Penste Religieuse de Descartes* (1924).

(A. Wo.)

DESCHAMPS, ÉMILE (1791–1871), French poet and man of letters, was born at Bourges. In 1818 he collaborated with Henri de Latouche in two verse comedies, *Selmours de Florian* and *Le Tour de faveur.* He and his brother were among the most enthusiastic disciples of the *cénacle* gathered round Victor Hugo, and in July 1823 Emile founded with his master the *Muse française,* which during the year of its existence was the special organ of the romantic party. His *Études françaises et étrangères* (1828) were preceded by a preface which may be regarded as one of the manifestos of the romanticists. The versions of Shakespeare's *Romeo and Juliet* (1839) and *Macbeth* (1844), important as they were in the history of the romantic movement, were never staged. He was the author of several libretti, among which may be mentioned the *Roméo et Juliette* of Berlioz. His works include two volumes of stories, *Contes physiologiques* (1854) and *Réalités fantastiques* (1854). He died at Versailles on April 23, 1871. His *Oeuvres complètes* were published in 1872–74 (6 vols).

His brother, Antoine François Marie, known as ANTONY DESCHAMPS, was born in Paris on March 12, 1800, and died at Passy on Oct. 29, 1869. Like his brother, he was an ardent romanticist, but his production was limited by a nervous disorder, which has left its mark on his melancholy work. He translated the *Divina Commedia* in 1829, and his poems, *Dernières Paroles* and *Résignation,* were republished with his brother's in 1841.

DESCHAMPS, EUSTACHE, called **MOREL** (1346?–1406?), French poet, was born at Vertus, Champagne. He studied at Reims, where he is said to have received some lessons in the art of versification from Guillaume de Machault, who is stated to have been his uncle. From Reims he proceeded *c.* 1360 to the University of Orleans to study law and the seven liberal arts. He entered the king's service as royal messenger *c.* 1367, and was sent on missions to Bohemia, Hungary and Moravia. In 1372 he was made *huissier d'armes* to Charles *V.* He received many other important offices, was *bailli* of Valois, and afterwards of Senlis, squire to the Dauphin, and governor of Fismes. In 1380 his patron, Charles V., died, and in the same year the English burnt his house at Vertus. In his childhood he had been an eye-witness of the English invasion of 1358; he had been present at the siege of Reims and seen the march on Chartres; he had witnessed the signing of the treaty of Bretigny; he was now himself a victim of the English fury. His violent hatred of the English found vent in numerous appeals to carry the war into England, and in the famous prophecy that England would be destroyed so thoroughly that no one should be able to point to her ruins. His own misfortunes and the miseries of France embittered his temper. He complained continually of poverty, railed against women and lamented the woes of his country. His last years were spent on his *Miroir de ntariage,* a satire of 13,000 lines against women, which contains some real comedy. The mother-in-law of French farce has her prototype in the *Miroir.*

The historical and patriotic poems of Deschamps are of much greater value. He does not, like Froissart, cast a glamour over the miserable wars of the time but gives a faithful picture of the anarchy of France, and inveighs ceaselessly against the heavy taxes, the vices of the clergy and especially against those who enrich themselves at the expense of the people. The terrible ballad with the refrain *Sà, de l'argent; sà, de l'argent* is typical of his work. Deschamps excelled in the use of the ballade and the chant royal. In ballade form he expressed his regret for the death of Du Guesclin, who seems to have been the only man except his patron, Charles V., for whom he ever felt any admiration. One of his ballades (No. 28j) was sent with a copy of his works to Chaucer, whom he addresses with the words:

> Tu es d'amours mondains dieux en Albie
> Et de la Rose en la terre Angélique.

Deschamps was the author of an *Art poétique,* with the title of *L'Art de dictier et de fere chancons, balades, virelais et rondeaulx.* He lays immense stress on the harmony of verse, because, as was the fashion of his day, he practically took it for granted that all poetry was to be sung.

The work of Deschamps marks an important stage in the history of French poetry. With him and his contemporaries the long, formless narrations of the *trouvères* give place to complicated and exacting kinds of verse. He was perhaps by nature a moralist and satirist rather than a poet, and the force and truth of his historical pictures gives him a unique place in 14th-century poetry. Raynaud fixes the date of his death in 1406, or at latest, 1407. Two years earlier he had been relieved of his charge as *bailli* of Senlis, his plain-spoken satires making him many enemies at court.

His *Oeuvres complètes* were edited (10 vols., 1878–1901) for the *Société des anciens textes français* by Queux dr Saint-Hilaire and Gaston Raynaud. The supplemrntary vol. ii. (1903) consists of an Introduction by *G.* Raynaud. *Set.* also E. Hoeppner. *Eustache Deschamps* (Strasbourg, 1904).

DESCHANEL, PAUL EUGENE LOUIS (1856–1922), French statesman, son of Émile Deschanel (1819–1904), professor at the Collilge de France and senator, was born at Brussels, where his father was living in exile (1851–59), owing to his opposition to Napoleon III. Paul Deschanel studied law, and began his career as secretary to Deshayes de Marcère (1876), and to Jules Simon (1876–77). In Oct. 1885 he was elected deputy for Eure and Loire. He was one of the most notable orators of the Progressist Republican group. In Jan. 1896 he was elected vice-president of the chamber. In June 1898 he was elected president of the chamber, and was re-elected in 1901, but rejected in 1902. In 1904 and 1905 he supported the law on the separation of Church and State. After presiding over the commission of foreign and colonial affairs (1905–09) and acting as reporter of the foreign office estimates committee, Deschanel filled many responsible positions. In Jan. 1920, he was elected president of the Republic, as being a "safer" candidate than Clemenceau, though the latter's popularity spoke strongly in his favour. In the autumn of the same year, however, failing health obliged him to resign office. He died in Paris on April 28, 1922, from the effects of a fall from a railway carriage. Deschanel was elected a member of the French Academy in 1899, his most notable works being *Orateurs et hommes d' état* (1888), *Figures de femmes* (1889), *La Décentralization* (1895), *La Question sociale* (1898).

DESCLOIZITE, a rare mineral species consisting of basic lead and zinc vanadate, crystallizing in the orthorhombic system and isomorphous with olivenite. It occurs as small prismatic or pyramidal crystals, usually forming drusy crusts and stalactitic aggregates; also as fibrous encrusting masses with a mammillary surface. The colour is deep cherry-red to brown or black, and the crystals are transparent or translucent with a greasy lustre; the streak is orange-yellow to brown; specific gravity 5.9 to 6.2; hardness $3\frac{1}{2}$. A variety known as cuprodescloizite is dull green in colour; it contains a considerable amount of copper replacing zinc and some arsenic replacing vanadium. Descloizite occurs in veins of lead ores in association with pyromorphite, vanadinite, wulfenite, etc. Localities are the Sierra de Cordoba in Argentina, Lake Valley in Sierra county, New Mexico, Arizona, Phoenixville in Pennsylvania, Kappel (Eisen-Kappel) near Klagenfurt in Carinthia, and Broken Hill, Rhodesia.

DESCLOT, BERNAT (*fl.* 2nd half of 13th century), Catalan historian, is known through his chronicle of the life of Peter III. of Aragon. It was printed in Barcelona 1616, at Paris in 1840 in *Chroniques étrangères relatives aux expéditions françaises pendant le XIIIe siècle,* and edited by J. Coroleu at Barcelona in 1885.

DESCRIPTION, in the strict sense, means an account of the perceptible qualities or characteristics of objects or events. In this sense it is commonly contrasted with explanation (*q.v.*), which usually seeks to account for what is perceptible by means of factors and processes which are not open to observation. Extreme empiricists maintain that science should confine itself to bare description and keep clear of any attempt at explanation. It is very easy, however, to smuggle what is really explanation into a so-called description. In the popular use of the term it is clear that a complete description of any object or event would include its explanation.

See A. Wolf, *Essentials of Scientific Method* **(1928).**

DESCRIPTIVE GEOMETRY is concerned with the methods of making accurate drawings to represent completely any object and to solve, with instrumental precision, problems relating to the position and shape of the object. It forms the theoretical basis of all architectural and mechanical drafting, and its practical applications are found in the drawing of machinery, buildings, bridges, vessels, in the representation of shades and shadows, in the construction of maps, and in the graphical solution of spherical triangles. It is the means by which the designer conveys his ideas to the builder or mechanic, and has been called the universal language of the engineer.

By the methods of descriptive geometry the solution of any problem concerning three-dimensional objects involves the following steps: (1) representation of the lines, surfaces, or solids in space by corresponding plane figures; (2) solution of the problem by means of the plane figures; (3) interpretation of this solution as a relation between the objects in space. In order to carry out these steps it is necessary to have a definite scheme by which it is possible to pass without ambiguity from the object in space to its representation by drawings in a plane, and also without ambiguity from the drawings to the object in space again. The scheme now universally used for this purpose was devised about the end of the 18th century by G. Monge (1746–1818).

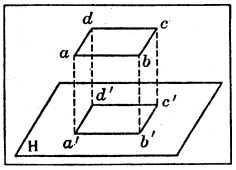

FIG. 1

The *orthographic projection* of a point *a* upon a plane is the point where a line from *a* perpendicular to the plane meets the plane. The orthographic projection of a point *a* in a room upon the floor is the point on the floor directly under the given point *a*. The projection upon a plane of any object in space is the figure on the plane made by projecting each point of the given object. For example (fig. 1) the plane of the square *abcd* is parallel to the plane H and the projection of *abcd* upon H is an equal square *a'b'c'd'*. If (fig. 2) the edge *ab* is parallel to H but the plane *abcd* is not parallel to H, the projection of the square *abcd* on H is the rectangle *a'b'c'd'* in which $a'b'=ab$ but *b'c'* is less than *bc*. If (fig. 3) the edge *ab* is parallel to H and the plane of *abcd* is perpendicular to H, the projection of the square *abcd* upon H is the straight line $a'b'=ab$. In fig. 4 the plane *abcd* is perpendicular to H and the diagonal *ac* is parallel to H. In this case the projection of the square is the line $a'c'=ac$.

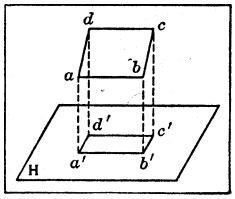

FIG. 2

The line *aa'* which projects a point *a* upon a plane is called a projecting *ray,* or *projector.* In orthographic projection the projecting rays are perpendicular to the plane of projection; consequently all projecting rays are parallel. An oblique projection is obtained when all projecting rays are parallel but are not perpendicular to the plane of projection. Oblique projection is used in the construction of shades and shadows. When the projecting rays are parallel the size of the projection does not depend upon the distance of the object from the plane of projection.

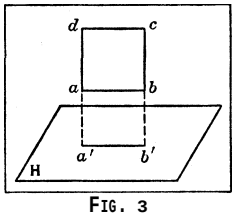

FIG. 3

A *scenographic projection,* or *perspective (see* PERSPECTIVE) is obtained when all of the projecting rays converge to a single point, the *point of sight* (fig. 5). This method produces a picture or representation of an object, or group of objects, as it appears to the eye. The size of the scenographic projection of an object depends upon the distances from it to the point of sight and to the plane of projection.

Unless otherwise specified, projection usually means orthographic projection.

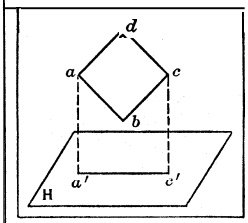

FIG. 4

Monge's method of representation of an object consists in making orthographic projections of the object on two (or more) planes and establishing a definite relation between the different projections. The two principal planes are the *vertical* (denoted by V) and the *horizontal* (denoted by H). The line of intersection of these planes is called the *ground line* (denoted by GL). Except for special cases H and V are sufficient for the solution of the problems of descriptive geometry. When a third plane, the *profile plane* (denoted by P), is desirable it is taken perpendicular to GL and is therefore perpendicular to both H and V.

The projection of an object on the vertical plane is called the *V-projection* or *elevation;* the projection on the horizontal plane is the *H-projection* or *plan.* In commercial terminology the elevation is called also the *front view,* or *rear view,* or *sectional elevation,* as the case may be. The plan is called also the *top view, bot-*

tom view, or sectional *plan.* Similarly, we have the profile or *end* view.

Notation. — A systematic notation is necessary for work in descriptive geometry but, unfortunately, no one system has been adopted by a majority of writers on the subject. In this article a point in space is denoted by a small letter, as a, b, the V-projection of a point a is denoted by a^v and the H-projection by a^h. A straight line is denoted by two points on it, the two end points if the line is of limited length, as ab. (The ground line is denoted by capital letters, GL.) A plane is denoted by a single capital letter, or may be designated by three points in it or by two lines in it.

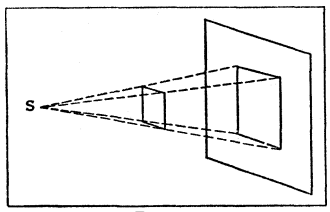

FIG. 5

Representation of a Point. — The position of a point a in space is determined if we know its V-projection and its H-projection. In fig. 6 imagine that H represents the floor of a room and V a wall. The V-projection of the point a is a^v; this determines the distance xa^v or height of the point above the floor. The H-projection, a^h, determines the length xa^h, or distance of the point from the wall. The position of the point from right to left is not given absolutely by this method, but its position with respect to other points of the object is determined.

The two principal planes of projection are supposed to be unlimited in extent and divide space into four compartments called quadrants or angles. In order to distinguish among these quadrants imagine an observer looking at the planes as they appear in fig. 6. He is above H and in front of V. This is the first quadrant. The second is above H and behind V. The third is below H and behind V. The fourth is below H and in front of V. An end view is shown in fig. 7.

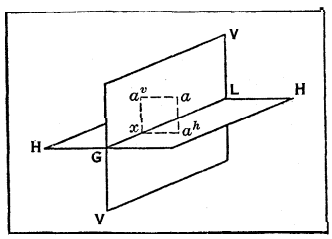

FIG. 6

The methcd of Monge for representing the position of a point in space by a plane drawing consists in turning the V-plane about GL as an axis until it coincides with the H-plane. The direction of rotation (fig. 7) is such that the upper part of V is made to coincide with the part of H which is behind GL.

It is one of the fundamental relations of orthographic projection that, in space, the two projections of any point together with the point itself must always be in a plane which is perpendicular to GL. After revolving V, the two projections of any point will lie in a straight line which is perpendicular to GL. The relation between a point in space and its plane representation is shown for each quadrant by figs 8–11.

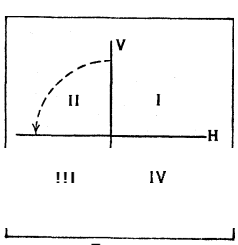

FIG. 7

In architectural drawing the objects are usually supposed to be located in the first quadrant, so that the elevation appears above the plan. In engineering drawings the objects are usually in the third quadrant. In perspective drawing the objects are usually in the second quadrant. The fourth quadrant is little used in practice

Representation of a Line. — The orthographic projection of a straight line upon a plane is a straight line, and a straight line in space is represented on the drawing plane by its V-projection and its H-projection. The truth of the three following statements can be made apparent by holding a pencil in various positions with respect to the floor and a wall. In each statement the letters H and V may be interchanged.

1. If a line of definite length is parallel to V alone, its V-projection is parallel and equal to the line, and its H-projection is parallel to GL.

2. If a line is perpendicular to V, its V-projection is a point, and its H-projection is perpendicular to GL.

3. If a line is parallel to H and V, both of its projections will be parallel to GL.

The projection of a line ab in space will be the lines joining the projections of a and b, that is (fig. 12), the V-projection of ab is a^vb^v and the H-projection is a^hb^h.

In general, any two lines assumed as projections in the plane drawing will determine a line in space. There are, however, exceptions when one or both of the projections are perpendicular to the ground line.

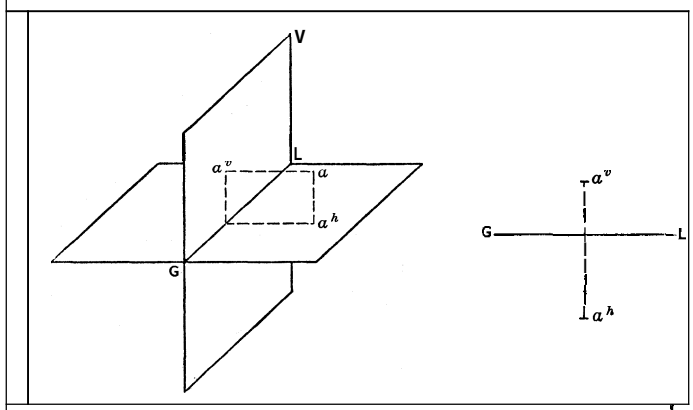

FIG. 8

A line of indefinite length, which is parallel to neither principal plane, will pierce H in a point called its *horizontal trace* and will pierce V in its *vertical trace.* These special points are sometimes used to represent the line in the drawing.

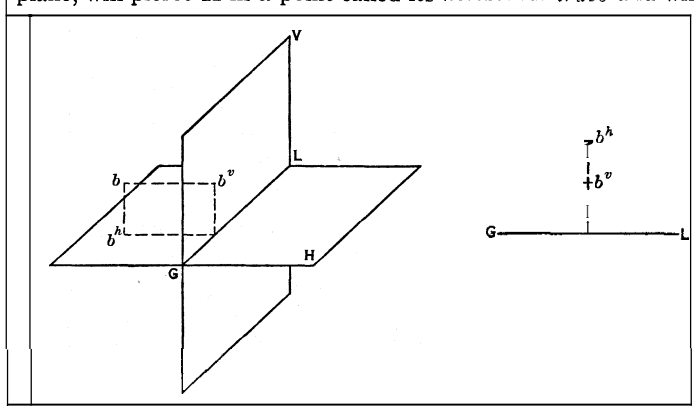

FIG. 9

Representation of a Plane.—A plane of unlimited extent cannot be represented by its projections because, in general, the projections of all of its puints would coinpletely cover both of the principal planes. Hence a plane is represented by its traces, that is, the lines in which it cuts the principal planes. The truth of the three following statements can be made apparent by holding a piece of csrdhoard in various positions with respect to the floor

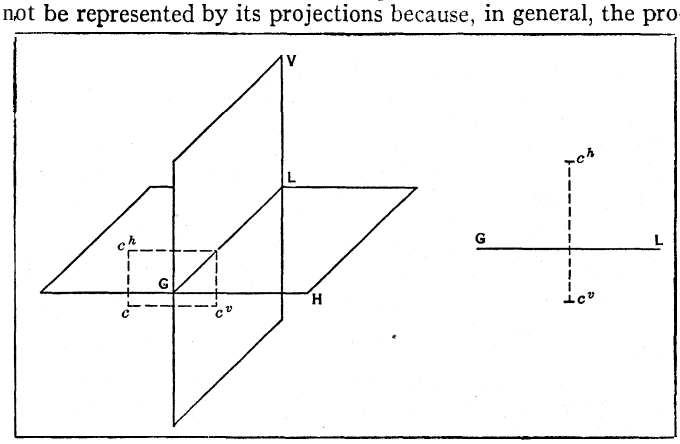

FIG. 10

and a wall. In each statement the letters H and V may be interchanged.

1. If a plane is parallel to V, it has no V-trace and its H-trace is parallel to GL.

2. If a plane is perpendicular to V, but oblique to H, its H-trace is perpendicular to GL.

3. If a plane is parallel to neither principal plane, its traces will

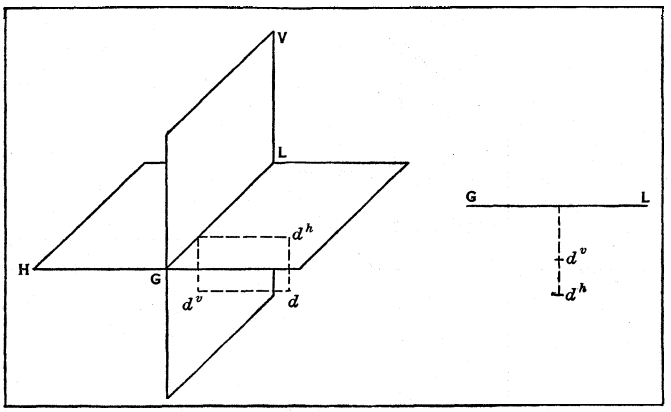

FIG. 11

either (a) both be parallel to GL, or (b) intersect GL in the same point.

A profile plane is perpendicular to both H and V. If a plane contains GL, it is represented by its trace on a profile plane.

In the plane drawing (fig. 13) any two i n s which meet GL at the same point may be taken as the traces of a plane, and they completely determine the position of the plane in space.

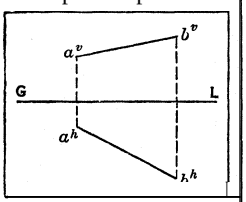

FIG. 12

The solution of a problem by the methods of descriptive geometry may be illustrated by the following simple example:

Problem. — TO find the true length of a line joining two given points in space.

Solution. — The end points a,b of the line are given, and hence their projections are known.

Theory. — Fig. **14** represents the line *ab* in space and shows the projection a^hb^h on the H-plane. Imagine the plane figure abb^ha^h to be revolved about the line a^hb^h as an axis into the H-plane. Point *a* will fall at *d* and b will fall at *b'*. Moreover $a'a^h$ is perpendicular to a^hb^h and is equal to *aha;* $b'b^h$ is perpendicular to a^hb^h and is equal to b^hb.

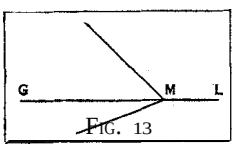

FIG. 13

Construction. — Fig, **15** is the plane drawing representing the given points a, *b* by their projections. From a^h lay off a^ha' perpendicular to a^hb^h and equal to xa^v. From b^h lay off b^hb' perpendicular to a^hb^h and equal to yb^v. Then $a'b'$ is the true length of *ab*.

The scope of the operations involving points, lines, and planes in descriptive geometry is indicated by the following partial list of standard problems:

1. To find the plane which contains two given intersecting or parallel lines.

2. To find the plane which contains a given line and is parallel to a second given line.

3. To find the plane which contains a given point and is parallel to each of two given lines.

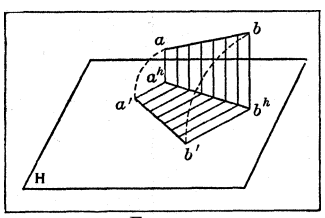

FIG. 14

4. To find the plane which contains a given point and is parallel to a given plane.

5. To find the plane which contains a given point and is perpendicular to a given line.

6. To find the plane which contains a given line and is perpendicular to a given plane.

7. To find the line of intersection of two planes.

8. To find the point in which a straight line intersects a plane.

9. To find the shortest distance from a point to a plane.

10. To find the perpendicular distance between two parallel planes.

11. To find the projections of a line making given angles with H and V.

12. To find the angles which an oblique plane makes with H and V.

13. To find the angle between two intersecting lines.

14. To find the angle between two planes.

15. To find the angle between a line and a plane.

16. To find the shortest distance from a point to a line.

17. To find the shortest distance between two lines not in the same plane.

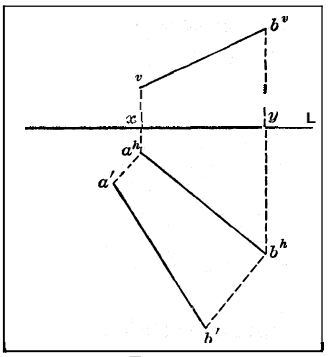

FIG. 15

18. At a given point in a plane, to draw a line which shall be perpendicular to the plane and of given length.

Surfaces. — The methods of descriptive geometry are applicable to the study of curved surfaces in space and of the curves of intersection of such surfaces. The process consists in examining various sections and projections of the figures involved. Of particular interest are those surfaces which can be formed by bending a plane surface without stretching, crumpling, or tearing. Such a surface is called a developable surface. Examples are a cylindrical surface (stove pipe) and a conical surface (funnel). A spherical surface is not developable. An important problem in descriptive geometry is to find the development of a given surface. This means to find the shape of the plane figure which would be obtained by rolling out a given developable surface. The result is illustrated by figs. **16,** 17, 18. Fig. 16 represents a truncated right circular cylinder, which means that the lower base is a circle, the elements of the curved surface are perpendicular to the lower base, and the upper base is not parallel to the lower base. Fig. 17 is the development of the curved surface.

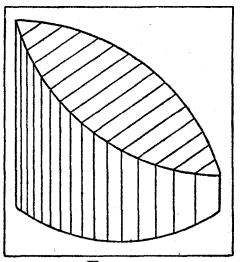

FIG. 16

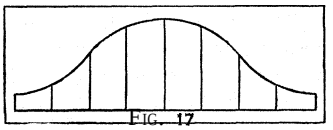

FIG. 17

Fig. **18** represents the development of the spout of a teapot. The problem involves the intersection of two conical surfaces. The development furnishes a pattern for cutting the metal from which the spout is made.

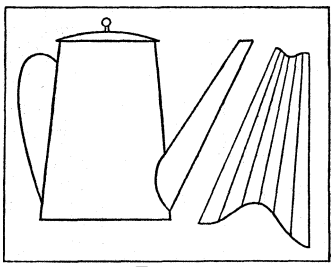

FIG. 18

Shades and shadows are studied by the methods of descriptive geometry. The technical meaning of the terms is shown by fig. 19. The rays of light are supposed to come from a source at a great distance, like the sun, and are regarded as parallel. In conventional drawings the rays are supposed to pass over the left shoulder of the observer at such an angle that their H and V projections make angles of 45° with GL. The illuminated *part* of an object is that part upon which rays of light fall. *Shade* is that part of an object not exposed to the rays of light. ***Line of*** shade is the line between the illuminated and shaded parts of an object. The part of unlighted space behind an object in light

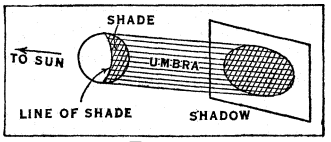

FIG. 19

is called the *umbra* or *indefinite shadow*. *Shadow* is the part of a surface in light from which rays of light are excluded by an opaque object. Problems of shades and shadows involve finding the shaded parts of given objects in given positions and the shadows cast by given objects upon other objects.

Descriptive geometry is a regular study in the curriculum of engineering students, and books on the subject are to be found in the list of every prominent publisher of educational texts for technical schools. (W. R. L.)

DESCRIPTIVE POETRY, the name given to a class of literature which may be defined as belonging to the 16th, 17th and 18th centuries in Europe. From the earliest times, all poetry which was not subjectively lyrical was apt to indulge in ornament which might be named descriptive. But the critics of the 17th century formed a distinction between the representations of the ancients and those of the moderns. We find Boileau emphasizing the statement that, while Virgil *paints*, Tasso *describes*. This may be a useful indication in defining not what should be, but what in practice has been, called "descriptive poetry." It is poetry in which the landscape, or architecture, or still life, or whatever may be the object of the poet's attention, is not used as an accessory, but is itself the centre of interest. It is, in this sense, not correct to call poetry in which description is only the occasional ornament of a poem, and not its central subject. descriptive poetry. The landscape or still life must fill the canvas, or, if human interest is introduced, that must be treated as an accessory. Thomson's *Seasons*, in which landscape takes the central place, and Drayton's *Polyolbion*, where everything is sacrificed to a topographical progress through Britain, are strictly descriptive.

It will be obvious from this definition that the danger ahead of all purely descriptive poetry is that it will lack intensity, that it will be frigid, if not dead. Boileau was naturally the first to see this and in verses of brilliant humour he mocked the writer who, too full of his subject, and describing for description's sake, will never quit his theme until he has exhausted it:

> Fuyez de ces auteurs l'abondance stérile
> Et ne vous chargez point d'un détail inutile.

But Boileau's humorous sallies do not quite meet the question whether such purely descriptive poetry as he criticizes is legitimate at all.

In England had appeared the famous translation (1592–1611), by Joshua Sylvester, of the *Divine Weeks and Works* of Du Bartas, containing such lines as those which the juvenile Dryden admired so much:

> But when winter's keener breath began
> To crystallize the Baltic ocean,
> To glaze the lakes, and bridle up the floods,
> And perriwig with wool the bald-pate woods.

There was also the curious physiological epic of Phineas Fletcher, *The Purple Island* (1633). But on the whole it was not until French influences had made themselves felt on English poetry, that description, as Boileau conceived it, was cultivated as a distinct art. The *Cooper's Hill* (1642) of Sir John Denham may be contrasted with the less ambitious *Penshurst* of Ben Jonson, and the one represents the new no less completely than the other does the old generation. If, however, we examine *Cooper's Hill* carefully, we perceive that its aim is after all rather philosophical than topographical. The Thames is described indeed, but not very minutely, and the poet is mainly absorbed in moral reflections. Marvell's long poem on the beauties of Nunappleton comes nearer to the type. But it is hardly until we reach the 18th century that we arrive, in English literature, at what is properly known as descriptive poetry. This was the age in which poets, often of no mean capacity, began to take such definite themes as a small country estate (Pomfret's *Choice*, 1700), the cultivation of the grape (Gay's *Wine*, 1708), a landscape (Pope's *Windsor Forest*, 1713), a military manoeuvre (Addison's *Campaign*, 1704), the industry of an apple orchard (Philip's *Cyder*, 1708) or a piece of topography (Tickell's *Kensington Gardens*, 1722), as the sole subject of a lengthy poem, generally written in heroic or blank verse.

This species of writing had been cultivated to a considerable degree through the preceding century, in Italy and (as the remarks of Boileau testify) in France, but it was in England that it reached its highest importance. The classic of descriptive poetry, in fact, the specimen which must be considered as the most important and the most successful, is *The Seasons* (1726–30) of James Thomson (*q.v.*). In Thomson, for the first time, a poet of considerable eminence appeared, to whom external nature was all sufficient, and who succeeded in conducting a long poem to its close by a single appeal to landscape, and to the emotions which it directly evokes. Coleridge, somewhat severely, described *The Seasons* as the work of a good rather than of a great poet, and it is an indisputable fact that, at its very best, descriptive poetry fails to awaken the highest powers of the imagination. A great part of Thomson's poem is nothing more or less than a skilfully varied catalogue of natural phenomena. Yet Thomson succeeds, as few other poets of his class have succeeded, in producing nobly-massed effects and comprehensive beauties such as were utterly unknown to his predecessors. He was widely imitated in England, especially by Armstrong, by Akenside, by Shenstone (in *The Schoolmistress*, 1742), by the anonymous author of *Albania*, 1737, and by Goldsmith (in *The Deserted Village*, 1770). No better example of the more pedestrian class of descriptive poetry could be found than the last-mentioned poem, with its minute and Dutch-like painting:

> How often have I paused on every charm:
> The sheltered cot, the cultivated farm;
> The never-failing brook, the busy mill,
> The decent church that topped the neighbouring hill:
> The hawthorn-bush, with seats beneath the shade.
> For talking age and whispering lovers made.

On the Continent of Europe the example of Thomson was almost immediately fruitful. Four several translations of *The Seasons* into French contended for the suffrages of the public, and J. F. de Saint-Lambert (1716–1803) imitated Thomson in *Les Saisons* (1769), a poem which enjoyed popularity for half a century, and of which Voltaire said that it was the only one of its generation which would reach posterity. Nevertheless, as Madame du Deffand told Walpole, Saint-Lambert is *froid, fade et faux*, and the same may be said of J. A. Roucher (1745–94), who wrote *Les Mois* in 1779, a descriptive poem, famous in its day. The Abbé Jacques Delille (1738–1813), perhaps the most ambitious descriptive poet who has ever lived, was treated as a Virgil by his contemporaries; he published *Les Géorgiques* in 1769, *Les Jardins* in 1782, and *L'Homme des champs* in 1803, but he went furthest in his brilliant, though artificial, *Trois règnes de la nature* (1809), which French critics have called the masterpiece of this whole school of descriptive poetry. Delille, however, like Thomson before him, was unable to avoid monotony and want of coherency. Picture follows picture, and no progress is made. The satire of Marie Joseph Chénier, in his famous and witty *Discours sur les poèmes descriptifs*, brought the vogue of this species of poetry to an end.

In England, again, Wordsworth, who treated the genius of Thomson with unmerited severity, revived descriptive poetry in a form which owed more than Wordsworth realized to the model of *The Seasons*. In *The Excursion* and *The Prelude*, as well as in many of his minor pieces, Wordsworth's philosophical and moral intentions cannot prevent us from perceiving the large part which pure description takes; and the same may be said of much of the early blank verse of S. T. Coleridge. Since their day, however, purely descriptive poetry has gone more and more completely out of fashion, and its place has been taken by the richer and directer effects of such prose as that of Xuskin in English, or of Fromentin and Pierre Loti in French.

DESERT, a term used for those lands which produce insufficient vegetation to support a human population. Deserts are classified according to the causes which give rise to them. In "cold deserts" the absence of vegetation is consequent on the prevailing low temperature, while in "hot deserts" the causes are high temperatures and deficient rainfall. Cold deserts accordingly occur in high latitudes or high altitudes. Hot deserts are primarily found along the hot, dry tropical belts of high atmospheric pressure, and on their equatorial sides, but the zonal arrangement is considerably modified in some regions by the influence of ele-

vated land. The northern hemisphere provides examples of this type in the African Sahara, the Asiatic deserts of Arabia and Iran, and in the Great Basin of North America. The southern hemisphere has the Kalahari in Africa, the deserts of Western Australia, and the Atacama in South America. Where a line of elevated land runs east and west in this zone as in Asia, the desert belt tends to occur eastwards in higher latitudes but where the line runs north and south, as in Africa, America and Australia, the desert zone weakens on the windward side of the elevation and the arid conditions are accentuated on the lee side. Desert conditions occasionally arise from somewhat obscure local causes, but the Indian desert (*q.v.*) seems to be situated in a region inaccessible to either of the two main branches of the wet south-west monsoon.

Although permanent rivers rising in wetter regions may traverse deserts (*e.g.,* the Nile) the fundamental-physical condition of an arid area is that it contributes nothing directly to oceanic waters. The rainfall chiefly occurs during violent cloudbursts (*q.v.*) and the soluble matter in the soil is carried down by intermittent streams to salt lakes around which deposits of economic value are found on evaporation. Surface erosion is caused by rapid and extreme changes of temperature, while wind action often forms dunes resembling waves. Dry valleys with precipitous sides, and cirque-like heads are probably caused by occasional cloud-bursts. Natural springs in some deserts give rise to oases which make trans-desert routes possible. When a desert-river has low banks (*e.g.,* the Nile) irrigation is made possible.

See *Das Gesetz der Wüstenbildung by* Walther, Berlin, 1900, for a general account of deserts.

DESERTION, the act of forsaking or abandoning; more particularly, the wilful abandonment of an employment, office or duty, in breach of a legal or moral obligation. For naval or military desertion, see MILITARY LAW; for desertion from the merchant service, see SEAMEN; for desertion of husband, see DIVORCE; for the desertion of children, see CHILDREN—PROTECTIVE LAWS and INFANT.

DESERT WILLOW (*Chilopsis* linearis), a small North American tree of the Bignonia family (Bignoniaceae), native to stream banks and the vicinity of springs in deserts from western Texas to southern California and southward to northern Mexico. It grows usually from 8 ft. to 25 ft. high, with stems from 2 in. to 10 in. in diameter, slender, ascending branches, and narrow, willow-like leaves. During summer it bears a succession of showy, funnel-shaped, pink flowers, about $1\frac{1}{2}$ in. long and $1\frac{1}{4}$ in. across, in profuse terminal clusters, followed in autumn by narrow seed-pods about 8 in. long. It is a characteristic plant of southwestern deserts, in appearance suggestive of a slender willow with catalpa-like flowers.

DESFORGES, PIERRE JEAN BAPTISTE CHOUDARD (1746–1806), French dramatist and man of letters, natural son of Dr. Antoine Petit, was born in Paris on Sept. 15, 1746, and educated at the Collkge Mazarin and the Collkge de Beauvais. After appearing on the stage of the ComCdie Italienne in Paris he joined a troupe of wandering actors, whom he served in the capacity of playwright. He married an actress, and the two spent three years in St. Petersburg, where they were well received. In 1782 he produced at the ComCdie Italienne an adaptation of Fielding's novel with the title Tom Jones *à* Londres. His first great success was achieved with *L'Épreuve* villageoise (1785) to the music of Grétry. La Femme *jalouse,* a five-act comedy in verse (1785), Joconde (1790) for the music of Louis Jaden, Les *Époux* divorce's (1799), a comedy, and other pieces followed. He has left a record of his own early indiscretions in Le *Poète,* ou *mémoires d'un* homme de lettres *écrits* par *lui-même* (4 vols., 1798). He died in Paris on Aug. 13, 1806.

DESGARCINS, MAGDELEINE MARIE (LOUISE) (1769–1797), French actress, was born at Mont Dauphin (Hautes Alpes). In her short career she became one of the greatest of French tragédiennes, the associate of Talma, with whom she nearly always played. She made her *début* at the ComCdie Française on May 24, 1788, in *Bajazet,* and was at once made *sociétaire.* She left the ComCdie Française in 1791 for the house in the Rue Richelieu, soon to become the Théâtre de la République, and there her triumphs were no less—in *King* Lear, Othello, La Harpe's *Mélanie* et Virginie, etc. She died insane, in Paris, on Oct. 27, 1797.

DESHAYES, GERARD PAUL (1795–1875), French geologist and conchologist, born at Nancy on May 13, 1795, was professor of natural history in the Muséum d'Histoire Naturelle. Deshayes examined the fossil Mollusca of the Paris Basin and of other Tertiary areas. His studies on the relations of the fossil to the recent species led him as early as 1829 to conclusions somewhat similar to those arrived at by Lyell, whom Deshayes assisted in the classification of the Tertiary system into Eocene, Miocene and Pliocene. His chief work, *Mollusques* de *l'Algérie,* the result of collections made in Algeria, where he was sent by the French Government in 1839, was issued (incomplete) in 1848. He died at Boran, Oise, on June g, 1875.

DESHOULIÈRES, ANTOINETTE DU LIGIER DE LA GARDE (1638–1694), French poetess, was born in Paris on Jan. 1, 1638. At the age of 13 she married Guillaume de Boisguerin, seigneur Deshoulikres, who followed the prince of Condé to the wars. Madame Deshoulikres returned for a time to the house of her parents, where she wrote poetry and studied the philosophy of Gassendi. She rejoined her husband at Rocroi, near Brussels, and was imprisoned in the chbteau of Wilworden because of her insistence that her husband's arrears of pay should be met. After a few months she was freed by her husband, who attacked the chbteau at the head of a small band of soldiers. They were amnestied, and returned to France, where Madame Deshoulikres soon became a conspicuous personage at the court of Louis XIV. and in literary society, some of her more zealous flatterers even going so far as to style her the tenth muse and the French Calliope. Voltaire pronounced her the best of French poetesses, and she was elected a member of the Academy of the Ricovrati of Padua and of the Academy of Arles. In 1688 she was pensioned by the king. She died in Paris on Feb. 17, 1694. Complete editions of her works were published at Paris in 1695, 1747 and 1882 (edit. Lescure). These include a few poems by her daughter, Antoine Thérèse Deshoulikres (1656–1718), who inherited her talent.

See Sainte-Beuve, *Portraits de femmes* (1892).

DESICCATION, the operation of drying or removing water from a substance. It is of particular importance in practical chemistry. If a substance admits of being heated to say 100°, the drying may be effected by means of a steam bath, which is simply an oven heated by steam; an air-bath may be used for higher temperatures. Otherwise a desiccator must be employed; this is essentially a closed vessel in which a hygroscopic substance is placed together with the substance to be dried. The process may be accelerated by exhausting the desiccator; this so-called vacuum desiccation is especially suitable for the concentration of aqueous solutions of readily decomposable substances. Hygroscopic substances in common use are phosphoric anhydride, concentrated sulphuric acid, potassium and sodium hydroxides, soda lime, anhydrous sodium sulphate and calcium chloride.

Two common types of desiccator are in use. In one the absorbent is placed at the bottom, and the substance to be dried above; in the other, this arrangement is inverted. Liquids are dried either by means of the desiccator, or, as is more usual, by shaking with a substance which removes the water. Fused calcium chloride is the commonest absorbent; but it must not be used with alcohols and certain other liquids with which it forms compounds. Quicklime, barium oxide and dehydrated copper sulphate are especially applicable to alcohol and ether; the last traces of water may be removed by adding metallic sodium snd distilling. Gases are dried by leading them through towers or tubes containing an appropriate drying material. The experiments of H. B. Baker on the influence of moisture on chemical combination have shown the difficulty of removing the last traces of water—see DRYNESS, CHEMICAL.

In chemical technology, apparatus on the principle of the

laboratory air-bath is mainly used. Crystals and precipitates, deprived of as much water as possible by centrifugal machines or filter-presses, are transported by means of a belt, screw or other form of conveyor, on to trays staged in brick chambers heated directly by flue gases or steam pipes; the latter are easily controlled, and if the steam be superheated a temperature of 300° and over may be maintained. In some cases the material traverses the chamber from the coolest to the hottest part on a conveyor or in wagons. Rotating cylinders are also used; the material to be dried is placed inside, and the cylinder heated by a steam jacket or otherwise.

DESIDERIO DA SETTIGNANO (1428–1464), Italian sculptor, was born at Settignano, near Florence, and was for a short time a pupil of Donatello, whom, according to Vasari, he assisted in the work on the pedestal of David, and he seems to have worked also with Mino da Fiesole, with the delicate and refined style of whose works those of Desiderio seem to have a closer affinity than with the perhaps more masculine tone of Donatello. It does not appear that Desiderio ever worked elsewhere than at Florence; for there are to be found there his few surviving decorative and monumental works, though a number of his delicately carved marble busts of women and children are to be found in the museums and private collections of Germany and France. The most prominent of his works are the tomb of the secretary of state, Marsuppini, in Santa Croce, and the great marble tabernacle of the Annunciation in San Lorenzo, both of which belong to his later period, and the cherubs' heads which form the exterior frieze of the Pazzi chapel. Vasari mentions a marble bust, by Desiderio, of Marietta degli Strozzi, which has been identified as a marble portrait bust acquired by the Berlin museum in 1842. The Berlin museum also owns a coloured plaster bust of an Urbino lady, by Desiderio. Other important busts by the master are in the Bargello, Florence, the Louvre in Paris and in private collections.

See Wilhelm Bode, *Die italienische Plastik* (Berlin, 1893).

DESIDERIUS, the last king of the Lombards, is chiefly known through his connection with Charlemagne. He was duke of Tuscany and became king of the Lombards in 756. Seeking to extend the Lombard power, he came into collision with the papacy, and about 772 Adrian I., implored the aid of Charlemagne against him. Other causes of quarrel already existed between the Frankish and the Lombard kings. In 770 Charlemagne had married a daughter of Desiderius; but he soon sent her back to her father. Moreover, Gerberga, Charlemagne's sister-in-law, had sought the protection of the Lombard king after her husband's death in 771; Desiderius had recognized her sons as the lawful Frankish kings, and had attacked Adrian for refusing to crown them. Such was the position when Charlemagne took the Lombard capital, Ticinum, the modern Pavia, in June 774, and appropriated the kingdom of Lombardy. Desiderius was carried to France, where he died, and his son, Adalgis, spent his life in futile attempts to recover his father's kingdom.

See S. Abel, *Untergang des Langobardenreichs* (Gottingen, 1859); and *Jahrbücher des fränkischen Reiches unter Karl dem Grossen* (Leipzig, 1865); Paulus Diaconus, *Historia Langobardorum,* ed. by L. Bethmann and G. Waitz (Hanover, 1878); L. M. Hartmann, *Geschichte Italiens im Mittelalter* (Gotha, 1903).

DESIGN is the arrangement of lines or forms which make up the plan of a work of art with especial regard to the proportions, structure, movement and beauty of line of the whole. A design may be naturalistic or wholly the abstract conception of the artist. Its structure is related to the structure of the frame and the rendering of the subject, but not to the structure or anatomy of the subject itself. A design may be successful which is incorrect in every detail of anatomy. Design in one sense is synonymous with composition, and has to do with all the arts, though more pronounced in the applied arts than in the fine arts.

The Japanese artist Korin arrived at much of his design through the selection of certain parts of purely natural arrangements which were simplified and selected as typical, but which were rendered in a naturalistic manner. Much of modern design is not so made up, but consists of gross distortion for the overstressing of structure or movement, with a complete loss of other characteristics. This type of design is so close to caricature that it often detracts rather than adds to the beauty of a work of art.

Design is concerned not only with typical movement but also with typical rhythms. Through the medium of parallel master strokes or accenting of repeating movements, rhythms are set

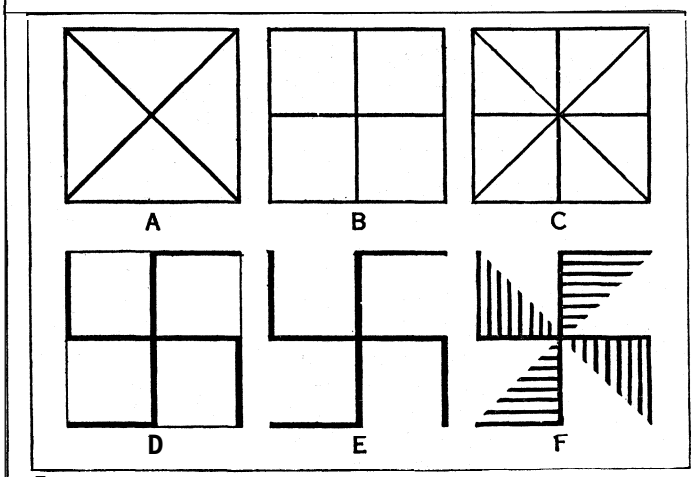

FIG. 1.— PROGRESSIVE STEPS IN THE FORMING OF A SWASTIKA WITHIN A SQUARE

up which should, like the rhythms of great poetry, accent the meaning and express a crystallization of the personality of the artist, and at the same time of his subject as seen through his eyes. Just as in "The Raven" by Poe, we have the summing up of all of Poe's mood in his work and at the same time have the summing up of the expression of all human despair in the bird's recurring "Never more," so in the design of a master of the graphic arts will be found accents and rhythms which build the mood he wishes to establish. Design is to the graphic arts what verse form and rhyme are to poetry: the ladder up which it climbs to the heights. Design can exist without colour, but just as there can be design in line and mass so there can also be design in colour, based upon the distribution of harmoniously blending or contrasting tones; when design is present in both line and colour the two must work together to further the effect of the conception. Every element of art can be designed separately and in relation to the other elements. Thus there can be structural design, movement design, outline design. (See DRAWING.)

Teaching.— In the teaching of design it is often helpful to have the student cut out various pieces of paper representing

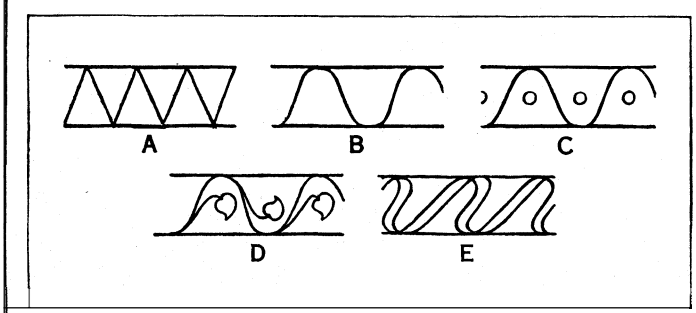

FIG. ,?.— DEVELOPMENT OF WAVE. OR VINE. DESIGN WITHIN PARALLEL LINES FROM SIMPLE GEOMETRICAL FORM

the main areas to be used and move them about within the size area, cut out of the centre of another piece of paper, upon which he is to work. When these have been arranged to his satisfaction, lines should be thrown in which tie the whole together; and finally, with these established areas and lines to guide him, work can be begun. The Chinese artist does this mentally as he sits contemplating the silk upon which he is to paint, for he has trained his mind to remember the arrangement once he has de-

cided upon it. The student can teach himself to do this, but it is well to begin with the more objective method.

It is interesting to note that in given areas only a certain number of effective designs are possible, and that man has hit upon them in every part of the world without intercommunication. Scientists have tried to prove a common origin for the race because of the almost universal use of the swastika, but many

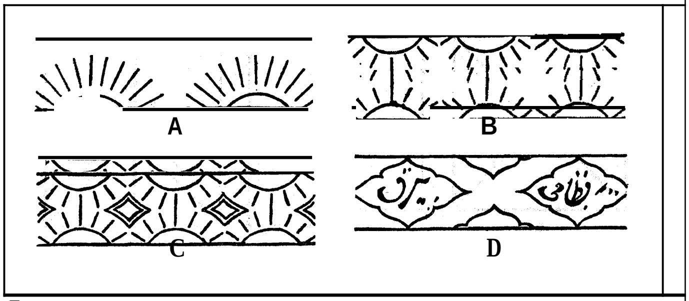

FIG. 3.—PROBABLE EVOLUTION OF TYPICAL PERSIAN OGEE DESIGN FROM OLD ZOROASTRIAN MOTIF

children who have never seen this sign arrive at it spontaneously, when left to decorate squares. The steps are simple (see fig. 1): (1) The corners, which catch the eye quickest for a starting point, are joined; (2) the sides; (3) both are combined and before long, in the age-old attempt to represent movement, the spurs are discovered and all sorts of variations follow. The "wave" or "vine" or "running" border is developed in like manner, because it is the most obvious way to decorate a narrow space between parallel lines. We usually find (A) the geometrical treatment (fig. 2); (B) the curve with open areas which are soon (C) filled with spots assuming the shape of leaves on a vine as time goes on (D), and an excuse for their being is demanded. Finally, as in (E), the movement is increased and it becomes on many Tzu Chow vases of China a leaping rather than a running border, representative of waves from which the fiery dragon ascends.

Development. — The typical Persian ogee design has an interesting origin which is demonstrable on existing vases. In fig. 3 (A) is shown the old Zoroastrian motif of the rising sun which only loosely filled the border; other suns were introduced at a still earlier period. In a further attempt to build the border together a design was inserted between them, which sometimes held written characters and finally, as the religion is developed, the suns disappear and ogee patterns are fitted together, becoming a typical national motif.

Design is, therefore, old and has been thought of for many thousand years, and the student does well to acquaint himself with early examples found in various parts of the world. It is almost as difficult to create a new design as it is to discover a new geometric principle; but another element enters design, and, once having learned it as one would learn geometry, there is available, instead of a cold, mathematical deduction, a vehicle for the expression of one's personal sense of beauty. (W. E. Cx.)

ORIGINALITY

Modern use has tended to associate design with the word "original" in the sense of new or abnormal. But the end of design is utility, fitness and delight. If a discovery, it should be a discovery of what seems inevitable, an inspiration arising out of the conditions, and parallel to invention in the sciences. The faculty of design has best flourished when an almost spontaneous development was taking place in the arts, and while certain classes of arts, more or less noble, were generally demanded and the demand copiously satisfied, as in the production of Chinese porcelain, Greek vases, Byzantine mosaics, Gothic cathedrals and Renaissance paintings. Thus where a "school of design" arises there is much general likeness in the products but also a general progress. The common experience — "tradition" — is a part of each artist's stock in trade; and all are carried along in a stream of continuous exploration. Some of the arts, writing, for instance, have been little touched by conscious originality in design, all has been progress, or, at least, change, in response to conditions. Under such a system, in a time of progress, the proper limitations react as intensity; when limitations are removed the designer has less and less upon which to react, and unconditioned liberty gives him nothing at all to lean on. Design is response to needs, conditions and aspirations. The Greeks so well understood this that they appear to have consciously restrained themselves to the development of selected types, not only in architecture and literature. but in domestic arts, like pottery. Design with them was less the new than the true.

For the production of a school of design it is necessary that there should be a considerable body of artists working together, and a large demand from a sympathetic public. A process of continuous development is thus brought into being which sustains the individual effort. It is necessary for the designer to know familiarly the processes, the materials and the skilful use of the tools involved in their production; [illegible] only one who practises a craft can design for it. It is necessary to enter into the traditions of the art, that is, to know past achievements. It is necessary, further, to be in relation with nature, the great reservoir of ideas, for it is from it that fresh thought will flow into all forms of art. These conditions being granted, the best and most useful meaning we can give to the word design is exploration, experiment, consideration of possibilities. Putting too high a value on originality other than this is to restrict natural growth from vital roots, in which true originality consists. To take design in architecture as an example, we have rested too much on definite precedent (a different thing from living tradition) and, on the other hand, hoped too much from newness. Exploration of the possibilities in arches, vaults, domes and the like, as a chemist or a mathematician explores, is little accepted as a method in architecture at this time, although in antiquity it was by such means that the great master-works were produced: the Pantheon, Santa Sophia, Durham and Amiens cathedrals. The same is true of all forms of design. Of course the genius and inspiration of the individual artist is not here ignored, but assumed. What we are concerned with is a mode of thought which shall make it most fruitful. See ARTS AND CRAFTS; RENDERING, ARCHITECTURAL. (W. R. LE.)

DESK, any kind of flat or sloping table for writing or reading. Its earliest shape was probably that with which we are familiar in pictures of the monastic *scriptorium*—rather high and narrow with a sloping slab. The primitive desk had little accommodation for writing materials, and no storage room for papers; drawers, cupboards and pigeonholes were the evolution of periods when writing grew common, and when letters and other documents requiring preservation became numerous. It was long the custom to secure papers in chests or cabinets, whereas the modern desk serves the double purpose of a writing-table and a storehouse for documents. The first development from the early stall-like desk consisted of the addition of a drawer; then the table came to be supported upon legs or columns. Eventually the legs were replaced by a series of superimposed drawers forming pedestals—hence the familiar pedestal writing-table.

For a long period there were two distinct contemporary forms of desk — the table and the bureau or escritoire. The latter shape attained a popularity so great that it was found even in houses in which there was little occasion for writing. The English-speaking people of the 18th century were amazingly fond of pieces of furniture which served a double or triple purpose. The bureau —the word is the French generic appellation for a desk—derives its name from the material with which it was originally covered (Fr. bure, woollen cloth). It consists of an upright carcass sloping inward at the top, and provided with long drawers below. The upper part is fitted with small drawers and pigeon-holes, and often with secret places, and the writing space is formed by a hinged slab supported on runners; when not in use this slab closes up the sloping top. During the 18th century innumerable thousands of these bureaux were made on both sides of the Atlantic — indeed, if we except tables and chairs, no piece of old furniture is more common. In the first part of that period they were usually of oak, but when mahogany was introduced into Europe it speedily ousted the heavier-looking wood. Its deep rich colour and the

high polish of which it was capable added appreciably to its ornamental appearance. While the pigeon-holes and small drawers were used for papers, the long drawers were often employed for purposes other than literary. In time the bureau-secretaire became a bureau-bookcase, the glazed shelves, which were often a separate erection, resting upon the top of the bureau. The cabinet-makers of the second half of the 18th century, the period of the greatest *floraison* of this combination, competed with each other in devising elegant frets for the glass fronts. Solid and satisfying to the eye, if somewhat severe in form, the mahogany bureau was usually an exceedingly presentable piece of furniture. Occasionally it had a *bombé* front which mitigated its severity; this was especially the case in the Dutch varieties, which were in a measure free adaptations of the French Louis Quinze *commode*. These Dutch bureaux, and the English ones made in imitation of them, were usually elaborately inlaid with floral designs in coloured woods; but whereas the Batavian marquetry was often rough and crude, the English work was usually of considerable excellence. Side by side with this form of writing apparatus was one variety or another of the writing-table proper. In so far as it is possible to generalize upon such a detail it would appear that the bureau was the desk of the yeoman and what we now call the lower middle class, and that the slighter and more table-like forms were preferred by those higher in the social scale.

A SCRIBE OF THE XVTH CENTURY WORKING AT HIS DESK

Just about the time when the flat table with its drawers in a single row was finally assuming its familiar modern shape, an invention was introduced which was destined eventually to supersede all other forms of desk. This was the cylinder-top writing-table. Nothing is known of the originator of this device, but it is certain that if not French himself he worked in France. The historians of French furniture agree in fixing its introduction about the year 1750, and we know that a desk worked on this principle was in the possession of the French crown in the year 1760. Even in its early days the cylinder took more than one form. It sometimes consisted of a solid piece of curved wood, and sometimes of a tambour frame—that is to say, of a series of narrow jointed strips of wood mounted on canvas; the revolving shutters of a shop-front are an adaptation of the idea. For a long period, however, the cylinder was most often solid, and remained so until the latter part of the 19th century, when the "American roll-top desk" began to be made in large numbers. This is indeed the old French form with a tambour cylinder, and it is now the desk that is most frequently met with all over the world for commercial purposes. Its popularity is due to its large accommodation, and to the facility with which the closing of the cylinder conceals all papers, and automatically locks every drawer. To France we owe the construction of many of the finest and most historic desks that have survived—the characteristic marquetry writing-tables of the Boulle period, and the gilded splendours of that of Louis XV. have never been surpassed in the history of furniture. Indeed, the "Bureau du roi" which was made for Louis XV. is the most famous and magnificent piece of furniture that, so far as we know, was ever constructed. This desk, which is now one of the treasures of the Louvre, was the work of several artist-artificers, chief among whom were Oeben and Riesener—Oeben, it may be added here as a matter of artistic interest, became the grandfather of Eugene Delacroix. The bureau is signed *Riesener* fa. 1769 *à l'Arsenal de Paris*, but it has been established that, however great may have been the share of its construction which fell to him, the conception was that of Oeben. The work was ordered in 1760; it would thus appear that nine years were consumed in perfecting it, which is not surprising when we learn from the detailed account of its construction that the work began with making a perfect miniature model followed by one of full size. The "bureau du roi" is a large cylinder desk elaborately inlaid in marquetry of woods, and decorated with a wonderful and ornate series of mounts consisting of mouldings, plaques, vases and statuettes of gilt bronze cast and chased. These bronzes are the work of Duplessis, Winant and Hervieux. The desk, which shows plainly the transition between the Louis XV. and Louis XVI. styles, is as remarkable for the boldness of its conception as for the magnificent finish of its details. Its lines are large, flowing and harmonious, and although it is no longer exactly as it left the hands of its makers (Oeben died before it was finished) the alterations that have been made have hardly interfered with the general effect. For the head of the king for whom it was made, that of Minerva in a helmet was substituted under his successor. The ciphers of Louis XV. have been removed and replaced by Sèvres plaques, and even the key which bore the king's initial crowned with laurels and palm leaves, with his portrait on the one side, and the *fleur de lys* on the other, has been interfered with by an austere republicanism. Yet no tampering with details can spoil the monumental nobility of this great conception.

AN XVIIITH CENTURY CYLINDER DESK IN LOUIS XVITH STYLE

DESMARETS or **DESMARETZ, JEAN,** SIEUR DE SAINT-SORLIN (1595–1676), French dramatist and miscellaneous writer, was born in Paris in 1595. The success of his romance *Ariane* in 1631 led to his admission to the circle that met at the house of Valentin Conrart and later developed into the Académie Française. Desmarets was its first chancellor. He began to write for the theatre at the request of his patron Richelieu. In this kind he produced a comedy long regarded as a masterpiece, *Les Visionnaires* (1637); a prose-tragedy, *Érigone* (1638); and *Scipion* (1639), a tragedy in verse. His success brought many official preferments. His long epic *Clovis* (1657) is noteworthy because Desmarets rejected the traditional pagan background and maintained that Christian imagery should supplant it. With this standpoint he contributed several works in defence of the moderns in the quarrel between the Ancients and the Moderns. In his later years Desmarets wrote religious poems. He was a violent opponent of the Jansenists, against whom he wrote a *Réponse à l'insolente apologie de Port-Royal* . . . (1666). He died in Paris on Oct. 28, 1676.

See also H. Rigault, *Histoire de la querelle des anciens et des modernes* (1856), pp. 80–103 and R. Kerviler, *Desmarets* (1879).

DESMARETS, NICOLAS, SIEUR DE MAILLEBOIS (1648–1721), French statesman, was born in Paris, Sept. 10, 1648. He was a nephew of J. B. Colbert, rose rapidly in the financial administration, and was disgraced after Colbert's death. In 1686 he was recalled, and during the next ten years presented to the controllers-general a series of remarkable memoirs exposing the desperate economic situation of France. He held office under Chamillart from 1699 onwards, and in 1708 succeeded him as controller-general. The situation was exceedingly grave. The ordinary revenues of the year 1708 amounted to 81,977,007 livres, of which 57,833,233 livres had already been anticipated, and the expenses to meet were 200,251,447 livres. In 1709 a famine reduced still more the tax

returns. Emission of paper money, and an improved collection of taxes tided over the years of 1709 and 1710. Then Dcsmarets decided upon an income tax. His "tenth" was based on Vauban's plan; but the privileged classes managed to avoid it. After the death of Louis XIV. Desinarets was dismissed by the regent and withdrew to his estates. He was certainly, after Colbert, the greatest finance minister of Louis XIV.'s reign. *See* Forbonnais, *Recherches et considérations sur les finances de la France* (2 vols. Basel, 1758); Montyon, *Particularités et observations sur les ministres des finances de la France* (1812); De Boislisle, *Correspondance de contrôleurs-généraux des finances* (3 vols. 1873–97); and the same author's "Desmarets et l'affaire des pièces de quatre sols" in the appendix to the seventh volume of his edition of the *Mémoires de Saint-Simon.*

DES MOINES (dĕ-moin′), the capital and largest city of Iowa, U.S.A., in the south-central part of the State, on the Des Moines river, at the mouth of the Raccoon; a port of entry and the county seat of Polk county. It is on Federal highways 6, 65 and 69, has municipal and commercial airports, and is served by the Burlington, the Chicago and North Western, the Chicago Great Western, the Chicago, Milwaukee, St. Paul and Pacific, the Fort Dodge, Des Moines and Southern, the Minneapolis and St. Louis, the Rock Island and the Wabash railways, and by interurban motor bus and trolley lines and additional railways for freight only.

The population in 1930 was 142,559 and in 1940 was 159,819 of which 89.4% were native white and 6.5% foreign-born white.

The city lies on both banks of the river, at an altitude of 861 ft., and has an area of 55.91 sq.mi. The state capitol (completed in 1882 at a cost of $3,000,000) stands on an eminence in a park of 80 acres. Near by is the State Historical, Memorial and Art building and the State library. Des Moines was one of the first among American cities to plan on a relatively generous scale for beauty in its development. A comprehensive city plan was adopted in 1924 and considerable progress has been made in carrying it out. Along the river front, through the heart of the city, extends the civic centre, in which have been erected (by 1941) a city hall ($500,000), a municipal courthouse ($600,000) a federal building, a post office and a coliseum with a seating capacity of 8,500 and other accommodations for large conventions. When completed the centre will contain other public buildings. The city's system of parks and playgrounds covers 1,400 ac., and the grounds of the state fair, which has an attendance of over 400,000 each year, have an area of 600 ac., and represent an investment of $1,500,000.

Drake university, founded in 1881 by the Disciples of Christ, is located here, and co-operates with the city in maintaining a municipal observatory. The assessed valuation of property in 1940 was $131.315,146.

Adjoining the city on the south is Ft. Des Moines, an important army post, where almost a full regiment of cavalry is stationed, besides various other troops. At Camp Dodge, 11 mi. north, now used by the national guard, thousands of soldiers were trained during the World War of 1914–18.

Since 1907 the city has been under a commission form of government, known as the "Des Moines Plan," which has been adopted by many other municipalities. Des Moines has the highest percentage of home ownership among the large American cities (50.8% in 1940).

The percentage of illiteracy is one of the lowest. The death rate is low.

In the heart of the corn belt, and surrounded by a coal field which has produced as much as 3,000,000 tons in a year, Des Moines is an important commercial centre. The jobbing business of its 396 wholesale houses amounts to more than $143,015,000 annually.

Its retail trading territory has a population of 821,393 Incoming and outgoing freight totals 2,500,000 tons in a year; and 200 package-freight cars leave the city daily. Manufactures also are important, with an output in 1939 valued at $79,125,123 Chief among them are meat products, flour, clothing, foundry products, brick and tile, printing and cosmetics. The printing and publishing of newspapers and periodicals is one of the leading industries. The city is the principal centre for the publication of farm journals.

Forty-four insurance companies, with aggregate assets of $546,337,907, have their home officesthere.

In 1843 a military post called Ft. Des Moines was established on the site of the city to protect the rights of the Sacs and Foxes, and in the same year the district was opened to settlement by the whites. The town was incorporated in 1851. In 1857 it was chartered as a city and was made the State capital, superseding Iowa City. The population in 1860 was 3,965, which grew to 12,035 in 1870, 22,408 in 1880, and 50,093 in 1890. Between 1890 and 1920, without any annexations of territory, the population increased 152%. The fort was re-established in 1900 The name of city and fort was taken from that of the river, which is supposed to be a corruption of the original Indian name, *Moingona,* by the French, who at first, using the abbreviation *moin,* called it *la rivière des moins,* and later, through its association with the Trappist monks, changed it to *la rivière des moines.*

DESMOND, EARLS OF: *see* FITZGERALD; DESMOND, GERALD FITZGERALD, 15TH EARL OF.

DESMOND, GERALD FITZGERALD, 15TH EARL OF (d. 1583), Irish leader, was son of James, 14th earl, by his second wife More O'Carroll. Young Gerald was to have been educated in England as the companion of the young king, Edward VI. Unfortunately for the subsequent peace of Munster these projects were not carried out. Claims on the Desmond estates were made by the Butlers, the hereditary enemies of the Geraldines, but temporary peace was made by Gerald's marriage with the daughter and heiress of the 11th earl of Desmond, who had previously married, first, the 9th earl of Ormonde and secondly, Sir Francis Bryan.

Gerald succeeded to the earldom in 1558; he was knighted by the lord deputy Sussex, and did homage at Waterford. He allied himself with his namesake Gerald Fitzgerald, 11th earl of Kildare (1525–1585), and with Shane O'Neill, and trouble was renewed between Ormonde and the Fitzgeralds. Desmond, summoned to appear in London to account for the misdeeds of his clan, delayed his appearance until May 1562. He was detained in London for two years, and after his return the death of his wife freed him from such restraint as had existed. Open war followed, and Desmond was defeated and taken prisoner. Desmond and his brother Sir John of Desmond were sent over to England, where they surrendered their lands to the queen after a short experience of the Tower.

Dcsmond was allowed to return to Ireland in 1573. He was detained for six months in Dublin, but in November slipped through the hands of the Government, and in a short time had reduced the province to a state of anarchy. On July 18, 1574, the Geraldine chiefs signed the "combination" promising to support the earl unconditionally; shortly afterwards Ormonde and the lord deputy, Sir William Fitzwilliam, marched on Munster, and put Desmond's garrison at Derrinlaur Castle to the sword. Desmond submitted at Cork on Sept. 2, handing over his estates to trustees. Sir Henry Sidney visited Munster in 1575, and affairs seemed to promise an early restoration of order. But Fitzmaurice had fled to Brittany in company with other leading Geraldines. He intrigued at the French and Spanish courts for a foreign invasion of Ireland, and at Rome met the adventurer Stucley, with whom he projected an expedition which was to make a nephew of Gregory XIII. king of Ireland. In 1579 he landed in Smerwick bay, where he was joined later by some Spanish soldiers at the Fort del Ore. His ships were captured on July 29, and he himself was slain in a skirmish while on his way to Tipperary. Desmond had perhaps been restrained before by jealousy of Fitzmaurice; his indecisions ceased when on Nov. 1 Sir William Pelham proclaimed him a traitor. The sack of Youghal and Kinsale by the Geraldines was speedily followed by the successes of Ormonde and Pelham acting in concert with Admiral Winter. In June 1581 Desmond had to take to the woods; on Nov. 11 he was seized and murdered by a small party of soldiers. His brother Sir John of Desmond had been caught and killed in Dec. 1581, and John Fitz-

gerald, seneschal of Imokilly, had surrendered on June 14, 1583.

By his second marriage with Eleanor Butler, the 15th earl left two sons, the elder of whom, James, 16th earl (1570–1601), spent most of his life in prison. After an unsuccessful attempt in 1600–01 to recover his inheritance he returned to England, where he died, the title becoming extinct.

See G. E. C(okayne), ***Complete Peerage;*** R. Bagwell, ***Ireland under the Tudors*** (1885–90); ***Annals of Ireland by the Four Masters*** (ed. J. O'Donovan, 1851); ***The Sidney Papers,*** ed. A. Collins (1746) and the article FITZGERALD.

DESMOND (Des-Mumha), an ancient kingdom of Ireland, covering southern Munster. About A.D. 200 Oilill, king of Munster, divided his territory between his two sons, giving Desmond to Eoghan and Thomond or N. Munster to Cormac Cas. In the 10th century Brian Boru, representing the latter, united all Munster, but in the 12th century the MacCarthys, descendants of Eoghan, became kings of Desmond. The Norman conquests reduced Desmond in size to the present county Cork and south Kerry, and the MacCarthys were driven into the south-west of Munster where they ruled till the 16th century as "kings of Desmond" or "MacCarthy More." The title "earl of Clancare" or "Clancarthy" was bestowed on MacCarthy More by Elizabeth, but this ancient family forfeited it as a result of the Jacobite war of 1690–91. In 1329 Maurice, head of the Munster Fitzgeralds, was created earl of Desmond, but this powerful family was extinguished in the "Desmond War" of 1579–83 when Gerald, the last true earl, was killed and his territories confiscated. Desmond was organized as a county for a time but ultimately its western part was added to county Kerry. In 1619 the earldom of Desmond was conferred on Richard Preston, Lord Dingwall, and after him on George Fielding, second son of the earl of Denbigh, through whom it has descended to the earls of Denbigh.

DESMOULINS, LUCIE SIMPLICE CAMILLE BENOIST (1760–1794), French journalist and politician, was born at Guise, in Picardy, on March 2, 1760. He was educated at the college of Louis-le-Grand. In this school, in which Robespierre was also a bursar and a distinguished student, Camille Desmoulins laid the solid foundation of his learning. He was admitted an advocate of the parlement of Paris in 1785. His professional success was not great; his manner was violent, his appearance unattractive, and his speech impaired by a painful stammer.

In March 1789 Desmoulins began his political career. Having been nominated deputy from the *bailliage* of Guise, he appeared at Laon as one of the commissioners for the election of deputies to the States-General summoned by royal edict of Jan. 24. Camille heralded its meeting by his *Ode to the States-General.* The sudden dismissal of Necker by Louis XVI. brought Desmoulins to fame. On July 12, 1789, Camille, leaping upon a table outside one of the cafés in the garden of the Palais Royal, announced to the crowd the dismissal of their favourite. He inflamed the passions of the people by his burning words and his call "To arms!" "This dismissal," he said, "is the tocsin of the St. Bartholomew of the patriots." This scene was the beginning of the actual events of the Revolution. Following Desmoulins the crowd surged through Paris, procuring arms by force; and on the 13th it was partly organized as the Parisian militia which was afterwards to be the National Guard. On the 14th the Bastille was taken.

His *La France libre* (1789) brought him the friendship of Mirabeau, and the studied abuse of numerous royalist pamphleteers. After the publication of his *Discours de* la *lanterne aux Parisiens,* Desmoulins was dubbed "Procureur-général de la lanterne."

Desmoulins was powerfully swayed by the influence of more vigorous minds; and for some time before the death of Mirabeau, in April 1791, he had begun to be led by Danton, with whom he remained associated during the rest of his life. In July 1791 Camille appeared before the municipality of Paris as head of a deputation of petitioners for the deposition of the king. In that month, however, such a request was dangerous; there was excitement in the city over the presentation of the petition, and the private attacks to which Desmoulins had often been subject were now followed by a warrant for the arrest of himself and Danton. Danton left Paris for a while; Desmoulins, however, remained there, appearing occasionally at the Jacobin club. Upon the failure of this attempt of his opponents, Desmoulins published a pamphlet, *Jean Pierre Brissot démasqué,* followed in 1793 by a *Fragment de l'histoire secrète de la Révolution,* in which the party of the Gironde, and specially Brissot, were most mercilessly attacked. Desmoulins took an active part on Aug. 10 and became secretary to Danton, when the latter became minister of justice. On Sept. 8 he was elected one of the deputies for Paris to the National Convention, where he was of the party of the "mountain," and voted for the abolition of royalty and the death of the king. The *Histoire des Brissotins* was inspired by Robespierre. The success of the *brochure,* so terrible as to send the leader? of the Gironde to the guillotine, alarmed Danton and the author. In 1789 he had issued a weekly journal, *Les Revolutions de France et de Brabant.* In Dec. 1793, appeared the first number of the *Vieux Cordelier,* which was at first directed against the Hébertists and approved of by Robespierre, but which soon formulated Danton's idea of a committee of clemency. Then Robespierre turned against Desmoulins and took advantage of the popular indignation roused against the Hébertists to send them to death. The time had come, however, when Saint Just and he were to turn their attention not only to *les enragés,* but to *les indulgents — the* powerful faction of the Dantonists. On Jan. 7, 1794, Robespierre in addressing the Jacobin club counselled not the expulsion of Desmoulins, but the burning of certain numbers of the *Vieux Cordelier.* By the end of March Danton, Desmoulins and the best of the moderates were arrested. On the 31st the warrant of arrest was signed and executed, and on the 3rd, 4th and 5th of April the trial took place before the Revolutionary Tribunal. Camille on being asked his age, replied, "I am thirty-three, the age of the *sans-culotte* Jesus, a critical age for every patriot." He was, in fact. thirty-four. The accused were prevented from defending themselves; a decree of the convention denied them the right of speech. Sentence of death was passed in absence of the accused, and their execution was appointed for the same day. Despite the indifference to death he had pretended to in his writings, Desmoulins showed little courage at his death, in sharp contrast to the brave and dignified death of his wife a week later.

On Dec. 29, 1790, Camille had married Lucile Duplessis, and their only child, Horace Camille, was born on July 6, 1792. The boy was afterwards pensioned by the French government, and died in Haiti in 1825.

DESNOYERS, AUGUSTE GASPARD LOUIS BOUCHER, BARON (1779–1857), French engraver, was born in Paris on Dec. 19, 1779. He started his artistic education at the age of 12 under Lethière. After visiting Italy he entered the studio of Alexandre Tardieu in 1799, and became one of the most eminent line engravers of his time. His fame was established in 1805 by an engraving after the "Belle Jardinière" of Raphael; whereupon Napoleon I. commissioned him to reproduce his full-length portrait in coronation robes by Gérard. He died in Paris on Feb. 2, 1857.

DE SOTO: *see* SOTO, FERDINANDO DE.

DE SOTO, a city of Jefferson county, Missouri, U.S.A., 42 mi. S.S.W. of St. Louis, on Joachim creek. It is served by the Missouri Pacific railroad. Pop. (1930) 5,069; in 1940 it was 5,121. It is in a fertile agricultural region, and lead, zinc, tin, barytes and silica are mined in the vicinity. The city has railroad shops, a plate-glass factory and large shoe and clothing factories. De Soto was laid out in 1855 and incorporated in 1869. It is the seat of Mt. St. Clement's college.

DESPARD, EDWARD MARCUS (1751–1803), Irish conspirator, was born in Queen's Co., Ireland, in 1751. In 1766 he entered the British navy, was promoted lieutenant in 1772, and stationed at Jamaica. He was promoted captain after the San

Juan expedition (1779), then made governor of the Mosquito shore and the Bay of Honduras, and in 1782 commander of a successful expedition against the Spanish possessions on the Black river. In 1784 he took over the administration of Yucatan. Upon frivolous charges he was suspended by Lord Grenville, and recalled to England. From 1790 to 1792 these charges were held over him, and when dismissed no compensation was forthcoming. His complaints caused his arrest in 1798, and with a short interval he remained in gaol until 1800. Despard was arrested on a charge of plotting to assassinate George III., tried before a special commission, found guilty of high treason, and, with six of his fellow-conspirators, sentenced in 1803 to be hanged, drawn and quartered. These were the last men to be so sentenced in England. Despard was executed on Feb. 21, 1803.

His eldest brother, JOHN DESPARD (1745–1829), had a long and distinguished career in the British army; gazetted an ensign in 1760, he became general in 1814. In the American War of Independence he was twice made prisoner.

See Sir Charles Oman, *The Unfortunate Colonel Despard and other studies* (1922).

DESPATCH or **DISPATCH,** to send off immediately, or by express; particularly in the case of the sending of official messages, or of the immediate sending of troops to their destination, or the like. The word is used as a substantive of written official reports of events, battles and the like, sent by ambassadors, generals, etc., by means of a special messenger, or of express correspondence generally. From the primary meaning of the prompt sending of a message, the word is used of the quick disposal of business, or of the disposal of a person by violence. The French word *dépêche* came into England as *depeach,* which was in use from the 15th century until "despatch" was introduced. An early use of "dispatch" occurs in a letter to Henry VIII. from Bishop Tunstall, commissioner to Spain in 1516–17.

DESBENSER, HUGH LE (d. 1265), chief justiciar of England, first played an important part in 1258, being prominent on the baronial side in the Mad Parliament of Oxford. In 1260 the barons chose him to succeed Hugh Bigod as justiciar, and in 1263 the king was further compelled to put the Tower of London in his hands. On the outbreak of civil war he joined the party of Simon de Montfort, earl of Leicester, and led the Londoners when they sacked the manor-house of Isleworth, belonging to Richard, earl of Cornwall, king of the Romans. Having fought at Lewes (1264) he was made governor of six castles after the battle, and was then appointed one of the four arbitrators to mediate between Simon de Montfort and Gilbert de Clare, earl of Gloucester. He was summoned to Simon de hlontfort's parliament in 1264, and acted as justiciar throughout the earl's dictatorship. Despenser was killed at Evesham in Aug. 1365.

See C. Bémont, *Simon de Montfort* (Paris, *1884)*; T. F. Tout in *Owens College Historical Essays,* pp. *76* ff. (Manchester, 1902).

DESPENSER, HUGH LE (1262–1326), English courtier, was a son of the justiciar, fought for Edward I. in Wales, France and Scotland, and in 1295 was summoned to parliament as a baron. Ten years later he was sent by the king to Pope Clement V. to secure Edward's release from the oaths he had taken to observe the charters in 1297. Almost alone Hugh spoke out for Edward II.'s favourite, Piers Gaveston, in 1308; but after Gaveston's death in 1312 he himself was the king's chief adviser until Edward's defeat at Bannockburn in 1314. Then, hated by the barons, and especially by Earl Thomas of Lancaster, as a deserter from their party, he was driven from the council, but was quickly restored to favour and loaded with lands and honours, being made earl of Winchester in 1322. Before this time Hugh's son, the younger Hugh le Despenser, had become associated with his father, and was enjoying a still larger share of royal favour. About 1306 this baron had married Eleanor (d. 1337), one of the sisters and heiresses of Gilbert de Clare, earl of Gloucester, who was slain at Bannockburn; and after a division of the immense Clare lands had been made in 1317 violent quarrels broke out between the Despensers and the husbands of the other heiresses, Roger of Amory and Hugh of Audley. Interwoven with this dispute was another between the younger Despenser and the Mowbrays, who were supported by Humphrey Bohun, earl of Hereford, about some lands in Glamorganshire. Fighting having begun in Wales and on the Welsh borders, the English barons showed themselves decidedly hostile to the Despensers, and in 1321 Edward II. was obliged to consent to their banishment. The elder Hugh left England for a time, but father and son were soon again at court. They fought against the rebellious barons at Boroughbridge, and after Lancaster's death in 1322 they practically ruled the country. But their next enemy, Queen Isabella, was more formidable, or more fortunate, than Lancaster. Returning from France in 1326 the queen directed her arms against her husband's favourites. The elder Despenser was seized at Bristol, where he was hanged on Oct. 27, 1326, and the younger was taken with the king at Llantrissant and hanged at Hereford on Nov. 24. The attainder against the Despensers was reversed in 1398. The intense hatred with which the barons regarded the Despensers was due to the enormous wealth which had passed into their'hands, and to the arrogance and rapacity of the younger Hugh. The younger Despenser left two sons, Hugh (1308–49), and Edward, who was killed at Vannes in 1342.

The latter's son EDWARD LE DESPENSER (d. 1375) fought at the battle of Poitiers; he was a patron of Froissart, who called him *le grand sire Despensier.* His son, THOMAS LE DESPENSER (1373–1400), the husband of Constance (d. 1416), daughter of Edmund of Langley, duke of York, supported Richard II. against Thomas of Woodstock, duke of Gloucester, and the other lords appellant in 1397, when he himself was created earl of Gloucester, but he deserted the king in 1399. Then, degraded from his earldom for participating in Gloucester's death, Despenser joined the conspiracy against Henry IV., but he was seized and executed by a mob at Bristol in January 1400.

The elder Edward le Despenser left another son, HENRY (*c.* 1341–1406), who became bishop of Norwich in 1370. In early life Henry had been a soldier, and when the peasants revolted in 1381 he took readily to the field, defeated the insurgents at North Walsham, and suppressed the rising in Norfolk with some severity. Pope Urban VI. in 1382 employed him to lead a crusade in Flanders against the supporters of the anti-pope Clement VII. After capturing several towns he was checked at Ypres, and defeated by the French. On his return the bishop was impeached and deprived of his lands; Richard II., however, stood by him. Almost alone among his peers Henry remained true to Richard in 1399; he was then imprisoned, but was quickly released. He died on Aug. 23, 1406. Despenser was an active enemy of the Lollards, whose leader, John Wycliffe, had fiercely denounced his crusade in Flanders.

The barony of Despenser, called out of abeyance in 1604, was held by the Fanes, earls of Westmorland, from 1626 to 1762; by the notorious Sir Francis Dashwood from 1763 to 1781; and by the Stapletons from 1788 to 1891. In 1891 it was inherited, through his mother, by the 7th Viscount Falmouth.

DES PÉRIERS, BONAVENTURE (*c.* 1500–1544), French author, was born of a noble family at Arnay-le-duc in Burgundy at the end of the 15th century. In 1533 or 1534 Des Périers visited Lyons, then the most enlightened town of France, and a refuge for many liberal scholars. He gave some assistance to Robert Olivetan and Lefèvre d'Étaples in the preparation of the vernacular version of the Old Testament, and to Étienne Dolet in the *Commentarii linguae latinae.* In 1536 he put himself under the protection of Marguerite d'Angoulême, queen of Navarre, who made him her *valet-de-chambre.* He acted as the queen's secretary, and transcribed the *Heptaméron* for her. It is probable that his duties extended beyond those of a mere copyist, and some writers have gone so far as to say that the *Heptame'ron* was his work. The free discussions permitted at Marguerite's court encouraged a licence of thought as displeasing to the Calvinists as to the Catholics. This free enquiry became scepticism in Bonaventure's *Cymbalum Mundi* . . . (1537), and the queen of Navarre disavowed the author, though she continued to help him privately until 1541. The book consisted of four dialogues in imitation of Lucian. Its allegorical form did not conceal its real meaning, and the Sorbonne secured the suppression of the edi-

tion (c. 1538) before it was offered for sale. The book was reprinted in Paris in the same year. It made many bitter enemies for the author. Henri Estienne called it dktestable, and Étienne Pasquier said it deserved to be thrown into the fire with its author if he were still living. Des Périers prudently left Paris, and settled at Lyons, where in 1544 he put an end to his existence by falling on his sword. In 1544 his collected works were printed at Lyons. The volume, Recueil des oeuvres de feu Bonaventure des Pkriers, included his poems, which are of small merit, the *Traité des quatre vertus cardinales après Sénèque*, and a translation of the Lysis of Plato. In 1558 appeared at Lyons the collection of stories and fables entitled the *Nouvelles récréations et joyeux devis*, the work on which his fame rests. Some of the tales are attributed to the editors, Nicholas Denisot and Jacques Pelletier, but their share is certainly limited to the later ones. The stories are models of simple, direct narration in the vigorous and picturesque French of the 16th century.

His Oeuvres françaises were published by Louis Lacour (Paris, 2 vols., 1856). See also the preface to the *Cymbalum Mundi* . . . (ed. F. Franck, 1874); A. Chenevière, *Bonaventure Desptriers, sa vie, ses poésies* (1885); and P. Toldo, *Contributo allo studio della novella francese del XV. e XVI. secolo* (Rome, 1895).

DESPORTES, PHILIPPE (1546–1606), French poet, was born at Chartres in 1546. As secretary to the bishop of Le Puy he visited Italy, where he gained a knowledge of Italian poetry. He then attached himself to the duke of Anjou, and followed him to Warsaw on his election as king of Poland. Nine months in Poland satisfied the civilized Desportes, but in 1574 his patron became king of France as Henry III. and gave the poet the abbey of Tiron and four other valuable benefices. A good example of the light and dainty verse in which Desportes excelled is furnished by the well-known *villanelle* with the refrain "Qui premier s'en repentira," which was on the lips of Henry, duke of Guise, just before his tragic death. Desportes imitated Petrarch, Ariosto, Sannazaro, and still more closely the minor Italian poets, and in 1604 a number of his plagiarisms were exposed in the *Reconcontres des Muses de France et d'Italie*. As a sonneteer he showed much grace and sweetness, and English poets borrowed freely from him. In his old age Desportes prepared a translation of the Psalms remembered chiefly for the brutal mot of Malherbe: *Votre potage vaut mieux que vos psaumes*. Desportes died on Oct. 5, 1606, leaving the reputation of the courtier poet.

BIBLIOGRAPHY.—Desportes had published in 1573 an edition of his works including *Diane, Les Amours d'Hippolyte, Élégies, Bergeries, Oeuvres chrétiennes*, etc. A splendid edition printed by Étienne appeared in 1579. An edition of his Oeuvres, by Alfred Michiels, was published in 1858.

DESPOT, in Greek usage the master of a household, hence the ruler of slaves (Gr. δεσπότης, lord or master). It was also used by the Greeks of their gods, but was principally applied to the absolute monarchs of the Eastern empires, and it is in this sense that the word, like its equivalent "tyrant," is in current usage for an absolute sovereign whose rule is not restricted by any constitution. In the Roman empire of the East "despot" was used as a title of honour or address of the emperor, and later of his sons, brothers and sons-in-law. Later still it was adopted by the vassal princes of the empire. This gave rise to the name "despotats" applied to the tributary states which survived the break-up of the empire in Epirus, Cyprus, Trebezond, etc. Under Ottoman rule the title was preserved by the despots of Serbia, etc.

DES PRÉS, JOSQUIN (c. 1445–1521), also called DEPRÉS or DESPREZ, and by a latinized form of his name, JODOCUS PRATENSIS or A. PRATO, French musical composer, was born, probably in Condé in the Hennegau, about 1445. He was a pupil of Ockenheim, and himself one of the most learned musicians of his time. In spite of his great fame, the accounts of his life are vague and the dates contradictory. In his early youth Josquin seems to have been a member of the choir of the collegiate church at St. Quentin; when his voice changed he took lessons in counterpoint from Okeghem; afterwards he again lived at his birthplace for some years and probably spent some time at various Italian courts until he joined the papal chapel in Rome in 1486. In Rome Des Prés lived till 1494, and it was there that many of his works were written He was considered by his contemporaries to be the greatest master of his age. Luther, who was a good judge, is credited with the saying that "other musicians do with notes what they can, Josquin what he likes." The composer's journey to Rome marks in a manner the transference of music's headquarters from the North to Italy, which for the next two centuries remained the centre of the musical world. To Des Prés and his pupils Arcadelt, Mouton and others, much that is characteristic in modern music owes its rise, particularly in their influence upon Italian developments under Palestrina. After leaving Rome Josquin accepted an invitation of King Louis XII. of France to become the chief singer of the royal chapel. Re was also, for a time at least, in the service of the emperor Maximilian I., and at the time of his death, on Aug. 27, 1521, was a canon of the cathedral of Condé.

The most complete list of his compositions—consisting of masses, motets, psalms and other pieces of sacred music—will be found in Fétis. The largest collection of his ms. works, containing no fewer than 20 masses, is in the possession of the papal chapel in Rome. During the 17th and 18th centuries Josquin's value was ignored, nor does his work appear in the collections of Martini and Paolucci. Burney was the first to recover him from oblivion, and Forkel continued the task of rehabilitation. Ambros furnishes the most exhaustive account of his achievements. An admirable account of Josquin's art will be found in the article "Josquin," by the Rev. J. R. Milne in Grove's *Dictionary of Music and Musicians*, 3rd ed. vol. ii. An edition of the complete works of Josquin has been undertaken by the *Vereeniging voor Noord-Nederlandsche Muziekgeschiedenis* under the editorship of A. Smijers. Seventeen of Josquin's masses were published during his lifetime by Perrucci (1502–16), and two others in 1539 by Johannes Ott at h'uremberg. Many of his motets were printed in various collections, notably in Commer's *Collectio operum musicorum Batavorum* (12 vols., 1840), and another selection of his works was edited by Eitner.

DESPRES, SUZANNE (1875–), French actress, was born at Verdun, and trained at the Paris Conservatoire. She then became associated with, and subsequently married, Aurelien Lugné-Poë (b. 1870), the actor-manager, who had founded a new school of modern drama, *L'Oeuvre*, and she had a brilliant success in several plays produced by him. In succeeding years she played at the Gymnase and at the Porte Saint-Martin, and in 1902 made her début at the Comédie Française, appearing in *Phèdre* and other important parts.

DESSAIX, JOSEPH MARIE, COUNT (1764–1834), French general, was born at Thonon, Haute Savoie, on Sept. 24, 1764. He studied medicine, took his degree at Turin and then went to Paris, where in 1789 he joined the National Guard. In 1791 he tried without success to raise an *kmeute* in Savoy. In 1792 he organized the "legion of the Allabroges," and served at the siege of Toulon, in the army of the Eastern Pyrenees, and in the army of Italy. Dessaix was elected a member of the council of Five Hundred, and opposed the *coup d'état* of the 18th Brumaire (Nov. 9, 1799). Promoted general of brigade in 1803, he fought at Wagram (1809), was made general of division and in 1810 a count. He took part in the expedition to Russia, and was for some time commandant of Berlin. He joined Napoleon in the Hundred Days, and in 1816 was imprisoned for five months. He died on Oct. 26, 1834.

See *Le Général Dessaix, sa vie politique et militaire*, by his nephew Joseph Dessaix (Paris, 1879).

DESSAU, the capital city of the Land of Anhalt, Germany, on the left bank of the Mulde, 2 mi. from its confluence with the Elbe, 67 mi. S.W. from Berlin and at the junction of lines to Cöthen and Zerbst.

Pop. (1939), 120,744.

Dessau, probably founded by Albert the Bear, had attained civic rights as early as 1213. It grew into importance at the close of the 17th century, after the religious emancipation of the Jews in 1686, and of the Lutherans in 1697.

Apart from the old quarter on the Mulde, the town is well built with spacious squares such as the Grosse Markt and the

public buildings of a capital. The Schlosskirche is adorned with paintings by Lucas Cranach, in one of which ("The Last Supper") are portraits of several reformers. The ex-ducal palace, standing in extensive grounds, contains a collection of historical curiosities and a gallery of pictures, which includes works by Cimabue, Lippi, Rubens, Titian and Van Dyck; the Amalienstift also has a picture gallery. Dessau manufactures sugar, chocolate, chemicals, small iron goods and machinery, various household objects and some textiles. There is also a considerable trade in corn and garden produce. Because of its airfield, its importance as a railway centre, and as the seat of the great Junkers plane factory, Dessau was frequently bombed by the British in World War II.

DESSOIR, LUDWIG (1810–1874), German actor, whose name was originally Leopold Dessauer, was born on Dec. 15, 1810, at Posen, the son of a Jewish tradesman. He made his first appearance on the stage there in 1824 in a small part. After some experience at the theatre in Posen and on tour, he was engaged at Leipzig from 1834–36. In 1836 he was at the Breslau municipal theatre, and during 1837–39 at Budapest. From there he went to Karlsruhe and in 1847 to Berlin where his success in *Othello* and *Hamlet* won him a permanent engagement at the Hof theatre. In 1853 he appeared in London. He retired in 1872 and died on Dec. 30, 1874, in Berlin. Dessoir was twice married; by his first wife he had one son, the actor Ferdinand Dessoir (1836–92). In spite of certain physical disabilities Ludwig Dessoir's genius raised him to the first rank of actors, especially as an interpreter of Shakespeare's characters. G. H. Lewes placed Dessoir's Othello above that of Kean, and the *Athenaeum* preferred him in this part to Brooks or Macready.

DE STEFANI, ALBERTO (1879–), Italian economist and statesman, was born at Verona on Oct. 6, 1879. Educated at the university of Padua he became professor of political economy at the Superior Commercial Institute of Venice. In 1921 he was returned to the Chamber as a Fascist and was Mussolini's first Minister of Finance. Later he was also entrusted with the Treasury department and welded the two into a single ministry. He abolished useless expenditure and simplified the fiscal system, reducing innumerable taxes to three main sources of revenue, with the result that, in three years a deficit of 6,500,000,000 lire was converted into a surplus of 209,000,000. His measures for restraining speculation in the currency and stock markets during the financial slump in the spring of 1925 were less successful; he lost the confidence of the banking community, and in July was superseded by Count Volpi.

DESTOUCHES, PHILIPPE (1680–1754), French dramatist, whose real name was Néricault, was born at Tours. He was attached successively to the French embassies in Switzerland and in London, and married a Lancashire lady, Dorothea Johnston. On his return to France (1723) he was elected to the Academy. He spent his later years at his chbteau of Fortoiseau, near Melun, dying on July 4, 1754. His early comedies were: *Le Curieux Impertinent* (1710), *L'Ingrat* (1712), *L'Irrésolu* (1713) and *Le Médisant* (1715). The best of these is *L'Irrésolu,* in which Dorante, after hesitating throughout the play between Julie and Célimène, marries Julie, but concludes the play with the reflection:—

"J'aurais mieux fait, je crois, d'épouser Célimène."

After 11 years of diplomatic service Destouches returned to the stage with the *Philosophe marié* (1727), followed in 1732 by his masterpiece *Le Glorieux,* a picture of the struggle then beginning between the old nobility and the wealthy *parvenus* who found their opportunity in the poverty of France. Among his later comedies may be mentioned: *Le Tambour nocturne* (1736), *La Force du naturel* (1750) and *Le Dissipateur* (1736).

His works were issued in collected form in 1755, 1757, 1811 and, in a limited edition (6 vols.), 1822.

DESTROYER, an unarmoured warship of approximately 1,000 to 1,400 tons, very fast, with a powerful torpedo armament and a few medium calibre guns (usually 4″ or 5″ dual purpose guns). A larger type, used as senior officer's ship of a division of destroyers, is known as a flotilla leader. These latter are of 1,500 to 2,000 tons and carry a rather more powerful gun armament.

The destroyer as a type was evolved about 1892 as the answer to the torpedo boat, which was then regarded as being as serious a menace to the large surface warship as is the submarine, in certain quarters, to-day. Partly as the result of the evolution of the destroyer, but largely because the ineffectiveness of the original small torpedo boat was gradually realized, the latter as a type has ceased to exist in all the more important navies, while the destroyer has not only replaced it as a means of executing torpedo attacks, but has proved of great value for innumerable other naval services. Destroyers are essential auxiliaries to the battle fleet. In a fleet action their functions are to attack the enemy's battle fleet under cover of the fire of their own battleships, or by taking advantage of low visibility or smoke screens; to counter the attacks of the enemy flotilla, by going out to meet them before they can manoeuvre into position to launch their torpedoes; and to form an anti-submarine and anti-aircraft screen to protect the battle fleet against these forms of attack, when necessary. As the principal safeguard of the battle fleet against submarine attack the destroyer proved efficient in the War of 1914–18, so much so that no single battleship or battle cruiser of the British Grand Fleet was torpedoed by a submarine throughout the war, although the fleet was repeatedly in waters where the German "U Boats" were in wait.

Destroyers may find special scope for their powers of offence during dark hours, particularly if they can locate their quarry and surprise it unprepared. On the other hand, the experience of the war showed that a battleship, well prepared and with a good fire control system for her secondary armament, is by no means the simple prey to the destroyer that it was sometimes anticipated she would be. For example: the German battle fleet, in its desperate break through the British destroyer flotillas the night after the battle of Jutland (*q.v.*), displayed remarkable powers of self-protection; although repeatedly engaged by torpedo craft, only one of their battleships was sunk. This ship succumbed to a well-executed attack by a British destroyer flotilla just before dawn. A battleship lying unprotected in an open roadstead is likely to fall an easy prey to a destroyer attack. (*See* DARDANELLES.)

In World War I, destroyers had to be built for many services besides battle fleet work. A large force was maintained at Harwich, where they co-operated with the light cruisers in making sweeps into the Heligoland Bight. Another force was employed in the Dover Command in safeguarding the approaches to the Channel, in supporting mine-sweeping and bombarding operations and in escorting transports, convoys and shipping generally. Some of the very oldest class of destroyers, known as the "30 knotters," were particularly hard worked in the early days of the War.

The question of whether, on the very limited displacement, a gun or a torpedo armament shall predominate has always been rather a moot one, but, with the increase in size of modern destroyers, a fairly satisfactory compromise has been arrived at; the torpedo armament is adequate for offensive purposes and the gun armament is sufficient to counter that of potential opponents of a similar type. Special destroyers are fitted for mine laying, their speed enabling them to dash in, under cover of fog or darkness, run their line of mines, and escape before they can be detected or brought to action. The extent to which the destroyer can provide protection to the larger surface ship against torpedo attack by aircraft is a problem which modern navies have yet to work out. (E. A.; X.)

TECHNICAL

Previous to 1877 the torpedo vessels of the various navies had been small craft fitted with spar or towing torpedoes; in that year the British Government introduced the "Lightning," the first torpedo-boat—a vessel of 34 tons and 19 knots, with one bow tube and equipped with the Whitehead torpedo. This step was soon followed by other navies. The torpedo boat steadily increased in speed and armament, till in 1908 the last torpedo boats built for the British Navy displaced 280 tons, carried two 12-pounder guns, three 18-in. tubes, and developed 26 knots.

The next step was to build boats capable of overtaking and destroying the torpedo boats before they could launch their attack. It was evident that the type of vessel to perform this duty must be very similar to the torpedo boat itself, but of larger size and

MODERN TYPES OF THE DESTROYER AND FLOTILLA LEADER

1. U.S.S. "Drayton": 5–5″ 38-calibre, 4 M.G. guns; 8 quadruple 21″ tubes; 42,800 h.p., 36.5 knots
2. Left, French destroyer "Orage," sunk off Dunkirk in 1940: right, French flotilla leader "Tigre"
3. H.M.S. "Ashanti": 8–4.7″ guns, 4–21″ torpedo tubes; 1,870 tons dis.; engines 44,000 h.p., 36.5 knots
4. Japanese destroyer "Harukaze": 1,270 tons dis.; engines 38.500 h.p., 34 knots
5. Italian flotilla leader "Leone": armament, 8 guns. 6 torpedo tubes: sunk in April 1941
6. German destroyer "Hans Ludemann," of 1,811-ton Roeder class, sunk in April 1940. Class has 5-5" guns; speed, 36 knots

greater speed and power. So the torpedo boat destroyer (to give the type its full name) appeared, and soon rendered the old torpedo boat ineffective and obsolete.

The first destroyers were the "Havoc," "Hornet," "Daring" and "Decoy," started in 1892. Their displacement was 275 tons, speed 27 knots (4,200 i.h.p.), and they were armed with one 12-pounder and three torpedo tubes. The success of these boats warranted the wholesale building of destroyers, and from that time until the outbreak of World War I in 1914, some 240 vessels of this type were built. The size and speed increased from year to year, and, by 1900, the speed had risen to 30 knots and the displacement ranged from 350 to 450 tons. A typical vessel of the period was the "Albatross" of 430 tons, 31 knots (7,500 i.h.p.), armed with one 12-pdr., five 6-pdr., and two 18-in. tubes.

With reciprocating machinery it was impracticable to obtain greater speed than 31 knots, but the advent of the steam turbine provided means of obtaining greater engine power, the first warships to be fitted with turbine machinery being the destroyers "Cobra" and "Viper," laid down in 1899. The power obtained was 12,000 s.h.p., giving a speed of 34 knots on a displacement of 370 tons.

In order to obtain high speeds on small displacements, destroyers up to this period were structurally very light and the machinery weights were reduced to the minimum possible. Several vessels after extended voyages showed signs of weakness and demands were made for greater strength and reliability. These were met in the "River" class of 1902–04. The displacement became 550–600 tons, they were armed with four 12-pdr. guns and two 18-in. torpedo tubes; and they were made more seaworthy by the addition of a forecastle.

In 1904, the Committee on Designs recommended the use of oil as the sole fuel for destroyers. This in conjunction with turbine machinery permitted the high speed desirable and enabled the engines and boilers to be handled with comparative ease, while there was a marked decrease in fuel consumption and consequent increase in radius of action. The first destroyers to have oil-fired boilers and turbines were the '(Tribal" class of "ocean-going" destroyers, of which 12 were built during the years 1905–08. The displacement of this class was 900 tons and speeds of 33 knots were obtained with 15,000 s.h.p. It was in the later vessels of this class that the 4-in. gun was first introduced into destroyer armament. The "Basilisk" class, which followed in 1908–09, saw the introduction of the 21-in. torpedo tube, all previous destroyers having mounted only 18-in. tubes. Destroyers subsequently continued to develop in the direction of increased speed and displacement and heavier armament both of guns and torpedoes, and at the outbreak of war the "M" class, of the 1913–14 program, were beginning to be delivered from the builders. These vessels had a displacement of 1,025 tons and were armed with three 4-in. guns, two 2-pdr. guns and four 21-in. torpedo tubes. The propelling machinery developed 25,000 s.h.p., which gave a speed of 34 knots.

The utility of destroyers was very fully demonstrated in World War I, and during the period of hostilities some 280 were built. The first destroyers under the war program, ordered in September 1914, were similar to the "M" class. Greater efficiency in the propelling machinery was realized in the "R" class which followed, as they had geared turbines in place of the direct drive hitherto fitted. This enabled the revolutions to be reduced and more efficient propellers to be fitted. The displacement of this class was 1,065 tons, the dimensions and armament remaining the same as in the "M" class. The horse-power was, however, increased to 27,000, giving a speed of 36 knots.

Developments during the war, and especially the heavier guns of the enemy submarines, made a more powerful gun armament indispensable for destroyers, and in the "V" and "W" classes which followed late in 1916, an advance in fighting power was made. They were fitted with four 4-in. guns of a heavier type, and the system of superimposing these guns in pairs forward and aft was adopted. This arrangement gives these vessels a high gun command and concentration of fire, so making them superior to the previous classes. They carry a 3-in. anti-aircraft gun amidships, and the torpedo armament is increased to two sets of 21-in. triple tubes. These improvements increased the displacement to 1,300 tons, and consequently the 27,000 s.h.p. propelling machinery entailed a reduction of speed to 34 knots.

Later vessels of the "W" class under construction at the cessation of the war, had the 4.7-in. gun in place of the 4-inch. These vessels, of which 14 were completed, also carry two 2-pdr. pom-poms, and six 21-in. tubes in two triple mountings, and in many respects approach more closely to a small light cruiser than to the destroyer of the pre-1914 period.

The progress of the war in 1914–18 called for many and varied duties, quite different from those for which the destroyer was primarily designed; not the least important of these was the active part taken in combating the enemy's submarine campaign, for which most British destroyers were fitted with special apparatus. A cast or forged steel ram, in association with double shell plating at the bows, proved successful in several instances in action with enemy submarines. Explosive "depth charges" fitted at the stern proved effective in dealing with submarines when they submerged before the destroyer could incapacitate them with gunfire or by ramming. Certain destroyers were fitted out as minelayers, and many were provided with mine and submarine sweep gear.

The building of British destroyers ceased altogether soon after the Armistice, and no vessels of the class were built till "Amazon" and "Ambuscade" were completed in 1927. These were followed by the eight vessels of the "Acasta" class built in 1930. All these vessels very closely followed the "W" class design.

During 1914–18 France built very few destroyers, but in 1917 obtained 12 vessels of the Japanese "Kaba" class. In 1922, 12 vessels of the "Bourrasque" class were laid down, followed in 1924 by 14 vessels of "L'Alcyon" class.

These last vessels were of 1,970 tons displacement, 34 knots (35,000 s.h.p.), armed with four 5.1-in. guns and one 3-in. anti-aircraft, with six 21.7-in. torpedo tubes.

Italy built destroyers steadily from 1916, averaging about three vessels per year, starting with "Sirtori" class of 800 tons and 30 knots speed.

Among the last to be laid down were the 16 ships of the "Nembo" class, the latest of which were of 1,350 tons displacement, 38 knots speed (44,000 s.h.p.), armed with four 4.7-in. guns and six 21-in. torpedo tubes.

American destroyers up to 1916 were of the "Porter" and "Manley" classes of 1.125 tons displacement, 32 knots speed (22,000 s.h.p.), armed with four 4-in. guns, one 3-in. anti-aircraft and twelve 21-in. torpedo tubes.

When the United States entered World War I in 1917, destroyers of 1.215 tons were constructed, carrying the same armament but with speeds up to 34 knots. Later types up to 1940 had a displacement of 1,570 tons, five 5-in. 38 calibre guns and twelve 21-in. torpedo tubes.

Japan's latest type of destroyer in 1914 was the "Kaba" class of 12 ships. 665 tons displacement. 30 knots speed (9,500 s.h.p.), armed with one 4.7-in. and four 18-in. torpedo tubes.

Ships of similar type to the British "R" and "W" classes were laid down, and the building of destroyers was thereafter continuous. the latest class being the "Kamikaze" class of 21 ships.

These are of 1,445 tons displacement. 34 knots speed (38,500 s.h.p.), armed with four 4.7-in. guns and six 21-in. torpedo tubes.

The most recent class of destroyers in each nation during the early part of World War II was approximately of the same type as the British "W" class, the principal difference being that, in France and Italy, greater length and power were adopted.

Flotilla-Leaders. — British destroyers on service are grouped in flotillas and there is insufficient room in a destroyer to provide the accommodation necessary for the officer commanding the flotilla with his staff and offices. A larger vessel uith the same general characteristics as the destroyer therefore became necessary; and such vessels were built, one for each flotilla, to act as its leader.

The forerunner of this class was the "Swift" of 1,800 tons displacement, built under the recommendations of the Committee on

Designs in 1904. The first leaders, built definitely to lead flotillas of destroyers, were the four vessels of the "Kempenfeldt" class—1,600 tons displacement, 34 knots speed, armed with four 4-in. guns and four torpedo tubes. These vessels were acting as leaders to flotillas of "K" and "L" class destroyers in 1914. During 1914–18, 25 leaders were constructed for service with flotillas of the "M," "R," "S" and "W" classes, the last being the "Campbell" class of 1,800 tons—36 knots (40,000 s.h.p.), armed with five 4.7-in. guns and six 21-in. torpedo tubes.

After 1918, the only flotilla leader laid down for the British navy was the "Codrington" of 1,520 tons displacement, speed 35 knots (39,000 s.h.p.), armed with five 4.7-in. guns and eight 21-in. torpedo tubes, built for service with "Acasta" class destroyers.

America by 1940 had started 20 ships of 1,630 tons with speeds up to 36.5 knots, and Japan had laid down 15 ships of the "Fubuki" class of 1,700 tons displacement, speed 34 knots (50,000 s.h.p.), armed with six 4.7-in. guns and nine 21-in. torpedo tubes.

After 1922 France laid down 6 flotilla leaders of the "Tigre" class, 2,360 tons displacement, speed 35.5 knots (50,000 s.h.p.), armed with five 5.1-in. and two 3-in. anti-aircraft guns, and six vessels of the "Guépard" class of 2,646 tons displacement, speed 38.5 knots (70,000 s.h.p.), armed with five 5.5-in. guns and six 21·7-in. torpedo tubes.

During the same years, Italy laid down three flotilla leaders of the "Leone" class, 1,960 tons displacement, speed 35 knots (42,000 s.h.p.), armed with eight 4.7-in. and two 3-in. anti-aircraft guns and six 18-in. torpedo tubes, and 12 ships of the "Navigatore" class, 1,980 tons displacement, speed 38 knots (50,000 s.h p.), armed with six 4.7-in. guns and six 21-in. torpedo tubes.

The tendency of flotilla leaders was to increase in size and speed, particularly in France and Italy, until they much more resembled light cruisers than leaders for torpedo boat destroyers.

DESTRUCTORS. This term is applied, particularly in England, by municipal engineers, to a battery of high-temperature furnaces constructed for disposing, by burning, of household and town refuse. Messrs. Manlove, Alliott and Co., of Nottingham first registered the word destructor as their special trade name for such a furnace. (For developments in the United States, *see* REFUSE DISPOSAL.) The first destructor built by this firm under Fryer's patent was erected in Manchester in 1874. Disposal of refuse is not, however, the only consideration. Utilization of refuse as fuel for steam production is also important. Many towns systematically utilize the calorific value of refuse.

A proper degree of caution, however, should be exercised when contemplating the use of refuse as a low grade fuel. When its value for this purpose was first recognized it was believed that the refuse of a given population was of itself sufficient to develop the necessary steam-power for supplying that population with their electric lighting requirements. The supposed economic importance of a combined destructor and electric undertaking of this character possibly had much to do, in some districts, with the development both of the adoption of the principle of dealing with refuse by fire and of lighting by electricity. Engineering experience, however, very often has shown this to be impractical. But, under favourable circumstances, determining the merits in each case, useful service to other power-using undertakings, such as sewage pumping, clinker crushing plants, etc., may be obtained.

Composition of Refuse.—The composition of house-refuse, which obviously affects its calorific value, varies widely in different districts. The following is an analysis of refuse as dealt with in destructors, based on the average of 12 towns in Great Britain. The percentages of the various constituents are as follows:—fine dust 45.45, ½in. to ¾in. and large cinders 36·16, bricks, pots, shale, etc., 6·5, tins 1·3, rags ·54, glass ·83, bones ·09, vegetable refuse 4·05, scrap iron ·42, paper 2.26, fish offal, greens, small paper bags, carpet, oil cloth, boots, etc., 2.4 per cent.

In London, the quantity of house-refuse amounts approximately to from 4cwt. to 5cwt. per head per annum, or to from 200 to 250 tons per 1,000 of the population per annum. Statistics, however, vary widely in different districts. At Ipswich 7·5cwt. per 1,000 of the population per working day are collected, whereas, at Merthyr Tydfil 40·1cwt. per 1,000 people per day are produced. Recent data show the normal quantity collected to lie between 15 and 20cwt. per 1,000 people per day. When estimating the required capacity of a destructor plant, the quantity of refuse produced by the particular town in question must first be independently investigated, and all calculations based accordingly.

A cubic yard of ordinary house-refuse weighs from 12 to 15cwt. but varies according to its condition whether wet or dry, etc. Shop refuse often consists largely of paper, packings, straw and cardboard. Its weight may be as little as 7cwt. per cubic yard.

Methods of **Disposal.**—Various methods of disposal of refuse are adopted by different towns according to local facilities and conditions. Owing to the high costs involved after World War I in the working of refuse destructors, a system of controlled tipping upon suitable land has been largely resorted to, notably at Bradford, where some 45 tips within the city boundaries are in use. The refuse is spread in layers of about 8ft. in depth and regularly covered with soil. By this means waste land, old quarries, etc., are reclaimed for future use as parks and open spaces. Pulverization of refuse has been adopted in some towns. The refuse is crushed to a small gauge, and where possible disposed of as manure, but the difficulty of securing a reliable market is usually considerable. When obtained such markets are not to be relied upon with any certainty of continuity. Another means of disposal is by the separation or salvage system. In this case the dust, cinders, paper, rags, glass, metals, tins, etc., are all separately sorted out and sold where markets can be found. The vegetable and other putrescible constituents are burned. The handling and redistribution of refuse material in this way amongst the population cannot be regarded with favour in the interests of public health. Disposal at sea and sinking in deep water are also practised, but is often rather costly and sometimes unsatisfactory.

The Destructor System.—The destructor system in which the refuse is burned to an innocuous clinker in specially constructed high-temperature furnaces is that which is most generally resorted to when other methods have proved unsatisfactory, especially in districts which have become well built up and thickly populated. Conditions regarding this method of disposal have, however, changed materially during recent years, particularly in reference to the present high capital costs and greatly increased working expenses. There has also been an appreciable deterioration in the calorific value of present-day refuse in many districts. These conditions have increased the difficulty of usefully combining a destructor with some form of power-using undertaking, with the object of earning credits as a set-off against the heavy working expenses of a destructor installation. The greatly extended use of electric and gas fires, improved types of oil and slow-combustion heating stoves, the high price of coal and the more economical habits of householders, have all contributed to the production of house refuse with a smaller proportion of cinders and scraps of coal, thereby resulting in a low calorific value, and also a poorer quality of clinker from the destructor furnace. At Farnborough it is found that the calorific value of refuse is now about 50% less than in pre-war days, and there has been similar experience at Southampton, Hull and elsewhere.

Many of the earlier destructor and electricity station combinations have not proved satisfactory for various reasons, and have been abandoned. One difficulty often experienced has been that of maintaining a steady and reliable steam pressure with so variable and uncertain a fuel.

A number of destructor-electric combinations are, however, working satisfactorily in districts where the local conditions are favourable, as at Rhondda, Wolverhampton and Pontypridd. At Rhondda and Pontypridd the refuse is of a high calorific value, and contains a relatively large percentage of small coal and unburnt cinders. During an official test, the Rhondda destructor (Heenan and Froude) evaporated 4·15 lb. of water per 1 lb. of refuse burned from and at 212°. This destructor was erected

in 1915, and the South Wales Power Co. purchased the electric current produced at this installation. The electrical energy generated is equal to 264 units per ton of refuse burnt.

The electrical output at the Rhondda destructor plant has not been equalled by any combined destructor and electric station. Other power-using services to which the surplus heat from a destructor is applied include the pumping of low level sewage, as carried out at Salisbury, Lincoln, Cambridge, Watford, Eastbourne, Luton, Felixstowe, Aldershot and Twickenham.

During recent years, the question of high running costs at destructor installations has been under careful review by many British public authorities, and many destructors have either been discontinued or rendered of limited service.

Conditions for Destructor System.—As regards the general question of the advisability or otherwise of erecting a destructor, each town should decide for itself, according to the local conditions and requirements. It is a question upon which it is unwise to generalize, but when considering the matter, some leading points to be kept in view are: (a) Is the district so closely built up and congested as to render all other less costly means of disposal impracticable, thus rendering the expense of a destructor necessary as a last resort? (b) Has the refuse sufficient calorific value to justify its use for steam-raising purposes, and are there any necessary local services, such as sewage pumping, upon which the heat from the destructor can be profitably utilized, and thus save the cost of coal as a set-off against the heavy working expenses? (c) Are any local markets available for the sale of surplus clinker, tins, etc.? (d) Can a suitable central site for a destructor be found in a populated area without involving additional expense in haulage to some outlying site, or causing nuisance from smells, dust, and the concentrated cartage of refuse, to the neighbouring inhabitants? *(e)* Can the existing system of disposal be carried on without risk of real danger (as distinguished from sentiment) to the public health? If not, the installation of a destructor must then be seriously considered.

Although the conditions arising out of the World War placed a check in Great Britain, in the United States and on the Continent upon the laying down of new destructor installations, and the maintenance of existing plants, the past few years have shown a renewal of activity in this direction.

Notwithstanding high capital costs and working expenses, necessity arising out of local conditions has led to the erection of new plants at Birmingham, Hornsey, Devonport, Rochdale, Wimbledon, Portsmouth, Brighton, Llandudno, East Ham, Hastings, Leicester, Leeds, Hereford, Accrington, Coventry, Edinburgh, Perth, Stoke, New York, Gibraltar and elsewhere.

Modern Equipment.—A modern installation usually includes, in addition to the leading feature of the destructor cells or furnaces, a mechanical power-driven plant used in connection with the preliminary screening of the refuse and comprising screens, elevators, etc., for the removal of dust up to about $\frac{1}{8}$in. gauge, an overhead runway for conveyance of hot clinkers from the furnace mouths, and storage accommodation for raw refuse for use when the collectors are not at work.

For the removal of tins and iron from the raw refuse electromagnetic separators are frequently installed where these materials have a marketable value. The tins are reduced in bulk to convenient blocks by means of a hydraulic baling-press. Clinker from the furnaces is reduced to saleable form by suitable clinker-crushing and screening plants. Other accessory machinery includes a strongly built mortar mill and a hydraulic press for the manufacture of slab-paving in order to utilize the surplus clinker, a power-driven fan with air-ducts for the supply of forced draught to the cells. Machinery for the manufacture of asphalt from clinker for the surfacing of roadways is in some cases also installed, as, *e.g.*, at Brighton and Abertillery. The motive-power for actuating all this accessory plant at the destructor station, including an electric lighting equipment, is usually economically obtainable from the surplus heat from the cells when applied to the generation of steam in a suitable boiler.

Forced Draught.—The forced draught to destructor cells may be given by an air fan or by steam blast. The air fan will require to work at about 6in. total water-gauge pressure, and to give from 2in. to ;in. of pressure in the ashpit itself. The actual pressure will vary according to the thickness of the fires being burnt at any given time. The power required to drive the air fan suitable for six furnaces of the Sterling type (New Destructor Co., Ltd.) will not exceed 25 brake horse-power.

In the case of steam blast with 2in. to $2\frac{1}{2}$in. water-gauge pressure in the ashpit, the quantity of steam used per hour would be approximately 1,000 lb. in four Heenan cells, or 250 lb. of steam per hour per grate of 30sq.ft. area. The temperature required to be developed in the combustion chamber is approximately 2,000°. The advantages of forced draught are that a much higher temperature is attained, little more air than the quantity theoretically necessary is needed, and the minimum amount of cold air is admitted to the furnaces. The air supply to modern furnaces is usually delivered hot—the inlet-air being first passed through an air-heater the temperature of which is maintained by the waste heat in the main flue.

Types of Cells.—The evolution of a good type of destructor cell or furnace, has occupied many years of experience, and has been the subject of much experiment and many failures. The principal towns in England which took the lead in the adoption of the destructor were Manchester, Birmingham, Leeds, Warrington, Blackburn, Bradford, Bury, Hull, Nottingham, Ealing and London. Ordinary furnaces, built mostly by dust contractors, began to come into use in London and in the north of England in the second half of the 19th century, but they were not scientifically adapted to the purpose, and necessitated the admixture of coal with the refuse to ensure its proper cremation.

The Manchester Corporation erected a furnace of this kind about the year 1873–74, and Messrs. Mead and Co. made an unsatisfactory attempt in 1870 to burn house-refuse in closed furnaces at Paddington. Shortly after Alfred Fryer erected his destructor at Manchester, several other towns also adopted this furnace. Other types were from time to time brought before the public, among which may be mentioned those of Pearce and Lupton, Pickard, Healey, Whiley, Thwaite, Young, Wilkinson, Burton, Hardie, Jacobs and Ogden. In addition to these the Beehive and the Nelson destructors became well known. The former was introduced by Stafford and Pearson of Burnley, and one was built in 1884 in the parish yard at Richmond, Surrey, but the results being unsatisfactory, it was closed during the following year. The Nelson furnace, patented in 1885 by Messrs. Richmond and Birtwistle, was erected at Nelson-in-Marsden, Lancashire, but, being costly in working, was abandoned.

Types of Destructors.—The principal types of destructors now in use are those of Fryer, Warner, Manlove-Alliott, Meldrum, Beamen and Deas, Heenan and Froude, and the Horsfall and Sterling destructor. The Fryer destructor was patented by Alfred Fryer in 1876. The cells are usually arranged in pairs back to back, and enclosed in a rectangular block of brickwork having a flat top on which the house-refuse is tipped from the carts. The furnace burns from four to six tons of refuse per cell per 24 hours. The outlets for the products of combustion are placed at the back near the refuse feed openings. This arrangement is imperfect in design as it permits offensive vapours from unburnt refuse to escape into the main flue with the products of combustion. Nuisances from smell arising from this cause led, in some instances, to the introduction of a secondary furnace, known as a cremator, which was patented by C. Jones of Ealing in 1885. This furnace was placed in the main flue leading to the chimney shaft for the purpose of cremating the organic matters in the vapours from the unburnt refuse, but it added considerably to the cost of running the destructor and was abandoned. The Fryer destructor, with a cremator, was largely used during the early history of destructors, but it has given place to more modern and improved designs of high temperature furnaces.

The Horsfall destructor is a high-temperature furnace of later design than the foregoing. Important improvements are to be found in the arrangement of the flues and flue outlets for the products of combustion, and in the provision of a forced draught duct through which air is supplied under pressure into a closed

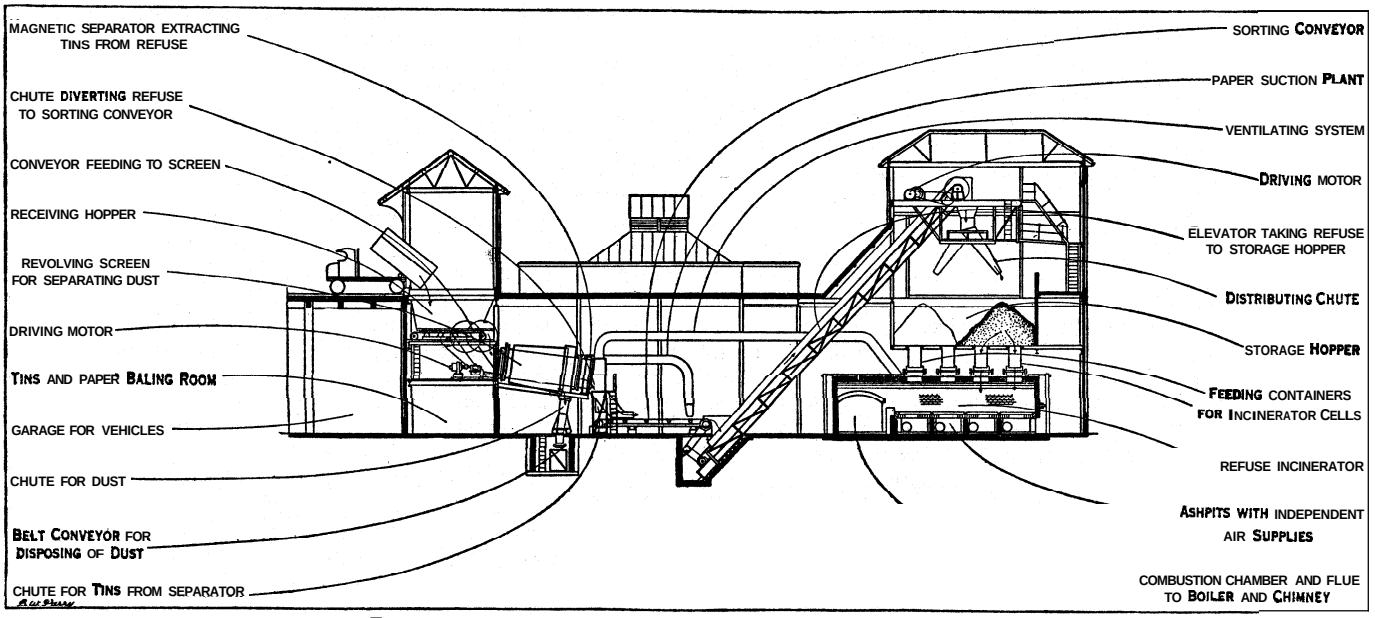

FIG 1.—CROSS SECTION THROUGH "HEENAN" DESTRUCTOR SYSTEM
Showing dust screening plant and entire course of the refuse from arrival in the refuse-collecting vehicle to its destruction in the furnaces

ashpit. The flue opening for the removal of gaseous products of combustion is placed at the front of the furnace over the dead plate whilst the feeding-hole for the raw refuse is situated at the back of and above the furnace. By these means the gases from the raw refuse must pass, on their way to the main flue, over the hottest part of the furnace and through the flue opening in the red-hot reverberatory arch. By means of the forced draught, a temperature of from 1,500° to 2,000°, as tested by a thermo-electric pyrometer, is attained in the main flue. Cast-iron boxes are provided at the sides of the furnaces, and through these the forced draught is conveyed on its way to the fire grate. The boxes are also designed to prevent the adhesion of clinker to the side walls of the cells and so to preserve the brickwork.

The standard arrangement for a modern Manlove-Alliott top-feed destructor is designed on the "continuous hearth" principle whereby the furnace gases pass from cell to cell on their way to the combustion chamber, thus ensuring a uniform temperature and minimising the cooling down effect when fresh refuse is charged into the furnaces. A joint destructor and sewage pumping scheme has been installed by the Borough of Guildford and the Rural District Council of Hambledon, in which sewage is raised by pneumatic ejectors worked by steam from the refuse. There are four cells of the top-feed type arranged with two water-tube boilers on the Wood and Brodie "Unit" system. Each boiler is sandwiched between a pair of cells, and the high-temperature gases pass immediately into contact with the boiler heating surface. There are eight ejector stations, in each of which two ejectors work as a pair, arranged so that both ejectors cannot be filling or discharging at the same time. The ejectors are of the Alliott and Philps's automatic improved type.

Warner's destructor (the "Perfectus") was similar to Fryer's in general arrangement, but was provided with special charging hoppers, dampers in flues, dust-catching arrangements, rocking grate bars, and other improvements. The refuse was tipped into feeding-hoppers, consisting of rectangular cast-iron boxes over which plates were placed to prevent the escape of smoke and fumes. When refuse was fed into the furnace a flap-door controlled by a lever was thrown over, the contents of the hopper dropped on to the sloping fire-brick hearth beneath, and the door at once closed again to prevent the admission of cold air into the furnace as far as possible. The cells were each 7ft. wide by 11ft. deep. The rear portion consisted of a fire-brick drying hearth, and the front of rocking grate bars upon which the combustion took place. The amount of refuse consumed varied from five to eight tons per cell per 24 hours.

The Meldrum "Simplex" destructor produced good steam raising results and was first installed at Rochdale, Hereford, Darwen, Nelson, Plumstead and Woolwich. Cells have also been erected at Burton, Hunstanton, Blackburn, Burnley, Cleckheaton, Lancaster, Sheerness and Weymouth. This destructor differs from those previously described in general arrangement. The fire-grates are placed side by side without separation except by dead plates, but, in order to localize the forced draught, the ashpit is divided into parts corresponding with the different grate areas. Each ashpit is closed airtight by a cast-iron plate, and is provided with an airtight door for removing the fine ash. Two Meldrum steam-jet blowers are provided for each furnace, supplying any required pressure of blast up to 6in. water column. The pressure usually used is about $1\frac{1}{2}$ to 2 inches. The furnaces are designed for hand-feeding from the front, but hopper-feeding can be applied if preferred. The products of combustion are led from the back of each fire grate into a common flue leading to the boilers and to the chimney shaft, or are conveyed sideways over the various grates and a common fire-bridge to the boilers or chimney. The heat in the gases, after passing the boilers, is still further used to heat the air supplied to the furnaces — the gases being passed through an air-heater or continuous regenerator consisting of a number of cast-iron pipes from which the air is delivered through the Meldrum blowers at a temperature of about 300°. At Rochdale, the Meldrum furnaces consumed from 53 lb. to 66 lb. of refuse per square foot of grate area per hour, as compared with 22·4 lb. per square foot in a low-temperature destructor burning six tons per cell per 24 hours with a grate-area of 25 square feet. The evaporative efficiency varied from 1·39 lb. to 1·87 lb. of water (actual) per 1 lb. of refuse burned, and the average steam pressure was about 114 lb. per square inch.

The Beaman and Deas destructor was installed at Warrington, Dewsbury, Leyton, Canterbury, Llandudno, Colne, Streatham, Rotherhithe, Wimbledon, Bolton and elsewhere. At Leyton, which, at the date when this destructor was installed, had a population of over 100,000, an eight-cell plant dealt with house refuse and filter press cakes of sewage sludge from the sewage disposal works adjoining. Each cell burnt about 16 tons of the mixture in 24 hours and developed about 35 i.h.p. continuously, at an average steam pressure in the boilers of 105 lb. The essential features of this destructor include a level fire-grate with ordinary type bars spaced only $\frac{3}{32}$ in. apart, a high-temperatured combustion chamber of about 2,000° at the back of the cells, a closed ashpit with forced draught, provision for the admission of a secondary air supply at the fire-bridge, and a fire-brick hearth sloping at an angle of about 52°. The forced draught is supplied from fans at a pressure of from $1\frac{1}{2}$ to 2in. of water gauge, and is

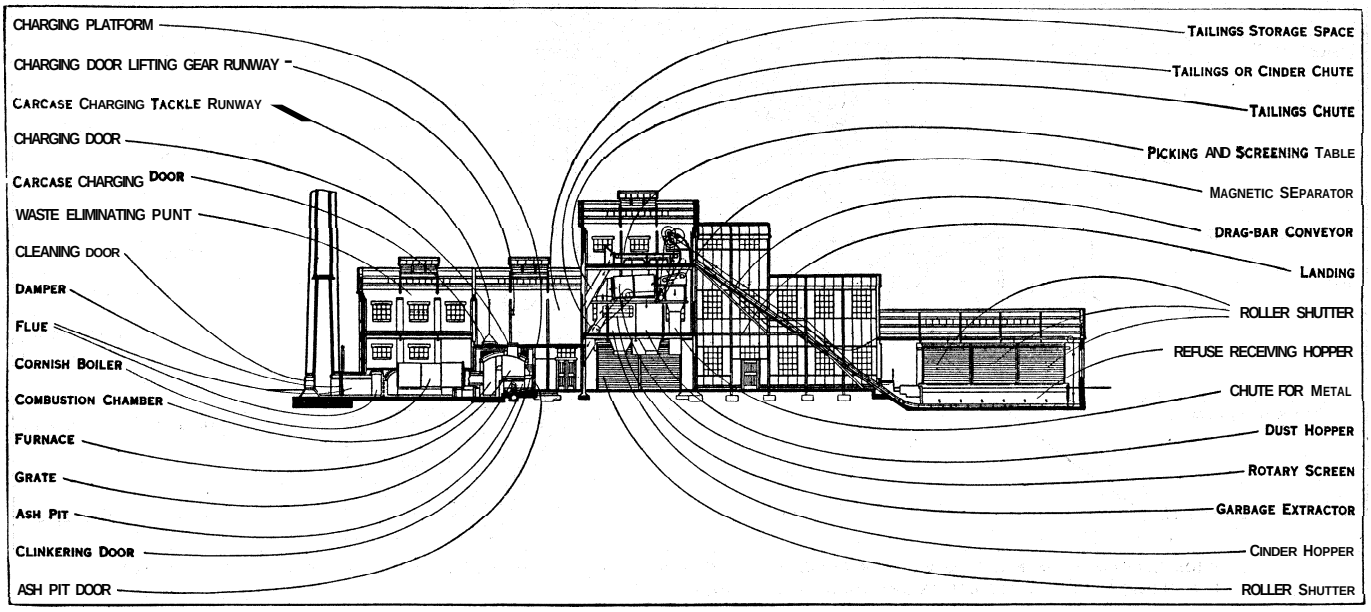

FIG. 2.— LONGITUDINAL SECTION OF REFUSE DISPOSAL PLANT OF THE NEW DESTRUCTOR COMPANY, WITH REFUSE-SCREENING PLANT
The refuse is delivered to "refuse receiving hopper," then raised by "dragbar conveyor" to the "picking and screening table." After sorting and screening, the "tailings" from the refuse are passed on to the "charging platform" over the destructor cells, where the material is burnt to an innocuous clinker

controlled by means of baffle valves worked by handles on either side of the furnace. The heat from the cells is used in conjunction with a water-tube boiler such as the Babcock and Wilcox, and the gases on their way from the combustion chamber to the main flue pass three times between the boiler tubes. The grate area of each cell is 25sq.ft. and the consumption varies from 16 to 20 tons of refuse per cell per 24 hours.

The Heenan destructor has been in use for over 25 years and a large number of installations have been erected in many of the largest cities throughout the world, including Birmingham, Glasgow, London, Leeds, Brussels, Paris, Rotterdam, Leningrad, New York, San Francisco, Montreal, Melbourne, Singapore, Edinburgh, Coventry, and many other places. The essential features of the Heenan System (fig. 1) include a continuous furnace chamber with divided ashpits, air heater or regenerator, combustion and gas mixing chamber, steam generator, forced draught supply with efficient air regulation and a ventilation system.

The cells may be designed for hand-feed under the direct control of the eye and hand of the stoker, either on the front-feed or back-feed system, or, where preferred, a system of mechanical charging and clinkering is installed. Mechanical clinkering has involved a change in grate design, and what is known as the trough-gate has been largely employed in the Heenan system. The advantages claimed are: perfect combustion and the maintenance of a regular temperature and boiler pressure during the process of feeding and clinkering; freedom from dust and a minimum of labour in the clinkering operations; the production of a hard clinker practically free from carbon, and a general cleanliness and expedition in the clinkering operations.

By means of the air-heater or regenerator system (placed in the path of the gases after these have passed through the boiler) employed with these furnaces, the thermal efficiency of the furnace is improved, excess of air in the cells is avoided, and more steady and better steaming results are obtained. Those destructors fitted with top-feed are either charged by container feed, skip feed, or feed by conveyor. The mechanical control of the doors permitting the fall of the refuse into the furnace chamber may be by hand operation from the clinkering floor, hydraulic operation with ram cylinders on platforms at the level of the top charging doors, or electric motors may be used for the opening and closing of the doors controlled from the clinkering floor.

Furnace doors are air-cooled. When clinkering, provision is made by means of an asbestos preparation to seal the doors to prevent the escape of fumes into the building. During the three years the Coventry Heenan plant was under observation, over 2 lb. of steam at 160 lb. pressure was produced for every 1 lb. of refuse burnt, and in colliery districts as much as 4 lb. of steam per 1 lb. of refuse have been developed from the refuse.

In the London metropolitan area an important installation of the Heenan system was installed at Ilford in 1916, embodying mechanical charging and clinkering accessories. The plant consists of two three-grate (trough-type) units, each unit comprising three mechanically charged and clinkered grates, one Babcock and Wilcox water-tube boiler of 200 lb. per square inch working pressure, one Foster superheater, three electrically operated top-charging doors with frames, shafting, drums, pulleys and wire ropes complete, one Heenan fan and engine for forced draught, and two electric ,cranes for lifting the refuse skips. The steam produced is used to drive generators in an adjoining station. The average rate of evaporation per hour, from and at 212° per square foot heating surface of boiler, under test, was 3.9 lb. The average rate of evaporation per 1 lb. of refuse burnt (from and at 212°) was 1·82 lb., and the steam pressure 155·8 lb. per square inch. The temperature of the combustion chamber was—maximum 2,462°, minimum 1,886°.

At a modern installation at Birmingham (Brookvale road depot) a specially designed suction plant was installed to collect waste paper from the end of the conveying belts, and to deliver it free of dust, to baling presses. To facilitate clinker handling, a monorail or overhead railway, with skips equipped with raising and lowering gear, provides convenient means of transporting the clinker to the cooling area or to the clinker plant.

The Heenan system had been largely used on the Continent, where some of the largest and best equipped installations are to be found. The plant erected at Rotterdam (Holland) in 1912 is a good example.

The refuse disposal plants of the New Destructor Co. include designs on the improved Horsfall and Sterling types. A typical plant is illustrated in fig. 2 showing the handling and path of the refuse from the time it is delivered to the destructor works until its reception into the furnaces. The cells are of modern continuous grate high-temperature type, and equipped for good steam-raising results. The Horsfall Poplar plant yields 700 h.p. from the combustion of the refuse, the power being used for generating electric current. The evaporation per 1 lb. of refuse burnt (from and at 212°) is about 1·5 lb. of water. The Mersey Dock and Harbour Board, Liverpool, use a Horsfall plant yielding 360h.p., for lighting, clinker treatment, etc., the capacity of five cells being 130 tons of refuse per 24-hour day. Sterling plants are used at Sydney (N.S.W.), Zurich, Colombo, Pittsburgh

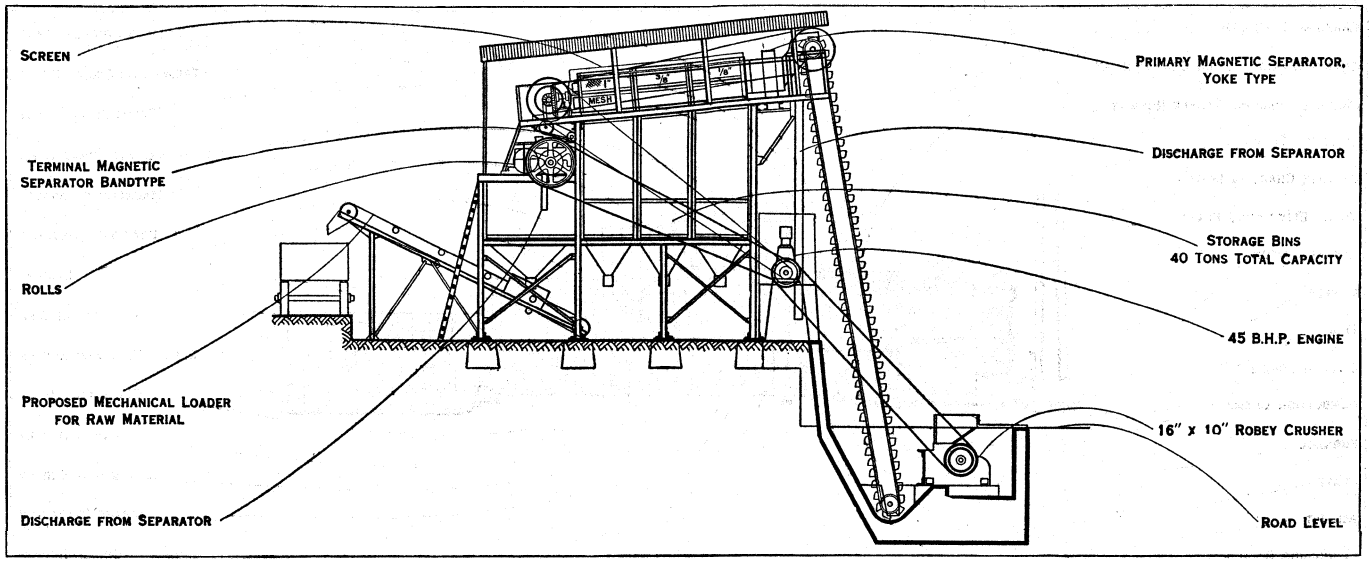

FIG. 3.—SIDE ELEVATION OF MILLAR'S CLINKER CRUSHING. SCREENING AND GRADING PLANT, FOR THE ECONOMICAL PREPARATION OF DESTRUCTOR CLINKER. BEFORE ITS USE IN THE MANUFACTURE OF ASPHALT

(U.S.A.), Berkeley (U.S.A.), and Toronto (Canada). The Colombo plant is a six-cell Horsfall back-feed type with continuous grate; each cell has a grate area of 30sq.ft. and is capable of burning ten tons per 24 hours. Forced draught is supplied by two positive blowers of the Roots pattern, exhausted through a galvanized-iron overhead main with its intake in the hoppers. The foul gases from the refuse are thus drawn over with the cold air and forced through the regenerative air heater and through underground ducts to the front of the furnace blocks. A 6in. cast-iron pipe is built into these ducts and connected to the side boxes for delivering the heated air to the underside of the grate bars.

Clinker asphalt machinery for the manufacture of road surfacing material is also provided, when required, in connection with Horsfall and Sterling furnaces. At an installation at Abertillery the cost per square yard of finished road including 2½in. base or binder course with a 1in. surfacing carpet costs about 7s. 3d. per square yard. Clinker-asphalt plants are also in use at Woolwich and Hendon, and a complete plant is being erected at Walthamstow.

Beast-cremating Chamber.—This installation includes two beast-cremating chambers to enable cattle, horses, dogs, etc., to be disposed of in the event of cattle murrain breaking out in the city. At the top of the chambers are large cast-iron doors lined with fire-bricks. The doors are fitted with a water seal to prevent hot gases blowing out. Carcasses are hoisted by pulley blocks mounted on a trolley fixed to steel joists so placed as to enable the beast to be lifted from the clinkering floor, traversed over the top of the furnaces to the centre of the cremating chamber, and dropped in by cutting a rope to avoid handling.

Destructor Records and Tests.—To judge correctly of the true performance of a destructor installation it is necessary to take careful observations and tests over long periods. Reliable records of every-day working throughout the whole year are necessary to gain a true knowledge of the performance of the plant. For such tests the destructor station should be provided with a road platform weigh-bridge, water meter, a pyrometer and, if possible, a carbon-dioxide recorder. The principal data to be noted include: the weight and description of refuse burned, the quantity of water evaporated in destructor-fired boilers, the average steam pressure, the weight of clinker and dust produced, the temperature in the combustion chamber and settings, and the percentage of carbon-dioxide in the flue gases. In order to determine the all-round efficiency of an installation, the leading facts to be ascertained from these data are: the weight of refuse burnt per square foot of grate area, the water evaporation per 1 lb. of refuse consumed from and at 212°, the average temperature of the combustion chamber, the average carbon-dioxide gas analysis, the percentage of steam required to operate the destructor and its accessory plant, and the percentage and quality of clinker compared with the weight of refuse consumed.

Temperatures in the combustion chamber may be obtained by the use of the Fêry radiation pyrometer, after the boiler by a mercury pressure pyrometer, and other temperatures by the mercury expansion thermometer. Other instruments used in connection with destructor tests are the Meyland-D'Arsonval galvanometer, and the Chatellier resistance pyrometer and galvanometer, as made by the Cambridge Scientific Instrument Co., Ltd. The continuous record of the chemical composition of the gases in the combustion chamber may be taken by means of the Simmance and Abady CO_2 recorder.

The higher the percentage of carbon-dioxide passing away in the gases the more efficient the furnace, provided there is no formation of carbon-monoxide the presence of which would indicate incomplete combustion. The theoretical maximum of carbon-dioxide for refuse burning is about 20%, and, by maintaining an even clean fire, by admitting secondary air over the fire, and by regulating the dampers or the air-pressure in the ashpit, an amount approximating to this percentage may be attained in a well designed furnace if properly worked. If the proportion of free oxygen (*i.e.*, excess of air) is large, more air is passed through the furnace than is required for complete combustion, and the heating of this excess is clearly a waste of heat.

Capital Costs and Working Expenses.—The capital cost of a destructor installation will depend very largely upon the local conditions, situation and nature of the site. In addition to the customary destructor buildings, cells, charging and clinkering machinery, brick settings, chimney shaft, inclined approach roadway, water supply, drainage, light, etc., a modern installation also usually comprises screening machinery for the removal of dust up to about ¼in. to ⅜in. gauge, power-driven elevators, sorting conveyor, electro-magnetic separators, clinker crusher and grading machinery, mortar mills, tin baling press, mess room and spray room, foreman's cottage, office, workshop, weigh-bridge, necessary road and yard formation, electric lighting and other accessories. The writer has had recent occasion closely to investigate the capital cost of such an installation for erection in Kent, capable of dealing with about 72 tons of refuse per 24 hours, and the inclusive cost, based on quotations received, was estimated at £19,700 including a 150h.p. Lancashire boiler, a 40b.h.p. horizontal engine, and a five-kilowatt electric lighting set, all comprised within destructor buildings built with steel stanchions, 14in. piers and gin. plain brick panels.

As regards the working expenses of dealing with the refuse by destructor, the average cost per ton of refuse, based on data from 20 towns in the south of England, was found to be 7s 4¾d. exclusive of loan charges. On a large portion of this class of

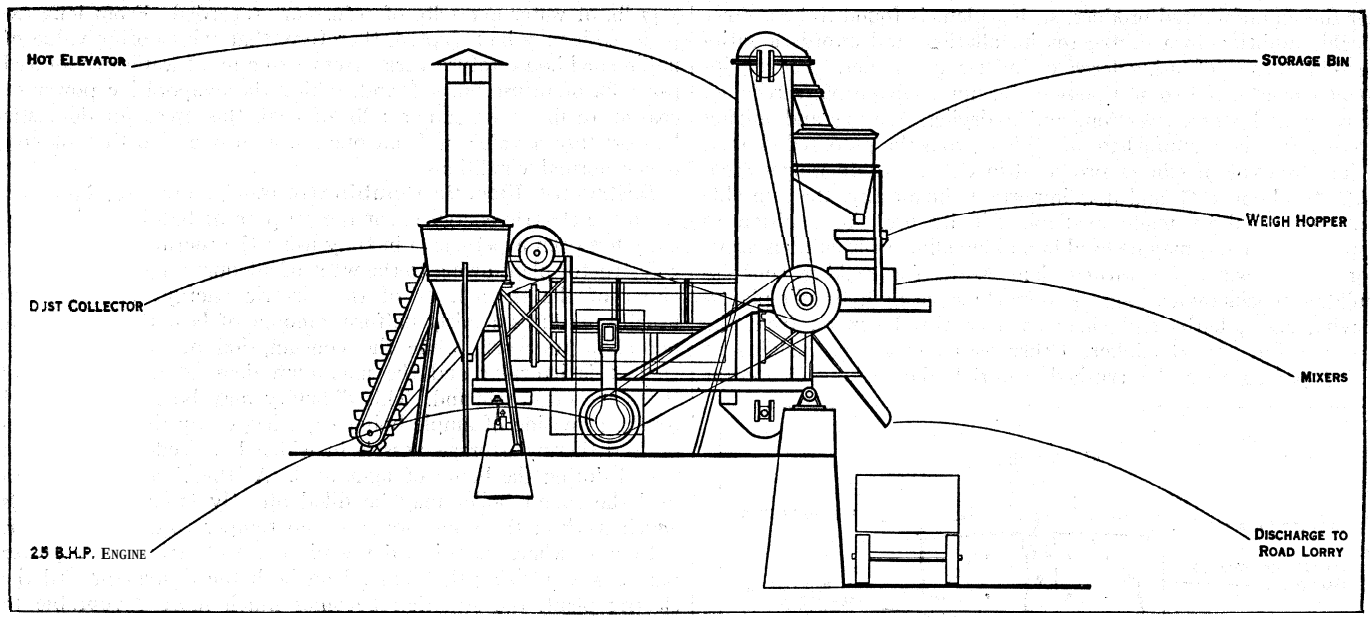

FIG. 4.— SIDE ELEVATION OF MILLAR'S CLINKER ASPHALT PLANT, FOR THE CONVERSION OF DESTRUCTOR CLINKER INTO ASPHALT FOR ROADWAYS

plant the depreciation and wear and tear are considerable. The loan period would therefore be relatively short, say from ten to 15 years only. Loan charges may amount to about 4s. per ton, under present conditions of high costs of building and machinery, on a complete scheme as outlined above. In view of the high temperature at which the cells work they would probably require relining within a period of ten years.

As regards labour required, stokers, with hand-fed plants, may deal with from five to six tons of refuse per man per eight-hour shift. For burning 50 tons of refuse per day of 16 hours four men per eight-hour shift would be required for stoking and firing. Extra labour would be needed for outside work such as clinker crushing, mortar making and other such work.

General Arrangement of Station. — In the general arrangement of a destructor station the cells are placed either side by side, with a common main flue in the rear, or back to back with the main flue arranged in the centre and leading to a tall chimney-shaft. The heated gases on leaving the cells pass through the combustion chamber into the main flue, and thence go forward to the boilers, where their heat is absorbed and utilized. Forced draught, or in many cases, hot blast, is supplied from fans through a conduit commanding the whole of the cells. An inclined roadway, of as easy gradient as circumstances will admit, is provided for the conveyance of the refuse to the tipping platform, from which it is fed, either by hand or mechanically, through feed-holes into the furnaces. In the installation of a destructor, the choice of suitable plant and the general design of the works must be largely dependent upon local requirements, and should be entrusted to an engineer experienced in these matters. The following primary considerations, however, may be enumerated as materially affecting the design of such works: (a) The plant must be simple, easily worked without stoppages, and without mechanical complications upon which stokers may lay the blame for bad results; (b) it must be strong, must withstand variations of temperature, must not be liable to get out of order, and should admit of being readily repaired; (c) it must be such as can be easily understood by stokers or firemen of average intelligence, so that the continuous working of the plant may not be disorganized by change of workmen; (d) a sufficiently high temperature must be attained in the cells to reduce the refuse to an entirely innocuous clinker, and all fumes or gases should pass either through an adjoining red-hot cell or through a chamber whose temperature is maintained by the ordinary working of the destructor itself at a degree sufficient to exclude the possibility of the escape of any unconsumed gases, vapours or particles. The temperature may vary between 1,800° and 2,000°.

Modern practice favours the continuous hearth principle whereby the furnace gases pass from one cell to another on their way to a common combustion chamber; *(e)* the plant must be so worked that while some of the cells are being recharged, others are at a glowing red heat, in order that a high temperature may be uniformly maintained; (f) the design of the furnaces must admit of clinkering and recharging being easily and quickly performed, the furnace doors being open for a minimum of time so as to obviate the inrush of cold air to lower the temperature in the main flues, etc.; (g) the chimney draught must be assisted with forced draught from fans or steam jet to a pressure of 1½in. to zin. under grates by water-gauge; (*h*) where a destructor is required to work without risk of nuisance to the neighbouring inhabitants, its efficiency as a refuse destructor plant must be primarily kept in view in designing the works, steam-raising being regarded as a secondary consideration; (i) where steam-power and a high fuel efficiency are desired a large percentage of carbon-dioxide should be sought in the furnaces with as little excess of air as possible,

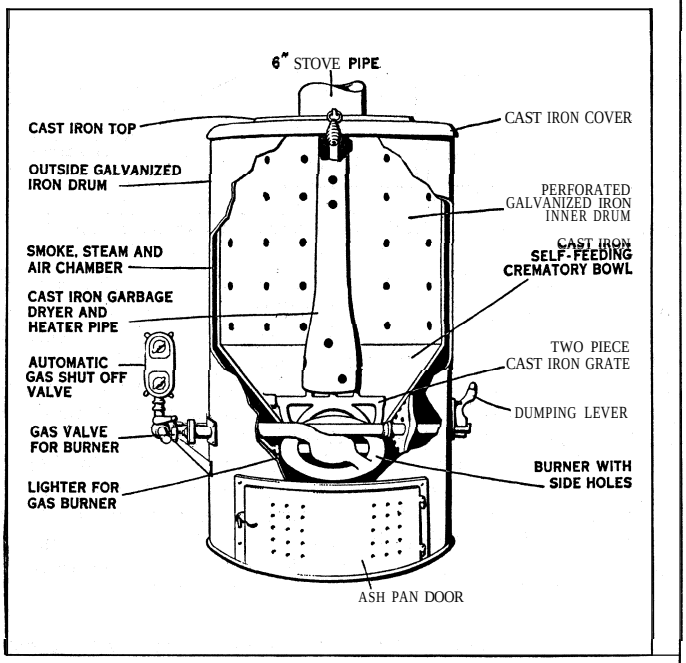
FIG. 5.— DIAGRAM OF THE INSIDE OF A DESTRUCTOR. DESIGNED TO DISPOSE OF REFUSE BY BURNING AND, AT THE SAME TIME, UTILIZE THE REFUSE AS FUEL TO DEVELOP STEAM POWER AND OTHER USEFUL SERVICES

and the flue gases should be utilized in heating the air-supply to the grates, and the feed-water to the boilers; (j) ample boiler capacity and hot-water storage feed-tanks should be included in the design where steam-power is required.

Clinker Asphalt Plants. — The cells at the Brighton destructor works have been reconstructed by Messrs. Heenan and Froude, Ltd., of Worcester, and a modern clinker asphalt plant installed. By means of this the destructor clinker is crushed, graded and mixed for use as an asphalt carpet or surfacing for roadways. This plant is illustrated in figs. 3 and 4. Where there is a suitable outlet

for the manufactured product, such a plant is found to be a serviceable addition to a destructor installation, and affords a satisfactory means of using large quantities of clinker. The equipment consists of two sections—a crushing, separating, screening, grading and storage section, and a drying, heating and mixing section for the manufacture of asphalt from the prepared clinker.

The amount of clinker produced in Great Britain ranges from 20% to about 35% and it is important, financially, that suitable outlets should be made available for its use. In addition to asphalt making, it may be used in making clinker bituminous grout for carriageways, for tarmacadam work, for making concrete building blocks by hand-operated machines or by hydraulic plants. Paving slabs, kerbs and channels may also be made from the crushed and graded clinker. Other uses include the bedding of street paving with the crushed material, the making of mortar



BY COURTESY OF HOME INCINERATOR CO.

FIG. 6—DIAGRAM OF THE INCINERATOR, A TYPE OF DESTRUCTOR

for building, and the bottoming of roads and footways.

The carbon content of the clinker is an indication of the efficiency of the combustion in the cell, and should always be low. The usual accessories for dealing with clinker include crushing, elevating and grading machinery, paving slab presses and machinery, clinker concrete block and brick making machines, mortar mills and asphalt plant. At the Coventry destructor the clinker represents about 25% of the refuse, and some 5,000 tons of clinker per annum are utilized for slab making, mortar making, tarmacadam work, for road foundations and similar requirements.

Use of Surplus Heat.—In order to render the refuse and gases therefrom perfectly innocuous and harmless, the modern high-temperature destructor must be worked at a temperature of not less than from 1,800° to 2,000°. The great heat thus developed has naturally suggested its utilization for steam production, and, where suitable outlets exist for its use, a reasonable additional expenditure on plant and labour is justified. The actual calorific value of refuse varies widely in different places and also during different seasons of the year, but as a general average, with a suitably designed and well managed plant, an evaporation of 1 lb. of water per 1 lb. of refuse burned is a result readily attainable, and one which affords a basis of calculation which engineers may adopt in practice. The evaporative results obtained depend also upon the industry and skill of the stokers as well as on the quality of the refuse. Many destructor steam-raising plants give considerably higher results than those named above, and evaporations approaching 2 lb. of water per 1 lb. of refuse are met with under favourable conditions. In the coal-mining districts of Rhondda and Pontypridd evaporations from and at 212° of 4·1j lb. and 3.47 lb. of water per 1 lb. of refuse are recorded. From long experience it may be accepted, therefore, that the calorific value of unscreened house-refuse varies from 1 to 2 lb. of water evaporated per 1 lb. of refuse burned, and, taking the evaporative power of coal at 10 lb. of water per 1 lb. of coal, this gives for domestic house-refuse a value of from one-tenth to one-fifth that of coal under normal conditions.

Destructor Electric Combinations.—In practice, however, when the electric energy is for the purpose of lighting only, difficulty has been experienced in fully using the thermal energy from a destructor plant owing to the want of adequate means of storage either of the thermal or of the electric energy. A destructor usually produces a fairly uniform amount of heat throughout the period of its work, while the consumption of electric lighting current is irregular and the maximum demand may be several times the mean demand. This difficulty may be greatly reduced by the provision of ample boiler capacity, or by the introduction of feed thermal storage vessels in which hot feed-water may be stored during the hours of light load. At the time of maximum load the steam boiler may be filled directly from these vessels which work at the same pressure and temperature as the boiler.

In cases where there is a day load, as for electric motive power purposes, equalizing the demand on both the destructor and the electric plant, the situation becomes much more favourable to the full utilization of the available surplus heat.

As regards sewage pumping, destructor installations of the New Destructor Co. are supplying power for this purpose at Gosport, Hampton, Leamington, Teddington, Worthing and other places, and a similar service is rendered by plants of Messrs. Manlove, Alliott and Co. at Guildford, Stroud and Cambridge, whilst the Heenan destructor affords power for sewage pumping at Portsmouth, Nuneaton, Hanwell, Lincoln and elsewhere. *(See* REFUSE DISPOSAL for American practice.)

DESTUTT DE TRACY, ANTOINE LOUIS, COUNT: *see* TRACY, ANTOINE LOUIS DESTUTT, COMTE DE.

DE TABLEY, JOHN BYRNE LEICESTER WARREN, 3rd BARON (1835–1895), English poet, eldest son of George Fleming Leicester (afterwards Warren), 2nd Baron De Tabley, was born on April 26, 1835, and died at Ryde on Nov. 22, 1895. He was educated at Eton and Christ Church, Oxford, where he took his degree in 1856 with second classes in classics and in law and modern history. In the autumn of 1858 he went to Turkey as unpaid attaché to Lord Stratford de Redcliffe, and two years later was called to the bar. In 1871 he removed to London, where he became a close friend of Tennyson for several years. From 1877 till his succession to the title in 1887 he lived in complete seclusion, but in 1892 he returned to London, and enjoyed a sort of renaissance of reputation and friendship.

De Tabley was at one time an authority on numismatics; he wrote two novels; published *A Guide to the Study of Book Plates* (1880); and the fruit of his careful researches in botany was printed posthumously in his elaborate *Flora of Cheshire* (1899).

From time to time he published volumes of verse under various pseudonyms. On the publication of *Philoctetes* in 1866 De Tabley met with wide recognition. *Philoctetes* bore the initials "M.A.," which were interpreted as meaning Matthew Arnold. He at once disclosed his identity. In 1867 he published *Orestes,* in 1870 *Rehearsals* and in 1873 *Searching the Net.* These last two bore his own name, John Leicester Warren. *The Soldier of Fortune* (1876), a drama on which he had bestowed much careful labour, proved a complete failure. The success of his *Poems, Dramatic and Lyrical* (1893), encouraged him to publish a second series in 1895, the year of his death. His posthumous poems were collected in 1902. The characteristics of De Tabley's poetry are

pre-eminently magnificence of style, derived from close study of Milton, sonority, dignity, weight and colour. He was always a student of the classic poets, and drew much of his inspiration directly from them.

See a sketch *by* Sir Edmund Gosse in his *Critical Kit-Kats* (1896).

DETAILLE, JEAN BAPTISTE EDOUARD (1848–1912), French painter of military subjects, was born in Paris on Oct. 5, 1848, and died there on Dec. 23, 1912. After working as a pupil of Meissonier's, he first exhibited, in the Salon of 1867, a picture representing "A Corner of Meissonier's Studio." He gained his reputation by depicting the scenes of a soldier's life with every detail truthfully rendered. He exhibited "A Halt" (1868); "Soldiers at rest, during the Manoeuvres at the Camp of Saint Maur" (1869); "Engagement between Cossacks and the Imperial Guard, 1814" (1870). The war of 1870–71 furnished him with a series of subjects which gained him repeated successes. Perhaps the most famous is the "Salut aux blessés" (1877). In 1884 he exhibited at the Salon the "Evening at Rezonville," a panoramic study, and "The Dream" (1888), now in the Luxembourg. He became a member of the Institute in 1898.

See Frédéric Masson, *Édouard Detaille and his* work (Paris and London, 1891); Marius Vachon, *Detazlle* (Paris, 1898).

DETAINER: *see* DETINUE.

DETECTIVE STORIES: *see* MYSTERY STORIES.

DETECTOR, that part of a wireless circuit whose function is to *pick up* or *detect* the electric oscillations which are set up in the antenna (*q.v.*) by the electromagnetic vibrations. (*See* WIRELESS TELEGRAPHY AND TELEPHONY.) As used in a radio receiving apparatus it is connected to a circuit carrying current of radio frequency, and translates the radio-frequency power into a form suitable for the operation of an indicator. This translation may be effected either by the conversion of the radio-frequency power into some other form or by the control of local power. The indicator may be a telephone receiver, loudspeaker, relaying device, tape recorder, etc. The most common type of detector is a vacuum tube operated on a non-linear portion of its characteristic curve, thereby converting a modulated radio-frequency current into a modulated direct current.

DETERMINANT, a special kind of algebraic expression involving a square number of quantities or elements, and usually denoted by arranging these elements in a square array with an upright line on each side:

$$a \quad a \quad ; \quad \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc;$$

$$\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix} = aei + bfg + cdh - afh - bdi - ceg; \text{ etc.}$$

A determinant with n^2 elements is said to be of the nth order, those just written being of the first, second and third orders respectively. It consists of the aggregate of all possible products of n of these elements taken one from each horizontal row and vertical column of the square array, with the sign + or − attached according to the rule of signs given below. The particular product whose factors are the elements in the *principal diagonal,* extending from the upper left-hand to lower right-hand corner of the array, always has the sign + attached.

The number of terms in a determinant increases rapidly with its order. Thus a determinant of the fourth order has 24 terms, a determinant of the fifth order has 120 terms, and so on.

If any k rows and k columns of the determinantal array be selected, the elements common to these rows and columns form an array of k^2 elements and define a *minor determinant,* or simply a *minor,* of order k. The minor formed from the n–k rows and $n-k$ columns not selected is called the *complementary minor.* Relations between a determinant and its minors play an important role in the theory of determinants.

The discovery of determinants is usually ascribed to G. W. Leibniz, who stated their law of formation in a letter written to De L'Hospital in 1693; however, a Japanese mathematician Seki Kōwa, had come close to the same discovery at least as early as 1683. The work of Leibniz seems to have exerted no influence. It was left to G. Cramer to rediscover determinants, and to publish first a statement of their law of formation in 1750. The convenient notation used above was introduced by A. Cayley in 1841. For these and other historical facts the reader may be referred to T. Muir's *The Tlzeory of Determinants in the Historical Order of Development,* vols. i.–iv. (London, 1906–20), and to D. E. Smith's and Y. Mikami's *A History of Japanese Mathematics* (Chicago, 1914).

Determinants necessarily arose as soon as two or more equations of the first degree in the unknown quantities were considered from an algebraic point of view. For example any two equations of the first degree may be written

$$ax + by = e,$$
$$cx + dy = f,$$

in which the letters a, b, . f stand for known quantities, while x and y are the two unknown quantities to be determined. If we multiply both sides of the first of these equations by d, and multiply both sides of the second equation by b, we obtain

$$adx + bdy = ed,$$
$$bcx + bdy = bf,$$

whence, by subtraction, there results

$$(ad - bc)x = (ed - bf) \text{ or } \begin{vmatrix} a & b \\ c & d \end{vmatrix} x = \begin{vmatrix} e & b \\ f & d \end{vmatrix}.$$

Hence x can be expressed as the quotient of two determinants of the second order, at least provided $(ad - bc)$ is not zero.

Similarly if there be given any number n of equations of the first degree in an equal number of unknown quantities, x, y, z, . . , these quantities can be expressed as quotients of determinants of the nth order. Such expressions for the quantities x, y, z , are obtained below.

Determinants are especially useful as an instrument of classification. Thus in dealing with equations of the first degree many possibilities exist, of which one, for instance, is that in which there are no values whatsoever of the unknown quantities satisfying the equations. The theory of determinants gives a comprehensive means of distinguishing between the various cases which may arise in this and many other algebraic questions.

The subject of determinants forms an extensive and fundamentally important part of higher algebra, and has application in nearly every mathematical field. The reader interested in the classical applications of determinants in higher algebra may be referred to M. Bôcher's *Introduction* to *Higher Algebra* (New York, 1907).

The daring notion of a determinant of infinite order was first developed by the American mathematician and astronomer, G. W. Hill (1877), in connection with his theory of lunar motion. This extension has proved to be one of importance. On the other hand determinants of n dimensions, based upon cubical arrays of elements ($n=3$) or, more generally on arrays of n dimensions, do not seem to be especially useful.

The Rule **of** Signs.—Suppose now that we select any particular product of n elements, one from each row and column of the square array, and count the number of pairs of letters in this product in which one letter of the pair appears to the right of and above the other. If there is an even number of such pairs, the sign + is to be prefixed to the product; if there is an odd number, the sign − is to be prefixed to the product. Since there are no pairs of this kind in the product formed from the Principal diagonal (and o is an even integer), the sign + is to be attached always to this especial product, as stated previously.

In illustration of this rule of signs we may consider the product $b\,h\,k\,m$ in the determinant of the fourth order

$$\Delta = \begin{vmatrix} a & b & c & d \\ e & f & g & h \\ i & j & k & l \\ m & n & o & p \end{vmatrix}.$$

The four pairs of letters bm, hk, hm, km, are to be counted: b appears to the right of and above m; h, to the right of and above k; etc. Hence the rule attaches a sign + to this one of the 24 products which appear in **A.**

The Fundamental Property of Determinants.—Imagine two adjacent rows or columns of a determinant to be interchanged. The only pair of elements of any product whose status changes as far as the rule of signs is concerned, is precisely the pair found in the two rows or columns which are interchanged. If this pair was counted before the interchange it will not be counted afterwards, and if not counted before, it will be counted afterwards. Hence such an interchange changes the number of pairs to be counted from odd to even, or from even to odd, and thus alters the sign of every product in the determinant.

Now to interchange any two rows or columns of a determinant requires an odd number of interchanges of adjacent pairs of rows or of columns. For example, in order to interchange the first and last rows in the above determinant A, the first row may be moved to the last position by three such interchanges of adjacent rows, and the row that stood last at the outset goes to the first position by two more such interchanges, so that five interchanges of adjacent rows suffice. In general, if two rows or columns are separated by k intervening rows or columns, evidently the odd number ak–I of interchanges of adjacent rows or columns will suffice. But each interchange of adjacent rows or columns alters the sign of every term in the determinant.

Thus the determinant has the fundamental property that the interchange of any two rows or columns reverses its sign.

In consequence, if two rows or two columns are made up of the same elements in the same order, the determinant must reduce to zero. For by the interchange of these two rows or columns the determinant is unaltered and yet is changed to its negative, and o is the only number equal to its negative.

The Solution of Equations of the First Degree.—Let us now return to the determinant of the fourth order written above, which can be regarded as associated with the four equations of the first degree, in x, y, z, w, written below:

$$ax+by+cz+dw=q,$$
$$ex+fy+gz+hw=r,$$
$$i\,x\,f\,j\,y\,f\,kz+lw=s,$$
$$mx+ny+oz+pw=t,$$

in which $a, b, \ldots, t$ are regarded as known quantities, and x, y, z, w, are unknown quantities to be determined. We propose to show that if Δ stands for the determinant written above, and $\Delta_1, \Delta_2, \Delta_3, \Delta_4$ stand for the four similar determinants obtained by replacing the first, second, third and fourth columns of A respectively by the column formed from the known quantities q, r, s, t, then the solution is given by the formulas:

$$x=\Delta_1/\Delta,\ y=\Delta_2/\Delta,\ z=\Delta_3/\Delta,\ w=\Delta_4/\Delta.$$

Let us denote the aggregate of all the products in Δ which contain a factor a by aA; similarly we may define bB, cC, ..., pP. Since every product in Δ contains one and only one element in the first column, we must have:

$$a\mathrm{A}+e\mathrm{E}+i\mathrm{I}+m\mathrm{M}=\Delta.$$

This gives a decompositidn of A in four parts; there are evidently seven other like decompositions of A obtained by considering the elements of any other column or of any row.

Now if we replace a, e, i, m, in the above equation by the elements of any other column of A, say by b, f, j, n respectively, the sum vanishes, *i.e.*,

$$b\mathrm{A}+f\mathrm{E}+j\mathrm{I}+n\mathrm{M}=0.$$

In fact this sum is evidently itself a determinant, obtained from Δ by replacing a, e, i, m, by b, f, j, n, respectively, and so its first two columns are the same. Consequently this sum will vanish.

Now multiply through the first of the four given equations by A, the second by E, the third by I, the fourth by M, and add all four equations. The co-efficient of x in the resulting equation is A. The co-efficient of y is the sum written above which vanishes. The co-efficients of z and w are similar sums which vanish also. On the right-hand side there is a sum which is evidently the determinant A_q. Thus we find $\Delta x=\Delta_1$, from which follows the expression for x as stated.

To obtain the expression for y it suffices to multiply the equations by B, F, J, N, respectively and add. A similar method expresses z and w in this manner.

Evidently this reasoning would establish the following general rule:

Let there be given any set of equations of the first degree with terms arranged according to the n unknown quantities in the left-hand members of the equations, while the terms on the right are known. If the determinant Δ formed from the square array of co-efficiepts on the left-hand side is not o, and if $\mathrm{A}_q, \mathrm{A}_r, \ldots, \mathrm{A}_t$ denote the n determinants obtained by replacing the first, second, ..., nth columns of A respectively by the sets of n constants on right-hand sides of the equations, then the unknown quantities are given by the quotients of determinants $\Delta_1/\Delta, \Delta_2/\Delta, \ldots, \Delta_n/\Delta$.

This general rule applies in case Δ is not zero, and actually furnishes the only possible set of values of the unknown quantities. No further consideration of the exceptional case when Δ is zero can be included here. (*G. D. Bi.*)

DETERMINISM, in ethics, the name given to the theory that all moral choice, so called, is the determined or necessary result of previously existing mental, physical or environmental causes (Lat. *determinare,* to prescribe or limit). It is opposed to the various doctrines of free-will, known as voluntarism, libertarianism, indeterminism, and is commonly regarded as more or less akin to necessitarianism and fatalism. There are various degrees of determinism. It may be held that every action is causally connected not only externally with the agent's environment, but also internally with his motives and impulses. In other words, if we could know exactly all these conditions, we should be able to forecast with mathematical certainty the course which the agent would pursue. On this theory the agent cannot be held responsible for his action in any sense. It is the extreme antithesis of indeterminism or indifferentism, the doctrine that a man is absolutely free to choose between alternative courses (the *liberum arbitrium indifferentiae*). Since, however, the evidence of ordinary consciousness almost always goes to prove that the individual, especially in relation to future acts, regards himself as being free within certain limitations to make his own choice of alternatives, many determinists go so far as to admit that there may be in any action which is neither reflex nor determined by external causes solely an element of freedom. This view is corroborated by the phenomenon of remorse, in which the agent feels that he ought to, and could, have chosen a different course of action. These two kinds of determinism are sometimes distinguished as "hard" and "soft" determinism. The controversy between determinism and libertarianism hinges largely on the significance of the word "motive"; indeed in no other philosophical controversy has so much difficulty been caused by purely verbal disputation and ambiguity of expression. How far, and in what sense, can action which is determined by motives be said to be free? The scientific doctrine of evolution has gone far towards obliterating the distinction between external and internal compulsion, *e g.*, motives, character and the like. In so far as man can be shown to be the product of, and a link in, a long chain of causal development, so far does it become impossible to regard him as entirely self-determined. Even in his motives and his impulses, in his mental attitude towards outward surroundings, in his appetites and aversions, inherited tendency and environment have been found to play a very large part; indeed many thinkers hold that the whole of a man's development, mental as well as physical, is determined by external conditions.

In the Bible the philosophical-religious problem is nowhere discussed, but the Bible usually assumes the freedom of the human will. It has been argued by theologians that the doctrine of divine foreknowledge, coupled with that of the divine origin of all things, necessarily implies that all human action was foreordained from the beginning of the world. Such an inference is, however, clearly at variance with the whole doctrine of sin, repentance and the atonement, as also with that of eternal reward and punishment, which postulates a real measure of human responsibility, impossible without free-will.

For the history of the free-will controversy, *see* the articles, FREE-WILL; PREDESTINATION (for the theological problems); ETHICS, KISTORY OF.

DETINUE, in law, an action whereby one who has an absolute or a special property in goods seeks to recover from another who is in actual possession and refuses to redeliver them. (See CONTRACT; TORT.)

DETMOLD, the capital city of the Land of Lippe, Germany, is on the east slope of the Teutoburger Wald, 25 mi. S. of Minden, on the Herford-Altenbeken line of the Prussian State railways. Pop. (1939) 23,314. The Renaissance château of the princes of Lippe-Detmold (1550) is an imposing building nearly in the centre of the town; whilst at the entrance to the large park on the south is the New Palace (1708–1718), enlarged in 1850. Detmold possesses a natural history museum, theatre, etc. Furniture, gloves, agricultural implements, etc., are made. About 3 mi. to the south-west of the town is the Grotenburg, with Ernst von Bandel's colossal statue of Hermann or Arminius, leader of the Cherusci. Detmold (Thiatmelli) was in 783 the scene of a conflict between the Saxons and the troops of Charlemagne.

DETONATORS. Devices employing certain explosives (*q.v.*) used to initiate the explosion of others, less sensitive but more easily regulated, or otherwise preferable for particular purposes. (See also MERCURY, FULMINATE OF; LEAD AZIDE; AZOIMIDE.)

DETROIT, Michigan, U.S.A., fronting *12* mi. an the Detroit river, and 4 mi. on the River Rouge, is the oldest city of any size in the U.S.A. west of the original seaboard colonies. Founded in 1701 by Antoine de la Mothe Cadillac with 100 settlers and soldiers, it was 17 years old when de Bienville began operations in New Orleans, and 63 years old before St. Louis was founded. The city antedates Buffalo by about a century, and it was 137 years old when Chicago received its first charter.

The first settlers as well as the first soldiers were French, and the government was French until 1760 when, as one of the results of the French and Indian War, it was occupied by the British under Col Robert Rogers. A few English settlers took up farms near by, but the place remained chiefly a military and trading post through the whole of the first century. During the Revolutionary War, Detroit was a centre of British influence, and a point from which Indian forays into the Ohio country were directed. Under the treaty that closed the war, Detroit passed nominally to the united colonies, but on various pretexts the British held possession until Jan. 11, 1796, when, under the Jay Treaty, the American flag was raised over the fort. During the War of 1812, the place was surrendered to the British under Gen. Brock, but the next year, after the battle of Lake Erie, it was returned to United States control. In the year 1805 Michigan was organized as a separate territory, with Detroit as its capital and also as the county seat of Wayne county, which included what are now Michigan, Wisconsin and part of Minnesota. The territory was afterwards narrowed down, and Detroit continued to be the capital of the territory until 1837, It was the capital of the state until 1847 when the seat of government changed to Lansing.

In 1805 every house in the town except one was destroyed by fire. This gave opportunity for an entire replanning of the place. The old division into narrow streets and small lots was entirely abandoned. To each citizen, whose old site was obliterated, a much larger lot was awarded free. The arrangement of streets left a number of open spaces which were dedicated as parks. The whole effect was one of openness and roominess unusual in the planning of towns at that early day. The older portions of the city retain the old characteristic of wide streets with occasional triangular parks. From this centre radiate the main thoroughfares which follow the lines of the old territorial roads. Michigan avenue is the starting point of the old "Chicago road"; Grand River avenue runs across the state to the "rapids of the Grand river," now the city of Grand Rapids; Woodward avenue leads north to "The Saginaws," and Gratiot to the foot of Lake Huron. Outside the city limits these roads were generally four rods wide, but modern improvement has transformed them mostly into wide paved roads. Woodward avenue is 120 ft. wide within the city limits and 204 ft. wide from the city limits to Pontiac, making it one of the finest main roads in the country. When the automobile began to create a need for improved highways, the county of Wayne, of whose wealth and population Detroit constitutes the largest part, established an efficient road commission. Through its work the county has been covered with an extensive network of paved roads. For a number of the main thoroughfares 204 ft. has been established as a standard width. The road system has been supplemented by ample provision for parks. The largest of these, River Rouge park, is 1,204 acres; but Belle Isle park is the gem of the system. It is an island of 985 ac. in the Detroit river, connected with the mainland by a bridge. Palmer park, 287 ac., Chandler, 230 ac. and Eliza Howell, 158 ac. are also highly developed. The total park system in 1940 comprised 3,651 ac. A boulevard 12 mi, long and 150 ft. wide encircles the central section of the city.

The city's remarkably rapid growth is shown by the increase in population, which in 1890 was 205,876; in 1900, 285,704; 1910, 465,766; 1920, 993,678; in 1930, 1,568,662; and in 1940 by federal census 1,623,452.

Administration. — When Michigan territory was first organized, both it and the town of Detroit came under the rule of the governor and judges. This administrative body had the very unusual combination of legislative, executive and judicial powers, and continued in force about 20 years. In 1818 the question of establishing a republican form of government with elective officers was submitted to the people, but the conservative French element voted it down. In 1824 a city charter was given to Detroit, and this was extensively amended or revised in 1827. 1837, 1857 and 1883. The settlement was officially styled the "Town of Detroit" till 1815. It was then called the "City of Detroit" till 1837, when it was enacted that the corporate name should be "The Mayor, Recorder and Aldermen of Detroit." In 1857 it again became the "City of Detroit." The old charters provided for elective officers, with aldermen elected by wards. The board of education and board of estimates were elected in the same way.

In 1918 an entirely new charter was adopted making radical changes in this form of government. In place of a board of aldermen of two members from each ward, there is a common council of nine members, elected at large and all elected at the same time. The term is two years. Members of the council must be at least 25 years old, and resident in Detroit at least three years, and may not hold any other civil office. The member having the highest number of votes at the election becomes president of the council and acting mayor in the absence of the elected mayor. The council is required to meet as a committee of the whole every day except Saturdays, Sundays and legal holidays for the purpose of receiving communications, complaints, petitions and reports, holding public hearings and discussing pending matters, and must meet in regular session at least once in each week in the evening. It has full legislative powers on all subjects that are within the scope of the city charter. At the same time that members of the common coupcil are chosen, the voters also elect a mayor, city clerk and city treasurer, nominations for all of these officers being made at a primary. The mayor under the new charter has exceedingly wide powers. He may veto acts of the common council. He has the appointment, without reference to the council, of a large number of administrative officials and commissions, and may remove most officials without trial or cause being given. The mayor also appoints the members of the board of assessors and board of health; city planning, public lighting, water, street railway, fire, public welfare, police and other commissions. An attempt to change the number of councillors to 15 chosen by wards and to reduce the mayor's power was defeated in November 1936 for the fourth time since the adoption of the 1918 charter.

The mayor and common council together have the final determination of tax levies and the issue of bonds, subject to certain limitations. The amounts to be raised by taxation in any one year, aside from the school expenses, cannot exceed 2% of the assessed valuation, and Detroit bonds are not marketable in New York if issued in excess of 9% of the assessed valuation. The charter also requires that all new issues of bonds shall be submitted to vote of the electorate. The heads of city departments are required to transmit to the controller, on or before Jan. 15, an itemized statement of amounts needed for the next fiscal year. The controller

compiles these in a budget book which he transmits to the mayor, who has until March 1 for its consideration. He may increase any items, but the total may not exceed the 2% limit, and the amounts required for interest and sinking fund of outstanding bonds may not be impaired. The mayor transmits the amended budget to the common council, which has about a month for its consideration. It is then returned to the mayor for his second revision which is final except that the council can, by seven affirmative votes, override the mayor's action on any particular item.

The city's fiscal year is from July 1 to June 30. On account of the expansion of its territory and business, its financial record has been on a constantly rising scale. The assessed valuation of the city for the fiscal year 1917–18 was $1,174,517,900; for 1940–41 it was $2,413,180,400. The tax rate was $13.80 in the former year and $28.08 for the latter; tax budget in the same period increased from $16,218,778 to $67,759,692. In 1911 the public debt, less amount in the sinking fund, was $8,088,098. Ten years later it was $68,208,347; in 1940 it had increased to $332,125,348. In the first period Detroit had the smallest *per* capita debt of any of the large cities in the country. In 1940, however, it had the third largest. In the fiscal year 1940–41 the total amount raised for municipal purposes mas $137,353,529, of which $67,759,692 was raised by tax levy while the remainder came from assessments, subventions, rent, department earnings and public-service earnings.

Manufacturing. — The modern growth of Detroit has been dependent largely upon manufacturing. According to the census reports for 1880 the city was nineteenth in the value of its manufactured products, that value being a little over $30,000,000. At the present time, the factories in Detroit take a little over three days to turn out products of that value. In 1899 the city was tenth with products valued at $88,640,000. Ten years later it was ninth with value of $252,992,000. In 1919 Detroit had risen to fourth place, with products (inclusive of those of Hamtramck and Highland Park) valued at $1,803,728,000. In 1925 the products of the city, together with its integrated suburbs, had increased to a total of $2,252,826,112, giving this industrial centre third place in manufactures among cities of the U.S.; the district was still third in 1937 when its products were worth $3,409,350,809.

To a remarkable extent the manufactures of Detroit have been associated with the instruments for transportation. The Pullman car works were first established there and continued in operation till 1893. The first freight car works were established in 1853. In the year 1904 these works employed 7,200 men with a production value of $23,000,000.

Detroit's situation led to the construction of small watercraft. The building of large vessels for lake traffic commenced in 1852 and has continued till the present day. In 1863 the building of marine engines was commenced; large shipyards on the river front and at Ashtabula, Ohio, were established. During the World War of 1914–18 many steamers were built in Detroit yards for overseas service.

About the time that freight car building began to decline, a new vehicle for transportation came into existence. Ransom E. Olds at Lansing and Henry Ford at Detroit were for years at work solving the problem of a vehicle to be "propelled by power generated within itself." Both succeeded, but Olds was first in the market. In 1899 he commenced the manufacture of the "Oldsmobile" in Detroit. The Cadillac Motor Car company was incorporated in 1901 and the Ford and Packard in 1903. This first appeared as a separate industry in the census reports in 1904 when it had 2,034 employees together with an output for the year valued at $6,240,000. From this beginning the increase was rapid. Detroit was well situated to become the centre of this new industry. Detroit and three of the neighbouring cities of Michigan had been centres of carriage making, and hence had the necessary raw materials available with workmen skilled in the making of springs, wheels and bodies and in upholstering. Detroit was making a larger number of gas engines than any other city in the entire country. With this reservoir of labour skilled in trades similar to those needed in the manufacture of automobiles, this industry became more and more concentrated in the Detroit area. In 1940 more than 90% of all American cars were produced by manufacturers whose main plants are in Michigan within 85 mi. of Detroit. In 1937, more than 5,000,000 cars, valued with replacement parts and accessories at $4,377,828,641, were produced, giving employment to 560,928 persons.

At the same time that the automobile was under production in such immense numbers, Detroit began taking a leading place in the making of the aeroplane. The first all-metal aeroplanes in the country were made here, and the construction of this kind of craft was conducted on an extensive scale. A canvass of the business made in the year 1929 by the board of commerce disclosed 57 companies in Detroit engaged in manufacturing or jobbing aircraft or their motors or supplies. Of these eight companies were assembling the completed planes, and 43 were making aircraft engines or parts. In 1941 there were about 75 companies making aircraft engines or parts in the Detroit area, and demands of the defence program were rapidly enlarging this activity, as the automobile manufacturers made available their enormous plants for the production of this vital defence item.

Apart from its prominence in the manufacture of aids to transportation lines the Detroit district has been notable for other achievements. The first iron furnace west of Pittsburgh mas built by Dr. Geo. B. Russel in Hamtramck in 1848. The first iron vessel built in the country was launched at the Wyandotte yards of the Detroit Dry Dock company and the first Bessemer steel forged in this country was produced at Capt. Ward's mill at Wyandotte. The city is one of the nation's leading steel centres. with products exceeded, in this area, only by the automobile industry. Other leading products in 1939 were nonferrous metal alloys, wirework, drugs, malt liquors, paints, stoves, electrical machinery and foundry and machine shop products.

Education and Culture. — By an act of the legislature approved by popular vote in 1916, the board of education in Detroit was changed from a large body elected by wards to a group of seven members elected at large. They are chosen two or three at a time on a general ticket. Nominations are made at a primary. Elections are held in the spring at the same time that supreme court judges are chosen. The names of candidates for members of the board are placed upon a separate ticket, upon which no party designations are allowed. The board has entire charge of the public schools, though the mayor has the veto power over particular acts, and the appropriations asked are subject to revision by the mayor and common council. At the end of 1940 there were in operation in the city 200 elementary schools, 19 intermediate schools and 25 high schools. There were also 43 schools housed in temporary buildings. Advance also has been made into the realm of higher education with the following six units of Wayne University: college of engineering, college of liberal arts, college of medicine and surgery, college of law, college of pharmacy and teachers college. In the grades as far as the high school, tuition is free to residents of Detroit. The number of teachers in the grade schools up to and including the high schools for the fall term of 1940 was 7,593; the number of pupils enrolled the same term, 255,647.

The appropriations for the public schools in Detroit for the fiscal year 1940–41 were as follows: from taxes $16,185,920; primary school money from state, $10,000,000; federal and other state aid, $552,800; county funds $304,000; all other sources $2,908,500; a total of $29,951,220. Of the total public debt of the city, $65,781,682 was incurred for school buildings.

Every year a census of "children of school age" (5 to 20 years) in the city is taken, and upon this is based a dividend from the primary school interest fund. The census showed 392,033 such persons in Detroit in the summer of 1940.

Besides public institutions there are in the city 132 parochial schools, chiefly Catholic and Lutheran, two law schools, the University of Detroit (Catholic) and a considerable number of private schools, literary, art and music. On opposite sides of Woodward avenue, each in the midst of grounds two blocks in extent, are the public library and the art institute. The library was established in 1865 with a collection of 5,000 volumes, occupying an annex to the old capitol building. It was for several years under the direction of a committee of the common council, but in 1880

VIEWS OF DETROIT

1. Air view showing the Detroit river, and Belle Isle in the distance: Canada is at the right
2. Cadillac square and Woodward avenue, Detroit's principal street
3. Sky line of the city as seen across the Detroit river from Belle Isle park
4. The Detroit Boat club on Belle Isle. The island, located near the centre of the city, also has a zoo, a golf course, swimming beach and playgrounds
5. Grand Circus park, a main thoroughfare of downtown Detroit

the control of the library was given to a board of six members elected by the board of education. The building at present occupied by the library is of white marble and is arranged in eight different departments, including the noted Burton historical collection. The library had 18 branches and 891,532 volumes in 1935.

The Detroit Institute of Arts goes back in its foundation to a noted loan exhibition in 1883. After the close of the exhibition a society was formed consisting of 40 incorporators each of whom contributed $1,000 for establishing a permanent art institution. The subscription was subsequently increased to $100,000, and the first art museum building was erected. It remained the property of the corporation until 1919 when it was taken over by the city. The new building which was opened to the public in Nov. 1927 is of Vermont marble, of Italian Renaissance style, and cost about $4,000,000. It is divided into three main departments, for European, American and Asiatic art.

Miscellaneous. — Detroit's land transportation needs are adequately supplied by the following railroads: Michigan Central, Pere Marquette, Wabash, Detroit, Toledo and Ironton, Grand Trunk and Canadian Pacific. The two first named have each a number of lines, and together form a network of tracks covering the whole of Michigan's lower peninsula. The two last named have direct connection with the whole Canadian railroad system. The railroads are supplemented by motorbus and motor truck lines extending in all directions from the city. Detroit's situation on the strait connecting the upper and lower lakes, gives the city peculiar advantages for water transportation.

The Detroit river ranks as the busiest inland waterway of the world. During the 1939 season, 91,643,043 tons of freight were transported through it to terminal and way ports of the Great Lakes. The chief commodities in order of their importance were iron ore, coal, petroleum, limestone and grain. Detroit has become an important factor in the air express business. In 1940 planes carried 1,091,901 lb. as contrasted with 489.348 lb. in 1938. This area in 1941 was served by three major air transport companies with nation-wide coverage. (H. CAM.)

DETTINGEN, village of Germany (Bavaria), 10 m. N.W. of Aschaffenburg, scene of the battle of Dettingen (1743) *(see* AUSTRIAN SUCCESSION, *WAR* OF THE).

DEUCALION, in Greek legend, son of Prometheus, king of Phthia in Thessaly, husband of Pyrrha, and father of Hellen, the mythical ancestor of the Hellenic race. When Zeus had resolved to destroy all mankind by a flood, Deucalion constructed a boat in which he landed on Mount Parnassus with his wife. Having offered sacrifice and enquired how to renew the human race, they were ordered to cast behind them the "bones of the great mother," that is, the stones from the hill-side. Those thrown by Deucalion became men, those thrown by Pyrrha, women.

DEUCE, a term applied to the "two" of any suit of cards, or of dice. It is also a term in tennis when both sides have each scored three points in a game, or five games in a set; to win the game or set two points or games must then be won consecutively, and the players return to a position of equality as often as they cannot score two such points or games consecutively. The earliest instances in English of the use of the slang expression "the deuce," in exclamations, date from the middle of the 17th century.

DEUS, JOÃO DE (1830–1896), the greatest Portuguese poet of his generation, was born at Messines in Algarve on March 8, 1830. Matriculating in the faculty of law at the University of Coimbra, he settled in the city, dedicating himself wholly to the composition of verses. In 1862 he left Coimbra for Beja, where he was appointed editor of *O Bejense,* and four years later he edited the *Folha do Sul.* As the pungent satirical verses entitled *Eleições* prove, he was not an ardent politician, and, though he was returned as Liberal deputy for the constituency of Silves in 1868. he acted independently and promptly resigned his mandate. In 1868 his friend José Antonio Garcia Blanco collected from local journals the series of poems, *Flores do campo,* which is supplemented by the *Ramo de pores* (1871). This is João de Deus's masterpiece. The *Folhas soltas* (1876) is a collection of verse in the manner of *Flores do campo,* brilliantly effective and exquisitely refined. Within the next few years the writer turned his attention to educational problems. This was a misfortune for Portuguese literature; his educational mission absorbed João de Deus completely, and is responsible for many publications of no literary value. A copy of verses in Antonio Vieira's *Grinalda de Maria* (1877), the *Loas á* Vwgem (1878) and the *Proverbios de Salomão* are evidence of a complete return to orthodoxy during the poet's last years. He died at Lisbon on Jan. 11, 1896, and was buried in the National Pantheon at Belem.

Next to Camoens and perhaps Garrett, no Portuguese poet has been more widely read, more profoundly admired than João de Deus; yet no poet in any country has been more indifferent to public opinion and more deliberately careless of personal fame. And yet, though he never appealed to the patriotic spirit, though he wrote nothing at all comparable in force or majesty to the restrained splendour of *Os Lusiadas,* the popular instinct which links his name with that of his great predecessor is just.

DEUSDEDIT or **ADEODATUS,** Pope and Saint (?–618), became pope on Oct. 19, 615, and died on Nov. 8, 618. The few decretals ascribed to him are unauthenticated and nothing is really known aboat him. He is said to have been the first pope to use leaden seals for pontifical documents.

DEUSSEN, PAUL (1845–1919), German philosopher and Sanskrit scholar, was born at Oberdreis on Jan. 7, 1845. He taught at Berlin (1881–89), and then became professor of philosophy in Kiel, where he died on July 7, 1919. As a philosopher, Deussen regarded the spatial world and objects as forms of the all-important empirical consciousness. The reality for him lay in a non-spatial, non-temporal and non-causal sphere to which we attain by moral activity rather than by intellect.

DEUTERIUM, or **HEAVY HYDROGEN,** is the isotope (*q.v.*) of hydrogen of atomic weight 2. A third isotope of hydrogen, tritium, is known having atomic weight 3. However, deuterium is the isotope which has been separated in appreciable quantities and which is of greatest interest at the present time.

Deuterium was discovered by Urey with the help of F. G Brickwedde and G. M. Murphy. Theory employing the third law of thermodynamics and the Debye theory of the solid state. predicted a difference in the vapor pressures of hydrogen and hydrogen deuteride and the possibility of concentrating the isotope by the distillation of liquid hydrogen at the triple point of hydrogen (13·92K). The deuterium was detected in the concentrates through its atomic spectrum. It was found that the concentration of deuterium had been increased from about one part in five or six thousand to approximately one part in 1,100.

The great scientific value of deuterium is due largely to the successful separation of this variety of hydrogen from natural hydrogen. Though the first effective concentration was made by the distillation of liquid hydrogen, large scale production of deuterium has been accomplished by the electrolytic method discovered by Dr. E. W. Washburn. This method makes use of the fact that in the electrolysis of water the rate of discharge of H_2 is more rapid than that for D_2, resulting in a concentration of D_2 in the electrolyte. By continuing the process until the residual water is sufficiently small, namely, about 1/100,000 of the original volume very nearly pure deuterium oxide or heavy water remains. In this way nearly pure heavy water was produced first by Lewis, and has since been produced in many laboratories of the world and now is an article of commerce.

Deuterium has also been produced by Hertz, using a method of diffusion of hydrogen gas through porous tubes, but this method cannot produce deuterium in as large quantities as the electrolytic method. The distillation of liquid hydrogen has been used by Brickwedde to produce hydrogen deuteride, which has not been prepared in any other way. Due to the difference in the vapor pressures of hydrogen oxide and deuterium oxide, that is, light and heavy water, it should be possible to separate the isotopes of hydrogen by fractional distillation of water if a sufficiently efficient fraction column can be devised. Lewis doubled the concentration of deuterium in water by such a distillation method, using a column of 40 theoretical plates. Although this method is

not as yet an accomplished fact, it appears probable that it will in the future replace the electrolytic methods.

The chemical properties of two isotopes are in general very similar, and this is true in the case of the hydrogen isotopes. Thus deuterium gas is very similar to hydrogen gas and deuterium oxide is in general very similar in its properties to hydrogen oxide. It is also true that other compounds in which deuterium replaces hydrogen are similar in their chemical and physical properties to the corresponding compounds of hydrogen. The differences in physical and chemical properties of hydrogen and deuterium and the corresponding compounds of hydrogen and deuterium, are much greater than in the case of any other two isotopes which have been investigated thus far. Thus the ratio of the vapor pressures of hydrogen oxide and deuterium oxide at the boiling point of water is approximately 1·05, while in the case of the two waters H_2O^{16} and H_2O^{18}, the ratio of the vapor pressures is 1·003 approximately. These comparatively great differences in the chemical properties of the hydrogen and deuterium compounds make possible the separation of these isotopes, whereas the separation of other isotopes has been accomplished only in a few cases or to very slight extents.

The difference in physical properties of hydrogen and deuterium may be illustrated by the melting points and boiling points of hydrogen, hydrogen deuteride, and deuterium, as shown in Table I.

Table I.

	H_2	HD	D_2
Gram molecular volume of solids	26 15 cc		23 17 cc
Heat of fusion.	28 0 cal.	37 0 cal.	52 3 cal.
Heat of vaporization at triple points	217 7 cal.	265 cal.	303 1 cal.
Triple point	13.92°K	16.60°K	18.71°K
Boiling Point.	20 38°K	22.13°K	23 59°K

The chemical properties of hydrogen and deuterium are qualitatively the same, though quantitatively there are marked differences. We may classify such differences with respect to the equilibrium and the kinetic properties of chemical reactions.

The velocities of chemical reactions in which deuterium replaces hydrogen differ more markedly than do the equilibrium properties. Hydrogen reacts with chlorine 13·4 times more rapidly at 0°C than deuterium, and similar differences are observed in the case of other chemical reactions.

The nucleus of the deuterium atom, known as the deuteron, can be used in transmutation reactions in much the same way as the proton or hydrogen nucleus; the nuclei of hydrogen atoms can be used in producing beams of high speed particles by allowing protons or deuterons to fall through large electric fields and then allowing them to impinge upon solid surfaces. In this way many of the chemical elements can be transmuted. Deuterons falling upon deuterium atoms produce hydrogen atoms and tritium atoms. Deuterium atoms falling upon lithium may produce helium atoms or helium atoms and neutrons. These transmutation reactions are of very great interest in connection with the study of the nuclei of atoms.

The biological effects of deuterium oxide are of considerable interest. It has been established that both plants and animals do not continue to live and thrive in water containing deuterium oxide of high concentrations. So far no case of acclimatization to the deuterium oxide has been observed.

Perhaps more interesting than the gross effects of life and death of living organisms in deuterium oxide can be secured by using deuterium as an indicator in the study of metabolic processes within living things. It often is of interest to trace a variety of atom or compound through living organisms. Deuterium makes possible such studies for if given to an animal in its food the particular compounds of the food can again be identified in the excretory products, in the blood, in the fat deposits of the body, or other tissues, and hence the course of the foods through the animal body can be traced. Studies of this kind will probably prove to be among the most interesting applications of deuterium.

DEUTERONOMY, the fifth book of the Law in the Old Testament. The name is a Greek mistranslation of the term Mishneh *hat-Torah,* "copy of the Law," found in Deut. xvii. 18 and Josh. viii. 32. It is ostensibly an account of the Law as given by Moses just before his death in the plains of Moab, the theory of the book being, apparently, that the Law given 38 years earlier at Horeb was confined to the "Ten Words" (see DECALOGUE), and that the present precepts are offered as a rule for life in the country which Israel will soon enter.

Contents and Structure. — The book falls into the following well marked divisions: (i.) i. 1–iv. 43. Introductory discourse by Moses, mainly a historical retrospect. (ii.) iv. 44–xi. 32. A second Introduction, consisting of a repetition of the Decalogue and an exhortation to observe the Law. (iii.) xii.–xxviii. A code containing both religious and civil laws, and including in ch. xxvii. instructions for the solemn ratification of the Law after the conquest of Canaan. (iv.) xxix.–xxxi. Concluding exhortation, with Moses's farewell to Israel. (v.) xxxii. and xxxiii. Two poems ascribed to Moses, the latter being a collection of tribal songs similar in form to Gen. xlix. (vi.) xxxiv. The death of Moses.

The original extent of the book is not fully determined. It may well have begun with iv. 44, or even with xii. 1 (though this is less probable). Chaps. xxvii., xxix.–xxxiv. may have been later appendices, and it is extremely unlikely that the two poems formed a part of the original book. There are signs of a double tradition, *e.g.,* xii. 2–7 and 8-14 cover the same ground ostensibly. The curious variation between the use of the second plural and the second singular in addressing Israel has led some scholars to believe that we have here the interweaving of two different documents, though it must be admitted that the two forms interchange so frequently and irregularly that analysis on this basis is most precarious. The tone and style of the book are very clearly marked. The whole has a humanitarian outlook, which is manifested both in modifications of existing laws and in the promulgation of new regulations. It thus contains repeated exhortations to love Yahweh, and to recognize His love to Israel. The ritual and ceremonial elements ate comparatively slight.

Date. — (a) *Comparative.* There are three other codes with which Deuteronomy may be compared, and the relation of the book to the work of some of the prophets, especially Hosea and Ezekiel, is of importance. In its present form it seems to be later than the Book of the Covenant (Exod. xx.–xxiii.) and Hosea, and earlier than the Priestly Code and, probably, Ezekiel. It may also be a little earlier than the Law of Holiness, though the affinities between these two documents suggest some connection. The order JE, D, Ezekiel, P, is, however, generally accepted.

(b) Absolute. Part of the importance of Deuteronomy for the history of Hebrew literature and thought lies in the fact that it seems possible to assign an actual date to its promulgation. Its main ritual provision, the concentration of sacrifice, finds practical expression in the religious measures of Josiah, 621 B.C. (II. Ki. xxii.; xxiii.) and Deuteronomy, or a nucleus of the book, has therefore been identified with the Book of the Law found by Hilkiah in the temple. If that view be correct, then Deuteronomy is a "programme" based on the teaching of the 8th century prophets, and compiled during the 7th century,

Whilst this is the "regnant hypothesis," it has not passed unchallenged. It involves two difficulties. One is that the provisions —or some of them — intended to meet the new order are unworkable in practice. Even in II. Ki. xxiii. 9 it is stated that the priests of the local sanctuaries, brought to Jerusalem as prescribed in Deut. xviii. 6–8, were not permitted to share in the offices performed by the Jerusalem priesthood in the temple. The other difficulty is that while the reform of Josiah tended to exalt Jerusalem, the Book of the Covenant (on which the Deuteronomic code is clearly based) and the historical traditions followed in Deuteronomy are of northern provenance, belonging to E rather than to J. Attempts have been made to solve these problems by throwing the date of the book either forward or backward.

Here it can only be remarked that these solutions raise other difficulties which would also have to be solved.

Whatever the exact date of the book may have been, its influence on Hebrew literature and thought is undeniable. In its spirit and from its point of view the Book of Kings was written, and some of the material now found in our prophetic books (especially Jeremiah) bears the same stamp, alike in matter and in style. It sprang out of and represents one of the most important schools of thought in the history of Israel.

DEUTSCH, IMMANUEL OSCAR MENAHEM (1829–1873), German orientalist, was born of Jewish extraction at Neisse on Oct. 28, 1829. His studies at the University of Berlin made him an excellent Hebrew and classical scholar, and in 1855 he became assistant in the British Museum library. He worked intensely on the Talmud and contributed more than 190 papers to Chambers's Encyclopaedia. His famous article on the Talmud in the *Quarterly* Review for Oct. 1867 was translated into many European languages. He died at Alexandria on May 12, 1873. His Literary Remains were edited by Lady Strangford in 1874.

DEUTSCHE BANK, German Bank, Berlin, was founded in 1870 for the special purpose of furthering and facilitating commercial relations between Germany and other countries and markets. It developed into one of the largest German banks. Its capital and reserves amounted in 1939 to 175,000,000 Reichmarks.

The Deutsche Bank was the first of the big German banks to found branch offices in the German seaports, to assist on a large scale the German export trade. It has maintained large offices in Bremen since 1871, and in Hamburg since the beginning of 1872, and by conceiving the idea of opening Depositenkassen (city offices) introduced the cheque system in connection with the receipt of interest-carrying cash deposits. In October 1929 a merger was arranged with the Disconto-Gesellschaft of Berlin, an important German Bank founded in 1851, which at that time had about 130 branches all over Germany and capital and reserves at about 186,000,000 Reichsmarks. The joint institution under the name of Deutsche Bank und Disconto-Gesellschaft developed a net of branches, densest in the industrial West. In 1939 the bank took over the branches of the Bohmische Union-Bank and of the Deutsche Agrar-und Industriebank situated in the Sudeten area. The Deutsche Bank has branches in 293 places. In addition, city offices have been opened in the larger towns. Foreign branches are maintained at Danzig, Katowice and Istanbul.

By virtue of its share holdings the Deutsche Bank is permanently interested in inter *alia* the Handelmaatschappij H. Albert de Bary & Co. N.V. in Amsterdam, the Kreditbank at Sofia and the Österreichische Creditanstalt-Wiener Bankverein, Vienna. It also holds a very large part of the share capital of the Deutsche O'oerseeische Bank (Banco Aleman Transatlantico) founded by the Deutsche Bank in 1886, which has its seat in Berlin and maintains 18 branches in Argentina, Brazil, Chile, Peru, and Uruguay and branches in Barcelona, Madrid and Seville.

In 1937 the bank resumed its old name, Deutsche Bank.

(E. WAG : X.)

DEUTSCHKRONE, town in the east of the Land of Prussia, Germany, between the two lakes of Arens and Radau, 15 mi. north-west of Schneidemiihl, a railway junction 60 mi. north of Posen. Pop. (1939) 15,044. It is the seat of the public offices for the district, and manufactures machinery, woollens and tiles.

DEUTZ (anc. Divitio), formerly an independent town of Germany, in the Prussian Rhine Province, on the right bank of the Rhine, opposite to Cologne, and incorporated with it since 1888. It contains the church of St. Heribert (a 17th century), cavalry barracks, artillery magazines, and gas, porcelain, machine and carriage factories. It has a handsome railway station on the banks of the Rhine. To the east is the manufacturing suburb of Kalk. The old castle in Deutz was in 1002 made a Benedictine monastery by Heribert, archbishop of Cologne. Permission to fortify the town was in 1230 granted to the citizens by the archbishop of Cologne. The fortifications were finally razed in 1888.

DEUX-SÈVRES, an inland department of western France, formed in 1790 mainly of the three districts of Poitou, Thouarsais, Gbtine and Niortais, added to a small portion of Saintonge and a still smaller portion of Aunis. Area. 2,338 sq.mi. Pop. (1936) 308,841. It is bounded N. by Maine-et-Loire, E. by Vienne, S.E. by Charente, S. by Charente-Inférieure and W. by Vendée. The Sèvre of Niort traverses the southern portion, and the Sbvre of Nantes (an affluent of the Loire) drains the north-west. There are three regions—the Gbtine, in the north and centre, the Plaine in the south and the Marais-distinguished by their geological and physical character. The Gâtine, formed of primitive rocks (granite and schists), is the continuation of the "Bocage" of Vendée and Maine-&-Loire. Its surface is irregular and covered with hedges and clumps of wood or forests. Application of lime has improved the soil, which is naturally poor. The Plaine, resting on oolite limestone, is treeless but fertile. The Marais, a low-lying alluvial district in the extreme south-west, is extremely productive when properly drained. The highest points, several above 700 ft., are found in a line of hills which begins in the centre of the department, to the south of Parthenay, and stretches north-west into the neighbouring department of Vendée. It divides the region drained by the Sbvre-Nantaise and the Thouet (both affluents of the Loire) in the north from the basins of the Sèvre-Niortaise and the Charente in the south, The climate is mild, the annual temperature at Niort being 52°, the rainfall nearly 25 in. Winters are colder in the Gâtine, summers warmer in the Plaine.

Three-quarters of the entire area of Deux-Sèvres, which is primarily an agricultural department, consists of arable land. Wheat and oats are the main cereals. Potatoes and mangold-wurzels are the chief root-crops. Niort is a centre for the growing of vegetables (onions, asparagus, artichokes, etc.) and of angelica. Much beetroot is raised to supply the distilleries of Melle. Colza, hemp, rape and flax are also grown. Vineyards are numerous in the neighbourhood of Bressuire in the north, and of Niort and Melle in the south. The department is well known for the Parthenay breed of cattle and the Poitou breed of horses; and good mules are reared in the south. The system of co-operative dairying is practised in some localities.

The apple-trees of the Gâtine and the walnut-trees of the Plaine bring a good return.

Some coal is mined, and the department produces building-stone and lime.

There is manufacture of textiles (serges, druggets, linen, handkerchiefs, flannels, and knitted goods). Tanning and leather-dressing are carried on at Niort and other places, and gloves are made at Niort.

Wool and cotton spinning, hat and shoe making, distilling, flour-milling and oil-refining are also main industries. The department exports cattle and sheep to Paris and Poitiers; also cereals, oils, wines, vegetables and its industrial products.

The Sèvre-Niortaise and its tributary the Mignon furnish 19 mi. of navigable waterway. The department is served by the Ouest-État railway. It contains a large proportion of Protestants, especially in the south-east. The two arrondissements are Niort and Parthenay; the cantons number 31, and the communes 357.

Deux-Sèvres is part of the region of the IX. Army Corps (Tours) and of the diocese and the *académie* (educational circumscription) of Poitiers, where also is its court of appeal.

Niort (the capital), Bressuire, Melle, Parthenay, St. Maixent, Thouars and Oiron are the principal places in the department. Several other towns contain features of interest. Among these are Airvault, where there is a church of the 12th and 14th centuries which once belonged to the abbey of St. Pierre, and an ancient bridge built by the monks; Celles-sur-Belle, where there is an old church rebuilt by Louis XI., and again in the 17th century; and St. Jouin-de-Marnes, with a fine Romanesque abbey church with Gothic restoration.

DEVA, a Roman legionary fortress in Britain on the Dee at the site of the modern Chester (q *v.*).

DEVA, DEWA, in the Zoroastrian mythology the Devs

were demons or evil spirits, but in the Indian Vedas. deva means a god, from Sanskr. *div,* "sky." In later Hindu, Buddhist and Jain literature the term denoted a god, demigod or spirit.

See A. A. Macdonell, *Vedic Mythology;* E. W. Hopkins, *Epic* Mythology,

DEVADATTA, the son of Suklodana, who was younger brother to the father of the Buddha (*Mahāvastu,* iii:76). Both he and his brother Ananda, who were considerably younger than the Buddha, joined the brotherhood in the twentieth year of the Buddha's ministry. Devadatta, fifteen years afterwards, having gained over the crown prince of Magadha, Ajātasattu, to his side, made a formal proposition, at the meeting of the order, that the Buddha should retire, and hand over the leadership to him, Devadatta (Vinaya Texts, iii:238; Jdtaka, i:142). This proposal was rejected, and Devadatta is said in the tradition to have successfully instigated the prince to the execution of his aged father and to have made three abortive attempts to bring about the death of the Buddha (Vinaya Texts, iii:241–250; Jhtaka, vi:131). Shortly afterwards, relying upon the feeling of the people in favour of asceticism, he brought forward four propositions for ascetic rules to be imposed on the order. These being refused, he appealed to the people, started an order of his own, and gained over 500 of the Buddha's community to join in the secession. We hear nothing further about the success or otherwise of the new order, but it may possibly be referred to under the name of the Gotamakas, in the Anguttara (see Dialogues of the Buddha, i:222), for Devadatta's family name was Gotama. But his community was certainly still in existence in the 4th century A.D., for it is especially mentioned by Fa Hien, the Chinese pilgrim (Legge's translation, p. 62). And it possibly lasted till the 7th century, for Hsiian Tsang mentions that in a monastery in Bengal the monks then followed a certain regulation of Devadatta's (T. Watters, On Yuan Chwang, ii:191). There is no mention in the canon as to how or when Devadatta died; but the commentary on the *Jātaka,* written in the 5th century A.D., has preserved a tradition that he was swallowed up by the earth near Sāvatthi, when on his way to ask pardon of the Buddha (Jdtaka, iv:158). The spot where this occurred was shown to both the pilgrims just mentioned (Fa Hien, *loc. cit.* p. 60; and T. Watters, On Yuan Chwang, i:390).

DE VALERA, EAMON (1882–), Irish politician, was born in New York city Oct. 14, 1882, of a Spanish father and an Irish mother. On the death of his father he was committed at the age of two to the care of his grandmother in County Limerick. He was educated at the local National school, the Christian Brothers' school at Charleville, Blackrock College, and graduated from the Royal university. In 1910 he married Jane Flannagan by whom he had six children. Although a teacher of mathematics he was an enthusiastic member of the Gaelic League. In 1913 he joined the newly-formed Irish Volunteers. He commanded a group of 50 in the Easter week rebellion (1916) and was the only leader to survive it. The British may have spared him because of his American birth. Instead, he was sentenced to life imprisonment at Dartmoor.

Upon his release in the general amnesty of June 1917 he worked for the Republican cause, and after the secession of the Sinn Fein members from parliament to form an Irish parliament, he was made president of the Sinn Fein government. In May 1918 he was re-arrested on the charge of planning another rising and imprisoned in Lincoln Gaol, England. In jail he pursued his mathematical interests. He escaped in Feb. 1919. From Ireland he went to the United States, where, as president of the Irish Republic, he collected more than $5,000,000 for the revolutionary movement on the security of Republican bonds.

In 1921 he appointed plenipotentiaries to negotiate a settlement with the British government. The treaty was not acceptable to him, for he demanded formal independence from Britain. The treaty was accepted by the Dail and upheld in elections. The Republican forces resisted the Free State government and De Valera was led to support their resistance.

In Aug. 1923 he was imprisoned by the Free State government. Upon his release in July 1924 he resumed active leadership of Sinn Fein as a Republican party with a policy of abstention from the Dail. Two years later Sinn Fein was split by the decision of a group led by De Valera to take the oath of allegiance to the king but only as "an empty political formula." This group became Fianna Fail and entered the Dail in 1927. The party was committed to removal of the oath, retention of the land annuities, an end of partition, preservation of the Gaelic language, and a policy of extensive social services and economic nationalism. After the 1932 election De Valera became president of the executive council of the Free State. He abolished the oath of allegiance, withheld payment of the land annuities and used the tariff retaliation of Britain as an excuse for hastening his self-sufficiency program. In 1933 and again in 1938–39 he was president of the League of Nations Assembly and called for a more effective league. Subsequently he opposed a proposal that the league use military sanctions. He was especially firm in supporting the nonintervention policy concerning the Spanish Civil war.

His relations with Neville Chamberlain were friendly. They modified the tariff war between Eire and Britain. By an agreement with Chamberlain (1938), De Valera received the naval bases of Cobh, Lough Swilly and Bearhaven. De Valera in turn supported the policy of appeasement. After the outbreak of World War II he attempted to follow a policy of strict neutrality. This policy was so widely supported in Eire that De Valera indicated that Eire would not participate in the war even if Northern Ireland were to be incorporated in Eire.

De Valera's economic policies were modified in his ten years of power. The economic war with Britain only emphasized Eire's dependence on the British market. In 1938 and 1939 De Valera expressed his awareness that this dependence might lead Ireland into a war in which Britain would be involved. This awareness and the trade agreements with Britain indicated a departure from the aim of self-sufficiency.

At home and abroad De Valera had serious trouble with the Irish Republican army. He was committed to the cause of Irish national independence and fought against the treaty (1921). He constantly criticized the Cosgrave government for the repressive measures it took against the I.R.A. He was unwilling to act severely or to condemn its terrorism unreservedly; his patience was several times strained. Finally in June 1939 the I.R.A. was declared an illegal organization.

In Feb. 1939 he attended the coronation of Pope Pius XII.

There are biographies of De Valera by Dwane, S. O'Faolain, Denis Gwynn and Desmond Ryan. (F. E. MN.)

DEVELOPMENT COMMISSION. The development commission was founded by act of parliament (1909) "to promote the economic development of the United Kingdom" by recommending advances for aiding and developing agriculture and rural industries, the reclamation and drainage of land, the development and improvement of fisheries, and the construction and improvement of harbours. Since 1921 Ireland has ceased to benefit under the act. There are eight commissioners appointed by royal warrant, each for a term of eight years, of whom one is salaried. The grants or loans recommended are made by the treasury from the development fund, into which the total amount paid by the exchequer down to March 31, 1939, was £10,518,000, most of which had been used by the end of that year. The commissioners' recommendations require treasury approval. Before deciding upon an application, the commissioners must receive a report from the government department concerned. They also appoint expert advisers and advisory committees to assist them. Advances may be made to government departments, public authorities, educational or other institutions, but not to individuals or to associations or companies trading for profit.

The agricultural research council, acting under the direction of a committee of the privy council, was established by royal charter in 1931. One of its functions is to act as advisers to the development commission in regard to all expenditure upon agricultural research.

A chain of institutions in Great Britain deals with research on such subjects as soils, plant physiology, plant breeding and diseases, fruit culture and preservation, the breeding, nutrition and diseases of animals, dairying, entomology, agricultural economics and machinery. There were 41 such institutes or stations in 1939 mostly based on universities, receiving maintenance grants from the development fund. District advisory officers have been provided to deal with local problems. Research scholarships are offered, and grants are made for researches into special problems, such as foot-and-mouth disease. On the agricultural education side, grants have been made for colleges and college farms, and for farm institutes, where less elaborate instruction is given suitable for farmers and small holders. Provision for agricultural scholarships has also been made.

In 1921, a rural industries bureau was set up in order to provide an intelligence and a technical advisory service for the development of rural industries work. The bureau is financed from the development fund and grants are also made from the fund to rural community councils in England and Wales for rural industries work carried out on a policy framed by the bureau. Loans are made for the erection and improvement of village halls. In a limited number of cases grants have been made on a diminishing scale for the establishment of new rural community councils. Grants of considerable amount have also been made to the national bodies in Great Britain responsible for the establishment of women's institutes in aid of their general work, for handicrafts instruction and for organizing the production and use of home-grown food. Advances have been made to the Land Settlement association, for experiments in the settlement of unemployed industrial workers on whole-time and part-time holdings.

Fisheries have been aided by grants for research made to the fishery departments and to various marine research institutes, the object being to gain that knowledge of fish and their environment which is necessary for the best exploitation of the resources of seas and rivers. Large loans have been made for installing motors in fishing boats, and co-operative societies organized to assist fishermen in marketing their catch. Fishery harbours have in many cases been improved and deepened, particularly in connection with the herring fishery in north-east Scotland.

The commissioners are empowered to make compulsory orders for the acquisition of land for purposes of development, and also for road improvements. An annual report is published.

DEVENS, CHARLES (1820–1891), American lawyer and jurist, was born in Charlestown, Mass., April 4, 1820. He graduated at Harvard college in 1838, and at the Harvard law school in 1840, and was admitted to the bar. Throughout the Civil War he served in the Federal Army, becoming colonel of volunteers in July 1861 and brigadier-general of volunteers in April 1862. After the war he was a judge of the Massachusetts superior court from 1867 to 1873, and was an associate justice of the supreme court of the State from 1873 to 1877, and again from 1881 to 1891. From 1877 to 1881 he was attorney-general of the United States in the Cabinet of President Hayes. He died at Boston, Mass., Jan. 7, 1891.

See his ***Orations and Addresses,*** with a memoir by John Codman Ropes (Boston, 1891).

DEVENTER, SIR JACOB LOUIS VAN (1874–1922), South African soldier, was born in the Orange Free State. He fought in the South African War of 1899–1902, becoming second-in-command to Gen. Smuts during the latter's invasion of Cape Colony. A colonel on the permanent staff of the South African defence force, Van Deventer served in the campaign in German South West Africa, 1914–15. His gifts as a general were shown later in the operations in East Africa, where in 1917 he was appointed commander-in-chief. He was then a major-general, and was given the temporary rank of lieutenant-general on becoming commander-in-chief. Shortly afterwards, he was created K.C.B. As commander-in-chief he brought the campaign to a successful end. He died on Aug. 27, 1922. (See EAST AFRICA, OPERATIONS IN.)

DEVENTER, a town in the province of Overysel, Holland, on the right bank of the Ysel, at the union of the Schipbeek, and a junction station 10 mi. N. of Zutphen. Pop. (1939) 40,311. In the 14th century Deventer was the centre of the famous religious educational movement associated with the name of Gerhard Groot (*q.v.*), who was a native of the town (see BROTHERS OF COMMON LIFE). The Groote Kerk (St. Lebuinus), dates from 1334, and occupies the site of an older structure of which the 11th-century crypt remains. The Roman Catholic Broederkerk, or Brothers' church, contains among its relics three ancient gospels attributed to St. Lebuinus (Lebwin), the apostle of the Frisians and Westphalians (d. c. 773). The Bergkerk, dedicated in 1206, has two late Romanesque towers. The town hall was built in 1693. In the fine square called the Brink is the old weigh-house, now a school (gymnasium), built in 1528, with a large external staircase (1644). The town library, also called the library of the Athenaeum, includes many mss. and incunabula, and a 13th-century copy of Reynard the ***Fox.*** The archives of the town are of considerable value. Besides a considerable agricultural trade, Deventer has important carpet and textile factories (the Smyrna carpets being especially famous).

In the church of Bathmen, a village 5 mi. E. of Deventer, some 14th-century frescoes were discovered. German troops occupied Deventer in 1940.

DE **VERE, AUBREY THOMAS** (1814–1902), Irish poet and critic, was born at Curragh Chase, Co. Limerick, being the third son of Sir Aubrey de Vere Hunt (1788–1846), also a poet, whose verses and a drama, Mary Tudor, were published by his son in 1875 and 1884. Aubrey de Vere was educated at Trinity college, Dublin, and in his 28th year published The Waldenses, which was the first of many volumes of verse and prose to his credit. In many of his poems, notably in the volume of sonnets called St. Peter's Chains (1888), he made rich additions to devotional verse. After Matthew Arnold's fine lecture on "Celtic Literature," nothing perhaps did more to help the Celtic revival than Aubrey de Vere's insight into the Irish character and his reproductions of the early Irish epic poetry.

A volume of ***Selections*** from his poems was edited in 1894 (New York and London) by G. E. Woodberry.

DEVIATION, in magnetism (*q.v.*), the horizontal angle through which a magnetic needle is deflected away from the magnetic meridian by the iron in a ship (see COMPASS).

DEVICE, a scheme or simple mechanical contrivance; also a design, particularly an heraldic design or emblem, often combined with a motto or legend. (See HERALDRY.)

DEVIDASI: see CASTE.

DEVIL is the generic name for a spirit of evil, especially the supreme spirit of evil, the foe of God and man, but also for minor evil spirits or "demons." It is given as a name to many destructive and repulsive animals, to apparatus for tearing cloth, etc., to highly seasoned dishes, to boy assistants in printing-houses (probably because of their inky appearance), and to juniors and hacks who prepare work (or "devil") for barristers, authors, etc. Here, however, we are concerned with the word only as used in mythology and religion.

The primitive philosophy of animism involves the ascription of all phenomena to personal agencies; the agents of good become gods, those of evil, demons. When the divine is most completely conceived as unity, the demonic is also so conceived, and over against God stands Satan, or the devil.

Though it is in connection with Hebrew and Christian monotheism that belief in the devil has been most fully developed there are approaches to the doctrine in other religions, *e.g.,* "the lady Nina" and the dragon Tiamat in Babylonian, the serpent Apap in Egyptian, the Titans and Prometheus in Greek, Hel and Loki among the Teutons and Ahi and Siva among Hindus. The opposition of good and evil is most fully carried out in Zoroastrianism. Opposed to Ormuzd, the author of all good, is Ahriman, the source of all evil; and the opposition runs through the whole universe (D'Alviella's Hibbert Lectures, pp. 158–164).

The conception of Satan belongs to the post-exilic period of Hebrew development, and probably shows traces of the influence of Persian on Jewish thought; it also has its roots in much older beliefs (cf. 1 Sam. xvi. 14; Judges ix. 23; 1 Ki. xxii. 22; Gen. vi. 1–4), and evil, whether as misfortune or as sin, is generally assigned to divine causality (1 Sam. xviii. 10; 2 Sam. xxiv. 1; 1 Ki. xxii. 20; Isa. vi. 10, lxiii. 17). After the Exile there is a tendency to protect the divine transcendence by the introduction of mediating angelic agency, and to separate all evil from God by ascribing its origin to Satan, the enemy of God and man. In the prophecy of Zechariah (iii. 1–2) he stands as the adversary of Joshua, the high priest; in the book of Job he presents himself before the Lord among the sons of God (ii. 1), yet is represented both as accuser and tempter; and while, according to 2 Sam. xxiv. 1, God himself tests David in regard to the numbering of the people, according to 1 Chron. xxi. 1, it is Satan who tempts him.

The development of the conception continued in later Judaism, which was probably more strongly influenced by Persian dualism, as in Tobit iii. 8, vi. 14; Ecclesiasticus xxi. 27; Wisdom ii. 24; Psalms of Solomon xvii. 49; and the book of Enoch. In the Jewish *Targums* Sammael "the highest angel that stands before God's throne, caused the serpent to seduce the woman"; he coalesces with Satan, and has inferior Satans as his servants. The birth of Cain is ascribed to a union of Satan with Eve. As accuser affecting man's standing before God he is greatly feared.

This doctrine, stripped of much of its grossness, is reproduced in the New Testament. Satan is the διάβολος, from διαβάλλειν, to slander (Matt. xiii. 39; John xiii. 2; Eph. iv. 27; Heb. ii. 14; Rev. ii. 10), slanderer or accuser, the πειράξων (Matt. iv. 3; 1 Thess. iii. 5), the tempter, the πονηρός (Matt. v. 37; John xvii. 15; Eph. vi. 16), the evil one, and the ἐχθρός (Matt. xiii. 39), the enemy. He is apparently identified with Beelzebub (or Beelzebul) in Matt. xii. 26, 27. Jesus appears to recognize the existence of demons belonging to a kingdom of evil under the leadership of Satan "the prince of demons" (Matt. xii. 24, 26, 27), whose works in demonic possessions it is his function to destroy (Mark

i. 34, iii. 11, vi. 7; Luke x. 17–20), but he himself conquers Satan in resisting his temptations (Matt. iv. 1–11). Simon is warned against him, and Judas yields to him as tempter (Luke xxii. 31; John xiii. 27). Jesus's cures are represented as a triumph over Satan (Luke x. 18). This Jewish doctrine is found in Paul's letters also. Satan rules over a world of evil. Paul's own "stake in the flesh" is Satan's messenger (2 Cor. xii. 7). According to Hebrews Satan's power over death Jesus destroys by dying (ii. 14). Revelation describes the war in heaven between God with his angels and Satan or the dragon, the "old serpent," the deceiver of the whole world (xii. 9), with his hosts of darkness. After the overthrow of the Beast and the kings of the earth, Satan is imprisoned in the bottomless pit a thousand years (xx. 2). Again loosed to deceive the nations, he is finally cast into the lake of fire and brimstone (xx. 10; cf. Enoch liv. 5, 6; 2 Peter ii. 4). In John's Gospel and Epistles Satan is opposed to Christ. Sinner and murderer from the beginning (1 John iii. 8) and liar by nature (John viii. 44), he enslaves men to sin (viii. 34), causes death (verse 44), rules the present world (xiv. 30), but has no power over Christ or those who are His (xiv. 30, xvi. 11; 1 John v. 18). He will be destroyed by Christ with all his works (John xvi. 33; 1 John iii. 8).

In the common faith of the Gentile Churches after the Apostolic age the influence of polytheism survived in the belief in the dominion of demons, from which Christ is the Redeemer. While Christ's First Advent delivered believers from Satan's bondage, his overthrow would be completed only by the Second Advent. The belief in Satan appears in fantastic forms in Gnosticism. The Fathers traced false doctrine as well as evil practice to him. In Irenaeus emerges the strange doctrine that the death of Christ was a ransom paid to the devil. God was represented by Origen as duping the devil, and His right to do so was justified. While this view was maintained by several Christian thinkers, others felt scruples about ascribing a "pious fraud" to God, and it at last fell into the background. The possibility of the redemption of Satan, advanced by Origen, however, was in the 5th century branded as a heresy. Persian dualism was brought into contact with Christian thought in the doctrine of Mani; and it is permissible to believe that the gloomy views of Augustine regarding man's condition are due in some measure to this influence. Mani taught that Satan attacked the earth, and defeated man sent against him by the God of light, but was overthrown by the God of light, who then delivered the primeval man. "During the middle ages," says Tulloch, "the belief in the devil was absorbing —saints conceived themselves and others to be in constant conflict with him." This superstition, perhaps at its strongest in the 13th to the 15th century, passed into Protestantism. Luther was always conscious of the presence and opposition of Satan. He held that this world will pass away with its pleasures, as there can be no real improvement in it, for the devil continues in it to ply his daring and seductive devices. This belief in the devil was specially strong in Scotland among both clergy and laity in the 17th century.

In more recent times a great variety of opinions has been expressed on this subject. The reality of demonic possession has been denied, and Satan variously represented as a personification of the principle of evil. But some Christian theologians, such as Daub, Dorner, Martensen, have tried to form a speculative defence of the common belief. A. Ritschl gives no place in his constructive doctrine to the belief in the devil; but recognizes that the mutual action of individual sinners on one another constitutes a kingdom of sin, opposed to the Kingdom of God (A. E. Garvie, *The Ritschlian Theology*, p. 304). In the boor entitled *Evil* and *Evolution* there is "an attempt to turn the light of modern science on to the ancient mystery of evil." The author contends that the existence of evil is best explained by assuming that God is confronted with Satan, who in the process of evolution interferes with the divine designs, an interference which the instability of such an evolving process makes not incredible. Satan is, however, held to be a creature who has by abuse of his freedom been estranged from, and opposed to his Creator, and who at last will be conquered by moral means. W. M. Alexander in his book on demonic possession maintains that "the confession of Jesus as the Messiah or Son of God is the classical criterion of genuine demonic possession" (p. 150) and argues that as "the Incarnation indicated the establishment of the kingdom of heaven upon earth," there took place "a counter movement among the powers of darkness," of which "genuine demonic possession was one of the manifestations" (p. 249).

Interesting as these speculations are, it may be confidently affirmed that belief in Satan is not now generally regarded as an essential article of the Christian faith, nor is it found to be an indispensable element of Christian experience. On the one hand science has so explained many of the processes of outer nature and of the inner life of man as to leave no room for Satanic agency. On the other hand the modern view of the inspiration of the Scriptures does not necessitate the acceptance of the doctrine of the Scriptures on this subject as finally and absolutely authoritative. The preaching of Jesus even in this matter may be accounted for as either an accommodation to the views of those with whom He was dealing, or more probably as a proof of the limitation of knowledge which was a necessary condition of the Incarnation, for it cannot be contended that as revealer of God and redeemer of men it was imperative that He should either correct or confirm men's beliefs in this respect. The possibility of the existence of evil spirits, organized under one leader Satan to tempt man and oppose God, cannot be denied; the sufficiency of the evidence for such evil agency may, however, be doubted; the necessity of any such belief for Christian thought and life cannot, therefore, be affirmed. *(See* also DEMONOLOGY; POSSESSION.)

DE VILLIERS, JOHN HENRY, BARON (1842–1914), first Chief Justice of the Union of South Africa, was born at Paarl, Cape Colony, in June 1842. He was educated at the South African college, Cape Town, and Utrecht and Berlin universities. In 1865 he was called to the bar by the Inner Temple and began practice in Cape Colony. Entering Cape politics in 1866, he was elected a member of the House of Assembly, became attorney-general of the Colony in 1872 and two years later was appointed Chief Justice of the Cape. In this capacity he succeeded, by his decisions, in adapting the Roman-Dutch law of the colony to modern requirements. He was appointed President of the National Convention in 1908 and in 1910 was raised to the peerage on becoming Chief Justice of the Union of South Africa. He died Sept. 2, 1914.

DEVIL'S ADVOCATE: *see* ADVOCATUS DIABOLI.

DEVIL'S ISLAND, a small island in the Atlantic Ocean off the coast of French Guiana, South America, used by the French as a penal settlement because of the difficulty of escape. It was here that Capt. Alfred Dreyfus (*q.v.*) was confined.

DEVILS LAKE, a city of North Dakota, U.S.A., on Devils Lake, 85m. W. by N. of Grand Forks; the county-seat of Ramsey county. It is on Federal highway 2, and is served by the Farmers Grain and Shipping Company, the Great Northern and the Soo Line railways. Population in 1940 federal census was 6,204. The city has creameries, flour mills and railroad shops. It is the seat of the state school for the deaf. The state university has a biological station on the lake, and just south of the lake is Sully's Hill national park, an important wild animal preserve, with historic associations. Devils Lake was settled in 1880 and incorporated in 1887.

DEVILS POSTPILE, a national monument (reservation) in the southeast corner of Madera county, California, U.S.A., and only a few miles southeast of Yosemite national park. The reservation (800 ac. in area) was created on July 6, 1911, to preserve an unusual mass of basaltic columns, 10 to 30 in. in diameter, and rising, like an immense pile of posts, as high as 60 ft. It is said to rank with the Giant's Causeway in Ireland.

DEVILS TOWER, first of the U.S. national monuments, on the Belle Fourche river about 25 mi. northwest of Sundance in Crook county, Wyoming, U.S.A. The area (1,152.91 ac.) was

established Sept. 24, 1906, to preserve a remarkable natural rock tower, of volcanic origin, 600 ft. from base to summit and 1,300 ft. above the Belle Fourche river.

DE VINNE, THEODORE LOW (1828–1914), the most eminent American printer during the later 19th century and the first decade of the 20th. He was known as an authority on the history of typography and was the author of many scholarly books on this subject. Born at Stamford, Conn., on Dec. 25, 1828, he took the first steps toward learning his trade in 1843 in a printing office at Fishkill, N.Y., but entered on his regular apprenticeship soon after in the office of the Gazette at Newburgh, N.Y. In 1847 he went to New York city and after working in several offices, in 1849 entered the employ of Francis Hart, one of the leading printers in that city, a relation destined to prove both happy and permanent. From work as a job compositor, he graduated in 1850 into the position of foreman. Nine years later, when De Vinne was offered a partnership elsewhere, Hart decided to hold him by making him a member of the firm. At this period the business of Francis Hart and Co. was tending more and more to book printing, a field to which De Vinne devoted most of his efforts from that time onward. About 1864 De Vinne began to write on printing, his earliest contributions dealing with the economic aspects of the business, but his attention soon turned to the aspects of typographic style and the history of the craft.

In 1873 the firm began to print St. Nicholas and soon after took on the Century Magazine, in printing the illustrations for which some new standards were established. The Century Dictionary was another job of importance produced under De Vinne's direction.

Francis Hart died in 1877 and in 1883 the name of the firm was changed to Theodore L. De Vinne and Company, the plant coming to be known as the De Vinne press, which earned a reputation as the outstanding printing office of the country. De Vinne was one of the founders of the Grolier Club and one of its most active members, printing most of the early books issued by that organization, and writing or editing a number of them. He died on Feb. 16, 1914.

As a printer De Vinne was a craftsman of high standards and stood head and shoulders above his contemporaries, but he could not be regarded as a great creative artist. His simplest books were his best. De Vinne's most important contributions to typographic literature were: The Practice of Typography (1900–04), a series of four manuals; The Invention of Printing (1876); Christopher *Plantin* and the *Plantin-Moretus Museum* at *Antwerp* (1888); and Notable Printers of *Italy* during the Fifteenth Century (1910). (D. C. McM.)

DEVISE or **DEVICE,** the conveyance of real property by will. See LEGACY.

DEVIZES, a market town and municipal borough in the eastern parliamentary division of Wiltshire, England, 86 mi. S.W. of London by the G.W. Ry. Pop. (1938) 7.000. Area 2.2 sq.mi. Its castle was built on a tongue of land flanked by two deep ravines, behind which the town grew up on a stretch of exposed tableland. Its main streets, in which a few ancient timbered houses are left, radiate from the market place, where stands a market cross with a remarkable inscription referring to a certain dishonest market transaction in 1753. The Rennet and Avon canal, now practically disused, is raised to two levels of ten towers through a chain of locks. St. John's church (12th century), one of the most interesting in Wiltshire, is cruciform, with a massive central tower and fine Norman chancel, and contains several ancient monuments, besides some beautiful carved stonework and oak ceilings. St. Mary's, a smaller church, is partly Norman, but was rebuilt in the 15th and restored in the 19th century. Roundway Down. on the edge of which the town stands, stretches eastward, and is the site of an ancient British earthwork, besides having yielded other remains. The county general and mental hospitals are situated in Devizes, which also has a museum, and is the depot of the Wiltshire regiment. It is an important corn, cattle and pig market, and has bacon and cheese factories. tileworks, engineering works and manufactures of snuff and tobacco. Assize courts are held at Devizes, which has its own commission of the peace and court of quarter sessions.

The construction at Devizes in the reign of Henry I. of a castle of exceptional magnificence by Roger, bishop of Salisbury, at once constituted the town an important political centre, and the name itself is possibly a corruption of the mediaeval Latin referring to the "castle at the boundaries" (ad *divisas*). After the disgrace of Roger in 1139 the castle was seized by King Stephen. In the 14th century it formed part of the dowry of the queens of England. Devizes' first charter, from Matilda, confirmed by successive later sovereigns, merely grants exemption from certain tolls and the enjoyment of undisturbed peace. Edward III. added a clause conferring on the town the liberties of Marlborough, and Richard II. instituted a coroner. A gild merchant was granted by Edward I., Edward II. and Edward III., and in 1614 was divided into the three companies of drapers, mercers and leather-sellers. The present governing charters were issued by James I. and Charles I., the latter being little more than a confirmation of the former, which instituted the common council. Devizes returned two members to parliament from 1295 until deprived of one member in 1867; its representation was merged in that of the county in 1885.

See *Vict.* County *Hist.*, Wiltshire; History *of* Devizes (Devizes, 1859).

DEVOLUTION, WAR OF (1667–68), the name applied to the war which arose out of Louis XIV.'s claims to certain Spanish territories in right of his wife Maria Theresa, upon whom the ownership was alleged to have "devolved." (See, for the military operations, DUTCH WARS.) The war was ended by the Treaty of Aix-la-Chapelle in 1668.

DEVON, EARLS OF. From the family of De Redvers (De Ripuariis; Riviers), who had been earls of Devon from about 1100, this title passed to Hugh de Courtenay (c. 1275–1340), but was subsequently forfeited by Thomas Courtenay (1432–1462), a Lancastrian who was beheaded after the battle of Towton. It was revived in 1485 in favour of Edward Courtenay (d. 1509), whose son Sir William (d. 1511) married Catherine, daughter of Edward IV. Too great proximity to the throne led to his attainder, but his son Henry (c. 1498–1539) was restored in 1517 as earl of Devon, and in 1525 was created marquess of Exeter; his second wife was a daughter of William Blount, 4th Lord Mountjoy. The title again suffered forfeiture on Henry's execution, but in 1553 it was recreated for his son Edward (1526–1556). At the latter's death it became dormant in the Courtenay family, till in 1831 a claim by a collateral branch was allowed by the House of Lords, and the earldom of Devon was restored to the peerage, still being held by the head of the Courtenays. The earlier earls of Devon were referred to occasionally as earls of Devonshire, but the former variant has prevailed, and the latter is now solely used for the earldom and dukedom held by the Cavendishes (see DEVONSHIRE, EARLS AND DUKES OF, and also the article COURTENAY).

DEVON, a south-western county of England, bounded north-west and north by the Bristol channel, north-east by Somerset and Dorset, south-east and south by the English channel, and west by Cornwall. The area, 2,612 sq.mi., is exceeded only by those of Yorkshire and Lincolnshire among the English counties. East to west structural lines dating from Armorican times are dominant features. The high ground to the north of Barnstaple may be considered as an extension of the Quantock hills—Brendon hills—Exmoor forest line, and terminates in Morte point and Baggy point, which face Lundy. Here are exposed a series of slates, grits and limestones considered so characteristic of the county that it was called the Devonian system (*q.v.*). It represents here the northern rim of a trough in the hollow of which lie the Culm measures of central Devon. The same series appears in the southern rim of the trough in the latitude of Tavistock, but this line is much affected by the granitic mass of Dartmoor, intruded into the Culm and Devonian strata in post-Carboniferous times and subsequently exposed by denudation. The hard core stands out in High Willhays (2,039 ft.), Yes Tor (2,028 ft.) and other peaks. Evidences of Devonian volcanic activity are abundant in the masses of diabase, dolerite, etc., at Bradford and Trusham, south of Exeter, around Plymouth and at Ashprington. Perhaps the most interesting is the Carboniferous volcano of

Brent Tor, near Tavistock. An Eocene deposit, the product of the denudation of the Dartmoor hills, lies in a small basin at Bovey Tracey; it yields beds of lignite and valuable clays.

The eastern side of the county is built of younger rocks, unconformable above the old ones and dipping gently eastwards. The lower and most westerly situated member of the younger rocks is a series of breccias, conglomerates, sandstones and marls which are exposed on the coast by Dawlish and Teignmouth, and extend inland, producing a red soil, past Exeter and Tiverton. A long narrow strip of the same formation reaches out westward on the top of the Culm as far as Jacobstow. Farther east, the Bunter pebble beds are represented by the well-known pebble deposit of Budleigh Salterton, whence they are traceable inwards towards Rockbeare. These are succeeded by Keuper marls and sandstones, well exposed at Sidmouth, where the Upper Greensand plateau is clearly seen to overlie them. Greensand covers all the high ground northward from Sidmouth as far as the Blackdown hills. At Beer Head and Axmouth the chalk is seen, and at the latter place is a landslip caused by the springs which issue from the Greensand below the chalk. The lower chalk at Beer has been mined for building stone, and was formerly in considerable demand. At the extreme east of the county, Rhaetic and Lias beds make their appearance, the former with a "bone" bed bearing the remains of saurians and fish.

Local Tertiary movements may account for relics of peneplains, one of which has been located at a height of about 1,000 ft. on the south-eastern edge of Dartmoor, and for the north-west and north-north-west systems of faults, which can be traced in several valleys on the eastern edge of Dartmoor. The raised beaches of Hope's Nose, the Thatcher Stone and other parts of the coast, together with traces of submerged forests, and most of all the long, steep-sided, drowned valleys forming the numerous inlets of the south Devon coast are evidences of recent coastal movements.

The Tamar, which constitutes the boundary between Devon and Cornwall, flows into the English channel. Its estuary has been utilized for the harbours of Plymouth and Devonport. The other principal rivers rise on Dartmoor. These include the Teign, Dart, Plym and Tavy, falling into the English channel, and the Taw flowing north towards Bideford bay. The river Torridge, also discharging northward, receives part of its waters from Dartmoor through the Okement, but itself rises in the angle of high land near Hartland point on the north coast. The lesser Dartmoor streams are the Avon, the Erme and the Yealm, all running south. The Exe rises on Exmoor in Somerset, but the main part of its course is through Devon, and it is joined on its way to the English channel by the lesser streams of the Culm, the Creedy and the Clyst. The Otter, rising on the Blackdown hills, also runs south, and the Axe, for part of its course, divides the counties of Devon and Dorset. The finds made at Oreston, near Plymouth, at Kent's Cavern, near Torquay, at Windmill Hill Cavern, Brixham, and at Cattedown, Plymouth, suggest that these limestone areas with southerly aspects were much favoured by Palaeolithic man. Later settlement seems to have been chiefly on the higher land of the interior. Tumuli, stone circles and alignments are numerous on Dartmoor, and are fairly well distributed over the high land of the county. Hill forts and camps occupy strategic positions and their distribution suggests that Dartmoor had already lost much of its former significance when they were built. Many are found around the coasts guarding routes into the interior.

Roman relics have been found from time to time at Exeter (Isca Damnoniorum), the only large Roman station in the county.

HISTORY

The Saxon conquest of Devon must have begun some time before the 8th century, for in 700 there existed at Exeter a famous Saxon school. By this time, however, the Saxons had become Christians, and established their supremacy, not by destructive inroads, but by a gradual process of colonization, settling among the native Welsh and allowing them to hold lands under equal laws. The final incorporation of the district which is now Devon with the kingdom of Wessex must have taken place about 766. At the beginning of the 9th century Wessex was divided into definite *pagi,* probably corresponding to the later shires, and the Saxon Chronicle mentions the district by name in 823, when a battle was fought between the Welsh in Cornwall and the people of Devon at Camelford. During the Danish invasions of the 9th century aldermen of Devon are frequently mentioned. In 851 the invaders were defeated by the fyrd and aldermen of Devon, and in 878 they were again defeated with great slaughter. In 1003, in the reign of Ethelred the Unready, the Danes sacked Exeter.

Devon, in the 7th century, formed part of the vast bishopric of Dorchester-on-Thames. In 705 it was attached to the newly-created diocese of Sherborne, and in 910 Archbishop Plegmund constituted Devon a separate diocese, and placed the see at Crediton. About 1030 the dioceses of Devon and Cornwall were united, and in 1049 the see was fixed at Exeter.

William the Conqueror immediately recognized the importance of securing the loyalty of the West by the capture of Exeter. The city withstood an 18-days' siege, and William was only admitted at length upon honourable terms. The many vast fiefs held by Norman barons in Devon were known as honours, chief among them being Plympton, Okehampton, Barnstaple, Harberton and Totnes. The honour of Plympton was bestowed in the 12th century on the Redvers family, together with the earldom of Devon; in the 13th century it passed to the Courtenay family (*q.v.*), who had already become possessed of the honour of Okehampton, and who in 1335 obtained the earldom. The dukedom of Exeter was bestowed, in the 14th century, on the Holand family, which became extinct in the reign of Edward IV. The ancestors of Sir Walter Raleigh, who was born at Budleigh, had long held considerable estates in the county. In 1204 the inhabitants paid 5,000 marks to have the county disafforested, with the exception of Dartmoor and Exmoor.

Devon ,had an independent sheriff, the appointment being at first hereditary, but afterwards held for one year only. In 1320 complaint was made that all the hundreds of Devon were in the hands of the great lords, who did not appoint a sufficiency of bailiffs for their proper government. The miners of Devon had independent courts, known as stannary courts, for the regulation of mining affairs, the four stannary towns being Tavistock, Ashburton, Chagford, and Plympton. The ancient miners' parliament was held in the open air on Crockern Tor. For mining purposes West Devon is in the Duchy of Cornwall and under the jurisdiction of the Stannary court.

In 1140 the castles of Exeter and Plympton were held against Stephen by Baldwin de Redvers. In the 14th and 15th centuries the French made frequent attacks on the coast. During the Wars of the Roses frequent skirmishes took place between the earl of Devon and Lord Bonville, the respective champions of the Lancastrian and Yorkist parties. In 1470 Warwick and Clarence were pursued as far as Exeter by Edward IV after the battle of "Lose-Coat Field." Warwick subsequently escaped to the Continent from Dartmouth. Richard III came to Exeter to punish personally those who had inflamed the West against him. Hundreds were outlawed, including the bishop and the dean. Perkin Warbeck besieged Exeter in 1497, and Henry VII came down to thank the citizens for their resistance and to judge the prisoners. Great disturbances in the county followed the inaugural service of Edward VI's prayer book on Whit Sunday, 1549. A priest at Sampford Courtenay was persuaded to read the old Mass on the following day. Swiftly the insubordination spread into a serious revolt, in which the men of Cornwall joined, and Exeter suffereda distressing siege before it was relieved by Lord Russell. On the outbreak of the Civil War the county as a whole favoured the parliament, but the prevailing desire was for peace, and in 1643 a treaty for the cessation of hostilities in Devon and Cornwall was agreed upon. Skirmishes, however, continued until 1646. After the Monmouth rebellion, Judge Jefferies held a "bloody assize" at Exeter. In 1688 the prince of Orange landed at Torbay and stayed for several days at Forde and at Exeter.

The tin mines of Devon have been worked from time immemorial, and in the 14th century mines of tin, copper, lead, gold and silver are mentioned. At the time of the Domesday Survey the salt industry was important, and there were 99 mills in the

county and 13 fisheries. From an early period the chief manufacture was that of woollen cloth, and a statute 4 Ed. IV permitted the manufacture of cloths of a distinct make in certain parts of Devon. About 1505 Anthony Bonvis, an Italian, introduced an improved method of spinning into the county, and cider-making is mentioned in the 16th century. In 1680 the lace industry was already flourishing at Colyton and Ottery St. Mary, and flax, hemp and malt were largely produced in the 17th and 18th centuries.

Devon returned two members to parliament in 1290, and in 1295 Barnstaple, Exeter, Plympton, Tavistock, Torrington and Totnes were also represented. In 1831 the county, with its boroughs, returned 26 members, but under the Reform Act of 1832 they were reduced to 18. Subsequent bills brought further reductions. The redistribution bill of 1918 left the county with a total of 11 members.

The churches are for the most part of the Perpendicular period, dating from the middle of the 14th to the end of the 15th century. Exeter cathedral is an exception, the whole (except the Norman towers) being very beautiful Decorated work. The special features of Devonshire churches are the richly-carved pulpits and chancel screens of wood. The largest and the most beautiful screen is that at Hartland (*c.* 1450). Granite crosses are frequent, the finest being that of Coplestone, near Crediton. A number of ancient rude stone crosses stand among the prehistoric pagan remains on the wastes of Dartmoor. Monastic remains are scanty; the principal are those at Tor, Buckfast, Tavistock and Buckland abbeys. Buckfast abbey was reconstructed (*see* BUCKFASTLEIGH). Among domestic buildings may be mentioned the 14th century parsonage at Little Hempston, the houses of Wear Gifford, Bradley and Dartington of the 15th century; Bradfield and Holcombe Rogus (Elizabethan) and Forde (Jacobean). The ruined castles of Okehampton (Edward I), Exeter, with its vast British earthworks, Berry Pomeroy (Henry III, with ruins of a large Tudor mansion). Totnes (Henry III) and Compton (early 11th century), are all interesting.

Climate and **Agriculture.**—The climate is more humid than that of the eastern or southeastern parts of England. The mean annual temperature somewhat exceeds that of the midlands, but the average summer heat is rather less than that of the southern counties to the east. The air of the Dartmoor highlands is sharp and bracing. Mists are frequent, and snow often lies long. On the south coast frost is little known, and hydrangeas, myrtles, geraniums and heliotrope live through the winter without protection. The climate of the watering places on this coast is very equable, the mean temperature in January being 43.9° at Plymouth. The north coast, exposed to the storms of the Atlantic, is more bracing; although there also, in the more sheltered nooks (as at Combe Martin), myrtles of great size and age flower freely.

The cultivated area falls a little below the average of the English counties. In 1939 there were, however, about 364,381 ac. of rough grazing and 708,272 ac. of permanent grass. The arable land was estimated at 415,438 ac. Oats, wheat, barley and root-crops are chiefly grown. The acreage under oats—83,600 ac.—was about four times that under barley. Wheat occupied 22,901 ac. The Devon breed of cattle is well adapted both for fattening and for dairy purposes; while sheep are kept in great numbers on the hill pastures (973,209 in 1939). Devon is specially famous for clotted cream and junket. The bulk of the acreage under green crops is occupied by turnips and swedes and mangolds at 22,335 ac. and 14,984 ac. respectively. Orchards occupy a large acreage, 21,400 ac. in 1939, and consist chiefly of apple trees, mainly for the manufacture of cider. The National Trust owned about 2,250 ac. in the county in 1942 and had a 500-year lease of 10,000 acres in Exmoor at a nominal rent.

Fisheries.—Large quantities of the pilchard and herrings caught in Cornish waters are landed at Plymouth. Much of the fishing is carried on within the three-mile limit; and it may be asserted that trawling is the main feature of the Devonshire industry, whereas seining and driving characterize that of Cornwall. pilchard, cod, sprats, brill, plaice, soles, turbot, shrimps, lobsters, oysters and mussels are met with, besides herring and mackerel, which are fairly plentiful. After Plymouth the principal fishing station is at Brixham, but there are many lesser stations.

Other Industries.—The principal industrial works are the various government establishments at Plymouth and Devonport. Among other industries may be noted the lace-works at Tiverton; the manufacture of pillow-lace for which Honiton and its neighbourhood has long been famous; and the potteries and terra-cotta works of Bovey Tracey and Watcombe. Woollen goods and serges are made at Buckfastleigh, while Plymouth produces chemical manure, soap, starch, blue and black lead.

Minerals.—Silver-lead was formerly worked at Combe Martin. near the north coast, and elsewhere. Tin has been worked on Dartmoor (in stream works) from an unknown period. Copper was not much worked before the end of the 18th century. Tin occurs in the granite of Dartmoor, and along its borders, and especially, with zinc and iron, around Tavistock, which has the Devon Great Consols mine within 4 mi., which from 1843–71 were the richest of copper mines. But Devonshire mining is affected by the same causes as that of Cornwall. The quantity of ore has greatly diminished. and the cost of raising it from the deep mines prevents competition with foreign markets. In many mines tin underlies the general depth of the copper, and is worked when the latter has been exhausted. Great quantities of refined arsenic have been produced at the Devon Great Consols mine, by elimination from the iron pyrites contained in the various lodes. Manganese occurs in the neighbourhood of Exeter, in the valley of the Teign and in north Devon; but the most profitable mines are in the Tavistock district. There are two mines for tungsten ores, at Gunnislake, near Tavistock, and Marytavy.

The other mineral productions of the county consist of marbles, building stones, slates and potters' clay. The granite of Dartmoor is much quarried near Princetown, near Moreton Hampstead on the northeast of Dartmoor, and elsewhere. Hard traps, which occur in many places, are also much used for building. as are the limestones of Buckfastleigh and of Plymouth. The Roborough stone, used from an early period in Devonshire churches, is found near Tavistock, and is a hard porphyrytic elvan, taking a fine polish. Excellent roofing slates occur in the Devonian series round the southern part of Dartmoor. The chief quarries are near Ashhurton and Plymouth (Cann quarry). Potters, clay is worked at King's Teignton, whence it is largely exported; at Bovey Tracey; and at Watcombe. The Watcombe clay is of the finest quality. China clay or kaolin is found on the southern side of Dartmoor, at Lee Moor, and near Lustleigh. There is a large deposit of umber close to Ashburton.

Communications.—The main line of the G.W. railway, entering the county in the east from Taunton, runs to Exeter, skirts the coast as far as Teignmouth, and continues a short distance inland by Newton Abbot to Plymouth, after which it crosses the estuary of the Tamar by a great bridge to Saltash in Cornwall Branches serve Torquay and other seaside resorts of the south coast; and among other branches are those from Taunton to Barnstaple, and from Plymouth northward to Tavistock and Launceston. The main line of the Southern railway between Exeter and Plymouth skirts the north and west of Dartmoor by Okehampton and Tavistock. A branch from Yeoford serves Barnstaple, Ilfracombe, Bideford and Torrington. The branch line to Princetown from the Plymouth-Tavistock line of the G.W. company in part follows the line of a very early railway—that constructed to connect Plymouth with the Dartmoor prison in 1819–21, which was worked with horse cars. The only waterways of any importance are the Tamar, which is navigable up to Gunnislake (3 mi. S.W. of Tavistock), and the Exeter ship canal, noteworthy as one of the oldest in England, for it was originally cut in the reign of Elizabeth.

The area of the administrative county is 2,582 sq mi. Pop. (est. 1938) 741,660. Wartime movements caused by evacuation from dangerous areas raised the population of Devon by 10% between Sept. 1939 and Feb. 1941. There were in 1943 ten municipal boroughs, two county boroughs, and 21 urban districts.

DEVONIAN SYSTEM, THE. The Devonian rocks receive their name from the locality where the stratigraphical and historical position of those of marine origin—between the Silurian below and the Carboniferous above—was first recognized. In some areas they consist of sediments laid down in fresh water or on land, and as these are usually arenaceous and red in colour, they are known as the Old Red Sandstone.

In Devonian times Africa was already an ancient continent, but it lay far south of its present position and extended into the Antarctic. A second continent stretched across northern Europe to the north-east of North America. Between them lay the ocean the geologists call Tethys. In the Western Hemisphere narrow seas existed in the east and west of what is now North America, and low land, submerged later, lay between. In the Old Red Sandstone are the first well preserved remains of vertebrates, comprising many strange types. (The letters D, L, M and U indicate the division of the period in which they occur—Downtonian [passage beds], Lower, Middle and Upper Devonian.)

Palaeospondylus M, was tadpole-shaped, perhaps allied to the lamprey.

The PLACODERMI were fish-like, but without jaws, or true paired limbs. Some (ANASPIDA), like *Birkenia* D, were protected only by tubercles. In others, such as *Cyathaspis* D, L, *Pteraspis* L, *Auchenaspis* D, *Cephalaspis*, D, L, M, U and *Psammosteus* D, U, the tubercles were fused into dorsal and ventral shields. The ANTIARCHI form a separate group with paired paddles, including *Pterichthys* M, U, *Asterolepis* U, and *Bothriolepis* U. The Arthrodira had jaws and articulated head and trunk shields. *Phlyctaenaspis* L, *Coccosteus M*, U, *Dinichthys M*, *U* and *Homosteus* M, U are examples. None of the above survived the Devonian.

With them are undoubted fish. The *Acanthodi* are elasmobranchs. Both paired and unpaired fins have a spine in front. *Mesacanthus* L, M, has additional paired fins between the pectorals and ventrals. Other genera are *Ischnacanthus* M, U; and *Parexus* L; the *Dipnoi* have a swimming-bladder lung. They are represented in the Old Red by *Dipterus* M, and *Phaneropleuron* U. The *Teleostomi* are represented by the *Crossopterygii* and the *Ganoidei*. The former have a radiate structure of the paired fins comparable to the limbs of higher vertebrates. One family, the *Holoptychiidae*, with *Glyptolepis* M, and *Holoptychius* U, has teeth with a folded structure like those of the labyrinthodonts. Another, the *Osteolepidae*, includes *Thursius M*, and *Osteolepis* M. The Ganoidei are represented by *Cheirolepis* M, U.

An amphibian footprint in the Upper Old Red of Pennsylvania shows that the higher vertebrates had made their appearance before the close of the period.

INVERTEBRATES

Among the invertebrates, the "eurypterids" allied to the king crabs and arachnids: include the genera *Eurypterus* D, L, *Pterygotus* D, L. The bivalve crustacean *Estheria* M, U is of interest as the genus is now confined to saline springs in deserts. Isopods and other crustaceans also occur. Myriapods are met with at different horizons, but true insects are unknown. A fresh-water lamellibranch *Archanodon* (*Amnigenia*) M, U is found in South Wales, Europe, North America and, it is said, Bolivia.

The plants are generalized types distantly allied to the ferns. Those best known are grouped as *Psilophytales*. In the Rhynie chert, silicified peat of Middle Old Red age, the minute structure of the plants *Rhynia, Hornia* and *Asteroxylon* has been preserved. In the Upper Old Red *Archaeopteris hibernica*, with fern-like foliage, is widely distributed.

The vegetation, like the animal life, was probably confined to streams, lakes and marshes, while the high ground was left unprotected by vegetation.

The **Marine** Fauna — The marine life of the Devonian is closely linked with that of the formations below and above it. The most important change is the disappearance of the graptolites. Their loss is partly made good by the goniatites and clymenias which, like their relatives, the ammonites, make excellent zone-fossils, as the species are widely extended in space but have a brief duration. The corals have also been employed for zoning. Most of the Silurian types continue, but with modifications. Among special Devonian forms may be mentioned *Pleurodictyum problematicum* L; the slipper-shaped *Calceola sandalina* M; *Phillipsastrea* U.

Brachiopods are numerous and the species of *Spirifer* are of especial value for zoning. Gastropods and lamellibranchs indicate littoral conditions, except those with thin shells, and certain thick-shelled lamellibranchs associated with coral reefs. Conical forms such as *Tentaculites* and *Styliolina* play an important part. Trilobites are less numerous than in the Silurian. They are often provided with spines.

It is only under special conditions that marine and continental sediments are associated. As the latter are more constant in character, they will be taken first. They include conglomerates laid down by torrents escaping from mountain ranges, and sandstones and shales spread out by streams traversing the plains. Some lake deposits are fluviatile in origin, others are formed of fine sand and dust, transported by the wind till they are arrested by sheets of water or by damp soil. Sometimes the sand is rounded by attrition. Arkose—disintegrated but undecomposed granite materials—is itself evidence of desert conditions. Where organic life was plentiful, the deposits may be bituminous, or coal may occur.

Sometimes there is evidence of alternation of wet and dry seasons. In the latter, the shallow lakes or moist areas dried up and the calcium carbonate that had been in solution separated out in the form of concretions or "cornstones." Gypsum and salt also occur in places.

On the Welsh border the transition to continental conditions is marked by the Ludlow Bone Bed, a widely extended layer some six inches in thickness consisting of fragments of fish and eurypterids. Then follows the Downton Sandstone and Temeside Shales, the Downtonian of Elles and Slater. This term has been extended by Wickham King to 700 ft. more of marls and sandstones in which *Lingula* and a few other marine forms are occasionally present. He calls it alternatively the "Anaspida Marls," and makes the Bone Bed the base not only of the Downtonian, but of the Old Red Sandstone. The Downtonian thus defined is characterized by *Cephalaspis lyelli, Cyathaspis*, and *Anaspida*. *Pteraspis* is absent. It is covered conformably by the "Dittonian" or "Pteraspis Cornstones," distinguished by *Cephalaspis murchisoni* and *Pteraspis*. This is followed, also conformably, by the unfossiliferous "Brownstonee," sandstones formerly referred to the Upper Old Red. This, however, overlaps not only them but the Dittonian and Downtonian and rests in Gower on the Silurian. In Cardiff and Bristol, it is conformable on the Lower Old Red. Among the Upper Old Red fossils are *Bothriolepis, Holoptychius* and *Archanodon*. It passes up conformably into the marine Carboniferous. In South Wales the Downtonian is represented by the Lower Red Marls, and the Dittonian by the Upper Red Marls and the Senni Beds, fossiliferous sandy beds formerly included in the Brownstones. The Old Red extends to Pembrokeshire where marine strata occur in the upper beds.

Similar marine deposits in South Ireland are known as the Coomhola Beds. Below them are the fresh-water Kiltorcan Beds with *Coccosteus disjectus* and *Archaeopteris hibernica*. The Irish Old Red rests unconformably on the Dingle Grits and Slates which are conformable to the Silurian.

Unfossiliferous rocks of Old Red types occur at the base of the Carboniferous of North Wales, the Lake district and Isle of Man.

The Old Red reappears in the Cheviots (where it is largely igneous) and on the margins of the Forth and Clyde syncline. Here both Downtonian and Dittonian are recognizable by their fossils. The former follows the Silurian conformably, but is frequently separated from the Dittonian by an unconformity. The latter includes conglomerates, lavas, tuffs and lacustrine deposits, with *Mesacanthus, Cephalaspis lyelli* and *Pteraspis.*

On the Moray Firth, in Caithness, the Orkneys and Shetlands are strata intermediate in age between the Dittonian and Upper Old Red, which are classed as Middle Old Red, but they are more allied to the Upper than to the Lower. In Caithness an unfossiliferous basement series is followed by conglomerate, and arkose, and then by thick beds of bituminous and calcareous flags and sandstones. Characteristic fossils are *Thursius, Dipterus valenciennesi, Mesacanthus, Coccosteus decipiens, Pterichthys, Estheria* and *Palaeospondylus.* A higher horizon, the John o' Groats beds, has a distinct fauna.

The Upper Old Red sandstone of Scotland overlies unconformably the Lower Old Red in the south and the Middle in the north. There are two horizons. The Lower, the Nairn sandstone, contains *Psammosteus tesselatus, Asterolepis maxima,* and the Upper, the Alves or Scaat Craig beds, has *Psammosteus pustulatus, Bothriolepis major* and *Holoptychius nobilissimus.* Only one form, H. *decoratus,* is common to both.

The Downtonian appears to occur in Norway and the Dittonian in Spitsbergen. Upper Old Red with *Holoptychius* and *Archaeopteris* is found in Bear island, associated with thin coals. In Nova Scotia and New Brunswick the Dittonian with *Cephalaspis* and *Pteraspis* rests unconformably on the Silurian. The Upper Old Red also occurs in the latter, and in New York State it is represented by the Oneonta beds with *Estheria,* and the Catskill with *Bothriolepis* and *Holoptychius.*

In Antarctica, the Upper Old Red age of the Beacon sandstone is indicated by the same two forms.

The marine succession sometimes includes continental intercalations, and even in the marine beds, different facies occur according to the varying conditions under which deposition took place.

Nearest to land were the brackish water and littoral deposits, which may show by red or purple coloration the desert origin of their materials. In deeper water and farther from shore terrigenous mud, now shale or slate, was laid down, and, where conditions were favourable, coral reefs or lenticular limestones were formed. At still greater depths and distance from land, calcareous ooze accumulated with thin shelled molluscs, goniatites and simple corals. The position of these different facies was modified by changes in the level of the sea and floor movements. To the former has been attributed the recession of the sea throughout the Northern Hemisphere at the beginning of the period. The shore line of the northern continent then passed south of Ireland, through Cornwall and south Devon, entered northern France near Boulogne, passed by way of Fepin to the north of the massives of the Rhine and Harz, and of Bohemia, then southward to the Dniester region and central Russia, and north-westward to the White sea. In the Middle Devonian an important advance of the sea began and reached its maximum at the close of the Middle or beginning of the Upper Devonian. The shore line of the northern continent then passed across south Ireland, Pembrokeshire, the Bristol channel, Middlesex, north Belgium, the Baltic, Finland, and Lapland. In the later Upper Devonian there was a new retirement of the sea, and the shore line moved southward again—in some places nearly as far as before, in others, as in Bohemia, still farther.

Parallel to the continental shores, the weight of the terrigenous sediments and accumulated limestones caused a sag of the sea bottom in "geosynclines," and this permitted a still heavier accumulation of deposits.

CENTRAL EUROPE

It is in the Palaeozoic massive of the Ardennes and the Rhineland that the marine Devonian has been most studied. There it has been thrown by the subsequent Armorican movements into folds dipping to the south, and it is in the troughs of these folds that the Middle and Upper Devonian are found as outliers in the Lower. On the Meuse are two main synclines, that of Namur in the north and that of Dinant in the south. On the southern limit of the latter the base of the system is formed by a conglomerate and arkose. These are covered by the Mondrepuits shales with *Spirifer sulcatus* (*mercurei*) which are correlated with the Downtonian. They are succeeded by the mottled Oignies shales containing *Pteraspis* and, therefore, presumably Dittonian

The next horizon, the Siegenian, is represented in Belgium by the Anor grits and the Montigny Greywacke, and in the Rhineland by the Taunus quartzite and the Hunsriick slates, or their equivalents, the Siegen slates. Then follows the Emsian with, on the Meuse, the Red shales of Vireux, and on the Rhine, the Lower Coblenz beds. A higher horizon is that of the Hierges Greywacke corresponding to the Coblenz quartzite and Upper Coblenz beds.

On the north of the Dinant syncline and near the former coastline, the Lower Devonian is represented only by the Burnot conglomerate. In the south-eastern Harz, the Lower Devonian has a deep water ("Hercynian") facies with *Spirifer togatus, Sp. hercyniae, Capulus* and *Phacops fecundus.* The same fauna appears in the Konjeprus limestone of Bohemia, Barrande's F_2 zone.

The Middle Devonian is divided into the Eifelian and the Givetian. At the base of the former is the *Spirifer cultrijugatus* zone. Then follow the *Calceola* Beds. The Givetian is distinguished by the large brachiopod *Stringocephalus.* The Middle Devonian is usually more calcareous than the Lower and the Givetian than the Eifelian. In the Namur syncline the *Calceola* beds rest directly, except for a conglomerate, on the Silurian. Still further north in Brabant, the Eifelian is absent and the Givetian is only separated from the Silurian by a similar conglomerate. In south-west Westphalia the Eifelian and Lower Givetian consist of sandy clays often more or less calcareous. They have yielded plants and *Archanodon* and were probably laid down in fresh water. Similarly in the Boulonnais, sandy beds with plants seem to represent the Eifelian as they are overlaid by a limestone with *Stringocephalus.* In the southern Rhineland the middle division consists of deep-water shales and limestones. In Bohemia the Eifelian is represented by Barrande's zones G_1, G_2 and G_3 deep-water limestones; the Givetian, on the other hand, by the zones H_1, H_2 and H_3, shales and sandstones with plants and Stringocephalus. The deep-water Middle Devonian has been zoned by species of goniatites. Of these, *Meneceras* and *Tornoceras* are characteristic of the Upper Givetian.

The Upper Devonian has two main divisions, the Frasnian and the Famennian. The former commences by limestone with *Buchiola retrostriata,* succeeded by the Biidesheim or Matagne shales, with characteristic goniatites, including *Manticoceras intumescens* and *Tornoceras simplex,* and the bituminous Kellwas limestone. Other Frasnian fossils are *Spirifer verneuili,* which extends through all the Upper Devonian and *Phillipsastrea.* The deep-water Famennian is characterized by the prevalence of the *Clymenia* group. In the lower Famennian it is accompanied by the goniatite genus *Cheiloceras* which marks the horizon of the Nehden shales. The Cypridina shales, laid down in shallower water, contain the small bivalve crustacean *Entomis*—formerly *Cypridina—serrato-striata* in large numbers. In the Namur syncline continental conditions prevailed in the upper Famennian with *Holoptychius* and *Archaeopteris,* though in some places littoral forms like *Cucullaea hardingi* are found. In the Boulonnais the *Stringocephalus* limestone is followed by fossiliferous Frasnian limestone, and then reddish shales with *Spirifer verneuili* and sandstone comparable with that of Condroz. In Bohemia there is no evidence of the Upper Devonian, but in the eastern Alps the whole formation is well represented.

In the south-west of England, the Devonian is also strongly folded. The lowest rocks in north Devon and west Somerset are the continental Foreland grits—red sandstones and conglomerates, of which the base is not seen as they form an anticline; they contain only scanty indeterminable fragments of fish and plants. The succeeding Lynton beds appear to include Dittonian beds, with *Pteraspis;* and Siegenian with *Spirifer primaevus* and *Sp.*

hystericus. They are overlaid by grits resembling the Forelands, and called collectively the Hangman grits. The lower beds, the Trentishoe grits, have yielded no fossils, but at a higher level are sandstones and shales with plant remains and a scale of *Coccosteus*, followed by littoral beds with casts of *Myalina*, *Cucullaea* and *Naticopsis*, and by calcareous grits with *Stringocephalus* which must be Givetian. Above these is a thick succession of grits, slates and limestones, the Ilfracombe beds. They include coral reefs with *Cyathophyllum* (*Phacellophyllum*) *caespitosum*, *Endophyllum*, and *Pachypora cervicornis*. At a somewhat higher horizon occur *Heliophyllum helianthoides* and *Spirifer verneuili*. The latter, at least, indicates the Upper Devonian. The higher beds, which are arenaceous, are succeeded by the smooth Morte slates with *Spirifer verneuili*, and then by the Pickwell Down sandstone, a continental deposit corresponding to the Condroz sandstone.

At the base is a bed of volcanic ash associated with fish remains including *Bothriolepis* and *Holoptychius*. The Pickwell Down sandstone passes up into the littoral Baggy and Marwood beds. These contain two fossils *Ciccullaea unilateralis* and *Ptychopteria damnoniensis*, also found in the marine beds in the Upper Old Red of Pembrokeshire and the Coomhola grits of Ireland. Then follow the Pilton beds which extend up into the Carboniferous, which occupies a great syncline crossing Devonshire from east to west. Beyond this the Devonian reappears in Cornwall and south Devon. In south-west Cornwall it rests on the Silurian, but the rocks are so dislocated that it is impossible to say whether the formations are conformable or not. The Downtonian may be represented by the Portscatho beds, arenaceous slates which pass up into the smooth Falmouth slates, apparently identical with the Dartmouth slates that form an anticline traversing south Devon and Cornwall. They contain *Cephalaspis* and *Pteraspis*, and appear to be fresh-water deposits of Dittonian age, except in south Devon, where the presence of *Bellerophon* and *Loxonema* indicates brackish conditions. The succeeding Meadfoot beds have yielded *Spirifer primaevus*, *Sp. hystericus*, and other marine fossils of Siegenian age. Then follow the Staddon grits which include beds of Emsian age, with *Tropidolephis rhenanus* and others at the base of the Middle Devonian, with *Spirifer cultrijugatus*.

Next are slates and slaty limestones with *Calceola*. There are also great developments of limestone near Plymouth and Torquay in which both Middle and Upper Devonian are represented, for the fossils include *Spirifer curvatus*, *Stringocephalus*, *Spirifer verneuili* and *Rhynchonella (Hypothyris) cuboides*. The Büdesheim horizon is found at Trevona bay, in North Cornwall, and Saltern cove, in South Devon; that of the Nehden shales at Port Quin in north Cornwall. Famennian horizons are also represented by strata with *Clymenia*, *Entomis serrato-striata* and *Styliolina*. The Devonian, south of the syncline, is overlapped by beds high up in the Carboniferous limestone, and the overlap increases to the south, but this relation is obscured by overthursts of the Devonian over the Carboniferous.

Deep under London both continental and marine Upper Devonian are met with. Many horizons of the Devonian occur in Armorican folds of the north-west of France. In the Devonian rocks of southern Europe, the Lower Devonian and Eifelian are represented by limestones and dolomites laid down at moderate depths; the Givetian and Upper Devonian by limestone accumulated in deeper water, with pale reddish or greenish tints, believed to characterize calcareous oozes.

In the Baltic and adjoining areas the Downtonian succeeds to the Silurian, but there is then a break (without unconformity) followed by typical Middle Old Red. This is, however, succeeded by marine Frasnian with *Spirijer Anossofi*, an eastern form. In the Famennian, continental conditions returned. Further south and east, however, there are marine intercalations, and in central Russia and the Urals, the Famennian is wholly marine. Both the Scotch zones of the Upper Old Red are represented in north-eastern Europe — the Nairn sandstone by the Wenden deposits on the Aa in Livonia, and the Alves by those of the Sjass river near Leningrad.

NORTH AMERICA

The seas on the east and west of the position of the present continent of North America were regions of sedimentation and subsidence, and from them the marine transgression spread over the intervening area. The succession in New York State where the beds have been but little disturbed, is given in the table. The Helderbergian consists of deep sea limestones similar to those of the Lower Devonian of Bohemia. It rests conformably on the Silurian, and is succeeded in the east by the Oriskany sandstone which occurs discontinuously as far west as the Mississippi. It resembles the Lower Devonian of the Meuse and Rhine. As the sea deepened and extended, the Onondaga limestone was laid down, which the presence of *Spirijer acuminatus (cultrijugatus)* would place low in the Eifelian. The limestone is represented by shales in the south, and is later itself replaced by the Marcellus shales which are correlated by their goniatites with the Wissenbach shales of Europe. They are followed by the more calcareous Hamilton shales, with increasing depth of the sea, which, at the end of the Middle Devonian, occupied 38% of the area of the present continent. Although the Hamilton was contemporaneous with the Givetian of Europe, the fauna is quite distinct from that of the Stringocephalus beds, which is, however, found in Manitoba. The affinities of the Hamilton are with southern areas.

The Upper Devonian commences with the Tully limestone, the equivalent of the Iberg limestone of Europe, followed by the Genesee bituminous and pyritous shale and the Portage beds with three facies; in the west the deep water Naples shales with *Gephyroceras intumescens;* in the east the Ithaca shales and sandstones with *Tropidoleptus carinatus*, also found in the Hamilton; and still further east the Oneonta. The Famennian is represented by the continental Catskill beds and the marine Chemung, with *Spirijer verneuili*. In Montana shaly marls with *Clymenia* and *Cheiloceras* indicate deeper water.

SOUTH AMERICA AND AFRICA

The most complete 'succession is found in Bolivia. Resting unconformably on the Ordovician are (1) the Icla sandstone with Silurian fossils near its base, (2) the sandy Icla shales, (3) the Huampampa sandstone, and (4) the Sicasica beds. The fauna of the Icla shales and the Huampampa sandstone is widespread through the Southern Hemisphere — in Paraná (Brazil), the Argentine, the Falklands, and the Bokkeveld beds, which overlie the Table Mountain sandstone in South Africa. *Spirifer antarcticus*, *Clzonetes falklandicus*, and *Leptocoelia flabellites* are found throughout. The fauna of the Sicasica beds is essentially Middle Devonian with some lower forms. It has affinities with the Hamilton. The Devonian fossils of the Sahara are related to North and South American forms. The Devonian of the Gold Coast appears to be a littoral facies of the Hamilton, and is linked with the Sicasica by *Homalonotus dehayi*.

The older southern fauna extending from the Sicasica shales to the Bokkeveld beds may be placed at the base of the Middle Devonian or high in the Lower. Its special characters, the scarcity of corals and bryozoa, the number of discinoid brachiopods, the absence of limestones and the dark grey, blue and green colouring have been attributed to polar conditions, a view supported by the occurrence of glaciation in the Table Mountain sandstone. Some indeterminate lamellibranchs at the base of the latter may be Silurian like the Icla sandstone, and not Devonian. The Bokkeveld passes up into the Witteberg, a series of sands and quartzites containing indistinct plant remains, which are believed to represent a passage into the Carboniferous.

Except for the Caledonian movement at its commencement the Devonian was a time of comparative quiet, but of slow movements, affecting the distribution of land and water and causing unconformities and overlaps.

The granite or granodiorite intrusions of the late Silurian in the north of Great Britain continued into the early Devonian. They were associated with volcanic activity, mainly of an andesitic or basaltic character, and minor intrusions of similar composition. In Devon and Cornwall there were, in later Devonian times, submarine outpourings of spilitic pillow lavas accompanied by tuffs.

They resemble the contemporaneous schalsteins of Germany.

ECONOMIC PRODUCTS

There are iron ores of some importance mostly occurring as replacements of limestone. The metalliferous lodes of Cornwall and Devon are largely in rocks of Devonian age, but are the result of Armorican igneous activity. The oil of Ontario has its source in Middle Devonian shales, while that of New York and Pennsylvania may be derived from the black shales of the Upper Devonian.

DEVONPORT, a seaport, garrison and market town of Devonshire, England, served by the S.R. and G.W.R. Devonport is the seat of one of the royal dockyards, and an important naval and military station. It is situated on the west of Plymouth and the east shore of the Hamoaze (or estuary of the Tamar and the Lynher) at its entrance into Plymouth sound. The "three towns" of Devonport, East Stonehouse (in the middle) and Plymouth now form one unit. Devonport is connected with East Stonehouse by a bridge over Stonehouse pool, an inlet of Plymouth harbour. A ferry across the Hamoaze connects it with the wooded peninsula of Mount Edgcumbe on the Cornish shore, and river steamers ply to Saltash and St. Germans higher up the river; at Morice Town a floating bridge connects with Tor point in Cornwall. Devonport, which owes its origin to the royal dockyard on the Hamoaze, begun in 1689 and now known as the "South Yard," was called Plymouth Dock until 1820, when it changed its name to Devonport. The "old town" which grew up around the dockyard is marked by the fortified "lines," known as the Brickfields, now mostly demolished and providing an open space and parade grounds, with Devonport park (37 ac.) at the northern end. Beyond lie the districts of Stoke or Stoke Damerel, Ford and Morice Town on the Hamoaze to the north. Stoke Damerel, a residential suburb, is the mother parish of Devonport and contains the old parish church of St. Andrew, originally Perpendicular with a 15th century tower. Morice Town is a rapidly growing district which has arisen round Keyham Steam yard, now the "North Yard," the second of the government dockyards, established in 1846, with its own iron and brass foundries, machinery shops, engineer students' shops, and docks and basins along the Hamoaze. St. Budeaux to the north was joined to Devonport in 1914.

There are several points of elevation in Devonport, and the prospect from Mount Wise at the southern extremity of the old town overlooking the harbour and its shores is one of the finest on the south coast. Here, together with a naval signalling station, is the residence of the commander-in-chief, or port admiral, of the Plymouth Naval Command, as well as the headquarters and residence of the general officer commanding the southwestern military area. A national memorial to Capt. R. F. Scott and his four companions of the South Polar expedition was erected here in 1925. From here the Raglan, George Square and other naval and military barracks and quarters extend northwards to the St. Budeaux barracks and naval armament depot at Bull point. Stonehouse pool is lined with the new quays, wharves and boat-building yards; at the northern end is the military hospital (1797) facing the naval hospital in Stonehouse. Among the public buildings and institutions of Devonport are the town hall (1822), market house (1852) and public library, close to which is a granite column, built in 1824, commemorating the renaming of the town, the Royal United Services' and the Royal Dockyard orphanages, as well as the Printe of Wales's hospital buildings and a Sailors' Rest.

Devonport is a station of the Western division of the Home fleet. The admiralty moorings in the Hamoaze extend for 3 miles. Between the South and the North yards is the Gun Wharf (*c.* 21 ac.) on the Hamoaze, first laid out in 1718, with armoury, storehouses, etc., the three establishments, with the naval barracks, known as H.M.S. Drake, being connected by a tunnel In 1907 an extension of 118 ac. was made to the North yard, including a tidal basin of 10 ac. and closed basin of 35½ ac. (with coaling depot and direct access to the Hamoaze), each with a depth of 32 ft. at low-water springs, and affording access to large new graving docks of 700–800 ft. length. The South yard also contains a sail factory and a ropery where a large part of the hempen ropes used in the navy are produced.

By the Reform act of 1832 Devonport became a parliamentary borough including East Stonehouse and returning two members. It was incorporated in 1837. In 1914 it amalgamated with Plymouth. The ground on which it stands is largely the property of the St. Aubyn family (Baron St. Levan), as lords of the manor.

DEVONPORT, EAST and **WEST,** a town of Devon county, Tasmania, Australia, situated on both sides of the mouth of the river Mersey, 193 mi. by rail N.W. of Hobart. Population. 5,153. Devonport ranks as the third port in Tasmania.

DEVONSHIRE, EARLS AND DUKES OF. The Devonshire title, now in the Cavendish family, had previously been held by Charles Blount (1563–1606), 8th Lord Mountjoy, great-grandson of the 4th Lord Mountjoy (d. 1534), the pupil of Erasmus; he was created earl of Devonshire in 1603 for his services in Ireland (1600–03); but the title became extinct at his death. In the Cavendish line the 1st earl of Devonshire was William (d. 1626), second son of Sir William Cavendish (*q.v.*), and of Elizabeth Hardwick, who afterwards married the 6th earl of Shrewsbury. He was created earl of Devonshire in 1618 by James I., and was succeeded by William, 2nd earl (1591–1628), and the latter by his son William (1617–1684).

WILLIAM CAVENDISH, 1st duke of Devonshire (1640–1707), English statesman, eldest son of the earl of Devonshire last mentioned, was born on Jan. 2, 1640. In 1661 he entered parliament, and soon showed himself a determined and daring opponent of the general policy of the court. In 1678 he was one of the committee appointed to draw up articles of impeachment against the lord treasurer Danby. In 1679 he was re-elected for Derby, and made a privy councillor by Charles II.; but he withdrew from the board with his friend Lord Russell, when he found that the Roman Catholic interest uniformly prevailed. He carried up to the House of Lords the articles of impeachment against Lord Chief-Justice Scroggs, and when the king declared his resolution not to sign the bill for excluding the duke of York, afterwards James II., he moved in the House of Commons that a bill might be brought in for the association of all his majesty's Protestant subjects. He appeared in defense of Lord Russell at his trial, and after his condemnation he offered to exchange clothes with him in the prison, remain in his place, and so allow him to effect his escape. In Nov. 1684 he succeeded to the earldom. He opposed arbitrary government under James II. with the same consistency and high spirit as during the previous reign. An imprudent quarrel at court was punished by a fine of £30,000 which he could not pay, and he was in prison for some time. After his discharge the earl occupied himself with the erection of a new mansion at Chatsworth designed by William Talman, with decorations by Verrio, Thornhill and Grinling Gibbons. The revolution again brought him into prominence. He was one of the seven who signed the original paper inviting the prince of Orange from Holland, and was the first nobleman who appeared in arms to receive him at his landing. He received the order of the Garter, and was made lord high steward of the new court. In 1690 he accompanied King William on his visit to Holland.

He was created marquis of Hartington and duke of Devonshire in 1694.

He had married in 1661 the daughter of James, duke of Ormonde, and was succeeded by his eldest son William as 2nd duke, and by the latter's son William as 3rd duke (viceroy of Ireland, 1737–44). The latter's son William (1720–64) succeeded in 1755 as 4th duke; he married the daughter and heiress of Richard Boyle, earl of Burlington and Cork, who brought Lismore castle and the Irish estates into the family; from Nov. 1756 to May 1757 he

was prime minister, mainly in order that Pitt, who would not then serve under the duke of Newcastle, should be in power. His son William (1748–1811), 5th duke, was the husband of the beautiful Georgiana Spencer, duchess of Devonshire (1757–1806), and of the intellectual Elizabeth Foster, duchess of Devonshire (1757–1824), both of whom Gainsborough painted. His son William, 6th duke (1790–1858), died unmarried. The title passed in 1858 to his cousin William (1808–91), 2nd earl of Burlington, as 7th duke, who, in 1829 was second wrangler at Cambridge, first Smith's prizeman and eighth classic, and subsequently became chancellor of the university.

DEVONSHIRE, SPENCER COMPTON CAVENDISH, 8TH DUKE OF (1833–1908), born at Holker Hall on July 23, 1833, was the son of the 7th duke (then earl of Burlington) and his wife, Lady Blanche Howard (sister of the earl of Carlisle). In 1854 Lord Cavendish, as he then was, took a second class in the mathematical tripos at Trinity college, Cambridge; in 1856 he was attached to the special mission to Russia for the new tsar's accession; and in 1857 he was returned to parliament as Liberal member for North Lancashire. At the opening of the new parliament of 1859 the marquis of Hartington (as he had then become) moved the amendment to the address which overthrew the government of Lord Derby. In 1862 he visited the United States, and in 1863 he became first a lord of the Admiralty, and then under-secretary for war in Lord Palmerston's government. and on the formation of the Russell-Gladstone administration at the death of Lord Palmerston he entered it as war secretary. He retired with his colleagues in July 1866 and used his comparative leisure to visit Germany and to meet Bismarck. On Gladstone's return to power in 1868 he became postmaster-general, an office which he exchanged against his own inclination, in 1871, for that of secretary for Ireland. When Gladstone, after his defeat and resignation in 1874, temporarily withdrew from the leadership of the Liberal Party in Jan. 1875, Lord Hartington reluctantly accepted the position of Liberal leader in the House of Commons, Lord Granville being leader in the Lords. W. E. Forster, who had taken a much more prominent part in public life, was the only other possible nominee, but he declined to stand The new leader of the House was a moderate critic of Disraeli's foreign policy in the near East, but emphatically condemned the conduct of Indian affairs which led up to the first Afghan War of 1878. After the Conservative defeat in the general election of 1880, the queen, in strict conformity with constitutional usage (though Gladstone himself thought Granville should have had the preference), sent for him as leader of the opposition, but Hartington declined the request to form a government, in view of Gladstone's position in the party. Hartington joined the new Gladstone government as secretary of State for India, from which office, in Dec. 1882, he passed to the War Office. His administration was responsible for the expeditions of Gen. Gordon and Lord Wolseley to Khartoum.

He shared the responsibility for sending Gordon to evacuate the Sudan, but it must be said that he repeatedly warned the cabinet of the urgency of the Wolseley relief expedition, and threatened resignation when a decision was delayed. In June 1885 he resigned along with his colleagues, and in December was elected for the Rossendale division of Lancashire, created by the new Reform Bill. Immediately afterwards Gladstone's conversion to home rule for Ireland forced on Lord Hartington the great political decision of his life. His refusal to follow his leader in this course inevitably made him the chief of the new Liberal Unionist Party. He moved the first resolution at the famous public meeting at the opera house in the Haymarket (April 14, 1886), when Lord Salisbury also was on the platform. In the House of Commons Hartington moved the rejection of Gladstone's bill on the second reading During the electoral contest which followed, no election excited more interest than Lord Hartington's for the Rossendale division, where he was returned by a majority of nearly 1,500 votes.

In the new parliament he held a position much resembling that which Sir Robert Peel had occupied after his fall from power, the leader of a small, compact party, the standing and ability of whose members were out of all proportion to their numbers, generally esteemed and trusted beyond any other man in the country. yet in his own opinion forbidden to think of office. Lord Salisbury's offers to serve under him as prime minister (both after the general election and again in Jan. 1887, when Lord Randolph Churchill resigned) were declined, and Lord Hartington continued to discharge the delicate duties of the leader of a middle party. It was not until 1895, when the differences between Conservatives and Liberal Unionists had become attenuated by changed circumstances, and the habit of acting together, that the duke of Devonshire, as he had become by the death of his father in 1891, entered Lord Salisbury's third ministry as president of the council, an office which carried at that time the responsibility for education. He also presided over the cabinet committee of defence. In 1892 he succeeded his father as chancellor of the University of Cambridge. In that year too he married the widow of the 7th duke of Manchester.

He continued to hold the office of lord president of the council till Oct. 3, 1903, when he resigned on account of differences with Balfour over the latter's attitude towards free trade. As Chamberlain had retired from the cabinet, and the duke had not thought it necessary to join Lord George Hamilton and Ritchie in resigning a fortnight earlier, the defection was unanticipated, and was sharply criticized by Balfour. But the duke had come to the conclusion that while he himself was substantially a free-trader, Balfour did not mean the same thing by the term. He necessarily became the leader of the Free Trade Unionists who were neither Balfourites nor Chamberlainites, and his weight was thrown into the scale against any association of Unionism with the constructive policy of tariff reform, which he identified with sheer protection. A struggle at once began within the Liberal Unionist organization between those who followed the duke and those who followed Chamberlain; but the latter were in the majority, and the duke resigned his chairmanship of the Liberal Unionist Association (May 1904), and became president of the new organizations, the Unionist Free Food league and the Unionist Free Trade club. In the autumn of 1907 his health gave way, and he wintered in Egypt. He died on his way home at Cannes on March 24, 1908. He had a firm friendship with the prince of Wales, afterwards Edward VII.

There was no issue of his marriage, and his successor as 9th duke was his nephew VICTOR CHRISTIAN CAVENDISH (1868–1938), who had been Liberal Unionist member for West Derbyshire since 1891, and was treasurer of the household (1900–03), financial secretary to the Treasury (1903–05), civil lord of the Admiralty (1915–16) and governor-general of Canada (1916–21); in 1892 he married a daughter of the marquess of Lansdowne. He was succeeded as 10th duke by his son, EDWARD WILLIAM SPENCER CAVENDISH.

See Bernard Holland, *Life of the 8th Duke of Devonshire* (1911).

DEVRIENT, the name of a family of German actors.

LUDWIG DEVRIENT (1784–1832), born in Berlin on Dec. 15, 1784, was the son of a silk merchant. He was apprenticed to an upholsterer, but joined a travelling theatrical company, and first appeared on the stage at Gera in 1804 as the messenger in Schiller's *Braut* von *Messina.* Eventually he obtained a permanent engagement at the ducal theatre in Dessau, where he played till 1809. He then went to Breslau for six years. His success in Shakespeare was such that Iffland feared for his own reputation, but generously recommended Devrient as his successor. On Iffland's death Devrient was summoned to Berlin, where for 15 years he was the popular idol. He died there on Dec. 30, 1832. He was equally good in comedy and tragedy. Falstaff, King Lear, Franz Moor, Shylock and Richard II. were among his best parts. Karl von Holtei in his *Reminiscences* has given a graphic picture of his acting.

See Z. Funck, *Aus dem Leben Zweier Schauspieler, Ifflands und Devrients* (Leipzig, 1838); H. Smidt in *Devrient-Novellen* (3rd ed. 1882); R. Springer, *Devrient und Hoffmann* (1873); Eduard Devrient, *Geschickte der deutschen Schauspielkunst* (Leipzig, 1861); G. Altmann, *Ludwig Devrient* (1926).

Three of the nephews of L. Devrient played an important part in the history of the German stage:—KARL AUGUST DEVRIENT

(1797–1872), whose most famous parts were Wallenstein and King Lear; PHILIPP EDUARD DEVRIENT (1801–1877), director of the court theatre at Dresden (1844–46) and of the Karlsruhe theatre (1852–69) and author of *Geschichte der deutschen Schauspielkunst* (Leipzig, 1848–74); GUSTAV EMIL DEVRIENT (1803–1872), tragedian at the Dresden court theatre (1831–68), whose Hamlet was considered finer than Kemble's or Edmund Kean's. OTTO DEVRIENT (1838–1894), son of P. E. Devrient, translated some plays of Shakespeare into German.

See Eduard Devrient, *Dramatische und dramaturgische Schriften* (10 vols., Leipzig, 1848–73); H. H. Houben, *Emil Devrient* (Frankfurt, 1903); *Brzefwechsel zwischen Eduard und Therese Devrient*, herausg. v. Hans Devrient, (Stuttgart 1903). R. K. Goldschmidt, *Eduard Devrients Buhnenreform am Karlsruher Theater* (Theatergesch. Forschungen No. 32, 1921).

DE **VRIES, HUGO** (1848–1935), Dutch botanist, was born at Haarlem, on Feb. 16, 1848, and educated at Leyden, Heidelberg and Würzburg. In 1871 he became a lecturer at the University of Amsterdam and in 1881 a professor. His attention was drawn to botany and to evolution by discovering on a field trip some new forms growing among a display of Oenothera, a plant that had been introduced from America. This suggested to him a new method of studying evolution, namely the experimental method rather than the old method of observation and inference. This method of investigating evolution may be regarded as his greatest contribution to science. It resulted in a new epoch in the history of evolution. He discovered in his cultures of Oenothera new forms appearing among the hosts of ordinary forms, and this method of producing new forms was named mutation (*q.v.*), as distinct from Darwin's natural selection. He showed that while species vary through natural selection, new species and varieties arise suddenly through mutation. In connection with his experimental work on the mutations of Oenothera, he visited the United States, to investigate the behaviour of this plant in its natural environment. After his retirement from the university of Amsterdam he made his residence in Lunteren, where he continued his experimental work in producing new forms through many generations of culture. His best known works are *Intracellular Pangensis* (1889); *The Mutation, Theory* (1901); and *Plant Breeding* (Chicago, 1907).

DEW. The word "dew" (O.E. *déaw;* cf. Ger. *Tau),* is a very ancient one. The *New English Dictionary* gives "the moisture deposited in minute drops upon any cool surface by condensation of the vapour of the atmosphere; formed after a hot day, during or towards night and plentiful in the early morning." If the deposit is in the form of ice it is called hoarfrost. Aitken's researches (Trans. Roy. Soc. of Edinburgh, xxiii., and "Nature" vol. xxxiii.) suggest that the words "by condensation of the vapour in the atmosphere" might be omitted because the large dewdrops on the leaves of plants, the most characteristic of all dew phenomena, are largely an exudation of water from the plant itself through the leaf-pores and are merely the continuation of the plant's irrigation process for supplying the leaves with water from the soil. The action, set up in full vigour in the daytime, is intended to maintain tolerable thermal conditions of the leaf surface in the hot sun, and continues after sunset.

Nevertheless, the typical experiment to illustrate dew formation is the production of a deposit of minute drops of moisture upon the exterior surface of a glass or polished metal vessel by the cooling of a liquid which it contains. The usual liquids are water, cooled by pieces of ice; or ether, volatilised by bubbling air through it. No deposit is formed by this process until the temperature is reduced to a certain critical level which depends upon the state of the surrounding air. The physical analogy between the natural formation of dew and this artificial production is considered so complete that the critical level below which the temperature of a surface must be reduced in order to obtain the deposit is known as the "dew-point."

Physicists consider the dew-point to be the temperature at which, *by being cooled without change of pressure,* air becomes saturated with water vapour, on account of a reduced capacity of the air at the lower temperature for holding water. It is a well-established proposition that the pressure of the existing water vapour remains constant if the air is cooled without change of its total external pressure, hence the saturation pressure at initial dew-point gives the pressure of the water vapour. Tables of pressures of saturated water vapour for various temperatures have been compiled, thus this mode of determining the dew-point is a recognized method of measuring the pressure, and amount of water vapour in the atmosphere; it is of fundamental importance in hygrometry.

The dew-point is of vital consequence in the matter of the oppressiveness of the atmosphere. High temperature with a low dew-point does not matter, but conditions become unpleasant when the dew-point begins to approach the normal temperature of the human body.

The physical explanation of dew formation is arrived at by determining the manner in which dew-laden objects in the open air have become cooled "below the dew-point."

Formerly, from the time of Aristotle at least, dew was supposed to "fall" ("Meteorologica," Bk. I., ch. 10), and that view of the process was not extinct at the time of Wordsworth. To Charles Wells, Physician to St. Thomas's Hospital, London, belongs the credit of introducing the study of radiation as a meteorological agency. By numerous and careful experiments described in his "Essay on Dew," London, 1814, he made it clear that the deposition of dew could be satisfactorily explained by the cooling of exposed objects on clear nights and his theory of automatic cooling by radiation has found a place in all text-books of physics. The process as represented by Wells is a simple one. All bodies which are at a higher temperature than their surroundings are constantly radiating heat, and cool unless they receive a corresponding amount of heat from other bodies. Good radiators, which are at the same time bad conductors of heat, such as blades of grass, on a clear night, become cooled below the dew-point of the atmosphere by radiation of heat to the surroundings.

The whole question of radiation was very fully studied by Melloni (1798–1854) and by other physicists, but little was added to the explanation given by Wells until in 1880, when John Aitken showed that condensation did not take place even when the air was cooled *below* dew-point if all nuclei for condensation had been removed, but his most important contribution on this matter was in 1885 when he called attention to the question whether the water of dewdrops on plants or stones came from the air or the earth, either by plants exuding dewdrops, or by evaporation and subsequent condensation in the lowest layer of the atmosphere. Aitken's views at least showed that the physical processes operative in the evolution of meteorological phenomena are generally complex. The conditions favourable for the formation of dew are (1) a good radiating surface, (2) a still atmosphere, (3) a clear sky, (4) thermal insulation of the radiating surface, (j) warm moist ground or some other supply of moisture in the surface layers of air, Aitken's main contribution showed that moisture of the ground as well as that of the air was important and that the temperature of both had to be considered. Of the five conditions, the first four are essential, but the fifth is very important for securing a copious deposit. It can hardly be maintained that no dew could form unless there were a supply of water by evaporation from warm ground, but the limited process of condensation which deprives the air of its moisture is soon terminable, while the process of distillation goes on as long as conditions are maintained. This indicates that wet soil can partly protect young plants against night frost. If distillation between the ground and the leaves is set up, the temperature of the leaves cannot fall much below the original dew-point because the requisite supply of water for condensation is kept up, otherwise the dew-point will get progressively lower as the mois-

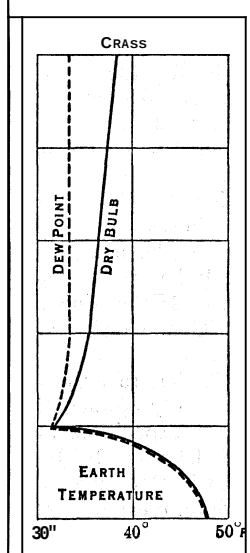

FIG. 1

ture is deposited and the cooling of the plant will continue.

In dew formation comparatively large changes take place within a layer a few inches thick, and for an adequate comprehension of the conditions close consideration is required. Figs. 1 and 2 show the condition of affairs, according to one of Aitken's observations. The vertical scale gives heights in feet, while the horizontal scale shows air temperatures, and the dew-points measured by an ordinary dry-bulb thermometer; their variations with height are represented by the curved lines. The line marked 0 is an arbitrary ground level, a rather indefinite quantity when the surface is grass. The special phenomena which are being considered take place in the layer which represents the rapid transition between the temperature of the ground 3 in. below the surface and that of the air a few inches higher.

If the dew-point curve and the "dry-bulb" curve cut above the surface, mist will result; if they cut at the surface, dew will be formed. Below the surface, it may be assumed that the air is saturated with moisture and any difference in temperature of the dew-point is accompanied by distillation. Incidentally, such distillation between soil layers of different temperatures must transfer considerable quantities of water either upward or downward, the direction varying according to the time of year.

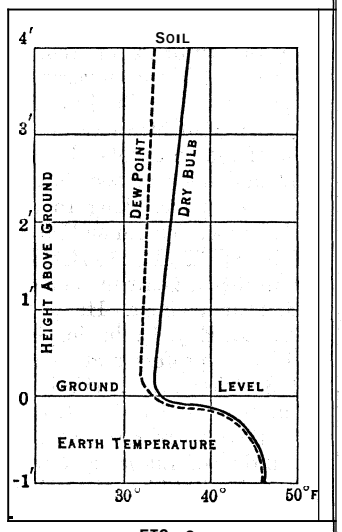

FIG. 2

The diagrams illustrate the importance of the warmth and moisture of the ground. At the surface there is a continual loss of radiated heat and a continual supply of warmth and moisture from below; but while the heat can escape, the moisture cannot. The dry-bulb line is thus deflected to the left as it approaches the surface from above and the dew-point is deflected to the right, consequently the effect of the moisture of the ground is to cause the lines to converge. Fig. 1 shows this and indicates that dew will be deposited. In the case of grass, fig. 2, the deviation of the dry-bulb line shows a sharp minimum of temperature at the surface. The dew-point line is also shown diverted to the left; but that could happen only in the unusual circumstance of so copious a condensation from the atmosphere as to make the air drier at the surface than up above. Along the underground line there must be a gradual creeping of heat and moisture towards the surface by distillation, becoming more rapid for a greater temperature gradient.

The amount of dew deposited may be considerable, and, in tropical countries, is sometimes sufficient to be collected by gutters, but it is not generally regarded as a large percentage of the total rainfall. Loesche probably overestimates a single night's dew deposition on the Loango coast at 3 mm., but measurements show that the aggregate annual deposit of dew corresponds to a depth of 1 to 1·5 in, of water near London (G. Dines), 1·2 in. at Munich (Wollnyj, 0·3 in. at Montpellier (Crova) and 1.6 in. at Tenbury, Worcestershire (Badgley).

The maintenance of "dew ponds" is intimately associated with this matter of total amount. "Dew-ponds" are certain isolated ponds on the upper levels of the chalk downs of the south of England and elsewhere used as a water-supply for cattle. Some of them are very ancient, as the title of a book on *Neolithic Dew-ponds,* London, 1904, 1907, by A. J. and G. Hubbard indicates. Their name implies that they depend upon dew and not entirely upon rain for their maintenance. Though the question has not been settled, the balance of evidence suggests that dew deposits do not make any important contribution to the water supply. The construction of dew ponds is, however, still practised on traditional lines. Although there is some difference of opinion on the matter, it seems necessary for a new dew pond to be filled artificially first as it will not function by a natural accumulation of water in the impervious basin.

DEWAN or **DIWAN,** an Oriental term for finance minister. The word is derived from the Arabian *diwan,* and is commonly used in India to denote a minister of the Mogul Government, or in modern days the prime minister of a native State. It was in the former sense that the grant to the East India Company of the *dewanny* of Bengal, Behar, and Orissa in 1765 first laid the legal foundation of the British Empire in India.

DEWAR, SIR JAMES (1842–1923), British chemist and physicist, was born at Kincardine-on-Forth, Scotland, on Sept. 20, 1842. He was very fond of music as a child, and when he met with an accident which prevented him from playing the flute he practised making fiddles, and so acquired a manual dexterity which served him in good stead in later years. He was educated at Dollar academy and Edinburgh university, being first a pupil, and afterwards the assistant, of Lyon Playfair, then professor of chemistry; he also studied under Kekulé at Ghent. In 1875 he was elected Jacksonian professor of natural experimental philosophy at Cambridge, and in 1877 he succeeded J. H. Gladstone as Fullerian professor of chemistry in the Royal Institution, London. He was president of the Chemical Society in 1897, and of the British Association in 1902, served on the Balfour commission on London water supply (1893–94), and as a member of the committee on explosives (1888–91) invented cordite jointly with Sir Frederick Abel. He was awarded the Rumford medal of the Royal Society in 1894; and the Smithsonian institution, the French Academy of Sciences, the Italian Society of Sciences and the Royal Society of Arts honoured his work. He was knighted in 1904, and died on March 27, 1923.

Dewar's scientific work covers a wide field. His earlier papers deal with organic chemistry, with measurement of high temperatures, with electro-photometry and the chemistry of the electric arc. With J. G. M'Kendrick, of Glasgow, he investigated the physiological action of light, and examined the changes which take place in the electrical condition of the retina under its influence. With G. D. Liveing, of Cambridge, he began in 1878 a long series of spectroscopic observations, the results of which were published in 1915 as *Collected Papers in Spectroscopy.* With *J. A.* Fleming, of University college, London, he investigated the specific inductive capacity of substances at very low temperatures. Dewar is best known for his work on the liquefaction of the so-called permanent gases *(see* LIQUEFACTION OF GASES), and his researches at temperatures approaching the absolute zero. His interest in this branch of inquiry dates back at least as far as 1874, when he discussed the "Latent Heat of Liquid Gases" before the British Association. Subsequently he was stimulated by the work of L. P. Cailletet and R. P. Pictet in 1877, and of Z. F. Wroblewski and K. S. Olszewski a few years later; and by 1891 Dewar had constructed a machine for producing liquid oxygen in quantity. He made use of this liquid for some low temperature experiments on meteorites, and in 1891 showed that both liquid oxygen and ozone are magnetic. About 1892 the idea occurred to him of using vacuum-jacketed vessels for the storage of liquid gases, and so efficient did this device prove in preventing the influx of external heat that it was found possible to preserve the liquids for comparatively long periods; this apparatus which he designed is known as the "Dewar flask," and is invaluable for low temperature work. The principle has been used extensively in the common "thermos" or vacuum flask. He next experimented with a high-pressure hydrogen jet by which low temperatures were realized through the Joule-Thomson effect *(see* THERNODYNAMICS), and the successful results thus obtained led him to build at the Royal Institution the large refrigerating machine by which hydrogen was first liquefied in 1898 and solidified in 1899. He investigated the gas-absorbing powers of charcoal cooled to low temperatures, and applied them to the production of high vacua and to gas analysis.

With collaborators he also studied the physical and chemical properties of iron and nickel carbonyls, the properties of thin films, and atomic heats at low temperatures. Dewar had a fine directing power and was able to do excellent work with competent assistants. His greatest strength was probably in his manipulative skill, and his lectures at the Royal Institution were always remarkable

for the experimental demonstrations which accompanied them. *See* Royal Institution Lecture H. E. Armstrong, Jan. 1924.

DEWAR VESSEL or **THERMOS FLASK,** a vacuum vessel invented by Sir J. Dewar during his research on the liquefaction of gases (*q.v.*).

DEWAS, two Indian states, in the Malwa Political Charge of Central India, founded in the first half of the 18th century by two brothers, Punwar Mahrattas, who came into Malwa with the peshwa, Baji Rao, in 1728. Their descendants are known as the senior and junior branches of the family, and since 1841 each has ruled his own portion as a separate state, though the lands belonging to them are so intimately entangled that even in Dewas, the capital town, the two sides of the main street are under different administrations and have different arrangements for water supply and lighting. The senior branch has an area of 449 sq.mi. (pop. 83,321) while the area of the junior branch is 419 sq.mi. (pop. 70,513). The two chiefs reside in different palaces in the town of Dewas, and each is entitled to a salute of 15 guns.

DEWBERRY or **TRAILING BLACKBERRY,** any blackberry lacking sufficiently woody fibre in the stems to stand more or less erect. In England and other countries of Europe, applied especially to *Rubus caesius,* a trailing plant, common in woods, hedges, and the borders of fields. The leaves have three leaflets, are hairy beneath, and of a dusky green; the flowers which appear in June and July are white, or pale rose-coloured. The fruit is closely embraced by the calyx, and consists of a few drupelets, black with a glaucous bloom; it has an agreeable acid taste. In the eastern, southern, and Pacific areas of the United States several trailing native species of *Rubus,* especially R. *flagellaris, R. baileyanus, R. hispidus, R. enslenii,* and *R. trivialis,* produce excellent fruits, some varieties of which, as the Lucretia (prob. R. *baileyanus* x *R. argutus),* Young (Youngberry), and Boysen (Boysenberry) are extensively cultivated. In the Pacific states various forms of the native trailing blackberry, R. *macropetalus,* are cultivated, as the Ideal Wild and Zielinski, while Cascade and Pacific are varieties derived from Zielinski x Logan (*see* LOGANBERRY). (G. *M.* D.)

DEW-CLAW, the name applied to the functionless toe or toes which do not reach the ground, found in many mammals. In deer there are two, forming the "false hoof." In the dog, the hallux (corresponding to the big toe in man) is the dew-claw.

D'EWES, SIR SIMONDS, BART. (1602–1650), English antiquarian, son of Paul D'Ewes of Milden, Suffolk, sat as member for Sudbury in the Long Parliament of 1640. D'Ewes appears to have projected a history of England based on original documents. But though excelling as a collector of materials, he died without publishing anything except an uninteresting tract, *The Primitive Practice for Preserving Truth* (1645), and some speeches. His *Journals of all the Parliaments during the Reign of Queen Elizabeth* was published in 1682. His large collections, including transcripts from ancient records, many of the originals of which are now dispersed or destroyed, are in the Harleian collection in the British Museum. His unprinted Diaries from 1621–24 and from 1643–47, the latter valuable for the notes of proceedings in parliament, are often the only authority for incidents and speeches during that period, and are amusing from the glimpses the diarist affords of his own character.

Extracts from his *Autobiography and Correspondence* from the mss. in the British Museum were published by J. O. Halliwell-Phillips in 1845, by Hearne in the appendix to his *Historia vitae et regni Ricardi II.* (1729), and in the *Bibliotheca topographica Britannica,* no. 15, vol. vi. (1783); and from a Diary of later date, *College Life in the Time of James I.* (1851). His Diaries have been extensively drawn upon by Forster, Gardiner, and by Sanford in his *Studies of the Great Rebellion.* Some of his speeches have been reprinted in the *Harleian Miscellany* and *Somers Tracts. The Journal of Sir Simonds D'Ewes,* ed. *W.* Notestein (New Haven, 1923).

DE WET, CHRISTIAN (1854–1922), Boer general and politician, was born on Oct. 7, 1854, at Leeuwkop, Smithfield district (Orange Free State) and later resided at Dewetsdorp. He served in the first Anglo-Boer War of 1880–81 as a field cornet, and from 1881 to 1896 he lived on his farm, becoming in 1897 member of the Volksraad. He took part in the earlier battles of the Boer War of 1899 in Natal as a commandant and later, as a general, he went to serve under Cronje in the west. His first successful action was the surprise of Sanna's Post near Bloemfontein, which was followed by the victory of Reddersburg a little later. He became the most formidable leader of the Boers in their guerrilla warfare. Sometimes severely handled by the British, sometimes escaping only by the narrowest margin of safety from the columns which attempted to surround him, and falling upon and annihilating isolated British posts, De Wet struck heavily where he could and evaded every attempt to bring him to bay. He shared in the peace negotiations of 1902, and visited Europe with the other generals. He wrote an account of his campaigns, an English version of which appeared in Nov. 1902 under the title *Three Years' War.* In Nov. 1907 he was elected a member of the first Legislative assembly of the Orange River colony and was appointed minister of agriculture. In 1908–9 he was a delegate to the Closer Union convention. In 1912–13 he supported Gen. Hertzog in his separatist policy, seceded from the South African party and helped to form the Nationalist party. Soon after the outbreak of World War I, De Wet rebelled against the South African Government and was captured at Waterberg on Dec. 1, 1914. On June 10, 1915, he was committed for trial on a charge of high treason, and on June 21 was found guilty on eight of the 10 counts. He was sentenced to six years' imprisonment and fined £2,000, but in the following December was released, on undertaking to abstain from political agitation. He died at Bloemfontein on Feb. 3, 1922.

DE WETTE, WILHELM MARTIN LEBERECHT (1780–1849), German theologian, was born on Jan. 12, 1780, at Ulla, near Weimar. He was educated at Weimar and at Jena, where H. E. J. Paulus inspired his free critical enquiry. In 1807 he became professor at Heidelberg in 1810 at Berlin, where he met Schleiermacher. His letter of consolation to the mother of Sand, the murderer of Kotzebue, led to his dismissal in 1819. After three years' retirement at Weimar, during which he prepared his edition of Luther and wrote the romance, *Theodor oder die Weihe des Zweiflers,* De Wette became professor of theology at Basle university. He died on June 16, 1849.

Wellhausen describes De Wette as "the epoch-making opener of the historical criticism of the Pentateuch." He prepared the way for the Supplement-theory.

BIBLIOGRAPHY.—His most important works *are:—Beitrage zur Einleitung in das Alte Testament* (2 vols., 1806); *Kommentar über die Psalmen* (1811); *Lehrbuch der hebraisch-judischen Archaologie* (1814); *Über Religion und Theologie* (1815); *Lehrbuch der christlichen Dogmatik* (1813–16); *Lehrbuch der historisch-kritischen Einleitung in die Bibel* (1817); *Christliche Sittenlehre* (1819–21); *Einleitung in das Neue Testament* (1826); *Religion, ihr Wesen, ihre Erscheinungsform, und ihr Einfluss auf das Leben* (1827); *Das Wesen des clzristlichen Glaubens* (1846); and *Kurzgefasstes exegetisches Handbuch zum Neuen Testament* (1836–48). De Wette also edited Luther's works (5 vols., 1825–28), and wrote a drama: *Die Entsagung* (1823).

DEWEY, DAVIS RICH (1858–1942), American economist and statistician, was born in Burlington, Vt., April 7, 1858. He was educated at the University of Vermont and at Johns Hopkins university, and afterwards became professor of economics and statistics at the Massachusetts Institute of Technology. He was chairman of the State board on the question of the unemployed (1893), member of the Massachusetts commission on public, charitable and reformatory interests (1897), special expert agent on wages for the 12th census, and member of a State commission (1904) on industrial relations. He wrote a *Syllabus on Political History since 1815* (1887), a *Financial History of the United States* (1902), *National Problems* (1907), and *Banking and Credit* (with M. J. Shugrue, 1922). From 1911 to 1940 he was managing editor of the *American Economic Review.* He died Dec. 13.

DEWEY, GEORGE (1837–1917), American naval officer, was born at Montpelier, Vt., on Dec. 26, 1837. He studied at Norwich university, then at Norwich, Vt., and graduated at the United States Naval Academy in 1858. He was commissioned lieutenant in April 1861, and in the Civil War served on the steamsloop "Mississippi" (1861–63) during Farragut's passage of the forts below New Orleans in April 1862 and at Port Hudson in March 1863; took part in the fighting below Donaldsonville,

La., in July 1863; and in 1864–65 served on the steam-gunboat "Agawam" with the North Atlantic blockading squadron and took part in the attacks on Fort Fisher in Dec. 1864, and Jan. 1865. He became a lieutenant-commander in 1865, commander in 1872, captain in 1884, and commodore in 1896.

In Nov. 1897 he was assigned, at his own request, to sea service, and sent to Asiatic waters. In April 1898, while with his fleet at Hong Kong, he was notified by cable that war had begun between the United States and Spain, and was ordered to "capture or destroy the Spanish fleet" then in Philippine waters. On May 1 he overwhelmingly defeated the Spanish fleet under Admiral Montojo in Manila bay, a victory won without the loss of a man of the American ships (see SPANISH-AMERICAN WAR). Congress, in a joint resolution, tendered its thanks to Commodore Dewey, and to the officers and men under his command, and authorized "the secretary of the navy to present a sword of honour to Commodore George Dewey, and cause to be struck bronze medals commemorating the battle of Manila bay, and to distribute such medals to the officers and men of the ships of the Asiatic squadron of the United States." He was promoted rear-admiral on May 10, 1898. On Aug. 18 his squadron assisted in the capture of the City of Manila. After remaining in the Philippines under orders from his government to maintain control, Dewey received the rank of admiral (March 3, 1899)—that title, formerly borne only by Farragut and Porter, having been revived by act of Congress (March 2, 1899)—and returned home, arriving in New York City, where, on Sept. 30, 1899, he received a great ovation. He was a member (1899) of the Schurman Philippine Commission, and in 1901 acted as president of the Schley court of inquiry.

By special provision Admiral Dewey was not retired, but continued in the service up to his death, being president of the General Board of the Navy for the last seven years of his life. To the end he continued to urge the building of large battleships, citing their superiority in the Battle of Jutland. In 1913 he published his *Autobiography*. He died in Washington, D.C., on Jan. 16, 1917, and was buried in the Arlington National cemetery. His body was transferred March 28, 1925, to the crypt of the Bethlehem chapel of the National Episcopal cathedral in Washington.

See John Barrett, *Admiral George Dewey* (1899); **C. M.** Dewey (ed.) *The Life and Letters of Admiral Dewey* (1899); *T.* **W.** Handford, *Admiral Dewey, the Hero of Manila* (1899); *J.* **L.** Stickney, *Admiral Dewey at Manila* (1899).

DEWEY, **JOHN** (1859–), American philosopher, psychologist and educator, was born in Burlington, Vt., on Oct. 20, 1859. He graduated at the University of Vermont in 1879 and at Johns Hopkins university in 1884. Then he went West, and taught philosophy at the universities of Minnesota (1888–89), Michigan (1889–94) and Chicago (1894–1904). It was as director of the School of Education at the last institution that he first won national fame; he established an experimental school and carried out the ideas of the "new pedagogy." It was in this experience that he came to formulate principles of democratic and occupational instruction which have revolutionized educational practice in America, and influenced many teachers in Europe and Asia. For two years he lectured on education and philosophy at the University of Peking; and the Turkish Government engaged him to draw up a report on the reorganization of its national schools.

Dewey's outlook on education reflects the industrial revolution and the development of democracy; it reacts strongly against the classical approach and authoritarian methods of aristocratic days when education consisted in learning how to talk about things rather than how to do them. The exodus from the field to the factory, the multiplication of machinery and the growing complexity of urban life, required a new curriculum, teaching through practice the arts and discipline of the industrial life. This plea for practicality formed a naturally systematic whole with Dewey's "instrumental" logic, and his lifelong effort to free American philosophy from its sterile preoccupation with German epistemology. In developing his thought out of the German idealism which marked the idealism of his early period—a change due largely to the influence of William James—he retained from it an enduring sense of the value of intelligence.

The starting-point of his system of thought is biological: he sees man as an organism in an environment, remaking as well as made. Things are to be understood through their origins and their functions, without the intrusion of supernatural considerations; even the Schopenhauerian *Wille* and the Bergsonian *Élan* vital are mystical phrases, which the philosopher will avoid. The only reality is experience; and all experience is of objects in relation. It is true that things are known only as known; but this knowledge, to be real, must be functional rather than conceptual; it must see not so much the abstract nature of the thing, as its actual operations and relations in the world of our living experience. Thought is an organ of response, it is an instrument of behaviour, rather than of knowledge in the older sense ("knowledge about"); every idea, to have meaning, must be a way of dealing specifically with actual stimuli and situations. (Here Dewey anticipated "Behaviourism," without falling into its exaggerations.) Thinking begins not with premises, but with difficulties; and it concludes not with a certainty but with an hypothesis that can be made "true" only by the pragmatic sanction of experiment. An idea, then, is true in proportion as it is an effective instrument in the illumination of experience and the realization of desire. Thought should aim not merely to "understand" the world, but to control and refashion it; the Spencerian definition of education as the adaptation of the individual to his environment must be replaced by the practice of education as the development of all those capacities in the individual which will enable him to control his environment and fulfil his possibilities.

Further, since the individual is to live in a society, he is to be studied as a citizen (actual or potential) growing and thinking in a vast complex of interactions and relationships, not as a solitary "self" or "soul." Through education, training, and suggestion of a thousand kinds, he is made in the image of his fellows; and his thinking is largely their thinking through him. If this reduces his uniqueness, it extends the limits of his possible development far beyond those within which it was confined by the old theory of unchangeable heredity. Faith in education as the soundest instrumentality of social, political and moral reconstruction is justified by this malleability of the instincts, and this illimitableness of human growth.

Our difficulties to-day, Dewey believes, are the difficulties of a chaotic adolescence, and the disproportion between our powers and our wisdom. "Physical science," he writes, in a passage that has influenced much later thinking, "has for the time being far outrun psychical. We have mastered the physical mechanism sufficiently to turn out possible goods; we have not gained a knowledge of the conditions through which possible values become actual in life, and so are still at the mercy of habit, of haphazard, and hence of force. . . . With tremendous increase in our control of nature, in our ability to utilize nature for human use and satisfaction, we find the actual realization of ends, the enjoyment of values, growing unassured and precarious. At times it seems as though we were caught in a contradiction; the more we multiply means the less certain and general is the use we are able to make of them." (*Influence of Darwin on Philosophy*, p. 71.)

The task of remaking man to a mental and moral level commensurate with the enlarged and intricate world in which his inventions have enveloped him lies upon democracy and education. Democracy not merely in voting but in opportunity equal to all, in education through comradely occupation, in industry through the replacement of autocracy with voluntary association. in foreign relations through the replacement of war with conference and law. And education not in theory but in specific and experimental thinking; our social ills are to be handled no longer with majestic abstractions like Individualism and Socialism, competition and cooperation, dictatorship and democracy, but with restricted enquiries, specific analysis, careful formulation, patient experimentation, and piecemeal renovation. We must attack the enemy as Napoleon did—in sections and detail.

The great need, then, is intelligence, and Socrates was not far wrong in counting this as the highest virtue. And again, not intellectuality, which is just the opposite of specific and realistic

thought; but that flexibility of mind which can readjust past experience to novel stimuli and purposes. There is no absolute good here, no *summum bonum;* the ethical aim must vary with time and person and place, and only intelligence can specifically and transiently determine it. One thing alone seems universally good, and that is growth. "Not perfection as a final goal, but the ever enduring process of perfecting, maturing, refining, is the aim in living. . . . The bad man is the man who, no matter how good he has been, is beginning to deteriorate, to grow less good. The good man is the man who, no matter how morally unworthy he *has* been, is moving to become better. Such a conception makes one severe in judging himself and humane in judging others." *(Reconstruction in Philosophy,* p. 177.)

It was not till Dewey came in 1904 to join the department of philosophy at Columbia university, that his influence began to reach out from pedagogy to the philosophical and social thought of his time. His classes became the meeting-place of alert students from every part of America; and though he had none of the arts of the popularizer, he left upon many of these students a profound and permanent influence. Through them, as well as through his own writing and speech, he has been one of the great sources of the realistic and experimental mood of the growing American mind.

Dewey's publications include *Leibnitz's Essays Concerning the Human Understanding* (Chicago, 1888); *Psychology* (New York, 1887); *Outlznes of a Critical Theory of Ethics* (Ann Arbor, 1891); *The Study of Ethics* (1894); *The Psychology of Number,* with Jas. A. McLellan (New York, 1895, 1896 and 1909); *Interest as Related to Will* (Bloomington, 1896); "Interpretation of the Culture-Epoch Theory," Natl. Herbart Soc. *Yearbook* (Bloomington, 1896); *My Pedagogic Creed* (New York, 1897); *The Significance of the Problem of Knowledge* (Chicago, 1897); *The Educational Situation* (Chicago, 1902); *Logical Conditions of a Scientific Treatment of Morality* (Chicago, 1903); *Studzes in Logical Theory* (Chicago, 1903–09); "The Philosophical Work of Herbert Spencer," *Phzladelphia Revzew,* vol xiii., No. 2, pp. 159–175 (1904); *The Relation of Theory to Practice in the Education of Teachers* (Chicago, 1904); *The Child and the Curriculum* (Chicago, 1906); *The School and the Child* (London, 1907); *Ethics,* with James *H.* Tufts (New York, 1908); *Ethics* (New York, 1908); "Does Reality Possess Practical Character?" in *Essays Philosophical and Psychological, in Honor of Wm. James* (1908); *Ethical Principles Underlying Education* (1909); *Moral Principles in Education* (Boston, 1909); *The Influence of Darwin on Philosophy* (New York, 1910); *How We Think* (Boston, 1910); *Educational Essays* (1910); *Interest and Effortin Education* (1917); *The School and Society* (Chicago, 1915); *German Philosophy and Politics* (1915); *Schools of Tomorrow,* with Evelyn R. Dewey (New York, 1915); *Democracy and Education* (1916); *Essays in Experimental Logic* (Chicago, 1916); *Creative Intelligence* (1917); *Enlistment for the Farm* (1917); *Reconstruction in Philosophy* (1920); *Letters from Japan,* with Alice Chipman Dewey, edit. by Evelyn Dewey (1920); *Human Nature and Conduct* (1922); supplementary essay by John Dewey in *Chance, Love and Logic,* by Chas. *S.* S. Peirce, edit. by Morris R. Cohen (1927); *Democracy and Education* (1927); *Experience and Nature* (Chicago, 1925); *The Public and Its Problems* (1927); *The Quest for Certainty* (1929).

DEWEY, MELVIL (1851–1931), American librarian, was born at Adams Center (N.Y.) on Dec. 10, 1851. He graduated in 1874 at Amherst college, where he became acting librarian. In 1877 he removed to Boston, there founding and editing *The Library Journal.* He was also one of the founders of the American Library Association. In 1883 he became librarian of Columbia college, and there founded the School of Library Economy, the first institution established for the instruction of librarians.

This school, which was very successful, was re-established in Albany as the State Library School under his direction; from 1889 to 1906 he was director of the New York State Library, from 1889 to 1900 was secretary of the University of the State of New York, and from 1904 to 1906 State director of libraries, completely reorganizing the State library, which he made one of the most efficient in America, and establishing the system of travelling libraries and picture collections. His "Decimal System of Classification" for library cataloguing, first proposed in 1876, is extensively used. Probably more than any other single individual he was responsible for the sound development of library science in America. He died Dec. 26, 1931.

DE WINT, PETER (1784–1849), English landscape painter, of Dutch extraction, son of an English physician, was born at Stone, Staffordshire, on Jan. 21, 1784, and died in London on Jan. 30, 1849. He studied under John Raphael Smith, the engraver, and in 1809 entered the Academy schools. In 1812 he became a member of the Society of Painters in Water-colours, where he exhibited for many years, as well as at the Academy. De Wint ranks as one of the chief English water-colourists. A number of his pictures are in the Tate Gallery and the Victoria and Albert Museum, London.

See William Bell Scott, *Our British Landscape Painters* (1876); W. Armstrong, *Memoir of Peter de Wint* (1888).

DE WINTER, JAN WILLEM (1750–1812), Dutch admiral, was born at Kampen, and in 1761 entered the naval service at the age of 12. He distinguished himself by his zeal and courage, and at the revolution of 1787 he had reached the rank of lieutenant. The overthrow of the "patriot" party forced him to fly to France. Here he threw himself into the cause of the Revolution, and took part under Dumouriez and Pichegru in the campaigns of 1792 and 1793, and was promoted to the rank of brigadier-general. When Pichegru in 1795 overran Holland, De Winter returned with the French army to his native country. The states general now utilized his experience as a naval officer by making him adjunct-general for the reorganization of the Dutch navy. In 1796 he was appointed vice-admiral and commander-in-chief of the fleet. He did his best to improve it and on Oct. 11, 1797, he encountered the British fleet under Admiral Duncan off Camperdown. After an obstinate struggle the Dutch were defeated, and De Winter was taken prisoner. He remained in England until December, when he was liberated by exchange. His conduct at Camperdown was declared by a court-martial to have nobly maintained the honour of the Dutch flag.

From 1798 to 1802 De Winter was ambassador to the French republic, and was then again appointed commander of the fleet. He was sent with a strong squadron to the Mediterranean to repress the Tripoli piracies, and negotiated a treaty of peace with the Tripolitan Government. He enjoyed the confidence of Louis Bonaparte, when king of Holland, and, after the incorporation of the Netherlands in the French empire, in an equal degree of the emperor Napoleon. By the former he was created marshal and count of Huessen, and given the command of the armed forces both by sea and land. Napoleon gave him the Grand Cross of the Legion of Honour and appointed him inspector-general of the northern coasts, and in 1811 he placed him at the head of the fleet he had collected at the Texel. Soon afterwards De Winter was seized with illness and compelled to betake himself to Paris, where he died on June 2, 1812. He had a splendid public funeral and was buried in the Pantheon. His heart was enclosed in an urn and placed in the Nicolaas Kerk at Kampen.

DE WITT, CORNELIUS (1623–1672), brother of John de Witt (*q.v.*), was born at Dort in 1623. In 1650 he became burgomaster of Dort and member of the states of Holland and West Friesland. He was afterwards appointed governor of the land of Putten and bailiff of Beierland. He associated himself closely with his brother, the grand pensionary, and supported him throughout his career with great ability and vigour. In 1667 as deputy chosen by the states of Holland to accompany Admiral de Ruyter in his famous expedition to Chatham, Cornelius de Witt distinguished himself by his coolness and intrepidity. He again accompanied De Ruyter in 1672 and took an honourable part in the great naval fight at Southwold Bay against the united English and French fleets. Compelled by illness to leave the fleet, he found the Orange party on his return to Dort in the ascendant, and himself and his brother the objects of popular suspicion. An account of his imprisonment, trial and death, is given below. (See DUTCH WARS.)

DE WITT, JOHN (1625–1672), Dutch statesman, was born at Dort, on Sept. 24, 1625, being a member of one of the old burgher-regent families of his native town. His father, Jacob, was six times burgomaster of Dort, and for many years sat for the town in the states of Holland. He was a strenuous adherent of the republican or oligarchical states-right party in opposition to the princes of the house of Orange, who represented the federal principle and had the support of the masses of the people. John was educated at Leyden and early displayed remarkable talents, especially in mathematics and jurisprudence. In 1645 he and his elder brother Cornelius visited France, Italy, Switzerland and England, and on his return he lived at The Hague as an advocate. In 16jo he was appointed pensionary of Dort, which made him the leader of the town's deputation in the states of Holland. In this year the states of Holland found themselves engaged in a struggle for provincial supremacy, on the question of the disbanding of troops, with the youthful prince of Orange, William II. William, with the support of the states general and the army, seized five of the leaders of the states-right party and imprisoned them in Loevestein castle; among these was Jacob de Witt. The sudden death of William, at the moment when he had crushed opposition, led to a reaction. He left only a posthumous child, afterwards William III. of Orange, and the principles advocated by Jacob de Witt triumphed, and the authority of the states became predominant in the republic.

It was his father's position which gave John his opportunity, but his own eloquence, wisdom and business ability which caused him to be appointed grand pensionary of Holland on July 23, 1653, at 28. He was re-elected in 1658, 1663 and 1668, and held office until just before his death in 1672. He found in 1653 his country brought to the brink of ruin through the war with England, which had been caused by the keen commercial rivalry of the two maritime states. The Dutch were unprepared and suffered severely through the loss of their carrying trade, and De Witt resolved to bring about peace. He rejected Cromwell's suggestion of the union of England and Holland, but in the autumn of 1654 peace was concluded by which the Dutch made large concessions and agreed to the striking of the flag to English ships in the narrow seas. The treaty included a secret article, which the states general refused to entertain, but which De Witt induced the states of Holland to accept, by which the provinces of Holland pledged themselves not to 'elect a stadtholder or a captain-general. This Act of Seclusion was aimed at the young prince of Orange, whose close relationship to the Stuarts made him an object of suspicion to the Protector. De Witt was favourable to this exclusion of William III. from his ancestral dignities, but he did not prompt Cromwell.

The policy of De Witt after the peace of 1654 was eminently successful. He restored the finances of the State and extended its commercial supremacy in the East Indies. In 1658–59 he sustained Denmark against Sweden, and in 1662 concluded an advantageous peace with Portugal. The accession of Charles II. to the English throne led to the rescinding of the Act of Seclusion; nevertheless De Witt steadily refused to allow the prince of Orange to be appointed stadtholder or captain-general. This led to ill-will between the English and Dutch governments, and to a renewal of the old grievances about maritime and commercial rights, and war broke out in 1665. The grand pensionary himself went to sea with the fleet and inspired all by the example he set of calmness in danger, energy in action, and inflexible strength of will. It was due to his exertions as an organizer and a diplomatist quite as much as to the brilliant seamanship of Admiral de Ruyter, that the treaty of Breda (July 31, 1667), maintaining the status quo was so honourable to the United Provinces. In 1667 he promulgated his eternal edict for the republican administration of Holland. A still greater triumph of diplomatic skill was the conclusion of the Triple Alliance (Jan. 17, 1668) between the Dutch Republic, England and Sweden, which checked the attempt of Louis XIV. to take possession of the Spanish Netherlands in the name of his wife, the infanta Maria Theresa.

In 1672 Louis XIV. suddenly declared war and invaded the United Provinces at the head of a splendid army. The voice of the people called William III. to the head of affairs, and there were violent demonstrations against John de Witt. His brother Cornelius was (July 24) arrested on a charge of conspiring against the prince. On Aug. 4 John de Witt resigned the post of grand pensionary. Cornelius was put to the torture, and on Aug. 19 sentenced to deprivation of his offices and banishment. His brother came to visit him in the Gevangenpoort at the Hague. A vast crowd, hearing this, collected outside and finally burst in, seized the two brothers and tore them to pieces. Their mangled remains were hung up by the feet to a lamp-post. Thus perished, by the savage act of an infuriated mob, one of the greatest statesmen of his age, and of Dutch history.

DEWLAP, the loose fold of skin hanging from the neck of cattle, also applied to similar folds in the necks of other animals and fowls, as the dog, turkey, etc. The American practice of branding cattle by making a cut in the neck is known as a "dewlap brand." The skin of the neck in human beings often becomes pendulous with age, and is sometimes referred to humorously by the same name.

DEW-POINT: *see* DEW.

DEWSBURY, market town, county and parliamentary borough, West Riding of Yorkshire, England, on the river Calder, 8 mi. south-south-west of Leeds, on the L.N.E. and L.M.S. railways. Pop. (1938) 52,860. Area 9.8 sq.mi. The parish church of All Saints was for the most part rebuilt in the 18th century; the portions still preserved of the original structure are mainly Early English. The chief industries are the making of blankets, carpets, druggets and worsted yarn; and there are iron foundries and machinery works. Coal is worked in the neighbourhood. The parliamentary borough returns one member. Dewsbury was incorporated in 1862 and was created a county borough in 1913. Edwin, king of Northumbria, had a mansion here in the 7th century. At Kirklees may be seen the remains of a Cistercian convent (12th century), in an extensive park, where tradition relates that Robin Hood died and was buried.

DEXIPPUS, PUBLIUS HERENNIUS (*c.* A.D. 210–273), Greek historian, statesman and general, was an hereditary priest of the Eleusinian family of the Kerykes, and held the offices of archon basileus and eponymus in Athens. When the Heruli overran Greece (269), Dexippus was made general and defeated them heavily. A statue was set up in his honour, the base of which, with an inscription recording his services, has been preserved (*Corpus Inscrr. Atticarum,* iii. No. 716). It is remarkable that the inscription is silent as to his military achievements. Photius (*cod.* 82) mentions three historical works by Dexippus, of which considerable fragments remain: (1) Τὰ μετ' Αλέξανδρον, an epitome of a similarly named work by Arrian; (2) Σκυθεκά, a history of the wars of Rome with the Goths (or Scythians) in the 3rd century; (3) Χρονική ἱστορία, a chronological history from the earliest times to the emperor Claudius Gothicus (270), frequently referred to by the writers of the Augustan history. The work was continued by Eunapius of Sardis down to 404. Photius places Dexippus on a level with Thucydides, an opinion by no means confirmed by the fragments (C. W. Muller, F.H.G. iii. 666–687).

DEXTER, HENRY MARTYN (1821–1890), American clergyman and author, was born in Plympton (Mass.), on Aug. 13, 1821. A graduate of Yale and Andover theological seminary, he was pastor of Congregational Churches in Manchester (N.H.), and Boston, and edited various magazines, including the *Congregational Quarterly* and *Congregationalist.* He died in New Bedford (Mass.), on Nov. 13, 1890. He was an authority on the history of Congregationalism and was a lecturer on that subject

at the Andover theological seminary in 1877–79. Dexter left his fine library on the Puritans in America to Yale university. Among his works are: *As to Roger Williams and* ***His*** *"Banishment" from the Massachusetts Colony* (1876); *The Congregationalism of the Last Three Hundred Years, as Seen in Its Literature* (1880); his most important work, *Common Sense as to Woman Suffrage* (1885); and many reprints of colonial pamphlets. His *The England and Holland of the Pilgrims* (1905) was completed by his son, Morton Dexter.

See American Antiquarian Society, *Proc.* (April 1891).

DEXTRIN or **DEXTRINE** is a generic and rather indefinite term applied to certain starch derivatives, intermediate in complexity between starch and sugars. They are usually yellowish or brownish powders, but are white when pure. When starch is acted upon by diastase, it gives ultimately maltose or malt sugar, $C_{12}H_{22}O_{11}$; prolonged action of acids, however, converts starch into glucose or grape sugar, $C_6H_{12}O_6$. By the controlled action of ferments or acids, or by roasting at 220°–230° C, the breakdown of the starch molecule can be arrested at some earlier stage to produce dextrin. Their physical and chemical properties depend upon the stage attained; thus, at one stage erythro-dextrin is produced which gives a red colour with iodine, and at a later stage achroodextrin, which gives *no* colour with iodine. All dextrins dissolve in water to give sticky solutions, and hence their chief use is as glues; they are also used to give glossy surfaces to cardboard, etc., and to produce a "head" on aerated liquids *(See* CARBOHYDRATES.)

DEY, an honorary title formerly bestowed by the Turks on elderly men, and appropriated by the janissaries as the designation of their commanding officers (an adaptation of the Turk. *dāī,* a maternal uncle). In the 17th century the deys of the janissaries in Algeria became the rulers of that country *(see* ALGERIA: *History).* From the middle of the 16th century to the end of the 17th century the ruler of Tunisia was also called dey, a title frequently used during the same period by the sovereigns of Tripoli.

BHAMMAPALA, the name of one of the early disciples of the Buddha, and therefore constantly chosen as their name in religion by Buddhist novices on their entering the brotherhood. The most famous of the Bhikshus so named, probably a Tamil, was the great commentator who lived in the latter half of the 5th century A.D. To him we owe the commentaries on seven of the shorter canonical books, consisting almost entirely of verses, and also the commentary on the Netti, perhaps the oldest Pāli work outside the canon. Dhammapāla confines himself rigidly to questions of the meaning of words, and to discussions of the ethical import of his texts. Other unpublished works, besides those mentioned above, have been ascribed to Dhammapāla.

DHANIS, FRANCIS, BARON (1861–1909), Belgian administrator, born in London and educated at the Belgian Ecole Militaire, went out to the Congo in 1887, and in 1892–94 commanded an expedition against the slave dealers. He captured in succession the three Arab strongholds at Nyangwe, Kassongo and Kabambari. He was raised to the rank of baron, and in 1895 was made vice-governor of the Congo State. In 1896 he took command of an expedition to the Upper Nile. His troops, largely composed of the Batetela tribes who had only been recently enlisted, and who had been irritated by the execution of some of their chiefs for cannibalism, mutinied and murdered many of their white officers. During 1897–98 he was engaged in a life-and-death struggle with them; eventually he succeeded in breaking up the bands of mutinous soldiers. In 1899 Baron Dhanis returned to Belgium. He died on Nov. 14, 1909

See Sidney Hinde, *The Fall of* ***the*** *Congo Arabs* (1897).

DHANUSHKODI, a seaport of Madras, India, on the island of Rameswaran, at the junction of Palk straits and the Gulf of Manar. The port was brought into being in 1913, when the new direct route of the South Indian railway to Ceylon was opened. The line is carried by an embankment and a bridge to Dhanushkodi, whence steamers run to Talai Manar (22 miles). Coffee, fish, rice, rubber, tea and cotton goods are exported, but no great influx of trade followed the foundation of the port. The population consists largely of railway employees.

DHAR, an Indian state in the Bhopawar agency, Central India. It includes many Rajput and Bhil feudatories, and has an area of 1,778 sq.m. The raja is a Ponwar Mahratta. The founder of the present ruling family was Anand Rao Ponwar, a descendant of the great Paramara clan of Rajputs who from the 9th to the 13th century, when they were driven out by the Mohammedans, had ruled over Malwa from their capital at Dhar. In 1742 Anand Rao received Dhar as a fief from Baji Rao, the peshwa, the victory of the Mahrattas thus restoring the sovereign power to the family which seven centuries before had been expelled from this very city and country. Towards the close of the 18th and in the early part of the 19th century, the state was subject to a series of spoliations by Sindia and Holkar, and was only preserved from destruction by the talents and courage of Anand Rao's widow. By a treaty of 1819 Dhar passed under British protection. The State was confiscated for rebellion in 1857, but in 1860 was restored, with the exception of the detached district of Bairusia, which was granted to the begum of Bhopal. The chief has the style of Maharaja and a salute of 15 guns. In 1931 the population was 243,430. The state includes the ruins of Mandu, or Mandogarh, the Mohammedan capital of Malwa.

The TOWN OF DHAR (pop. [1931] 19,607), is picturesquely situated among lakes and trees surrounded by barren hills, and possesses, besides its old walls, many interesting buildings, Hindu and Mohammedan, some of them containing records of great historical importance. The Lat Musjid, or Pillar Mosque, was built by Dilawar Khan in 1405 out of the remains of Jain temples. It derives its name from an iron pillar, supposed to have been originally set up at the beginning of the 13th century in commemoration of a victory, and bearing a later inscription recording the seven days' visit to the town of the emperor Akbar in 1598. The pillar, which was 43 ft. high, is now overthrown and broken. The Kamal Maula is an enclosure containing four tombs, the most notable being that of Shaikh Kamal Maulvi (Kamal-ud-din), a follower of the famous 13th-century saint Nizam-ud-din Auliya. The mosque known as Raja Bhoj's school was built out of Hindu remains in the 14th or 15th century: its name is derived from the slabs, covered with inscriptions giving rules of Sanskrit grammar, with which it is paved. On a small hill to the north of the town stands the fort, a conspicuous pile of red sandstone, said to have been built by Mohammed ben Tughlak of Delhi in the 14th century. It contains the palace of the raja.

The town is of great antiquity, and was made the capital of the Paramara chiefs of Malwa by Vairisinha II., who transferred his headquarters hither from Ujjain at the close of the 9th century. During the rule of the Paramara dynasty Dhar was famous throughout India as a centre of culture and learning; but, after suffering various vicissitudes, it was finally conquered by the Mohammedans at the beginning of the 14th century. Subsequently, in the time of Akbar, Dhar fell under the dominion of the Moguls, in whose hands it remained till 1730, when it was conquered by the Mahrattas.

DHARAMPUR, native state, India, in the Surat political agency division of Bombay. Area, 704 sq m. Pop. (1931), 54,068. Tribute, with Bauda and Sachin, £610. The chief is a Sesodia Rajput. The State contains one town, Dharampur (pop. in 1931, 7,218). Only a small part of the state, the climate of which is very unhealthy, is cultivated. Rice, millet, pulse, etc., are grown and there are extensive forests.

DHARMSALA, a hill-station and sanatorium of the Punjab, India, situated on a spur of the Dhaola Dhar, 16 m. north-east of Kangra town, at an elevation of some 6,000 ft. Pop. (1931) 6,359 The spur is thickly wooded with oak and other trees; behind it the pine-clad slopes of the mountain tower towards the jagged peaks of the higher range, snow-clad for half the year; while below stretches the luxuriant cultivation of the Kangra valley.

In 1855 Dharmsala was made the headquarters of the Kangra district of the Punjab in place of Kangra, and became the centre of a European settlement and cantonment, largely occupied by Gurkha regiments. The station was destroyed by earthquake in 1905.

DHARWAR, town and district, British India, in the southern division of Bombay. The town (pop. in 1931, 41,671) is a railway centre, formerly headquarters of the Southern Mahratta railway, now amalgamated with the Madras railway. It contains a jail for juvenile criminals, a mental hospital, a college and two training colleges, and is a centre of the Basle mission.

The district of Dharwar has an area of 4,606 sq. miles. In the north and north-east are plains of black soil, favourable to cotton-growing; in the south and west are ranges of low hills, with flat fertile valleys between them. The whole district lies high and has no large rivers. In 1931 the population was 1,102,677. The principal products are millets, pulse, cotton and timber. The centres of the cotton trade are Hubli and Gadag, junctions on the Madras and Southern Mahratta railway, which traverses the district in several directions.

The early history of the territory comprised within the district of Dharwar has been to a certain extent reconstructed from the inscription slabs and memorial stones which abound there. From these it is clear that the country fell in turn under the sway of the various dynasties that ruled in the Deccan, memorials of the Chalukyan dynasty, whether temples or inscriptions, being especially abundant. In the 14th century the district was first overrun by the Mohammedans, after which it was annexed to the newly established Hindu kingdom of Vijayanagar, an official of which named Dhar Rao, according to local tradition building the fort at Dharwar town in 1403. After the defeat of the king of Vijayanagar at Talikot (1565), Dharwar was for a few years practically independent under its Hindu governor; but in 1573 the fort was captured by the sultan of Bijapur, and Dharwar was annexed to his dominions In 1864 the fort was taken by the emperor Aurangzeb, and Dharwar, on the break-up of the Mogul empire, fell under the sway of the peshwa of Poona. In 1764 the province was overrun by Hyder Ali of Mysore, who in 1778 captured the fort of Dharwar. This was retaken in 1791 by the Mahrattas. On the final overthrow of the peshwa in 1817 Dharwar was incorporated with the territory of the East India company.

DHOLE, the "Red Dog" of India, Cyon *dukhunensis.* It is distinguished from the true dog (*Canis*) by possessing one molar less in the lower jaw. A rufous brown in colour, the dhole is somewhat larger than a jackal and hunts in large packs. It is principally found in the Deccan, and is the hero of one of Kipling's best stories. The name may be extended to all species of Cyon.

DHOLPUR, an Indian state in the Rajputana agency, with an area of 1,155 sq.m. All along the bank of the river Chambal the country is deeply intersected by ravines; low ranges of hills in the western portion of the state supply inexhaustible quarries of fine-grained and easily-worked red sandstone. In 1931 the population of Dholpur was 254,986.

The TOWN OF DHOLPUR is 34 m. S. of Agra by rail. Pop. (1931) 19,586. The present town, which dates from the 16th century, stands somewhat to the north of the site of the older Hindu town built, it is supposed in the 11th century by the Tonwar Rajput Raja Dholan (or Dhawal) Deo, and named after him Dholdera or Dhawalpuri. Among the objects of interest in the town may be mentioned the fortified *sarai* built in the reign of Akbar, within which is the fine tomb of Sadik Mohammed Khan (d. 1595), one of his generals.

Local tradition affirms that Dholpur was ruled by the Tonwar Rajputs, who had their seat at Delhi from the 8th to the 12th century. In 1527, after a strenuous resistance, the fort was captured by Baber and with the surrounding country passed under the sway of the Moguls, being included by Akbar in the province of Agra. During the dissensions which followed the death of Aurangzeb in 1707, Raja Kalyan Singh Bhadauria obtained possession of Dholpur, and his family retained it till 1761, after which it was taken successively by the Jat raja, Suraj Mal of Bharatpur, by Mirza Najaf Khan in 1775, by Sindhia in 1782, and in 1803 by the British. It was restored to Sindhia by the Treaty of Sarji Anjangaon, but in consequence of new arrangements was again occupied by the British.

The maharaj rana of Dholpur belongs to the clan of Bamraolia Jats. A sixteenth-century ancestor, Singhan Deo, having distinguished himself in an expedition against the freebooters of the Deccan, was rewarded by the sovereignty of the small territory of Gohad, with the title of *rana.* In 1779 the rana of Gohad joined the British forces against Sindhia, under a treaty which stipulated that, at the conclusion of peace between the English and Mahrattas, all the territories then in his possession should be guaranteed to him, and protected from invasion by Sindhia. This protection was subsequently withdrawn, the rana having been guilty of treachery, and in 1783 Sindhia crushed his Jat opponent and seized the whole of Gohad. In 1804, however, the family were restored to Gohad by the British government; but, owing to the opposition of Sindhia, the rana agreed in 1805 to exchange Gohad for his present territory of Dholpur, which was taken under British protection. The chief has a salute of 15 guns. Kirat Singh, the first maharaj rana of Dholpur, was succeeded in 1836 by his son Bhagwant Singh, who showed great loyalty during the Mutiny of 1857, and was created a K.C.S I. and G.C.S.I. in 1869. He was succeeded in 1873 by his grandson Nehal Singh, who received the C B. and frontier medal for services in the Tirah campaign. He died in 1901 and was succeeded by his eldest son, Ram Singh. His Highness Lt.-Col. Sir Rais-ud-Daula Jai Deo, K.C.S I., K.C.V.O., the present ruler, is the second son of the maharaj rana Nehal Singh and was born on Feb. 12, 1893. On the death of his brother maharaj rana Ram Singh, his Highness succeeded to the gadi in March 1911 and was invested with full ruling powers on Oct. 9, 1913.

DHOW, a type of vessel used throughout the Arabian Sea. The language to which the word belongs is unknown. Used of any craft along the East African coast, it is usually applied to the vessel of about 150 to 200 tons burden with a stem rising with a long slope from the water; dhows generally have one mast with a lateen sail, the yard being of enormous length. Much of the coasting trade of the Red Sea and Persian Gulf is carried on by these vessels. They were the regular vessels employed in the slave trade from the east coast of Africa.

DHRANGADHRA, native state, India, in the Western Indian States Agency, situated in the north of the peninsula of Kathiawar, Bombay. Area is 1,167 sq m. Pop. (1931) 88,961. Tribute, to the British government and Tunagadh, £3,000. There is a state railway (metre gauge) from Wadhwan through the town of Dhrangadhra to Halvad, a distance of 40 m., and a short line to the state salt works was opened in 1923. The chief town, Dhrangadhra, has a population (1931) of 17,538.

The chief of Dhrangadhra, who bears the title of Raj Sahib, with the predicate of His Highness, is head of the ancient clan of Jhala Rajputs, who are said to have entered Kathiawar from Sind in the 8th century. The Raj Sahib who succeeded in 1869 was distinguished for the enlightened character of his administration, and the state continues to make progress under its present ruler, who succeeded in 1911. It came into direct relations with the British Government in 1924.

DHULEEP SINGH (1837–1893), maharaja of Lahore, was born in Feb. 1837, and was proclaimed maharaja on Sept. 18, 1843, under the regency of his mother the rani Jindan, a woman of great capacity and strong will, but extremely inimical to the British. He was acknowledged by Ranjit Singh and recognized by the British Government. After six years of peace the Sikhs invaded British territory in 1845, but were defeated in four battles, and terms were imposed upon them at Lahore, the capital of the Punjab. Dhuleep Singh retained his territory, but it was administered to a great extent by the British Government in his name. This arrangement increased the regent's dislike of the British, and a fresh outbreak occurred in 1848–49. The Sikhs were routed at Gujarat, and in March 1849 Dhuleep Singh was deposed, a pension of £40,000 a year being granted to him and his dependents. He became a Christian and elected to live in England. On coming of age he made an arrangement with the British

Government by which his income was reduced to £25,000 in consideration of advances for the purchase of an estate, and he finally settled at Elveden in Suffolk. In 1864 he married Miss Bamba Müller, a German missionary worker in Egypt, by whom he had six children. After her death he married in 1890 an Englishwoman, Miss Ada Wetherill. The maharaja was passionately fond of sport, and his shooting parties were celebrated, while he himself became a *persona grata* in English society. The result, however, was financial difficulty and in 1882 he appealed to the government for assistance, making various claims based upon the alleged possession of private estates in the Punjab, and upon the surrender of the Koh-i-noor diamond to the British Crown. His demand was rejected, whereupon he started for India, after drawing up a proclamation to his former subjects. But as it was deemed inadvisable to allow him to visit the Punjab, he remained for some time as a guest at the residency at Aden, and was allowed to receive some of his relatives to witness his abjuration of Christianity, which actually took place within the residency itself. As the climate began to affect his health, the maharaja at length left Aden, and returned to Europe. He stayed for some time in Russia, hoping that his claim against England would be taken up by the Russians; but when that expectation proved futile he proceeded to Paris, where he lived for the rest of his life on the pension allowed him by the Indian government. His death from an attack of apoplexy took place at Paris on Oct. 22, 1893

The maharaja's eldest son, Prince VICTOR ALBERT JAY DHULEEP SINGH (1866–1918) was educated at Trinity and Downing colleges, Cambridge. In 1888 he obtained a commission in the 1st Royal Dragoon Guards. In 1898 he married Lady Anne Coventry, youngest daughter of the earl of Coventry. He died without issue on June 7, 1918.

DHULIA, town, British India, administrative headquarters of West Khandesh district in Bombay, on the right bank of the Panjhra river. Pop. (1931) 39.939. Considerable trade is done in cotton and oil-seeds, cotton and wool are woven, cotton ginning and pressing carried on. There is a technical school. A railway connects Dhulia with Chalisgaon, on the main Great Indian Peninsula railway.

DIABASE, in geology, a term which has at different times carried so many meanings that it has now lost all definite significance. Originally it was applied on the Continent to many pre-Tertiary basic igneous rocks, mostly of extrusive character. Later it was widely accepted as the group-name for the basic hypabyssal intrusives now called dolerites. The term is still used fairly often, especially in the literature of mining geology, and is useful as a field-name, if it is clearly understood as indicating only a somewhat decomposed basic igneous rock whose exact nature and origin has not been determined by precise methods. In this sense it is much the same as greenstone (*q.v.*).

The minerals of diabase, have been classed as the same as those of dolerite, viz., olivine, augite, and plagioclase felspar, with subordinate quantities of hornblende, biotite, iron oxides and apatite. To nearly every variety in composition and structure presented by the diabases a counterpart can be found among the Tertiary dolerites. In the older rocks, however, certain minerals are more common than in the newer. Hornblende, mostly of pale green colours and somewhat fibrous habit, is very frequent in diabase; it is in most cases secondary after pyroxene, and is then known as uralite; often it forms pseudomorphs which retain the shape of the original augite. Where diabases have been crushed or sheared, hornblende readily develops at the expense of pyroxene, sometimes replacing it completely. In the later stages of alteration, the amphibole becomes compact and well crystallized; the rocks consist of green hornblende and plagioclase felspar, and are then generally known as epidiorites, or amphibolites. Chlorite is also abundant both in sheared and unsheared diabases, and with it calcite may make its appearance, or the lime set free from the augite may combine with the titanium of the iron oxide and with silica to form incrustations or borders of sphene around the original crystals of ilmenite. Epidote is another secondary lime-bearing mineral which results from the decomposition of the soda lime felspars and the pyroxenes.

Diabases are exceedingly abundant among the older rocks of all parts of the globe. They form excellent road-mending stones, being tough, durable and resistant to wear, so long as they are not extremely decomposed.

DIABELLI, ANTON ANTONIO (1781–1858), composer of pianoforte and church music, was born on Sept. 6, 1781, at Mattsee, near Salzburg, Austria. He was educated in the convent of Raichenhaslach, it being intended that he should become a priest. He abandoned the idea of taking orders, however, on the secularization of the Bavarian convents in 1803. Diabelli went to Vienna where his piano pieces and arrangements became extremely popular. His other compositions included songs and an operetta, *Adam* in *der Klemme,* while his masses, particularly the *Landmessen,* are widely known in Austria.

With the aid of money he earned as a teacher of the guitar and pianoforte, he was able to become a partner of Peter Cappi, the music publisher, in 1818. Six years later the firm became known as Diabelli and Co., which published for Schubert, Czerny, Strauss, Lanner, and others. On a waltz of Diabelli's, Beethoven wrote his 33 Variations (Op. 120).

DIABETES INSIPIDUS is a morbid condition characterized by the passage of excessive amounts of urine of very low specific gravity (1·002–1·005). The urine contains no abnormal constituent. The patient has intense and constant thirst and sometimes health appears to suffer very slightly, for the disease runs a slow course. Nevertheless, its debilitating effects may predispose to serious and fatal complications. It may terminate in diabetes mellitus. The polyuria must be distinguished from that due to chronic granular kidney and lardaceous disease *(see* KIDNEY DISEASES) and from that occurring in some cases of hysteria. It is best treated by tonics and generous diet, and a free supply of water to drink should never be withheld. Valerian has been found a useful drug. The cause is unknown.

DIABETES MELLITUS is **a** morbid condition in which the body is unable to metabolize sugars efficiently. It is this condition which is commonly termed "diabetes" *(see* METABOLIC DISEASES), and it is believed that it is produced when there is insufficient available insulin (*q.v.*) in the body. The first suggestion that the pancreas is necessary for the complete utilization of carbohydrates in the animal body was made by Brunner in 1682. The relationship of the pancreas to diabetes was first suggested in 1788 by Cowley, an English physician. In 1889 von Mering and Minkowski showed that the complete removal of the pancreas from animals resulted in a condition which is practically identical with diabetes mellitus in man. Although attempts were made to secure an anti-diabetic substance from the pancreas by scores of investigators, this substance was not proven to be present until 1921 *(see* INSULIN).

Diabetes is a common disease more prevalent in towns and especially modern city life than in primitive rustic communities and frequently occurs in Jews. In the United States it is said that it affects 1% of the population. No age is exempt but most sufferers are 50–60 years. Males are affected twice as frequently as females and fair more often than dark people, while obese individuals more often suffer from diabetes than those of normal weight.

Symptoms. — The untreated diabetic patient suffers from extreme thirst, hunger, loss of weight and strength. He excretes abnormally large quantities of urine of high specific gravity (1·030–1·050). He is very susceptible to infection and this condition, when established, is difficult to eliminate. The diabetic is unable to burn sugar. This sugar accumulates in the blood and is excreted in the urine. Not only are the sugars imperfectly

metabolized, the fats are also not utilized in a normal manner and certain products of their abnormal or incomplete decomposition accumulate in the blood and produce the conditions of acidosis and coma.

The diabetic condition is suspected when a patient complains of one or more of the symptoms or signs mentioned above. An analysis of the urine for sugar should always be made. Diabetes may be present and sugar may be found in the urine when the patient is not aware of any of these symptoms. The routine analysis of the urine in life insurance examinations has resulted in the early diagnosis of many cases of diabetes. The prognosis of the early case is, of course, much better than the advanced case since treatment can be instituted earlier in the disease. The amount of sugar in the blood, under certain standard conditions, is a valuable indication of the severity of the disease. The presence in the urine of the acetone bodies formed from the abnormal breakdown of fats is a warning that acidosis or coma is imminent. The presence of these substances in the body can sometimes be suspected by the characteristic odour which they impart to the breath.

By evaporation crystals of sugar may be obtained from diabetic urine, which also yields the characteristic chemical tests of sugar. The quantity of sugar passed daily may vary from a few ounces to two or more pounds, and is markedly increased after saccharine or starchy food has been taken. Sugar may also be found in the blood, saliva, tears, and in almost all the excretions.

Diabetes as a rule advances comparatively slowly except in the young, in whom its progress is often rapid. The complications of the disease are many and serious. It may cause impaired vision by weakening the muscles of accommodation, or by lessening the sensitiveness of the retina to light. Also cataract is very common. Skin affections of all kinds may occur and prove very intractable. Boils, carbuncles, cellulitis and gangrene are all apt to occur as life advances. Diabetics are especially liable to phthisis and pneumonia, and gangrene of the lungs may set in if the patient survives the crisis in the latter disease. Digestive troubles, kidney diseases and heart failure due to fatty heart are all of common occurrence. But the most serious complication of all is diabetic coma, which is very commonly the final cause of death. The onset is often insidious, but may be indicated by loss of appetite, a rapid fall in the quantity of both urine and sugar, and by either constipation or diarrhoea. More rarely there is most acute abdominal pain. At first the condition is rather that of collapse than true coma, though later the patient is absolutely comatose. The patient suffers from a peculiar kind of dyspnoea, and the breath and skin have a sweet ethereal odour. The condition may last from twenty-four hours to three days only very rarely longer, but is almost invariably the precursor of death.

Treatment.— Patients suffering from diabetes mellitus are treated by dietetic measures, and if the condition is severe, by the administration of insulin. Before the discovery of insulin the methods of treatment introduced by Allen and Joslin of drastic restrictions in diet prolonged the lives of many severe diabetics.

Several important principles underlie the dietetic treatment of this disease. The diet must supply sufficient calories to the patient in order that his weight may be kept constant at the proper level. Protein, preferably as lean meat, eggs or milk, must not be reduced below a certain minimum value. If this substance is unduly reduced, the tissue protein of the patient's body is utilized. The carbohydrates and fats of the diet must be in a certain fixed proportion to each other. If the fats are present in excess of this proportion, there is danger of the production of the poisonous acetone bodies. In calculating the sugar in a diet, it is necessary to remember that sugar is formed from protein and to a lesser extent from fat, as well as from the carbohydrate of the diet. The diabetic patient is given as much sugar-forming food as he can utilize. Sugar in excess of what is utilized is excreted in the urine. The amount of excess sugar can therefore be determined by analysis.

Dietetic Measures.—The diabetic diet should consist as far as possible of easily available seasonable foods along the line of a normal diet. It is much more satisfactory for the patient to obtain the essentials of his diet from among these natural foods than to be dependent upon specially prepared diabetic foods. The diabetic diet need not be monotonous.

Mild cases of diabetes can be successfully treated by dietetic measures. If a patient excretes sugar on a diet which is sufficient only for his needs insulin must be supplied. The amount necessary is proportional to the severity of the disease. Insulin, which is distributed as a sterile, watery solution, is administered hypodermically. It is not effective when given by mouth. Insulin is usually administered twice a day, 15 to 30 minutes before breakfast and again before the evening meal. Some patients require only one dose per day, while in very severe cases three doses are necessary.

If the diabetic patient is using a diet which is too high in fats or too low in sugar, coma may develop. A large percentage of diabetics died of coma before insulin was discovered. The treatment of coma was to put the patient to bed, to supply fluids and alkalis, heat and stimulants and to give sugar by mouth or into a vein. These measures are still necessary. Insulin has proved a specific drug in the treatment of this condition and, when administered sufficiently early, and in large doses, the results have been very successful.

Insulin is a very powerful drug. A very serious condition may be produced by the administration of an overdose. This may be avoided on the physician's part by a very careful balancing of diet against dosage of insulin employed, and on the patient's part by a close and intelligent observance of the diet, together with a thorough understanding of the premonitory symptoms of a beginning hypoglycaemic reaction. These symptoms of slight hypoglycaemia are sudden hunger, fatigue, a peculiar restlessness often described by the patient as a feeling of "inward trembling," pallor or flushing of the face, and an increased pulse rate which is a valuable sign in children. If the overdose of insulin is large and corrective measures are not taken, the patient may show profuse perspiration, tremor, emotional disturbances, collapse and unconsciousness. The treatment of mild degrees of hypoglycaemia consists of the administration of carbohydrate in any convenient form, such as sugar candy. Should the more serious symptoms develop, orange juice with sugar added, or corn syrup, may be given by mouth. In the very severe cases, sterile dextrose is given intravenously.

In the past, less than 20% of patients suffering from severe diabetes lived more than 10 years. Children, who usually have the disease in a severe form, seldom lived for more than 6 years. The diabetes which develops in individuals over 50 years of age is usually mild and the patients may live their allotted span of years. It is not possible to state definitely as yet the exact effect of insulin on diabetic mortality. It is certain, however, that thousands are now alive who would have died had it not been for insulin. In some cases it appears that patients need less insulin than they required when treatment with the material was commenced. In the great majority of cases, however, the insulin requirement has not been markedly reduced. The severe diabetic receiving insulin is now able to live practically a normal life, but the insulin treatment cannot be discontinued.

DIABOLO, a game played with a sort of top in the shape of two cones joined at their apices, which is spun, thrown, and caught by means of a cord strung to two sticks. The idea of the game appears originally to have come from China. In 1812 it became popular in France under the name of *"le diable."* In 1906 Gustave Phillipart, a French engineer, devised a top with a double cone and, for a short period, the game was extremely popular in France and England.

DIACONICON, in the Greek Church, the name given to a chamber on the south side of the central apse, where the sacred utensils, vessels, etc., of the church were kept. In the reign of Justin II. (565–574), owing to a change in the liturgy, the diaconicon was located in an apse at the east end of the south aisle; a similar apse at the east end of the north aisle was used as the prothesis (*q.v.*)—the place where the elements of the Communion were prepared. In the churches in central Syria, of slightly earlier date, there is only one apse and the diaconicon is rectangular. (T. F. H.)

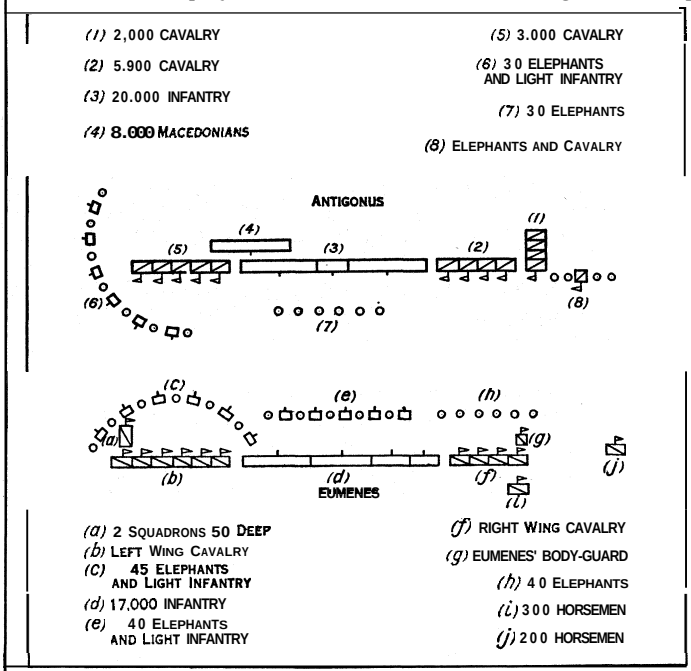
DIADOCHI, *i.e.,* "Successor" (Gr. διαδέχεσθαι), the name given to the Macedonian generals who fought for the empire of Alexander after his death in 323 B.C. The name includes Antigonus and his son Demetrius Poliorcetes, Antipater and his son Cassander, Seleucus, Ptolemy, Eumenes and Lysimachus. The kingdoms into which the Macedonian empire were divided under these rulers are known as Hellenistic. The chief were Asia Minor and Syria under the Seleucid dynasty (*q.v.*), Egypt under the Ptolemies (*q.v.*), Macedonia under the successors of Antigonus Gonatas, Pergamum (*q.v.*) under the Attalid dynasty. Gradually these kingdoms were merged in the Roman empire. (See MACEDONIAN EMPIRE.) (X.)

DIADOCHI, WARS OF (323–281 B.C.). The wars of the Diadochi, or Successors, though outwardly civil wars ending in the disruption of the Alexandrine empire, were inwardly the birth pangs of a new civilization begotten by Persian gold set into circulation through strife. Few periods in history have produced so many great generals, the reason being that the chief participators in these wars, namely, Antipater, Craterus, Perdiccas, Ptolemy, Lysimachus, Seleucus and Eumenes had all been selected by Alexander and trained in his campaigns.

To *the Death* of *Perdiccas*, 321 B.C.—Alexander died in June 323, but before the year was out civil war was raging throughout Greece. This conflagration was known as the Lamian war, and to quell it Antipater sent for Craterus then in Cilicia on his way back to Greece with Alexander's discharged veterans. On his arrival he met the Grecian allied forces on the plains of Crannon and routed them. Free of this menace, Antipater and Craterus, fearing the growing power of Perdiccas, entered into a league with Ptolemy, who was nervous lest Perdiccas should attempt to dispossess him of Egypt. Nor were his fears unfounded, for in the spring of 321 Perdiccas, accompanied by Philip Arrhidaeus, the weak-minded half-brother of Alexander, marched against Egypt, whereupon Craterus and Neoptolemus invaded Asia, both being killed in a battle with Eumenes. Perdiccas did not, however, live to hear of this victory, for on the Pelusiac branch of the Nile his men mutinied and assassinated him. The battle fought by Eumenes is mainly of strategical interest, since Perdiccas and Eumenes held a central position and were threatened by Antipater from the west and by Ptolemy from the south. Antipater's plan was first to smash Eumenes and hold off Perdiccas, secondly to concentrate against the latter. Perdiccas attempted to counter this plan by sending Eumenes to hold back Antipater's two generals whilst he fell upon Ptolemy. Both coalitions aimed at destroying each other in detail, the one working on interior lines and the other on exterior. From the very outset of this war we find strategy dominating tactics, the reason being that all the generals concerned are men of high military ability.

To *the Death* of *Eumenes*, 316 B.C.—By the death of Perdiccas the preponderance of power was thrown into the hands of Antipater, Ptolemy and Antigonus. As Antipater had just suffered a reverse, Antigonus, seeing Eumenes without an ally, marched against him. Eumenes, robbed of the fruits of his victory, was faced by a mutinous army. Putting to death the ringleaders he turned to meet Antigonus, whereupon his cavalry under Apollonides deserted to the enemy. This compelled Eumenes to seek refuge in the fortress of Nora, which was at once besieged by Antigonus. Meanwhile Antipater died, but shortly before his death he set aside his son Cassander and appointed as his successor Polysperchon. Antigonus, hearing of the differences between these two, saw a chance of increasing his dominion, and to be quit of the siege he proposed favourable terms to Eumenes, who was at once bought over by Polysperchon, who sent to him the Argyraspides (Silver Shields), a formidable body of Alexander's veterans. A series of manoeuvres now took place, the two antagonists coming into contact in Media. Eumenes had 35,000 foot, 6,100 horse, and 114 elephants; and Antigonus 82,000 foot, 8,500 horse and 65 elephants. The orders of battle of the two armies are given in the diagram.

The tactics of this battle are interesting. Antigonus, seeing that Eumenes had deployed his best horsemen on his right, drew up



PLAN OF THE FIRST BATTLE BETWEEN EUMENES AND ANTIGONUS

1,000 horse archers and 1,000 lancers in columns of squadrons so that they could "charge in manner of a running fight, wheeling off one after another, and so still renew the fight by fresh men." He did this to hold his enemy's main attack. Eumenes, to protect his left wing, drew up his elephants in a demi-lune, from which it may be inferred that this wing was to be refused. Antigonus in order to protect his right wing, which was to deliver the main attack, extended his elephants in a semi-circle on its outer flank.

Antigonus advanced with his right leading, but not being able to encounter the elephants he wheeled outwards and poured showers of arrows on to his enemy's left flank. Eumenes, withdrawing a force of cavalry from his right, fell upon the flank and rear of Antigonus's right wing and pursued it into the mountains. The phalanxes now clashed together, the Silver Shields carrying all before them. Antigonus was advised to retire, but he was too good a soldier to take this course. He noticed that the pursuit of Eumenes and the movement of the Silver Shields had created a gap between the phalanx and the left wing cavalry. Through this gap he charged, and struck Eumenes' right flank in rear driving it from the field. The battle was indecisive, and during the night both armies retired. Eumenes was now compelled to disperse his force in order to live. Antigonus, determining to take advantage of this, abandoned the main road for a little-known desert track. Learning of this, Eumenes lit fires "within the compass of 70 furlongs," which so completely deceived Antigonus that he abandoned the track; this allowed Eumenes to concentrate his forces. The armies now met, that of Antigonus numbering 22,000 foot, goo horse, and 65 elephants; and that of Eumenes 36,700 foot, 6,050 horse, and 114 elephants. (See plan below.)

Eumenes, hearing that Antigonus was with his right wing, faced him with his left, in front of which he drew up in a half-moon formation, the bulk of his elephants linking them up with light infantry. In his centre he marshalled his targeteers in front, the Silver Shields behind them, and the "foreigners" in rear. In front of the targeteers he extended a line of elephants and light troops, his right wing being ordered "to retire leisurely as he fought, and

diligently to observe the events of the other side." As the elephants advanced on each other a tremendous dust was raised, under cover of which Antigonus sent out a force of cavalry to pass round the enemy's flank and seize his baggage camp. Eumenes charged forward through the dust, a large number of his horse deserting him. He was followed by the Silver Shields who once again carried all before them, but on account of the flight of Eumenes' cavalry they were surrounded by the enemy's. Learning that their baggage and wives were in the enemy's hands they were thrown into consternation. Thereupon Antigonus offered to hand their camp back to them if they would desert and surrender Eumenes. This they agreed to do, and after a week's captivity Eumenes was put to death by his guard.

To the Death of Heracles, 310 B.C.—Whilst Eumenes was warring in Asia, Olympias, the mother of Alexander, put to death Philip Arrhidaeus. Thereupon Cassander, who by bribery had won over many of Polysperchon's soldiers, besieged her in the fortress of Pydna. In the spring of 316, with Roxana and her child (Alexander's widow and son), she surrendered to him and shortly after was assassinated. The death of Eumenes having freed Antigonus from opposition in Asia, he made the assassination of Olympias an excuse to destroy Cassander. Through self-preservation, Lysimachus, Ptolemy and Seleucus formed an alliance against him, and in 314, to weaken Cassander, Antigonus promised freedom to the Grecian cities. The result of this was that the Aetolians entered into alliance with him, and Cassander was forced to march against them. Meanwhile Seleucus gained over Babylonia and founded the Seleucid dynasty.

In 311, Cassander having defeated the Aetolians, a temporary peace was patched up, the terms of which were: That Cassander was to hold Macedonia until Roxana's child should come of age; Lysimachus to govern Thrace; Ptolemy to retain Egypt, and Antigonus to rule all the provinces of Asia. No sooner was this peace agreed upon than Cassander assassinated Roxana and her child, whereupon Polysperchon, influenced by Antigonus, espoused the cause of Heracles the pretender, proclaiming him Alexander's son by his mistress Barsine. Cassander, whose position was insecure, offered Polysperchon complete control of the Peloponnesus if he would put Heracles out of the way, which was promptly done.

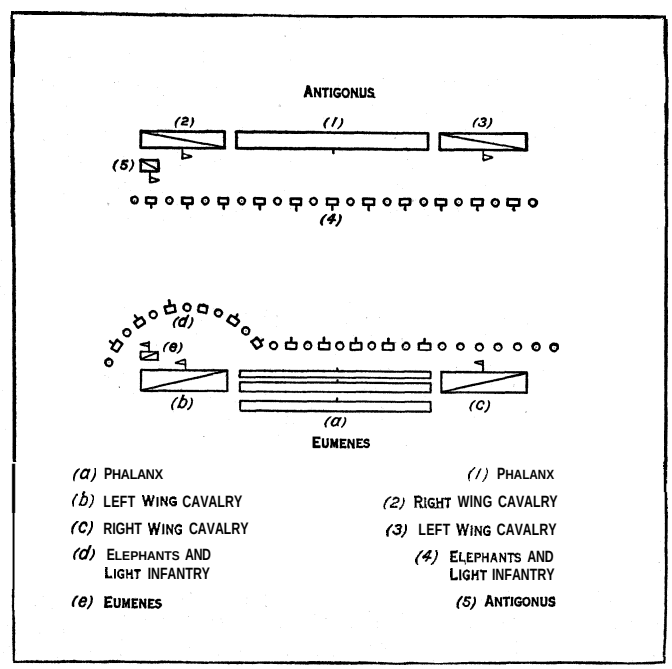
To the Death of Antigonus, 300 B.C.—To punish Cassander, in 307 B.C., Antigonus sent his son Demetrius to the Peiraeeus. The Athenians mistaking his fleet for that of Ptolemy allowed him to enter the port, whereupon Athens opened her gates to him. The next three years were spent by Demetrius in a series of campaigns. At the battle of Gaza, 312 B.C., he was defeated by Ptolemy and Seleucus, captured and at once released. Concentrating his main cavalry force in his right wing, Ptolemy protected it against Demetrius's elephants by a palisade pointed with iron spikes, in front of which he placed his light infantry. As the elephants advanced they were plied with darts, and when they struck the iron spikes they were thrown into such confusion that the Demetrians lost heart and withdrew.

In 308 B.C. Demetrius, realizing that Ptolemy's strength lay in his command of the sea, defeated him in a naval battle off Cyprus, and in the following year he set sail for Rhodes, the siege of which was the greatest exploit of his eventful life. At this siege every type of device was made use of by besieged and besieger. Demetrius employed 30,000 artificers and workmen to build his towers and engines; Helepolis, the largest tower he built, required 3,400 men to move it. He constructed a ram 18oft. long which was moved on wheels by 1,000 men. In place of ramming his enemy's war galleys, he cleared their decks by veritable broadsides of missiles, and Plutarch tells us that he built galleys of 13 banks of oars, and some of even 15 and 16 which "were as wonderful for their speed . . . as for their size." Nevertheless, in spite of his inventive genius, in the autumn of 302 B.C. he was compelled to raise the siege, for Ptolemy, still controlling the seas, resupplied the city,

Returning to Athens, in April 301, as he was marching into Thessaly to meet Cassander, Demetrius was recalled to Asia by Antigonus. The reason for this was that Ptolemy, Seleucus and Lysimachus, fearing that should Cassander be defeated Greece would be added to the kingdom of Antigonus, determined to relieve the pressure by attacking Antigonus in Asia. In the spring of 300 B.C. the opposing forces met at Ipsus, in Phrygia. Demetrius with the main force of cavalry charged Antiochus, the son of Seleucus, routed him, and then pursued him. Seeing what had happened Seleucus blocked his return by a line of elephants, and then in place of charging Antigonus threatened him with attack, so giving time to such of the enemy who wished to desert to come over. This a large body did, and when a strong force of the enemy drew up to charge Antigonus, one of those about him cried out: "Sir, they are coming upon you!" To which the old general replied dryly: "What else should they do?" and was at once smitten down by a multitude of darts. His kingdom was then broken up, chiefly to the profit of Seleucus.

To the Death of Seleucus, 281 B.C.—In 296 B.C. Cassander died, and Demetrius returning to Greece became master of Macedonia. There he prepared to invade Asia, which threat resulted in an alliance between Seleucus, Ptolemy and Lysimachus. Demetrius, forsaken by his troops, surrendered himself to Seleucus, who kept him a prisoner until his death in 283 B.C. In 277 B.C. his son Antigonus Gonatas regained the throne of Macedonia, and his descendants, the Antigonid kings, held it until the battle of Pydna, in 168 B.C. In 283 B.C., Ptolemy, king of Egypt, died at the age of 84, and two years later, at the battle of Coron, Lysimachus, at the age of 80, was killed by Seleucus, who himself was murdered by Reraunos, the eldest son of Ptolemy, in 281 B.C. Thus perished the last of the Diadochi.

The Art of War of the Period.—In spite of their many brilliant episodes, the wars of the Diadochi constituted a period of military decadence. The first cause for this rot was the sudden loss of Alexander's genius; the second, the imitation by the Successors of his actions without understanding them, and, lastly, the immense influx of Persian gold.



PLAN OF THE SECOND BATTLE BETWEEN EUMENES AND ANTIGONUS, 316 B.C.

When Alexander died his art died with him; and though several of his generals showed true knowledge of the art of war and on occasion actually improved on his minor tactics, they lacked his vision, and after his death the glamour they had gathered was lost and only a dream was left, which as years passed by grew fainter and more obscure. Eumenes was an able leader, full of resources and craftiness, yet in his first battle with Antigonus he merely copied the Alexandrine tactics in place of breathing out their spirit. He made his right wing the decisive attack, as Alexander had done; but Alexander always struck at his enemy's command,

the decisive point, and as Antigonus was commanding his own right wing Eumenes should have attacked him with his left. In his second battle he does not repeat this mistake, which shows how little of essential value is learnt even by intelligent soldiers until disaster hammers knowledge home.

The Persian gold, with which Alexander intended to develop his empire, was spent in war. The mercenary now came into his own, and not only was he bought and sold on the battlefield, which if it did not destroy discipline destroyed all reliance in it, but he changed the art of leadership and of military organization. A mercenary army will serve any master for pay, and when a general is forced to hire mercenaries he looks for the most formidable type of troops. In this day the sarissa armed hoplites were of this category, consequently a man who looked for employment as a mercenary knew that as a hoplite he would command higher pay than as an archer or a peltast. The result was a disruption of Philip of Macedon's organization and a steady return to the Spartan tactics.

In the army of Alexander leadership was based on heroism, but in the armies of the Diadochi it was based on pay. The result of this was that heroism was replaced by craft. Warfare, in a low and underground way, became more intellectual, and leadership had to follow suit. The leader was no longer a hero but a diplomatist, and as he led by gold in place of by valour, he crept behind his men, or, more frequently still, hired a hero to lead them, and from a safe distance instructed him what to do. Thus the mercenary separated leadership from command, and the whole art of war changed. Another influence of gold was that warfare became mechanized. Gold stimulated invention, and invention stimulated industry, and industry was applied to war. Projectile weapons came more and more into use, and as they were difficult to move on the battlefield they induced generals more and more to adopt defensive tactics. The anti-elephant palisades at the battle of Gaza are an example of this.

The whole tendency of this period is one from prowess to cunning. Under the Diadochi we see strategy steadily coming to the fore. Antipater and Ptolemy go into league against Perdiccas, and their movements, as well as their ideas, are combined. At the battle of Ipsus it is the same, and out of these various transient combinations may be seen evolved from cunning a definite conception of the balance of power, in the making and unmaking of which more and more does command of the sea play a decisive part. Ptolemy holds it, then Antigonus attempts to wrest it from him; such was the cause of the siege of Rhodes. Each king wants to secure his frontiers, and the only one who succeeds in doing so is Ptolemy—as long as he can command the sea. With this command Egypt is virtually an island. Surrounded by deserts, it is all but unassailable save from the sea. The result of this security is immense prosperity, which gives birth to an economic and ethical outlook on war. Ptolemy from a leader steps into the position of a modern commander, a true general in chief. He is a statesman, and he understands that ethics may be used as a weapon—witness his treatment of Demetrius after the battle of Gaza, and this was not an isolated case. He knows the value of his immense resources, and to him they are weapons of war. He saves Rhodes by means of dried peas, and not by pikes, and plans campaigns whilst his generals fight his battles. Thus we see, in many unlooked for ways, how the unleashing of the power of gold transformed civilization and with it the art of war

The Foundations of Modern Europe.—The influence on western civilization of these 40 years of incessant war was profound. Alexander had dreamt of a world empire through a fusion of races, and, curious as it may seem, it was through the wreck of his empire that this idea took form. At his death Greece and Persia disappeared and the Hellenistic world was established in their stead, a world of decadence and of progress which was destined to fertilize Rome, and later on Arabia. "As Greece had transmuted the barbaric tinsels of the Orient into rich gold, so the East once more seized upon the jewels of Greece and wove them into mystic cabalistic webs, into its gnosticisms and theologies." Without Alexander and his Successors there would have been no Christian religion nor would there have been an Arabian civilization—in fact the world to-day would not be the world we know. (J. F. C. F.)

DIAGHILEV, SERGEI PAVLOVICH (1872–1929), Russian ballet producer, was born in the province of Novgorod, Russia, March 19, 1872. After studying law and music he organized art exhibitions in St. Petersburg (Leningrad). In 1899 he founded the review *Mir Iskusstra* (The World of Art), to which Somov and Bakst contributed, and which exercised a powerful influence on Russian art. From 1907 onwards he occupied himself with musical and theatrical productions and organized a number of Russian concerts in Paris; there he produced in 1908 and 1909 Russian operas *(Boris Godunov* and *The Maid* of *Pskof)* and ballets. Subsequently he organized successful ballet and opera seasons in London, Paris, Berlin, America and elsewhere. One of his most successful operatic productions was that of Moussorgsky's *Khovanshtchina.* In England the originality of his conceptions may be said to have effected a revolution in choreographic art, and further put new life into stage dancing, which by the end of the 19th century had degenerated into a spectacular show of little artistic significance. Among his numerous successful ballets may be mentioned: *Carnaval* (music by Schumann), *Scheherazade* (music by Rimsky-Korsakov), *Petrouschka* (music by Stravinsky), *La Boutique Fantasque* (music by Rossini) and *The Three Cornered Hat* (music by de Falla)—to name but a few of a very large number. In 1904 M. Diaghilev produced a valuable book on the painter Levitsky. A collection of photographs and drawings illustrating the ballet, *Les Biches,* was published in 1924 by B. Koshno. *(See* also **BALLET.**) He died at Lido, Aug. 19, 1929.

DIAGNOSIS, or the process of identifying the disease by consideration of the history (*anamnesis*), symptoms, physical signs and examination in every way of the patient, includes differential diagnosis or its distinction from other diseases.

Importance in Treatment.—Diagnosis is essential for rational treatment, for without a knowledge of its cause treatment of a morbid symptom is merely empirical or, as it is often called, symptomatic, and, if beneficial, is so for the time being only and is not curative. The ideal of diagnosis is the discovery, as early as possible, of the disturbing factor at work, so that it may be removed or neutralized before structural damage results. In most diseases symptoms precede the signs or evidence of organic change in the body; but correlation of the earlier symptoms with the later physical signs indicating the presence of structural change has made it possible to predict the nature, course and proper treatment of the disease. This knowledge is more advanced in acute than in chronic diseases, in which the processes are less obvious and may be more complicated. It is therefore important to study the earliest manifestations of disordered function and by keeping the patient under observation to collect data for the recognition of the beginnings of chronic disease. This was one of the objects of the clinic at St. Andrews, inspired and opened by the late Sir James Mackenzie in 1919. Diagnosis is a logical process based on all the available data and is the outcome of their analysis in the light of knowledge gained by experience; diagnosis therefore leads to prognosis.

Methods and Symptoms.—Diagnostic methods include investigation of the patient's past history and of his environmental conditions, of the symptoms of which he complains, and methodical examination of the patient and of his organs and of the manner in which they are performing their functions. This examination is physical and physiological; an example of the physical signs is a tumour which can be felt; the physiological method is seen in the estimation of the functional efficiency of the heart or nervous system by means of exercises or special tests. Physical examination detects gross organic changes; functional tests reveal the disordered action of the organs, which is present in the earlier stage of symptoms without physical signs, mainly before structural damage has been produced. But it must be

admitted that the sequence of symptoms first and bodily changes with physical signs later is not invariable; for a slow change in the organs or tissues of the body may be accompanied by compensatory processes so complete as to prevent any functional impairment; thus an innocent tumour may grow to considerable size before it produces any symptoms, which may then be mechanical. A patient's past history is important not only as regards bodily illnesses, but with reference to mental experiences, which having become subconscious memories may be responsible for neurosis; Freud and his followers, by psycho-analysis (*q.v.*), have brought the trauma buried in the subconscious into the field of consciousness when other psychotherapeutic means can be employed.

Use of Physical Signs.—Physical signs, in contradistinction to subjective symptoms of which the patient complains, are observed by the medical man. First, inspection in a good light may give a shrewd idea of what is the matter—for example severe anaemia, the pigmentation of Addison's disease, the cachexia of advanced malignant disease, the bony changes in acromegaly, the swollen features of myxoedema and cretinism and the shrivelled, sharp-featured countenance of acute peritonitis (*facies Hippocratica*). Facial diagnosis without further examination is not without its fallacies, but an experienced practitioner may possess "clinical instinct" which, without a conscious logical process, at once tells him what is the matter, and is probably due to recognition by the subconscious mind of a similar condition seen years before but forgotten. The use of vision in diagnosis has been greatly extended in recent years. The ophthalmoscope, invented by Charles Babbage (1792–1871) and modified by Helmholtz, enables the retina at the back of the eye, which is an expansion of the brain, to be seen in all its details, similarly the laryngoscope, and more recently the bronchoscope, oesophagoscope, sigmoidoscope, endoscope for lighting up and bringing before the observer's eye the interior of the bronchial tubes, the gullet, the lower part of the bowel, and of the urinary bladder, have greatly facilitated the detection of disease in these situations. Endoscopes have also been introduced into the chest (thoracoscopy) and into the abdomen (laparoscopy or coelioscopy).

Skiagraphy.—Skiagraphy or examination of the body by X-rays (see ANATOMY; RÖNTGEN RAYS) has revolutionized diagnosis by rendering the greater part of the body translucent while the bony skeleton and certain abnormal formations remain opaque; X-rays provide a photograph or skiagram of great use in diagnosis; thus fractures can be shown, and similarly tumours, foreign bodies, certain morbid conditions, such as abscesses and collections of fluid, stones in the kidney and bismuth when introduced into the alimentary canal appear dark, while the surrounding parts are light. In this way malignant disease, aneurysms, tuberculosis and other diseases of the lungs, and the condition of the alimentary canal can be recognized. Further by introducing air into the abdomen the picture produced is rendered much clearer; recently the ingestion of dyes (tetraiodophenolphthalein or tetrabromphenolphthalein) which are excreted into the bile have been found to show up the gall bladder (cholecystography).

Use of Instruments of Precision.—The well-established and obvious method of palpation or examination of the body by the hand has been greatly supplemented by the introduction of instruments of precision which record the movements of the heart, arteries and muscles; graphic records of the pulse by the polygraph, of blood pressure by the sphygmomanometer and of the heart by the electrocardiograph have added accuracy to the unaided but trained senses. The various forms of cardiac irregularity have thus become clearly unravelled, and fresh information about the condition of the heart muscle and its beats, such as the *pulsus alternans* and auricular fibrillation, has been secured. The electrocardiograph requires special technical skill (see HEART, DISEASES OF THE); but when once the existence of the underlying condition has been definitely established in diseases also accompanied by more obvious manifestations, the presence of the latter has now become sufficient to justify a diagnosis of the primary cause, and so to indicate its prognosis and appropriate treatment. This simplification of diagnosis by associated phenomena will, it is to be hoped, follow in many diseases, in which the full explanation can originally be provided only by laboratory methods too elaborate for ordinary practice.

Laboratory Tests.—These methods of physical diagnosis are clinical and have been increasingly supplemented by tests adopted from those carried out in laboratories. The distinction between the clinical and laboratory methods of diagnosis is one of degree, for some, such as the counting of blood corpuscles and the detection of various animal parasites, do not require the help of a specialized laboratory: hence clinical laboratories have now become an essential part of the equipment of a modern hospital or clinic. But other valuable tests are not possible in less favourable circumstances. The chemical examination of the blood for its content or' sugar and non-protein nitrogen has an invaluable bearing on diabetes and renal disease; the examination of the blood for antibodies has enabled the diagnosis of infectious diseases to be made when ordinary clinical methods fail, for example the Wassermann reaction in the detection of syphilis, and the Widal (also a complement-fixation) test in the diagnosis of enteric fever. Bacteriological examination of discharges and excretions, such as swabs from the throat in diphtheria, of the expectoration in pulmonary consumption, of the urine and of the blood, of the cerebrospinal fluid and of the faecal excreta, has enormously advanced the exact diagnosis of infectious diseases. Thus to take an example, diseases which formerly were sometimes with difficulty distinguished by clinical examination (enteric fever, generalized tuberculosis, malaria and malignant endocarditis) can now be identified readily by examination of the blood. Chemical investigation of, and examination of the cells in, the blood, the fluids already mentioned and especially of the gastric juice by the method of fractional test meals have also rendered eminent service in the diagnosis of many diseases.

Immunity **Tests.**—Immunology (see IMMUNITY) or the science of the reactions given by persons who are immune or susceptible to certain infections or poisons has made it possible to say whether a person is liable to contract certain infections; thus by the Widal complement-fixation test to determine whether or not an individual is protected against enteric fever, by the Schick test, against diphtheria and by the Dick test against scarlet fever. In the two Iatter the diphtheria toxin or the scarlatina1 haemolytic streptococcus toxin is injected between the layers of the skin; a local reaction shows that the individual is susceptible to the disease, against which he can then be protected by injections into his muscles of the corresponding toxin. This protective diagnosis will no doubt become more general in application.

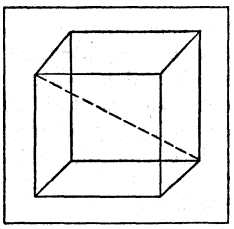
Individual Idiosyncrasies.—The exact cause of idiosyncrasies to certain foods, for example eggs, or to animal or vegetable substances, such as hair, feathers and pollen, can be determined by rubbing on the abraded skin extracts of substances likely to be the exciting cause of one of the "toxic idiopathies," such as asthma or nettlerash. If an individual suspected to be hypersensitive to, say, the dandruff of horses, is thus tested with such an extract, the appearance at the point inoculated of a red area or wheal, much larger and more prominent than that produced on a control area of skin similarly treated, except that saline solution is applied, strongly suggests that the disorder, such as asthma, is due to hypersensitiveness to this particular foreign protein.

General Disease.—General ill-health (dis-ease, want of ease), often of a vague character as shown by undue fatigue, but sometimes severe and prominent, such as pernicious anaemia or ulcerative endocarditis, and also local affections, such as arthritis, are commonly due to some primary condition often in a distant part of the body, such as disease of the tonsils, in connection with the teeth, the gall bladder or the vermiform appendix. The symptoms are frequently, especiaily in the examples first mentioned, due to some local infection providing micro-organisms or their poisons only, which when carried to other parts of the body, *e* g., the central nervous system, the blood-forming organs, the heart or the joints, set up changes and attract attention, while

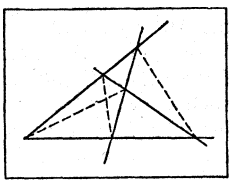
the fons *et origo* remains latent. In such cases, and they are numerous, of secondary disease, search for the primary infective focus is the scientific method of diagnosis, and may require expert advice from the laryngologist, dentist, the radiologist or other specialists. In other instances the primary cause sets up, through the nervous system, symptoms often in a comparatively remote part, which are described as due to disordered reflex action; just as a decayed tooth may cause headache, a blow on the ulnar nerve at the elbow (the "funny bone") tingling and pain in the little finger, so may a stone in the kidney show itself by pain in the testicle on the same side, or a chronically inflamed appendix or gall bladder be responsible for dyspepsia.

Conclusions. — The foregoing examples show that with the advance and necessary specialization of medicine diagnosis may make demands which no one man can efficiently meet, and that in certain cases a satisfactory solution can be obtained only after examination and report by specialists. He is a wise man who knows enough to recognize his limitations and to call for such assistance, whereas the converse course leads to the empirical treatment of symptoms, the continued discomfort and dependence, if nothing worse, of the patient and eventually perhaps to the doctor's discredit. Recognizing this, hospitals have long carried out the combined diagnostic method, and more recently, especially in America, groups of doctors, each proficient in some branch of the healing art, have amalgamated to form "diagnostic clinics" and to practise "group medicine."

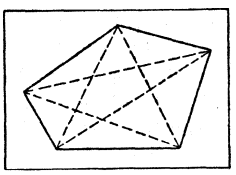
(H. R.)



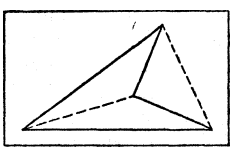
DIAGONAL OF CUBE



DIAGONALS OF A COMPLETE QUADRILATERAL



DIAGONALS OF A PENTAGON



DIAGONALS OF A RE-ENTRANT QUADRILATERAL

DIAGONAL, in geometry, a line joining the intersections of two pairs of sides of a rectilinear figure (Gr. διά, through, γωνία, a corner).

DIAGORAS, of Melos, surnamed the Atheist, poet and sophist, flourished in the second half of the 5th century B.C. Religious in his youth and a writer of hymns and dithyrambs, he became an atheist because a great wrong done to him was left unpunished by the gods. In consequence of his blasphemous speeches, and especially his criticism of the Mysteries, he was condemned to death at Athens, and a price set upon his head (Aristoph. *Clouds*, 830; *Birds*, 1,073 and Schol.). He fled to Corinth, where he is said to have died. His work on the Mysteries was called Φρύγιοι λόγοι or Ἀποπυργίζοντες, in which he probably attacked the Phrygian divinities.

DIAGRAM, a figure drawn so that geometrical relations among its parts illustrate relations among the objects represented by the figure, supplemented sometimes by numerical or other entries on the figure itself to show relations not represented graphically by the figure. The purpose of a diagram is to present vividly to the eye the principal relations on which one desires to fix attention and even sometimes to show, by measurements on the figure, the exact numerical values of certain important quantities associated with the object which it represents. Owing to the generality of the concept, diagrams are useful for a great variety of specific purposes.

Mathematical Diagrams. — In mathematical treatises diagrams are used principally to help the reader follow the reasoning. Figures are drawn to represent to the eye the relations among the parts involved in a proposition to be proved and in the auxiliary propositions employed in the demonstration. In the proof itself attention is fixed upon the relations which are relevant to the matter in hand so that the demonstration is made general and is quite independent of the extraneous properties involved in the form of the particular figure employed. The construction of the figure is usually so well defined in words that the reader could easily draw one for himself if the author did not supply it. Such a diagram is a good one if it sets forth clearly those features which are involved in the proposition to be demonstrated.

Diagrams in Chemistry and Crystallography. — John Dalton (*q.v.*) published many diagrams setting forth his conception of the configurations of the atoms in a large number of common chemical compounds; and the method has since been widely used by chemists. With the advance of chemistry it has been found that there are many pairs of substances such that the two substances in a given pair have the same molecular formula while they differ widely in some of their important properties. This difference of properties, where there is identity of molecular formulae and where we are forced to admit the same atomic linking, can be explained only by ascribing the difference to a different space distribution of the atoms in the molecule. This has given rise to the development of a branch of chemistry dealing with stereo-isomerism, a subject in which the space diagrams of the positions of atoms play an important rôle in the explanation of structure. Similarly, in crystallography (*q.v.*) diagrams are likewise employed freely in the explanation of crystal structure. In recent years we have had a like analysis of atomic structure itself by means of diagrams.

Diagrams Showing Measurements. — In a quite different way, diagrams may be used for purposes of measurement; they are then called *metrical diagrams.* The plans and designs of architects and engineers, necessarily drawn to scale and made as accurate as possible, are employed in determining various dimensions of the objects represented, by measuring the lengths of corresponding lines in the diagrams. Such diagrams serve a purpose far beyond that of mere illustration; they afford a means of actual measurements relating to the objects themselves. They are strongly contrasted with diagrams of illustration, which are suggestive merely and need not show the forms of the parts provided only their relevant connections are properly exhibited. Of the latter kind are many diagrams in the mathematical subject of analysis situs (*q.v.*) and also those employed to show electrical connections, as, for instance, in the descriptions of radio receivers

Geographical maps afford examples of diagrams of still another sort. In these the distances and relative positions among places on the earth are exhibited by their positions on the maps. By means of colours important features of various areas are often indicated, as, for instance, their political connections, or their geological character, or the distribution of rainfall or other climatic features, or the distribution of terrestrial magnetism, or the variation of elevation above sea level. The heights of places above sea level are often indicated also by the insertion of numbers on the map to indicate the number of feet above sea level of each place so designated. Another (and more effective) method of serving the same purpose is that in which a line called a contour line is drawn through all places on the map having the same height above sea level. When such contour lines are drawn sufficiently close together and when each of them is marked in one or more places with a number to denote the height above sea level of the places through which it passes, we may obtain from them precise information concerning the character of the surface of the country. In this method the diagram is partly graphical and partly symbolic, and some things are presented by the contour lines and accompanying numbers which are not shown by the relations among the parts of the diagram itself.

Diagrams for Objects Having Three Dimensions. — It is possible to use a system of diagrams for the graphical representation of the relations among any set of magnitudes involving more than two variables. In particular, to represent the relations among the parts of an object having a distribution in three dimensions we may employ two or more diagrams, each of them showing the relations of parts in a single plane or plane section of the object. Thus construction engineers employ plans and elevations and sections in diifferent planes. In such a system of diagrams a definite indication must be given of the way in which the diagrams are severally related to the structure as a whole and to each other. Examples of this type are afforded by the plans for buildings or

for bridge construction. (*See* BRIDGES and ARCHITECTURE.)

But it is also possible to represent solids and other figures in three dimensions by means of a single diagram drawn in a plane. One of the objects of descriptive geometry (*q.v.*) is to develop methods for attaining this end.

The stereoscope (*q.v.*) furnishes a means for the use of two diagrams for the representation of three-dimensional objects in such a way that their forms are readily recognized. The two diagrams are two plane projections of the bodies taken from separated points of view which are yet near to each other. These two plane figures are nearly alike, their difference being due to the difference in point of view. When these two figures are placed in the stereoscope one of them is seen with one eye and the other with the other eye, in such a way that we intuitively identify the corresponding parts of the two figures. In pure geometry the method of projections, which underlies the diagrams used in the stereoscope, has led to many extensions of the science. In fact, on it are founded the principles and results of projective geometry (*q.v.*).

Diagrams in Mechanics. — It is probably in mechanics (*q.v.*), both theoretical and applied, that diagrams have been used for the greatest variety of specific purposes. Their application to statics is particularly convenient, owing to the fact that there is no motion of parts in a statical system. Consequently there has arisen an important branch of knowledge under the name of Graphic Statics. In the *diagram of configuration* it is convenient to represent the objects by points and to denote their relative positions by means of the relative positions of these points. This method is also applicable to the case of bodies in motion, the diagram of configuration then representing the relative positions of the objects at a given instant. If several diagrams of configuration are constructed, one for each of several given instants of time, then, by a comparison of these diagrams, it is possible to see the relative displacements which have taken place in the various intervals of time involved; but the system of configurations will not give the details of the motion during the interval between two consecutive instants for which diagrams of configuration have been constructed.

As an example of a different kind, let us consider the diagram in fig. 1. This is a parallelogram formed from two directed lines *AB* and *AC*, issuing from a common point *A*, by drawing the related lines *CD* and *BD*. Attention is also placed on the directed diagonal *AD* issuing from *A*. We may use *AB* to denote a force applied to an object at *A*, the direction of *AB* representing the direction in which the force acts and the length of *AB* denoting the magnitude of the force. Similarly, *AC* will denote, in magnitude and direction, another force operating upon the same object at *A*. In mechanics it is shown that these two forces operating upon the body at *A* are equivalent, so far as their effect upon *A* is concerned, to a single force operating in the direction of the diagonal *AD* and of a magnitude represented by the length of *AD*. Thus a simple diagram enables us readily to find the (so-called) resultant force *AD* which is equivalent to the two given forces *AB* and *AC*.

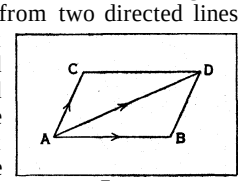


FIG. 1

Now *BD* is equivalent, in direction and length, to *AC*. Hence we might think of the resultant force *AD* as the third side of the triangle determined by the given forces *AB* and *BD*, where it is understood that the force represented by *BD* operates at *A*. Then we may call *ABD* the *triangle of forces*, whereas *ABDC* would be called the *parallelogram of forces*. Now the triangle of forces is capable of a ready generalization, which we shall describe by aid of fig. 2. Let several forces all operate upon an object at *A;* and let the magnitudes and directions of these forces be respectively those which are indicated by the directed lines *AB, BC, CD, DE*, placed end to end as in the figure. (These lines may or may not be in one plane.) Then *AE* will represent, both in magnitude and direction, a single force which is equivalent, in its effect upon the object at *A*, to the combined effects of the several forces denoted by *AB, BC, CD* and *DE*, respectively. This figure *ABCDE* is called a *polygon of forces*. If there is added to the system of given forces already described a single force *EA* acting upon *A* but having the direction and magnitude denoted by EA, then the new system of forces will be in equilibrium in the sense that their combined effect upon the object *A* will be to leave that object undisturbed in position. The diagram afforded by the polygon of forces furnishes one of the most important means in mechanics for the analysis of the relations of forces.

Now the meaning of a diagram depends upon the point of view from which one considers it. This is well illustrated by the diagrams afforded by figs. 1 and 2, as we shall now show by giving interpretations of them in terms of velocities and accelerations. If *AB* and *AC* in fig. 1 denote velocities, both in magnitude and in direction, then *AD* denotes the resultant velocity. Thus if *AB* denotes the velocity of a ship relative to the earth and if *AC* denotes the velocity with which one is walking relative to the deck of the ship, then *AD* will represent, both in magnitude and in direction, the velocity of the walker relative to the earth. The combination, or *composition*, of several velocities is represented in a similar way by the polygon in fig. 2. Again, if *AB* and *AC* in fig. 1 denote accelerations, then *AD* denotes the resultant acceleration which is equivalent to a combination of the two given accelerations; and this may of course be extended to the case of the polygon of accelerations. These diagrams afford one of the most important means for the investigation of velocities and accelerations.

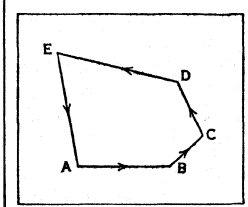

FIG. 2

Work and the Indicator Diagram. — If *AB*, in fig. 3, represents the path of a moving body and if for each position P of that body the force acting upon it, in the line of motion and opposed to its motion, is represented in any convenient scale by the length of the perpendicular PO from *AB* to the curve *COD*, then the area of the figure *ABDC* represents (in a corresponding scale) the work required to be done upon the moving body during its motion from *A* to *B*.

If the piston of an engine is moving back and forth along the line *AB* in fig. 4 and if the area *ABDEC* represents the work done on the piston in moving from *A* to *B* while the area *ABDFC* represents the work done by the piston against retarding forces on its return stroke, then the area *CFDEC* will represent the effective work which may be accomplished by the piston thrust in a single back and forth motion. The figure by means of which this effective work done by the piston is shown is known as the *indicator diagram* of the motion of the piston. It is of fundamental importance in analysing the effective working capacity of the engine.

Other Diagrams. — Brief definitions of various other diagrams will now be given. In an *Argand diagram* the complex numbers $x+yi$ are represented by corresponding points (x, y) with reference to a system of rectangular co-ordinates in a plane. An *automatic diagram* is one which is constructed automatically by a machine to show the related variations of two variables, as, for instance, the change of temperature with time during the day; in these cases the completed diagram often consists of a graph drawn automatically upon specially prepared co-ordinate paper. In many cases of this sort a piece of paper is made to move (uniformly or otherwise) in a given direction, let us say horizontally, while a tracing pencil point is made to move vertically across it, the height of the tracing point varying proportionately to the magnitude of the quantity whose variation is to be registered. Machines of this sort are employed for the automatic registration of phenomena of many kinds, from those in meteorology and the theory of magnetism and electricity to those connected with the movements of plants and animals.

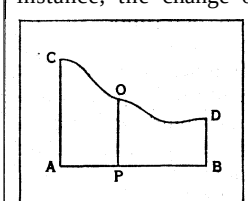

FIG. 3

An *entropy diagram* shows the change of entropy in a thermodynamic cycle. *Euler's diagram* gives a graphic representation of logical relations, circles or other figures being used to denote (by their enclosed surfaces) the classes of objects to which given pred-

icates apply; many other logical relations have also been denoted by various diagrams. In a *frame diagram* the positions of joints are shown by points and the connecting links by lines; it is often united with a diagram of forces showing the components of force through the various joints. *Hertz's diagram* represents the changes of temperature, pressure and moisture of a given mass of air when its volume is changing adiabatically; and *Neuhoff's diagram* is analogous to it. In *Newton's diagranz* colours are represented by points, with weights attached to them to denote intensities of luminosity, while the arrangement of points is such that those which are on the same straight line can be produced by the mixtures of two colours. The *Puiseux diagram* is a certain collocation of points employed in mathematics in the study of functions. In two *reciprocal diagrams* each point of junction of lines in either diagram corresponds to a closed polygon in the other.

A strain diagram is a figure which shows the relation between the amount of stress applied by pressure or otherwise to a test piece of material and the strains which it undergoes on account of this stress. It is usually drawn automatically by means of an instrument attached to the machine and the piece being tested, the deformations being amplified by aid of a suitable mechanism. A *stress diagram* is a figure in which each joint of a framework is represented by a funicular polygon (such a figure as is formed by a string supported at the ends and acted on by several pressures), while each link in the frame is represented by a line belonging to one or more of the funicular polygons; it is also called a *funicular diagram. A variation diagranz* sets forth the changes in the indicator diagram of an engine for successive strokes of the piston; it is used to determine whether the governor is acting properly. The word *diagram* is also used in numerous other combinations many of which are self-explanatory.

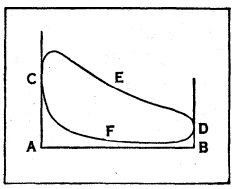

FIG. 4

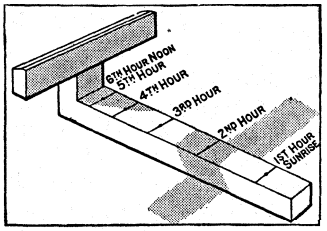
Diagrams appear in literature mainly as incidental to the subjects in connection with which they are employed, as has been indicated in the course of the article. Consequently the bibliographies are to be found by consulting the articles dealing with these subjects. (R. D. CA.)

DIALA, the largest tributary of the Tigris rises in the Persian highlands near Merivan and, for a short distance south of Haleboja, forms the Perso-Iraq frontier. It joins the Tigris just south of Baghdad. After leaving the Jebel Hamrin the river runs over shingle deposits and is extensively used for irrigation. The principal canals are the Beled Ruz and the Khorassan on the left bank and the Khalis and its branches on the right. Baquba lies at the end of the Khorassan canal, 52 miles from the mouth. This region is extremely fruitful and the river is navigable as far as this point from December to April. The metre gauge railway operating from Baghdad to Kirkuk runs along the valley of the Diala and offers a further outlet for the development of this well watered region.

DIAL and **DIALLING.** Dialling, sometimes called gnomonic~treats of the construction of sundials, that is, of those instruments, either fixed or portable, which determine the divisions of the day (Lat. *dies)* by the motion of the shadow of some object on which the sun's rays fall. It must have been one of the earliest applications of a knowledge of the apparent motion of the sun; though for a long time men would probably be satisfied with the division into morning and afternoon as marked by sun-rise, sun-set and the greatest elevation.

History. — The earliest mention of a sundial has been thought to be found in Isaiah xxxviii. 8: "Behold, I will bring again the shadow of the degrees, which is gone down in the *sundial* of Ahaz, ten degrees backward." But a more correct translation may be "down the *steps* of Ahaz, 10 steps backwards." The date of this would be about 700 years before the Christian era, but there is no evidence that there was a sundial. The earliest of all sundials of which we have any certain knowledge is a ⌐-shaped Egyptian dial in the Berlin museum, in which the upright of the ⌐ throws longer or shorter shadows along the horizontal limb which is divided into six hours. Another early classical type was the hemicycle, or hemisphere, of the Chaldean astronomer Berosus, who probably lived about 300 B.C. It consisted of a hollow hemisphere placed with its rim perfectly horizontal, and having a style, the point of which was at the centre. So long as the sun remained above the horizon the shadow of the point would fall on the inside of the hemisphere, and the path of the shadow during the day would be approximately a circular arc. This arc, divided into 12 equal parts, determined 12 equal intervals of time for that day. Now, supposing this were done at the time of the solstices and equinoxes, and on as many intermediate days as might be considered sufficient, and then curve lines drawn through the corresponding points of division of the different arcs, the shadow of the bead falling on one of these curve lines would mark a division of time for that day, and thus we should have a sundial which would divide each period of daylight into 12 equal parts. These equal parts were called *temporary hours;* and, since the duration of daylight varies from day to day, the temporary hours of one day would differ from those of another; but this inequality would probably be disregarded at that time, and especially in countries where the variation between the longest summer day and the shortest winter day is much less than in our climate.



AFTER A RESTORATION BY BREASTED FROM ORIGINAL IN BERLIN MUSEUM

FIG. 1.— EARLY EGYPTIAN SUNDIAL OF PERIOD OF THOTHMES III., *c.* 1500 B.C.

In the morning the crosspiece was turned to the east. and in the afternoon to the west

The dial of Berosus remained in use for centuries. The Arabians, as appears from the work of Albategnius, still followed the same construction about the year A.D. 900.

Herodotus recorded that the Greeks derived from the Babylonians the use of the gnomon, but the great progress made by the Greeks in geometry enabled them in later times to construct dials of great complexity and ingenuity. Ptolemy's *Almagest* treats of the construction of dials by means of his *analemma,* an instrument which solved a variety of astronomical problems. The constructions given by him were sufficient for regular dials, that is, horizontal dials or vertical dials facing east, west, north, or south, and these are the only ones he treats of. It is certain, however, that the ancients were able to construct declining dials, as is shown by that most interesting monument of ancient gnomics — the Tower of the Winds at Athens. This is a regular

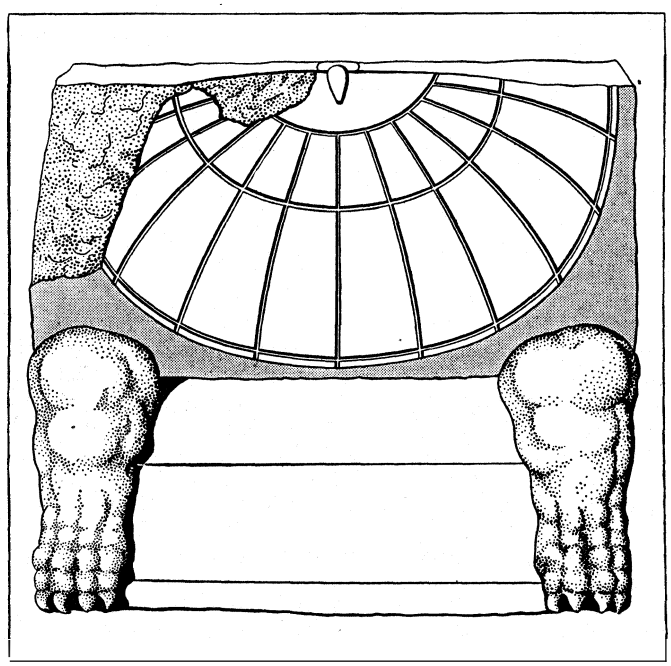


FIG. 2.— HEMICYCLIC DIAL. FOUND IN POMPEII IN 1854

octagon, on the faces of which the eight principal winds are represented, and over them eight different dials—four facing the cardinal points and the other four facing the intermediate directions. The date of the dials is apparently coeval with that of the tower; for there has been found at Tenos a marble block with similar dials inscribed with the name of Andronicus Kyrrhestes, the builder of the tower. The hours are still the temporary hours or *hectemoria.*

The first sundial erected at Rome was in the year 290 B.C., and this Papirius Cursor had taken from the Samnites; but the

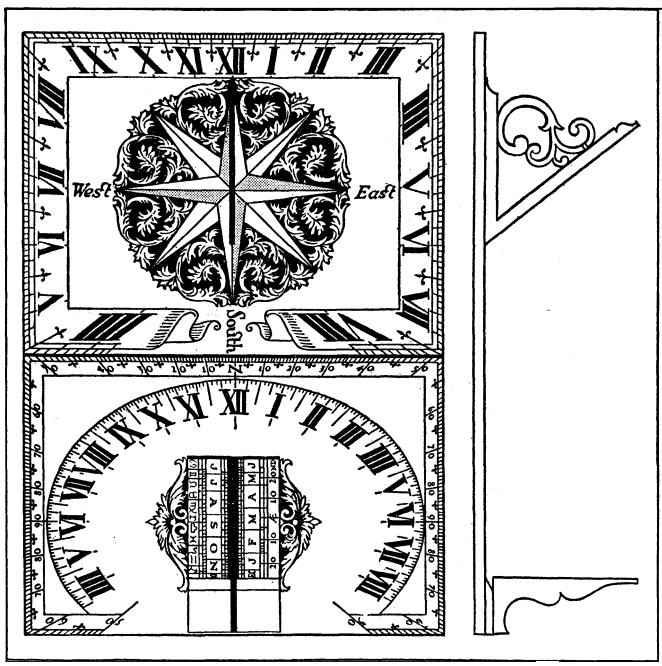

FIG. 3.— PORTABLE ANALEMMATIC SUNDIAL OF THE 16TH CENTURY
This consists of two dials. When they have been so adjusted that the two readings agree, the correct time is indicated

first dial actually constructed for Rome was made in 164 B.C., by order of Q. Marcius Philippus. Vitruvius mentions 13 kinds of dials, including portable dials, the most interesting examples of which are the "Ham" dial, excavated at Herculaneum and the adjustable circular dial in the Lewis Evans collection at Oxford.

The Arabians were much more successful. They attached great importance to gnomonics, the principles of which they had learned from the Greeks; but they greatly simplified and diversified the Greek constructions. One of their writers, Abu'l Hassan, who lived about the beginning of the 13th century, taught them how to trace dials on cylindrical, conical, and other surfaces. He even introduced *equal* or *equinoctial hours* which were used for astronomical purposes while the temporary hours alone continued in use.

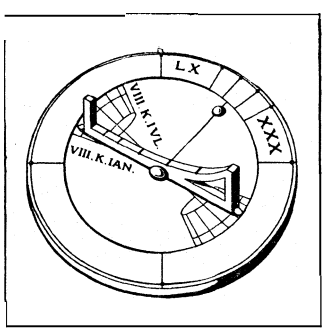

FIG. 4.— ROMAN PORTABLE DIAL
Portable dials were generally of pocket size. The one above dates from about A.D. 250 and has adjustments for the seasons and for latitude from 30° to 60°

The great and important step already conceived by Abu'l Hassan, and perhaps by others, of reckoning by *equal* hours, was probably adopted between the 13th to the beginning of the 16th century. The change would necessarily follow the introduction of striking clocks in the earlier part of the fourteenth century; for, however imperfect these were, the hours they marked would be of the same length in summer and in winter, and the discrepancy between these equal hours and the temporary hours of the sundial would soon be too important to be overlooked. Now, we know that a striking clock was put up in Milan in 1336, and we may reasonably suppose that the new sundials came into general use during the 14th and 15th centuries.

Among the earliest of the modern writers on gnomonics was Sebastian Miinster (*q.v.*), who published his *Horologiographia* at Basle in 1531. He gives a number of correct rules, but without demonstrations. Among his inventions was a moon-dial. A dial

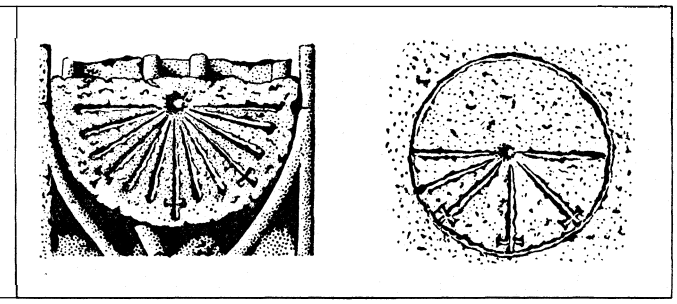

FIG. 5.— EARLY SUNDIALS WITH TIDE-LINES (LINES WITH CROSSES) MARKING THE FOUR "TIDES" INTO WHICH THE SAXONS DIVIDED THEIR DAY
Left: Earliest English Sundial, Bewcastle Cross. Right: Saxon Sundial at Daglingworth, Gloucestershire

adapted for use as a moon-dial when the moon's age is known, may be seen in Queens' college, Cambridge.

During the 17th century dialling was a special branch of education. The great work of Clavius, a quarto volume of 800 pages, was published in 1612, and may be considered to contain all that was known at that time.

In the 18th century clocks and watches began to supersede sundials, and the latter gradually fell into disuse, except dials in a garden or in remote country districts, where the old dial on the

FIG. 6.— DRAKE'S PORTABLE DIAL BY HUMPHREY COLE. A.D. 1569
The Equatorial Dial is set for latitude by the quadrant, and in the meridian by the magnetic compass. The instrument includes a tide-table, a nocturnal, a diagram of planetary aspects, and a circumferentor

church tower still serves as an occasional check on the modern clock by its side.

General Principles.— The daily and the annual motions of the earth are the elementary astronomical facts on which dialling is founded. That the earth turns upon its axis uniformly from west to east in 24 hours and that it is carried round the sun in one year at a nearly uniform rate is the correct way of expressing these facts. But the effect will be precisely the same, and it will suit our purpose better and make our explanations easier, if we adopt the ideas of the ancients, of which our senses furnish apparent confirmation, and assume the earth to be fixed Then, the sun and

stars revolve round the earth's axis uniformly from east to west once a day—the sun lagging a little behind the stars, making its day some four minutes longer—so that at the end of the year it finds itself again in the same place, having made a complete revolution of the heavens relatively to the stars from west to east.

The fixed axis about which all these bodies revolve daily is a line through the earth's centre; but the radius of the earth is so small, compared with the enormous distance of the sun, that, if we draw a parallel axis through any point of the earth's surface, we may safely look on that as being the axis of the celestial motion. The error in the case of the sun would not, at its maximum, that is, at 6 A.M. and 6 P.M., exceed half a second of time, and at noon would vanish. An axis so drawn is in the plane of the meridian, it points to the pole, and its elevation is equal to the latitude of the place.

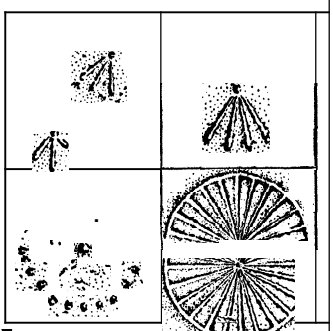

FIG. 7.—SCRATCH DIALS, COMMON UPON EARLY ENGLISH CHURCH WALLS

The diurnal motion of the stars is strictly uniform, and so would that of the sun be if the daily retardation of about four minutes, spoken of above, were always the same But this is constantly altering, so that the time, as measured by the sun's motion, and also consequently as measured by a sundial, does not move on at a strictly uniform pace. This irregularity, which is slight, would be of little consequence in the ordinary affairs of life, but clocks and watches being mechanical measures of time could not, except by extreme complication, be made to follow it.

A clock is constructed to mark uniform time in such wise that the length of the clock day shall be the average of all the solar days in the year. Four times a year the clock and the Sundial agree exactly; but the sundial, now going a little slower, now a little faster, will be sometimes behind, sometimes before the clock—the greatest accumulated difference being about 16 minutes for a few days in November. The four days on which the two agree are April 15, June 15, Sept. 1 and Dec. 24.

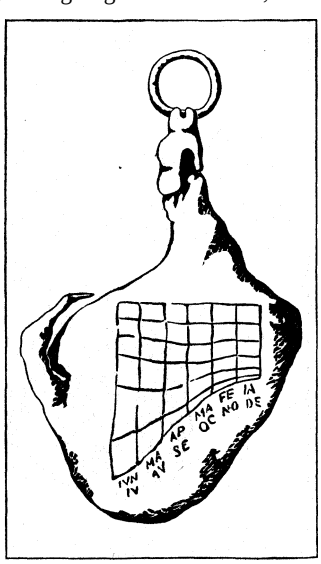

FIG. 8.— HAM DIAL, C. A.D. 50

The index on the left, having been brought over the vertical line of the appropriate month, casts a shadow on the oblique

Clock time is called mean time, that marked by the sundial is called apparent time, and the difference between them is the equation of *time.* It is given in most calendars and almanacs, frequently under the heading "clock slow," "clock fast." When the time by the sundial is known, the equation of time will at once enable us to obtain the corresponding clock time, or vice versa.

The general principles of dialling will now be readily understood. The problem before us is the following.--A rod, or *style,* as it is called, being firmly fixed in a direction parallel to the earth's axis, we have to find how and where hour-lines of reference must be traced on some fixed surface behind the style so that when the shadow of the style falls on a certain one of these lines we may know that at the moment it is solar noon—that is, that the plane through the style and through the sun then coincides with the meridian; again, that when the shadow reaches the next line of reference it is 1 o'clock by solar time, or, which comes to the same thing, that the above plane through the style and through the sun has just turned through the 24th part of a complete revolution; and so on for the subsequent hours, the hours before noon being indicated in a similar manner.

The position of an intended sundial having been selected, the surface must be prepared, if necessary, to receive the hour-lines. The style must be accurately fixed in the meridian plane, and must make an angle with the horizon equal to the latitude of the place. The latter condition will offer no difficulty, but the exact determination of the meridian plane which passes through the point where the style is fixed to the surface is not so simple.

The position of the XII o'clock line is the most important to determine accurately, since all the others are usually made to depend on this one. R e cannot trace it correctly on the dial until the style has been itself accurately fixed in its proper place. When that is done the XII o'clock line will be found by the intersection of the dial surface with the vertical plane which contains the style; and the most simple way of drawing it on the dial will be by suspending a plummet from some point of the style whence it may hang freely, and waiting until the shadows of both style and plumb-line coincide on the dial. This single shadow will be the XII o'clock line In one class of dials, namely, all the vertical ones, the XII o'clock line is simply the vertical line from the centre; it can, therefore, at once be traced on the dial face by using a fine plumbline. The XII o'clock line being traced, the easiest and most accurate method of tracing the other hour lines would, at the present day when good watches are common, be marking where the shadow of the style falls, when 1, 2, 3, etc., hours have elapsed since noon, and the next morning by the same means the forenoon hour lines could be traced; and in the same manner the hours might be subdivided into halves and quarters, or even into minutes. But formerly, when watches did not exist, the tracing of the I, II, III, etc., o'clock lines was done by calculating the angle each would make with the XII o'clock line.

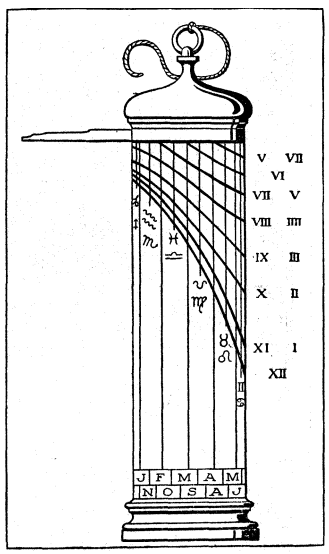

FIG 9.—CYLINDER OR SHEPHERD'S DIAL, A.D. 1531

The artist has shown all the months of the year on one side of the cylinder. In modern examples of the dial used in the Pyrénées, the lines for 6 months only would appear on one side

Dials received different names according to their position:—*Horizontal* dials, when traced on a horizontal plane; Vertical dials, when on a vertical plane facing one of the cardinal points; Vertical declining dials, when on a vertical plane not facing a cardinal point; Inclining dials, when traced on planes neither vertical nor horizontal (these were further distinguished as reclining when leaning backwards from an observer, *proclining* when leaning forwards); Equinoctial dials, when the plane is at right angles to the earth's axis, etc.

There are many early vertical south dials of great archaeological interest on the walls of English churches. The simplest of all are the Anglo-Saxon dials, in which the day is divided into four tides of three hours each. A good example may be seen at Daglingworth. In the dial on Bewcastle Cross of the 7th century, hour lines have been intercalated between the early tide lines, which are marked with crosses. Upon church walls of the Early English period Scratch dials or Mass dials of various types are often found. In their simplest form they consist of a few hour lines radiating from a central hole in which a wooden style would have been inserted. A vertical noon line is always present. Lines at right angles to it would have been for 6 A.M. and 6 P.M., and one half way between the former and the noon line would have been for 9 A.M. Occasionally a circle of holes takes the place of the hour lines

In the commonest type of horizontal dials the dial plate is of metal, as well as the vertical piece upon it, and they may be purchased ready for placing on the pedestal, the dial with all the

hour lines traced on it and the style plate firmly fastened in its proper position, or cast in the same piece with the dial plate.

When placing it on the pedestal care must be taken that the dial be perfectly horizontal and accurately oriented. The levelling will be done with a spirit level and the orientation will be best effected either in the forenoon or in the afternoon, by turning the dial plate till the time given by the shadow (making the small

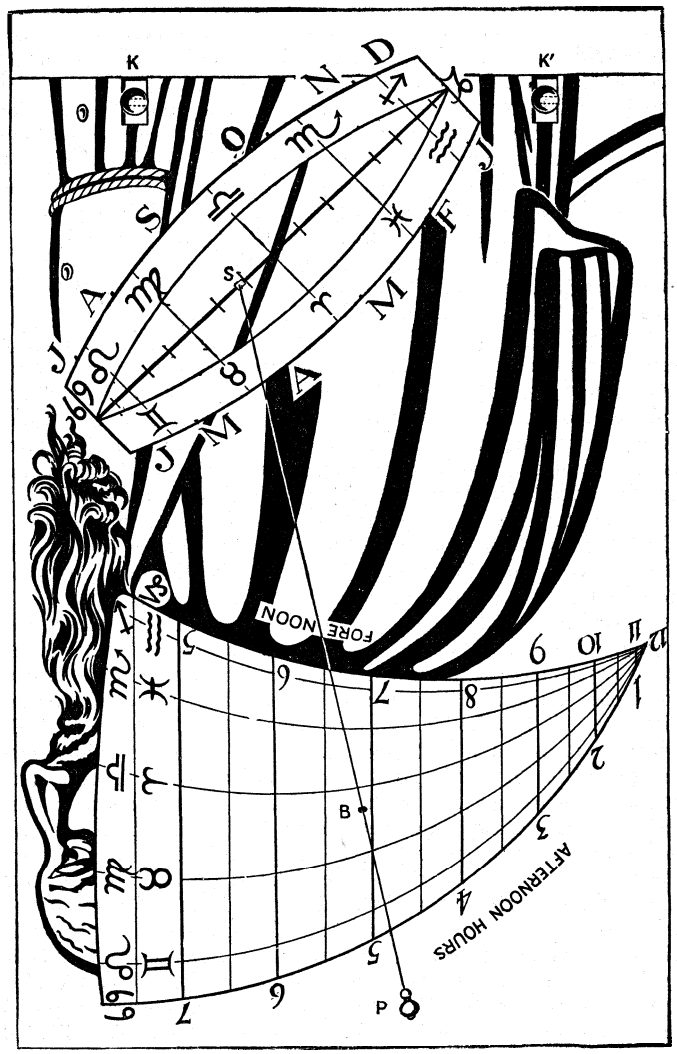

FIG. 10.—THE CAPUCHIN. A FLAT ALTITUDE DIAL OF THE 17TH CENTURY
In use, the end S. of the plumb line, SP, is moved along a slot to the day of the month, and the bead, B', is shifted to the hour 12. The sights, KK', at the upper edge, are then pointed at the sun, and the bead on the plumb line will show the hour. In Sir John Findlay's Collection

correction mentioned above) agrees with a good watch whose error on solar time is known. It is, however, important to bear in mind that a dial, so built up beforehand, will have the angle at the base equal to the latitude of some selected place, such as London, and the hour lines will be drawn in directions calculated for the same latitude. Such a dial, therefore, could not be used near Edinburgh or Glasgow, although, it would, without appreciable error, be adapted to any place whose latitude did not differ more than 20 or 30m. from that of London.

Portable Dials were made generally of a small size, so as to be carried in the pocket; and these, so long as the sun shone, answered the purpose of a watch. The description of the portable dial has often been mixed up with that of the fixed dial, as if it had been merely a special case, and the same principle had been the basis of both; but although some are like the fixed dials, with the addition of some means for orientating the dial, others depend on the *very irregularly* varying zenith distance of the sun.

Portable dials fall into two main classes: *Altitude Dials* and *Compass Dials*.

I. Altitude Dials find the time from the altitude of the sun, allowance being made for the season of the year. An early example was the Roman Ham dial excavated at Herculaneum under the Vesuvian muds of the eruption of A.D. 79. It is marked with the months of July and August and must therefore be more recent than 27 B.C. It was only serviceable in one latitude. A more useful type of altitude dial "for all climates," as Vitruvius describes it, is a Roman dial of about A.D. 250 in the Lewis Evans collection, which has adjustments both for the seasons and for latitude from 30° to 60°. Another form of altitude dial is known as the Shepherd's dial or Cylinder dial. The earliest description of them is by Hermannus Contractus (1013–1054), and they are still in use among the peasants in the Pyrénées.

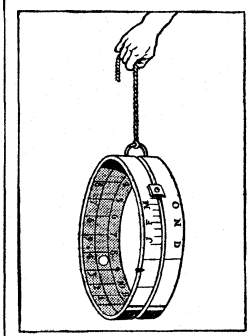

FIG. 11.—ENGLISH RING DIAL, WHICH ALLOWS FOR CORRECTIONS FOR DAYS OF THE YEAR AND FOR LATITUDE ADJUSTMENT

In this type there is a horizontal gnomon and the hour lines are curves of the length of the shadow of this gnomon on a vertical surface, according to the hour and season. These curves are drawn either on a cylinder or a flat surface. The seasons are represented by vertical lines, and the gnomon is moved to the appropriate line, the dial being so placed that the shadow falls perpendicularly and the hour read on the hour line.

A very neat and ingenious flat altitude dial on *a Card* is attributed by Ozanam to a Jesuit Father, De Saint Rigaud, but it dates from the time of Regiomontanus. It was sometimes called the capuchin, from some fancied resemblance to a cowl thrown back.

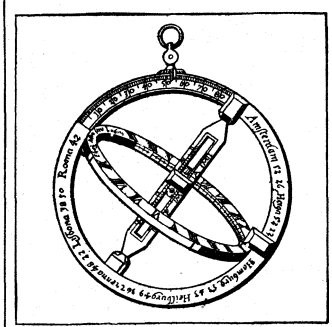

FIG. 12.—ASTRONOMICAL RING DIAL MADE BY ELIAS ALLEN
The outer ring shows approximate latitudes of Amsterdam, The Hague, Hamburg, Heilburg, Vienna. Lisbon and Rome

Other altitude dials are the Quadrant dials, Ring dials, and Universal Ring dials. The Ring dial consists of a ring of brass that can be suspended by a small loop. A second, sliding ring within the first is drilled with a conical hole, with its apex towards the inside. When the sun's rays pass through this hole they make a spot of light upon the opposite inner surface of the ring, which is divided by hour lines. The time can thus be read off. The sliding ring is for adjustment for the latitude of the place, and the hour lines run diagonally for correction for the season of the year.

In the Universal Astronomical Ring dial a metal ring represents the meridian, and is suspended by a small ring and shackle adjustable for latitude. Pivoted to the meridian ring, so that it will fold within it when not in use, is a second or equatorial ring, divided into the 24 hours. On the line of the polar axis is a flat metal plate with a longitudinal slot, in which slides a block with a pinhole in it. This being adjusted for the sun's declination by means of a scale on the plate, and the instrument suspended with its meridian circle in the meridian, the rays of the sun passing through the pinhole will fall on the hour of the equatorial circle.

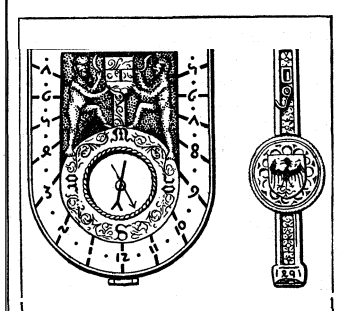

FIG. 13.—THE OLDEST KNOWN COMPASS DIAL. A.D. 1451
This was probably made at Nuremberg, and is now at Innsbruck

II. *Compass Dial;* made their appearance in the 15th century, some 150 years after the description of the magnetic compass by Peter Peregrinus. In their simplest form they consist merely of a horizontal dial and a compass; but to these numerous acces-

sories were added in rapid succession, the most important being an adjustment for change of latitude, a plummet for levelling, subsidiary vertical and other dials for showing the various kinds of hours in use, a wind rose, volvelles for showing the phases of the moon or for use as adjustable calendars. These and other devices exercised the ingenuity of the master craftsmen of Augsburg and Nuremberg, who vied with one another in the construction of a beautiful series of timepieces, which passed into all the countries of Europe. They were made of metal, wood, or ivory and the gnomons were either of metal or of a string that could be threaded through holes so as to vary the inclination with the latitude.

A second type of compass dial is the Equatorial dial, in which the plane of the dial is at right angles to the style and can be adjusted parallel to the equator. It is the- simplest of all- dials. A circle, divided into 24 equal arcs, is placed at right angles to the style, and hour divisions are marked upon it. Then, if care be taken that the style point accurately to the pole and that the noon division lies in the meridian plane, the shadow of the style will fall on the other divisions, each at its proper time. The divisions must be marked on both sides of the dial, because the sun will shine on opposite sides in the summer and in winter.

Equatorial dials were very widely used in the 17th and 18th centuries and were sometimes combined with geared clock movements, by which the hour and minute could be read on a clock face.

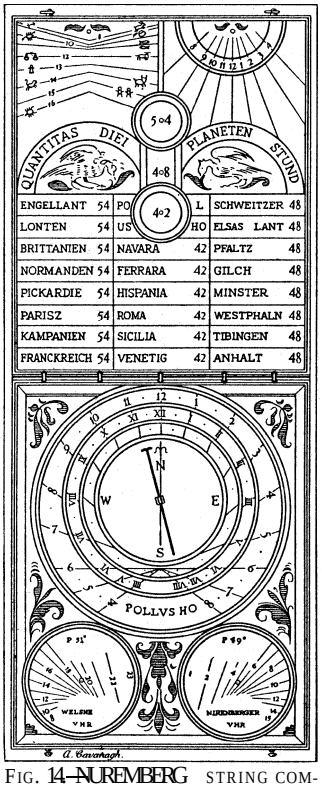

FIG. 14.—NUREMBERG STRING COMPASS DIAL, c. A.D. 1570

This was made in ivory by Hans Ducher. In the four corners are (1) Dial showing length of day. (2) Dial for "ancient" or "planetary" hours. (3) Dial for Italian hours for latitude 51°. (4) Dial for Babylonian hours for latitude 49°. The table of latitudes of towns is for setting the string gnomon of the compass dial

The Analemmatic Sundial differs from other portable sundials in that it can be set for finding the time without a compass. It includes two dials, an ordinary horizontal dial and an elliptical dial with a perpendicular gnomon which is set to the declination on a scale of months and days engraved along the minor axis of the ellipse. In use, the two styles cast two shadows on their respective hour scales. The instrument is then turned about until the two readings agree; when this happens the hour indicated is the correct time and the central line is true north and south.

Nocturnals were dials used for finding time by certain circumpolar stars.

BIBLIOGRAPHY.—The following list includes the principal writers on dialling whose works have come down to us, and to these we must refer for descriptions of the various constructions, some simple and direct, others fanciful and intricate, which have been at different times employed: Ptolemy, *Analemma,* restored by Commandine; Vitruvius, *Architecture;* Regiomontanus, *Calendarum Romanum;* Sebastian Miinster, *Horologiographia;* Orontius Fineus, *De horologiis solaribas;* Mutio Oddi da Urbino, *Horologi solari;* Dryander, *De horologiorum comporitione;* Conrad Gesner, *Pandectae;* Andrcas Schöner, *Gnomonicae; F.* Commandine, *Horologiorum descriptio;* Joan. Bapt. Benedictus, *De gnomonurn usu;* Georgius Schomberg, *Exegesis fundamentorum gnomonicorum;* Joan Solomon de Caus, *Horologes solaires;* Joan. Bapt. Trolta, *Praxis horologiorum;* Desargues, *Manière universelle pour poser l'essieu,* etc.; Ath. Kircher, *Ars magna lucis et Umbrae;* Hallum, *Explicatio horologii in horto regio Londini;* Joan. Mark, *Tractatus horologiorum;* Clavius. *Gnomonices de horologiis.* Also among more modern writers, Deschales, Ozanam, Schottus, Wolfius, Picard, Lahire, Walper; in German, Paterson, Michael, Miiller; in English, Foster, Wells, Collins, Leadbetter, Jones, Leybourn, Emerson, Ferguson, Evans and Sir J. Findlay. *See* also Gatty, *Book of Sundials* (enlarged, 1900); Horne, *Scratch Dials* (Taunton, 1917); Drecker, *Theorie der Sonnenuhren* and *Zeitmessung* (1925). (H. Go.; R. T. G.)

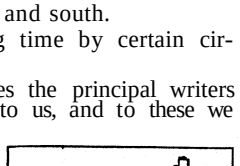

FIG. 15.—A NUREMBERG STRING COMPASS DIAL

DIALECT, a characteristic manner of speech, so any variety of a language (from Gr. **διάλεκτος,** conversation, manner of speaking). In its widest sense languages which are branches of a common or parent language are its "dialects" as Attic, Ionic, etc. and the various Romance languages of Latin. Where there have existed side by side, as in England, various branches of a language, such as the languages of the Angles, the Jutes or the Saxons, and the descendant of one particular language has predominated, the traces of the others remain in the "dialects" of the districts where once the original language prevailed. Thus "dialect" varieties of a language need not, historically, represent degradations. **A** "literary" accepted language, such as modern English, represents the original language spoken in the Midlands, with accretions of various sources, while the present-day "dialects" preserve traces of the original local variety of the language. See the articles on languages (English, French, etc.).

DIALECTIC (DIALECTICS), a logical term, generally used in common parlance in a contemptuous sense for verbal or purely abstract disputation devoid of practical value (from Gr. **διάλεκτος,** discourse, debate; **ἡ διαλεκτική, *sc.* τέχνη,** the art of debate). According to Aristotle, Zeno of Elea "invented" dialectic, the art of disputation by question and answer, while Plato developed it metaphysically in connection with his doctrine of "Ideas" as the art of analysing ideas in themselves and in relation to the ultimate idea of the Good (*Repub.* vii.). The special function of the so-called "Socratic dialectic" was to show the inadequacy of popular beliefs. Aristotle himself used "dialectic," as opposed to "science," for that department of study which examines the presuppositions lying at the back of all the particular sciences. Each particular science has its own subject matter and special principles (**ἴδιαι ἀρχαί**) on which the superstructure of its special discoveries is based. The Aristotelian dialectic, however, deals with the universal laws (**κοιναὶ ἀρχαί**) of reasoning, which can be applied to the particular arguments of all the sciences. The sciences, for example, all seek to define their own species; dialectic, on the other hand, sets forth the conditions which all definitions must satisfy whatever their subject matter. Again, the sciences all seek to educe general laws; dialectic investigates the nature of such laws, and the kind and degree of necessity to which they can attain. To this general subject matter Aristotle gives the name "Topics" (**τόποι,** loci, communes loci). "Dialectic" in this sense is the equivalent of "logic." Aristotle also uses the term for the science of probable reasoning as opposed to demonstrative reasoning (**ἀποδεικτική**). The Stoics divided **λογική** (logic) into rhetoric and dialectic, and from their time till the end of the middle ages dialectic was either synonymous with, or a part of, logic.

In modern philosophy the word has received certain special meanings. In Kantian terminology Dialektik is the name of that portion of the Kritik der *reinen Vernunft* in which Kant discusses the impossibility of applying to "things-in-themselves" the principles which are found to govern phenomena. In the system of Hegel the word resumes its original Socratic sense, as the name of that intellectual process whereby the inadequacy of popular conceptions is exposed. The word, together with other Hegelian terminology was taken over by Karl Marx (*q.v.,* for "Marxian dialectic").

DIALLAGE, a variety of monoclinic pyroxene (*q.v.*) usually aluminous (see AUGITE), characterized by a prominent parting parallel to the orthopinacoid (100) and often showing a fibrous structure. The schiller appearance of diallage is due as in bronzite (*q.v.*) to the interposition along the plane (100) of thin plates of ilmenite, which facilitate mechanical separation along this plane. Lamellar twinning on (100) is also not uncommon. These inclusions probably result from unmixing in the solid state of ilmenite in solid solution in diallage at the temperature of crystallization. Fine parallel intergrowths of diallage and rhombic pyroxene are not infrequent in gabbros, of which diallage is

especially characteristic. It is scarcely represented among the younger volcanic rocks.

DIALOGUE, properly the conversation between two or more persons, reported in writing, a form of literature invented by the Greeks for purposes of rhetorical entertainment and instruction, and scarcely modified since the days of its invention. A dialogue is in reality a little drama without a theatre, and with scarcely any change of scene.

The systematic use of dialogue as an independent literary form is commonly supposed to have been introduced by Plato, whose earliest experiment in it is believed to survive in the *Laches.* The Platonic dialogue, however, was founded on the mime, which had been cultivated half a century earlier by the Sicilian poets, Sophron and Epicharmus. The works of these writers, which Plato admired and imitated, are lost, but it is believed that they were little plays, usually with only two performers. The recently-discovered mimes of Herodas (Herondas) give us some idea of their scope. Plato further simplified the form, and reduced it to pure argumentative conversation, while leaving intact the amusing element of character-drawing. He must have begun this about the year 405 B.C., and by 399 B.C. he had brought the dialogue to its highest perfection, especially in the cycle directly inspired by the death of Socrates. All his philosophical writings, except the *Apology,* are cast in this form. In the 2nd century A.D., Lucian of Samosata achieved a brilliant success with his ironic dialogues "Of the Gods," "Of the Dead," "Of Love" and "Of the Courtesans." In some of them he attacks superstition and philosophical error with the sharpness of his wit; in others he merely paints scenes of modern life. The title of Lucian's most famous collection was borrowed in the 17th century by two French writers of eminence, each of whom prepared *Dialogues des morts.* These were Fontenelle (1683) and Fénelon (1712). In English non-dramatic literature the dialogue had not been extensively employed until Berkeley used it, in 1713, for his Platonic treatise, *Hylas and Philonus.* Landor's *Imaginary Conversations* (1821–28) is the most famous example of it in the 19th century. In Germany, Wieland adopted this form for several important satirical works published between 1780 and 1799. In Spanish literature, the dialogues of Valdés (1528) and those on painting (1633) by Vincenzo Carducci, are celebrated. In Italian, collections of dialogues, on the model of Plato, have been composed by Torquato Tasso (1586), by Galileo (1632), by Galiani (1770), by Leopardi (1825), and by a host of lesser writers. In modern times the French have returned to the original application of dialogue, and the inventions of "Gyp," of Henri Lavedan and of others, in which a mundane anecdote is wittily and maliciously told in conversation, would probably present a close analogy to the lost mimes of the early Sicilian poets, if we could meet with them.

DIALYSIS, in chemistry, a process invented by Thomas Graham for separating colloidal and crystalline substances. If a salt solution be placed in a drum provided with a parchment bottom, termed a "dialyser," and the drum and its contents placed in a larger vessel of water, the salt will pass through the membrane; hence the derivation (from the Gr. διά, through, λύειν, to loosen). If the salt solution be replaced by one of glue, gelatin or gum, it will be found that the membrane is impermeable to these solutes. To the first class Graham gave the name "crystalloids," and to the second "colloids." By adding hydrochloric acid to a dilute solution of an alkaline silicate, no precipitate will fall, and the solution will contain hydrochloric acid, an alkaline chloride, and silicic acid. If the solution be transferred to a dialyser, the hydrochloric acid and alkaline chloride will pass through the parchment, while the silicic acid will be retained.

DIAMAGNETISM. Substances which, like iron, are attracted by the pole of an ordinary magnet are commonly spoken of as magnetic, all others being regarded as non-magnetic. It was noticed by A. C. Becquerel in 1827 that a number of so-called non-magnetic bodies, such as wood and gum lac, were influenced by a very powerful magnet, and he appears to have formed the opinion that the influence was of the same nature as that exerted upon iron, though much feebler, and that all matter was more or less magnetic. Faraday showed in 1845 *(Experimental Researches,* vol. iii.) that while practically all natural substances are indeed acted upon by a sufficiently strong magnetic pole, it is only a comparatively small number that are attracted like iron, the great majority being repelled. Bodies of the latter class were termed by Faraday *diamagnetics.* The strongest diamagnetic substance known is bismuth, its susceptibility being—0·000014, and its permeability 0.9998. The diamagnetic quality of this metal can be detected by means of a good permanent magnet, and its repulsion by a magnetic pole had been more than once recognized before the date of Faraday's experiments. *(See* MAGNETISM.)

DIAMANTE, JUAN BAUTISTA (1640?–1684?), Spanish dramatist, was born at Castillo about 1640, entered the army, and began writing for the stage in 1657. Like many other Spanish dramatists of his time, Diamante is deficient in originality, and his style is riddled with affectations; *La Desgraciada Raquel,* which was long considered to be his best play, is really Mira de Amescua's *Judia de Toledo* under another title; and the earliest of Diamante's surviving pieces, *El Honrador de su padre* (1658), is virtually a free translation of Corneille's *Le Cid.* Diamante is historically interesting as the introducer of French dramatic methods into Spain.

DIAMANTINA (formerly called *Tejuco*), a mining town of the State of Minas Gerais, Brazil, in the northeastern part of the State, 3,710 ft. above sea level. Pop. about 8,000; the municipality (1940) 53,764. Diamantina is built partly on a steep hillside overlooking a small tributary of the Rio Jequitinhonha (where diamond-washing was once carried on), and partly on the level plain above. The town is roughly but substantially built, with broad streets and large squares. It is the seat of a bishopric, with an episcopal seminary, and has many churches, a lunatic asylum, a theatre, military barracks, hospitals and a secondary school. There are several small manufactures, including cotton-weaving, tanning and shoemaking, and diamond-cutting is carried on. Diamantina is the commercial centre of an extensive region, and has long been noted for its wealth.

The present name of the town was assumed (instead of Tejuco) in 1838, when it was made a *cidade.*

(See MINAS GERAIS.)

DIAMANTINO, a small town of the State of Mato Grosso, Brazil, near the Diamantino river, about 6 mi. above its junction with the Paraguay, in 14° 24′ 33″ S., 56° 8′ 30″ W.

The population of the municipality (1940) is 5,442, mostly Indians. It stands in a broken sterile region 1,837 ft. above sea level and at the foot of the great Mato Grosso plateau. The first mining settlement dates from 1730, when gold was found in the vicinity. On the discovery of diamonds in 1746 the settlement drew a large population and for a time was very prosperous.

The mines failed to meet expectations, however, and the population declined; it has grown slowly since 1880.

Ipecacuanha and vanilla beans are the principal articles of export.

DIAMETER, in geometry, a straight line passing through the centre of a conic section and terminated by the curve (from the Gr. διά, through, μέτρον, measure). The "principal diameters" of the ellipse and hyperbola coincide with the "axes" and are at right angles; "conjugate diameters" are such that each bisects chords parallel to the other. The diameter of a quadric surface is a line at the extremities of which the tangent planes are parallel. Newton defined the diameter of a curve of any order as the locus of the centres of the mean distances of the points of intersection of a system of parallel chords with the curve. The word is also used as a unit of linear measurement of magnifying power.

In architecture, the term is used with reference to the lower part of the shaft of a column. It is employed by Vitruvius (iii. 2) to determine the height of a column, and it is generally the custom to fix the lower diameter of the shaft by the height required and the Order employed. Thus the diameter of the Roman Doric should be about one-eighth of the height, that of the Ionic one-ninth and of the Corinthian one-tenth. *(See* ORDER.)

DIAMOND, mineral universally recognized as chief among precious stones; it is the hardest, the most imperishable, and also the most brilliant of minerals. These qualities alone have made it

supreme as a jewel since early times, and yet the real brilliancy of the stone is not displayed until it has been faceted by the art of the lapidary (*q.v.*) and this was scarcely developed before the year 1746. The consummate hardness of the diamond, in spite of its high price, has made it most useful for purposes of grinding, polishing and drilling. Numerous attempts have been made to manufacture the diamond by artificial means, and these attempts have a high scientific interest on account of the mystery which surrounds the natural origin of this remarkable mineral. Its physical and chemical properties have been the subject of much study, and have a special interest in view of the extraordinary difference between the physical characters of the diamond and those of graphite (blacklead) or charcoal, with which it is chemically identical, and into which it can be converted by the action of heat or electricity.

The name *Ἀδάμας* "the invincible," was probably applied by the Greeks to hard metals, and thence to corundum (emery) and other hard stones. According to Charles William King, the first undoubted application of the name to the diamond is found in Manilius (A.D. 16)—Sic *Adamas, punctum lapidis; pretiosior* auro, —and Pliny (A.D. 100) speaks of the rarity of the stone, "the most valuable of gems, known only to kings." Pliny described six varieties, among which the Indian, having six pointed angles, and also resembling two pyramids (turbines, whip-tops) placed base to base, may probably be identified as the ordinary octahedral crystal (fig. 1). The diamond (Yahalom) in the breastplate of the high priest (Ex. xxxix. 11) was certainly some other stone, for it bore the name of a tribe, and methods of engraving the true diamond cannot have been known so early. The stone can hardly have become familiar to the Romans until introduced from India, where it was probably mined at a very early period. But one or other of the remaining varieties mentioned by Pliny (the Macedonian, the Arabian, the Cyprian, etc.) may be the true diamond, which was in great request for the tool of the gem-engraver. Later Roman authors mentioned various rivers in India as yielding the *Adamas* among their sands. The name *Adamas* became corrupted into the forms adamant, diamaunt, *diamant,* diamond; but the same word, owing to a mediaeval misinterpretation which derived it from *adamare* (compare the French word *aimant*), was also applied to the lodestone.

Scientific Characters.— Diamond is almost always found in single crystals, which show no signs of previous attachment to any matrix; the stones were, until the discovery of the South African mines, almost entirely derived from sands or gravels, but owing to the hardness of the mineral it is rarely, if ever, waterworn, and the crystals are often very perfect. The crystals belong to the cubic system, generally assuming the form of the octahedron (fig. 1), but they may, in accordance with the principles of crystallography, also occur in other forms symmetrically derived from the octahedron; e g, the cube, the 12-faced figure known as the rhombic dodecahedron (fig. 2), or the 48-faced figure known as the hexakis-octahedron (fig. 3), or in combinations of these. The octahedron faces are usually smooth; most of the other faces are rbunded (fig. 4). The cube faces are rough with protruding points. The cube is sometimes found in Brazil, but is very rare among the South African stones; and the dodecahedron is perhaps more common in Brazil than elsewhere. The crystals are sometimes tetrahedral in aspect. There are also "twins" of diamond in which two octahedra (fig. 5) are united by contact aiong a surface parallel to an octahedron face; sometimes they interpenetrate. They are generally flattened along the plane of union. The crystals often display triangular markings, either elevations or pits, upon the octahedron faces (fig. 6). They have probably been produced by the action of some solvent. The actual arrangement of the carbon atoms in the crystal has now been ascertained by means of X-ray investigations.

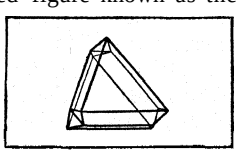

FIG. 5.—TWIN DIAMOND, SHOWING TWO OCTAHEDRA JOINED ALONG A SURFACE PARALLEL TO AN OCTAHEDRON FACE

Diamond possesses a brilliant "adamantine" lustre, but this tends to be greasy on the surface of the natural stones and gives the rounded crystals somewhat the appearance of drops of gum. Absolutely colourless stones are not so common as cloudy and faintly coloured specimens; the usual tints are grey, brown, yellow or white; and as rarities, red, green, blue and black stones have been found. The colour can sometimes be removed or changed at a high temperature, but generally returns on cooling. It is therefore more probably due to metallic oxides than to hydrocarbons. Sir William Crookes has, however, changed a pale yellow diamond to a bluish-green colour by keeping it embedded in radium bromide for 11 weeks. Diamond may break with a conchoidal fracture, but the crystals always cleave readily along planes parallel to the octahedron faces; of this property the diamond cutters avail themselves when reducing the stone to the most convenient form for cutting; a sawing process, however, has now been introduced, which is preferable to that of cleavage. It is the hardest known substance (though tantalum, or an alloy of tantalum, now competes with it) and is chosen as ten in the mineralogist's scale of hardness; the Borneo stones are said to be harder than others. The specific gravity ranges from 3.56 to 3·50, generally about 3·52. The co-efficient of expansion increases very rapidly above 750°, and diminishes very rapidly at low temperatures; the maximum density is attained when a temperature of about −42° Centigrade is reached.

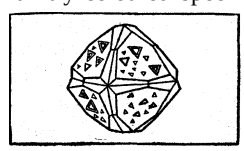

FIG. 6.—DIAMOND CRYSTAL, OCTAHEDRON, SHOWING TRIANGULAR MARKINGS

Brilliancy and "Fire."—The very high refractive power (index=2·417 for sodium light) gives the stone its extraordinary brilliancy; for light incident within a diamond at a greater angle than 24½° is reflected back into the stone instead of passing through it; the corresponding angle for glass is 40½°. The very high dispersion (index for red light= 2·402, for blue light= 2.460) gives it the wonderful "fire"—or display of spectral colours. Unlike other cubic crystals, diamond experiences a diminution of refractive index with increase of temperature. It is very transparent for Rontgen rays, whereas paste imitations are opaque. It is a good conductor of heat, and therefore feels colder to the touch than glass and imitation stones. The diamond has also a somewhat greasy feel. The specific heat increases rapidly with rising temperature up to 60° C., and then more slowly. Crystals belonging to the cubic system should not be birefringent unless strained; diamond often displays double refraction particularly in the neighbourhood of inclusions, both liquid and solid; this is probably due to strain, and the spontaneous explosion of diamonds has often been observed. Diamond differs from graphite in being a bad conductor of electricity; it becomes positively electrified by friction. The electrical resistance is about that of ordinary glass, and is diminished by one-half during exposure to Rontgen rays; the dielectric constant (16) is greater than that which should correspond to the specific gravity.

The phosphorescence produced by friction has been known since the time of Robert Boyle (1663); the diamond becomes luminous in a dark room after exposure to sunlight or in the presence of radium; and many stones phosphoresce beautifully (generally with a pale green light) when subjected to the electric discharge in a vacuum tube. Some diamonds are more phosphorescent than others, and different faces of a crystal may display different tints. The combustibility of the diamond was predicted by Sir Isaac Newton on account of its high refractive power; it was first established experimentally by the Florentine academicians in 1694. In oxygen or air diamond burns at about 850°, and only continues to do so if maintained at a high temperature; but in the absence of oxidizing agents it may be raised to a much higher temperature. It is, however, infusible at the temperature of the electric arc, but becomes blackened superficially. Experiments on the combustion of diamond were made by Smithson Tennant (1797) and Sir Humphry Davy (1816), with the object of proving that

PROCESSES IN DIAMOND FINISHING

1. Notching the stones for cleaving by a single blow. Before cleaving, the stones must be notched or grooved so that they will break on the exact line which the operator desires. Cleavage takes place along planes parallel to the octahedron faces of the crystal
2. Splitting or cleaving diamonds. After the diamond has been notched to determine its plane of cleavage, it is held in the instrument illustrated and split by a single sharp blow
3. The metal clutch which holds the diamond in secure position for cutting. The gem is placed between the Prongs of the apparatus, and the teeth are tightened by screwing down on the ring at the base. This holds the stone firmly clamped
4. Turning on a lathe; the abrasive used in the cutting process must be another diamond, which is the hardest substance known
5. Inspecting the work of a group of diamond cutters
6. Diamond polishers giving the gems their final polish under the eyes of an inspector

it is pure carbon. Diamond is insoluble in acid and alkalis, but is oxidized on heating with potassium bichromate and sulphuric acid.

Uses of the Diamond. — The use of the diamond for other purposes than jewellery depends upon its extreme hardness: it has always been the only material used for cutting or engraving the diamond itself. The employment of powdered bort (*q.v.*) and the lapidary's wheel for faceting diamonds was introduced by L. von Berquen of Bruges in 1476. Diamonds are now employed not only for faceting precious stones, but also for cutting and drilling glass, porcelain, etc.; for fine engraving such as scales; in dentistry for drilling; as a turning tool for electric-light carbons, hard rubber, etc.; and occasionally for finishing accurate turning work. It is also used for bearings in watches and electric meters. The best glaziers' diamonds are chosen from crystals such that a natural curved edge can be used. For rock drills, and revolving saws for stone cutting, either diamond, bort or carbonado (*q.v.*) is employed, set in steel tubes, discs or bands. Rock drilling is the most important industrial application; and for this, owing to its freedom from cleavage, the carbonado is more highly prized than diamond. Another application of the diamond is for wire drawing; a hole tapering towards the centre is drilled through a diamond, and the metal is drawn through this. No other tool is so durable, or gives such uniform thickness of wire.

Distribution and Mining. — The most important localities for diamonds have been: (1) India, where they were mined from the earliest times till the close of the 19th century; (2) South America, where they have been mined since the middle of the 18th century; and (3) South Africa, to which almost the whole of the diamond-mining industry has been transferred since 1870.

Indian Diamonds. — The diamond is here found in ancient sandstones and conglomerates, and in the river gravels and sands derived from them. The sandstones and conglomerates belong to the Vindhyan formation and overlie the old crystalline rocks: the diamantiferous beds are well defined, often not more than 1ft. in thickness, and contain pebbles of quartzite, jasper, sandstone, slate, etc. The mines fall into five groups situated on the eastern side of the Deccan plateau. The mining has always been carried on by natives of low caste, and by primitive methods which do not differ much from those described by the French merchant, Jean Baptiste Tavernier (1605–89), who paid a prolonged visit to most of the mines between 1638 and 1665 as a dealer in precious stones.

At some of the Indian localities spasmodic mining has been carried on at different periods for centuries; at some the work which had been long abandoned was revived in recent times, at others it has long been abandoned altogether. Many of the large stones of antiquity were probably found in the Kollar group, where Tavernier found 60,000 workers in 1645 (?), the mines, according to native accounts, having been discovered about 100 years previously. Golconda was the fortress and the market for the diamond industry at this group of mines, and so gave its name to them. Very few Indian diamonds now find their way out of the country, and so far as the world's supply is concerned, Indian mining of diamonds may be considered extinct. The first blow to this industry was the discovery of the Brazilian mines in Minas Gerais and Bahia.

Brazilian Diamonds. — Diamonds were found about 1725 at Tejuco (now Diamantina) in Minas Gerais, and the mining became important about 1740. The Rio Abaete district was worked on a considerable scale between 1785 and 1807, but is now abandoned. Diamantina is at present the most important district; it occupies a mountainous plateau, and the diamonds are found both on the plateau and in the river valleys below it. The mountains consist here of an ancient laminated micaceous quartzite, which is in parts a flexible sandstone known as itacolumite. and in parts a conglomerate. The diamond is found under three conditions: (1) in the gravels of the present rivers, embedded in a ferruginous clay-cemented conglomerate known as *cascalho;* (2) in terraces occupying higher levels; (3) in plateau deposits embedded in the red clay which cements the larger blocks. The terraces are probably a first concentration of the plateau material by the old rivers; and the *cascalho* a second concentration by the modern rivers.

In recent years the Minas Gerais mines have been rivalled by the yield in Bahia. The diamond here occurs in river gravels and sands associated with the same minerals as in Minas Gerais; since 1844 the richest mines have been worked in the Serra de Cincora, where the mountains are intersected by the River Paraguassu and its tributaries; it is said that there were as many as 20,000 miners working here in 1845, and it was estimated that 54,000 carats were produced in Bahia in 1858. But the enormous development of the South African mines, which in 1906 supplied about 90% of the world's produce, has thrown the Brazilian production into the shade.

African Diamonds. — The first discovery was made in 1867 by Dr. W. G. Atherstone, who identified as diamond a pebble obtained from a child in a farm on the banks of the Orange river and brought by a trader to Grahamstown; it was bought for £500 and displayed in the Paris Exhibition of that year. In 1869 a stone weighing 83½ carats was found near the Orange river; this was purchased by the earl of Dudley for £25,000 and became famous as the "Star of South Africa." A rush of prospectors at once took place to the banks of the Orange and Vaal rivers, and resulted in considerable discoveries, so that in 1870 there was a mining camp of no less than 10,000 persons on the "River Diggings." In the River Diggings the mining was carried on in the coarse river gravels, and by the methods of the Brazilian negroes and of gold placer-miners. A diggers' committee limited the size of claims to 30ft. square, with free access to the river bank; the gravel and sand were washed in cradles provided with screens of perforated metal, and the concentrates were sorted by hand on tables by means of an iron scraper.

But towards the close of 1870 stones were found at Jagersfontein and at Dutoitspan, far from the Vaal river, and led to a second great rush of prospectors, especially to Dutoitspan, and in 1871 to what is now the Kimberley mine in the neighbourhood of the latter. At each of these spots the diamantiferous area was a roughly circular patch of considerable size, and in some it occupied the position of one of those depressions or "pans" so frequent in South Africa. These "dry diggings" were therefore at first supposed to be alluvial in origin like the river gravels; but it was soon discovered that, below the red surface soil and the underlying calcareous deposit, diamonds were also found in a layer of yellowish clay about soft. thick known as "yellow ground." Below this again was a hard bluish-green serpentinous rock which was at first supposed to be barren bed-rock; but this also contained the precious stone, and has become famous. under the name of "blue ground," as the matrix of the South African diamonds. The yellow ground is merely decomposed blue ground. In the Kimberley district five of these round patches of blue ground were found within an area little more than 3m. in diameter; that at Kimberley occupying ten ac., that at Dutoitspan 23 acres. There were soon 50,000 workers on this field, the canvas camp was replaced by a town of brick and iron surrounded by the wooden huts of the natives, and Kimberley became an important centre.

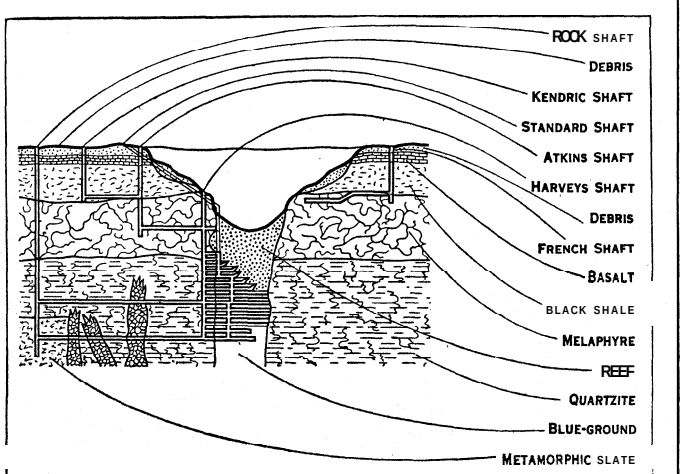
It was soon found that each mine was in reality a huge vertical funnel or crater descending to an unknown depth, and filled with diamantiferous blue ground. At first each claim was an independent pit 31ft. square sunk into the blue ground; the diamantiferous rock was hoisted by bucket and windlass, and roadways were left across the pit to provide access to the claims. But the roadways soon fell in, and ultimately haulage from the claims could only be provided by means of a vast system of wire ropes extending from a triple staging of windlasses erected round the entire edge of the mine, which had by this time become a huge open pit; the ropes from the upper windlasses extended to the centre, and those from the lower tier to the sides of the pit; covering the whole mass like a gigantic cobweb of taut steel ropes. The buckets of blue ground were hauled up these ropes by means of horse whims, and in 1875 steam winding engines began to be employed. By this time also improved methods in the treatment of the blue ground were introduced. It was carried off in carts to open spaces. where an exposure of some weeks to the air was found to pulverize

the hard rock far more efficiently than the old method of crushing with mallets. The placer-miner's cradle and rocking-trough were replaced by puddling troughs stirred by a revolving comb worked by horse power; reservoirs were constructed for the scanty water-supply, bucket elevators were introduced to carry away the tailings; and the natives were confined in compounds. For these improvements co-operation was necessary; the better claims, which in 1872 had risen from £100 to more than £4,000 in value, began to be consolidated, and a mining board was introduced.

In a very few years, however, the open pit mining was rendered impossible by the mud rushes, by the falls of the masses of barren rock known as "reef," which were left standing in the mine, and by landslips from the sides, so that in 1883, when the pit had reached a depth of about 400ft., mining in the Kimberley crater had become almost impossible. By 1889, in the whole group of mines, Kimberley, Dutoitspan, De Beers and Bultfontein, open pit working was practically abandoned. Meanwhile mining below the bottom of the pits by means of shafts and underground tunnels had been commenced; but the full development of modern methods dates from the year 1889 when Cecil Rhodes and Alfred Beit, who had already secured control of the De Beers mine, acquired also the control of the Kimberley mine, and shortly afterwards consolidated the entire group in the hands of the De Beers Company (see KIMBERLEY).

The scene of native mining was now transferred from the open pit to underground tunnels; the vast network of wire ropes disappeared, and with it the cosmopolitan crowd of busy miners working like ants at the bottom of the pit. In place of all this, the visitor to Kimberley encounters at the edge of the town only a huge crater, silent and apparently deserted, with no visible sign of the great mining operations which are conducted far below the surface.

A vertical shaft through the basalt, shale and granite is sunk in the vicinity of the mine, and from this horizontal tunnels are driven into the pipe at different levels separated by intervals of 40 feet. Through the blue ground itself on each level a series of parallel tunnels about 120ft. apart are driven to the opposite side of the pipe, and at right angles to these, and 36ft. apart, another series of tunnels. When the tunnels reach the side of the mine



FROM GARDNER WILLIAMS, "DIAMOND MINES OF SOUTH AFRICA" (MACMILLAN & CO.)

FIG 7.— SECTION OF THE KIMBERLEY DIAMOND MINE IN SOUTH AFRICA
From vertical shafts sunk near the mine, horizontal tunnels are driven into the pipe of blue ground, at levels 40 ft. apart, the excavated material being brought up through the rock shafts

they are opened upwards and sideways so as to form a large chamber, and the overlying mass of blue ground and dkbris is allowed to settle down and fill up the gallery. On each level this process is carried somewhat farther back than on the level below (fig. 7); material is thus continually withdrawn from one side of the mine and extracted by means of the rock shaft on the opposite side, while the superincumbent débris is continually sinking, and is allowed to fall deeper on the side farthest from the shaft as the blue ground is withdrawn from beneath it. In 1905 the main shaft had been sunk to a depth of 2,600ft. at the Kimberley mine.

For the extraction and treatment of the blue ground the De Beers Company in its great winding and washing plant employs labour-saving machinery on a gigantic scale. The ground is transferred in trucks to the shaft where it is automatically tipped into skips holding 96 cu. ft. (six truck loads); these are rapidly hoisted to the surface, where their contents are automatically dumped into side-tipping trucks, and these in turn are drawn away in a continual procession by an endless wire rope along the tram lines leading to the vast "distributing floors." These are open tracts upon which the blue ground is spread out and left exposed to sun and rain until it crumbles and disintegrates, the process being hastened by harrowing with steam ploughs; this may require a period of three or six months, or even a year. The stock of blue ground on the floors at one time in 1905 was nearly 4,500,000 loads. The disintegrated ground is then brought back in the trucks and fed through perforated cylinders into the washing pans; the "hard blue" ground which has resisted disintegration on the floors, and the lumps which are too big to pass the cylindrical sieves, are crushed before going to the pans. These are shallow cylindrical troughs containing muddy water in which the diamonds and other heavy minerals (concentrates) are swept to the rim by revolving toothed arms, while the lighter stuff escapes near the centre of the pan. The concentrates are then passed over sloping tables (pulsator) and shaken to and fro under a stream of water which effects a second concentration of the heaviest material.

Until recently the final separation of the diamond from the concentrates was made by hand picking, but even this has now been replaced by machinery, owing to the remarkable discovery that a greased surface will hold a diamond while allowing the other heavy minerals to pass over it. The concentrates are washed down a sloping table of corrugated iron which is smeared with grease, and it is found that practically all the diamonds adhere to the table, and the other minerals are washed away. At the large and important Premier mine in the Transvaal the Elmore process, used in British Columbia and in Wales for the separation of metallic ores, has been also introduced. In the Elmore process oil is employed to float off the materials which adhere to it, while the other materials remain in the water, the oil being separated from the water by centrifugal action.

In all the South African mines the diamonds are not only crystals of various weights from fractions of a carat to 150 carats, but also occur as microscopic crystals disseminated through the blue ground. In spite of this, however, the average yield in the profitable mines is only from 0·2 carat to 0·6 carat per load of 1,600 lb., or on an average about 1½ grs. per ton. The annual output of diamonds from the De Beers mines was valued in 1906 at nearly £5,000,000; the value per carat ranging from about 35 to 70 shillings.

Pipes similar to those which surround the Kimberley have been found in other parts of South Africa. One of the best known is that of Jagersfontein, which was really the first of the dry diggings (discovered in 1870). This large mine is near Fauresmith and 80m. to the south of Kimberley. In 1905 the year's production from the Orange River Colony mines was more than 320,000 carats, valued at £938,000. But by far the largest of all the pipes hitherto discovered is the Premier mine in the Transvaal, about 300m. to the east of Kimberley. This was discovered in 1902 and occupies an area of about 75 acres. Comparatively few of the pipes which have been discovered are at all rich in diamonds, and many are quite barren; some are filled with "hard blue" which, even if diamantiferous, may be too expensive to work.

The most competent South African geologists believe all these remarkable pipes to be connected with volcanic outbursts which occurred over the whole of South Africa during the Cretaceous period (after the deposition of the Stormberg beds), and drilled these enormous craters through all the later formations. Over a great part of Cape Colony have been discovered what are probably similar pipes filled with agglomerates, breccias and tuffs, and some with basic lavas.

The River Diggings on the Vaal river are still worked upon a small scale, but the production from this source is so limited that they are of little account in comparison with the mines in the blue

ground. The stones, however, are good; since they differ somewhat from the Kimberley crystals it is probable that they were not derived from the present pipes. Considerable finds of diamonds were reported in 1905 and 1906 from gravels at Somabula near Gwelo in Rhodesia. Diamonds have also been reported from kimberlite "pipes" in Rhodesia.

The South African output in 1926 was 3,000,000 carats. Diamonds have been found in considerable numbers in sand near Liideritz bay in South-West Africa (1908); the output from this district in 1926 was 515,000 carats. The Congo has become an important source since the first discovery in 1903; the diamonds are found in alluvial deposits of the River Kasai and its affluents. The output in 1926 was 1,108,000 carats from Belgian Congo, and 150,000 carats from Angola. Other African localities are the Gold Coast and Tanganyika.

Other Localities. — In addition to the South American localities mentioned above, small diamonds have also been mined since their discovery in 1890 on the River Mazaruni in British Guiana, and finds have been reported in the gold washings of Dutch Guiana. The output from British Guiana in 1926 was 182,000 carats. Borneo has possessed a diamond industry since the island was first settled by the Malays. Australia has yielded diamonds in alluvial deposits near Bathurst (where the first discovery was made in 1851) and at other places in New South Wales; in South Australia; in Victoria; in Western Australia; and in Queensland. In Tasmania also diamonds have been found in the Corinna goldfields. Europe has produced few diamonds. They have been found (1829) in the gold washings of Bissersk, and at other spots in the Urals. Also in Lapland and Siberia. In North America small stones have been found in alluvial deposits, mostly auriferous, in Georgia, North and South Carolina, Kentucky, Virginia, Tennessee, Wisconsin, California, Oregon and Indiana. Considerable interest attaches to the diamonds found in Wisconsin, Michigan and Ohio near the Great Lakes, for they are here found in the terminal moraines of the great glacial sheet which is supposed to have spread southwards from the region of Hudson bay.

Origin of the Diamond in Nature. — It appears from the foregoing account that at most localities the diamond is found in alluvial deposits probably far from the place where it originated. The minerals associated with it do not afford much clue to the original conditions; they are mostly heavy minerals derived from the neighbouring rocks, in which the diamond itself has not been observed.

There are only a few localities at which the diamond has been supposed to occur in its original matrix — in India, in Minas Gerais, and at Inverell in New South Wales, but the evidence is certainly not sufficient to establish the presence of an original matrix. Finally there is the remarkable occurrence in the blue ground of the African pipes.

There has been much controversy concerning the nature and origin of the blue ground itself; and even granted that (as is generally believed) the blue ground is a much serpentinized volcanic breccia consisting originally of an olivine-bronzite-biotite rock (the so-called kimberlite), it contains so many rounded and angular fragments of various rocks and minerals that it is difficult to say which of them may have belonged to the original rock, and whether any were formed in *situ,* or were brought up from below as inclusions. Carvill Lewis believed the blue ground to be true eruptive rock, and the carbon to have been derived from the bituminous shales of which it contains fragments. The Kimberley shales, which are penetrated by the De Beers group of pipes, were, however, certainly not the source of the carbon at the Premier (Transvaal) mine, for at this locality the shales do not exist. The view that the diamond may have crystallized out from solution in its present matrix receives some support from the experiments of W. Luzi, J. Friedlander, R. von Hasslinger and J. Wolff. E. Cohen, who regarded the pipes as of the nature of a mud volcano, and the blue ground as a kimberlite breccia altered by hydrothermal action, thought that the diamond and accompanying minerals had been brought up from deep-seated crystalline schists. Other authors have sought the origin of the diamond in the action of the hydrated magnesian silicates on hydrocarbons derived from bituminous schists, or in the decomposition of metallic carbides.

Of great scientific interest in this connection is the discovery of small diamonds in certain meteorites, both stones and irons; *e.g.,* in the stone which fell at Novo-Urei in Penza, Russia, in 1886, in a stone found at Carcote in Chile, and in the iron found at Cañon Diablo in Arizona. Graphitic carbon in cubic form (cliftonite) has also been found in certain meteoric "irons," and is now generally believed to be altered diamond. The claim by H. Moissan to have produced the diamond artificially, by allowing dissolved carbon to crystallize out at a high temperature and pressure from molten iron, coupled with the occurrence in meteoric iron, has led Sir William Crookes and others to conclude that the mineral may have been derived from deep-seated iron containing carbon in solution *(see* the article GEM, ARTIFICIAL).

On the other hand, the occurrence in meteoric stones, and the experiments mentioned above, show that the diamond may also crystallize from a basic magma, capable of yielding some of the metallic oxides and ferro-magnesian silicates; a magma, therefore, which is not devoid of oxygen. This is still more forcibly suggested by the remarkable eclogite boulder found in the blue ground of the Newlands mine, not far from the Vaal river, and described by T. G. Bonney. The boulder is a crystalline rock, and is studded with diamond crystals; a portion of it is preserved in the British Museum (Natural History). Similar boulders have also been found in the blue ground elsewhere. It seems therefore that a holo-crystalline pyroxene-garnet rock may be one source of the diamond found in blue ground. Some regard the eclogite boulders as derived from deep-seated crystalline rocks, others as concretions in the blue ground. None of the inclusions in the diamond gives any clue to its origin.

Finally, then, both experiment and the natural occurrence in rocks and meteorites suggest that diamond may crystallize not only from iron but also from a basic silicate magma, possibly from various rocks consisting of basic silicates. The blue ground of South Africa may be the result of the serpentinization of several such rocks, and although now both brecciated and serpentinized some of these may have been the original matrix. A circumstance often mentioned in support of this view is the fact that the diamonds in one pipe generally differ somewhat in character from those of another, even though they be near neighbours.

History of Diamonds. — All the famous diamonds of antiquity must have been Indian stones. The first author who described the Indian mines at all fully was the Portuguese, Garcia de Orta (1565), who was physician to the viceroy of Goa. Before that time there were only legendary accounts like that of Sindbad's "Valley of the Diamonds," or the tale of the stones found in the brains of serpents. V. Ball thinks that the former legend originated in the Indian practice of sacrificing cattle to the evil spirits when a new mine is opened; birds of prey would naturally carry off the flesh, and might give rise to the tale of the eagles carrying diamonds adhering to the meat.

The following are some of the famous diamonds of the world:—

A large stone found in the Golconda mines and said to have weighed 787 carats in the rough, before being cut by a Venetian lapidary, was seen in the treasury of Aurangzeb in 1665 by Tavernier, who estimated its weight after cutting as 280 (?) carats, and described it as a rounded rose-cut-stone, tall on one side. The name *Great Mogul* has been frequently applied to this stone. Tavernier states that it was the famous stone given to Shah Jahan by the emir Jumla. The *Orloff,* stolen by a French soldier from the eye of an idol in a Brahmin temple, stolen again from him by a ship's captain, was bought by Prince Orloff for £90,000, and given to the empress Catharine II. It weighs $194\frac{3}{4}$ carats, is of a somewhat yellow tinge, and is among the Russian Crown jewels The *Koh-i-nor,* which was in 1739 in the possession of Nadir Shah, the Persian conqueror, and in 1813 in that of the raja of Lahore, passed into the hands of the East India Company and was by them presented to Queen Victoria in 1850. It then weighed $186\frac{1}{16}$ carats, but was recut in London by Amsterdam workmen, and now weighs $106\frac{1}{16}$ carats. There has been much discussion concerning the possibility of this stone and the Orloff being both fragments of the Great Mogul. The Mogul Baber in his memoirs (1526)

relates how in his conquest of India he captured at Agra the great stone weighing 8 mishkals, or 320 ratis, which may be equivalent to about 187 carats. The Koh-i-nor has been identified by some authors with this stone and by others with the stone seen by Tavernier. Tavernier, however, subsequently described and sketched the diamond which he saw as shaped like a bisected egg, quite different therefore from the Koh-i-nor. Nevil Story Maskelyne has shown reason for believing that the stone which Tavernier saw was really the Koh-i-nor, and that it is identical with the great diamond of Baber; and that the 280 carats of Tavernier is a misinterpretation on his part of the Indian weights. He suggests that the other and larger diamond of antiquity which was given to Shah Jahan may be one which is now in the treasury of Teheran, and that this is the true Great Mogul which was confused by Tavernier with the one he saw. *(See* Ball, Appendix I. to Tavernier's *Travels* (1889); and Maskelyne, *Nature,* 1891, 44, p 555.)

The *Regent* or *Pitt* diamond is a magnificent stone found in either India or Borneo; it weighed 410 carats and was bought for £20,400 by Pitt, the governor of Madras; it was subsequently, in 1717, bought for £80,000 (or, according to some authorities. £135,000) by the duke of Orleans, regent of France; it was reduced by cutting to 136$\frac{14}{16}$ carats; was stolen with the other Crown jewels during the Revolution, but was recovered and is still in France. The *Akbar Shah* was originally a stone of 116 carats with Arabic inscriptions engraved upon it; after being cut down to 71 carats it was bought by the gaikwar of Baroda for £35,000. The *Nizam,* now in the possession of the nizam of Hyderabad, is supposed to weigh 277 carats; but it is only a portion of a stone which is said to have weighed 440 carats before it was broken. The *Sancy,* weighing 53$\frac{12}{16}$ carats, is said to have been successively the property of Charles the Bold, de Sancy, Queen Elizabeth, Henrietta Maria, Cardinal Mazarin, Louis XIV.; to have been stolen with the *Pitt* during the French Revolution; and subsequently to have been the property of the king of Spain, Prince Demidoff and an Indian prince.

The *Great Table,* a rectangular stone seen by Tavernier in 1642 at Golconda, was found by him to weigh 242$\frac{3}{16}$ carats; Maskelyne regards it as identical with the *Darya-i-nur,* which is also a rectangular stone Weighing about 186 carats in the possession of the shah of Persia. Another stone, the *Taj-e-mah,* belonging to the shah, is a pale rose pear-shaped stone and is said to weigh 146 carats.

Coloured Indian diamonds of large size are rare; the most famous are: a beautiful blue brilliant, 67$\frac{2}{16}$ carats, cut from a stone weighing 112$\frac{3}{16}$ carats brought to Europe by Tavernier. It was stolen from the French Crown jewels with the *Regent* and was never recovered. The *Hope,* 444 carats, has the same colour and is probably a portion of the missing stone: it was so-called as forming part of the collection of H. T. Hope bought for £18,000, and was sold again in 1906 (resold 1909). Two other blue diamonds are known, weighing 13$\frac{3}{4}$ and 1$\frac{3}{4}$ carats, which may also be portions of the French diamond. The *Dresden Green,* one of the Saxon Crown jewels, 40 carats, has a fine apple-green colour. The *Florentine,* 133$\frac{1}{8}$ carats, one of the Austrian Crown jewels, is a very pale yellow.

The most famous Brazilian stone was the *Star of the South,* found in 1853, when it weighed 254$\frac{1}{2}$ carats and was sold for £40,000; when cut it weighed 125 carats and was bought by the gaikwar of Baroda for £80,000.

The Largest Diamond. — Many large stones have been found in South Africa; some are yellow but some are as colourless as the best Indian or Brazilian stones. The most famous are the following: — The *Star of South Africa,* or *Dudley,* mentioned above, 83$\frac{1}{2}$ carats rough, 46$\frac{1}{2}$ carats cut. The *Stewart,* 288$\frac{3}{8}$ carats rough, 120 carats cut. Both these were found in the river diggings. The *Porter Rhodes* from Kimberley, of the finest water, weighed about 1jo carats. The *Victoria,* 180 carats, was cut from an octahedron weighing 457$\frac{1}{2}$ carats, and was sold to the nizam of Hyderabad for £400,000. The *Tiffany,* a magnificent orange-yellow stone, weighs 125$\frac{1}{2}$ carats cut. A yellowish octahedron found at De Beers weighed 428$\frac{1}{2}$ carats, and yielded a brilliant of 228$\frac{1}{2}$ carats. Some of the finest and largest stones have come from the Jagersfontein mine; one, the *Jubilee,* found in 1895, weighed 634 carats in the rough and 239 carats when cut. Until 1905 the largest known diamond in the world was the *Excelsior,* found in 1893 at Jagersfontein by a native while loading a truck. It weighed 969$\frac{1}{2}$ carats, and was ultimately cut into ten stones weighing from 68 to 13 carats. But all previous records were surpassed in 1905 by the *Cullinan Diamond* more than three times the size of any known stone, which was found in the yellow ground at the newly discovered Premier mine in the Transvaal. It was purchased by the Transvaal Government in 1907 and presented to King Edward VII. It was sent to Amsterdam to be cut, and in 1908 was divided into nine large stones, the four largest weighing 516$\frac{1}{2}$ carats, 309$\frac{3}{16}$ carats, 92 carats and 62 carats respectively, and a number of small brilliants. The Jonker diamond, weighing 726 carats, was found in Elandsfontein in 1934, and was sold in May, 193j, to an American for about £150,000.

Diamonds are invariably weighed in carats. One English carat = 3·17 grains = ·2,053 grams. One metric carat (now nearly universally used) = ·200 grams or 200 milligrams. *(See* CARAT.)

DIAMOND MATCH COMPANY, THE, largest match company in the United States, was incorporated on December 26, 1930, under the laws of the State of Delaware, succeeding an Illinois corporation of the same name. It is engaged in the manufacture and the sale of matches, of match-making machinery, of lumber and lumber products, and of other similar products.

The company holds a minority interest in the British Match Corporation, Limited, of Great Britain and, with that firm and several others, in the Eddy Match Company, Limited, located in Canada.

The properties of The Diamond Match Company and its subsidiaries include factories in nine different States of the Union, namely: New York, Maine, Massachusetts, Ohio, Wisconsin, New Jersey, Utah, Washington and California; they include also large timber tracts in the States of Maine, Georgia, Idaho, California and Washington; 64 lumber yards owned and operated in the Sacramento valley, California, and 22 in the New England states. and in addition a large card-board operating, printing and book match assembly plant at Springfield, Massachusetts.

The following figures give a comprehensive view of the extensive financial operation of the company: the total current assets as of December 31, 1939, were $27,448,793.33; the total assets, $34,380,742.16; the net working capital, $26,050,559.14; the net income, $2,136,750.49; the total surplus, $3,466,833.31.

The aggregate net income for the five years from 1935–1939, inclusive, was $10,654,906.53, making an annual average, for that five-year period, of the sum of $2,130,981.30.

The headquarters of the company are in the city of New York.

CUT AND UNCUT DIAMONDS

1. The "Koh-i-Nor," re-cut in 1862, as a shallow brilliant, weighing 106 carats. 2. Rough diamonds from mines at Kimberley, South Africa, the world's richest diamond centre. 3. The "Excelsior," discovered in the Jagersfontein mine. Weight in the rough, 971 carats. 4. The "Cullinan," the world's largest diamond, showing the rough gem and stones cut from it. 5. The "Nassak," weight 89.59 carats. brought to New York in 1927. 6. The "Florentine," or "Tuscany," weight 133⅛ carats, formerly owned by the Austrian Imperial Family. 7. The "Sancy," 53 carats, a gem which has had many historic owners, among them Cardinal Mazarin, Louis XIV. and Elizabeth of England

DIAMOND NECKLACE, THE AFFAIR OF THE, a mysterious incident at the court of Louis XVI. of France, which involved the queen, Marie Antoinette. The Parisian jewellers Boehmer and Bassenge had spent some years collecting stones for a necklace which they hoped to sell to Mme. Du Barry, the favourite of Louis XV., and after his death to Marie Antoinette. They were considerably embarrassed by their failure to do so.

Since his recall in disgrace from Vienna in 1774, Louis, cardinal de Rohan, had been anxious to be reconciled to the queen. In March 1784 he took as mistress a certain Jeanne de St. Remy de Valois, who had married a *soi-disant* comte de Lamotte. She persuaded him that she had been received by the queen and enjoyed her favour, and carried on for him a pretended correspondence with the queen, the adventuress duly producing replies to Rohan's notes in the queen's name. The tone of the letters became very warm, and the cardinal, convinced that Marie Antoinette was in love with him, became ardently enamoured of her. A secret meeting took place in Aug. 1784, in a grove in the garden at Versailles, between Rohan and a lady whom the cardinal believed to be the queen herself. Rohan offered her a rose, and she promised him that she would forget the past. The jewellers also believed in the relations of the countess with the queen, and they resolved to use her to sell their necklace. She agreed, and shortly after Rohan purchased it for 1,600,000 livres, payable in instalments. He said that he was authorized by the queen, and showed the jewellers the conditions of the bargain approved in the handwriting of Marie Antoinette. The necklace was given up. Rohan took it to the countess's house, where a man, in whom Rohan believed he recognized a valet of the queen, came to fetch it. Boehmer and Bassenge, before the sale, in order to be doubly sure, had sent word to the queen of the negotiations in her name. Marie Antoinette allowed the bargain to be concluded, and after she had received a letter of thanks from Boehmer, she burned it.

When the time came to pay, the comtesse de Lamotte presented the cardinal's notes; but these were insufficient, and Boehmer complained to the queen, who told him that she had received no necklace and never ordered it. Then followed a coup de *théâtre.* On Aug. 15, 1785, Assumption Day, when the whole court was awaiting the king and queen in order to go to the chapel, the cardinal de Rohan, who was preparing to officiate, was arrested and taken to the Bastille. The police also arrested Mme. de Lamotte, and some minor accomplices. A sensational trial before the *parlement* of Paris resulted (May 31, 1786) in the acquittal of the cardinal. The comtesse de Lamotte was condemned to be whipped, branded and shut up in the Salpetrière. Her husband, who is believed to have escaped with the necklace to London, was condemned, in his absence, to the galleys for life. Various circumstances fortified the popular belief that Marie Antoinette, in her hatred of the cardinal, had deliberately trapped Rohan—her disappointment at Rohan's acquittal, the fact that he was deprived of his charges and exiled to the abbey of la Chaise-Dieu, and finally the escape of the comtesse de Lamotte from the Salpetrière, with the connivance, as people believed, of the court. Mme. de Lamotte, having taken refuge abroad, published *Mémoires,* in which she accused the queen.

DIAN, a patrilineal people closely related to the Lobi and the Gan but more advanced, living near Diebougou, Gaoua district, Upper Volta, Africa.

See Labouret, "La Terre, la chasse et la guerre parmi les populations du Lobi," *Annuaires et Mémoires, Comité Études Hist. et Scient.* (Dakar, 1916–17).

DIANA, in Roman mythology, an Italian goddess in later times identified with the Greek Artemis (q.v.). That she was originally an independent Italian deity is shown by the presence of her cult at Nemi, which shows no foreign influence. This was in a grove beside the lake of (Nemus) Nemi, near Aricia (whence her title of Nemorensis). Here she was worshipped side by side with an obscure male deity, Virbius (q.v.). Her priest, called *Rex Nemorensis,* who was a runaway slave, was obliged to qualify for office by slaying his predecessor in single combat (Strabo v. 239; Suetonius, *Caligula,* 35). This led to the identification of Diana with the Tauric Artemis, whose image was said to have been removed by Orestes to the grove of Aricia (see ARICINI).

After the destruction of Alba Longa, this grove was for a long time the united sanctuary of the Latin League, until Rome became supreme. The festival of the goddess was on the ides (13th) of August, the full moon of the hot season. She was worshipped with torches, her aid was sought by women seeking a happy deliverance in childbirth, and many votive offerings have been found on the site. The worship of Diana was brought to Rome, and her temple on the Aventinc was founded, according to tradition, by Servius Tullius, originally as a sanctuary of the Latin League (Dion. Halic. iv. 26,3). On the day of its dedication (Aug. 13) the slaves kept holiday (Plutarch, Quaest. *Rom.,* 100), which was explained as a reference to the founder's servile origin. Another celebrated sanctuary of Diana was that on the slopes of Mount Tifata, near Capua, where she was worshipped under the name of Tifatina.

BIBLIOGRAPHY.—*See* J. G. Frazer, *Golden Bough;* Lang, *Magic and Religion,* p. 205 *et seq.;* Rose, *Rom. Qbest.,* p. 89; Wissowa, *Religion u. Kultus,* p. 247 (2nd ed.).

DIANA MONKEY, a west African guenon monkey (*q.v.*), taking its name, Cercopithecus diana, from the white crescent on the forehead; another characteristic feature being the pointed white beard. The general colour is greyish, with a deep tinge of chestnut on the hinder back. Together with C. neglectus of east and central Africa, C. *ignitus* of Liberia, and C. roloway of the Gold Coast, the diana represents the subgenus Pogonocebus.

DIANE DE FRANCE (1538–1619), duchess of Montmorency and Angoulême, was the natural daughter of Henry II. of France and a young Piedmontese, Filippa Duc. She was a beautiful and accomplished girl. She married in 1553 Horace Farnese, son of the duke of Parma, who was killed at the siege of Hesdin shortly after the marriage. In 1559 she married François de Montmorency, one of the leaders of the *politiques.* After her husband's death she exercised a wise and moderating influence at the courts of Henry III. and Henry IV. successively.

See Brantome, ed. *by* Lalanne in the *Coll. de* la *société d'histoire de France,* Vol. viii. (1875); J. de Thou, *Historia sui temporis . . .* (1733); Matthieu de Morgues, *Oraison funèbre de Diane de France* (Paris, 1619).

DIANE DE POITIERS (1499–1566), duchess of Valentinois, mistress of Henry II. of France, was the daughter of Jean de Poitiers, seigneur de St. Vallier, who came of an old family of Dauphin&. In 1515 she married Louis de Brézé, grand seneschal of Normandy, by whom she had two daughters. After her husband's death in 1533, she became the mistress of Prince Henry, who became dauphin in 1536. She inspired in the young prince, who was ten years her junior, a passion which lasted until his death. The accession of Henry II. in 1547 was also the accession of Diane: she was virtual queen, while Henry's lawful wife, Catherine de'Medici, lived in comparative obscurity. Diane devoted her energies chiefly to augmenting her income, and providing for her family and friends. Henry gave her the duchy of Valentinois. Catherine drove her from the court after Henry's death, and forced her to restore the crown jewels and to accept Chaumont in exchange for Chenonceaux. Diane retired to her château at Anet, where she died in 1566.

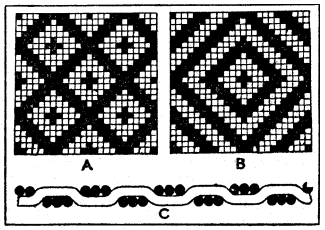
The story that she had been the mistress of Francis I., in order to obtain the pardon of ner father, who had been condemned to death as an accomplice of the constable de Bourbon, has no serious foundation. Diane was a patroness of the arts. She entrusted to Philibert de l'Orme the building of her chbteau at Anet, and it was for her that Jean Goujon executed his masterpiece, the statue of Diana, now in the Louvre.

See G. Guiffrey, *Lettres inédites de Diane de Poytiers* (1866) and *Procès criminel de Jehan de Poytiers* (1867); Capefigue, *Diane de Poitiers* (1860); Hay, *Madame Dianne de Poytiers* (1900).

DIANTHUS: *see* CARNATION.

DIAPASON (Gr. διά πασῶν, through all), a term in music originally denoting the interval of an octave. The Greek is an abbreviation of ἡ διὰ πασῶν χορδῶν συμφωνία, a consonance through all the tones of the scale. In this sense it is only used now, loosely, for the compass of an instrument or voice, or for a harmonious melody. The name is given to the two foundation stops of an organ, the open and the stopped diapason *(see* ORGAN) and to a standard of musical pitch, as in the French *diapason normal (see* PITCH, MUSICAL).

DIAPER, the name given to a textile fabric, formerly of a rich and costly nature with embroidered ornament, but now of linen or cotton, with a simple woven pattern; and particularly restricted to small napkins. In architecture, the term "diaper" is given to any small pattern of a conventional nature repeated continuously and uniformly over a surface; the designs may be purely geometrical, or based on floral forms, and in early examples were regulated by the process of their textile origin. Subsequently similar patterns were employed in the middle ages for the surface decoration of stone, as in Westminster Abbey and Bayeux cathedral in the spandrils of the arcades of the choir and nave; also in mural painting, stained glass, incised brasses, encaustic tiles, etc. Probably in most cases the pattern was copied, so far as the general design is concerned, from the tissues and stuffs of Byzantine manufacture, which came over to Europe and were highly prized as ecclesiastical vestments.



DIAPER, A AND B SHOW TWO VARIETIES OF DIAMOND PATTERN DIAPERS, AND C SHOWS THE WARP AND WEFT

In its textile use, the term diaper was originally applied to silk patterns of a geometrical pattern; it is now almost exclusively used for diamond patterns made from linen or cotton yarns. An illustration of two patterns of this nature is shown in the figure. The floats of the warp and the weft are mostly in three; indeed the patterns are made from a base weave which is composed entirely of floats of this number. It will be seen that both designs are formed of what may be termed concentric figures—alternately black and white. Pattern B differs from pattern A only in that more of these concentric figures are used for the complete figure. If pattern B, which shows only one unit, were extended, the effect would be similar to A, except for the size of the unit. In A there are four complete units, and hence the pattern appears more striking. Again, the repeating of B would cause the four corner pieces to join and to form a diamond similar to the one in the centre. The two diamonds in B would then alternate diagonally to left and right. Special names are given to certain kinds of diapers, *e.g.*, "bird's-eye," "pheasant's eye"; these indicate, to a certain extent, the size of the complete diamond in the cloth—the smaller kind taking the name "bird's-eye." The size of the pattern on paper has little connection with the size of the pattern in the cloth, for it is clearly the number of threads and picks per inch which determine the size of the pattern in the cloth from any given design. Although A is larger than what is usually termed the "bird's-eye" pattern, it is evident that it may be made to appear as such, provided that the cloth is fine enough. These designs, although adapted mostly for cloths such as nursery-diapers, for pinafores, etc., are sometimes used in the production of towels and table-cloths. In the figure, the first pick in A is identical with the first pick in B, and the part C shows how each interweaves with the 24 threads.

DIAPHONIA, in Greek musical terminology, dissonance, as opposed to consonance. Later, that is, in the early middle ages, the term signified one of the earliest kinds of descant (*q.v.*), also known as organum, in which the parts moved by unvaried parallel motion in fourths and fifths.

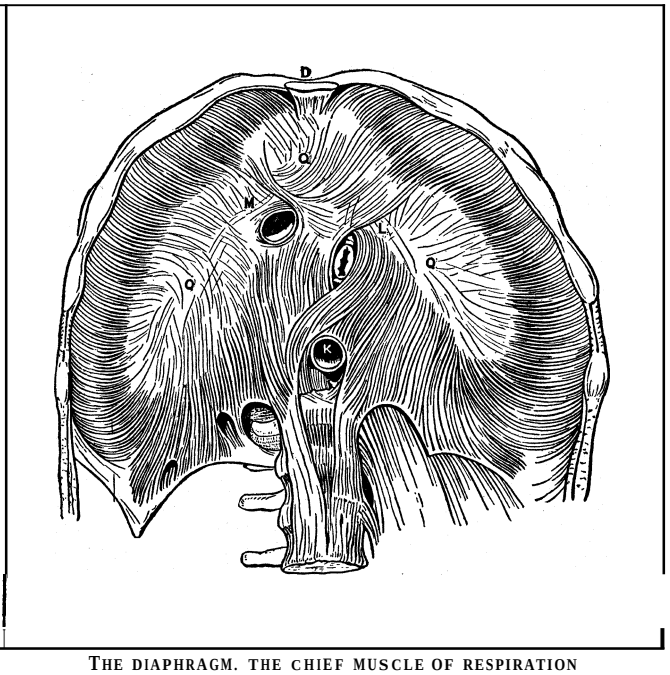
DIAPHORETICS, the name given to those remedies which promote perspiration. Among the best known are vapour or hot-water baths, or that part of the process of the Turkish bath which consists in exposing the body to a dry and hot atmosphere. Such measures, particularly if followed by the drinking of hot liquids and the wrapping of the body in warm clothing, seldom fail to excite copious perspiration. Numerous medicinal substances have the same effect.

DIAPHRAGM (dī'ă-frăm) (or midriff). In human anatomy a large fibro-muscular partition between cavities of the thorax and abdomen; it is convex toward the thorax, concave toward the abdomen, and consists of a central tendon and a muscular margin. The *central tendon (see* fig.) is trefoil in shape. The fleshy fibres rise, in front, from the back of the xiphoid cartilage, laterally by six serrations, from the inner surfaces of the lower six ribs, posteriorly from the five arcuate ligaments, two external, two internal, and one median. There are three large openings in the diaphragm; the *aortic* is behind the middle arcuate ligament and transmits the aorta, the vena azygos major, and the thoracic duct. In the right leaflet is an opening for the inferior vena cava and a branch of the right phrenic nerve, while in front and a little to the left of the aortic opening is one for the oesophagus and the two pneumogastric nerves.

Through the crura pass the splanchnic nerves. The sympathetic nerves usually enter the abdomen behind the internal arcuate ligaments. The phrenic nerves, which are the main supply of the diaphragm, divide before reaching the muscle and pierce it in a number of places to enter its abdominal surface, but some of the lower intercostal nerves assist in the supply.

For the action of the diaphragm *see* RESPIRATORY SYSTEM, ANATOMY OF.

Embryology.—The diaphragm is at first developed in the neck region of the embryo, and this accounts for the phrenic nerves, which supply it, rising from the fourth and fifth cervical. With growth of the body and development of the lungs the diaphragm shifts its position downwards. *(See* A. Keith, "On the Development of the Diaphragm," *Jour. of Anat. and Phys.* vol. *39.)* A. Paterson has recorded cases in which the left half of the diaphragm is wanting (*Proceedings* of the Anatomical Society of Gt. Britain, June 1900; *Jour. of Anat. and Phys.* vol. 34), and occasionally deficiencies are found elsewhere, especially in the sternal portion.



THE DIAPHRAGM. THE CHIEF MUSCLE OF RESPIRATION
Abdominal surface, showing origin of central tendons (Q) from xiphoid cartilage (D), and openings for aorta (K), inferior vena cava (M), pneumogastric nerves (L), and oesophagus

Comparative **Anatomy.**—A complete diaphragm is characteristic of the Mammalia; it usually has the human structure and relations except that below the Anthropoids it is separated from the pericardium by the azygous lobe of the lung. In some Mam-

mals, *e.g.*, Echidna and Phocoena, it is entirely muscular. In the Cetacea it is remarkable for its obliquity; this allows a larger lung space in the dorsal than in the ventral part of the thorax, and may be concerned with the equipoise of the animal. Below the mammals incomplete partitions are found in chelonians, crocodiles and birds, and in amphibians (*Xenopus* and *Pipa*).

DIAPHRAGM (in physics), the thin sheet of metal or other material used in the telephone (*q.v.*), microphones (*q.v.*), gramophones (*q.v.*) and loud speakers, whose function is to convert the electric oscillations into sound waves or vice versa.

DIARBEKR[1] or DIYARBEKIR, chief town of a vilayet of Turkey, situated on a basaltic plateau on the right bank of the Tigris, which there flows in a deep open valley. The town is still surrounded by the masonry walls of black basalt which give it the name of *Kara* or Black Amid; they are well built and imposing on the west facing the open country, but almost in ruins where they overlook the river. A mass of gardens and orchards covers the slope down to the river on the southwest. Pop. (1940) 43,264. The streets are narrow, badly paved and dirty; the houses and shops are low, mostly of stone, and some of stone and mud. The bazaar is a good one, and gold and silver filigree work is made, peculiar in character and design. Fruit is good and abundant as the rich volcanic soil is well watered from the town springs. The size of the melons is specially famous. To the south, the walls are some 40 ft. high, faced with large cut stone blocks of very solid construction, with towers and square bastions rising to 500 ft. There are four gates: on the north the Kharput gate, on the west the Rum, on the south the Mardin and on the east the Yeni Kapu or new gate. A citadel enclosure stands at the northeast corner and is now partly in ruins, but the interior space is occupied by the government konak. The summer climate in the confined space within the town is excessively hot and unhealthy. Winters are frequently severe but do not last long. The town is supplied with water both by springs inside the town and by aqueducts from fountains at Ali Punar and Hamervat. The principal exports are wool, mohair and copper ore, and imports are cotton and woollen goods, indigo, coffee, sugar, petroleum, etc. Cereals, cotton, tobacco, rice and silk are produced, and a school has been opened to give villagers instruction in silkworm culture. An exceptionally rich copper mine exists at Arghana Maden; galena mineral oil and silicious sand are also found. Scorpions noted for their virulence abound.

The Great Mosque, Ulu Jami, formerly a Christian church, occupies the site of a Sassanian palace and was built with materials from an older palace, probably that of Tigranes II. The churches of greatest interest are those of SS. Cosmas and Damian (Jacobite) and the church of St. James (Greek). In the 19th century Diarbekr was one of the largest and most flourishing cities of Asia. It is at the head of the navigation of the Tigris, which is traversed downstream by *keleks* or rafts supported by inflated skins. There is a good road to Aleppo and Alexandretta on the Mediterranean, and to Samsun on the Black sea by Kharput, Malatia and Sivas. There are also routes to Mosul and Bitlis. Railroad service to Diarbekr from Ankara was inaugurated on Nov. 22, 1935.

Diarbekr became a Roman colony in A.D. 230 under the name of Amida. It was enlarged and strengthened by Constantius II, in whose reign it was taken after a long siege by Shapur (Sapor) II, king of Persia. The historian Ammianus Marcellinus, who took part in the defense, gives a detailed account of it. In the later wars between the Persians and Romans it more than once changed hands. Though ceded by Jovian to the Persians it again became annexed to the Roman empire, and in the reign of Anastasius (A.D. 502) was once more taken by the Persians. It was taken c. 638 by the Arabs, and afterwards passed into the hands of the Seljuks and Persians, from whom it was finally captured by Selim I in 1515; and since that date it has remained under Ottoman rule. About 2 mi. below the town is a masonry bridge over the Tigris, the older portion being probably Roman, and the western part, which bears a Kufic inscription, being Arab.

(C. W. W.; F. R. M.)

[1]From *Diar,* land, and **Bekr** (*i.e.,* Abu **Bekr, the caliph).**

DIARRHOEA, an excessive looseness of the bowels, a symptom of irritation which may be due to various causes, or may be associated with some specific disease. The treatment in such latter cases necessarily varies, since the symptom itself may be remedial, but in ordinary cases depends on the removal of the cause of irritation by the use of aperients, various sedatives being also prescribed. In chronic diarrhoea careful attention to the diet is necessary, and careful search must be made for the underlying cause; it may be very serious.

DIARY, the book in which are preserved the daily memoranda regarding events and actions which come under the writer's personal observation, or are related to him by others. The person who keeps this record is called a diarist.

It is not until the close of the Renaissance (but *see* COMMENTARII) that we find diaries beginning to have literary value. In the 17th century they began to be largely written in England, although in most cases without any idea of even eventual publication. Sir William Dugdale (1605–86) had certainly no expectation that his slight diary would ever see the light. Bulstrode Whitelocke (1605–75), whose *Memorials of the English Affairs* covers the ground from 1625–60, was a genuine diarist. So was the elder George Fox (1624–91), who kept not merely "a great journal," but "the little journal books," and whose work was published in 1694. The famous diary of John Evelyn (1620–1706) professes to be the record of 70 years, and, although large tracts of it are covered in a very perfunctory manner, while in others many of the entries have the air of having been written in long after the event, this is a very interesting and amusing work; it was not published until 1818. It would hold a still higher position in the history of literature than it does if it were not overshadowed by what is unquestionably the most illustrious of the diaries of the world, that of Samuel Pepys (1633–1703) (*q.v.*). This was begun on Jan. 1, 1660, and was carried on until May 29, 1669. The extraordinary value of Pepys' diary consists in its fidelity to the portraiture of its author's character. In the age which succeeded that of Pepys, a diary of extraordinary emotional interest was kept by Swift from 1710 to 1713, and was sent to Ireland in the form of a *Journal to Stella;* it is a surprising amalgam of ambition, affection, wit and freakishness. John Byrom (1692–1763), the Manchester poet, kept a journal, which was published in 1854. The diary of the celebrated dissenting divine, Philip Doddridge (1702–51), was printed in 1829. Of far greater interest are the admirably composed and vigorously written journals of John Wesley (1703–91). But the most celebrated work of this kind produced in the latter half of the 18th century was the diary of Fanny Burney (Madame d'Arblay), published in 1842–46. It will be perceived that, without exception, these works were posthumously published. Boswell's *Journal of* a *Tour to the Hebrides* (1785), a genuine diary though somewhat expanded, was published during the author's lifetime.

Many of the diaries described above were first published in the opening years of the 19th century, and the interest which they awakened led to their imitation. Diaries ceased to be rare, but as a rule the specimens which have hitherto appeared have not presented much literary interest. Sir Walter Scott's *Journal* (published in 1890) and the diaristic portions of R. B. Haydon's *Autobiography and Journal* are eminent exceptions. Exception must also be made in favour of the journals of two minor politicians, Charles Greville (1794–1865) and Thomas Creevey (1768–1838), whose indiscretions have added much to the gaiety of nations; the papers of the former appeared in 1874–87, those of the latter in 1903. The diary of Henry Crabb Robinson (1775–1867), printed in 1869, contains excellent biographical material. Tom Moore's journal, published in 1856 by Lord John Russell, disappointed its readers. Darwin's historic *Voyage round the World* is written in diary form. Emerson's *Journals* are the notebook of an author rather than a book of intimate confessions. In the 20th century many men and women have published their diaries during their lifetime. Colonel Repington's *Diary* of World War I was a monument of indiscretion. "W. N. P. Barbellion" was still alive when his tragic *Diary of* a *Disappointed Man* was published. Of recent diaries none has possessed more

literary grace than the *Journal of Katherine Mansfield*.

It was natural that the form of the diary should appeal to a people so sensitive to social peculiarities as the French. A mediaeval document of immense value is the diary kept by an anonymous curé during the reigns of Charles VI. and Charles VII. This *Journal d'un bourgeois de Paris* was kept from 1409–31, and was continued by another hand down to 1449. The marquis de Dangeau (1638–1720) kept a diary from 1684 till the year of his death; this is an inexhaustible storehouse of facts about the reign of Louis XIV. Saint-Simon's own brilliant memoirs, written from 1691 to 1723, may be considered as a sort of diary. The lawyer, Edmond Barbier (1689–1771), wrote a journal of anecdotes from 1718–62. The song-writer, Charles Collé (1709–83), kept a *journal historique* from 1758–82; it is full of vivacity, but very scandalous. Petit de Bachaumont (1690–1771) had access to remarkable sources of information, and his *Mémoires secrets* contains a valuable mass of documents. In recent times the posthumous publication of the diaries of the Russian artist, Marie Bashkirtseff (1860–84), produced a great sensation in 1887. The brothers Jules and Edmond de Goncourt kept a very minute diary of artistic and literary Paris: after the death of Jules, in 1870, this was continued by Edmond, who published the three first volumes in 1888.

DIASPORE, a native aluminium hydroxide, AlO (OH) or $Al_2O_3{\cdot}H_2O$, crystallizing in the orthorhombic system and isomorphous with goethite and manganite. It occurs sometimes as platy crystals, but usually as lamellar or scaly masses, the flattened surface being a direction of perfect cleavage on which the lustre is markedly pearly in character. It is colourless or greyish-white, yellowish, sometimes violet in colour, and varies from translucent to transparent. It may be readily distinguished from other colourless transparent minerals, with a perfect cleavage and pearly lustre—mica, talc, brucite, gypsum—by its greater hardness of 6½–7. The specific gravity is 3·4. When heated before the blowpipe it decrepitates violently, breaking up into white scales.

DIASTYLE, an intercolumniation (*q.v.*) of three or four diameters.

DIATHERMY, a term first applied by Nagelschmidt in 1908 to the use of high frequency currents for heating locally the tissues of the body. The frequencies employed are 300,000 per sec. or above, which are too rapid to affect the nerve endings. Hence currents of an ampere or more can be used, the patient feeling only a sensation of warmth. The currents are generated in a coil of appreciable inductance and very low resistance by the oscillatory discharge of a condenser. The condenser is charged to a high voltage by a step-up transformer on an A.C. supply, and the discharge is produced by the passage of a spark through a multiple tungsten-faced spark gap. The oscillations are of the necessary high frequency and are maintained continuously by the spark discharge. The currents are led to the patient by pads or flexible metal sheets. (*See* ELECTROTHERAPY.)

DIATOMACEAE: *see* BACILLARIALES.

DIATONIC, a musical term signifying literally "through the tones," otherwise music in the case of which the notes employed are confined to those of the key, major or minor as the case may be, in which it is written. Hence diatonic music gives a general impression of strength, simplicity and solidity as distinguished from the more restless and poignant character of that in which notes from foreign keys are introduced by accidentals (*q.v.*).

DIAULOS, originally, in Greece, a race of twice the usual length, or two stadia; also, in architecture, the colonnade surrounding the great court of the Greek palaestra. so-called because its total circuit was about two stadia, or about 1,200 feet.

DIAVOLO, FRA (1771–1806), the popular name given to a famous Italian brigand. His real name was Michele Pezza, and he was born of low parentage at Itri; he had committed many murders and robberies in the Terra di Lavoro, but escaped capture, whence his name, popular superstition having invested him with the characters of a monk and a demon, and it seems that at one time he actually was a monk. Fra Diavolo was made leader of one of the bands raised by the Bourbon king, Frederick IV. against the French occupation, and succeeded in interrupting the enemy's communications between Rome and Naples. But although he wore a military uniform and held military rank, and was even created duke of Cassano, his atrocities were worthy of a bandit chief. On one occasion he threw some of his prisoners, men, women and children, over a precipice, and on another he had a party of 70 shot. He was for a short time imprisoned in the castle of St. Angelo, but was soon liberated. Joseph Bonaparte put a price on Fra Diavolo's head. For some time he evaded his pursuers, but at length, hungry and ill, he went in disguise to the village of Baronissi, where he was arrested, tried by an extraordinary tribunal, condemned to death and shot. His name has gained a world-wide celebrity as the title of a famous opera by Auber.

See A. Luzio, *Profili e bozzetti storici* (Milan, 1906).

DIAZ, ARMANDO (1861–1928), Italian marshal, was born in Naples on Dec. 6, 1861. He served in the Italo-Turkish War, and in 1914 was promoted to major-general. On Italy's entry into the World War he was director of military operations, and in 1916 became lieutenant-general in command of the 49th Division. In 1917 he was put in command of the XXIII. Corps and saw much hard fighting on the Carso. In Nov. 1917, after Caporetto, Diaz succeeded Cadorna as chief of the general staff. Under him the battle front was successfully reconstituted, and the Austrian armies were destroyed at Vittorio Veneto (Oct.–Nov. 1918). Diaz had proved himself not only a great commander in the field, but an organizer who saw that the army was well provided. After the signature of the Armistice he became inspector-general of the army. He received many honours, Italian and foreign, and in 1921 was created Duca della Vittoria. On the advent of the Fascist Government he was appointed minister of war, and held that appointment until ill health obliged him to resign in April 1924. On Nov. 4, 1924, the newly created rank of marshal was conferred on him. He died on Feb. 29, 1928, at Milan.

DÍAZ DEL CASTILLO (c. 1492–*c.* 1593), Spanish soldier and author, was born at Medina del Campo. In 1514 he visited Cuba and five years later accompanied Cortez to Mexiço where he died. He is known chiefly by his *True Account of the Discovery of New Spain* (3 vols., 1632; critical edition by Garcia, Mexico, 1904; Eng. trans. by Maudslay, 3 vols., 1908).

DIAZ, NARCISSE VIRGILE (1809–1876), French painter of the Barbizon school, was born in Bordeaux of Spanish parents, on Aug. 25, 1809. At first a figure-painter who indulged in strong colour, in his later life Diaz became a painter of the forest and a "tone artist" of the first order. He had an unhappy childhood. He lost a leg through a badly dressed insect-bite, and worked for some time as a porcelain painter at Sèvres. About 1831 Diaz encountered Théodore Rousseau, for whom he entertained a great veneration, although Rousseau was four years his junior. Ten years later Diaz found Rousseau painting his wonderful forest pictures, and determined to paint in the same way if possible. Rousseau was touched with the passionate words of admiration, and finally taught Diaz all he knew. Diaz exhibited many pictures at the Paris Salon, and was decorated in 1851. After 1871 he became fashionable and he worked constantly and successfully. In 1876 he caught cold at his son's grave, and on Nov. 18 of that year he died at Mentone. Diaz's finest pictures are his forest scenes and storms. There are several fairly good examples of his work in the Louvre, and three small figure pictures in the Wallace collection, Hertford House, London. Perhaps the most notable of Diaz's works are "La Fée aux Perles" (1857), in the Louvre; "Sunset in the Forest" (1868); "The Storm," and "The Forest of Fontainebleau" (1870) at Leeds. Diaz had no well-known pupils, but Léon Richet followed markedly his methods of tree-painting, and J. F. Millet at one period painted small figures in avowed imitation of Diaz's then popular subjects.

See A. Hustin, *Les Artistes célèbres: Diaz;* J. Claretie, *Peintres et sculpteurs contemporains: Diaz* (1882); D. Croal Thomson, *The Barbizon School of Painters* (1890); J. W. Mollett, *Diaz* (1890).

DÍAZ, JOSÉ DE LA CRUZ PORFIRIO (1830–1915), Mexican soldier and statesman, born in the city of Oaxaca, State of Oaxaca, Sept. 15, 1830. His family was poor, and his mother was part Indian. He was educated for the church, then the only career open to a youth without wealth. At the age of

fifteen he entered the Seminario Pontifical in Oaxaca, but in 1849, falling under the influence of Benito Juárez, rector of the university, he relinquished his clerical ambitions to undertake the study of law with Juárez in the Institute of Arts and Sciences, where he passed his examinations in civil and canon law in 1853. But he was pre-eminently a man of action. During the war with the United States (1847–48) he left home to serve in the army. In the plebiscite of 1855 he repudiated the dictatorship of Santa Anna. When the anti-clerical measures of the Constitution of 1857 resulted in the War of Reform (1858–61), Diaz supported Juirez, now president of the country, and aided materially in the overthrow of the clerical revolution and the final establishment of the Reform Laws. He was one of the first to oppose the French invasion of 1862, and after the establishment of Maximilian in Mexico in 1864, he was the most prominent figure in the struggle against the empire. He defeated a French attack upon Puebla in 1862, and in 1865, when the republican fortunes seemed at their nadir, he formed the "army of the east," recaptured Puebla in the spring of 1867, and on June 21, 1867, two days after the execution of Maximilian at Querétaro, re-entered the capital. Placing the city under martial law he maintained order until he was able to hand over his command to Juirez. Then he resigned his position in the army and retired to Oaxaca. He took no part in the Government until 1871. Dissatisfied with Juárez's policy, he appeared as a candidate for the presidency against Juárez and Lerdo de Tejada, and when congress proclaimed the re-election of Juárez, led an unsuccessful revolt in protest. In 1872 Lerdo succeeded as president in an administration which brought discord and disorder, and when he attempted to be re-elected in 1876, Diaz took the leadership of a revolution, proclaimed the principle of non-re-election, and defeated the Government forces in the battle of Tecoac, on Nov. 16, 1876. He was elected president in May 1877, and at once forged ahead with financial and political reform, the centralization of the Government, the re-establishment of public security, the scrupulous settlement of all national debts, and the building of railroads and telegraphs. His rule was stern, his methods sometimes brutal, but he achieved amazing results. In 1880 he was succeeded by Manuel González, the former minister of war, in whose cabinet he sat for some time as minister of *Fomento*, but in 1884 was unanimously re-elected to the presidency. Continuing his programme of political reorganization and economic reform, he opened the nation's natural resources to the world, succeeded in attracting great quantities of foreign capital, and won for Mexico, for the first time in her history, a position of respect among the nations. Political crises which arose with Guatemala, Austria and the United States he handled to the advantage of Mexico. In 1887 and 1892 the Constitution was amended to permit his re-election and from 1884 until 1911 he was continuously in office. But material prosperity was achieved at the cost of repression and increasing discontent. The land problem became acute, education was inadequate, and agitators fomented wide-spread dissatisfaction at the alleged control of the country by foreign capitalists. An incipient revolt headed by Gen. Bernardo Reyes in 1903 was quickly crushed, but in 1910 the standard of agrarian revolt was raised; the movement spread swiftly over the country; the Government was unable to control the army, and on May 4, 1911, Díaz resigned his post and left for Europe. He died in Paris on July 2, 1915, having seen destroyed most of the stability which he had brought to his country.

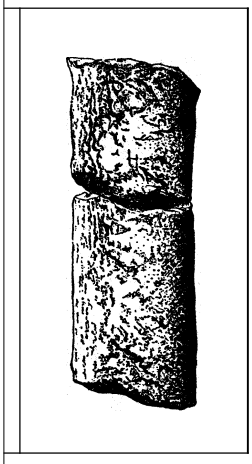
DIAZ DE NOVAES, BARTKOLOMEU (*fl.* 1481–1500), Portuguese explorer, discoverer of the Cape of Good Hope, was probably a kinsman of João Diaz, one of the first Portuguese to round Cape Bojador (1434), and of Diniz Diaz, the discoverer of Cape Verde (1445). In 1478 a Bartholomeu Diaz, probably identical with the discoverer, was exempted from certain customary payments on ivory brought from the Guinea coast. In 1481 he commanded one of the vessels sent by King John II. under Diogo d'Azambuja to the Gold Coast. On Oct. 10, 1486, he received an annuity of 6,000 reis from King John for "services to come"; and some time after receiving the money he left Lisbon with three ships fully manned and equipped to carry on the work of African exploration which had been so greatly advanced by Diogo Cão (1482–86).

Passing Cão's farthest point near Cape Cross (in the modern German South-west Africa and in 21° 50′ S.), he erected a pillar on what is now known as Diaz Point, south of Angra Pequena or Luderitz bay, in 26" 38' S.; of this fragments still exist. From this point (according to De Barros) Diaz ran 13 days southwards, in a comparatively high southern latitude, considerably south of the Cape. Failing, after several days' search, to find land, the Portuguese turned north, and so struck the south coast of Cape Colony at Mossel bay (Diaz' Bahia dos Vaqueiros), half way between the Cape of Good Hope and Port Elizabeth (Feb. 3, 1488). Thence they coasted eastward, passing Algoa bay (Diaz' Bahia da Roca). The officers and men now began to insist on return, and Diaz could only persuade them to go as far as the estuary of the Great Fish river. Here, however, half way between Port Elizabeth and East London, the north-easterly trend of the coast became unmistakable: the way round Africa had been definitely laid open by the Portuguese explorer.



BY COURTESY OF SOCIEDADE DE GEOGRAFIA DE LISBOA

FRAGMENTS OF A PILLAR ERECTED BY DIAZ IN 1487 AT ANGRA PEQUENA OR LÜDERITZ BAY, SOUTH-WEST AFRICA

On his return Diaz perhaps named Cape Agulhas after St. Brandan; while on the southernmost projection of the modern Cape peninsula, whose remarkable highlands doubtless impressed him as the practical termination of the continent, he bestowed, says De Barros, the name of Cape of Storms (*Cabo Tormentoso*); this name was changed by King John to that of Good Hope (*Cabo* da Boa *Esperança*). Some authorities, however, make Diaz himself give the Cape its present name. After touching at the Ilha do Principe (Prince's island, south-west of the Cameroons) as well as at the Gold Coast, he returned to Lisbon in Dec. 1488. He had discovered 1,260 m. of hitherto unknown coast; and his voyage, taken with the letters soon afterwards received from Pero de Covilhão (who by way of Cairo and Aden had reached Malabar on one side and the "Zanzibar coast" on the other as far south as Sofala, in 1487–88) was rightly considered to have solved the question of an ocean route round Africa to the Indies and other lands of South and East Asia.

No record has yet been found of any adequate reward tendered to Diaz for his great achievement; on Cabral's voyage of 1500 it has been recorded he was indeed permitted to take part in the discovery of Brazil (April 22), and thence should have helped to guide the fleet to India; but he perished in a great storm off his own Cabo Tormentoso, now known as Good Hope, and which he discovered in 1488. As Galvano says, he was allowed to see the

Promised Land, but not to enter in.

See João de Barros, *Asia,* Dec. I. bk. iii. ch. 4. (ed. A. A. Grillo and G. A. Grillo, 1866, etc.); Duarte Pacheco Pereira, *Esmeraldo de situ orbis (see* Raphael Basto, *Introduction* to his edition, 1892; also ed. A. da Silva Dias, 1905). A marginal note, probably by Christopher Columbus himself, on fol. 13 of a copy of Pierre d'Ailly's *Imago mundi,* now in the Colomhina at Seville, fixes Diaz's return to Lisbon in Dec. 1488. The writer says he was present at Diaz's interview with the King of Portugal, when the explorer described his voyage and showed his route upon the chart he had kept. *See* also the *Journal of the First Voyage of Vasco de Gama* (Hakluyt Society, ed. E. G. Ravenstein, 1898); F. Lopes de Castanheda, *Historia* (bk. i., Coimbra 1551); A. Galvão, *Descobrimentos (Discoveries of the World)* (Hakluyt Society, 1862); E. G. Ravenstein, "Voyages of Cão and Dias" in *Geographical Journal* (vol. xvi., 1900).

DIAZO-COMPOUNDS, in organic chemistry, compounds containing the characteristic group –N:N–, generally, although not invariably, joined to only one carbon atom, the other valency being satisfied either by (1) an electro-negative or acidic radical, as in the diazonium salts; (2) an oxygen atom in the diazohydroxides $R{\cdot}N_2{\cdot}OH$ and diazo-oxides, $R'{\cdot}N_2{\cdot}OR$; or (3) a nitrogen atom in the diazo-amino-compounds (diazo-amines). The diazo-compounds are not only of scientific interest but of considerable industrial importance, for they are essential to the manufacture of azo-dyes—the largest group of synthetic colouring matters. *(See* DYES, SYNTHETIC.) These diazo-compounds were discovered by P. Griess (1858), who pursued this investigation while engaged as chemist in the brewery of Allsopp & Co. of Burton-on-Trent.

The diazotization of aniline and other similarly constituted aromatic primary amines is carried out on a manufacturing scale as a necessary step in the production of colouring matters. More than 1,000 tons of para-nitraniline are diazotized annually in the formation on cotton fibre of "para-nitraniline red."

AROMATIC DIAZONIUM SALTS

In diazotizing aniline and other aromatic amines the base is first converted into its salt, usually the hydrochloride, by the addition of excess of acid (3 molecular proportions of hydrochloric acid). The solution or suspension is cooled and aqueous sodium nitrite is added with stirring, when the nitrous acid liberated substitutes one nitrogen atom for three hydrogen atoms present in the molecule of the organic salt:

$$C_6H_5{\cdot}NH_3Cl+HNO_2=C_6H_5{\cdot}N_2{\cdot}Cl+2H_2O.$$

It is on account of this replacement of hydrogen by nitrogen, which becomes attached to the nitrogen atom already present in the molecule, that the products now containing a double portion of nitrogen (azote) are termed diazo-compounds. *Benzenediazonium chloride,* represented by the above formula, is an extremely soluble salt of explosive character, and for ordinary synthetic and industrial purposes it is not necessary to isolate it. This and other diazonium salts have, however, been prepared in an anhydrous condition by diazotizing the amine salt in alcohol or glacial acetic acid with methyl, ethyl or amyl nitrite, when the diazonium salt is precipitated on the addition of ether (E. Knoevenagel, E. Bamberger, A. Hantzsch).

Diazonium salts have been obtained with a large variety of acid radicals but, being endothermic compounds, they are all liable to explode in the dry state; and since the diazonium chromates and perchlorates detonate with considerable violence, these salts have been suggested for use as explosives. When a diamine not containing its amino-groups in either ortho- or peri-positions is wholly diazotized a bisdiazonium salt results. If the two amino-groups are in the same nucleus a mixture of mono- and bisdiazonium salts is frequently produced, as in the case of paraphenylenediamine hydrochloride. When the amino-groups are in different aromatic rings, the bisdiazonium salt is produced with much greater facility. Benzidine, dianisidine and tolidine are the most outstanding examples of readily diazotizable diamines, and their bisdiazonium salts are largely employed in the manufacture of certain azo-dyes which, having considerable affinity for cotton fibre, are termed direct cotton dyes.

In addition to the employment of diazonium salts in colour making, these reactive compounds are utilized in many synthetic operations both in the laboratory and in the works. Their application to synthesis depends on the fact that through the diazo-reaction the amino-group originally present in an aromatic amine becomes replaceable by other elementary or compound radicals.

Reactions.— (I) *Decontposition by water:*

$$R{\cdot}N_2{\cdot}HSO_4+H_2O=R{\cdot}OH+N_2+H_2SO_4.$$

On boiling with water the diazonium salt (preferably the sulphate) loses nitrogen and its inorganic acidic radical and furnishes the phenol, $R{\cdot}OH$, corresponding with the original base, $R{\cdot}NH_2$. Guaiacol, $CH_3O{\cdot}C_6H_4{\cdot}OH$, is thus obtained through the diazonium salt of ortho-anisidine. The manufacture of α-naphtholsulphonic acids from the diazo-derivatives of the α-naphthylaminesulphonic acids is an industrial application of this decomposition by water. *(See* NAPHTHALENE.)

(2) *Replacentent of the diazo-group by hydrogen.* The amino-group of the aromatic amine can be replaced by hydrogen when the diazonium salt is treated with a reducing agent (aluminium powder, sodium stannite, hypophosphorous acid) or by boiling with alcohol. In the latter process the product is frequently a mixture of hydrocarbon and mixed ether, the alcohol behaving partly as a reducing and partly as an etherifying agent.

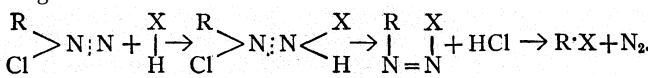
(3) *Replacement of the diazo-group by halogen, cyanide, cyanate and thiocyanate radicals.* Fluorine may be introduced into the aromatic nucleus by treating diazonium salts or diazo-amino-compounds *(see* below) with hydrofluoric acid. A more convenient method depends on the use of diazonium borofluorides (G. Balz and G. Schiemann, 1927), $R{\cdot}N_2BF_4$, which are readily obtainable in a solid state. When heated these salts decompose in the following manner and introduce fluorine into the aromatic nucleus: $R{\cdot}N_2BF_4=R{\cdot}F+N_2+BF_3$. Chlorine and bromine radicals are introduced into aromatic nuclei by warming diazonium salts with acid solutions of the corresponding cuprous salt (T. Sandmeyer, 1884) or with copper powder (L. Gattermann, 1890). Iodine is readily substituted for the diazo-group by adding potassium iodide to the solution of diazonium sulphate. Appropriate modifications of the Sandmeyer and Gattermann reactions furnish means for the introduction of cyanide, cyanate, thiocyanate and selenocyanate radicals into the aromatic nucleus.

(4) *Replacement* of the *diazo-group* by *sulphur* and *sulphur-containing radicals.* When copper powder is added to a solution of diazonium sulphate saturated with sulphur dioxide, nitrogen is eliminated and an aromatic sulphinic acid is produced. Aromatic thiophenols or disulphides are obtained by adding potassium xanthate, $C_2H_5{\cdot}CS{\cdot}SK$, to diazonium salts with subsequent hydrolysis of the resulting aromatic xanthate (Leuckart, 1887).

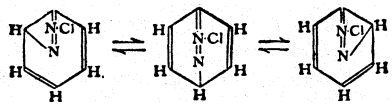
(5) *Replacement of the diazo-group by a nitro-group.* Potassium mercuric nitrite gives with aqueous benzenediazonium nitrate the double salt $C_6H_5N_2{\cdot}NO_3{,}Hg(NO_2)_2$, which on being warmed with copper powder yields nitrobenzene (A. Hantzsch, 1900). The treatment of a diazonium sulphate with cuprosocupric sulphite and alkali nitrite leads to exchange of the diazo-radical for the nitro-group.

Constitution.—On account of their condensation to form azo-compounds (*q.v.*) and their reduction to hydrazines, $R{\cdot}NH{\cdot}NH_2$, diazonium salts were assumed by A. Kekule (1866) to be compounds having the general formula $R{\cdot}N{:}N{\cdot}Cl$, but this formulation hardly accounts satisfactorily for their physical and chemical properties. Benzenediazonium chloride and its analogues dissolve in water to neutral solutions in which, as determinations of electrical conductivity indicate, their salts are highly ionized. The rate of migration of the benzenediazonium ion, $C_6H_5{\cdot}N_2$, has been ascertained to be 45.7 at 25°, and is thus comparable with the rates of migration of methylpyridinium and tetramethylammonium ions, which are respectively 44.3 and 43·6. The striking similarity in the properties of dissolved diazonium and quaternary ammonium salts suggests the presence of quinquevalent nitrogen in the former series, and for these reasons the diazonium formula first proposed by Blomstrand (1869) has been adopted generally, $C_6H_5{\cdot}\overset{\displaystyle N}{\underset{\displaystyle N}{\vdots\!\vdots}}{\cdot}Cl$.

Hantzsch explains the characteristic reactions of the diazonium compounds by the assumption that an addition compound is first formed, which breaks down with the elimination of the hydride of the acid radical, and the formation of an unstable syn-diazo-compound, which, in its turn, decomposes with evolution of nitrogen.

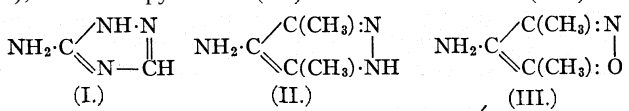


This conception of diazonium structure fails, however, to express one important point, namely, the dependence of the stability of the diazo-group on its attachment to an unsaturated organic radical. Accordingly, J. C. Cain proposed an alternative para-quinonoid formula for diazonium salts, and subsequently G. T. Morgan and F. M. G. Micklethwait (1908) developed the idea that diazonium salts may possess a dynamic constitution, Cain's structure representing the middle phase of the molecular oscillation,



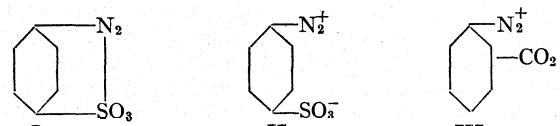
This idea of a rhythmic change of structure in diazonium salts is comparable with the dynamic conception of the benzene molecule advanced by Kekulé in propounding his cyclic theory of the constitution of aromatic hydrocarbons. These quinonoid formulations are supported by the fact that, although the simpler benzenoid diazonium salts are colourless, yet in the diphenyl, naphthalene and carbazole series such salts are frequently coloured.

Non-aromatic Diazonium Salts.—The foregoing conception of the structure of diazonium salts, which bases their existence on the unsaturated nature of associated organic complex, derives additional support from the fact that many non-aromatic amines containing unsaturated organic groups are diazotizable. Among the simplest bases which display this property are aminotriazole (I.), the aminopyrazoles (II.) and aminoisoxazole (III.).



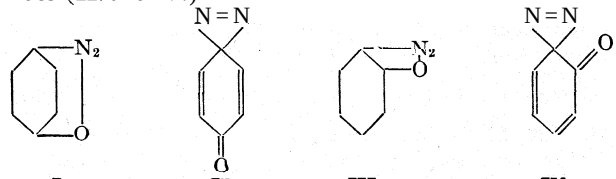
It will be noticed that the grouping  is common to all diazotizable arnines.

Internal **Diazonium Salts.**—Sulphonated amines of the benzene and naphthalene series give rise to industrially important diazo-derivatives which are erroneously termed diazo-sulphonic acids although actually internal diazonium sulphonates, formerly formulated as cyclic compounds (I.).



But in accordance with current views on the electronic nature of valency, such substances are more correctly represented as containing two bound ions, the two groups N_2 and SO_3 being associated, not by a valency linking, but by the transfer of an electron from the diazonium group to the sulphonate ion (II.). Somewhat allied to these internal diazonium sulphonates are the internal diazonium carboxylates (III.) and the diazo-oxides derived from ortho- and para-aminophenols.

Internal Diazo-oxides.—These diazo-oxides have been formulated either as cyclic derivatives (I. and III.) or as quinone-diazides (II. and IV.).



Two outstanding facts support the foregoing quinone-diazide formulae. These diazo-oxides are all yellow substances and they are never obtained from meta-aminophenols in which quinonoid formulation would be impossible. A similar group of diazoimines and diazoimides has been recorded (G. T. Morgan and F. M. G. Micklethwait and others, 1908–18). These substances may be represented by two alternative formulae (V. and VI.).

The latter formulation derives support from the circumstance that the diazoimines and diazoimides are yellow and obtainable only from para-diamines and not from meta-diamines.

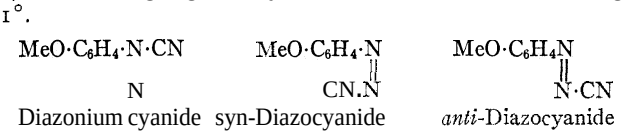
Cyclic Diazo-compounds.—When nitrous acid reacts with the salt of an orthodiamine or a peridiamine (see NAPHTHALENE), cyclic diazo-compounds are produced, *ortho-phenylenediamine* yielding phenylene-o-diazoimine (aziminobenzene, Formula I.), and peri- or 1:8-naphthylenediamine giving rise to naphthylene-1:8-diazimine (1:8-aziminonaphthalene, Formula II.).

The nitrogenous rings in these cyclic diazo-compounds are very inert and the substances do not couple with phenols or amines to yield azo-dyes.

Metallic Derivatives of Diazo-compounds.—In 1894 Schraube and Schmidt found that by adding aqueous *p*-nitrobenzenediazonium chloride to warm sodium hydroxide solution a well-defined salt separated in yellowish bronzy leaflets. Its composition corresponded with the formula $NO_2{\cdot}C_6H_4{\cdot}NNa{\cdot}NO,H_2O$. When treated with dilute acetic acid this salt yields a nitrosamine, $NO_2{\cdot}C_6H_4{\cdot}NH{\cdot}NO$, but with hydrochloric acid it reverts to the diazonium chloride, $NO_2{\cdot}C_6H_4{\cdot}N_2Cl$. The yellow sodium salt is a very stable substance and has been employed industrially in the production of para-nitraniline red. Homologues of this metallic diazo-salt are used increasingly in conjunction with Naphthol AS (see NAPHTHALENE) for dyeing cotton in fast red shades.

These stable metallic diazo-salts are produced from diazonium salts and warm caustic alkali, but another less stable series of metallic diazo-salts is formed by the use of cold alkali. A. Hantzsch suggested that the two series were stereoisomeric, but this view is not universally held.

Diazo-cyanides.—This group of substances having the general formula Ar.N,.CN, where Ar is an aromatic group, are diazo-compounds in which the azo-group is attached on both sides to carbon. In this respect they represent an intermediate group between ordinary diazo-derivatives and azo-compounds (*q.v.*) Moreover, the diazo-cyanides are of interest as furnishing the best example of Hantzsch's theory of stereoisomeric diazo-compounds. Thus from p-anisidine he obtained three isomeric diazo-cyanides: the colourless diazonium cyanide, an electrolyte obtained in the form of a double salt, $CH_3O{\cdot}C_6H_4{\cdot}N_2{\cdot}CN,HCN,2H_2O$, and two reddish insoluble diazo-cyanides, the unstable syn-form melting at 51°, which changes gradually to the stable anti-form melting at 121°.



Similar stereoisomeric relationships have been detected but with less certainty among diazo-sulphonates, $Ar{\cdot}N{:}N{\cdot}So_3K$.

Diazoamines.—The diazoamines, $R{\cdot}N_2{\cdot}NHR$, may be prepared by the action of the primary and secondary amines on the diazonium salts, or by the action of nitrous acid on the free primary amine. In the latter reaction it is assumed that the isodiazohydroxide $R{\cdot}N{:}NOH$ first formed is immediately attacked by a second molecule of the amine. They are yellow crystalline solids, which do not unite with acids. They are readily converted into the isomeric aminoazo-compounds, either in alcoholic solution or by warming with a mixture of the parent base and its hydrochloride; the diazo-group preferably going into the para-position to the amino-group. When the para-position is occupied the diazo-group takes the ortho-position. H. Goldschmidt and R. U. Reinders have shown that the transformation is a unimolecular reaction, the velocity of transformation in moderately dilute solution being independent of the concentration, but proportional to the amount of the catalyst present (amine hydrochloride) and to the temperature. Diazoaminobenzene, $C_6H_5N_2{\cdot}NHC_6H_5$, crystallizes from light petroleum or benzene in golden yellow laminae. Concentrated hydrochloric acid converts it into chlorobenzene, aniline and nitrogen. Zinc dust and alcoholic acetic acid reduce it to aniline and phenylhydrazine. The mixed diazoimines exhibit tautomerism (*q.v.*) behaving as if they had the dual structures $X{\cdot}N_2{\cdot}NHY$ and $XNH{\cdot}N_2Y$.

Azimino- or Triazo-compounds, $R{\cdot}N_3$, may be regarded as derivatives of azoimide (*q.v.*); they are formed by the action of ammonia on the diazoperbromides, by the action of hydroxylamine on the diazonium sulphates, and by adding sodium oxide to solutions of diazonium salts. Diazobenzeneimide, $C_6H_5N_3$, is a yellowish oil of stupefying odour. It boils at 59° C (12mm.), and explodes when heated. Concentrated hydrochloric acid decomposes it with formation of chloroanilines and elimination of nitrogen, whilst on being heated to boiling point with sulphuric acid it is converted into aminophenols.

ALIPHATIC DIAZO-COMPOUNDS

The esters of the aliphatic amino-acids may be diazotized in a manner similar to the primary aromatic amines, a fact discovered by T. Curtius. The first aliphatic diazo-compound to be isolated was *diazoacetic ester*, $N_2{\cdot}CH{\cdot}CO_2C_2H_5$, which is prepared by the action of potassium nitrite on the ethyl ester of glycine hydrochloride, $HCl{\cdot}NH_2{\cdot}CH_2{\cdot}CO_2C_2H_5 + KNO_2 = CHN_2{\cdot}CO_2C_2H_5 + KCl + 2H_2O$. It is a yellowish oil which melts at −24° C; it boils at 143–144° C, but cannot be distilled safely as it decomposes violently, giving nitrogen and ethyl fumarate. It explodes in contact with concentrated sulphuric acid. On reduction it yields ammonia and glycine. The diazo-ester condenses with benzene and its homologues giving rise to esters containing seven-membered hydrocarbon rings (Bucherer, 1896). The constitution of the diazo-fatty esters is inferred from the fact that the two nitrogen atoms, when split off, are replaced by two univalent elements or groups, thus leading to the formula $\begin{matrix}N\\ \|\\ N\end{matrix}\!\!>\!CH{\cdot}CO_2C_2H_5$, for diazoacetic ester.

Diazomethane, CH_2N_2, was first obtained in 1894 by H. v. Pechmann. It is prepared by the action of aqueous or alcoholic solutions of the caustic alkalis on the nitroso-acidyl derivatives of methylamine (such, for example, as *nitrosomethyl urethane*, $NO{\cdot}N(CH_3){\cdot}CO_2C_2H_5$, which is formed on passing nitrous fumes into an ethereal solution of methyl urethane). E. Bamberger regards it as the anhydride of iso-diazomethane, $CH_3{\cdot}N{:}N{\cdot}OH$, and has prepared it by a method similar to that used for the preparation of iso-diazobenzene. By the action of bleaching powder on methylamine hydrochloride there is obtained a volatile liquid *methyldichloroamine*, $CH_3{\cdot}NCl_2$, boiling at 58–60° C, which explodes violently when heated with water, yielding hydrocyanic acid ($CH_3NCl_2 = HCN + 2HCl$). Well-dried hydroxylamine hydrochloride is dissolved in methyl alcohol and mixed with sodium methoxide; a solution of methyldichloroamine in absolute ether is then added and an ethereal solution of diazomethane distils over. Diazomethane is a yellow inodorous gas, very poisonous and corrosive. It may be condensed to a liquid, which boils at about 0° C. It is a powerful methylating agent, reacting with water to form methyl alcohol, and converting acetic acid into methyl-acetate, hydrochloric acid into methyl chloride, hydrocyanic acid into acetonitrile, and phenol into anisole, nitrogen being eliminated in each case. It is reduced by sodium amalgam (in alcoholic solution) to *methylhydrazine*, $CH_3{\cdot}NH{\cdot}NH_2$. It unites directly with acetylene to form pyrazole.

See G. T. Morgan, *B.A. Rep.* (1902); J. Cain, *The Chemistry and Technology of the Diazo-compounds* (1920); T. E. Thorpe, *Dictionary of Applied Chemistry*, "Diazo-compounds" (1921). **(G. T. M.)**

DIBDIN, CHARLES (1745–1814), British musician, dramatist, novelist, actor and songwriter, the son of a parish clerk, was born in Southampton on or before March 4, 1745, and was chorister at Winchester from 1756 to 1759. At the age of 1j, he was engaged to sing at Covent Garden. His first work, an operetta entitled *The Shepherd's Artifice*, with words and music by himself, was produced there on May 21, 1762. Dibdin was connected with Drury Lane, both as composer and as actor for some years, and produced during this period two of his best known works, *The Waterman* (1774) and *The Quaker* (1775). A quarrel with Garrick led to the termination of his engagement. In *The Comic Mirror* he ridiculed prominent contemporary figures through the medium of a puppet show. In 1782 he became joint manager of the Royal circus, afterwards known as the Surrey theatre. In three years he lost this position owing to a quarrel with his partner. His opera *Liberty Hall*, containing the successful songs "Jock Ratlin," "The High-mettled Racer," and "The Bells of Aberdovey," was produced at Drury Lane theatre on Feb. 8, 1785. In 1788 he sailed for the East Indies, but the vessel having put in to Torbay in stress of weather, he changed his mind and returned to London. In a musical variety entertainment called *The Oddities*, he introduced the popular songs: "'Twas in the good ship 'Rover,'" "Saturday Night at Sea," "I Sailed from the Downs in the 'Nancy' " and the immortal "Tom Bowling," written on the death of his eldest brother, Capt. Thomas Dibdin, at whose invitation he had planned to visit India. In a series of monodramatic entertainments which he gave at his theatre, Sans Souci, he first introduced many of those sea-songs which stimulated the spirit of the navy during the war with France. Dibdin died of paralysis in London on July 25, 1814. Besides his *Musical Tour through England* (1788), his *Professional Life*, an autobiography published in 1803, a *History of the Stage* (1795), and several smaller works, he wrote upwards of 1,400 songs and about 30 dramatic pieces. His sons, Charles and Thomas John Dibdin (*q.v.*), were also popular dramatists in their day.

DIBDIN, THOMAS FROGNALL (1776–1847), English bibliographer, born at Calcutta, was the son of Thomas Dibdin, the sailor brother of Charles Dibdin. He was educated at St. John's college, Oxford, and was entered at Lincoln's Inn. After an unsuccessful attempt to obtain practice as a provincial counsel at Worcester, he was ordained at the close of 1804, being appointed to a curacy at Kensington. In 1823 he received the living at Exning, in Sussex. Soon afterwards he was appointed by Lord Liverpool to the rectory of St. Mary's, Bryanston square, which he held until his death. The first of his numerous bibliographical works was his *Introduction to the Knowledge of Editions of the Classics* (1802), which brought him under the notice of the third Earl Spencer, who threw open to him the rich library at Althorp; he spent much of his time in it, and in 1814–15 published his *Bibliotheca Spenceriana*. In 1818 he was commissioned by Earl Spencer to purchase books for him on the Continent, an expedition described in his sumptuous *Bibliographical, Antiquarian and Picturesque Tour in France and Germany* (1821). Dibdin was the originator and vice-president of the Roxburghe Club, founded in 1812.

Other works of his are *Bibliomania* **(1809)**; *Reminiscences of a Literary Life* (1836), and *Bibliographical, Antiquarian and Picturesque Tour in the Northern Counties of England and Scotland* **(1838)**.

DIBDIN, THOMAS JOHN (1771–1841), English dramatist and song-writer, son of Charles Dibdin, the song-writer, the composer of "Tom Bowling," was born on March 21, 1771.

He was apprenticed to his maternal uncle, a London upholsterer, and later to William Rawlins, afterwards sheriff of London, from whose service he ran away to join a company of country players. He returned to London in 1795, having married two years before; and in the winter of 1798–99 his Jew and the Doctor was produced at Covent Garden. His 70 comedies, operas and farces brought immense popularity to the writer and immense profits to the theatres. It is stated that the pantomime of Mother Goose (1807) produced over £20,000 for the management at Covent Garden theatre, and The High-mettled Racer, adapted as a pantomime from his father's play, £18,000 at Astley's. Dibdin was prompter and pantomime writer at Drury Lane until 1816, when he took the Surrey theatre. This venture proved disastrous. After this he was manager of the Haymarket, but without his old success, and his last years were passed in comparative poverty. In 1827 he published two volumes of Reminiscences. Of his songs "The Oak Table" and "The Snug Little Island" are well known. He died in London on Sept. 16, 1841.

See Reminiscences of Thomas Dibdin **(1827)**; and **E.** R. Dibdin The Dibdins **(1888)**.

DIBRA (Serbian Debar), a fortified city in S. Serbia, Yugoslavia, and the key to the upper valley of the Black Drin. Pop. (1931) 6,913, of Albanians, Bulgars and Serbs. There are two Serbian schools. Cattle breeding is the chief occupation but some maize and tobacco are grown. There are sulphurous springs in the neighbourhood. It was captured by the Serbs in the Balkan Wars (1912–13) and assigned to them by the Treaty of Bucharest (1913). It was occupied by Bulgaria in 1941.

DIBRUGARH, a town of British India, headquarters of the Lakhimpur district of Assam, on the Dibru river about 4 m. above its confluence with the Brahmaputra. Pop. (1931) 18,734. It is the terminus of steamer navigation on the Brahmaputra, and also of a railway line, which connects with the Assam-Bengal system. The town contains a cantonment, the headquarters of the Assam Valley Light Horse and various educational institutions. In 1900 a medical school was established from a bequest by J. Berry-White, to train hospital assistants for the tea gardens.

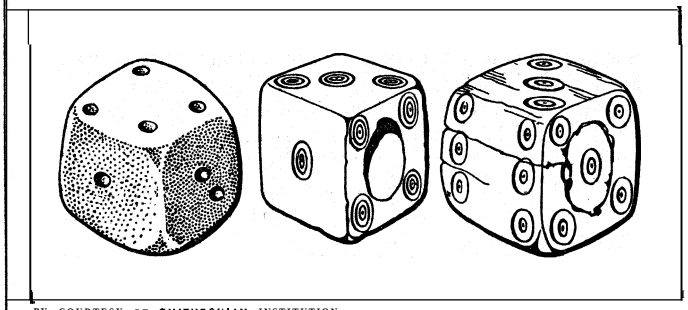
DICAEARCHUS, of Messene in Sicily, Peripatetic philosopher and pupil of Aristotle, historian, and geographer, flourished about 320 B.C. He was a friend of Theophrastus, to whom he dedicated the majority of his works. Of his writings only the titles and a few fragments survive. The most important of them was his *βίος τῆς Ἑλλάδος* (Life in Greece), in which the moral, political, and social condition of the people was fully discussed. In his Tripolitikos he described the best form of government as a mixture of monarchy, aristocracy, and democracy, and illustrated it by the example of Sparta. Among the philosophical works of Dicaearchus may be mentioned the Lesbiakoi, a dialogue in three books, showing that the soul is mortal, to which he added a supplement called Korinthiakoi. He also wrote a Description of the *World,* illustrated by maps, in which was probably included his *Measurements* of Mountains. A description of Greece (150 iambics, in C. Miiller Frag. *hist.* Graec. i. 238–243) was formerly attributed to him, but was really the work of Dionysius, son of Calliphon. The De *republica* is supposed to be founded on one of Dicaearchus's works.

The best edition of the fragments is by M. Fuhr (1841), a work of great learning; see also a dissertation by F. G. Osann, Beitriige *zur* rom. und griech. Literatur, ii. pp. 1–117 **(1839)**; Pauly-Wissowa, Realencyklopadie der *klass. Altertumswiss,* v. pt. 1 (1905).

DICE, small cubes of ivory, bone, wood or metal used in gaming (O.Fr. de, derived from Lat. dare, to give). The six sides of a die are each marked with a different number of incised dots in such a manner that the sum of the dots on any two opposite sides shall total seven. Dice seem always to have been employed, as they still are, for gambling, and in games like backgammon. There are many methods of playing, from one to five dice being used, the dice being thrown on to a smooth surface either from the hand or dice-box.

It is a remarkable fact that, wherever dice have been found, whether in the tombs of ancient Egypt, of classic Greece, or of the far East, they differ in no material respect from those in use to-day, the elongated ones with rounded ends found in Roman graves having been not dice but tali, or knuckle-bones. Eight-sided dice have comparatively lately been introduced in France as aids to children in learning the multiplication table. The teetotum, or spinning die, used in many modern games, was known in ancient times in China and Japan.

The increased popularity of the more elaborate forms of gaming has resulted in the decline of dicing. One method is to throw three



BY COURTESY OF SMITHSONIAN INSTITUTION

SIX-SIDED EARLY EGYPTIAN DICE AND TWO ROMAN DICE

Dice similar to those used to-day have been used from the earliest times. being found among ancient relics in Egypt, the Mediterranean and the Far East

times with three dice. If one or more sixes or fives are thrown the first time, they may be reserved, the other throws being made with the dice that are left. The object is to throw three sixes=18 or as near that number as possible.

The most popular form of pure gambling with dice at the present day is craps, or *crap-shooting,* a simple form of hazard, of French origin. Two dice are used. Each player puts up a stake and the first player may cover any or all of the bets. He then "shoots," *i.e.,* throws the dice from his open hand upon the table. If the sum of the dice is 7 or 11 the throw is a nick, or natural, and the player wins all stakes. If the throw is either 2, 3 or 12 it is a *crap,* and the player loses all. If any other number is thrown it is a point, and he continues until he throws the same number again, in which case he wins, or a 7, in which case he loses. Poker dice are marked with ace, king, queen, jack, ten and nine spot. Five are used and the object is, in three throws, to make pairs, triplets, full hands or fours and fives of a kind, five aces being the highest hand. Straights do not count.

History.—Dice were probably evolved from knucklebones. The antiquary Thomas Hyde, in his *Syntagma,* records his opinion that the game of "odd or even," played with pebbles, is nearly coeval with the creation of man. It is almost impossible to trace clearly the development of dice as distinguished from knucklebones, on account of the confusing of the two games by the ancient writers. It is certain, however, that both were played in times antecedent to those of which we possess any written records. Sophocles, in a fragment, ascribed their invention to Palamedes, a Greek, who taught them to his countrymen during the siege of Troy, and who, according to Pausanias (on Corinth, xx.), made an offering of them on the altar of the temple of Fortune. Herodotus (Clio) relates that the Lydians, during a period of famine in the days of King Atys, invented dice, knucklebones and indeed all other games except chess. The fact that dice have been used throughout the Orient from time immemorial, as has been proved by excavations from ancient tombs, seems to point clearly to an Asiatic origin. Dicing is mentioned as an Indian game in the Rig-veda. In its primitive form knucklebones was essentially a game of skill, played by women and children, while dice were used for gambling, and it was doubtless the gambling spirit of the age which was responsible for the derivative form of knucklebones, in which four sides of the bones received different values, which were then counted, like dice.

Gambling with three, sometimes two, dice (*κύβοι*) was a very popular form of amusement in Greece, especially with the upper classes, and was an almost invariable accompaniment to the symposium, or drinking banquet. The dice were cast from conical beakers, and the highest throw was three sixes, called *Aphrodite,* while the lowest, three aces, was called the dog. Both in Greece

and Rome different modes of counting were in vogue. Roman dice were called *tesserae* from the Greek word for four, indicative of the four sides. The Romans were passionate gamblers, especially in the luxurious days of the empire, and dicing was a favourite form, though it was forbidden except during the Saturnalia. The emperor Augustus wrote in a letter to Suetonius concerning a game that he had played with his friends: "Whoever threw a *dog* or a six paid a *denarius* to the bank for every die, and whoever threw a *Venus* (the highest) won everything." In the houses of the rich the dice-beakers were of carved ivory and the dice of crystal inlaid with gold. Mark Antony wasted his time at Alexandria with dicing, while, according to Suetonius, the emperors Augustus, Nero and Claudius were passionately fond of it, the last named having written a book on the game. Caligula notoriously cheated at the game; Domitian played it, and Commodus set apart special rooms in his palace for it. The emperor Verus, adopted son of Antoninus, is known to have thrown dice whole nights together.

Fashionable society followed the lead of its emperors, and, in spite of the severity of the laws, fortunes were squandered at the dicing-table. Horace derided the youth of the period, who wasted his time amid the dangers of dicing instead of taming his charger and giving himself up to the hardships of the chase. Throwing dice for money was the cause of many special laws in Rome, according to one of which no suit could be brought by a person who allowed gambling in his house, even if he had been cheated or assaulted. Professional gamblers were common, and some of their loaded dice are preserved in museums. The common public-houses were the resorts of gamblers, and an old fresco is extant showing two quarrelling dicers being ejected by the indignant host. That the barbarians were also given to gaming, whether or not they learned it from their Roman conquerors, is proved by Tacitus, who states that the Germans were passionately fond of dicing, so much so, indeed, that, having lost everything, they would even stake their personal liberty. Centuries later, during the middle ages, dicing became the favourite pastime of the knights, and both dicing schools *(scholae deciorum)* and guilds of dicers existed. In France both knights and ladies were given to dicing, which repeated legislation did not abolish. In India and the Far East dice have always been popular and are still.

Dice-boxes have been made in many shapes and of various materials, such as wood, leather, agate, crystal, metal or paper, and many of them contain bars within to ensure a proper agitation of the dice, and thus defeat trickery. Some, formerly used in England, were employed with unmarked dice which were thrown upon a board marked with squares numbered from 1 to 6.

See L. Becq de Fouquières, *Les Jeux des Anciens* (1869); Bolle, *Das Knöcheispiel der Alten* (Wismar, 1886); Stewart Culin, *Chinese Games with Dice* (Philadelphia, 1889); *Korean Games* (Philadelphia, 189;); R. F. Foster, *Encyclopaedia of Indoor Games* (new ed. 1916). *Historie du Canada,* etc., par Gabriel Sagard Theodat (new ed. Paris, 1866, vol. 1, pp. 243–4).

North American Indians are said to have played dice as far back as 1636. In his revelations of the time, Father Brebeuf gives long accounts of the game, the causes for its being played and the excesses in gambling to which it led. Even up to about 1860, the Indians were known to stake all they had, frequently losing all their earthly possessions. Dice or *Craps* was a popular game among the American soldiers in France during the World War, the Afro-Americans possessing a marked fondness for the "bones."

DICENTRA, a genus of perennial herbs of the fumitory family (Fumariaceae), containing 1 j species, natives of Asia and North America, 8 of which occur in the United States and Canada. They are mostly low or stemless plants, a few of which are cultivated for their attractive deeply cut or dissected foliage and handsome irregular flowers. The familiar bleeding-heart (D. *spectabilis)* of the gardens, with showy rose-red, heart-shaped flowers, an inch or more long, is a native of Japan. The eastern bleeding-heart (D. *eximia),* with pink, narrow, heart-shaped flowers, about ¾ in. long, of the Allegheny Mountain region, and the western bleeding-heart (D. *formosa),* with similar rose-purple flowers, of mountain woods from California to British Columbia, are both more or less cultivated. Other noteworthy American species are the Dutchman's breeches *(D. cucullaria),* one of the most attractive wild flowers of eastern North America; the squirrel-corn (D. *canadensis),* of similar range, the small tubers of which resemble grains of Indian corn (maize); and the golden ear-drops (D. *chrysantha),* a smooth, stiff-stemmed plant, 2 ft. to 5 ft. high, with large panicled clusters of yellow flowers, widely distributed in California. *(See* DUTCHMAN'S BREECHES.)

DICETO, RALPH DE (d. c. 1202), dean of St. Paul's, London, and chronicler, is first mentioned in 1152, when he received the archdeaconry of Middlesex. He was probably born between 1120 and 1130; of his parentage and nationality nothing is known. Diceto was selected, in 1166, as the envoy of the English bishops when they protested against the excommunications launched by Becket. About 1180 he became dean of St. Paul's. In this office he distinguished himself by careful management of the estates, by restoring the discipline of the chapter, and by building at his own expense a deanery-house. Diceto's most important historical works, the *Abbreviationes Chronicorum* and the *Ymagines Historiarum,* cover the history of the world from the birth of Christ to the year 1202. The former, which ends in 1147, is a work of learning and industry, but almost entirely based upon extant sources. The latter, beginning as a compilation from Robert de Monte and the letters of Foliot, becomes an original authority about 1172, and a contemporary record about 1181. The *Ymagines* is a valuable authority for the last years of the reign of Henry II. and for the reign of Richard I.

See the introduction to W. Stubbs's edition of the *Historical Works* of Diceto (Rolls ed. 1876, 2 vols.). Diceto's fragmentary Domesday of the capitular estates has been edited by Archdeacon Hale in *The Domesday of St. Paul's,* pp. 109 ff. (Camden Society, 1858).

DICEY, EDWARD (1832–1911), English writer, son of T. E. Dicey of Claybrook Hall, Leicestershire, was born on May 1 j, 1832, and educated at Trinity college, Cambridge, where he took mathematical and classical honours. He visited the United States in 1862, and in 1863 wrote *Six months in the Federal States,* in which he took the part of the North. He was called to the bar in 1875, became a bencher of Gray's Inn in 1896. and was treasurer in 1903–04. He was connected with the *Daily Telegraph* from 1862 onwards as leader writer and then as special correspondent, and after a short spell in 1870 as editor of the *Daily News,* he became editor of the *Observer,* a position which he held for 19 years. Of his many books on foreign affairs perhaps the most important are his *England and Egypt* (1884), *Bzilgaria, the Peasant State* (1895), *The Egypt of the Future* (1907). He died in London on July 7, 1911.

His brother ALBERT VENN DICEY (1835–1922), English jurist, was educated at Balliol college, Oxford, and was called to the bar at the Inner Temple in 1863. He held fellowships successively at Balliol, Trinity and All Souls', and from 1882 to 1909 was Vinerian professor of law. He became Q.C. in 1890. His chief works are the *Introduction to the Study of the Law of the Constitution* (1885; 6th ed. 1902), a standard work on the subject; *England's Case against Home Rule* (1886); *A Digest of the Law of England with Reference to the Conflict of Laws* (1896), and *Lectures on the Relation between Law and Public Opinion in England during the 19th century* (1905). He died on April 7, 1922.

DICHOTOMY, literally a cutting asunder, the technical term for a form of logical division, consisting in the separation of a class into two sub-classes, one of which has and the other has not a certain quality or attribute (Gr. δίχα, apart, τέμνειν, to cut). Men may be thus divided into white men and men who are not white; each of these may be subdivided similarly. On the principle of contradiction this division is both exhaustive and exclusive; there can be no overlapping, and no members of the original genus or the lower groups are omitted. This method of classification, though formally accurate, has slight value in the exact sciences, partly because at every step one of the two groups is merely negatively characterized and may be unreal; it is useful, however, in setting forth clearly the gradual descent from the most inclusive genus (*summum genus*) through species to the lowest class (*infima species),* which is divisible only into individ-

ual persons or things. (*See* DIVISION.) In astronomy the term is used for the aspect of the moon or of a planet when apparently half illuminated, so that its disc has the form of a semicircle.

DICK, ROBERT (1811–1866), Scottish geologist and botanist, was born in Tullibody, Clackmannanshire, the son of an officer of excise. He became a baker and worked at his trade until his death in Thurso on Dec. 24, 1866. He never published anything, but from 1835 onwards, when he first discovered fossils in the Caithness flags, he sent his specimens to Hugh Miller and others. His herbarium, which consisted of about 200 folios of mosses, ferns and flowering plants, is now stored, with many of his fossils, in the museum at Thurso.

See Samuel Smiles, *Robert Dick, Baker of Thurso, Geologist and Botanist* **(1878).**

DICKCISSEL (*Spiza americana*), a common North American bird between the Rockies and the Alleghenies from Minnesota and Western Ontario southwards. It is recognized by its yellow breast, wing-band, sides of throat and eye-streak, and is slightly over 6in. long.

DICKENS, CHARLES JOHN HUFFAM (1812–1870), the most popular and perhaps the greatest of English novelists, was born on Feb. 7, 1812 in Landport, a division of Portsea; in a house in Mile End terrace, Commercial road. The house can be identified and is in some sense a popular shrine or memorial, enabling the sightseer to link up in one journey two of the most romantic national names, associating Dickens with Portsea and Nelson with Portsmouth. But beyond this symbolic and almost legendary local interest, the actual address indicates little more than the drifting and often decaying fortunes of the class and family from which he came. It would be an exaggeration to compare it to Lant street, in the Borough, of which, it will be remembered, "the inhabitants were migratory, disappearing usually towards the verge of quarter-day." But there is the note of something nomadic about the social world to which he belonged. We talk of the solid middle class; he belonged, one might almost say, to the liquid middle class; certainly to the insecure middle class. His father, John Dickens, was a clerk in the Navy-Pay Office, and all through life a man of wavering and unstable status, partly by his misfortunes and partly by his fault. It is said that Dickens sketched him in a lighter spirit as Micawber and in a sadder and more realistic aspect as Dorrit. The contrast between the two men, as well as the two moods, should be a warning against the weakness of taking too literally the idea of Dickensian "originals." The habit has done grave injustice to many people, such as Leigh Hunt; and it may involve a grave injustice to John Dickens; and perhaps an even graver injustice to Mrs. John Dickens, née Elizabeth Barrow, whom a similar rumour reports as the real Mrs. Nickleby. Some may question, not without grief, whether there really could be a real Mrs. Nickleby. But in any case there certainly could not be a man who was both Dorrit and Micawber. The truth is that we shall misunderstand from the beginning the nature of the Dickensian imagination, if we suppose these things to be mechanical portraits in black and white, taken by "the profeel machine," as Mr. Weller said. It is the whole point of Dickens that he took hints from human beings; and turned them, one may say, into superhuman beings. But it is true that John Dickens was of the type that is often shifted from place to place; and this is the chief significance of Charles Dickens's connection with Portsea, or rather of his lack of connection with it. He can only have been two years old when the household moved for a short time to London and then for a longer time to Chatham. It was perhaps lucky that the formative period of his first childhood was also the most fortunate period of his not very fortunate family. The dockyard of Chatham, the towers of Rochester, the gardens and the great roads of Kent remained to him through life as the only normal memory of a nursery and a native soil; his house in later years looked down on the great road from Gads hill and the cathedral tower rose again in his last vision, in the opium dream called "Edwin Drood." Here he had leisure to learn a little from books, who was so soon to learn only from life; first in the stricter sense of school-books, from a Mr. Giles, a Baptist minister in Chatham; and second, and probably with greater profit, from a random heap of old novels that included much of the greatest English literature and even more of the type of literature from which he could learn most; *Roderick Random* and *Robinson Crusoe* and *Tom Jones* and *The Vicar of Wakefield.*

He can hardly have been ten years old when the household was once more upon the march. John Dickens had fallen heavily into debt; he continued the tendency to change his private address; and his next private address was the Debtors' Prison of the Marshalsea. His wife, the mother of eight children of whom Charles was the second; had to encamp desolately in Camden Town and open a dingy sort of "educational establishment." Meanwhile the unfortunate Charles was learning his lessons at a very different sort of educational establishment. After helping his mother in every sort of menial occupation, he was thrown forth to earn his own living by tying and labelling pots of blacking in a blacking warehouse at Old Hungerford Stairs. The blacking was symbolical enough; Dickens never doubted that this piece of his childhood was the darkest period of his life; and he seems indeed to have been in a mood to black himself all over, like the Othello of the Crummles Company. Of his pessimistic period, of the heartrending monotony and ignominy, he has given little more than a bitter abbreviation in *David Copperfield.* But he was storing up much more than bitterness; it is obvious that he had already developed an almost uncanny vigilance and alertness of attention. By the time his servitude came to an end, by his father falling into a legacy as he had fallen into a jail (there was really a touch of Micawber in the way in which things turned up and turned down for him) the boy was no longer a normal boy, let alone a child. He called his wandering parent "the Prodigal Father"; and there was something of the same fantastic family inversion in the very existence of so watchful and critical a son. We are struck at once with an almost malicious maturity of satire; some of the best passages of the prison life of the Pickwicks and the Dorrits occur in private letters about his own early life. He had shared, of course, the improvement in the family condition; which was represented in his case by a period of service as a clerk to a Mr. Blackmore, a Grays Inn solicitor, and afterwards in the equally successful, and much more congenial, occupation of a newspaper reporter and ultimately a Parliamentary reporter. His father had taken up the trade; but his son was already making a mark in it, as reporter to *The True Sun, The Mirror of Parliament* and *The Morning Chronicle.* In all these aspects and attitudes, at this time, he appears as alert, sharp-witted and detached; recalling that sort of metallic brightness which an observer at this period so often saw flash upon his face. It is worthy of note, because certain healthy social emotions which he always championed have somewhat falsified his personality in the eyes of the prigs whom he loved to rap over the head. He was a genuine champion of geniality; but he was not always genial; certainly not only genial. One of his earliest sketches, published not long after this time, was a defence of the Christian festivity of Christmas against the Puritans and the Utilitarians; it was called "Sunday Under Three Heads." All his life he defended valiantly the pleasures of the poor; and insisted that God had given ale and rum, as well as wine, to make glad the heart of man. But all this has clouded his character with fumes of mere conviviality and irresponsibility which were very far from being really characteristic Even in youth, which is the period of irresponsibility, Dickens appears in some ways as highly responsible. He was in sharp reaction against the futility of his family; he was both ambitious and industrious; and there were some who even found him hard. In many moods he had as angry a dislike of the Skimpoles as of the Gradgrinds.

Indeed he had come in more ways than one to the high turning-point of his fortunes. His marriage and his first real literary work can be dated at about the same time. He had already begun to write sketches, chiefly in *The Old Monthly Magazine,* which were in the broadest sense caricatures, of the common objects of the street or the market-place. They were illustrated by Cruikshank; and in these early stages of the story the illustrator is often more important than the author. This was notoriously true of his next

and perhaps his greatest experiment; but it is typical in any case of his time and his time of life. The prose sketches were signed "Boz" and the signature had become a recognized pseudonym when Messrs. Chapman and Hall, the publishers, approached him with the suggestion of a larger scheme. A well known humorous artist of that epoch, Seymour, was to produce a series of plates illustrating the adventures, or misadventures, of the Nimrod Club, a group of amateur sportsmen, destined to dwindle and yet to grow infinitely greater in the single figure of Mr. Nathaniel Winkle. Dickens consented to write the letter-press, which was little more than a running accompaniment like an ornamental border around the drawings; and in that strange fashion, secondary, subordinate and even trivial, first formed itself in the human fancy the epic and pantomime of *Pickwick* (1837). Dickens persuaded the publishers to let the Pickwick Club represent more varied interests or eccentricities, retained Mr. Winkle to represent or misrepresent the original notion of sport; and by that one stroke of independence cut himself free from a stale fashion and started a new artistic adventure and revolution. He gave as one of his reasons the fact that he had no special knowledge of sports or games, and proceeded to drive his argument home triumphantly by his description of the cricket-match at Dingley Dell. And yet that cricket-match alone might illustrate exactly the game which Dickens so gloriously won; and why that wild and ill-instructed batsman has had so many thousand runs and is not out. What did a few mistakes in the description of cricket, or even in the description of real life, matter in a man who could invent that orator at the cricket-dinner, who complimented the defeated eleven by saying, with the gesture of Alexander, "If I were not Dumkins, I would be Luffey; if I were not Podder, I would be Struggles"? Men do not read that sort of thing to learn about cricket, or even about life, but to find something more living than either. There had broken through the entanglements of that trumpery bargain a force of comic genius which swallowed up its own origin and excuses; a wild animal big enough to eat all its direction labels. People forgot about Seymour; forgot about sport; forgot about the Nimrod Club; soon forgot about the Pickwick Club. They forgot all that he forgot and followed whatever he followed; much bigger and wilder game than any aimed at by the mere gun of Mr. Winkle. The track of the story wandered; the tone of the story changed; a servant whom Pickwick found cleaning boots in an inn-yard took the centre of the stage and towered even over Pickwick; Pickwick from being a pompous buffoon became a generous and venerable old English gentleman; and the world still followed that incredible transformation-scene and wishes there were more of it to this day. This was the emergence of Dickens into literature. It had, of course, many secondary effects in life. One was the first and almost the most bitter of his quarrels; Seymour may be excused for having been annoyed at the relations of artist and author being thus turned upside down in a whirlwind; but Seymour was not therefore necessarily justified in saying, as he did say and his widow long continued to say, that Dickens had gained glory from another man's ideas. Nobody, we may well imagine, believes that the oration of Sergeant Buzfuz or the poem of Mrs. Leo Hunter, were Mr. Seymour's ideas. Dickens had an inexhaustible torrent of such ideas; and no man on earth could pretend to have provided them. But it is true that in this quarrel, as in others, some found a touch of sharpness and acid self-defence in Dickens; and he was never without his enemies. His ideal was certainly the leisure and geniality of Pickwick; but he was fighting rather too hard for his own hand and had too much at stake and too pressing a knowledge of poverty to be anything but practical.

As Pickwick was the foundation of his public life, his marriage was naturally the foundation of his private life; and in this also he has been an object of criticism as he was certainly an object of sympathy. Very little good is done by making guesses about a story of which the spiritual balance and proportion were probably never known to more than three or four people. It is sufficiently significant that those who were nearest to it, and who survive to speak or rather to be silent, agree in laying no very heavy blame upon anyone involved One of the principals of the *Morning Chronicle*, George Hogarth, had been so much struck by the "Boz" sketches as to insist on an improvement in the payment of the writer; he introduced Dickens to his family and especially (we may say) to his daughters, with all of whom the young journalist seems to have been on very friendly and even affectionate terms. One of them, Catherine, he married, and certainly married for love; but not perhaps with the sort of love which gives a man a full and serious realization of what he is doing. It is the pathos of the story that in a sense the friendship outlasted the love; for another sister, who understood him better, remained his friend long after his marriage had become a prolonged misunderstanding. All this, however, happened long afterwards; for the moment his marriage may be taken as marking his step into security and success; especially as he was probably stimulated and, as it were, intoxicated, by a romance that brought him into more refined social surroundings than his o n. From that moment he was launched as a popular writer and a power in the world; and he never went back, until he died of popularity thirty years afterwards.

It is notable that his next work was *Oliver Twist* (1838); which might be meant for a contrast to *Pickwick*. If the first trick had succeeded, nobody could accuse the conjurer of trying the same trick twice. He was probably proud of proving his range; but he was certainly courageous in testing his popularity. It is true that Oliver Twist consists of a queer mixture of melodrama and realism; but both the realism and the melodrama are deliberately dark and grim. Nevertheless it is fortunate that with his second book he thus brought into play what may be called his second talent. It is too common to compare his humour with his pathos; for indeed there is no comparison. But there really is a comparison between his humour and his horror; and he really had a talent for a certain sort of horror, which is exactly rendered by the popular phrase of supping on horrors. For there is a sort of lurid conviviality that accompanies the panic; as if the nightmare could accompany and not follow the heavy meal. This suppressed vitality is due to his never for an instant losing the love of life; the love of death, which is despair and pessimism, was meaningless to him till he died. The sort of horror which afterwards conceived the death of Krook is already found in Oliver Twist; as in that intolerable repetition throbbing in the murderer's ears; "will wash out mud-stains, blood-stains" and so on. For the rest, the plot is preposterous and the flashes of fun excellent but few; yet there is another aspect of the book which makes it important in the story of Dickens. It is not only the first of his nightmare novels, but also the first of his social tracts. Something of social protest could be read between the lines of Pickwick in prison; but the prison of Pickwick was very mild compared with the charitable almshouse of Oliver. Dickens is witness, with Hood and Cobbett and many others, that the workhouse was felt by all generous people as something quite unnaturally new and hard and inhuman. It is sometimes said that he killed Bumble; it would be truer to say that, by making Bumble live, he created something by which it will always be possible to kill bureaucracies.

Whether we call the transition from *Pickwick* to *Oliver Twist* a change from comedy to tragedy, or merely a change from farce to melodrama, it is notable that the next act of Dickens is to mix the two in about equal proportions. Having shown how much he can vary, he tries to show how well he can combine. It is worth noting because it explains much of the failure as well as the success of his art as a whole. We may even say that, to the last, this sort of exhibition of power remained his principal weakness. When the critics, like those of *The Quarterly*, called him vulgar, it meant nothing except that the critics themselves were snobbish. There is nothing vulgar about drinking beer or describing the drinking of beer, or enjoying the humours of really humorous people who happen to black boots, like Sam Weller. But there is something just a little vulgar about professing to be a Universal Provider; a man who writes not only something that he wants to write, but anything that anybody wants to read. Anything in his work that can really be called failure is very largely due to this appetite for universal success. There is nothing

wrong about the jester laughing at his own jokes; indeed they must be very poor jokes if even he cannot laugh at them. Dickens, in one of those endless private letters which are almost more entertaining than his published novels, describes himself as "a gentleman with rather long hair and no neckcloth, who writes and grins, as if he thought he was very funny indeed"; and so he was. But when he set out to prove that he was not only very funny, but very pathetic, very tragic, very powerful, he was not always enjoying the sense of power over his work, he was enjoying the sense of power over his audience. He was an admirable actor in private theatricals; and sometimes, unfortunately, they were public theatricals. And on this side of his character he had the proverbial itch of Toole to act Hamlet. When he was rendering the humours of the crowd, he was that rather rare thing, a real democrat. But when he was trying to command the tears and thrills of the crowd, he was something of a demagogue; that is, not one mingling with the crowd, but one trying to dazzle and to drive it. One of the ways in which he displayed this attribute, if not of vulgarity at least of vanity, was in his habit, from this time onwards, of running side by side in the same book about five different stories in about five different styles. It pleased the actor in him to show his versatility and his ease in turning from one to the other. He did not realize clearly enough that in some of the parts he was a first-rate actor and in some a second-rate and in some a fifth-rate actor. He did not remind himself that though he turned to each topic with equal ease, he did not turn to each with equal effect. But, whatever the disadvantages of the universal ambition, it definitely dates from the period of his next book. *Pickwick* has a prevailing tint of gaiety and Oliver *Twist* of gravity, not to say grimness; but with Nicholas *Nickleby* (1839) we have the new method, which is like a pattern of bright and dark stripes. The melodrama is if possible even more melodramatic than in Oliver *Twist;* but what there is of it is equally black and scowling. But the comedy or farce has already displayed the rapid ripening of his real genius in letters. There is no better company in all literature than the strolling company of Mr. Vincent Crummles; though it is to be hoped that in any convivial meeting of it, Miss Snevellicci will remember to invite her incomparable papa. Mr. Mantalini also is one of the great gifts of Dickens to the enduring happiness of humanity. For the rest, it is very difficult to take the serious part of the story seriously. There is precious little difference between the rant and claptrap of the Crummles plays, which Dickens makes fun of, and the rant and claptrap of Ralph Nickleby and Mulberry Hawke which Dickens gravely narrates to us. All that, however, was of little consequence either immediate or permanent. Dickens was not proving that he could write smooth and probable narratives, which many people could do. He was proving that he could create Mantalini and Snevellicci, which nobody could do.

Nevertheless, this pretence of providing for all tastes, which produced the serio-comic novel, is also the explanation of the next stage of his career. There runs or recurs throughout his whole life a certain ambition to preside over a more or less complex or many-sided publication; a large framework for many pictures; a system of tales within tales like the Arabian Nights or the tales of the Tabard. It is the ambition that he afterwards gratified by becoming the editor of two magazines, *Household Words* and All the Year Round. But there is here something of a shadow of the original meaning of the word magazine, in the sense of a shop; and another hint of that excessive desire to keep a shop that sells everything. He had been for a time editor of something of the sort in *Bentley's Miscellany,* but the final form taken by this mild and genial megalomania (if we may so describe it) was the plan which Dickens formed immediately after the success of Nicholas Nickleby. The serial scheme was to be called, "Master Humphrey's Clock," and was to consist of different stories told by a group of friends. With the idea of making them the more friendly he turned some of them into old friends; reintroducing Mr. Pickwick and the two Wellers, though these characters were hardly at their best, the author's mind being already on other things. One of these things was a historical novel, perhaps conceived more in the romantic manner of Scott than the prosaic manner of Smollett, which Dickens generally followed. It was called Barnaby Rudge (1840) and the most interesting part of it perhaps is the business of the Gordon Riots; and the mob that has a madman for its mascot and a penny-dreadful prentice for its comic relief. But there is also a plot as complicated as, though rather clearer than, that of Oliver Twist; a plot that intensely interested the detective mind of Poe. *Barnaby Rudge,* however, is not so directly Dickensian as the romance that preceded or the romance that followed it. The second story, somewhat insecurely wedged into the framework of Master *Humphrey's* Clock, was The Old *Curiosity* Shop (1841), as the opening and some of the references in the story still vaguely attest. The public reception of this story very sharply illustrates what has been said about the double character of his success. On the one side was his true success as a craftsman carving figures of a certain type, generally gargoyles and grotesques. On the other side was his inferior success as a jack-of-all-trades tending only too much to be a cheapjack. As a matter of fact, The Old *Curiosity* Shop contains some of the most attractive and imaginative humour in all his humorous work; there is nothing better anywhere than Mr. Swiveller's imitation of the brigand or Mr. Brass's funeral oration over the dwarf. But in general gossip and association, everything else in the story is swallowed up in the lachrymose subject of Little Nell. There can be no doubt that this unfortunate female had a most unfortunate effect on Dickens's whole conception of his literary function. He was flattered because silly people wrote him letters imploring him not to let Little Nell die; and forgot how many sensible people there were, only hoping that the Marchioness would live for ever. Little Nell was better dead, but she was an unconscionable long time dying; and we cannot altogether acquit Dickens of keeping her lingering in agony as an exhibition of his power. It tended to fix him in that unfortunate attitude, of something between a showman and a magician, which explains almost all the real mistakes of his life.

About this time a very determining event interrupted his purely literary development, his first visit to America. It was destined to have, apart from any other results, a direct effect upon his next book, which was Martin *Chuzzlewit* (1844). There were, of course, many purely practical and personal elements in the criticism which he directed against the western democracy. An unjust copyright law, or one which he at any rate thought very unjust, had enabled Americans to pirate his most popular works; and it would seem that the people he met were, in their breezy way, but little inclined to apologize for the anomaly. But it would be very unjust to Dickens to deny that his sense and sensibility were alike irritated by some real divisions in the international relation. There were things in the American culture, or lack of culture, which he could not be expected to understand but which he might reasonably be expected to dislike. His English law-abiding liberalism would in any case have been startled by a certain streak of ferocity and persecution that there really is in the Americans; just as he might have recoiled from the same fierceness in the Irish or the Italians. But in the Americans it was also connected with something crude and incomplete in the society, and was not softened by tradition or romance. He was also both annoyed and amused at the American habit of uttering solemn idealistic soliloquies and of using rhetoric very rhetorically. But all these impressions are important chiefly as they changed the course of his next important narrative; and illustrated a certain condition or defect of his whole narrative method.

All these early books of Dickens, from Pickwick onward, appeared, it must always be remembered, serially and in separate parts. They were anticipated eagerly like bulletins; and they were often written up to time almost as hastily as newspaper reports. One effect of this method was that it encouraged the novelist in a sort of opportunism and something of a hand to mouth habit of work. And a character that always belonged, in varying degrees, to his novels is first and most sharply illustrated in Martin *Chuzzlewit.* The earlier numbers, though they contained the two superb caricatures called Pecksniff and Mrs. Gamp, had not for some reason been so popular as the caricatures called Pickwick and Miss Squeers. Dickens was already beginning

to show something of that feverish fatigue which was the natural reaction of his fervid industry. He feared that the public was bored with the book; he became perhaps subconsciously a little bored with it himself. He conceived the bold idea of breaking the story in the middle and putting in a purple patch woven from his wild memories of the Yankees. It was completely successful, in the comedy sense; but it is worth noting that Dickens did something curiously Dickensian in thus suddenly sending Martin Chuzzlewit across the sea to America. It is not easy to imagine Thackeray suddenly hurling Pendennis from Mayfair into the middle of Australia; or George Eliot dislodging Felix Holt and flinging him as far as the North Pole. The difference was partly the result of the Dickensian temper and partly of the method of publication. But it will be well to remember it: for there is more than one example of what looks like a positive change of plan in the Dickens stories, made more possible by this early habit of not producing the work of art as a whole. Some have suggested that the degeneration of Boffin was originally meant to be real, and his rather clumsy plot an afterthought: and the same idea has figured in the reconstructions of *Edwin Drood*.

At this point there is a break in the life of Dickens, in more ways than one. It is represented by his decision to live abroad for a time, chiefly on grounds of economy; the last lingering results of the relative failure of *Martin Chuzzlewit*. He took a villa in the neighbourhood of Genoa in 1844; and he and his family, already a fairly large one, settled down there with a certain air of finality that deserved for a time the name of exile. But it is curious to note that the literary work done there has something of the character of an interlude, and indeed of a rather incongruous interlude. For it was in that Italian landscape that he concentrated on a study so very domestic, insular and even cockney as *The Chimes* (1845); and industriously continued the series of short Christmas stories which had recently begun in the very London fog of *A Christmas Carol* (1843). Whatever be the merits or demerits of the *Christmas Carol*, it really is a carol; in the sense of being short and direct and having the same chorus throughout. The same is true in another way of *The Chimes;* and of most things that occupied him in his Italian home. He had not settled down to another long and important book; and it soon became apparent that he had not settled down at all. He returned to London, the landscape which for him was really the most romantic and even historic; and did something so ominously typical of the place and time as almost to seem like tempting Providence. He became the first editor of the *Daily News*, a paper started to maintain those Liberal, if not Radical opinions of which he always shared the confident outlook and the humane simplicity. He did not long remain attached to the editorial chair or even to the metropolis, for this was the most restless period in all his restless life. He immediately went back to Lausanne and immediately wanted to go back to London. It seems probable that this break in his social life corresponded to a break in his artistic liie: which was in a sense just about to begin all over again and begin at the other end. He did indeed write one more full-size novel of the earlier type, *Dombey and Son* (1846–48); but it has very much the character of the winding up of an old business, like the winding up of the Dombey firm at the end of it. It is comic as the earlier books were comic, and no praise can be higher; it is conventional as the earlier plots were conventional, and never really pretended to be anything else; it contains a dying child upon the pattern of Little Nell; it contains a very amusing major much improved from the pattern of Mr. Dowler. But underneath all this easy repetition of the old dexterity and the old clumsiness the mind of the conjurer is already elsewhere. *Dombey and Son* was more successful in a business sense than *Martin Chuzzlewit;* though really less successful in many others. Dickens settled again in England in a more prosperous style; sent his son to Eton and, what was more sensational, took a rest. It was aiter a long holiday at Broadstairs, in easier circumstances more favourable to imaginative growth and a general change of view, that there appeared in 1849 an entirely new novel in an entirely new style.

There is all the difference between the life and adventures of David Copperfield and the life and adventures of Nicholas Nickleby, that there is between the life of Charles Dickens and the life of Amadis of Gaul. The latter is a good or bad romance; the former is a romantic biography, only the more realistic for being romantic. For romance is a very real part of liie and perhaps the most real part of youth. Dickens had turned the telescope round or was looking through the other end of it; looking perhaps into a mirror, looking in any case out of a new window. It was life as he saw it, which was somewhat fantastically; but it was his own life as he knew it, and even as he had lived it. In other words, it is fanciful but it is not fictitious; because not merely invented in the manner of fiction. In Pickwick or Nickleby he had in a sense breathed fresh imaginative life into stock characters, but they were still stage characters; in the new style he may be extravagant, but he is not stagey. That vague glow of exaggeration and glamour which lies over all the opening chapters of *David Copperfield,* which dilates some figures and distorts others, is the genuine sentimentalism and suppressed passion of youth; it is no longer a convention or tradition of caricature. There are men like Steerforth and girls like Dora; they are not as boys see them; but boys do see them so. This passionate autobiography, though it stiffens into greater conventionality at the real period of passion, is really, in the dismally battered phrase, a human document. But something of the new spirit, more subtle and sympathetic but perhaps less purely creative, belongs to all the books written after this date. The next of the novels in point of time was *Bleak House* (1853), a satire chiefly directed against Chancery and the law's delay, but containing some brilliant satire on other things, as on the philanthropic fool whose eyes are in the ends of the earth. But the description of the feverish idleness of Rick has the new note of one for whom a well-meaning young man is no longer merely a "first walking gentleman." After a still more severe phase in *Hard Times* (1854) (historically important as the revolt of a Radical against the economic individualism which was originally identified with Radicalism) he continued the same tendency in *Little Dorrit* (1857), the tone of which is perhaps as sad as anything illustrated by Dickensian humours can be; broke off into an equally serious and more sensational experiment in historical romance in *A Tale of Two Cities* (1859), largely an effect of the influence of Carlyle; and finally reached what was perhaps the height of his new artistic method in a purely artistic sense. He never wrote anything better, considered as literature, than the first chapters of *Great Expectations* (1861). But there is, after all, something about Dickens that prevents the critic from being ever quite content with criticizing his work as literature. Something larger seems involved, which is not literature, but life; and yet the very opposite of a mere recorded way of living. And he who remembers Pickwick and Pecksniff, creatures like Puck or Pan, may sometimes wonder whether the work had not most life when it was least lifelike.

The stretch of stories following on *David Copperfield,* from 1850 onwards, fall into the framework of another of Dickens's editorial schemes; and this time a much more successful one. He began to edit *Household Words,* in which some, though not all of his later tales appeared; and continued to do so until he exchanged it in 1859 for another and similar periodical called *All the Year Round*. Just as we find him about this time induced at last to settle down finally in a comparatively comfortable editorial chair, so we find him at last settled more comfortably in a domicile that could really be called a home, when, returning at last to his beloved Rochester district on the great road of Kent, he set up his house at Gads hill. It is sad to realize that this material domestic settlement had followed on a moral unsettlement; and the separation of Dickens and his wife, by agreement (of which the little that needs saying has already been said) had already taken place in 1856. But indeed, even apart from that tragedy, it is typical of Dickens that his repose could never be taken as final. His life was destined to end in a whirlwind of an entirely new type of activity; which none the less never interrupted that creative work which was the indwelling excitement of all his days. He wrote one more complete novel, *Our Mutual*

Friend (1864–65), and it is more complete than most. Indeed it is one of the best though not one of the most Dickensian of the Dickens novels. He then turned his restless talent to something in the nature of a detective story, more in the manner of his friend Wilkie Collins; the sort of story which begins by asking a question; in this case a question about the secret and the sequel of the fate of the hero, Edwin Drood. The question will never be answered; for it was cut short by the only thing that could be more dramatic than the death of the hero; the death of the author. Charles Dickens was dead.

He died very suddenly, dropping from his chair at the dinner-table, in the year 1870 at the comparatively early age of fifty-eight. A death so abrupt, and essentially so premature, could not but raise doubts about the wisdom of his impetuous industry and debates almost as varied as those round the secret of Edwin Drood. But without exaggerating any one of the elements that contributed to it, we may note that the very last phase of his life was a new phase; and was almost entirely filled with his new activity in giving public readings from his works. He had gone to America once more in the November of 1867, with this particular purpose; and his campaign of public speaking in this style was truly American in its scope and scale. If he had indeed been unjust to America as a writer, it is curious that he should have reached his final popularity and perhaps his final collapse, in a character so supremely American. Differences exist about how far he exaggerated the function or how far his biographer exaggerated the danger; but his own letters, ragged with insomnia and impatience, full of desperate fatigue and more desperate courage, are alone enough to show that he was playing a very dangerous game for a man approaching sixty. But it is certainly true, as is alleged on the other side, that this was nothing new in the general conduct of Dickens; that he had long ago begun burning the candle at both ends; and there have been few men, in the matter of natural endowments, with so great and glorious a candle to burn.

He was buried in the Poet's Corner of Westminster Abbey; and new and vulgar as many critics had called his work, he was far more of a poet than many who were buried there as poets. He left a will commending his soul to God, and to the mercy of Jesus Christ, and leaving his works to the judgment of posterity; and in both respects the action was symbolic and will remain significant in history. Intellectually limited as he was by the rather cheap and cheery negations of an age of commercial rationalism, he had never been a bitter secularist or anti-clerical; he was at heart traditional and was drawn much more towards Anglican than Puritan Christianity; and his greatest work may yet prove to be the perpetuation of the joyful mystery of Christmas. On the other side, he has suffered and may suffer again the changes in the mere fashions of criticism; but his work was creative, it added something to life; and it is hard to believe that something so added will ever be entirely taken away. The defects of his work are glaring; they hardly need to be detected; they need the less to be emphasized because, unfortunately, he always emphasized them himself. It may be a fault, it is certainly a fact, that he enjoyed writing his worst work as much as his best.

The charge of exaggeration is itself exaggerated. It is also, which is much more important, merely repeated mechanically, without any consideration of its true meaning. Dickens did exaggerate; but his exaggeration was purely Dickensian. In this sense his very vulgarity had the quality of distinction. Mere overstatement, to say that a tall man is ten feet high, to say that a frosty morning froze Niagara; this is something relatively easy to do, though sometimes very cleverly done, especially by Americans. But the distinction of Dickens can be stated even in the common charge against him. He is said to have turned men into monsters of humour or horror, whereas the men were really commonplace and conventional persons in shops and offices. If any critic depreciates the Dickensian method as mere overstatement, the answer is obvious: let him take some of these commonplace people and overstate them. He will soon discover that he has not the vaguest notion of what to overstate. He will soon realise that it is not a simple matter of mere exaggeration, in the sense of mere extension. It is not a matter of making a man a little taller or a morning a little colder; the challenge to imagination is not whether he can exaggerate, but whether he can find anything worth exaggerating. Now the genius of Dickens consisted in seeing in somebody, whom others might call merely prosaic, the germ of a sort of prose poem. There was in this or that man's attitude, or affectation, or habit of thought, something which only needed a touch of exaggeration to be a charming fantasy or a dramatic contradiction. The books of Dickens are in fact full of bores; of bores who do not bore us, merely because they did not bore him. We have all of us heard a hundred times the tiresome trick of public speakers, of asking themselves rhetorical questions which they do not want answered. Any of us might have heard a fat Dissenting minister doing it at a tea-party and thankfully forgotten all about him. But Dickens seized on the fallacy and turned it into a fantasy; into Mr. Chadband's demands to know why he could not fly, or his wild and beautiful apologue about the elephant and the eel. We talk of the power of drawing people out; and that is the nearest parallel to the power of Dickens. He drew reels and reels of highly coloured caricature out of an ordinary person, as dazzlingly as a conjurer draws reels and reels of highly coloured paper out of an ordinary hat. But if anybody thinks the conjuring-trick is easy to perform, let him try it with the next ordinary person he sees. The exaggeration is always the logical extension of something that really exists; but genius appears, first in seeing that it exists, and second in seeing that it will bear to be thus exaggerated. That is something totally different from giving a man a long nose; it is the delicate surgical separation or extension of a living nerve. It is carrying a ludicrous train of thought further than the actual thinker carries it; but it requires a little thinking. It is making fools more gloriously foolish than they can be in this vale of tears; and it is not every fool who can do it.

There were other reasons for the injustice in the particular case of Dickens. Though his characters often were caricatures, they were not such wild caricatures as was supposed by those who had never met such characters. And the critics had never met the characters; because the critics did not live in the common life of the English people; and Dickens did. England was a much more amusing and horrible place than it appeared to the sort of man who wrote reviews in The Quarterly; and, in spite of all scientific progress or social reform, it is still. The poverty and anarchy of Dickens's early life had stuffed his memory with strange things and people never to be discovered in Tennysonian country houses or even Thackerayan drawing-rooms. Poverty makes strange bedfellows, the same sort of bedfellows whom Mr. Pickwick fought for the recovery of his nightcap. In the vivid phrase, he did indeed live in Queer street and was acquainted with very queer fish. And it is something of an irony that his tragedy was the justification of his farce. He not only learnt in suffering what he taught in song, but what he reridered, so to speak, in a comic song.

It is also true, however, that he caught many of these queer fish because he liked fishing in such troubled waters. A good example of this combination of opportunity and eccentricity is to be found in his affection for travelling showmen and vagabond entertainments of all sorts, especially those that exhibited giants and dwarfs and such monstrosities. Some might see in this truth a sort of travesty of all his travesties. It would be easy to suggest a psychological theory, by which all his art tended to the antics of the abnormal; it would also be entirely false. It would be much truer to say that Dickens created so many wild and fantastic caricatures because he was himself commonplace. He never identifies himself with anything abnormal, in the more modern manner. In his travelling show, the Giant always falls far short of being a Superman. And though he was tempted only too easily to an obvious pathos, there was never anything particularly pathetic about his dwarfs. His fun is more robust; and even, in that sense, more callous. The truth is that Dickens's attitude to the abnormal has been misunderstood owing to the modern misunderstanding of the idea of the normal. He was in many ways a wild satirist, but still a satirist; and satire is founded on sanity. He had his real

Cockney limitations. But his moderation was not a limitation but a liberty; for it allowed him to hit out in all directions. It was precisely because he had an ordinary and sensible view of life that he could measure the full madness both of Gradgrind's greed or Micawber's improvidence. It was because he was what we call commonplace that Dombey appeared to him so stiff or Jellaby so slovenly. In a later generation a real person often assumed such an unreal pose and lost the power of merely laughing at it; as, for example, when Oscar Wilde said seriously all that Skimpole had said absurdly. The Victorian commonsense was not a complete commonsense; and Dickens did suffer from having a narrower culture than Swift or Rabelais. But he did not suffer from being sensible; it was even more from his sense than his sensibility, it was from a sort of inspired irritation and impatience of good sense, that he was able to give us so radiant a fairyland of fools.

His literary work produced of course much more than a literary effect. He was the last great poet, in the true sense of maker, who made something for the people and was in the highest sense popular. He still gives his name, not to a literary clique, but to a league or fellowship numbering thousands all over the world. In this connection it is often noted that he achieved many things even considered as a practical political and social reformer. He let light into dark corners, like the dens of dirt and brutality often called schools, especially in Yorkshire; he probably had much to do with making the professional nurse a duller but more reliable person than Mrs. Gamp; it is likely enough that his vivid descriptions, assisted by the whole trend of the time, hastened the extinction of ordinary imprisonment for debt and clarified much of the original chaos of Chancery. But precisely because this has often been said, it will be well not to say it too often. It has the effect of making his satire appear much more superficial and utilitarian than it really was; for the great satirist is concerned with things not so easily destroyed. We do more honour to Dickens in noting the evils he did not destroy than those he did. The eager worship of a man merely wealthy, however dull and trivial, which appears in the affair of Merdle, has by no means disappeared from our own more recent affairs. The pompous old Barnacle and the agreeable young Barnacle are still almost as much alive as in Dickens's day. The sweeping away of a genuine gentry, in the person of Mr. Twemlow, on the tide of a new plutocracy, represented by Mr. Veneering, has gone much further than in Dickens's day. But this makes Dickens's satire the more rather than the less valuable to posterity. The other mood, which pictures all such abuses as things of the past, tends not to reform but only too much to repose; and to the perpetuation of a rather snobbish and paltry version of the Dickensian tradition. In that spirit we may hear to this day a Stiltstalking telling the House of Commons that Stiltstalkings have perished before the march of progress; or in the law courts a Buzfuz quoting Buzfuz and jeering at himself as an extinct monster.

The future of the fame of Dfckens is no part of the Dickens record and a very dubious part of the Dickens criticism. Some have suggested that his glory will fade as new fashions succeed those he satirized; others have said, at least equally reasonably, that the difference itself fades when all the fashions have grown old; and that Aristophanes and Cervantes have outlived their descendants as well as their contemporaries. But there can be no question of the importance of Dickens as a human event in history; a sort of conflagration and transfiguration in the very heart of what is called the conventional Victorian era; a naked flame of mere natural genius, breaking out in a man without culture, without tradition, without help from historic religions or philosophies or from the great foreign schools; and revealing a light that never was on sea or land, if only in the long fantastic shadows that it threw from common things. (G. K. C.)

DICKINSON, EMILY (1830–1886), American poet, was born on Dec. 10, 1830, at Amherst, Mass., where her grandfather, Samuel Fowler Dickinson, had been one of the founders of the town, church and college. Her father, Edward Dickinson, was a lawyer and treasurer of the college; her mother, Emily Norcross Dickinson, a model New England housewife who "did not care for thought." In all her heredity, according to her biographer, traced back nine generations in America and 13 in England, there is nothing to explain her genius—nor to confute it. As a child she went to public school, went berrying and chestnutting, learned the household arts and crafts. As a girl she made a herbarium, embroidered the usual book-marks, and wrote sentimental letters in the verbose style of the time. In the fall of 1847 she entered South Hadley seminary, where she studied chemistry, physiology and English composition, and where she was "cramped, curbed and repressed in every natural desire or impulse." She left the seminary in 1848, re-entered Amherst academy for a while, and then, except for the lectures of the resident and visiting professors and her own reading, her education was finished. The winter of 1853 she spent in Washington, where her father was serving two terms in Congress, and on a visit to Philadelphia in the spring experienced an unhappy love affair—she firmly renouncing the man because she would not "wreck another woman's life." This possibly influenced the change from an apparently normal, witty young woman, to an increasingly mystical poet. By 1862 she had practically withdrawn from the world, venturing out of her father's house only at dusk to attend to her plants, but remaining always the "ecstatic daredevil, shy paradox," to her brother's family and to a very few intellectual friends. She died at Amherst on May 16, 1886. During her lifetime she had allowed only three or four of her poems to be published. In 1892 her friend, Col. Thomas Wentworth Higginson, published a small collection with a success almost unparalleled in American literature, but it was not until 1924 that her complete poems and her *Letters* were published, making her work generally accessible. Her poetry has been described as suggestive of William Blake in its "flashes of wholly original and profound insight into nature and life." She herself has been described as the epigrammatical Walt Whitman, and she remains a strange and entirely original genius, "defiant of outward form, sometimes obscure, at times inscrutable," but more often with a perfection in the mating of word and idea that has rarely been achieved.

DICKINSON, JOHN (1732–1808), American statesman and pamphleteer, was born in Talbot county, (Md.) Nov. 8, 1732. He removed with his father to Kent county (Del.), in 1740, studied under private tutors, read law, and, in 1753, entered the Middle Temple, London. Returning to America in 1757, he practised law in Philadelphia and started, in 1760, his long public career. Since Pennsylvania and Delaware were under the same proprietor and the same governor, he acted in the same capacity at various times for both colonies—member of the assembly, president of the executive council, and representative in the Continental Congress. He was sent from Pennsylvania to the Stamp Act Congress (1765), served for a time as private, and later as brigadier-general, in the Delaware militia, and represented Delaware at the Annapolis Convention of 1786 and the Federal Constitutional Convention of 1787. He was most important, however, as the "Penman of the Revolution." Scarcely any other writer of the day presented arguments so numerous so timely and so popular. He drafted the "Declaration of Rights" of the Stamp Act Congress, the "Petition to the King" and the "Address to the Inhabitants of Quebec" of the Congress of 1774, the second "Petition to the Ring" and "Articles of Confederation" of the Second Congress. Most influential of all, however,

were The Letters of a Farmer in *Pennsylvania* written in 1767–68 in condemnation of the Townsend Acts of 1767, in which he rejected speculative natural rights theories, and appealed to the common sense of the people through simple legal arguments. By opposing the Declaration of Independence, he lost his popularity and never entirely regained it. As the representative of a small state, he championed the principle of state equality in the Constitutional Convention; but he was one of the first to advocate the compromise, which was finally adopted, providing for equal representation in one house and proportional representation in the other. After the adjournment of the convention he defended its work in a series of forceful letters signed "Fabius." Largely through his influence Delaware and Pennsylvania were the first two states to ratify the Constitution. Dickinson's interests were not exclusively political. He helped to found Dickinson college (named in his honour) at Carlisle (Pa.), in 1783, was the first president of its board of trustees, and was for many years its benefactor. He died Feb. 14, 1808, and was buried in the Friends' burial ground in Wilmington (Del.).

See C. J. Stillé, "Life and Times of John Dickinson" *(Memoirs of the Historical Society of Pennsylvania,* vol. xiii., Philadelphia, 1891); P. L. Ford, editor, "The Writings of John Dickinson," *(ibid.,* vol. xiv., 1895); and R. R. Richards, "The Life and Character of John Dickinson" (Delaware Historical Society, *Papers,* No. 30).

DICKINSON, a city in the south-western part of North Dakota, U.S.A., on the Heart river and Federal highway 10, at an altitude of 2,430ft.; the county seat of Stark county. It is a division point on the Northern Pacific Railway, which has repair shops here. The population in 1940 federal census was 5,839. Dickinson is the shipping-point for a farming and grazing region; and has foundry and machine shops, brick works, flour-mills, lignite coal mines and a plant for the manufacture of briquettes. One of the State normal schools is located here, and the State agricultural college has established here a branch of the agricultural experiment station. The city was settled about 1882 and incorporated in 1900. It was named after W. S. Dickinson of Malone, N.Y., an enthusiastic advocate of the country west of the Missouri.

DICKSEE, SIR FRANCIS BERNARD (1853–1928), English painter, born in London on Nov. 27, 1853, son of Thomas Dicksee, artist, was President of the Royal Academy in 1924. He belongs to the older academic school, whoseaim was to express poetic sentiments in a realistic pictorial form. His pictures are painted with extreme sensibility and his execution is always skilful and competent. Two of his principal works were bought under the Chantrey bequest for the Tate gallery: "Harmony" (1877) and "The Two Crowns" (1900). He died Oct. 17, 1928.

DICKSON, SIR ALEXANDER (1777–1840), British artillerist, passed out of the Royal Military academy into the Royal Artillery in 1794. He served in Minorca (1798), at Malta (1800), in the Montevideo expedition (1806–7), and in 1809 accompanied Howorth to the Peninsula as brigade-major of the artillery. In the end he became commander of the whole of the artillery of the allied army, and though still only a substantive captain in the British service he had under his orders some 8,000 men. At Vitoria, the battle of the Pyrenees and Toulouse he directed the movements of the artillery. He served on the artillery staff at Quatre Bras and Waterloo, and subsequently commanded the British battering train at the sieges of the French fortresses left behind the advancing allies. He died, a major-general and G.C.B., in 1840. He was an early fellow of the Royal Geographical Society.

His diaries kept in the Peninsula were the main source of information used in Duncan's *History of the Royal Artillery.*

DICKSON, SIR JAMES ROBERT (1832–1901), Australian statesman, was born in Plymouth on Nov. 30, 1832. In 1854 he emigrated to Victoria, but after some years spent in that colony and in New South Wales, he settled in 1862 in Queensland, where he was connected with the Royal Bank of Queensland. He entered the Queensland house of assembly in 1872, and became minister of works (1876), treasurer (1876–1879, and 1883–1887), acting premier (1884), but resigned in 1887 on the question of taxing land. In 1889 he retired from business, and spent three years in Europe before resuming political life. He fought for the introduction of Polynesian labour on the Queensland sugar plantations at the general election of 1892, and was elected to the house of assembly in that year and again at the elections of 1893 and 1896. He became secretary for railways in 1897, minister for home affairsin 1898, represented Queensland in the federal council of Australia in 1896 and at the postal conference at Hobart in 1898, and in 1898 became premier. His energies were now devoted to the formation of an Australian commonwealth. He secured the reference of the question to a plebiscite, the result of which justified his anticipations. He resigned the premiership in Nov. 1899, but in the ministry of Robert Philp, formed in the next month, he was reappointed to the offices of chief secretary and vice-president of the executive council which he had combined with the office of premier. He represented Queensland in 1900 at the conference held in London to consider the question of Australian unity, and on his return was appointed minister of defence in the first government of the Australian commonwealth. He died at Sydney on Jan. 10, 1901, in the midst of the festivities attending the inauguration of the new state.

DICKSON CITY, a borough of Lackawanna county, Pa., U.S.A., in the anthracite region. It is on the Lackawanna river, 5m. N.E. of Scranton, and is served by the Delaware and Hudson, the Erie, and the New York, Ontario and Western railways. The population in 1930 was 12,395 and in 1940, 11,548.

DICOTYLEDONS, in botany, the larger of the two great classes of angiosperms (*q.v.*), embracing most of the common flower-bearing plants. The name expresses the most universal character of the class, the importance of which was first noticed by John Ray namely, the presence of a pair of seed-leaves or cotyledons, in the plantlet or embryo contained in the seed. The embryo is generally surrounded by a larger or smaller amount of foodstuff (endosperm) which serves to nourish it in its development to form a seedling when the seed germinates; frequently, however, the whole of the nourishment for future use is stored in the cotyledons themselves, which then become thick and fleshy. In germination of the seed the rudimentary root at the distal end of the hypocotyl develops the primary root; this is usually followed by growth of the hypocotyl which carries the cotyledons above ground, where they become the first green leaves of the plant. Lying between the bases of the cotyledons and terminating the axis of the plant is the first stem bud (epicotyl of the embryo).

Size and manner of growth of the adult plant show variety, from the small herb lasting for one season only, to the forest tree living for centuries. The arrangement of the conducting tissue in the Stem is characteristic; a transverse section of the very young stem shows a number of distinct conducting strands—vascular bundles—arranged in a ring round the pith; these soon become united to form a closed ring of phloem and wood, separated by a layer of cambium. In perennials the stem shows a regular increase in thickness each year by the addition of a new ring of wood outside the old one—for details of structure see PLANTS: Anatomy. A similar growth occurs in the root. This increase in the diameter of stem and root is correlated with the increase in leaf-area each season, due to the continued production of new leaf-bearing branches. A characteristic of the class is afforded by the complicated network formed by the leaf-veins,—well seen in a skeleton leaf, from which the soft parts have been removed by maceration. The parts of the flower are most frequently arranged in fives, or multiples of fives; for instance, a common arrangement is as follows,—five sepals, succeeded by five petals, ten stamens in two sets of five, and five or fewer carpels. An arrangement in fours is less frequent, while the arrangement in threes, so common in monocotyledons, is rare in dicotyledons. In some families the parts are numerous, chiefly in the case of the stamens and the carpels, as in the buttercup and other members of the Ranunculaceae and in the Rosaceae. The characters of the flower and fruit are described in the articles FLOWER; FRUIT and SEED.

DICTATING MACHINES: see OFFICE APPLIANCES.

DICTATOR, in modern usage, a ruler enjoying extra-constitutional power, in ancient times, an extraordinary magistrate

in the Roman commonwealth (from the Lat. *dictare,* frequentative of *dicere*). The earlier official title was *magister populi,* which may mean "head of the host" as opposed to his subordinate, the *magister equitum,* who was "head of the cavalry." Emphasis was thus laid on the military aspect of the dictatorship, and, in fact, the office seems to have been instituted for the purpose of meeting a military crisis too serious for the annual consuls with their divided command. The repression of civil discord was one of the motives for the institution of a dictatorship. Such is the view expressed by Cicero in the *De legibus* (iii., *3, 9*) and by the emperor Claudius in his extant *Oratio* (i., 28). This function of the office is attested by the internal history of Rome. In the crisis of the agitation at the time of the Licinian laws (367 B.C) a dictator was appointed, and in 314 B.C. a dictator was created for purposes of criminal jurisdiction *(quaestionibus exercendis).* The dictator appointed to meet the dangers of war, sedition, or crime was described as "the administrative dictator" *(rei gerundae causa).* For minor purposes we find dictators appointed to hold the elections, to celebrate games, to establish festivals, and to drive the nail into the temple of Jupiter—an act of natural magic which was believed to avert pestilence. These dictators retired from office as soon as their function was completed. The "administrative dictator" held office for six months.

The powers of a dictator were a temporary revival of those of the kings, with some limitations. He was never concerned with civil jurisdiction. His military authority was confined to Italy; and his power of life and death was limited. By the *lex Valeria* of 300 B.C. he was made subject to the right of criminal appeal (*provocatio*) within the limits of the city. But all the magistrates of the people were regarded as his subordinates. The dictator was nominated by one of the consuls. But the senate claimed authority over the magistrates, and suggested not only the nomination but also the name of the nominee. After the nomination, the imperium of the dictator was confirmed by a *lex curiata (see* COMITIA). To emphasize the superiority of this imperium, the dictator might be preceded by twenty-four lictors, and, at least in the earlier period of the office, these lictors bore the axes, the symbol of life and death, within the city walls.

The first dictator is said to have been created in 501 B.C.; the last of the "administrative" dictators belongs to the year 216 B.C. The epoch of the Second Punic War was marked by experiments with the office, such as the election of Q. Fabius Maximus by the people, and the co-dictatorship of M. Minucius. The emergency office of the early and middle republic has little in common with the dictatorship as revised by Sulla and by Caesar. Sulla's dictatorship was the form taken by a provisional government. He was created "for the establishment of the republic." Caesar's renewed dictatorships created a temporary monarchy, whatever may have been his wishes as to its permanency. Ostensibly to prevent its further use for such a purpose, M. Antonius in 44 B.C. carried a law abolishing the dictatorship.

DICTIONARY, a book containing a collection of the words of a language, arranged alphabetically or in some other definite order, with explanations of their meanings and often with other information concerning them, in the same or another language. Besides the meanings, there may be given, and usually is in the larger dictionaries; much additional information, such as pronunciation, etymology, illustrative quotations, synonyms and idiomatic phrases. The word is used also, especially when accompanied by a qualifying term, to mean a word-book or lexicon of the terms used in some subject or some part or form of a language, as a dictionary of music, of law, of etymology or of a dialecl. A geographical dictionary is generally called a *gazetteer.* An *index* is an alphabetical arrangement of selected words of some book or author with references to the place where they occur. When under each word the phrases containing it are added together with references, the work is called a *concordarice.* When the words are few in number, being only a small part of those belonging to the language or subject, or when they are given with little or no explanation, the work is called a *vocabulary.* When the work is merely a list of explanations of the difficult words and expressions in some particular subject or writing, it is called a *glossary.*

The first dictionaries explained only the words, or certain words, of a language. But as the names of things, persons and places are words and often require explanation even more than other classes of words, dictionaries gave increasing attention to things, persons and places. In time, books were devoted to them alone, sometimes limited to special subjects, and these books have so multiplied that they now rival in number and variety dictionaries of words or of languages, and often far surpass them in bulk. There are dictionaries of biography and history, real and fictitious, general and special, relating to men of all countries, characters and professions; the English *Dictionary of National Biography* is an outstanding instance of one form of these. There are dictionaries of bibliography, relating to all books, or to those of some particular kind or country; dictionaries of geography *(gazetteers)* of the whole world, of particular countries, of small districts, of towns and of villages; dictionaries of philosophy; of the Bible; of mathematics; of zoology; of botany; of chemistry, geology and mineralogy; of architecture, painting and music; of medicine; and of very many other subjects. And lastly, there are dictionaries of the arts and sciences, and their comprehensive offspring, *encyclopaedias* (*q.v.*), which include in themselves every branch of knowledge. This article is confined to an account of those dictionaries which are primarily word-books. This is practically the most convenient distinction from the subject-book or encyclopaedia. The two characters are often combined in one work; thus the *Century Dictionary* has encyclopaedic features, while the present edition of the *Encyclopedia Britannica,* embodies dictionary features. The tendency of general dictionaries as they become larger is to unite in themselves all the peculiar features of special dictionaries.

English lexicography began with attempts to explain Latin words by giving English equivalents. In the *Promptorium Parvulorum,* compiled in 1440 by Galfridus Grammaticus, a Dominican monk of Lynn Episcopi, in Norfolk, and printed by Pynson in 1499, English words were explained in Latin. The first dictionaries of English words were not meant to be complete, but were limited to "hard" words, typically those derived from foreign languages, words in common use being presumed to require no attention; thus Edward Phillips, nephew of John Milton, described his *New World of English Words* (1658) as "containing the interpretation of such hard words as are derived from other languages." The first approach to success in collecting and defining all words in good usage in the English language was made by Nathan Bailey in his folio dictionary published in 1730.

The lexicographer was long expected to register only words deemed "good" for literary use, with their "proper" meanings; it was his duty to sift and refine, to decide authoritatively questions of usage, and thus to fix the language as completely as might be possible within the limits determined by the literary taste of his time. Thus the Accademia della Crusca, founded near the close of the 16th century, was established for the purpose of purifying in this way the Italian tongue, and in 1613 the *T'ocabolorio degli Accademici della Crusca,* long the standard of that language, was published. The Académie Française, the first edition of whose dictionary appeared in 1694, had a similar origin. In England the idea of constructing a dictionary upon this principle arose during the second quarter of the 18th century. It was imagined by men of letters—among them Addison, Swift and Pope—that the English language had then attained such perfection that further improvement was hardly possible, and it was feared that if it were not fixed by lexicographic authority deterioration would soon begin. Since there was no English "academy," it was necessary that the task should be entrusted to some one whose learning would command respect, and the man who was chosen was Samuel Johnson. His dictionary, the first edition of which, in two folio volumes, appeared in 1755, was for its quotations and pithy

definitions admirable, but it was inadequate even as a standard of the then existing literary usage. Johnson himself did not long entertain the belief that the natural development of a language can be arrested in that or in any other way. His work was, however, generally accepted as a final authority, and the ideas upon which it was founded dominated English lexicography for more than a century.

The first effective protest in England against the supremacy of this literary view was made by Dean (later Archbishop) Trench, in a paper on "Some Deficiencies in Existing English Dictionaries" read before the Philological Society in 1857. "A dictionary," he said, "according to that idea of it which seems to me alone capable of being logically maintained, is an *inventory of the language;* much more, but this primarily. . . . It is no task of the maker of it to select the *good* words of the language. . . The business which he has undertaken is to collect and arrange *all* words, whether good or bad, whether they commend themselves to his judgment or otherwise. . . *He is an historian of* (the language), *not a critic."* In other words, for the literary view of the chief end of the general dictionary should be substituted the philological or scientific, In Germany this substitution had already been effected by Jacob and Wilhelm Grimm in their dictionary of the German language, the first volume of which appeared in 1854. In brief, then, the philologist's view is that the general dictionary of a language should be a record of all the words — current or obsolete — of that language, with all their meanings and uses, but should not attempt to be, except secondarily or indirectly, a guide to "good" usage.

This theoretical requirement must, of course, be modified considerably in practice. The date at which a modern language is to be regarded by the lexicographer as "beginning" must, as a rule, be somewhat arbitrarily chosen; while considerable portions of its earlier vocabulary cannot be recovered because of the incompleteness of the literary record. Moreover, not even the most complete dictionary can include all the words which the records — earlier and later — actually contain. Many words, that is to say, which are found in the literature of a language cannot be regarded as, for lexicographic purposes, belonging to that language; while many more may or may not be held to belong to it, according to the judgment of the lexicographer. This is especially true of English.

Another important principle upon which Trench insisted, and which also expresses a requirement of modern scientific philology, is that the dictionary shall be not merely a record, but also an *historical* record of words and their uses. From the literary point of view the most important thing is present usage. To that alone the idea of a "standard" has any application. Dictionaries of the older type, therefore, usually make the common or "proper" meaning of a word the starting point of its definition and arrange its other senses in a logical or accidental order, commonly ignoring the historical order in which the various meanings arose. The philologist, however, for whom the growth, or progressive alteration, of a language is a fact of central importance, regards no record of a language as complete which does not exhibit this growth in its successive stages. He desires to know when and where each word, and each form and sense of it, are first found in the language; if the word or sense is obsolete, when it died; and any other fact that throws light upon its history and implications. He requires, accordingly, of the lexicographer that, having ascertained these data, he shall make them the foundation of his exposition — in particular, of the arrangement of his definition, that sense being placed first which appeared first in time.

The adoption of the historical principle involves a further noteworthy modification of older methods, namely, an important extension of the use of quotations. To Dr. Johnson belongs the credit of showing how useful, when properly chosen, quotations may be, not only in corroborating the lexicographer's statements, but also in revealing special shades of meaning or variations of use which his definitions cannot well express. No part of Johnson's work is more valuable than this. The idea was more fully developed and applied by Dr. Charles Richardson. whose *New Dictionary of the English Language . . . Illustrated by Quotations from the Best Authors* (1837) still remains a most valuable collection of literary illustrations. Until recently, however, with few exceptions lexicographers have employed quotations chiefly for the ends just mentioned — as instances of use or as illustrations of correct usage — with scarcely any recognition of their value as historical evidence; and they have taken them almost exclusively from the works of the "best" authors. But since the data upon which conclusions with regard to the history of a word can be based must be collected chiefly from the literature of the language, it is evident that, in so far as the lexicographer is required to furnish evidence for an historical inference, a quotation is the best form in which he can give it. A further rule of scholarly lexicography, accordingly, is that quotations should be used, primarily, as historical evidence, and that the history of words and meanings should be exhibited by means of them. The earliest instance of use that can be found, and (if the word or sense is obsolete) the latest, are as a rule to be given; while in the case of an important word or sense, instances taken from successive periods of its currency also should be cited. Moreover, a quotation which contains an important bit of historical evidence must be used, whether its source is "good," from the literary point of view, or not — whether it is a classic of the language or from a daily newspaper; though where choice is possible, preference should, of course, be given to quotations from the best writers.

Lastly, a much more important place in the scheme of the dictionary is now assigned to the *etymology* of words. This may be attributed, in part, to the rapid development of etymology as a science, and to the greater abundance of trustworthy data; but chiefly to the fact that from the historical point of view the connection between that section of the biography of a word which lies within the language and its antecedent history has become more vital and interesting. Etymology, in other words, is essentially the history of the *form* of a word up to the time when it became a part of the language, and is, in a measure, an extension of the history of the development of the word in the language. Moreover, it is the only means by which the exact relations of allied words can be ascertained, and the separation of words of the same form but of diverse origin (homonyms) can be effected, and is thus, for the dictionary, the foundation of all *family history* and correct *genealogy*. Related to the etymology of words are the changes in their form which may have occurred while they have been in use as parts of the language — modifications of their pronunciation, changes resulting from analogy, and the like.

The ideal thus developed is primarily that of the general dictionary of the purely philological type. The encyclopaedic type of dictionary, although it has often been criticized as hybrid — as a mixture of two things which should be kept distinct — is entirely defensible. Between the dictionary and the encyclopaedia the dividing line cannot be sharply drawn. There are words the meaning of which cannot be explained fully without some description of things, and, on the other hand, the description of things and processes often involves the definition of names. The large vocabulary of the general dictionary makes it possible to present certain kinds of encyclopaedic matter with a degree of fulness and a convenience of arrangement which are possible in no single work of any other class. In fact, it may be said that if the encyclopaedic dictionary did not exist it would have to be invented: that its justification is its indispensableness. Not the least of its advantages is that it makes legitimate the use of diagrams and pictorial illustrations, which are valuable aids to definition.

On its practical side the advance in lexicography has consisted in the elaboration of methods long in use rather than in the invention of new ones. The only way to collect the data upon which the vocabulary, the definitions and the history are to be based is, of course, to search for them in the written monuments of the language. But the wider scope and special aims of the new lexicography demand that the investigation shall be vastly more comprehensive, systematic and precise. It is necessary, in brief, that, as far as may be possible, records of every kind and of every period shall be examined systematically, in order that all the words, and senses and forms of words, which have existed may be found, and that enough excerpts to cover all the essential facts

shall be made. The books, pamphlets, journals, newspapers, documents and so on which must thus be searched will be numbered by thousands, and the quotations selected may (as in the case of the Oxford *New English Dictionary)* be counted by millions. This task is beyond the powers of any one man, even though he be a Johnson, a LittrC or a Grimm, and it is now assigned to a corps of readers whose number is limited only by the ability of the editor to profit by such assistance. The modern method of editing the material thus accumulated — the actual work of compilation — also is characterized by the application of the principle of co-operation. Johnson boasted that his dictionary was written with but little assistance from the learned, and the same was in large measure true of that of LittrC. Such attempts on the part of one man, with a few assistants, to write practically the whole of a general dictionary are no longer possible, not merely because of the vast labour necessitated by modern aims, but more especially because the immense development of the vocabularies of the special sciences, arts and technology renders indispensable the assistance, in the work of definition, of persons who are expert in their intricacies. The tendency, accordingly, has been to enlarge greatly the editorial staff, scores of sub-editors and contributors being now employed where a dozen or fewer were formerly sufficient. In other words, the making of a dictionary has become a co-operative enterprise, to the success of which workers in all the fields of knowledge contribute.

The most complete exemplification of these principles and methods is the Oxford *New English Dictionary, on historical principles, founded mainly on the materials collected by the Philological Society.* This monumental work originated in the suggestion of Trench, in 1857, that an attempt should be made, under the direction of the Philological Society, to complete the vocabulary of existing dictionaries and to supply the historical information which they lacked. The suggestion was adopted, considerable material was collected, and Mr. Herbert Coleridge was appointed general editor. He died in 1861, and was succeeded by Dr. F. J. Furnivall. Little was done, however, beyond the collection of about 2,000,000 quotations, until in 1878 the expense of printing and publishing the proposed dictionary was assumed by the delegates of the Oxford University Press, and the editorship was entrusted to Dr. (afterwards Sir) J. A. H. Murray. As the historical point of beginning, the middle of the 12th century was selected, all words that were obsolete at that date being excluded, though the history of words that were current both before and after that date is given in its entirety; and it was decided that the search for quotations — which, according to the original design, was to cover the entire literature down to the beginning of the 16th century and as much of the subsequent literature (especially the works of the more important writers and works on special subjects) as might be possible-:should be made more thorough. More than 800 readers, in all parts of the world, offered their aid; and when the preface to the first volume appeared in 1888, the editor was able to announce that the readers had increased to 1,300 and that 3,500,000 quotations, taken from the writings of more than 5,000 authors, had already been amassed. The whole work was planned to be completed in ten large volumes, each issued first in smaller parts. The first part was issued in 1884, and the dictionary, in ten full volumes or twenty half-volumes, was completed in 1928. The historical method of exposition, particularly by quotations, is applied in the Oxford *New English Dictionary,* if not in all cases with entire success, yet, on the whole, with a regularity and a precision which leave little to be desired. Special features of the book are the completeness with which variations of orthography (with dates) are given; the fullness and scientific excellence of the etymologies, which abound in new information and correction of old errors; the phonetic precision with which the present (British) pronunciation is indicated; and the elaborate subdivision of meanings. The definitions as a whole are marked by a high degree of accuracy, though in a certain number of cases (not explicable by the dates of the volumes) the meanings are not so full as one would expect. Work of such magnitude and quality is possible, practically, only when the editor of the dictionary can command not merely the aid of a very large number of scholars and men of science, but their gratuitous aid. In this the Oxford *New English Dictionary* was singularly fortunate. The conditions under which it originated, and its aim, interested scholars everywhere and led them to contribute their knowledge and time. The long list of names of such helpers in Sir J. A. H. Murray's preface is in curious contrast with their absence from Dr. Johnson's and the few which are given in that of LittrC. Dr. Murray's chief collaborators and successors were Dr. Henry Bradley, Dr. William A. Craigie and Mr. Charles T. Onions. Of the dictionary as a whole it may be said that it is one of the greatest achievements of modem scholarship and research.

In the *Deutsches Worterbuch* of Jacob and Wilhelm Grimm the scientific spirit, as was said above, first found expression in general lexicography. The desirability of a complete inventory and investigation of German words was recognized by Leibnitz and by various 18th century scholars, but the plan and methods of the Grimms were the direct product of the then new scientific philology. Their design, in brief, was to give an exhaustive account of the words of the literary language (New High German) from about the end of the 15th century, including their earlier etymological and later history, with references to important dialectal words and forms; and to illustrate their use and history abundantly by quotations. The first volume appeared in 1854. Jacob Grimm (died 1863) edited the first, second (with his brother, who died in 1859) and third volumes and a part of the fourth; the others have been edited by various distinguished scholars.

These general principles lie also at the foundation of the scholarly *Dictionnaire de la langue française* of *E.* LittrC, though they are there carried out less systematically and less completely. In the arrangement of the definitions the first place is given to the most primitive meaning of the word instead of to the most common one, as in the dictionary of the Academy; but the other meanings follow in an order that is often logical rather than historical. Quotations also are frequently used merely as literary illustrations, or are omitted entirely; in the special paragraphs on the history of words before the 16th century, however, they are put to a strictly historical use. This dictionary — perhaps the greatest ever compiled by one man — was published in 1863–72.

In the making of all these great dictionaries the needs of the general public as well as those of scholars were kept in view. But the type to which the general dictionary designed for popular use has tended more and more to conform is the *encyclopaedic.* This combination of lexicon and encyclopaedia is exhibited in an extreme form in the *Grand dictionnaire universal du XIX siècle* of Pierre Larousse. Besides common words and their definitions, it contains a great many proper names, with a correspondingly large number of biographical, geographical, historical and other articles, the connection of which with the strictly lexicographical part is purely mechanical. Its great utility makes it a model in many respects. Fifteen volumes were published (1866–76), and supplements were brought out later. The *Nouveau Larousse illustré* started publication in 1901, and was completed in seven volumes in 1904. This was not an abridgment or a fresh edition of the *Grand Dictionnaire* of Pierre Larousse, but a distinct publication, as is also the *Larousse Universel* in two volumes (1923).

The notable work of this class in English is the *Century Dictionary,* an American product, edited by Professor W. D. Whitney, and published in 1889–91 in six volumes, containing 7,046 pages (large quarto). It conforms to the philological mode in giving with great fullness the older as well as the present vocabulary of the language, and in the completeness of its etymologies; but it does not attempt to give the full history of every word within the language. Among its other more noteworthy characteristics are the inclusion of a great number of modern scientific and technical words, and the abundance of its quotations. The quotations are for the most part provided with references, but they are not dated. The *Century's* great merits are the excellent enumeration of meanings and the accuracy of its explanations. In the application of the encyclopaedic method the *Century* is conservative, restricting, for the most part, the encyclopaedic matter to descriptive and other details which may legitimately be added to the definitions. Its pictorial illustrations are very numerous

and well executed. In the manner of its compilation it is a good example of modern co-operative dictionary-making, being the joint product of a number of specialists.

No account of the dictionary would be complete that did not mention its educational influence in America. From the appearance of the *American Dictionary of the English Language* by Noah Webster, in 1828, the dictionary has served in America, in offices, schools and homes, as a working tool for masses of people with a common interest in understanding and using their mother tongue. The American dictionary, typically in one large volume, is, then, not primarily for a literary class, as Dr. Johnson's dictionary was, and is not primarily, like the Oxford dictionary, a contribution to linguistic scholarship. It gives citations, since, as Voltaire said, a dictionary without them is a skeleton; but it does not necessarily retain obsolete spelling in citations or use space in dating them and in giving precise references to edition and page. It seeks to register the forms in which words are currently written and printed, the pronunciations that are acceptable and the recognized meanings. Its compactness, considering its comprehensiveness, is attained by technique in editing and typography. In addition to the *New International Dictionary*, which continues with honourable distinction the work begun by Noah Webster, an outstanding dictionary of this type is the *Standard Dictionary* (1893 *seqq.*).

DICTUM DE OMNI ET NULLO. This is the name of the alleged Aristotelian principle of deductive inference. There are various formulations of it. That given by Crackenthorpe is perhaps as near to Aristotle's meaning as any: *Quidquid affirmatur (sive negatur) universaliter de aliquo, idem affirmatur (sive negatur) etiam de omni de quo illud praedicatur.* The more usual and concise form is, *Quod de aliquo omni praedicatur, praedicatur etiam de qualibet eius* parte—"What is predicated of any whole is predicated of any part of it." If "whole" be taken to mean "a kind" (or "class" in the sense of a "kind" or "type," *see* CLASS), then the *dictum* may be said to express the principle, that is, the form or spirit, of *deductive* inference. It is invariably treated as formulating the principle of *syllogistic* inference; but this is not quite correct, as it does not apply to syllogisms composed of singular terms, and, on the other hand, it applies to the immediate inference of a particular or singular proposition from a general proposition as much as to deductive syllogisms.

See H. W. *B.* Joseph, *Introduction to Logic* (1916); *A.* Wolf, *Essentials of Logic* (1926).

DICTYONEMA. A genus of important fossils composed of a network of filaments radiating from a base of cell-bearing branches, their structure being similar to *Fenestella. (See* also GRAPTOLITES.) It is characteristic of the uppermost Cambrian in Europe and America and in Silurian formation. *Dictyonema* is also the name of a genus of lichens (*q.v.*).

DICTYS CRETENSIS, of Cnossus in Crete, the supposed companion of Idomeneus during the Trojan War, and author of a diary of its events. The ms. of this work, written in Phoenician characters was translated into Greek by the order of Nero. In the 4th century A.D. a certain Lucius Septimius brought out *Dictys Cretensis Ephemeris belli Troiani,* which professed to be a Latin translation of the Greek version. Possibly the Latin Ephemeris was the work of Septimius himself. Its chief interest lies in the fact that (with Dares Phrygius's *De excidio Troiae)* it was the source from which the Homeric legends were introduced into the romantic literature of the middle ages.

BIBLIOGRAPHY.—Best edition by F. Meister (1873), with short but useful introduction and index of Latinity; *see* also G. Korting, *Diktys und Dares* (1874), with concise bibliography; E. Collilieux, *Etude sur Dictys de Crète et Darès de Phrygie* (1887), with bibliography; F. Colagrosso, "Ditte Cretese" in *Atti della r. Accademia di Archeologia* (Naples, 1897, vol. 18, pt. ii. 2); N. E. Griffin, *Dares and Dictys, Introduction to the Study of the Medieval Versions of the Story of Troy* (1907).

DICUIL (*fl.* 825), Irish monk, grammarian and geographer. His *De mensura orbis terrae,* finished in 825, contains the earliest notice of a European discovery of and settlement in Iceland and the most definite Western reference to the old fresh-water canal between the Nile and the Red sea, blocked up in 767. In 795 Irish hermits had visited Iceland, where they marvelled at the perpetual day of midsummer. Relics of their settlements were found by the permanent Scandinavian colonists of Iceland in the 9th century. Of the old Egyptian fresh-water canal Dicuil learnt from one "brother Fidelis," probably another Irish monk, who, on his way to Jerusalem, sailed along the "Nile" into the Red sea—passing on his way the "Barns of Joseph" or Pyramids of Giza, which are well described. Dicuil's reading was wide; he quotes from, or refers to, 30 Greek and Latin writers, the patristic St. Isidore and Orosius, and his contemporary the Irish poet Sedulius; he professes to utilize the alleged surveys of the Roman world executed by order of Julius Caesar, Augustus and Theodosius (whether Theodosius the Great or Theodosius II. is uncertain).

A short astronomical treatise written between A.D. 814 and 816 and dedicated to Louis le Debonnaire, the Frankish king in whose kingdom Dicuil was teaching, has been edited by Mario Esposito in the *Proceedings of the Royal Irish Academy,* vol. xxvi. s. C. (1907). Editions of the *De Mensura* were made by C. A. Walckenaer (Paris, 1907), A. Letronne (Paris, 1814) and G. Parthey (Berlin, 1870, best as to text). *See* also C. R. Beazley, *Dawn* of *Modern Geography,* vol. i. (1897).

DIDA, a bush population of the French Ivory Coast between the Bandama river and the Rio Fresco. Their language is related to Bete.

See Delafosse, *Vocabulaires comparatifs* (1904).

DIDACHĒ, THE, or *Teaching of the (twelve) Apostles.* This early Christian document is one of the most important discoveries of the second half of the 19th century. There are several references to it in Eusebius and elsewhere, and by applying to these the methods of comparative criticism a rough reconstruction of its contents had been obtained. But in 1875 Bryennios discovered it in the Patriarchal Library at Constantinople, in the ms. which also contains I. and II. Clement.

The Didachē, as we now have it in the Greek, falls into two marked divisions: *(a)* a book of moral precepts, opening with the words, "There are two ways"; (b) a manual of church ordinances, linked on to the foregoing by the words, "Having first said all these things, baptize," etc. Each of these must be considered separately before we approach the question of the locality and date of the whole book in its present form.

The author of the complete work, as we now have it, has modified an earlier document entitled *The Two Ways,* which may have been a Jewish manual carried over into the use of the Christian Church. Near the beginning he has inserted a considerable section containing, among other matter, passages from the Sermon on the Mount, in which the language of St. Matthew's Gospel is blended with that of St. Luke's. He has also added at the close a few sentences, beginning, "If thou canst not bear (the whole yoke of the Lord), bear what thou canst" (vi. 2); and among minor changes he has introduced, in dealing with confession, reference to "the church" (iv. 14).

The second part of the *Teaching* might be called a church directory. It consists of precepts relating to church life, which are couched in the second person plural; whereas *The Two Ways* uses throughout the second person singular. It appears to be a composite work. (1) First (vii. 1–xi. 2) is a short sacramental manual intended for the use of local elders or presbyters, though such are not named, for they were not yet a distinctive order or clergy. This section was probably added to *The Two Ways* before the addition of the remainder. It orders baptism in the threefold name, and adds directions as to the manner of baptism and preparation for it. Then follows the Lord's Prayer, almost exactly as in St. Matthew, with a brief doxology—"for Thine is the power and the glory for ever." This is to be said three times a day. Next come three eucharistic prayers, the language of which is clearly marked off from that of the rest of the book, and shows parallels with the diction of St. John's Gospel. As in Ignatius and other early writers, the eucharist, a real meal (x. 1) of a family character, is regarded as producing immortality *(cf.* "spiritual food and drink and eternal life"). None are to partake of it save those who have been "baptized in the name of the Lord" (an expression which is of interest in a document which prescribes the threefold

formula). The "prophets" are not to be confined to these forms, but may "give thanks as much as they will." This appears to show that a "prophet," if present, would naturally preside over the eucharist. (2) The next section (xi. 3–xiii.) deals with the ministry of spiritual gifts as exercised by "apostles," "prophets" and "teachers." An apostle is to be 'received as the Lord"; but he must follow the Gospel precepts, stay but one or two days, and take no money, but only bread enough for a day's journey. Here we have that wider use of the term "apostle" to which Lightfoot had already drawn attention. A prophet, on the contrary, may settle if he chooses, and in that case he is to receive tithes and first-fruits; "for they are your high priests." If he be once approved as a true prophet, his words and acts are not to be criticized; for this is the sin that shall not be forgiven. (3) Next comes a section (xiv., xv.) reflecting a somewhat later development concerning fixed services and ministry; the desire for a stated service, and the need of regular provision for it, is leading to a new order of things. The eucharist is to be celebrated every Lord's Day, and preceded by confession of sins: "appoint therefore unto yourselves bishops and deacons, worthy of the Lord, men meek and uncovetous, and true and approved; for they also minister unto you the ministration of the prophets and teachers." This is an arrangement recommended by one who has tried it, and he reassures the old-fashioned believer who clings to the less formal régime (and whose protest was voiced in the Montanist movement), that there will be no spiritual loss under the new system. The book closes (chap. xvi.) with exhortations to steadfastness in the last days, at the coming of the "world-deceiver" or Antichrist, which will precede the coming of the Lord. This section is perhaps the actual utterance of a Christian prophet, and may be of earlier origin than the two preceding sections.

It will now be clear that indications of the locality and date of the present *Teaching* must be sought for only in the second part, and in the Christian interpolations in the first part. We have no ground for thinking that the second part ever existed independently as a separate book. The whole work was in the hands of the writer of the seventh book of the *Apostolic Constitutions* (*q.v.*), who embodies almost every sentence of it, interspersing it with passages of Scripture, and modifying the precepts of the second part to suit a later (4th-century) stage of church development; this writer was also the interpolator of the Epistles of Ignatius, and belonged to the Syrian Church. The *Apostolic Church Order* has several passages closely parallel to *The Two Ways;* but the only parallel to the second part of the *Teaching* is in a quotation from one of the eucharistic prayers. The anti-Jewish tone of the second part suggests the neighbourhood of Jews, from whom the Christians were to be sharply distinguished. Either Egypt or Syria would satisfy this condition, and in favour of Syria is the fact that the presbyterate there was to a late date regarded as a rank rather than an office. But all that we can safely say as to locality is that the community here represented seems to have been out of touch with the larger centres of Christian life.

This last consideration helps us in discussing the question of date. For such an isolated community may have preserved primitive customs for some time after they had generally disappeared. Certainly the stage of development is an early one, as is shown, *e.g.,* by the prominence of prophets, and the need that was felt for the vindication of the position of the bishops and deacons (there is no mention at all of presbyters); moreover, there is no reference to a canon of Scripture (though the written Gospel is expressly mentioned) or to a creed. On the other hand the "apostles" of the second part are obviously not "the twelve apostles" of the title; and the prophets seem in some instances to have proved unworthy of their high position. The ministry of enthusiasm which they represent is about to give way to the ministry of office, a transition which is reflected in the New Testament in the 3rd Epistle of John. Three of the Gospels have clearly been for some time in circulation; St. Matthew's is used several times, and there are phrases which occur only in St. Luke's, while St. John's Gospel lies behind the eucharistic prayers which the writer has embodied in his work. There are no indications of any form of doctrinal heresy as needing rebuke; the warnings against false teaching are quite general. While the first part must be dated before the Epistle of Barnabas, *i.e.,* before A.D. 90, it seems wisest not to place the complete work much earlier than A.D. 120, and there are passages which may well be later,.

BIBLIOGRAPHY.—A large literature has sprung up round *The Didachē* since 1884. Harnack's edition in *Texte und Untersuchungen* vol. ii. (1884) is indispensable to the student; and his discussions in *Geschichte der altchristlichen Literatur* give clear summaries of his work. Other editions of the text are those of F. X. Funk, *Patres Apostolici,* vol. i. (Tubingen, 1901); H. Lietzmann (Bonn, 1903; with Latin version). Dr. C. Taylor in 1886 drew attention to some important parallels in Jewish literature; his edition contains an English translation. Dr. Rendel Harris published in 1887 a complete facsimile, and gathered a great store of patristic illustration. Text and translation will also be found in Lightfoot's *Apostolic Fathers* (shorter edition). The fullest critical treatment in English is by Dr. Vernon Bartlet in the extra volume of Hastings's *Dictionary of the Bible;* the most complete commentary on the text is by P. Drems in Hennecke's *Handbuch zu den N.T. Apocryphen* (1904). The most convenient edition with text and translation is that of Kirsopp Lake, *The Apostolic Fathers,* vol. i. (the Loeb Classical Library).

DIDACTIC **POETRY,** that form of verse the aim of which is less to excite the hearer by passion or move him by pathos than to instruct his mind and improve his morals. The Greek word *διδακτικός* signifies apt for teaching, and poetry of the class under discussion approaches us with the arts and graces of a schoolmaster. Modern criticism is inclined to exclude the term "didactic poetry" from our nomenclature, as a phrase absurd in itself and indeed obsolete. But in earlier times, in the absence of all written books, this was the easiest way in which information could be made attractive to the ear and be retained by the memory.

In the prehistoric dawn of Greek civilization there was a great body of verse occupied entirely with increasing the knowledge of citizens in useful branches of art and observation; these were the beginnings of didactic poetry, and we class them together under the dim name of Hesiod. The *Works and Days,* which passes as the direct masterpiece of Hesiod (*q.v.*), may be taken as the type of all the poetry which has had education as its aim. In somewhat later times, as the Greek nation became better supplied with intellectual appliances, the stream of didactic poetry flowed more and more closely in one, and that a theological, channel. The great poem of Parmenides On *Nature* and those of Empedocles exist only in fragments, but enough remains to show that these poets carried on the didactic method in mythology. Cleostratus of Tenedos wrote an astronomical poem in the 6th century. and Periander a medical one in the 4th; but didactic poetry did not flourish again in Greece until the 3rd century, when Aratus. in the Alexandrian age, wrote his famous *Phenomena,* a poem about things seen in the heavens.

By far the greatest didactic Latin poet known to us is Lucretius, who composed, in the 1st century before Christ, his magnificent *De rerum natura.* By universal consent, this is the noblest didactic poem in the literature of the world. It was intended to instruct mankind in the interpretation and in the working of the system of philosophy revealed by Epicurus. What gave the poem of Lucretius its extraordinary interest, and what has prolonged and even increased its vitality, was the imaginative and illustrative insight of the author, piercing and lighting up the recesses of human experience. On a lower intellectual level, but of a still greater technical excellence, was the *Georgics* of Virgil, *a* poem on the processes of agriculture, published about 30 B.C. The brilliant execution of this famous work has justly made it the type and unapproachable standard of all poetry which desires to impart useful information in the guise of exquisite literature. In the rest of surviving Latin didactic poetry the influence and the imitation of Virgil and Lucretius are manifest. Manilius produced a fine *Astronomica* towards the close of the reign of Augustus. Columella, regretting that Virgil had omitted to sing of gardens, composed a smooth poem on horticulture. Natural philosophy inspired Lucilius junior, of whom a didactic poem on Etna survives. Long afterwards, under Diocletian, a poet of Carthage, Nemesianus, wrote in the manner of Virgil the *Cynegetica,* a poem on hunting with dogs, which has had numerous imitations in later European literatures.

In Anglo-Saxon and early English poetic literature, and espe-

cially in the religious part of it, an element of didacticism is not to be overlooked. The first English poem, however, which we can in any reasonable way compare with the classic works of which we have been speaking is the *Hundreth Good Pointes* of *Husbandrie*, published in 1557 by Thomas Tusser; these humble Georgics aimed at a practical description of the whole art of English farming. In the early part of the 17th century one or two writers appeared who were as didactic as the age would permit them to be, Samuel Daniel with his philosophy, Fulke Greville (Lord Brooke) with his "treatises" of war and monarchy. After the Restoration, as the lyrical element rapidly died out of English poetry, there was more and more room left for educational rhetoric in verse. The poems about prosody, founded upon Horace and signed by John Sheffield, 3rd earl of Mulgrave (1648–1721), and Lord Roscommon, were among the earliest purely didactic verse-studies in English. John Philips deserves a certain pre-eminence, as his poem called *Cyder*, in 1706, set the fashion, which lasted all down the 18th century, of writing precisely in verse about definite branches of industry or employment. None of the greater poets of the age of Anne quite succumbed to the practice, but there is a very distinct flavour of the purely didactic about a great deal of the verse of Pope and Gray. In such productions as Gilbert West's (1703–56) *Education*, Dyer's *Fleece*, and Somerville's *Chase*, technical information is put forward as the central aim of the poet. In 1748 Gray began, though he failed to finish, a didactic poem on *The Alliance of Education and Government*. Didactic poems were discredited by the publication of *The Sugar-Cane* (1764), a long verse-treatise about the cultivation of sugar by negroes in the West Indies, by James Grainger (1721–66). Whether so great a writer as Cowper is to be counted among the didactic poets is a question on which readers of *The Task* may be divided; this poem belongs rather to the class of descriptive poetry, but a strong didactic tendency is visible in parts of it. Perhaps the latest frankly educational poem which enjoyed a great popularity was *The Course of Time* by Robert Pollok (1798–1827), in which a system of Calvinistic divinity is laid down in the pomp of blank verse. This kind of literature had already been exposed, and discouraged, by the teaching of Wordsworth, who had insisted on the imperative necessity of charging all poetry with imagination and passion. Oddly enough, *The Excursion* of Wordsworth himself is perhaps the most didactic poem of the 19th century, but it must be acknowledged that his influence, in this direction, was saner than his practice.

The history of didactic poetry in France repeats, in great measure, but in drearier language, that of England. Boileau, like Pope, but with a more definite purpose as a teacher, offered instruction in his *Art poétique* and in his *Epistles*. But his doctrine was always literary, not purely educational. At the beginning of the 18th century the younger Racine (1692–1763) wrote sermons in verse, and at the close of it the Abbé Delille (1738–1813) tried to imitate Virgil in poems about horticulture.

During the century which preceded the Romantic revival of poetry in Germany didactic verse was cultivated in that country on the lines of imitation of the French, but with a greater dryness and on a lower level of utility. Modern German literature began with Martin Opitz (1597–1639) and the Silesian School, who were in their essence rhetorical and educational, and who gave their tone to German verse. Albrecht von Haller (1708–77) brought a very considerable intellectual force to bear on his huge poems, *The Origin of Evil*, which was theological, and *The Alps* (1729), botanical and topographical. Johann Peter Uz (1720–96) wrote a *Theodicée*, which was very popular, and not without dignity. Johann Jacob Dusch (1725–87) undertook to put *The Sciences* into the eight books of a great didactic poem. Tiedge (1752–1840) was the last of the school; in a once-famous *Urania* he sang of God and Immortality and Liberty. These German pieces were the most unswervingly didactic that any modern European literature has produced. There was hardly the pretence of introducing into them descriptions of natural beauty, as the English poets did, or of grace and wit like the French.

DIDEROT, DENIS (1713–1784), French man of letters and encyclopaedist, was born at Langres on Oct. 5, 1713. He was educated by the Jesuits, and then threw himself into the vagabond life of a bookseller's hack in Paris. An imprudent marriage (1743) did not better his position. His wife, Anne Toinette Champion, was a devout Catholic, but her piety did not restrain a narrow and fretful temper, and Diderot's domestic life was irregular and unhappy. He sought consolation, first with a Madame Puisieux, and then with Sophie Voland, to whom he was constant for the rest of her life. His letters to her are among the most graphic of all the pictures that we have of the daily life of the *philosophes* who dined once a week at the baron D'Holbach's, to listen to the wild sallies and the inspiring declamations of Diderot.

Diderot earned a little by doing various translations, among these being one of Shaftesbury's *Inquiry Concerning Virtue and Merit* (1745), with some original notes of his own. He then composed a volume of stories, the *Bijoux indiscrets* (1748), of which he afterwards repented. From tales Diderot went back to the more congenial region of philosophy. Between the morning of Good Friday and the evening of Easter Monday he wrote the *Pensées philosophiques* (1746), and he presently added a short complementary essay on the sufficiency of natural religion. In these he pressed the ordinary rationalistic objections to a supernatural revelation. In 1747 he wrote the *Promenade du sceptique*. Diderot's next piece was his famous *Lettre sur les aveugles* (1749). The immediate object of this short but pithy writing was to show the dependence of men's ideas on their five senses. It considers the case of the intellect deprived of the aid of one of the senses; and in a second piece, published afterwards, Diderot considered the case of a similar deprivation in the deaf and dumb. The *Lettre sur les sourds et muets*, however, is substantially a digressive examination of some points in aesthetics. The philosophic significance of the two essays is in the advance they make towards the principle of relativity. But what interested the militant philosophers of that day was an episodic application of the principle of relativity to the master-conception of God. What makes the *Lettre sur les aveugles* interesting is its presentation, in a distinct though undigested form, of the modern theory of variability, and of survival by superior adaptation. It is worth noticing, too, as an illustration of the comprehensive freedom with which Diderot felt his way round any subject he approached, that in this theoretic essay he suggests the possibility of teaching the blind to read through the sense of touch. The speculation of the *Lettre sur les aveugles* was too hardy for the authorities, and he was thrown into the prison of Vincennes, where he spent three months; on his release he entered on the gigantic undertaking of his life.

A MONUMENTAL WORK

The Encyclopaedia. — The bookseller Lebreton had suggested to him the publication of a translation into French of Ephraim Chambers's *Cyclopaedia*, undertaken in the first instance by an Englishman, John Mills, and a German, Gottfried Sellius (for particulars *see* ENCYCLOPAEDIA). Diderot accepted the proposal, but in his busy and pregnant intelligence the scheme became transformed. He persuaded the bookselier to enter upon a new work, which should collect under one roof all the active writers, all the new ideas, all the new knowledge, that were then moving the cultivated class to its depths, but still were comparatively ineffectual by reason of their dispersion. His enthusiasm infected the publishers; D'Alembert was persuaded to become Diderot's colleague; the requisite permission was procured from the Government; and in 1; 51 the first volume was given to the world. The last of the letterpress was issued in 1765, but it was 1772 before the subscribers received the final volumes of the plates. These 20 years were to Diderot years not merely of incessant drudgery, but of harassing persecution, of sufferings from the cabals of enemies, and of injury from the desertion of friends. The ecclesiastical party detested the *Encyclopaedia*, in which they saw a rising stronghold for their philosophic enemies. By 1757 they could endure the sight no longer. To any one who turns over the pages of these redoubtable volumes now, it seems surprising that their doctrines should have stirred such portentous alarm. There is no atheism, no overt attack on any of the cardinal mysteries of the faith, no direct denunciation even of the notorious abuses of the

church. Yet the atmosphere of the book may well have been displeasing to authorities who had not yet learnt to encounter the modern spirit on equal terms. The *Encyclopaedia* takes for granted the justice of religious tolerance and speculative freedom. It asserts in distinct tones the democratic doctrine that it is the common people in a nation whose lot ought to be the main concern of the nation's Government. From beginning to end it is one unbroken process of exaltation of scientific knowledge on the one hand, and pacific industry on the other. All these things were odious to the old governing classes of France; their spirit was absolutist, ecclesiastical and military. Perhaps the most alarming thought of all was the current belief that the *Encyclopaedia* was the work of an organized band of conspirators against society, and that a pestilent doctrine was now made truly formidable by the confederation of its preachers into an open league. When the seventh volume appeared, it contained an article on "Geneva," written by D'Alembert. The writer contrived a panegyric on the pastors of Geneva, of which every word was a stinging reproach to the abbés and prelates of Versailles. At the same moment Helvétius's book, *L'Esprit,* appeared, and gave a still more profound shock to the ecclesiastical party. In 1759 the *Encyclopaedia* was formally suppressed.

The decree, however, did not arrest the continuance of the work: it went on, but with its difficulties increased by the necessity of being clandestine. D'Alembert, wearied of shifts and indignities, withdrew from the enterprise. Other powerful colleagues, Turgot among them, declined to contribute further. Diderot was left to bring the task to an end as he best could. For seven years he laboured like a slave at the oar. He wrote several hundred articles, some of them very slight, but many of them most laborious, comprehensive and ample. He spent his days in the workshops, mastering the processes of manufactures, and his nights in reproducing on paper what he had learnt during the day. And he was incessantly harrassed all the time by alarms of a descent from the police. At the last moment, when his immense work was just drawing to an end, he discovered that the bookseller had struck out from the proof sheets, after they had left Diderot's hands, all passages that he chose to think too hardy. The monument to which Diderot had given the labour of 20 long and oppressive years was irreparably mutilated and defaced. It is calculated that the average annual salary received by Diderot for his share in the *Encyclopaedia* was about £120 sterling. "And then to think," said Voltaire, "that an army contractor makes £800 in a day!"

Other Works.—Although the *Encyclopaedia* was Diderot's monumental work, he is the author of a shower of dispersed pieces that sowed nearly every field of intellectual interest with new and fruitful ideas. He wrote plays—Le *Fils naturel* (1757), and *Le Pbre de famille* (1758), which he accompanied by essays on dramatic poetry, including especially the *Paradoxe sur le comkdien,* in which he announced the principles of a new drama—the serious, domestic, bourgeois drama of real life, in opposition to the stilted conventions of the classic French stage. Diderot's lessons and example gave a decisive bias to the dramatic taste of Lessing, whose plays and *Hamburgische Dramaturgie* (1768) mark an epoch in dramatic history. Diderot's most intimate friend was Grimm, who wrote news-letters to various high personages in Germany, reporting what was going on in the world of art and literature in Paris. Diderot helped his friend at one time and another between 1759 and 1779, by writing for him an account of the annual exhibitions of paintings. These *Salons* are among the most readable of all pieces of art criticism. They have a freshness, a reality, a life, which take their readers into a different world from the dry and conceited pedantries of the ordinary virtuoso.

DIDEROT'S VERSATILITY

Diderot's interest in human nature expressed itself in didactic and sympathetic form; in two, however, of the most remarkable of all his pieces, it is not sympathetic, but ironical. *Jacques le fataliste* (written in 1773, but not published until 1796) is in manner an imitation of *Tristram Shandy* and *The Sentimental Journey. Le Neveu de Rameau* is a far superior performance. Its intention has been matter of dispute; whether it was designed to be merely a satire on contemporary manners, or a reduction of the theory of self-interest to an absurdity, or the application of an ironical clincher to the ethics of ordinary convention, or a mere setting for a discussion about music, or a vigorous dramatic sketch of a parasite and a human original. There is no dispute as to its curious literary flavour, its mixed qualities of pungency, bitterness, pity and, in places, unflinching shamelessness. Goethe's translation (1805) was the first introduction ,of *Le Neveu de Rameau* to the European public. After executing it, he gave back the original French manuscript to Schiller, from whom he had it. No authentic French copy of it appeared until 1823.

It would take several pages merely to contain the list of Diderot's miscellaneous pieces, from an infinitely graceful trifle like the *Regrets sur ma vieille robe de chambre* up to *Le Rêve de D'Alembert,* where he plunges into the depths of the controversy as to the ultimate constitution of matter and the meaning of life. It is a mistake to set down Diderot for a coherent and systematic materialist. We ought to look upon him "as a philosopher in whom all the contradictions of the time struggle with one another" (Rosenkranz). That is to say, he is critical and not dogmatic. There is no unity in Diderot, as there was in Voltaire or in Rousseau. Yet he drew at last to the conclusions of materialism, and contributed many of its most declamatory pages to the *Systbme de la nature* of his friend D'Holbach,—the very Bible of atheism, as some one styled it. All that he saw, if we reduce his opinions to formulae, was motion in space: "attraction and repulsion, the only truth." If matter produces life by spontaneous generation, and if man has no alternative but to obey the compulsion of nature, what remains for God to do? In proportion as these conclusions deepened in him, the more did Diderot turn for the hope of the race to virtue, in other words, to such a regulation of conduct and motive as shall make us tender, pitiful, simple, contented. Hence his one great literary passion, his enthusiasm for Richardson, the English novelist. Hence, also, his deepening aversion for the political system of France, which makes the realization of a natural and contented domestic life so hard. Diderot had almost as much to say against society as even Rousseau himself. The difference between them was that Rousseau was a fervent theist. The atheism of the Holbachians, as he called Diderot's group, was intolerable to him; and this feeling, aided by certain private perversities of humour, led to a breach of what had once been an intimate friendship between Rousseau and Diderot (1757). Diderot was still alive when Rousseau's *Confessions* appeared, and he was so exasperated by Rousseau's stories about Grimm, then and always Diderot's intimate, that in 1782 he transformed a life of Seneca, that he had written four years earlier, into an *Essai sur les règnes de Claude et de Néron* (1778–82), which is much less an account of Seneca than a vindication of Diderot and Grimm, and is one of the most rambling and inept productions in literature. As for the merits of the old quarrel between Rousseau and Diderot, we may agree with the latter, that too many sensible people would be in the wrong if Jean Jacques was in the right.

Diderot's mental activity was not of a kind to bring him riches. He could not even obtain that bare official recognition of merit which was implied by being chosen a member of the Academy. The time came for him to provide a dower for his daughter, and he saw no other alternative than to sell his library. When the empress Catherine of Russia heard of his straits, she commissioned an agent in Paris to buy the library at a price equal to about £1,000 of English money, and then handsomely requested the philosopher to retain the books in Paris until she required them, and to constitute himself her librarian, with a yearly salary. In 1773 Diderot passed some months at St. Petersburg. The empress received him cordially. The strange pair passed their afternoons in disputes on a thousand points of high philosophy, and they debated with a vivacity and freedom not usual in courts. *"Fi, donc,"* said Catherine one day, when Diderot hinted that he argued with her at a disadvantage, *"is there any difference among men?"* Diderot returned home in 1774. Ten years remained to him, and he spent them in the industrious acquisition of new knowledge. in the composition of a host of fragmentary pieces, and in luminous declamations with his friends. Diderot was seen at his best in conversation. "He who only knows Diderot in his writings," says

Marmontel, "does not know him at all. When he grew animated in talk, and allowed his thoughts to flow in all their abundance, then he became truly ravishing. In his writings he had not the art of ensemble; the first operation which orders and places everything was too slow and too painful to him."

Diderot died on July 30, 1784, six years after Voltaire and Rousseau, one year after his old colleague D'Alembert, and five years before D'Holbach, his host and intimate for a lifetime. An elaborate and exhaustive collection of his writings in 20 stout volumes, edited by MM. Assézat and Tourneux, was completed in 1875–77. (J. Mo.; X.)

DIDIUS SALVIUS IULIANUS, MARCUS, Roman emperor for two months (March 28–June 2, A.D. 193). He was the grandson of Salvius Iulianus, a famous jurist under Hadrian and the Antonines, and the son of a distinguished general. On the death of Pertinax, the praetorian guards offered the throne to the highest bidder. Didius and Sulpicianus (prefect of the city) bid against each other, and finally the throne was knocked down to Didius. The senate and nobles professed their loyalty; but the people made no attempt to conceal their indignation at this insult to the State, and the armies of Britain, Syria and Illyricum revolted. Septimius Severus, the commander of the Pannonian legions, was declared emperor and hastened to Italy. Didius, abandoned by the praetorians, was condemned and executed by order of the senate, which at once acknowledged Severus.

DIDO or ELISSA, the reputed founder of Carthage (*q.v.*), daughter of the Tyrian King Mutton, wife of Acerbas. Her husband having been slain by her brother Pygmalion, Dido fled to Cyprus, and thence to the coast of Africa, where she purchased from a local chieftain, Iarbas, a piece of land on which she built Carthage. The city soon began to prosper and Iarbas sought Dido's hand in marriage, threatening her with war in case of refusal. To escape from him, Dido constructed a funeral pile, on which she stabbed herself before the people (Justin xviii. 4–7). Virgil, in defiance of the usually accepted chronology, makes Dido a contemporary of Aeneas, with whom she fell in love after his landing in Africa, and attributes her suicide to her abandonment by him at the command of Jupiter. Dido was identified with the Virgo Caelestis; *i.e.,* Tanit, the tutelary goddess of Carthage. Timaeus is the oldest authority for the story; the meaning of the name Dido is uncertain.

DIDON, HENRI (1840–1900), French Dominican, was born at Trouvet, Isère, on March 17, 1840. Joining the Dominicans in 1858, he completed his theological studies at the Minerva convent at Rome. His brilliant preaching career began on his return to Paris in 1868. He concentrated on the relations between religion and science, and social problems, especially divorce. His disputes with the secular press led his superiors to interdict him from preaching and send him to the convent of Corbara in Corsica, whence he visited Palestine and also the German universities In 1892 he returned to France, becoming director of the Collège Albert-le-Grand at Arcueil, and founding three auxiliary institutions, École Lacordaire, Ecole Laplace and École St. Dominique He wrote several works on educational questions, an often-translated *Life of Christ* (Paris, 1890), and *Les Allemands* (Eng trans. 1884). *His Spiritual Letters* have been translated by A. G Nash (London, 1906). He died at Toulouse on March 13, 1900.

See the biographies by J. de Romano (1891) and A. de Coulanges (1900); and especially Stanislas Reynaud, *Le Père Didon, sa vie et son oeuvre* (1904).

DIDOT, the name of a family of learned French printers and publishers. FRANÇOIS DIDOT (1689–1757), founder of the greatness of his family, was born at Paris. He began business as a bookseller and printer in 1713, and among his famous productions was a collection of the travels of his friend the Abbé Prévost, in twenty volumes (1747). FRANÇOIS AMBROSE DIDOT (1730–1804), son of François, made important improvements in type-founding, and was the first to attempt printing on vellum paper (1780). Among the works which he published was the famous collection of French classics prepared by order of Louis XVI. for the education of the Dauphin, *in usum Delphini,* and the folio edition of *L'Art de vérifier les dates.* PIERRE FRANÇOIS DIDOT (1732–1795), his brother, devoted much attention to the art of type-founding and to paper-making. Among the works which issued from his press was an edition in folio of the *Imitatio Christi* (1788). HENRI DIDOT (1765–1852), son of Pierre François, is celebrated for his "microscopic" editions of various standard works, for which he engraved the type when nearly seventy years of age. He was also the engraver of the *Assignats* issued by the Constituent and Legislative Assemblies and the Convention. DIDOT SAINT-LÉGER (1767–1829), second son of Pierre François, was the inventor of the paper-making machine known in England as the Didot machine. PIERRE DIDOT (1760–1853), eldest son of François Ambroise, is celebrated as the publisher of the beautiful "Louvre" editions of Virgil, Horace and Racine. The Racine, in three volumes folio, was pronounced in 1801 to be "the most perfect typographical production of all ages." FIRMIN DIDOT (1764–1836), his brother, second son of François Ambroise, invented the process of stereotyping, and coined its name. He was the author of two tragedies—La *Reine de Portugal* (1824) and *La Mort d'Annibal* (1817); and he wrote metrical translations from Virgil, Tyrtaeus and Theocritus. AMBROISE FIRMIN DIDOT (1790–1876) was his eldest son. On the retirement of his father in 1827 he undertook, in conjunction with his brother HYACINTHE FIRMIN DIDOT (1794–1880), the direction of the publishing business. Their greatest undertaking was a new edition of the *Thesaurus Graecae linguae* of Henri Estienne, under the editorial care of the brothers Dindorf and M. Hase (g vols., 1855–1859). Among the numerous important works published by the brothers, the 200 volumes forming the *Bibliothèque des auteurs grecs, Bibliothèque latine,* and *Bibliothèque française* deserve special mention. Ambroise Firmin Didot was the first to propose (1823) a subscription in favour of the Greeks, then in insurrection against Turkish tyranny. The works include a translation of Thucydides. In 187j he published a very learned and elaborate monograph on Aldus Manutius. His collection of mss., the richest in France, was said to have been worth, at the time of his death, not less than 2,000,000 francs.

See P. G. Brunet, *Firmin Didot et sa famille* (1870).

DIDYMI or **DIDYMA,** an ancient sanctuary of Apollo in Asia Minor in the territory of Miletus and on the promontory Poseideion. It was sometimes called *Branchidae* from the name of its priestly caste which claimed descent from Branchus, a youth beloved by Apollo. As the seat of a famous oracle, the original temple attracted offerings from Pharaoh Necho (in whose army there was a contingent of Milesian mercenaries), and the Lydian Croesus, and was plundered by Darius of Persia. Xerxes finally sacked and burnt it (481 B.C.) and exiled the Branchidae to the far north-east of his empire. The celebrated cult-statue of Apollo by Canachus, familiar to us from reproductions on Milesian coins, was also carried to Persia, there to remain till restored by Seleucus I. in 295, and the oracle ceased to speak for a century and a half. The Milesians were not able to undertake the rebuilding till about 332 B.C., when the oracle revived at the bidding of Alexander. The work proved too costly, and despite a special effort made by the Asian province nearly 400 years later, at the bidding of the emperor Caligula, the structure was never quite finished: but even as it was, Strabo ranked the Didymeum the greatest of Greek temples and Pliny placed it among the four

most splendid and second only to the Artemisium at Ephesus. The area covered by the platform measures roughly 360×160 feet.

No excavation was attempted till MM. E. Pontremoli and B. Haussoullier were sent out by the French Schools of Rome and Athens in 1895. They cleared the western facade and the *pro*-domos, and discovered inscriptions giving information about other parts which they left still buried. Finally the site was purchased by, and the French rights were ceded to, Dr. Th. Wiegand, the German explorer of Miletus, who in 1905 began a thorough clearance of what is incomparably the finest temple ruin in Asia Minor.

The temple was a decastyle peripteral structure of the Ionic order, standing on seven steps and possessing double rows of outer columns 60 ft. high, twenty-one in each row on the flanks. It is remarkable not only for its great size, but (*inter alia*) for (1) the rich ornament of its column bases, which show great variety of design; (2) its various developments of the Ionic capital, *e.g.*, heads of gods, probably of Pergamene art, spring from the "eyes" of the volutes with bulls' heads between them; (3) the massive building two storeys high at least, which served below for *prodomos*, and above for a dispensary of oracles χρησμογράφια mentioned in the inscriptions) and a treasury; two flights of stairs called "labyrinths" in the inscriptions, led up to these chambers; (4) the pylon and staircase at the west; (5) the frieze of Medusa heads and foliage. Two outer columns are still erect on the north-east flank, carrying their entablature, and one of the inner order stands on the south-west.

See Dilettanti Society, *Ionian* Antiquities, ii. (1821); C. T. Newton, *Hist.* of Discoveries, etc. (1862) and Travels in the Levant, ii. (1865); O. Rayet and A. Thomas, *Milet* et le Golfe *Latmique* (1877); E. Pontremoli and B. Haussoullier, Didymes (1904).

DIDYMIUM, originally regarded as a chemical element, was found by A. von Welsbach in 1885 to be a mixture of the two elements, praseodymium (*q.v.*) and neodymium (*q.v.*). (See also RARE EARTHS.)

DIDYMUS (309?–394), surnamed "the Blind," ecclesiastical writer of Alexandria, was, in spite of becoming blind at the age of four, one of the most learned men of his day, respected by Jerome and Athanasius. He became head of the catechetical school of Alexandria. He was condemned by the sixth and seventh general councils as a continuator of Origen, but he stoutly opposed Arian and Macedonian teaching. His surviving writings show a remarkable knowledge of Scripture, and have distinct value as theological literature. They include the De Trinitate, De *Spiritu Sancto* (Jerome's Latin trans.), *Adversus Manichaeos*, and expositions of various books, especially the Psalms and the Catholic Epistles.

See Migne, Patrol. Graec. xxxix.; J. Leipoldt, "Didymus der Blinde" in Texte u. *Untersuchungen* zur Gesch. der altchrist. Lit., vol. xiv. (Leipzig, 1906); Tixeront, *Hist.* of Dogma, vol. ii. (1914).

DIDYMUS CHALCENTERUS (*c.* 63 B.C.–A.D. 10), Greek scholar and grammarian, flourished in the time of Cicero and Augustus, and taught in Alexandria and Rome. His surname, which means "brass-bowelled," came from his industry; he was said to have written more than 3,500 books. He wrote a treatise on Aristarchus' recension of Homer, of which fragments have been preserved in the Venetian Scholia. He also wrote commentaries on many other Greek poets and prose authors, and the extant scholia to Pindar, Sophocles and Aristophanes are largely due to Didymus. His work, though it showed no great critical acumen, was valuable because it collected the results reached by earlier scholars. (Ammianus Marcellinus, xxii. 16).

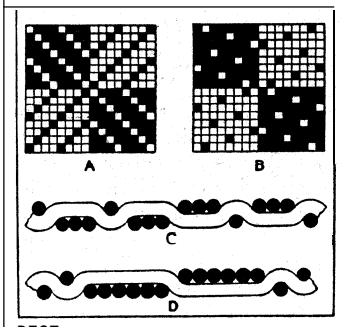
DIE, a town of south-eastern France, capital of an arrondissement in the department of Drôme, 43 m. E.S.E. of Valence on the Paris-Lyons railway. Pop. (1936) 2,717. Under the Romans, Die (Dea *Augusta Vocontiorum*) was an important colony. It was formerly the seat of a bishopric, united to that of Valence from 1276 to 1687 and suppressed in 1790. Previous to the revocation of the Edict of Nantes in 1685 it had a Calvinistic university. The town stands in a plain enclosed by mountains on the right bank of the Drôme below its confluence with the Meyrosse, which supplies power to some of the industries. The old cathedral has a porch of the 11th century supported on granite columns from an ancient temple of Cybele; and the Porte St. Marcel is a Roman gateway flanked by massive towers. There are also ruins of Roman aqueducts and altars. Die is the seat of a sub-prefect, and of a tribunal of first instance. The manufactures are silk, cloth, lime and cement, and there are saw mills. Trade is in timber, especially walnut, and in white wine known as *clairette* de **Die.** The mulberry is largely grown for the rearing of silkworms.

DIE, a word used in various senses for a small cube of ivory, etc. (see DICE); for the engraved stamps used in coining money, etc.; and various mechanical appliances in engineering. In architecture a "die" is the term used for the square base of a column, and it is applied also to the vertical face of a pedestal or podium.



DICE PATTERNS. SHOWING WEAVES A is formed from two four-thread twill weaves; B from two double-damask weaves; C shows the arrangement of the warp and weft in A, while D shows the arrangement of B

The fabrics known as "dice" take their name from the rectangular form of the figure. The original figures would probably be perfectly square, but to-day the same principle of weaving is applied, and the name dice is given to all figures of rectangular form. The different effects in the adjacent squares or rectangles are due to precisely the same reasons as those explained in connection with the ground and the figure of damasks (*q.v.*). The same weaves are used in both damasks and dices, but simpler weaves are generally employed for the commoner classes of the latter. The effect is, in every case, obtained by what are technically called warp and weft float weaves. The illustration B shows the two double damask weaves arranged to form a dice pattern, while A shows a similar pattern made from two four-thread twill weaves. C and D represent respectively the disposition of the threads in A and B with the first pick, and the solid marks represent the floats of warp. The four squares, which are almost as pronounced in the cloth as those of a chess-board, may be made of any size by repeating each weave for the amount of surface required. It is only in the finest cloths that the double damask weaves B are used for dice patterns, the single damask weaves and the twill weaves being employed to a greater extent. This class of pattern is largely employed for the production of table-cloths of low and medium qualities. The term damask is often applied to cloths of this character, and especially so when the figure is formed by rectangles of different sizes.

DIEBITSCH, HANS KARL FRIEDRICH ANTON (1785–1831), Count von Diebitsch and Narden, called by the Russians Ivan Ivanovich, Count Diebich-Zabalkansky, Russian field-marshal, was born at Grossleipe, Silesia, on May 13, 1785. He was educated at the Berlin cadet school, but passed into the service of Russia in 1801. He served in the campaign of 1805, and was wounded at Austerlitz, fought at Eylau and Friedland, and after Friedland was promoted captain. He distinguished himself very greatly in Wittgenstein's campaign, and in particular at Polotzk (Oct. 18 and 19, 1812), and was promoted major-general. In the latter part of the campaign he served against the Prussian contingent of Gen. Yorck (von Wartenburg), with whom, through Clausewitz, he negotiated the convention of Tauroggen, serving thereafter with Yorck in the early part of the War of Liberation. After the battle of Lützen he served in Silesia and took part in negotiating the secret treaty of Reichenbach. He fought at Dresden and Leipzig. At the crisis of the campaign of 1814 he urged the march of the allies on Paris. In 1815 he attended the congress of Vienna, and was afterwards made adjutant-general

to the emperor. In 1820 he had become chief of the general staff, and in 1825 he assisted in suppressing the St. Petersburg *émeute*. His greatest exploits were in the Russo-Turkish War of 1828–29, which was decided by Diebitsch's brilliant campaign of Adrianople; this won him the rank of field-marshal and the honorary title of Zabalkanski to commemorate his crossing of the Balkans. In 1830 he was appointed to command the army destined to suppress the insurrection in Poland. He won the terrible battle of Gróchow on Feb. 25, and was again victorious at Ostrolenka on May 26, but soon afterwards he died of cholera (or by his own hand) at Klecksewo near Pultusk, on June 10, 1831.

See Belmont (Schiimberg), *Graf* Diebitsch (Dresden, 1830); Stürmer, Der *Tod* des Grafen Diebitsch (1832); Bantych-Kamenski, *Biographies of* Russian Field-Marshals (in Russian, St. Petersburg, 1841).

DIEDENHOFEN: see THIONVILLE.

DIEKIRCH, a small town of Luxembourg, situated on the banks of the Sûre. Pop. (1930) 3,858. Its name is said to be derived from Dide or Dido, granddaughter of Odin and niece of Thor. Diekirch was an important Roman station, and in the 14th century John of Luxemburg, king of Bohemia, fortified it. In the 19th century during their occupation the French changed the fortifications into boulevards.

DIELECTRIC. The insulating medium separating the conductors in a condenser was called by Faraday the insulating dielectric. The term dielectric is now used to denote any insulator when it is regarded as a medium in which electromagnetic stresses may be set up. The dielectric constant for a substance is the ratio of the capacity of a condenser when that substance fills the space between the plates to the capacity of the same condenser when air is the dielectric. (See CONDENSER [ELECTRICAL] and ELECTRICITY.)

DIELMANN, FREDERICK (1847–1935), U.S. portrait and figure painter, was born at Hanover, Germany, Dec. 25, 1847. He was taken to the United States in early childhood; studied under Diez at the Royal academy at Munich; was first an illustrator, and became a distinguished draughtsman and painter of genre pictures. His mural decorations and mosaic panels for the Congressional library, Washington, are notable. He was president of the National Academy of Design (1899–1909), president of the Fine Arts Federation of New York (1910–15), professor of art at the College of the City of New York (1903–18) and art director of Cooper Union, New York city (1905–31).

DIEMEN, ANTHONY VAN (1593–1645), Dutch admiral, became governor-general of the East Indian settlements in 1636, and captured the Portuguese possessions in Ceylon and Malacca. He developed the prosperity both of the Indies and of Dutch trade with them, ensuring the Dutch monopoly, *e.g.*, of pepper in Sumatra, etc. He greatly extended the commercial relationships of the Dutch, opening up trade with Tong-king, China and Japan. Exploring expeditions were sent to Australia under his auspices in 1636 and 1642, and Abel Tasman named after him (Van Diemen's land) the island now called Tasmania. Van Diemen died at Batavia on April 19, 1645.

DIEPENBECK, ABRAHAM VAN (1599–1675), Flemish painter, was born at Herzogenbusch, in 1599, and died at Antwerp, where he was buried in Dec. 1675. He studied painting at Antwerp as one of Rubens' "Hundred pupils." Most of Diepenbeck's important canvases are in continental galleries. The best are the "Marriage of St. Catherine" at Berlin and "Mary with Angels Wailing over the Dead Body of Christ" at Vienna. But Diepenbeck spent much more of his time on glass painting, though he failed to master the secrets of gorgeous tinting, which were lost in the 16th century. In 1635 he finished 40 scenes from the life of St. Francis of Paula in the church of the Minimes at Antwerp. In 1644, he received payment for four windows in St. Jacques of Antwerp, two of which are still preserved and represent Virgins to whom Christ appears after the Resurrection.

DIEPPE, a seaport of northern France, capital of an arrondissement in the department of Seine-Inférieure, on the English channel, 38 mi. N. of Rouen, and 105 mi. N.W. of Paris by the Western railway. Pop. (1936) 25,304. It is suggested that Dieppe owed its origin to Norman adventurers, who found its "diep" or inlet suitable for their ships. In 1197 it was bestowed by Richard I of England on the archbishop of Rouen in return for territory near the latter city. In 1339 it was plundered by the English, but it soon recovered, and, in spite of opposition from the lords of Hantot, fortified itself. In the same year, the Dieppois plundered Southampton. Its commercial activity was already great, and it is believed that its seamen visited the coast of Guinea in 1339, and founded there a Petit Dieppe in 1365. The town was occupied by the English from 1420 to 1435. A siege undertaken in 1442 by John Talbot, first earl of Shrewsbury, was raised by the dauphin, afterwards Louis XI, and the day of the deliverance continued for centuries to be celebrated. The prosperity of the town in the 15th century was mainly due to its seamen and corsairs. Its inhabitants in great number embraced the reformed religion; and they were among the first to acknowledge Henry IV, who fought one of his great battles at the neighbouring village of Arques. From 1668 to 1670 the population of Dieppe was ravaged by the plague; some 10,000 died.

Few cities suffered more from the revocation of the edict of Nantes in 1685; this blow was followed in 1694 by a terrible bombardment on the part of the English and Dutch. The town was rebuilt after the peace of Ryswick, but its modern prosperity dates only from the 19th century, partly owing to Marie Caroline, duchess of Berry, who brought it into fashion as a watering place; and also because the railway gave an impetus to its trade. The Dieppois played an important part in the colonization, the evangelization and the defense of Canada from the 16th to the 18th centuries. Two monuments were erected in Dieppe to commemorate its everlasting ties with Canada. During the Franco-German War the town was occupied by the Germans from Dec. 1870 till July 1871.

During World War II, on August 19, 1942, a commando raid executed by 7,000 Allied troops, mostly Canadian, was launched on Dieppe, occupied by the Germans in June 1940. Almost half the attacking force was lost, as well as a large number of tanks, ships and planes, but the damage inflicted upon the German occupation forces was extremely heavy. This raid was not an invasion attempt by the Allies, but merely a raid considered as a full-dress rehearsal for the second front in Europe.

Dieppe stands at the mouth of the river Arques in a valley bordered on each side by steep white cliffs. The main part of the town lies to the west, and the fishing suburb of Le Pollet to the east of the river and harbour. The sea front of Dieppe, which in summer attracts large numbers of visitors, consists of a pebbly beach backed by a handsome marine promenade. Dieppe has a modern aspect and two squares side by side form the nucleus of the town. The church of St. Jacques, founded in the 13th century, consists largely of later workmanship and was restored in the 19th century. The castle, overlooking the beach from the summit of the western cliff, was built in 1435. The church of Notre-Dame de Bon Secours on the opposite cliff, and the church of St. Remy, of the 16th and 17th centuries, are noteworthy. A well-equipped casino stands on the sea front. The public institutions include the subprefecture, tribunals of first instance and commerce, a chamber of commerce and a school of navigation.

Dieppe has one of the safest and deepest harbours on the English channel. A curved passage cut in the bed of the Arques and protected by an eastern and a western jetty gives access to the outer harbour, which communicates at the east end by a lock-gate with the Bassin Duquesne and the Bassin Bérigny, and at the west end by the New channel, with an inner tidal harbour and two other basins. Vessels drawing 20 ft. can enter at neap tide. The harbour railway station is on the northwest quay of the outer harbour. The distance of Dieppe from Newhaven, with which there has long been daily communication, is 64 mi. The imports include silk and cotton goods, thread, oil-seeds. timber, coal, iron, patent fuel cement, china-clay, machinery, tobacco and mineral oil; leading exports are wine, silk, woollen and cotton fabrics, vegetables and fruit and flint-pebbles. The industries comprise shipbuilding, oil refining, steam-sawing, the manufacture of machinery, rope, porcelain and briquettes. Lace-making and production of articles in ivory and bone, dating from the 15th century, are carried on. The fishermen of Le Pollet, traditionally of Venetian origin. are among the main providers of the Parisian market. Two miles to the northeast of the town

is the ancient camp known as the Cité de Limes, which perhaps furnished the nucleus of the population of Dieppe.

See L. Vitet, *Histoire de Dieppe* (Paris, 1844); D. Asseline, *Les Antiquités et chroniques de la ville de Dieppe*, a 17th-century account published at Paris in 1874; Quentin Reynolds, *Dress Rehearsal* (1943).

DIERX, LÉON (1838–1912), French poet, was born in the island of Réunion in 1838, and died in Paris on June 11, 1912. He came to Paris to study at the Central School of Arts and Manufactures. A friend and disciple of Leconte de Lisle, Dierx was one of the most distinguished of the Parnassians. On the death of Stéphane Mallarmé in 1898 he was acclaimed "prince of poets" by "les jeunes." The most significant of his volumes of verse is *Lèvres closes* (1867). His *Oeuvres* (2 vol., 1894–96) contain much exquisite verse.

DIES, CHRISTOPH ALBERT (1755–1822), German painter, was born at Hanover, and learned the rudiments of art there. For one year he studied in the academy of Diisseldorf, and then he started, at the age of 20, with 30 ducats in his pocket, for Rome. There he lived till 1796. He published, in partnership with Méchan, Reinhardt and Frauenholz, the series of plates known as the *Collection de vues pittoresques de l'Italie* (1799).

In 1787 he swallowed by mistake three-quarters of an ounce of sugar of lead. His recovery from this poison was slow and incomplete, and he eventually lost the use of one of his hands. He died at Vienna in 1822, after years of suffering.

DIESEL, RUDOLF (1858–1913), German engineer, was born in Paris, March 18, 1858, of German parents. He was educated at the Munich Polytechnic school and spent a short time in Paris as manager of a company which manufactured refrigerating equipment, but returned to Munich, where in 1893 he published *The Theory and Construction* of *a Rational Heat Motor,* the result of his studies on what was to become the Diesel oil engine. In the same year work began at the Krupp and Augsburg machine factories on the construction of the Diesel engine (*q.v.*). Work continued on the motor until 1897, and in 1898 it was publicly displayed for the first time at Munich. In 1899 Diesel founded a factory for the construction of the engines at Augsburg and spent the greater part of the rest of his life perfecting the machine, although he did not live to see its possibilities fully exploited. On the night of Sept. 29–30, 1913, he fell overboard the Antwerp-Harwich mail steamer in the English channel and was drowned. In the last year of his life he wrote *The Genesis* of *Diesel Motors.*

For a discussion of the practical uses of Diesel's invention, *see* AERO ENGINES; MARINE ENGINEERING; LOCOMOTIVE.

DIESEL ENGINE. In 1892 Dr. Rudolf Diesel (*q.v.*) patented the type of internal-combustion engine with which his name is now inseparably associated, though it was not until 1895 that the first real "diesel" was built. Independent tests of an engine were conducted by Prof. Schroter at Augsburg in 1897, and diesel engines were first publicly exhibited at the Munich exhibition of 1898.

In a paper read before the Congress at Paris in 1900 Diesel stated that the cycle of operations finally adopted by him 'after extended experiments was as follows:

(1) A suction stroke during which air alone at atmospheric pressure was drawn into the cylinder.

(2) A compression stroke in which this air was next compressed "adiabatically" to a pressure of 500–600 lb. per sq.in.

(3) From, and for a short period after, the end of the compression stroke, regulated admission of the fuel in the form of a fine spray in such manner as to cause combustion to occur at (approximately) constant pressure.

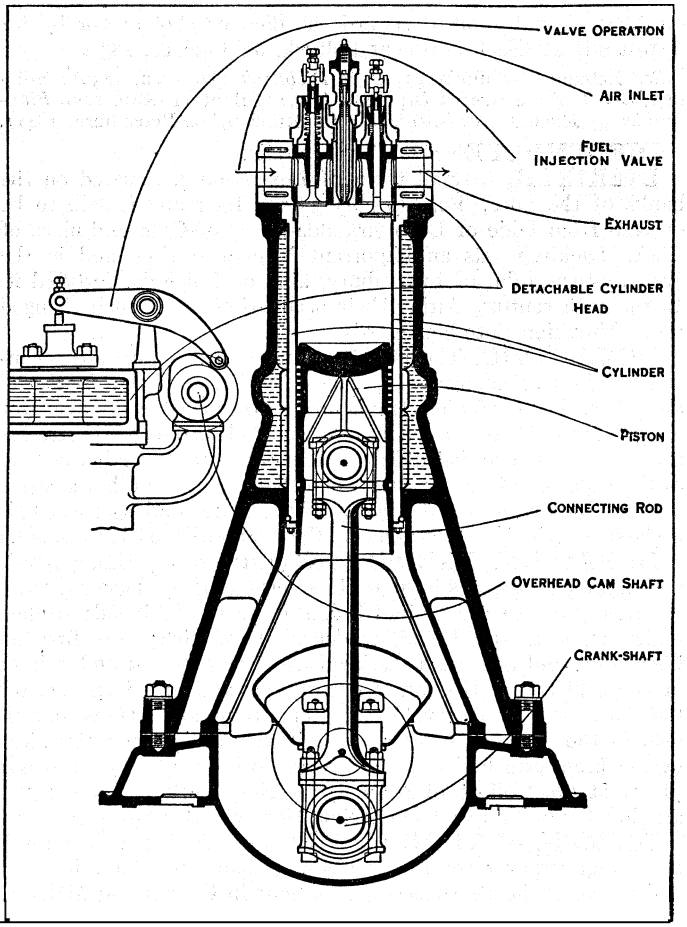
(4) Expansion of the ignited mixture of fuel spray and air during the remainder of the working stroke.

(5) Expulsion of the burnt products during the next stroke.

The cycle thus described was of the ordinary four-stroke type with stroke-sequence of suction, compression, working and exhaust; and the engine contemplated was of the normal single-acting type furnishing one working impulse in each two complete revolutions of the crankshaft.

The special feature of the diesel cycle is the regulated introduction of the fuel spray giving a combustion at approximately constant pressure, so that, in normal conditions of running, the maximum pressure of compression is not exceeded. In other internal-combustion engines the combustion or "explosion" of the working charge at the end of the compression stroke results in an almost instantaneous rise of pressure to a peak value much in excess of that of the compression.

It is stated above that the air is considered to be compressed. and that the burning gases are expanded "adiabatically"; by this



FROM C. A BURLS AND SIR DUGALD CLERK IN "DICT. OF APPLIED PHYSICS" (MACMILLAN)

FIG. 1.— SECTIONAL VIEW OF A TYPICAL 4-STROKE DIESEL ENGINE. SHOWING. ALSO. USUAL MODE OF VALVE ACTUATION

is meant that the air and gases are supposed for the sake of simplicity to be compressed and expanded respectively, without any loss or gain of heat to the containing cylinder. Actually of course some heat is lost to the cylinder during the compression and expansion (working) strokes; nevertheless the rapid squeezing-up of the air during the compression stroke results in increase of its temperature to about 1,000° F, which is sufficient to cause spontaneous ignition of the fuel spray during its injection; thus no igniting apparatus is required with diesel engines.

Neither the suction and subsequent compression of air alone, nor the absence of igniting apparatus in the diesel engine was novel. Akroyd Stuart (1886–90) injected the fuel spray into a hot-bulb prolongation at the combustion chamber end of the cylinder, and atmospheric air, during compression, formed with this heated spray the working charge, which ignited spontaneously and explosively, at the end of the compression stroke. The characteristic feature of the diesel procedure is the regulated admission of the fuel spray by which combustion at constant pressure is realized.

Definition of a Diesel Engine.— The accepted definition of a diesel engine is as follows:—A *diesel engine is a prime mover actuated by the gases resulting from the combustion of a liquid or pulverized fuel injected in a state of fine subdivision into the engine cylinder at or about the end of the compression stroke. The heat generated by the compression of air in the cylinder is*

STATIONARY DIESEL ENGINES. FOUR PLANTS SHOWING USES OF THE MODERN OIL ENGINE

1. Three 900-h.p. and one 1400-h.p. diesels in light and power plant
2. Six 300-h.p. 3-cylinder engines in an oil pipe-line station
3. High-pressure water pump operated by direct-connected diesel engine
4. Small 2-cycle diesels (180 and 120 h.p.) for municipal power plant

the sole means of *igniting the charge*. Combustion of *the* charge proceeds at, or *approximately at,* constant *pressure.*

A sectional view of a simple four-stroke diesel engine appears in fig. 1; the inverted vertical frame design shown is almost universally adopted. The piston reciprocates within the cylinder and drives the crankshaft through connecting rod. On the first down stroke air is drawn through the air inlet and valve into the cylinder; this air is next compressed on the return up stroke of the piston, and the fuel spray is then forcibly injected into this compressed and consequently highly heated mass of air through the fuel valve; spontaneous ignition takes place and the piston is driven down and performs the "working stroke." Near the bottom of this stroke the exhaust valve is opened and the burnt gases are discharged through the exhaust into the atmosphere during the final up stroke of the piston; this completes the cycle.

The inlet and exhaust valves are usually of the "poppet" or "mushroom" type as shown, and all valves are cam-driven from a "half-speed" shaft in the manner indicated in the illustration substantially as in an ordinary motor-car engine. It will be noted that the cylinder is well water-jacketed, and that the engine generally is of massive design.

In normal working the maximum pressure, as already stated, does not exceed that of compression, *i.e.,* 500–600 lb. per sq.in., but the engine has to be built safely to resist occasional excessive pressures that occur if, *e.g.,* a leaky fuel valve permits admission of oil during suction with subsequent vaporization during the compression stroke, and pre-ignition near the end of the compression; in this way momentary pressures of fully 1,000 lb. per sq.in. not uncommonly occur, and have to be provided against. Accordingly, in general, the diesel is a heavy internal-combustion engine in relation to its power development.

Ideal Diesel Indicator Diagram. — An ideal indicator diagram of a four-stroke diesel engine is given in fig. 2. Horizontal measurements represent volumes, and vertical measurements pressures in lb. per sq.in., each to some convenient scale. Thus at the commencement of the cycle, the combustion chamber, of volume V_0 is, in the simplest theory, filled with air at atmosphere pressure p_0. The piston performs the suction stroke, and the line 01 is traced on the diagram; at the end of the suction stroke the cylinder contains a volume V_1 of air at atmospheric pressure. The inlet valve is now closed and the returning piston compresses

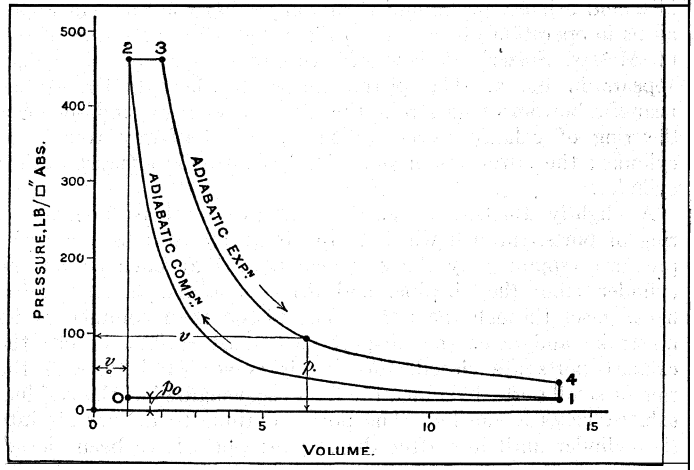

FIG. 2. — IDEAL INDICATOR DIAGRAM OF A 4-STROKE DIESEL ENGINE

the entrapped air adiabatically at constantly increasing pressure as indicated by the curve $\overline{12}$; at the end of this stroke the air, now at high temperature, has a volume $V_2(=V_0)$, and pressure p_2 lb. per square inch. The regulated charge of fuel is next sprayed into this mass of highly heated and compressed air during the first part of the downward movement of the piston on its working stroke; spontaneous ignition takes place, and continues at constant pressure to some point, as 3, indicated by the horizontal line $\overline{23}$; the fuel is then cut oti and the working mixture expands at rapidly falling pressure and temperature, driving the piston downwards, until the point 4, the end of the working stroke, is reached.

The exhaust valve is now suddenly opened and the burnt gases escape into the atmosphere, falling instantly from pressure p_4 to $p_1(=p_0)$. Finally, during the return of the piston from 1 to 0, the remaining exhaust gas is expelled. This cycle is then repeated indefinitely.

Simple Theory. — The working fluid is regarded as a perfect gas, conforming strictly to the relation:

$$PV = c.T \qquad (1)$$

where T denotes absolute temperature (say, in °F) and c is a constant, being equal to the difference $(C_p - C_v)$ between the specific heat of the fluid at constant pressure and that at constant volume. The compression and expansion curves are regarded as truly adiabatic, so that the fluid neither gains nor loses heat, *qua* heat, during these periods. Hence, on these simplifying assumptions, the heat given to the working fluid per cycle is $H = K_p(T_3 - T_2)$ British thermal units. While the heat rejected per cycle (*see* the indicator diagram, at $\overline{41}$) is

$$R = K_v(T_4 - T_1) \text{ British thermal units.}$$

The useful work done, expressed in heat units, is $(H - R)$. Thus an expenditure of H, B.T.U. gives a return of $(H - R)$B.T.U. of useful work; and accordingly the "thermodynamic efficiency" of the cycle is expressed by the fraction $\frac{H-R}{H}$, thus,

$$\text{Thermodynamic efficiency} = \frac{H-R}{H} = 1 - \frac{R}{H}. \qquad (2)$$

That is, denoting as usual the ratio of the specific heats, viz. $\frac{k_p}{K_v}$, by γ:

$$\text{Thermodynamic efficiency} = 1 - \frac{1}{\gamma} \cdot \frac{T_4 - T_1}{T_3 - T_2}. \qquad (3)$$

This expression gives the value of the ideal thermodynamic efficiency of the diesel cycle in terms of the absolute temperatures at the four corners of the indicator diagram; these temperatures are not, however, readily ascertainable; but the efficiency can, fortunately, also be expressed in terms of magnitudes immediately measurable from the indicator diagram, as follows:

The volume ratio of compression, commonly termed the "compression ratio," $\frac{V_1}{V_2}$ (fig. 2), is usually denoted by r; it will be seen that this is the same as $\frac{V_4}{V_3}$; thus $r = \frac{V_1}{V_2} = \frac{V_4}{V_3}$.

Also $\frac{V_3}{V_2}$, the ratio of expansion at constant pressure (*i.e.,* of combustion at constant pressure) is commonly denoted by *p;* thus $\rho = \frac{V_3}{V_2}$.

Note here also that $\frac{V_3}{V_4} = \frac{V_3}{V_2} \cdot \frac{V_2}{V_4} = \frac{\rho}{r}$. Now it may be shown that when any perfect gas is compressed or expanded adiabatically, the product $TV^{\gamma-1}$ remains constant along the curve; hence by aid of Eqs. (1) and (3), and the above results we have from fig. 2:

$$T_2V_2^{\gamma-1} = T_1V_1^{\gamma-1}. \quad \text{Therefore } \frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{\gamma-1} = r^{\gamma-1}.$$

Thus $T_2 = r^{\gamma-1}T_1\frac{T_3}{T_2} = \frac{V_3}{V_2} = \rho$. Therefore $T_3 = \rho T_2$;

and thus $T_3 = \rho r^{\gamma-1}T_1$;

and accordingly $T_3 - T_2 = r^{\gamma-1}(\rho - 1)T_1. \qquad (4)$

Again: $T_4V_4^{\gamma-1} = T_3V_3^{\gamma-1} = \rho r^{\gamma-1}V_3^{\gamma-1}T_1.$

Therefore $\frac{T_4}{T_1} = \rho r^{\gamma-1}\left(\frac{V_3}{V_4}\right)^{\gamma-1}$; *i.e.*, $\frac{T_4}{T_1} = \rho r^{\gamma-1}\left(\frac{\rho}{r}\right)^{\gamma-1} = \rho^{\gamma}$;

and thus $T_4 = \rho^{\gamma} T_1$;

so that $T_4 - T_1 = (\rho^{\gamma} - 1)T_1$. (5)

Substituting, now, in (3) from (4) and (5) we get:

$$\text{Thermodynamic efficiency} = 1 - \left(\frac{1}{r}\right)^{\gamma-1} \times \frac{\rho^{\gamma} - 1}{(\rho - 1)\gamma} \quad (6)$$

and thus the diesel cycle efficiency is expressed in terms of the compression and expansion ratios only. Eq. (6) is the exact expression for the efficiency, on the ordinary simple theory, and as Table I. below shows, the efficiency falls as p, *i.e.*, the period of constant-pressure combustion, increases. When the constant-pressure combustion period is extremely short, *i.e.*, when $\rho = 1$, the expression (6) above reduces to $1 - \left(\frac{1}{r}\right)^{\gamma-1}$. Now it is shown in the article on gas engines (*q.v.*) that for the type of four-stroke cycle in general use in gas and petrol engines known as the "constant-volume" cycle, the thermodynamic efficiency, with the usual simplifying assumptions, is expressed by the formula $1 - \left(\frac{1}{r}\right)^{\gamma-1}$, where r is, again, the ratio of adiabatic compression.

A committee of the Institution of Civil Engineers in 1905 after careful consideration recommended the adoption of this formula for estimating the ideal maximum of thermodynamic efficiency of the internal-combustion engines in general use at that date, all such engines being assumed as working with a perfect gas for which the value of γ was taken as 1·4. Thus the

$$1905 \text{ Air Standard} = 1 - \left(\frac{1}{r}\right)^{0.4} \quad (7)$$

and this has been largely used from that date in connection with all internal-cornbustion engines, including diesels. The 1905 Air Standard makes the efficiency increase with the compression ratio, thus:

For r =	3.	4.	5.	6.	7.	8.	10.	12.	14.
The Air Std =	·356	·426	·475	·513	·541	·565	·602	·630	·652

and the diesel engine owes its position as one of the most economical engines in fuel consumption to the high compression ratio (14–15) employed. This high compression ratio is practicable on account of air alone being compressed; in the case of gas engines, and of many oil engines, much lower compression ratios must be used in order to avoid detonation of the working charge, and in such cases the value of r ranges from about 3 to 7.j only. The ideal diesel efficiency is, however, somewhat over-estimated if Eq. (7) be used, as is shown in Table I. below, which exhibits the true efficiency values from Eq. (6) for a compression ratio of 14, and with p ranging from its minimum value 1 to the maximum, in practice, of about 2.

Two-stroke Cycle Diesel Engines.—All the earliest diesel engines were operated on the four-stroke cycle, but two-stroke cycle engines are now (1928) common and are increasing in favour. The sequence of operations is as follows:—

(1) On the first up-stroke of the piston, air alone is adiabatically compressed into the combustion chamber, becoming in consequence highly heated.

(2) The charge of fuel is then forcibly injected at a regulated rate into this compressed and heated air just as in the four-stroke cycle engine, and spontaneous ignition occurs and continues at approximately constant pressure during the early part of the working down-stroke.

(3) When about 80% of the down-stroke has been completed, the piston over-runs a ring of ports in the lower part of the

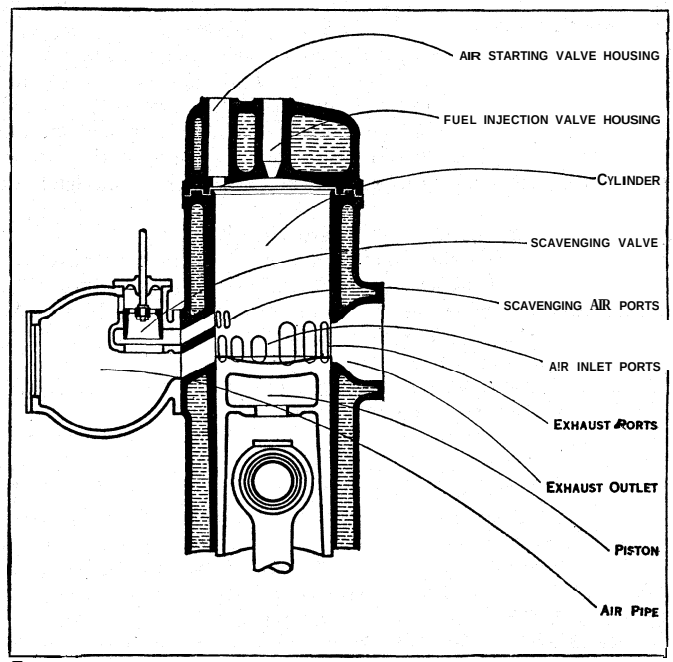

FIG. 3.— DIAGRAM OF A TYPICAL 2-STROKE DIESEL ENGINE. SHOWING INLET. EXHAUST AND SCAVENGING PORTS

cylinder through which the burnt gas discharges itself into the atmosphere. Simultaneously air, supplied by a so-called scavenge pump under a pressure of 1·5 to 3 lb. per sq.in. enters the cylinder through a valve, or ports, and causes the expulsion of any remaining exhaust gas, so that at the end of the working stroke the cylinder is again filled with air alone. This completes the cycle. The piston on the return up-stroke first closes the rings of air inlet and exhaust ports, and then compresses the now entrapped air as in operation (1) above. A diagrammatic illustration of one of Messrs. Sulzér's designs of two-stroke cycle diesel engines appears in fig. 3. The piston works in the cylinder. When near the bottom of its stroke the piston over-runs. and so opens the ring of exhaust ports, which extends half-way round the cylinder; the burnt gas at once escapes into the exhaust outlet; cylinder.

A slightly further descent of the piston then uncovers a ring of ports, through which fresh air at 1·5 to 3 lb. per sq.in. pressure (supplied by the scavenge pump) at once enters the cylinder from the air-pipe, and drives out the remaining exhaust gases through the ports. The piston then commences its up-stroke and after the air-ports are masked, but before the exhaust ports are closed. further air is admitted through the ring of small ports, by which the final "scavenging" of the residual exhaust gases is effected. The ports continue to deliver air into the cylinder until just after the exhaust ports have been closed, so that in this ingenious manner the cylinder is charged with fresh air at slightly above atmospheric pressure.

The supply of air to the ports is regulated by a reciprocating valve operated from the crankshaft. The only valves in the cylinder head in this type of engine are (1) the fuel injection valve and (2) the air-starting valve. The massive strength of the design and the liberal water-jacketing provided should be noticed.

The ideal two-stroke cycle engine would develop twice the power of a four-stroke of equal size; actually, as only about 80% of the stroke can be utilized on account of the presence of the scavenging and exhaust ports, and as some power is absorbed

in driving the scavenging pump, the two-stroke diesel in practice is usually a little less efficient than the four-stroke. Another difficulty with the two-cycle is that it is practically impossible to get complete scavenging, especially at high speeds, where the scavenging pressures and consequent losses are necessarily much higher. It possesses, however, the important advantages (1) that it is lighter for the same power output; (2) that it possesses fewer moving parts, and is thus simpler; and (3) that it is very readily reversed. With reference to (3), it is obvious that a two-stroke cycle engine will work equally well in whichever direction it may be started; it is therefore only necessary to move the crankshaft operating the fuel inlet valve through a small angle in order to change the injection-period to that suitable for reverse running.

Fuel: Fuel Injection: **Fuel** Consumption. — Although many liquid and even some solid (pulverized) fuels, as coal dust, have been tried in diesel engines, practically the only fuels employed are (1) crude and residual petroleum oils and (2) coal-tar oils obtained from the large-scale distillation of coal. Suitable petroleum oils have a specific gravity (water = 1) of ·85–·95 at 60° F, a flash point of 150–250° F (by close test), and a lower heat value of 18,000–19,000 B.T.U. per pound. Oils having an asphalt base are liable to gum-up the valves, and are thus less favoured.

Coal-tar oils often show a flash point of 400° F or more, a sp gr. of 1·0–1·1 and a (lower) heat value of about 16,000 B.T.U. per lb. These oils require in general a very high temperature to produce spontaneous ignition and this proved at first an obstacle to their employment in the diesel engine; the difficulty was completely removed by injecting through the fuel inlet valve into the cylinder a minute quantity of some more readily ignitable oil (as gas oil), immediately before, or simultaneously with, the main charge of tar oil; by aid of this "pilot jet" combustion is initiated, and entirely satisfactory performance obtained.

The injection of the charge of fuel oil into the compressed and heated mass of air in the combustion chamber at and for a short period after the instant when the piston has reached the top of its stroke is effected through a spring-seated needle valve (the fuel inlet valve) located in the cylinder head, in one of two ways:

(1) By a blast of *air* supplied from a special air reservoir at a pressure of up to 1,000 lb. per sq.in. Air blast injection has given, in general, a somewhat better distribution of the sprayed and "pulverized" fuel throughout the combustion chamber, with consequent improvement in fuel economy. It is thought that one of the principal contributions of air-blast injection is the turbulence thus introduced into the combustion space. However, it involves the provision of bulky and costly air-compressing apparatus which absorbs in its operation 6–7% of the whole power output of the engine. Accordingly great attention was devoted to the discovery of a means of dispensing with the air-blast, and recent engines are provided in increasing numbers with: —

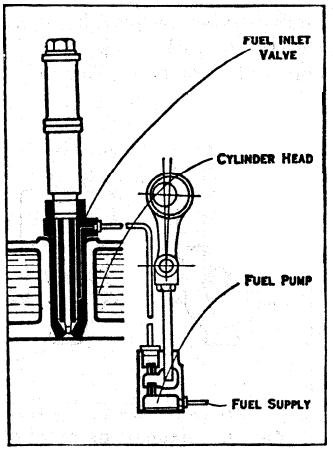

FIG. 4.—DIAGRAM SHOWING "SOLID" FUEL INJECTION

(2) *"Airless" or "Solid" Injection* —In this method the charge of fuel is forced through a cam-operated, or automatic, spring-loaded fuel injection valve into the cylinder by a small quick-acting mechanically-operated pump at a pressure of 4,000–7,000 lb. per sq.in. The fuel consumption per indicated horse-power-hour is usually a little greater than with air-blast injection; on the other hand the elimination of the air-blast apparatus increases the mechanical efficiency of the engine, and in consequence the fuel consumption per brake-horse-power-hour with airless injection compares quite favourably with that when an air blast is used.

A diagrammatic illustration of a fuel injection valve and fuel pump for airless injection appears in fig. 4; the small solid-plunger eccentric-driven fuel pump is shown on the right by which the charge of oil is delivered at high pressure into the space surrounding the needle valve which is simultaneously raised just off its seat, against the pressure of its spring, by a cam-operated lever; the oil immediately enters the combustion chamber in a finely pulverized condition in the form of a hollow cone, and instant ignition occurs; in true diesel engines the inlet is held open during an appreciable portion of the down stroke, and the continued supply of oil then causes the combustion to continue at approximately constant pressure until cut-off. In the important class of so-called "semi-diesel" engines *(see* OIL ENGINES), the fuel inlet valve is not cam-operated, but is forced open, against the pressure of its closing spring, by the pump delivery pressure, and the whole charge of oil is suddenly sprayed into a heated chamber, usually a prolongation or extension of the combustion chamber; in such engines the combustion is practically instantaneous, with resulting rise of pressure considerably above that of compression.

The diesel, of all internal-combustion engines, is the most economical in fuel consumption, and Table II. illustrates in a general way not only the high economy of the type but also the progress that has been made since its introduction; all the figures given relate to single-acting four-stroke cycle inverted-vertical engines at full load, using petroleum oils as fuel:

TABLE II.—*Fuel Consumption of Diesel Engines 1897–1927*

Date	Authority	Leading dimensions of engines				Actual brake horse power	Lb. of fuel per b.h.p. hour	Brake thermal efficiency
		Number of cyl.	Cyl. bore in inches	Stroke in inches	Normal speed. rev. per min.			
								%
1897	Schroter	1	9·8	15·7	171·8	19·6	·548	25.2
1900	Meyer	1	11·8	18·1	181·2	29·7	·457	30·0
1903	A. Clark	2	15·75	23.6	154·5	164·8	·406	32.6
1905	Longridge	3	22·05	29·52	152·8	459	·451	31·7
1910	Mirrlees	3	12·0	18·25	200	130	·42j	31·6
..	Eberle	2	16·9	26.8	160·2	197·9	·416	34.8
1927	Charing Cross	6	21·5		300	1750	'39	35'5

These figures show a steady increase in the brake thermal efficiency; the highest value included, viz., 35·5%, is that of a 6-cyl. 1,750 b.h.p. engine installed in 1927 at Charing Cross for the Charing Cross Electricity Supply Co., Ltd.; this was, at that date, the largest stationary oil engine built in Britain. An external view of this engine is given in fig. 5. With special types of diesel even higher values are obtained; for example, tests conducted by the marine oil engine trials committee on a Scott-Still diesel-steam engine of 1,250 b.h.p. showed a consumption of only ·354 lb. of fuel per b.h.p. hour corresponding to a brake thermal efficiency of 36·9%. According to H. R. Ricardo, "almost, if not quite, the highest thermal efficiency ever yet recorded on a diesel engine, namely 38·8% on the net shaft horse-power, was obtained by the Royal Aircraft Establishment on a high-speed diesel engine of 8 in. bore running at 1,000 revolu-

TABLE III.

Type of engine	Best brake thermal eff.
	%
Non-condensing steam engines	8·4

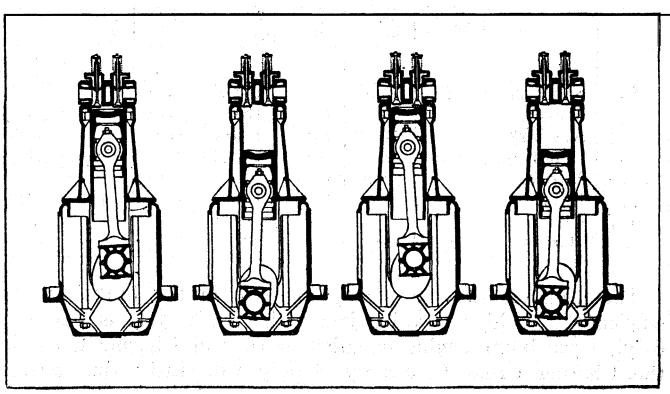
tions per minute." It is of interest to compare these figures with the best attained with other types of prime mover, and the figures on p. 3j1 (Table III.) include some given by *A.* B. Chalkley, *Diesel Engines* (6th ed., 1927).

General.— A fundamental disadvantage of the four-stroke cycle engine, especially when of the predominating single-acting type *(see* fig. 1), is the infrequency of the working impulses, and



BY COURTESY OF THE WORTHINGTON PUMP & MACHINERY CORP.

FIG. 8.— DIAGRAM OF A SINGLE-ACTING FOUR-CYCLE DIESEL ENGINE
Only during one stroke in four does combustion and generation of power occur

a reasonable degree of uniformity of revolution speed can only be obtained in single-cylindered or few-cylindered engines by the provision of heavy fly-wheels. The drawback is minimized in practice by constructing engines having two, three, four, six, eight, and even more, cylinders arranged in line and acting upon a common crankshaft, but the one impulse per cylinder in every two crankshaft revolutions is still an objection, as such engines necessarily remain very bulky and costly in relation to their power output.

The two-stroke engine at once doubles the impulse frequency, but for long the design of completely satisfactory engines of this type proved difficult, largely from the serious piston- and cylinder-cooling troubles encountered; these difficulties were in due course entirely overcome, and the attention of designers was next concentrated upon the problem of the production of double-acting engines, *i.e.*, engines in which working impulses are caused to occur on each side of the piston; this problem was obviously of extreme importance in relation to marine applications on account of the great value of space and weight saved on a ship. The double-acting engine, however, raised again in an acute form the problems of piston- and cylinder-cooling, and many experimental engines were built before success was finally attained. By the end of 1927, however, large double-acting diesel engines both of the four-stroke and two-stroke type were running regularly in commercial service; in all these the pistons are necessarily cooled by the continuous circulation through them of a current of water or oil. The piston rod terminates in an external crosshead—as in the normal type of steam engine—by which the piston is entirely relieved of the side thrust of the connecting-rod, this thrust being taken by a well-lubricated and water-cooled crosshead guide.

British engineers for long favoured the single-acting type of engine with uncooled pistons; with these the cylinder diameter is limited to a maximum of about 26 in. and is usually considerably less than this limit; with water- or oil-cooled pistons the diameter is independent of cooling considerations.

Of land installations in 1926 the largest was a 15,000 b.h.p. double-acting two-stroke diesel engine built for the Hamburg electricity works; this engine had nine cylinders, each 33·86 in. bore and 59·05 in. stroke, and ran normally at 94 revs. per minute.

FIG. 7.— DIAGRAM OF SINGLE-ACTING TWO-CYCLE DIESEL ENGINE
Power stroke occurs once per revolution, and for equal size cylinder the output is double that of the single-acting four-cycle type

An idea of its size may be formed from the statement that it had an over-all length of 77 ft., width of 14 ft. and height of $33\frac{1}{2}$ ft. The fuel consumption (using gas oil of ·875 sp.gr.) on trial was only 0·392 lb. per b.h.p. hour at full load. Among large marine installations may be mentioned:—

(1) The engines of the 23,900 ton, 19-knot, motor ship "Saturnia," launched late in 1927; this vessel is propelled by two 10,000 horse-power eight-cylindered double-acting four-stroke supercharged diesel engines of jj in. bore and 59 in. stroke; and

(2) The engines of the 32,650 ton, 19-knot, motor ship "Augus-

tus," also built in 1927, and fitted with four double-acting two-stroke diesels aggregating 25,000 b.h.p. The report of Lloyd's Register at the end of June 1927 showed that throughout the world at that date there were under construction 268 motor ships aggregating 1,459,595 tons, and 30 steam ships aggregating 1,366,809 tons; and that for the first time the motor tonnage under construction throughout the world exceeded that of steam.

FIG. 8.— DOUBLE-ACTING TWO-CYCLE DIESEL ENGINE. HAVING THE SAME WORKING SEQUENCE AS IN THE STEAM ENGINE— FOUR POWER STROKES FOR EACH FOUR STROKES OF THE ENGINE

In this necessarily limited article only a general sketch can be presented. The diesel engine forms already a highly specialized branch of engineering calling for great knowledge and skill in designing and extreme accuracy and refinement in construction. An instructive series of articles on earlier developments will be found in the pages of ***The Engineer*** from April to Oct. 1913; development since then has been so phenomenally rapid that reference must mainly be made to the many technical papers dealing with the type: ***Tha Engineer, Engineering, The Motor Ship, The Marine Engineer, Gas and Oil Power,*** etc. Of special treatises wholly devoted to the subject there are but a few, the principal, in Britain, being that of A. B. Chalkley, *Diesel Elcgines for Land and Marine Work* (6th ed., 1927), in which a very clear and complete account is given. (G. A. Bu.)

United States.— American practice in diesels is tending distinctly towards supercharging. The practice at this date is supercharging which is measurable in ounces of super-atmospheric pressure. This has two very beneficial tendencies: (1) it contributes in an engine of a given size a larger combustion space, therefore smaller ratio of chilled walls; (2) more oxygen with its complement of fuel demand per stroke. The difficulty with supercharging is that the exhaust valve or exhaust passages open at somewhat higher temperatures and pressures. It is a logical sequence that, when supercharging rises to really considerable pressures, the corresponding increased pressures at the point of exhaust opening should be utilized by farther expansion in a cylinder provided for this purpose. One group of engineers in America has been pursuing this type of design for some time with results which indicate ultimate success. The increased temperatures and pressures which the exhaust valves are compelled to handle in case of supercharging engines entail difficulties in connection with the heat erosion of the valve seats. A complete remedy for this has been found in compounding, where proper cushioning in the low pressure cylinder does away entirely with high velocity in gases passing through the exhaust port, which opens under conditions of equal pressure on both sides, the velocity being reduced to a value due to piston movement, and erosion is suppressed.

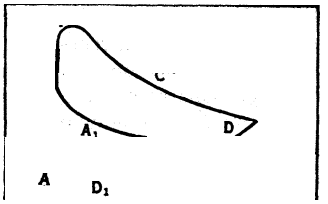

FIG. 9.— INDICATOR CARD FOR SUPERCHARGING ENGINE

Fig. 9 gives a typical card from such an engine, the supercharged induction pressure being indicated at A_1, the compression proper at BC, the fuel injection at C_1, the double expansion curve in the high pressure cylinder being indicated at C'' and that in the low pressure from E to D, the final exhaust passage opening at point D_1 near the atmospheric line.

Sleeve Valve.— Ricardo succeeded in adapting the sleeve valve to diesel operation in England in 1926. Since that time considerable advance has been made in the utilization of this type of valve for high speed engines. The great advantage of its adoption consists in giving sufficient port opening to permit the transference of gases to the low pressure cylinder. Further, the internal shape of the combustion chamber permits the supercharging pressures to be utilized by its tangential inlet direction to secure an extremely high state of turbulence, by a simple solid fuel injection nozzle. This achieves two important functions: (1) almost instantaneous co-mingling of the fuel and oxygen; (2) it allows the solid injection to reach a very much more increased amount of the oxygen present than ever before. The design lends itself, therefore, to high fuel efficiency and high speed operation. (E. A. Sp.)

DIESEL LOCOMOTIVE: see LOCOMOTIVE.

DIE SINKING, art of making tools, called dies, by means of which metals and other materials are pressed or cut into various shapes by a hammer or an arrangement of levers. The die is usually cut from steel by a machine, but where extreme accuracy is required, *e.g.*, when engraving dies for coins, goldsmiths' work and for some parts of machines, hand work predominates. Here an exact copy of the design is traced on a thin coating of wax spread over the prepared smooth surface, and is then engraved on the metal by recessing or *sinking*. The tools used are chisels, gravers and rifflers, which are small files with curved ends for negotiating curves and recessed portions. First the sinker recesses the master die by engraving, in intaglio, the design on a piece of soft steel called the *hub,* which is then hardened to form the *matrix.* By means of the matrix, the design is expressed in relief on a second piece of softened steel called the punch which in turn is hardened and held in the press to strike the softened face of the working die. Several operations are necessary to bring the impressions to a perfect state, the first blow being made on the die while in cone shape (see fig. 1). The blow changes the form to that in the second view. The working die must then be annealed, and its edge turned off a little smaller; a complete, perfectly clean impression is produced, the die appearing as in the third view.

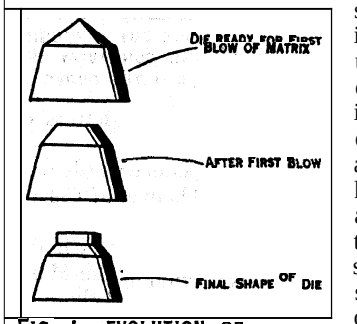

FIG. 1.—EVOLUTION OF COINING

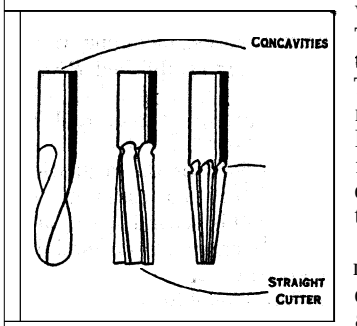
Dies for stamping coins are not actually cut by hand, but are multiplied from a hardened matrix, which has been struck from an engraved die. A number of heavy blows cause the soft working die to impress its pattern upon the



CUTTERS

Milling cutters eliminate hand cutting. The die is moved about under the cutters as required by slides controlled with screws and hand wheels

Considerable quantities of metal must be removed in sinking dies, and machine cutting, as far as possible, is essential to save hand labour. Dies which have the shape cut through from top to bottom, for press work, are roughed out on a metal jig-sawing machine, and finished on a slotting machine or a filing machine. which passes a file up and down while the die is held on a table and moved about as required. Large dies are often cut out by means of the oxy-acetylene blowpipe. A die-sinking machine, which is a milling machine, uses a variety of revolving cutters (see fig. 2). The difficulty with half-dies, pairs of which make cylindrical or spherical shapes, is the cutting of the half-round recesses. A *cherry* cutter is utilized for these; instead of revolving it is made to oscillate by the action of a curved slide on the machine, this motion (not required in other metal-working operations) cutting a half-round recess as sketched. The principle of

the copying lathe applied to the die-sinking machine, enables it to cut any intricate shapes from a pattern in sheet metal, or sunk in iron or brass, the milling cutters being guided by the movement of an arm controlled by the pattern. Pantograph engraving and die-sinking machines also work from a copy, and cut the dies to an enlarged or reduced scale. A celluloid or sheet metal copy can be used also for guidance when cutting lettering, the copy being either in one piece, or made up of the separate letters or figures clamped in a holder.

DIESTERWEG, FRIEDRICH ADOLF WILHELM (1790–1866), German educationist, was born at Siegen on Oct. 29, 1790. Educated at Herborn and Tiibingen universities, he began teaching in 1811. In 1820 he was appointed director of the teachers' seminary at Mörs, where he put in practice the methods of Pestalozzi. In 1832 he became director of the new state-schools seminary in Berlin. In 1846 he established the Pestalozzi institution at Pankow, and the Pestalozzi societies for the support of teachers' widows and orphans. In 1858 he was elected to the chamber of deputies as member for Berlin, and voted with the Liberal opposition. He died in Berlin on July 7, 1866. Diesterweg wrote several text-books and educational works, including *Wegweiser f. deutsche* Lehrer (1834), and in 1827 established *Rheinische Blätter* f. *Erziehung* u. Unterricht.

See W. Kreitz, Diesterweg *u.* die *Lehrerbildung* (1890) and K. Richter, Diesterweg *nach seinem* Leben und Wirken (1890).

DIET, a term used in two senses, (1) food or the regulation of feeding (see DIET AND DIETETICS), (2) an assembly or council. We are only concerned here with this second sense, and in particular with the diet of the Holy Roman empire and its relation to its successors in modern Germany.

The origin of the diet, or deliberative assembly, of the Holy Roman empire must be sought in the *placitum* of the Frankish empire. This represented the tribal assembly of the Franks, meeting partly for a military review on the eve of the summer campaign, partly for deliberation on important matters of politics and justice. By the side of this larger assembly, however, which contained in theory, if not in practice, the whole body of Franks, available for war, there had developed, even before Carolingian times, a smaller body composed of the magnates of the empire, both lay and ecclesiastical. The germ of this smaller body is to be found in the episcopal synods, which, afforced by the attendance of lay magnates, came to be used by the king for the settlement of national affairs. It is from this assembly of magnates that the diet of mediaeval Germany springs. The general assembly became meaningless and unnecesary, as the feudal array gradually superseded the old levy en *masse,* in which each freeman had been liable to service; and after the close of the 10th century it no longer existed.

The imperial diet (*reichstag*) of the middle ages might sometimes contain representatives of Italy; but it was practically always confined to the magnates of Germany. The regular members were the princes (*Fürsten*), both lay and ecclesiastical. In the 13th century the seven electors began to disengage themselves from the princes as a separate element; and the Golden Bull (1356) made their separation complete; from the 14th century onwards the nobles (both counts and other lords) attend along with the princes; and after 1250 the imperial and episcopal towns often appear through their representatives. By the 14th century, therefore, the originally homogeneous diet of princes is already, in practice, if not yet in legal form, divided into three colleges—the electors, the princes and nobles, and the representatives of the towns (though as we shall see, the latter can hardly be reckoned as regular members until the century of the Reformation). The powers of the diet during the middle ages extended to matters such as legislation, the decision upon military expeditions (especially the *expeditio* Romana), taxation and changes in the constitution of the principalities or the empire. The election of the king which was originally regarded as one of the powers of the diet, had passed to the electors by the middle of the 13th century.

A new era in the history of the diet begins with the Reformation. The division of the diet into three colleges was henceforth definite and precise. The representatives of the towns became regular members; but it was not until 1648 that they were recognized as equal to the other estates of the diet. The estate of the princes and counts, which stood midway between the electors and the towns, also attained, in the years that followed the Reformation, its final organization. The vote of the great princes ceased to be personal and began to be territorial: it was not the status of princely rank, but the possession of a principality which was henceforward a title to membership. The position of the counts and other lords, who joined with the princes in forming the middle estate, was also finally fixed by the middle of the 17th century. While each of the princes enjoyed an individual vote, the counts and other lords were arranged in groups, each of which voted as a whole, though the whole of its vote (*Kurialstimme*) only counted as equal to the vote of a single prince (Virilstimme).

There were six of these groups; but as the votes of the whole college of princes and counts (at any rate in the 18th century) numbered 100, they could exercise but little weight.

The last era in the history of the diet may be said to open with the treaty of Westphalia (1648). The treaty acknowledged that Germany was no longer a unitary State, but a loose confederation of sovereign princes; and the diet accordingly ceased to bear the character of a national assembly, and became a mere congress of envoys. The last diet which issued a regular "recess" (*reichsabschied*—the term applied to the *acta* of the diet, as formally compiled and enunciated at its dissolution) was that of Regensburg in 1654. The next diet, which met at Regensburg in 1663, never issued a recess, and was never dissolved; it continued in permanent session, as it were, till the dissolution of the empire in 1806. This result was achieved by the process of turning the diet from an assembly of principals into a congress of envoys. The emperor was represented by two *commissarii;* the electors, princes and towns were similarly represented by their accredited agents. In practice the diet had nothing to do; and its members occupied themselves in "wrangling about chairs"—that is to say, in unending disputes about rights of precedence.

In the Germanic Confederation, which occupies the interval between the death of the Holy Roman empire and the formation of the North German Confederation (1815–66), a diet (*Bundestag*) existed, which was modelled on the old diet of the 18th century. It was a standing congress of envoys at Frankfurt-on-Main. In the North German Confederation (1867–70) a new departure was made, which was followed in the constitution of the German empire after 1870. Two bodies were instituted—a bundesmt, which resembled the old diet in being a congress of envoys sent by the different States of the confederation, and a reichstag, which bore the name of the old diet, but differed en-

tirely in composition. The new *reichstag* was a popular representative assembly, based on wide suffrage and elected by ballot; and, above all, it was an assembly representing, not the several States, but the whole empire, which was divided for this purpose into electoral districts. Both as a popular assembly, and as an assembly which represents the whole of a united Germany, the *reichstag* of modern Germany goes back, one may almost say, beyond the diet even of the middle ages, to the days of the old Teutonic folk-moot.

See R. Schroder, *Lehrbuch der deutschen Rechtsgeschichte* (1902), pp. 149, 508, 820, 880. Schroder gives a bibliography of monographs bearing on the history of the mediaeval diet. (E. B.)

DIET and **DIETETICS,** that part of science which deals with food, its composition and its value to the animal economy in supplying the necessary material for life and work.

Food may be defined as that which when taken into the body may be utilized for the formation and repair of body tissues and for the production of energy. When a living being is increasing in size, materials must obviously be supplied for the purpose, and the food must contain in some form the actual chemical constituents of the new tissues which are being laid down. Even in the adult the various parts of the body undergo wear and tear just as any machine does and this loss of substance must be replaced from the food.

It is not necessary that all the chemical compounds which are found in the body shall be present in the food; but the necessary chemical elements and certain complex groupings must be provided from which the body can build up what it needs. Only a small part of the ingested food is made use of for purposes of growth or replacement; most of it is needed for the liberation of energy to perform muscular and glandular work, and partly for conversion into heat. The law of conservation of energy has been found to apply to man and animals as well as to inanimate nature; the income and expenditure of energy in the body are equal.

The energy value of foodstuffs is universally expressed in terms of heat units or *calories* (referred to in this article as C.). The calorie (C) is the quantity of heat energy required to raise the temperature of one kilogram of water by 1° Centigrade. The total energy that can be obtained from food is determined by burning a known weight of foodstuff in oxygen and measuring the amount of heat produced by the combustion.

Essential Constituents. — The essential constituents of a diet are *proteins, fats, carbohydrates, vitamins, water* and *salts. Proteins* are complex bodies containing the elements C, H, O, N, and sometimes P, S, and Fe. They are the only constituents of the diet which contain nitrogen in a form which may be used for purposes of body building or of repair. The albumen of egg white, vitellin of egg yolk, myosin of meat, casein of milk and glutein of flour are examples. Meat extract, soups and beef tea have practically no energy value though they probably improve the appetite and increase the flow of the digestive juices.

Fats are compounds of glycerin with acids containing a large number of carbon, hydrogen and oxygen atoms and afford much energy when burnt. Butter, lard, suet, olive oil are examples of nearly pure fats, but fat is a constituent of most natural foodstuffs in varying quantity.

Carbohydrates contain carbon, hydrogen and oxygen, the two latter elements being present in the same proportions as they are in water. They are met in a variety of *forms* — *starch,* a prominent constituent of wheat and other cereals and potatoes; *sugar,* of which several kinds are distinguished; e.g., *cane sugar* of sugar cane and beetroot, milk sugar or *lactose* of milk, *glucose* and *fructose* in fruits and honey.

These three kinds of foodstuffs yield energy on being oxidized in the body, so that in a diet they may be replaced one by the other to a considerable extent. But we shall see that certain minimal amounts of the individual foodstuffs are essential if health and growth are to be maintained. The accepted values for the energy liberated by 1gm. of each of the foodstuffs when burnt in the body are as follows: — Protein 4·1 C.; carbohydrate 4·1 C.; fat 9.3 C. If protein is completely combusted outside the body it yields 5·6 C. per 1 gm. The destruction of protein in the body is, however, not so complete, as a certain number of products are excreted in the urine which are capable of still further oxidation and liberation of energy.

ENERGY REQUIREMENTS

Basal Metabolism. — For a first calculation it is desirable to determine the total food requirements in terms of calorie value, for we have to provide sufficient energy to meet individual needs. Living matter is continually undergoing chemical changes and as a result of these activities energy is being liberated. This process is taking place on a considerable scale even when the body is under conditions of complete physical and mental rest. The amount of energy evolved is found to be correlated most closely with the *surface area* and less closely with the body weight.

It is found desirable for comparative purposes to determine the energy output first under so-called *basal* conditions — namely at complete bodily rest after the digestion and absorption of the last meal has been completed. In adult males the energy liberated under such conditions (basal metabolism) is 40 C. per sq. metre of body surface per hour or less accurately 1 C. per kg. body weight per hour. The surface area can be calculated from du Bois' formula $S = \cdot 007184 \times W^{0.425} \times H^{0.725}$, where S is the surface in sq. metre, W the weight in kilograms and H the height in centimetres. In females the metabolic processes are slightly less active and only amount to 37 C. per sq. metre per hour.

Mean Heights, Weights and Surface Area

	Height.	Weight.	Surface area.
Men.			
American and Canadian insured persons 1912 .	5′ 8·5″ (174 cm.)	155 lb. (70·3 kilo)	1·792 sq. metres
British Association (1883) for England (ages 20–50)	5′ 7·4″ (171 cm.)	155 lb. (70·3 kilo)	1·772 sq. metres
Women.			
American and Canadian persons 1912 .	5′ 4·5″ (163·8 cm.)	134 lb. (60·8 kilo)	1·60j sq. metres
British Association (1883) for England (ages 20–50)	5′ 2·7″ (159·3 cm.)	122·8 lb. (55·7 kilo)	1·511 sq. metres

The weights quoted are with the clothes on; 10 lb. has been subtracted from them before compiling the surface area to allow for the weight of the clothes.

The English figures are old, but have recently been confirmed for nearly 5,000 working women. An English adult with a surface area of 1·772 sq. metre would have a basal metabolism of 1·772 × 40 C. per hr. or 1701 C. per 24 hours. The basal metabolism diminishes slightly as age advances, so that the resting energy requirements of the old are less than those of young adults. This large resting energy output is devoted to a small extent to maintain the activity of the vital organs — to enable the heart, the brain, the respiratory muscles and the essential glands to continue their functions; but in the main the energy is converted into heat and used to maintain the normal temperature of the body.

The basal metabolism is altered by changes of external temperature. On exposure to cold, metabolism is stimulated, chiefly by increased muscular activity; on exposure to heat, it is somewhat surprising to find that there is little depression of the metabolism. Immediate compensation is established by sweating and flushing the skin with blood. In the tropics, however, it has been shown by de Almeida that the metabolic rate is about 25% lower than it is in the temperate zone, and food requirements would be correspondingly diminished. A rise of 1° F. in body temperature causes an increase of 7% in the metabolism, so that a patient with a temperature of 105° F. would have a metabolic rate which is 50% above normal.

Prolonged under-nutrition results in a great lowering of the resting metabolism and this may be regarded as a protective reaction on the part of the tissues to the unfavourable environment.

The ingestion of *food* results in an increase in metabolism; this is mainly due to the stimulating action exerted by the products of digestion on the tissue cells. This effect varies with the kind of food consumed, and is more marked with protein than with fats or carbohydrates. This property of protein is referred to as its "specific dynamic action" and is due to the action of the amino-acids of which it is composed, more especially glycine and alanine. It is difficult to see what advantage is conferred on the body by the specific dynamic action of protein; it gives rise to a wasteful expenditure of energy quite independently of the needs of the body. The effect of an ordinary mixed diet is to increase the daily metabolism by about 10%.

Finally energy is needed for the carrying out of physical *work*. It is difficult to compute the energy expended during ordinary body movements and in the various avocations. It must be remembered that the mechanical efficiency of the body is about **25%;** by this is meant that only 25% of the energy freed as a result of the chemical transformation in the muscles is converted into work and the remaining 75% is dissipated as heat. Consequently if the energy value of the work done is expressed in heat units, this figure must be multiplied by four to obtain the amount of energy liberated in the body during the process. An example may help to make this clearer. It is usual to assume that the average amount of work done daily may be represented by eight hours' continuous moderate work. It has been shown by Waller that a young man may perform in eight hours without fatigue about 100,000 kilogram-metres of work in raising his body by going up a staircase. This is equivalent to **240** C. when expressed in heat units. The total energy liberated during the process is $240 \times 4 = 960$ C. An increase of about 20% in the metabolism is produced by moving about a room, carrying out the small activities of daily life and being exposed to fluctuations in the external temperature.

Average Calorie Requirements — We can now calculate the daily calorie requirements of an average man in whom the basal metabolism is 71·1 C. per hour. It is convenient to divide the day into three eight-hour periods:

Eight hours' sleep, eight hours' rest and eight hours' work

	Calories
eight hours asleep at 71·1 (Basal metabolism)	568.8
eight hours awake at 92·4 (basal+30% *i.e.*+ 10% for action of food and 20% for minor activities)	739·2
eight hours' work (basal+960 C.)	1,528·8
Total	2,836·8
Add for locomotion and travelling	300
	3,136·8 (Starling)

In the above-given estimate an allowance had been made for the energy expended in travelling between home and place of occupation. The Food (War) Committee of the Royal Society suggested that the various occupations should be classified as follows as far as the energy requirements for the work are covered: —

Sedentary: less than 400 C. in excess of resting requirements.
Light work: 400 to 700 C. in excess of resting requirements.
Moderate work: 700–1,100 C. in excess of resting requirements.
Heavy work: 1,100–2,000 C. in excess of resting requirements.

Among the sedentary pursuits must be included all classes of brain worker. Even the most intense mental activity causes no appreciable increase in the metabolism. In a country like Great Britain determinations of the total energy expended by different classes of workers have shown that the average is about **3,000** C. per diem. A distinction must be drawn between the energy value of the digested food and of the food as purchased. A small percentage of the food escapes digestion and absorption and is eliminated in the fæces; this is more marked on a vegetable than on an animal diet. It is usual to deduct 10% from the theoretical calorie value of the mixed diet to allow for this loss. Thus if 3,000 C. are needed by the body, the daily ration should contain 3,300 C. and this represents a fair average allowance for each adult male of the population. The energy requirements of working *women* can be similarly calculated and found to be about 2,200 C. A net allowance of 2,400 C. would be ample and leave an adequate surplus for household duties. The calorie value of the food as purchased should be **2,650** C. The food requirements of a purely sedentary worker should not exceed 2,100 C.

Calorie Needs of Children. — The energy needs of *children* are extremely difficult to compute. The basal metabolism in children per square metre of body surface per hour is considerably higher than in adults; *e.g.* age **6,** 57·5 C.; age 12·6, 50·4 C.; age 13·7, **49.4** C.; age **16**·5, 43·0 C.; age 20·25, 40·7 C. (du Bois). Greenwood has calculated from the scanty data available the basal requirements in calories of boys and girls.

Age	5	6	7	8	9
Boys	1026	1100	1159	1197	1262
Girls	1008	1057	1110	1163	1201
Age	**10**	**11**	**12**	**13**	**14**
Boys	1328	1358	1389	1430	1499
Girls	1266	1321	1399	1476	1539

The fact that *growth* is occurring implies that excess of energy must be taken over and above that required to furnish the energy output of the body. Between the ages of 11 and **16** both sexes put on weight at the average rate of about **4** kilos a year. This is equivalent to only **30** C. per day; but the growing body is formed at the expense of many different varieties of food which have to undergo chemical conversions of different kinds before they can take their place as part of the living body, so that probably the amount of energy which must be provided in the food to produce the necessary increase in weight is considerably in excess of 30 C. It is very difficult to compute the energy output due to muscular activity in children. Lusk gives the following table to show the food requirements of children in relation to that of an average man or woman:

Age.	Coefficients.	Utilizable calories.
Averageman	1·0	3,000
Average woman	0·83	2,500
0–6 (both sexes)	0·5	1,500
6–10 (,, ,,)	0·7	1,800
10–14 (,, ,,)	0·83	2,500
14–20 (boys)	1·0	3,000
14–20 (girls)	0·83	2,500

Average and Total "Man Value." — By using these coefficients we can determine the "average and total man value" of a mixed population.

Ages.	Population.	"Man Value" per head.	Total "Man Value."
0–6	5,772,153	0·5	2,886,076
6–10	3,708,513	0·7	2,595,959
10–14	3,548,403	0·83	2,945,174
Males 14 and upward	15,436,633	1·0	15,436,633
Females 14 and upward	16,807,929	0·83	13,950,581
	45,273,631	0·835	37,814,423

The table quoted from Starling shows the calculation made for **1911** population of the United Kingdom. Allowing 3,300 C. per man per day, the total requirements of the whole population would amount to approximately **45.5** billion calories. It is interesting to note that the average annual requirements per head are **1,200,000** C. A computation has been made of the calorie value of the food available for consumption in the United Kingdom during the years 1909–13. It amounted to just over **47** billion calories, which gave a daily ration of 3,410 C. per "average man." In France, according to official statistics, the average consumption per man per day before the war was 3,800 C.; in 1916–17, **3,300** C.; in 1917–18, **2,900** C. Some small addition must be added to these figures for the calorie value of cottage and garden production which cannot be determined accurately. The average energy consumption per head for all countries is **3,400** C.

World's Calorie Requirements. — Holmes has presented data to show the amount of energy contributed annually to the world's requirements by the more important food materials. Expressed in trillion calories the figures are: — Rice 900, wheat 382, sugar 209, rye 164, barley 119, potatoes 99, meat 62. The figures show clearly how dependent mankind is on cereals for the major part of its energy needs. The consumption of meat is concentrated in relatively few countries. No data are available for China, India or Japan where the amount used is known to be small. The highest figures are those of the meat raising countries, Australia, Argentine and the U.S.A. where the number of lb. of meat and meat products consumed per head annually are 262.6, 140 and 171 lb. respectively. In Great Britain the figure is 119 lb. and in Portugal only 44 lb.

If the diet of many nations is surveyed, it is found that meat, including fish, poultry and eggs, supplies 20% of the calories and about the same percentage of the protein; milk and its produces 13–17% of the calories and 14–25% of the protein; cereals 35–40% of both calories and protein. The greatest variation is found in the nature of the cereal used. In Great Britain and France it is almost exclusively wheat; in U.S A. maize is not unimportant; in Germany especially among the rural population, rye is used almost exclusively. The part played by sugar is greatest in Great Britain and the U.S.A. but is considerable in all countries. Potatoes usually furnish 10–12% of the total energy needs and a somewhat smaller part of the protein.

COMPOSITION OF COMMON FOODSTUFFS

The coinposition of the common foodstuffs must now be surveyed.

Table of composition and calorie value of more important foodstuffs adopted by the Inter-Allied Scientific Food Commission. (The carbohydrate content is not quoted but is taken into account in calculating the energy values.)

Commodity.	Protein %.	Fat %.	Calories per kg.
Cereals			
Wheat and barley flour	11·5	1·0	3,640
Oatmeal	16·0	8·0	4,000
Barley meal	10·5	2·2	3,600
Rice	8·0	0·3	3,540
Meat			
Beef, prewar	14·5	22·5	2,690
Beef, wartime	15·0	18·0	2,290
Veal	16·0	6·3	1,230
Mutton	13·5	24–30	2,790–3,340
Bacon	9·5	60·0	6,000
Ham	14·5	34·0	3,750
Poultry and game	15·0	9·5	1,500
Herrings	11·6	4·0	850
Fresh fish	10·0	1·0	500
Dairy produce			
Eggs at 2 oz	12·0	9·5	1,400
Milk	3·3	3·7	700
Butter	1·0	85·0	7,950
Cheese	25·0	30·0	4,000
Margarine	1·2	83·5	7,800
Lard	2·2	94·0	8,800
Fresh fruits	av. 0·7	0·4	500
Nuts	av. 6·5	22·8	2600
Potatoes	1·8	0·1	700
Shelled peas and beans	7·0	0·5	1,000
Dried peas	24·3	1·3	3,600
Refined sugar	..	..	4,100
Cocoa	15·0	34·0	4,800
Olive oil	..	100·0	9,300

The percentage *carbohydrate* content of the different classes of food are: cereals 66–75; meat and poultry, eggs, fish, butter, olive oil, nothing or a trace; milk j; cheese 24; peas and beans 60; potatoes 14–18; fruits 4–14; starch go; sugar 100.

The percentage composition of *bread* is: protein 9·0, fat 1·5, carbohydrate 53, calories 1,200 per 1 lb.

The proportions of protein, carbohydrates and fat in a normal diet have been given somewhat differently by different authorities. (1) Royal Society Food (War) Committee; (2) and (3) from Voit.

Protein. — As has been pointed out previously, protein is an essential constituent of the diet because it is the only class of foodstuff containing Nitrogen (and Sulphur) in a form which can be assimilated by the tissue cells and used for the replacement of the nitrogen lost as a result of the normal cell activities.

Anywhere in the world except among the destitute, the protein consumption does not fall below 1 g. per kilo. per diem, or 70 g. for a man of average weight; in N. Europe and the U S.A the figure is more like 1·3 g. to 1·5 g. per kilo. or about 100 g. per man. 8·5% of the total calories needed are obtained from protein in the Orient and among the poorer classes of mankind; 18 to 19% in Swedish and Finnish diets; 44% among the Esquimaux; the average for normal diets is 12–15% and only exceeds 18% in exceptional circumstances. The amount of protein consumed varies directly with the wealth and social position of the individual; it is not increased in the case of men doing hard work. Thus the lumber men of Maine or Sweden who consume 8,000–9,000 calories daily, obtain only 10·5% of their calories from protein and about 58% from fat.

The *minimum* protein requirements are probably 30 to 40 g. per day, provided that the protein is of the proper constitution. On such a ration, if enough carbohydrate and fat is consumed to provide the full energy requirements of the individual nitrogenous balance may be maintained, the amount of nitrogen lost (chiefly in the urine), being no greater than the amount ingested. But with certain kinds of protein it is impossible to obtain nitrogen balance no matter how much is consumed. Some of the amino-acids present in protein are essential for the proper functioning of the body, presumably because they cannot be synthesized and so must be provided in the food and serve for the formation of essential secretions or enzymes. These amino-acids are tryptophane, tyrosine, lysine, cystine and histidine. Without tryptophane or histidine body weight cannot be maintained; without lysine growth cannot occur. Adequate amounts of cystine are essential if a normal rate of growth is to occur. Proteins which are deficient in any of these amino-acids are of inferior biological value and cannot in themselves produce healthy development. *Gliadin* of wheat contains no lysine; *zein* of maize is deficient in tryptophane and lysine; *gelatin* contains no tryptophane or tyrosine; *casein* is deficient in cystine but together with the lactalbumen of milk forms a satisfactory source of protein. Proteins which contain all the essential amino-acids are ovalbumen (egg), glutein (wheat), glutelin (maize), excelsin (brazil nut), lactalbumen (milk).

Experiments have been carried out by Chittenden, Hindhede and others, in which nitrogenous equilibrium, unimpaired health, and mental and physical vigour have been maintained for months or years on diets which contained no more than 30 to 50 g. protein daily. But the proteins were specially selected and were of high biological value. To provide a margin of safety when consuming a mixed diet. a minimum of 80 g. should be aimed at and this tallies better with the general experience of mankind. Bayliss said "Take care of the calories and the proteins will take care of themselves" because if dietaries are studied it is found that if the calorie value of a mixed diet is adequate it will probably contain 100 g. of protein or even more.

Vegetable proteins as a class are rather less effective as body builders, but there are marked exceptions; the proteins of potato being one of the most efficient. The mixed proteins of wheat or maize as found in flour or meal will maintain nitrogenous equilib-

rium at a fairly low level, particularly if whole grain is used and if it be supplemented by small quantities of other proteins such as those of milk.

Fat.—The amount of fat consumed varies with the country, economic status, occupation and the time. The maximum fat content of the native diets in Japan is about 30 g. per day, which is (except during the war period) the European minimum. The amount of fat eaten increases steadily with the income. The Inter-Allied Food Commission adopted 57 g. daily as the minimum fat ration, during the war. Experiments of short duration have been carried out (Hindhede) in which health and weight were maintained on diets of high total calorie value with as little as 10·9, 13·8 and 13·9 g. of fat daily. Although the body can adapt itself to partial or even complete deprivation of fat for short periods (probably preparing the necessary fat from the carbohydrate of the food) deleterious effects will become apparent after months or years. The significance of fat in the diet depends on several factors. It is highly assimilable and is almost entirely absorbed from the alimentary canal. But its absorption is a gradual process, not reaching its maximum till five or six hours after a meal. Man is unaccustomed to work with the alimentary canal entirely at rest, and when the digestion of the last meal is finished, hunger recurs and affects the efficiency of the work.

The bulk of the food becomes of importance when the total energy requirements of the body are very large. Weight for weight fat has double the calorie value of starch or sugar. Fat, in addition, is taken without admixture in a pure form, whereas the other foods are all mixed with a considerable proportion of water; when starch is cooked it is swollen up with fire to ten times its voiume of water. As has been pointed out, the Swedish and American lumbermen and the Welsh miners obtain a large part of their huge calorie intake from fat. Carbohydrates are more subject to fermentative changes in the intestine with the production of gases and general discomfort. A study of dietaries shows that a normal diet of 3,000 C. should contain 75 g. fat (698 C.); the proportion of fat in the diet may be increased to 35% of the total calories where there is abundance of animal food; the fat ration should always be high if there is a large increase in the energy expenditure of the body, either in the form of work or in consequence of exposure to cold (Starling).

As is shown below, the animal fats are the most important sources of some of the vitamins; *i.e.*, A, D and E. The vegetable fats are an equally effective source of energy, but are deficient in vitamins. It is advisable from the point of view of the health of the community that margarine should not be made exclusively from vegetable oils, but should have added to it animal fats (not lard) or milk fats.

Carbohydrates furnish more than 50% of the energy content of most diets, and are a cheap and readily obtained food. If greatly reduced in amount. the fats are incompletely oxidized and give rise to poisonous bodies such as β-hydroxy-butyric acid and aceto-acetic acid. As both carbohydrate and fat serve chiefly as sources of energy, they can replace one another to a considerable extent, so long as precautions are taken to ensure the minimum amounts of fat specified above.

Vitamins.—The vitamins (*q.v.*) or accessory food factors are a group of substances of unknown chemical composition present in the food which are essential for adequate growth and for the maintenance of health. Five such bodies have been described—vitamins **A,** B, C, D and E.

Vitamin A (fat soluble A) is found associated with certain animal fats; *e.g.*, butter, cream, beef-fat, cod liver oil, eggs and the embryo of seeds; and green vegetables. It is absent from root vegetables and from vegetable fats; *e.g.*, linseed oil, olive oil. It is not found to any extent in lard. It is therefore absent in purely vegetable margarine. It is a fairly stable substance and can resist the ordinary processes of cooking. It is essential for *growth* in young animals and promotes the resistance of the various mucous membranes, as of the intestinal or respiratory tract or the eye, against infection. in its absence disorders like broncho-pneumonia, enteritis and inflammation of the eyes are common

Vitamin B (water soluble B) is found in most natural foodstuifs, especially in seeds and eggs. In the pulses it is found throughout the seed; in the cereals it is only found in the germ and the bran. It is present in yeast. It is absent from white flour and is apparently present in inadequate amounts in white bread, in spite of the yeast which is added previous to baking. Wholemeal bread is an important source of the vitamin. This vitamin probably exerts a specific stimulating action on the functions of the digestive tract, increases the movements of the bowel and aids effective digestion and absorption of the food.

Vitamin C (antiscorbutic vitamin) is found in *fresh* foodstuffs: fruit juices; *e.g.*, lemon, orange; vegetables; *e.g.*, raw cabbage leaves, raw juice of swedes, and to some extent in potato. It is present in small amounts in fresh milk, and it is formed during the process of germination of seeds. This vitamin is rapidly destroyed by heating at 100° C. (especially in an alkaline medium) and by drying. It is absent from dried, canned or preserved foods. The absence of the vitamin results in a condition called scurvy which is characterized by haemorrhages from different parts of the body.

Vitamin D (anti-rachitic vitamin) has a very similar distribution in nature to Vitamin A. It can be synthesized from a complex lipoid, ergosterol, by means of ultra-violet rays. It is present in cod-liver oil, beef suet, lard and to a less extent in vegetable fats. It is believed to promote the absorption of calcium and phosphorus from the bowel and thus ensure sufficient concentrations of these substances in the blood to ensure normal development of the skeleton.

Vitamin E is a recently described accessory factor which is necessary for fertility in both sexes. It is present in whole wheat. wheat germ, lettuce, rolled oats and milk fat.

It is clear from this brief survey of the distribution and properties of the vitamins that *animal fats, eggs, milk, fresh fruit and vegetables* and *whole cereals* should be present in adequate amounts in the dietary to ensure normal growth, health and reproductory vigour.

WATER, SALTS, COOKING, ETC.

Water and Mineral **Salts.**—*Water* does not afford energy since it is already completely "burnt" or oxidized. It may be looked on, however, as a kind of food as it is necessary for the proper working of the animal machine; it can be compared to some extent to the lubricating oil used for the moving parts of the petrol motor. Water is continually being lost in the urine and lungs and sweat and faeces and it must be replaced. The *mineral* constituents of the human body amount to 4·3–4·4%. The only salt commonly consumed as such is table salt or sodium chloride (NaCl). The various salts needed by the body are present in small amounts in food, particularly in milk and in vegetables. 1–2 g. of NaCl are needed daily, and while custom varies considerably, the average intake is probably nearer 8–10 g. Possibly habit has resulted in the use of much more NaCl in the human dietary than is physiologically necessary. 0·9–1 g. of *calcium* is needed daily (Sherman), and the minimum necessary for the maintenance of a calcium balance is 0.63 g. calcium per 70 kg. of body weight. Of the American diets investigated by Sherman 15% were found to be deficient in calcium. A sufficient calcium supply is very important, especially in children because calcium phosphate is the chief constituent of bone and is best obtained by the ingestion of liberal quantities of milk Of *phosphate* 0·88 g. is the minimum needed per 70 kg. body weight, but there is no risk of phosphorus shortage in diets yielding 3,000 C. daily unless large amounts of degerminated patent flour are consumed as the principal cereal.

Iron is an essential constituent of the food since it is its presence in the haemoglobin of the red corpuscles which endows the blood with the power of transporting oxygen from the lungs to the tissues. The daily intake of iron should be not less than 12 mgm daily, a figure which should be increased in pregnancy and in lactation. it must be mentioned that milk is very deficient in iron, and that this substance is principally obtained from animal Food and the chlorophyll of green vegetables. It has been shown in animal experiments that iron deficiency leads to impoverish-

ment of the blood and stunting of growth. A similar anaemia develops in infants at the 6th month if they have been fed exclusively on milk, hut rapid recovery is noted when a mixed diet is commenced. It is now advised thai infants shall be given small amounts of soups prepared from marrow bones and mixed vegetables from the 3rd month onwards, partly to prevent this anaemia.

Iodine in minute traces is essential for the preparation of thyroxin which is the name given to the active principle of the secretion of the thyroid gland. In districts in which the iodine supplies in the drinking water are insufficient simple goitre frequently develops. This may be prevented or the condition may be cured by the use of iodized table salt, or by the deliberate addition of iodine to the water supply *(see* GOITRE).

Vegetarian Diet.—The real objection to the free use of meat *(see* VEGETARIANISM) is that though animals are partly fed on materials not required for human consumption (cow, sheep), they are to some extent grain fed (pig, fowl), or live on products that are grown on land which might otherwise be used for vegetables, grain or fruit. To this extent animals compete with man for utilizable foods. The cow, pig and fowl consume 12–14 lb. dry fodder for each 1 lb. of dry human food produced (as meat, eggs, etc.); the sheep 24 lb. and the ox 64 lb. (Wood). Prime beef is thus the most extravagant of all forms of animal food as regards the quantity of vegetable food required to produce it. Because of these facts, meat is dear, and if too large a proportion of the income is expended on meat there is not enough left for milk and vegetables which are indispensable constituents of the diet.

The great disadvantage of a purely vegetarian diet is its bulk. This objection does not apply to a lacto-vegetarian diet which permits the free use of milk and eggs; in fact such a diet has much to commend it (Greenwald). It need not be bulky. The milk and eggs furnish protein of exceptionally good quality to compensate for possible deficiencies in those supplied by other articles of the diet, and they contain much phosphorus and calcium, the latter of which is apt to be present in inadequate amounts if milk is not included in the diet and they furnish a considerable, if seasonally-varying quantity of some of the vitamins. Moreover the cow and hen return in the form of milk and eggs much more of the energy they receive than they do if kept for their meat (Armsby).

Cooking.—The great value of cooking lies in making dishes attractive to the palate and other senses and thus ensuring an adequate intake of food; it improves the digestibility of certain classes of food partly by splitting the envelopes of the starchy granules and also by destroying certain substances which prevent the action of the digestive enzymes. It kills micro-organisms and other parasites. It has a destructive action, however, on some of the vitamins, but this is of considerable extent only in the case of the antiscorbutic factor, and it can be readily compensated for by taking fresh fruit or vegetables.

When the diet is controlled by authority the essential points to be borne in mind are:—the prbvision of the necessary *calories,* which will almost certainly ensure adequate amounts of protein; the maintenance of a minimum *fat* supply; plentiful supplies of *milk* and milk products especially for children and of *fresh vegetable food.*

Army and Navy Food Scales.—To illustrate how the practical problems of dietetics are treated, a brief reference will be made to the procedure in the navy and army.

In the British navy *(see* Appendix XIX. King's Regulations and Admiralty Instructions) the daily standard ration, service afloat, is 10 oz. bread, ½ lb. fresh meat, 1 lb. fresh vegetables or 4 oz. haricot beans or marrow fat beans when fresh vegetables are not available, ½ pint spirit, 2 oz. sugar, ½ oz. tea, ½ oz. chocolate (or 1 oz. coffee), ¾ oz. condensed milk, 1 oz. jam, marmalade or pickles, 4 oz. corned beef on one day of the week in harbour or on two days at sea, mustard, pepper, vinegar and salt as required. This ration is supplemented by money allowances, out of which the men purchase at their discretion the extra foodstuffs necessary to complete their messing.

In the army *(see* 40/WO/8263 [Management of Soldiers Messing] and 40/WO/9071 [Manual of Military Cooking and Dietary]) the diet provided contains Protein 136 g., Fats 138 g., Carbohydrates 442 g.

The daily scale of rations is:—Meat, fresh or frozen 12 oz. (or preserved meat 9 oz.); bread 16 oz. (or biscuits 12 oz.); bacon 2 oz.; sugar 1½ oz.; tea ⅜ oz.; suet ¼ oz.; cheese 1 oz.; jam or syrup 1½ oz.; margarine 1 oz. Messing cash allowance of 3½ d. per day.

DIETARY: *see* DIET AND DIETETICS.

DIETERICI, FRIEDRICH (1821–1903), German orientalist, and a pioneer in mediaeval Arabic studies, was born on July 6, 1821, in Berlin, where he died on Aug. 18, 1903. He travelled in Egypt and the Near East from 1847–49 and on his return became professor at Berlin. His writings did much to stimulate an appreciation of the speculations of the mediaeval Arabs; they include *Alfijgah, carmen grammaticum auctore Ibn Mâlik* (1851); *Mutanabbii carmina cum commentario Wâhidii* (1858); *Die Philosophie der Araber im 9 u. 10 Jhr. n. Chr.* (1876–95); *Die sogenannte Theologie des Aristoteles* (trans. from Arabic, 1883); *Der Streit zwischen Mensch u. Thier . . . aus den Schriften der lauteren Brüder übersetzt* (1858); *Alfarabis philosophische Abhandlungen* (Arabic ed. 1892); *Der Musterstaat von Alfarabi* (trans. from Arabic, 1900); *Christomathie Ottomane* (1854) and an oriental novel, *Mirjant* (1886).

DIETHER VON ISENBURG (1412–1463), second son of Count Diether of Isenburg-Biidingen, was rector of the University of Erfurt in 1434 and became archbishop of Mainz in 1450. He led the movement for the reform of the empire, and the opposition to the papal encroachments, supporting the theory of Church government enunciated at the Councils of Basel and Constance and condemned in Pius II.'s bull, *Execrabilis. (See* PAPACY.)

DIETRICH, CHRISTIAN WILHELM ERNST (1712–1774), German painter and engraver, was born at Weimar on Oct. 31, 1712, and died at Dresden on April 24, 1774. He was taught by his father, Johann George, painter of miniatures to the court and was then sent to Dresden to work under Alexander Thiele, the landscape painter. Augustus II., king of Saxony, sent him to Italy and the Netherlands where he learnt to imitate the masters of the previous century with amazing fidelity. At Dresden there are pictures acknowledged to be his, bearing the fictitious dates of 1636 and 1638 and the name of Rembrandt. His "Itinerant Musicians," in the manner of Ostade, is in the National Gallery, London. In 1741 he was appointed court painter to Augustus III. at Dresden, with an annual salary conditional on the production of four pictures a year and there are 52 of his canvases and panels in one room at the Dresden Museum. A collection of his engravings at the British Museum, produced on the lines of earlier men, such as Ostade and Rembrandt, reveal both spirit and skill. Dietrich, after his return from Italy generally signed himself "Dietericij." He was director of painting at the Meissen porcelain factory and professor of the Dresden academy of arts.

DIETRICH OF BERNE, name given in popular story to Theodoric the Great. The legend differs so widely from the true history that even in mediaeval times some doubted the connection, and noted the staring anachronisms. But the identity seems to be proved by the names Dietrich (Theodoric), Dietmar (Theudemir), Berne (Verona), Raben (Ravenna); and there is some resemblance in character between Theodoric and Dietrich. The South-German cycle of Dietrich-songs is partially preserved in the *Heldettbuch* (*q.v.*), *Dietrichs Flucht,* the *Rabenschlacht,* and *Alpharts Tod;* but it was reserved for a 13th century Ice-

lander to compile a consecutive account. This prose redaction *(Vilkina* or *Thidreks Saga)* incorporates much matter from the Nibelungen and Wayland legends; in fact practically the whole South-German epos.

There are traces of a form of the story in which the hero started out from Byzantium for the conquest of Italy. But this was very early superseded by the existing legend, in which, perhaps by epic fusion with his father Theudemir, he was associated first with Attila and then with Ermanaric, by whom he was driven from his kingdom of Berne. After years of exile at Attila's court he returned with a Hunnish army and defeated Ermanaric in the Rabenschlacht (battle of Ravenna). Attila's two sons fell in the fight, and Dietrich returned to Attila to answer for their death: this seems to suggest that originally the Rabenschlacht was a defeat. In *Ermenrichs Tod* he slays Ermanaric, as in fact Theodoric slew Odoacer; and in the *Hildebrandslied* "Otacher" takes the place of Ermanaric. Dietrich's long stay with Attila represents Theodoric's youth spent at the Byzantine court; the period of exile was as usual adorned with marvellous exploits, most of which had no connection with the cycle; the poems of *König Laurin, Sigenot, Eckenlied,* and *Virginal* are based largely on independent traditions. Through Attila Dietrich enters the Nibelung cycle. In the final catastrophe it is he who, to avenge his Amelungs, at last delivers Hagen to Kriemhild. His "flame-breath" seems to be pure myth; but the tales of his demonic origin and of his being carried off by the devil may be ascribed to clerical hostility to Theodoric's Arianism.

Dietrich typifies the wise and just ruler as opposed to Ermanaric the typical tyrant. He is invariably represented as slow to anger; but once roused he overcomes even Siegfried (but probably the fight in the rose garden at Worms is a late accretion). The chief heroes of the Dietrich cycle are his tutor and comrade Hildebrand *(see* HILDEBRAND, LAY *OF),* with his nephews the Wolfings Alphart and Wolfhart; Wittich, who renounced his allegiance and slew Attila's sons; Heime and Biterolf.

The poems of the Dietrich-cycle are summarized by Uhland, *Zur Geschichte der Dichtung und Sage* (Stuttgart, 1873). *Thidrekssaga* (ed. Unger, Christiania, 1853) is translated into German by v. der Hagen, *Altdeutsche Heldensagen* (Breslau, 3rd ed., 1872). A summary of the legend is in Hodgkin, *Theodoric* (1891). Part of *Thidrekssaga* is in Mobius, *Analecta Norroena* (Leipzig, 1877). *See* also W. Grimm, *Deutsche Heldensage* (1867); accounts in Sandbach, *Saga-cycle of Dietrich* (1906); Jiriczek, *Deutsche Heldensage* (trans. Bentinck-Smith, *Northern Legends,* 1902). Original extracts, Jiriczek, *Kudrun und Dietrichepen* (Stuttgart, 189;). For full bibliography *see* Symons, *D. Heldensage,* in Paul's *Grundriss;* also Goedeke, *Geschichte der d. Dichtung* (1857–81).

DIEZ, FRIEDRICH CHRISTIAN (1794–1876), German philologist, the founder of Romance philology, was born at Giessen, Hesse-Darmstadt, on March 1;, 1794. A visit to Goethe in 1818 decided the direction to his studies. Goethe had been reading Raynouard's *Choix de poésies originales des troubadours,* and advised the young scholar to explore the rich mine of Provencal literature which the French savant had opened up. Henceforth Diez devoted himself to Romance literature. He removed in 1822 to Bonn, where he held the position of privat-docent. His *Poesie der Troubadours* (1826) and *Leben und werke der Troubadours* (1829), of both of which there are modern editions edited by Karl Bartsch, were his earliest important studies. In 1830 he became professor of modern literature at Bonn. The rest of his life was mainly occupied with the composition of the two great works on which his fame rests, the *Grammatik der romanischen Sprachen* (3 vols., Bonn. 1836–44; 5th ed. 1882), and the *Etymologisches Wörterbuch der romanischen Sprachen* (2 vols., Bonn, 1853; 5th ed. 1887); in these two works Diez did for the Romance group of languages what Jacob Grimm did for the Teutonic family. He died at Bonn on May 29, 1876. He also wrote works on Spanish and Portuguese language and early literature.

See W. Foerster, *Friedrich Diez* (1894).

DIEZ, town of Hesse-Nassau, Prussia, Germany, in the deep valley of the Lahn, crossed by an old bridge, 30 m. east from Coblenz on the railway to Wetzlar. Population 3,850. It is overlooked by a former castle of the counts of Nassau-Dillenburg, now a prison. Close by, on an eminence above the river, lies the castle of Oranienstein, formerly a Benedictine nunnery. The industries include iron works, machine-making, colour preparation, lime-burning and quarrying. In the vicinity are Fachingen, celebrated for its mineral waters, and the castle of Schaumburg.

DIFFERENTIAL, in a motor car (*q.v.*), the system of gears (usually situated in the back axle) by means of which one driving wheel may revolve with increased speed while the other is checked (in taking corners, etc.). In physics, differential apparatus, *e.g.,* a differential thermometer *(see* THERMOMETRY), is designed in such a manner that errors due to extraneous effects in the experiments are eliminated.

DIFFERENTIAL CALCULUS, ABSOLUTE: *see* TENSOR ANALYSIS.

DIFFERENTIAL EQUATIONS. If we have given the relation $y=\sin x$ and differentiate twice with respect to x, we find that $y''+y=0$. This latter equation is an ordinary differential equation. In general, an equation involving derivatives of y with respect to x, together possibly with x and y, is called an *ordinary differential equation.*

TYPES AND SOLUTIONS

Need For Differential Equations. — These equations are of frequent occurrence in mathematical analysis, geometry, physics, and chemistry. For example, the equation just referred to describes the law of motion of a particle moving in a straight line subject to an attraction, from a point in the line, that is proportional to the distance of the particle from the centre of attraction. Here x represents the time and y the distance. In order to determine where the particle will be at a given moment, we must find a function y of x that is connected with its second derivative in the way described by the equation. That is, we must do what is described as solving the differential equation.

In general, we say that a function y of the independent variable x is a solution of a differential equation if the two sides of the equation are identically equal — that is, equal for all values of x when for y and its various derivatives in the equation there are substituted the given function and its corresponding derivatives. It is not evident that a differential equation selected at random has a solution, but it will be shown later that under certain rather broad conditions solutions do exist. It is however evident independently of this that many of the simpler and more common differential equations, such as we shall discuss in the first part of this article, have solutions, as these solutions either can be seen directly or can be found by more or less ingenious devices.

Many problems might be cited from physics and chemistry to show how the statement of a natural law gives us a differential equation and how the solution of this equation furnishes information concerning natural phenomena.

An ordinary differentia1 equation is said to be of order n if it contains the nth derivative of y with respect to x, but no derivative of higher order.

Common **Types** and Solutions. — We consider now the solution of a few of the simpler and more common types. But first it should be observed that the equation

$$\frac{dy}{dx}=f(x, y) \qquad (1)$$

can be written in the form

$$dy=f(x, y)dx, \qquad (2)$$

where dx and dy represent the differentials of x and y respectively. The reader may refer to a standard text on the calculus (*q.v.*) for the precise significance of differentials.

(1) *Variables Separable.* — *If* (1) can be written in such a way that one member contains only x and its differential, the equation can be solved by two integrations, or quadratures, as they are sometimes called. For example, the equation $\frac{dy}{dx}=\frac{y}{x}$ can be written in the form $\frac{dy}{y}=\frac{dx}{x}$. Here the variables are separated. By in-

tegration we get $\log y = \log x + \log c$, or $y = cx$. Since we can give to c any constant value, we have here a whole family of loci which are all straight lines through the origin. The fact that there is an unlimited number of these loci is in agreement with the theorem to be established in the second part of this article that there is a solution passing through an arbitrary point of the plane.

(2) Exact Equations.—When (1) is written in the form

$$M dx + N dy = 0, \tag{3}$$

where M and N are functions of x and y, it may be that the left member is the exact differential of some function of x and y, as $\phi(x, y)$. When this is the case the equation is said to be exact. The solution is then obviously given by the equation $\phi(x, y) = c$. For example, the left member of the equation

$$y dx + x dy = 0$$

is the differential of xy. Hence the solution is given by the equation $xy = c$. The curves of this family are equilateral hyperbolas (see HYPERBOLA). On the other hand, the left member of the equation

$$y dx - x dy = 0$$

is not an exact differential. But if we divide through by y^2 we get

$$\frac{y dx - x dy}{y^2} = 0,$$

and the left member of this equation is the differential of $\frac{x}{y}$. Hence $\frac{x}{y} = c$ gives the solution. 4 factor, such as $\frac{1}{y^2}$ in this case, which when introduced into equation (3) makes the left member an exact differential is called an integrating factor. Every equation of the form (3) has an unlimited number of integrating factors. The actual determination of such factors is, however, in most cases a difficult matter. In a few simple cases they can be determined by inspection or by the application of simple rules.

(3) Homogeneous *Equations.*—The function $f(x, y)$ is said to be *homogeneous* of degree m if the equation

$$f(u, v) = t^m f(x, y)$$

is identically satisfied when we put $u = tx$ and $v = ty$. If now in equation (1), $f(x, y)$ is homogeneous of degree zero and we take $t = \frac{1}{x}$, we get

$$f\left(1, \frac{y}{x}\right) = f(x, y).$$

This tells us that $f(x, y)$ can be expressed as a function of $\frac{y}{x}$ alone, and suggests that we write (1) in terms of a new dependent variable v connected with x and y by the relation $v = \frac{y}{x}$, or $y = vx$. In order to do this we must know what dy is in terms of v and x and their difierentials. We find by differentiation that $dy = v dx + x dv$. Hence (1) becomes $v dx + x dv = f(1, v) dx$, or $\frac{dv}{f(1, v) - v} = \frac{dx}{x}$, and the variables are separated.

(4) Linear Equations.—Equations of the form

$$\frac{dy}{dx} + P(x) y = Q(x), \tag{4}$$

are linear with respect to y and $\frac{dy}{dx}$. They are therefore called linear equations. They are also of the first order. We shall later discuss linear equations of higher orders.

We could solve (4) if we knew an integrating factor. If v is such a factor $v(x)y' + P(x)v(x)y$ is the derivative with respect to x of some function. Since this expression contains the term vy', we are led to consider whether v can be so determined that $vy' + Pvy$ shall be the derivative of vy. In order for this to be the case we must have

$$vy' + Pvy = vy' + v'y,$$

or $v' = Pv$. This requires that

$$\log v = \int P(x) dx + c,$$

or

$$v = e^{\int P(x) dx + c}.$$

Since any integrating factor will answer our purpose, we can put $c = 0$.

If we apply this factor $e^{\int P(x) dx}$ to (4) we get

$$e^{\int P(x) dx} y' + P e^{\int P(x) dx} y = Q e^{\int P(x) dx}.$$

Hence

$$e^{\int P(x) dx} y = \int Q e^{\int P(x) dx} dx + C,$$

or

$$y = e^{-\int P(x) dx} \int Q e^{\int P(x) dx} dx + C e^{-\int P(x) dx}.$$

(5) Equations of Order Higher Than the First.—We mention first certain equations of the second order whose solution can be made to depend upon the solution of equations of the first order—for example, the equation

$$\frac{d^2 s}{dt^2} = f(s),$$

which occurs in mechanics. If we put $v = \frac{ds}{dt}$, we have $\frac{dv}{dt} = f(s)$, or $v \frac{dv}{ds} = f(s)$. This is of the first order and the variables can be separated. Having determined v, we can find s by a quadrature. As a second example, consider the differential equation of the catenary,

$$\frac{d^2 y}{dx^2} = \frac{1}{c} \sqrt{\left[1 + \left(\frac{dy}{dx}\right)^2\right]}.$$

Its solution can be reduced to the solution of an equation of the first order by putting $\frac{dy}{dx} = p$.

The equations that are linear and homogeneous in y and its derivatives, and have constant coefficients, form another simple class under this head. They are of the form

$$p_0 y^{(n)} + p_1 y^{(n-1)} + \ldots + p_{n-1} y' + p_n y = 0. \tag{5}$$

If the right member is a function of x, instead of 0, we have the non-homogeneous equation with constant coefficients

$$p_0 y^{(n)} + p_1 y^{(n-1)} + \cdots + p_{n-1} y' + p_n y = f(x). \tag{6}$$

Equations of this form are in general much more difficult to solve than those of form (5). We shall therefore consider first those of form (5).

In case $n = 1$, we have $p_0 y' + p_1 y = 0$, and we know from the discussion of equation (4), since P is here a constant and $Q = 0$, that $y = Ce^{rx}$, where r is a constant, is a solution. We are therefore led to inquire whether $y = e^{rx}$ is a solution of (5) for a properly chosen constant value of r. If we substitute this function for y in (5), the left member becomes

$$e^{rx}(p_0 r^n + p_1 r^{n-1} + \cdots + p_{n-1} r + p_n).$$

This equals zero if, and only if, r is a root of the equation

$$p_0 r^n + p_1 r^{n-1} + \ldots + p_{n-1} r + p_n = 0. \tag{7}$$

This equation is called the auxiliary equation of (5). The manner of its formation from (5) is obvious.

If (7) has n distinct roots, $r_1, r_2, \ldots, r_n$, (5) has the linearly independent solutions

$$y_1 = e^{r_1 x}, \; y_2 = e^{r_2 x}, \; \cdots, \; y_n = e^{r_n x}.$$

Now it is a property of linear, homogeneous differential equations that the sum of two solutions is also a solution, and that the product of a solution by any constant is a solution. Hence

$$y = c_1 y_1 + c_2 y_2 + \ldots + c_n y_n, \tag{8}$$

where $c_1, c_2, \ldots, c_n$ are arbitrary constants, is a solution of (5). Moreover any solution of (5) can be obtained from (8) by assigning to the c's proper values, as will appear from the theoretical discussion to be given later. For this reason (8) is called the

general solution of (j). But if equation (7) has multiple roots we cannot get the general solution of (5) in this way, although we can get certain particular solutions. If r is a k-fold root of (7) and we put $y=x^i e^{rx}$, where i is any positive integer less than k, we shall get from the left member of (5)

$$e^{rx}[f^{(i)}(r)+i_1 x f^{(i-1)}(r)+i_2 x^2 f^{(i-2)}(r)+\cdots+x^i f(r)].$$

where $i_j=\dfrac{i(i-1)\cdots(i-j+1)}{j!}$ *Now this is zero since r is a k-fold root of (7) and $i<k$. Hence*

$$y_1=e^{rx},\ y_2=xe^{rx},\ \cdots,\ y_{-k}=x^{k-1}e^{rx}$$

are solutions of (j). Taking into consideration the solutions obtained in this way from each of the distinct roots of (7), we get in all n linearly independent solutions from which we can form the general solution as in (8). The problem of the solution of the non-homogeneous equation (6) is much more difficult. However, if $\phi(x)$ is any solution of it and (8) is the general solution of the corresponding homogeneous equation, the general solution of (6) is

$$y=c_1y_1+c_2y_2+\cdots+c_ny_n+\phi(x).$$

The function

$$c_1y_1+c_2y_2+\cdots+c_ny_n$$

is called the complementary function pertaining to (6).

Since we now know how to solve the homogeneous equation, we need to consider only the problem of finding a particular solution of (6). Various special devices for finding this particular solution are given in the textbooks. They depend upon special forms of the function f(x). A more general method due to Lagrange (q.v.) is based on the idea of taking the complementary function and replacing the n arbitrary constants in it by such functions of x as will give us a solution of (6). It turns out that this can be done in a variety of ways, but the details cannot be given here.

The problem of solution is still more difficult if the coefficients in (6) are functions of x. Many of the equations that are of importance in mathematical physics are of this type. They are however, for the most part of the second order, and we shall accordingly confine our discussion to equations of this order.

Consider the equation

$$p_0y''+p_1y'+p_2y=f(x), \qquad (9)$$

where the coefficients are either constants or functions of x. If we know a solution v of the homogeneous equation

$$p_0y''+p_1y'+p_2y=0, \qquad (10)$$

and if we introduce a new dependent variable z by virtue of the relation $y=vz$, we get

$$p_0vz''+(2p_0v'+p_1v)z'+(p_0v''+p_1v'+p_2v)z=f(x).$$

But v is a solution of (10). Hence

$$p_0vz''+(2p_0v'+p_1v)z'=f(x).$$

Now, although this last equation is of the second order, it contains no term in z. If therefore we put $t=z'$, we get

$$p_0vt'+(2p_0v'+p_1v)t=f(x).$$

By the solution of this linear equation of the first order we get t. Then an integration gives z, and an algebraic operation gives y.

This method reduces the solution of linear equations of order greater than one to the solution of similar equations of order one less. The practical difficulty consists in finding a particular solution of the corresponding homogeneous equation. If the original equation is homogeneous we have a close analogy with the fact that the solution of an algebraic equation of degree n can be reduced to the solution of one of degree $n-1$ when we know one root of the original equation.

(6) Equations of the first order that can be solved for y. These can be written in the form $y=f(x,p)$, where p represents $\dfrac{dy}{dx}$.

By differentiation we get $p=f_x+f_p\dfrac{dp}{dx}$. This is an equation of the first order and first degree in x and p. We can therefore solve it and get a relation between x and p. This relation, together with the original equation between y and p gives a parametric representation of the integral curves, p playing the role of parameter.

If the given equation can be solved for x in terms of y and p, a similar procedure can be followed.

Singular Solutions.— If the family of integral curves of a differential equation of the first order has an envelope, this envelope is a solution of the differential equation, since at any of its points it is tangent to an integral curve. It may be included in the general solution, but in general it is not. In the latter case it is called a singular solution. Consider, for example, the equation $y=px+\dfrac{1}{p}$. This is a special form of what is known as Clairaut's equation, the general form being $y=px+f(p)$. Differentiation with respect to x gives us

$$p=p+x\frac{dp}{dx}-\frac{1}{p^2}\frac{dp}{dx},$$

or

$$\frac{dp}{dx}\left(x-\frac{1}{p^2}\right)=0.$$

Hence either $\dfrac{dp}{dx}=0$ and $p=c$, or $x-\dfrac{1}{p^2}=0$. If $p=c$, we have as the general solution $y=cx+\dfrac{1}{c}$. But if we eliminate p from $x=\dfrac{1}{p^2}$ and the original equation, we get $y^2=4x$. This is the equation of the envelope of the family of straight lines $y=cx+\dfrac{1}{c}$, and is therefore a singular solution of the given equation. It can be shown in a similar way that the general Clairaut equation has a singular solution.

It should be observed that an equation of the first order and the first degree does not have a singular solution.

Solution in Series.—In a large class of cases, which includes all that we have already discussed and many others not readily solvable otherwise, we can obtain solutions in power series. The Bessel equation

$$xy''+y'+xy=0$$

affords a good illustration of this method. If

$$y=a_0+a_1x+a_2x^2+\cdots+a_nx^n+\cdots$$

is a solution, the coefficients $a_0, a_1, a_2, \ldots$ must have definite values (up to an undetermined factor) which can be found by substitution of this value of y in the given equation. The series turns out to be

$$1-\frac{x^2}{2^2}+\frac{x^4}{2^2\cdot4^2}-\frac{x^6}{2^2\cdot4^2\cdot6^2}+\cdots$$

and is commonly represented by the symbol $J_0(x)$. It converges for all finite values of x. All the solutions of the given Bessel equation that are linearly independent of this one are of a more complicated nature. We shall have more to say concerning integration by series in the second part of this article.

This is a method for the approximate solution of differential equations. We refer the reader to the book by Runge cited in the bibliography at the end of this article for the details concerning other methods, for this kind of solution.

The reader will have observed in the preceding discussion a complete lack of any general method of procedure for the solution of ordinary differential equations. A general method of approach to this problem has, however, been given by Sophus Lie (q.v.) in his theory of one-parameter groups. We refer the reader to the work of Lie mentioned in the bibliography.

Partial Differential Equations.— An equation involving certain independent and dependent variables and partial derivatives of the dependent variables with respect to the independent variables is called a partial differential equation. In the discussion of partial differential equations we shall confine our at-

tention to the case of two independent variables and one dependent variable, although we shall have occasion to mention equations that contain more than two independent variables. The linear equation

$$P\frac{\partial z}{\partial x}+Q\frac{\partial z}{\partial y}=R, \tag{11}$$

where P, Q, and R are continuous functions of x, y and z and P and Q do not vanish simultaneously, is the simplest of these equations. Suppose that (11) has a solution

$$z=\phi(x,y)$$

Now the direction cosines of the normal to the surface represented by this equation at the point (x_0, y_0, z_0) are proportional to the values of $\frac{\partial z}{\partial x}, \frac{\partial z}{\partial y}$ and -1 at this point. Moreover, the values of P, Q, and R at (x_0, y_0, z_0) are proportional to the direction cosines of a line through this point, and the differential equation says that the normal to the surface at (x_0, y_0, z_0) is perpendicular to this line. That is, at every point of an integral surface the differential equation determines a unique line that is perpendicular to the normal to the surface at this point. These lines are tangent to the curves defined by the system of ordinary equations

$$\frac{dx}{P}=\frac{dy}{Q}=\frac{dz}{R}. \tag{12}$$

These curves are called the characteristic curves of the given differential equation.

As a simple illustration we cite the equation

$$x\frac{\partial z}{\partial x}+y\frac{\partial z}{\partial y}=z. \tag{13}$$

The differential equations of the characteristic curves are

$$\frac{dx}{x}=\frac{dy}{y}=\frac{dz}{z}=dt, \tag{14}$$

where t is a parameter. The equations of the characteristic that passes through the point (x_0, y_0, z_0) are therefore $x=x_0e^t$, $y=y_0e^t$ and $z=z_0e^t$. If we let the point (x_0, y_0, z_0) vary along the curve $y=x+2$, $z=x^2-1$, we get a one-parameter family of characteristic curves whose equations are

$$x=x_0e^t, \quad y=(x_0+2)e^t, \quad z=(x_0^2-1)e^t.$$

If we eliminate x_0 and t from these equations, we get

$$z=\frac{4x^2-(y-x)^2}{2(y-x)}.$$

This represents an integral surface through the given curve.

Since $y-c_1x=0$ and $z-c_2x=0$ are solutions of (14), $\phi\left(\frac{y}{x},\frac{z}{x}=0\right)$ where $\phi(u,v)$ is an arbitrary function containing v, defines an integral surface of (13). But when we obtain an integral surface in this way we do not know whether it passes through a given curve, or not.

Equations of the First Order.—The general partial differential equation of the first order is of the form

$$F(x, y, z, p, q)=0, \tag{15}$$

where $p=\frac{\partial z}{\partial x}$ and $q=\frac{\partial z}{\partial y}$. We shall assume that F, together with its first partial derivatives, is a continuous function of its arguments throughout a certain region U. As a matter of convenience we shall adopt the following notation:

$$X=\frac{\partial F}{\partial x}, \quad Y=\frac{\partial F}{\partial y}, \quad Z=\frac{\partial F}{\partial z}, \quad P=\frac{\partial F}{\partial p}, \quad Q=\frac{\partial F}{\partial q}.$$

Let

$$z=\phi(x, y)$$

be an integral surface S of (15). If (x_0, y_0, z_0) is a point on S, the equation of the tangent plane to S at this point is

$$z-z_0=p_0(x-x_0)+q_0(y-y_0), \tag{16}$$

where p_0, q_0 and -1 are proportional to the direction cosines of the normal to S at this point. The plane is determined by the values of p and q, and any set of values of p and q that satisfy the equation

$$F(x_0, y_0, z_0, P, q)=0$$

determine the tangent plane to some integral surface at this point. This singly infinite set of planes envelopes a cone whose vertex is at the point (x_0, y_0, z_0).

We consider a curve on an integral surface whose tangent at a given point is an element of the cone corresponding to this point. The values of x, y, z, p, and q vary from point to point along this curve. It can be shown that they satisfy the system of ordinary equations

$$\frac{dx}{P}=\frac{dy}{Q}=\frac{dz}{pP+qQ}=-\frac{dp}{X+pZ}=-\frac{dq}{Y+qZ}=dt \tag{17}$$

where t is a parameter. These equations determine x, y, z, p and q as functions of t and an initial set of values of the dependent variables. The functions determining x, y and z define a set of curves that are known as the characteristic curves of the equation (15). If the equation is linear, these curves are the same as the characteristic curves already defined for linear equations. The values of p and q determined by the remaining equations serve to orient a plane through the point (x_0, y_0, z_0). This plane is tangent to the integral surface on which the characteristic lies. The set of five values (x, y, z, p, q) are said to form a *surface* element and the set of surface elements along a characteristic curve are said to form a characteristic strip.

We have thus far looked upon the characteristics as determined by the integral surfaces. But the differential equations (17) of the characteristic strips can be written donn directly without any reference to the integral surfaces. We then naturally enquire whether we can make use of the integrals of these equations in the determination of the integral surfaces. It turns out that this can be done, but we cannot go into the details here.

Equations of the Second Order.—From the point of view of mathematical physics the linear partial differential equations of the second order with two or three independent variables and one dependent variable are of great importance. We have space only for a brief reference to the more important types with brief statements of the physical problems that give rise to them.

(a) We mention first Laplace's equation in two and three dimensions,

$$\frac{\partial^2u}{\partial x^2}+\frac{\partial^2u}{\partial y^2}=0 \tag{18}$$

and

$$\frac{\partial^2u}{\partial x^2}+\frac{\partial^2u}{\partial y^2}+\frac{\partial^2u}{\partial z^2}=0. \tag{19}$$

As an illustration of a physical problem that gives rise to an equation of this kind the following may be cited: Let K be a conductor of heat whose bounding surface is maintained at a constant temperature—that is, the temperature at any point of the surface is kept at a constant value U which varies continuously from point to point on the surface. After a time the temperature u at a given point within the conductor will no longer vary with the time, but will vary continuously from point to point in such a way that u will satisfy equation (19).

The potential function due to the attraction of gravitating matter, or to an electric or magnetic field also satisfies (19). For this reason a function of x, y and z that satisfies this equation is called a *Newtonian* potential *function.*

But in order to determine the temperature within the conductor we must find not merely a solution of (19), but a solution that is equal to U on the bounding surface. This gives rise to the important problem of finding a function of x, y and z that satisfies (19) within the region bounded by a given surface and has upon this surface prescribed values. This is known as *Dirichlet's* problem.

A function of x and y that satisfies (18) is called a *logarithmic* potential. The function $\log\sqrt{(x^2+y^2)}$ is such a function. Solutions of (18) and (19) are also called *harmonic functions.*

The problem of the solution of Laplace's equation is closely connected with a problem in the calculus of variations (*q. v.*); namely, the problem of determining a function u of x, y and z that is continuous throughout a region V, together with its partial derivatives of the first two orders, and assumes prescribed values on the boundary, in such a way that it shall make the integral

$$\iiint_V \left[\left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 + \left(\frac{\partial u}{\partial z}\right)^2\right] dV$$

a minimum. A necessary condition that u shall have these properties is that it shall satisfy (19).

Neumann's problem is similar to Dirichlet's with the difference that it requires the normal derivative of u to have assignedvalues on the bounding surface. Obviously, a solution of this problem can be determined only up to an additive constant. Moreover, if u is a solution, then all solutions that are subject to certain natural conditions are of the form $u+c$, where c is a constant. Both Laplace's and Neumann's problems can be solved by the methods of integral equations.

(*b*) D'Alembert's equation for the motion of a vibrating string is

$$\frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2}$$

This equation is of interest historically from the fact that it was the first partial differential equation to be studied by mathematicians. It has as a solution $u=f(x-at)+F(x+at)$, where f and F are arbitrary functions.

(c) The equation for the motion of a vibrating membrane is

$$\frac{\partial^2 u}{\partial t^2} = a^2\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right).$$

This involves three independent variables and one dependent variable.

(d) The equation of wave-propagation in three dimensions is

$$\frac{\partial^2 u}{\partial t^2} = a^2\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2}\right).$$

Here we have four independent variables.

(e) The equation for the flow of electricity in wires—the so-called telegraph equation—is

$$\frac{\partial^2 u}{\partial t^2} + b\frac{\partial u}{\partial t} = a^2 \frac{\partial^2 u}{\partial x^2}.$$

Total Differential Equations.—An equation of the form

$$P(x, y, z)dx + Q(x, y, z)dy + R(x, y, z)dz = 0 \qquad (20)$$

is called a total *differential* equation. Total differential equations may contain any number of variables. The first question that arises in connection with an equation of this kind concerns the existence of a function $u(x, y, z)$ such that the left member of (20) is its total differential. If there is such a function, $\frac{\partial u}{\partial x}$, $\frac{\partial u}{\partial y}$, and $\frac{\partial u}{\partial z}$ are equal to P, Q and R respectively. Hence if (x_0, y_0, z_0) is any point on the surface $u(x, y, z)=0$ the tangent plane to the surface at this point is

$$P(x_0, y_0, z_0)(x-x_0) + Q(x_0, y_0, z_0)(y-y_0) + R(x_0, y_0, z_0)(z-z_0) = 0. \qquad (21)$$

Any curve in this surface satisfies (20). The necessary and sufficient condition for the existence of such a function $u(x, y, z)$ is

$$P\left(\frac{\partial Q}{\partial z} - \frac{\partial R}{\partial y}\right) + Q\left(\frac{\partial R}{\partial x} - \frac{\partial P}{\partial z}\right) + R\left(\frac{\partial P}{\partial y} - \frac{\partial Q}{\partial x}\right) = 0. \qquad (22)$$

When this condition is not satisfied there is no surface such that every curve in it satisfies (20). But if we take an arbitrary surface $v(x, y, z)=0$, its tangent plane at the point (x_0, y_0, z_0) is

$$\left(\frac{\partial v}{\partial x}\right)_0 (x-x_0) + \left(\frac{\partial v}{\partial y}\right)_0 (y-y_0) + \left(\frac{\partial v}{\partial z}\right)_0 (z-z_0) = 0. \qquad (23)$$

This plane and the plane (21) in general determine a line through (x_0, y_0, z_0), and the family of curves in $v=0$ that have these lines for tangents satisfies equation (20).

EXISTENCE THEOREMS AND GENERAL THEORY

On the theoretical side the first question that presents itself in connection with a given differential equation concerns the existence of solutions. Suppose that we have the equation

$$\frac{dy}{dx} = f(x, y), \qquad (24)$$

where f(x , y) is an analytic function of x and y that is regular in the neighbourhood of the point (x_0, y_0). Then the existence of an analytic solution $y=y(x)$, that is regular in the neighbourhood of the point $x=x_0$ and takes the value y_0 when $x=x_0$ may be established as follows:

From (24) we get by successive differentiations

$$\frac{d^2y}{dx^2} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}\frac{dy}{dx}$$

$$\frac{d^3y}{dx^3} = \frac{\partial^2 f}{\partial x^2} + 2\frac{\partial^2 f}{\partial x \partial y}\frac{dy}{dx} + \frac{\partial^2 f}{\partial y^2}\left(\frac{dy}{dx}\right)^2 + \frac{\partial f}{\partial y}\frac{d^2y}{dx^2}.$$

In the right members of (24) and these successive equations we put x_0 for x and y_0 for y, and use the resulting values of the successive derivatives of v to form the series

$$\phi(x) = y_0 + \left(\frac{dy}{dx}\right)_0 (x-x_0) + \left(\frac{d^2y}{dx^2}\right)_0 \frac{(x-x_0)^2}{2!} + \cdots + \left(\frac{d^ny}{dx^n}\right)_0 \frac{(x-x_0)^n}{n!} + \cdots. \qquad (25)$$

If this power series converges within a certain interval for x, we know from the theory of power series that it can be differentiated term-by-term within this interval. Hence

$$\frac{d\phi}{dx} = \left(\frac{dy}{dx}\right)_0 + \left(\frac{d^2y}{dx^2}\right)_0 (x-x_0) + \cdots + \left(\frac{d^ny}{dx^n}\right)_0 \frac{(x-x_0)^{n-1}}{(n-1)!} + \cdots. \qquad (26)$$

But the series in the right member of this equation is the expansion of the analytic function in the right member of (24) after y has been replaced by the analytic function $\phi(x)$. Moreover, $\phi(x_0)=y_0$. We have therefore in (25) a solution of (24) that satisfies the given conditions, provided that the series in the right member of (24) converges within some interval. The establishment of this convergence is the crux of this proof of the existence of an integral. It is accomplished by recourse to what Cauchy (*q.v.*), to whom we are indebted for this proof, called the "Calculus of Limits." The essential feature of this method consists in setting up, a so-called *majorant function* of whose convergence we are assured. This majorant function is represented by a power series each of whose coefficients is positive and not less than the absolute value of the corresponding coefficient in (25). We cannot give the details here. The solution obtained in this way is obviously unique.

Picard established the existence of these solutions by making use of a method of successive approximations. In his proof it is not necessary that $f(x, y)$ be analytic. It is sufficient to assume that for $|x-x_0|<a$ and $|y-y_0|<b$ the function $f(x, y)$ be continuous and satisfy Lipschitz's condition; namely,

$$|f(x, y_1) - f(x, y_2)| < M|y_1 - y_2|, \qquad (27)$$

where the points (x, y_1) and (x, y_2) are in the given neighbourhood and M is a constant.

The successive approximations y_i are obtained from the following equations

$$\frac{dy_i}{dx} = f(x, y_{i-1}) \quad (i>1),$$

subject to the condition that $y_i(x_0)=y_0$. By integration we get

$$y_1 = \int_{x_0}^{x} f(x, y_0)dx + y_0,$$

$$y_i = \int_{x_0}^{x} f(x, y_{i-1})dx + y_0. \quad (i>1)$$

Now the proof consists in showing that for a sufficiently small a all the functions y_i satisfy the inequality $|y_i - y_0| < b$, and that the series $\sum_{i}^{\infty} (y_{-i} - y_{i-1})$ converges to a definite function, $y(x)$, which satisfies the differential equation and the given initial conditions. This solution is unique.

Each of these existence proofs suggests a method for obtaining an approximate solution of the equation,

Only slight modifications need to be made in these proofs to have them applicable to systems of n equations of the first order in one independent and n dependent variables. And since an ordinary equation of order n is equivalent to a system of n equations of the first order of the kind described, it follows that these theorems also apply to ordinary equations of order n. For such an equation there is, therefore, a unique solution y such that y and its first $n-1$ derivatives have assigned values for $x = x_0$, provided that the conditions set forth in the existence theorem are satisfied.

In the preceding discussion we have confined our attention to the domain of real variables. There is, however, at times an advantage in including the domain of complex numbers (*q.v.*). In this more extended domain the proofs of the existence theorems given above are valid, provided that in the second one we restrict the functions to being analytic.

We add a brief sketch of two points in the general theory. These concern equations of the second order of the form

$$y'' + [\sigma(x) + \lambda\rho(x)]y = 0, \qquad (28)$$

where $\sigma(x)$ and $\rho(x)$ are continuous and $\rho(x) > 0$ in the interval (x_0, x_1). We wish to know whether there are solutions y of (28) that satisfy the two conditions

$$y(x_0) = 0 \quad \text{and} \quad y(x_1) = 0. \qquad (29)$$

Heretofore we have imposed on the solution the condition that it and its first derivative shall have definite values at the initial point, whereas here the conditions prescribe the values of the solution at the two ends of an interval. It is for this reason that the problem is described as a "boundary-value problem." There are, of course, more general boundary-value problems.

Now it turns out that (28) has a unique solution that satisfies conditions (29) if, and only if, λ is one of an infinite set of values $\lambda_1, \lambda_2, \ldots, \lambda_n, \ldots$. These are called the *characteristic values*, and the unique solutions $y_1(x), y_2(x), \ldots, y_n(x), \ldots$ corresponding to these are called the *characteristic functions*, of the problem.

If in (28) $\sigma(x) \equiv 0$, $\rho(x) \equiv 1$, $x_0 = 0$, and $x_1 = \pi$, it can readily be seen that $\lambda_n = n^2$ and $y_n = \sin nx$, where n is a positive integer. Now it is well known that functions satisfying certain conditions can be represented in the interval $(0, \pi)$ by the series

$$\sum_{n=1}^{\infty} a_n \sin nz.$$

This is merely a special case of Fourier's series (*q.v.*), which, in its turn, is a special case of an important and general theorem concerning the characteristic functions of equation (28) with the boundary conditions (29). This theorem is as follows:

Any function $f(x)$ that is continuous in the interval (x_0, x_1), together with its first two derivatives, and vanishes at the ends of the interval can be represented in this interval by the uniformly convergent series

$$\sum_{n=1}^{\infty} a_n y_n(x),$$

where $a_n = \int_{x_0}^{x_1} f(x) y_n(x) \rho(x) dx$, and each $y_n(x)$ has been multiplied by a properly chosen constant factor.

DIFFERENTIAL FORMS. The theory of differential forms is a branch of mathematics which presupposes several other branches, including differential calculus, algebra, and theory of functions. In essence, it is a theory of transformations of co-ordinates, such as

$$\begin{aligned} x &= f(x', y', z') \\ y &= g(x', y', z') \\ z &= h(x', y', z') \end{aligned} \qquad (1)$$

which are analytic and have single-valued inverses. This transformation carries any set of values of the variables x, y, z into a definite set of values of x', y', z'. It also *induces* the transformation of *differentials*

$$\begin{aligned} dx &= \frac{\partial f}{\partial x'}dx' + \frac{\partial f}{\partial y'}dy' + \frac{\partial f}{\partial z'}dz', \\ dy &= \frac{\partial g}{\partial x'}dx' + \frac{\partial g}{\partial y'}dy' + \frac{\partial g}{\partial z'}dz', \\ dz &= \frac{\partial h}{\partial x'}dx' + \frac{\partial g}{\partial y'}dy' + \frac{\partial h}{\partial z'}dz' \end{aligned} \qquad (2)$$

The differentials, it should be understood, are merely a second set of independent variables associated with the first set x, y, z.

Now consider a function of these two sets of variables, for example,

$$P(x, y, z)dx + Q(x, y, z)dy + R(x, y, z)dz, \qquad (3)$$

in which P, Q, and R represent analytic functions of any sort of x, y, and z. This function has a definite numerical value whenever definite values are assigned to the variables x, y, z, dx, dy, dz. If we substitute for these variables according to the equations (1) and (2) we obtain a function

$$P'(x', y', z')dx' + Q'(x', y', z')dy' + R'(x', y', z')dz', \qquad (4)$$

which has the same value as (3) whenever x', y', z', dx', dy', dz' and x, y, z, dx, dy, dz are assigned values which are related by the equations (1) and (2). The two functions (3) and (4) are representations or *components* in different co-ordinate systems of the same *differential form*. In this case, since the expressions (3) and (4) are both linear functions, the differential form is said to be *linear*.

The components of a differential form can also be quadratic in the differentials, for example,

$$Edu^2 + 2Fdudv + Gdv^2, \qquad (5)$$

in which E, F, and G are functions of two variables u and v. In general, the components of a differential form are required to be functions which are analytic in the variables x, y, etc., and analytic and homogeneous in the differentials dx, dy, etc. In the cases usually considered they are homogeneous polynomials in the differentials. They may also be functions of several sets of

differentials. For example, the quadratic form (5) is intimately related to the bilinear form,

$$E\,du\,\delta u+F(du\,\delta v+dv\,\delta u)+G\,dv\,\delta v.$$

It is obviously a fundamental problem to determine whether two differential expressions, such as (3) and (4) for example, are or are not components of the same differential form. This is known as the *equivalence* problem. The study of this problem, as well as of related problems, has led to the discovery of differential invariants of various kinds. The simplest of these are functions formed from the given form which are unchanged in value by transformations of coordinates. For example, an invariant of (3) is the bilinear form,

$$\left(\frac{\partial P}{\partial y}-\frac{\partial Q}{\partial x}\right)(dx\,\delta y-dy\,\delta x)+\left(\frac{\partial Q}{\partial z}-\frac{\partial R}{\partial y}\right)(dy\,\delta z-dz\,\delta y)$$
$$+\left(\frac{\partial R}{\partial x}-\frac{\partial P}{\partial z}\right)(dz\,\delta x-dx\,\delta z).$$

This example illustrates one of the uses to which differential invariants are put. For the vanishing of this bilinear form is a necessary and sufficient condition that (3) be a "complete differential." In other words, there exists a function $F(x, y, z)$ such that

$$dF(x, y, z)=Pdx+Qdy+Rdz,$$

if and only if this bilinear form vanishes. Other properties of the differential form (3) are expressed by the vanishing of other invariants. Indeed, the typical way of saying anything about a differential form is to assert that such and such an invariant vanishes—and a very large proportion of the theorems of geometry and physics reduce to such statements.

Returning to the example of a linear differentia1 form which has the components (3) and (4) in two coordinate systems we find, on carrying out the substitution of (1) and (2) in (3), that

$$\begin{aligned}P'(x', y', z')&=P\frac{\partial f}{\partial x'}+Q\frac{\partial g}{\partial x'}+R\frac{\partial h}{\partial x'},\\ Q'(x', y', z')&=P\frac{\partial f}{\partial y'}+Q\frac{\partial g}{\partial y'}+R\frac{\partial h}{\partial y'},\\ R'(x', y', z')&=P\frac{\partial f}{\partial z'}+Q\frac{\partial g}{\partial z'}+R\frac{\partial h}{\partial z'},\end{aligned}\qquad(6)$$

In these equations P stands for the function of x', y', z', obtained by substituting (1) in $P(x, y, z)$; similarly Q and R. In the language of Tenson Analysis (*q.v.*) the equations (6) state that the coefficients of a linear differential form are the components of a covariant vector. In like manner we can work out the equations of transformation, analogous to (6), of the coefficients of a differential form of any degree. It comes out that whenever the differential form is a polynomial in the differentials, the coefficients are the components of a covariant tensor. The theory of these differential forms is therefore co-extensive with that of covariant tensors.

The theory even of linear differential forms is very extensive and has applications in a wide variety of fields of mathematics and physics. We need only mention line integrals, vector analysis (*q.v.*), and electricity and magnetism (*qq.v.*). The higher theory of linear differential forms and systems of linear differential forms is to be found in mathematical books usually under the heading "The problem of Pfaff," so called because the first investigations of the subject were made by Pfaff in 1814 and 1815. The further development of the subject is associated with the names of Gauss, Jacobi, Natani, Clebsch, Grassmann, Frobenius, Darboux and Cartan.

The theory of quadratic differential forms was initiated in 1827 by Gauss, who showed that the metric properties of surfaces depend on forms of the type (5). This work of Gauss is also the foundation of modern differential geometry (*q.v.*). From the point of view of differential forms his chief contribution was the discovery of an invariant, called the *curvature*, which is a function of E, *F*, and *G*, and their first and second derivatives, which is unaltered by all analytic transformations of the variables u, v. The next important step was taken by Riemann, who in 1854 outlined the theory in its full generality and used it as the basis of what has come to be known as Riemannian geometry. He also showed that the curvature of Gauss must be replaced in the general case by what is now called the curvature tensor. The work of Riemann was followed immediately by that of Christoffel and Lipschitz. The former introduced the functions often called Christoffel symbols or the components of affine connection, and gave a solution of the equivalence problem. Lipschitz developed the calculus of variations (*q.v.*) side of the subject and also the system of normal coordinates which had been sketched by Riemann. This work was followed by a long series of researches by such mathematicians as Ricci, Voss, Lie, Levi-Civita, Zorawski, Wright and Haskins. Differential forms of degree higher than the second have been studied by Lipschitz, E. Noether, E. Pascal, and others.

The theory of quadratic differential forms has found many applications in geometry and physics, notably in dynamics. In recent years it has received a great deal of attention and been generalized in various directions because it is the foundation of Einstein's theory of relativity. In the researches of Einstein, as extended by Weyl and others, the phenomena of gravitation and electricity are described by means of a quadratic and a linear differential form restricted by the vanishing of certain invariants.

DIFFERENTIAL GEOMETRY embodies the theorems concerning curves, surfaces and other manifolds which involve applications of the calculus. Straight lines, circles, planes and spheres are geometrical entities possessing the common property that any part of one of them has the same shape as any other part. Other curves and surfaces do not possess this property, as for example, conics, ellipsoids and paraboloids. The geometrical character of these entities varies in general continuously from point to point, and consequently the calculus is needed in order to study many of their geometrical properties.

Most of the older differential geometry, and much of the recent, in so far as magnitudes are concerned, rests upon the assumption that the curves and surfaces under consideration lie in ordinary, or Euclidean, space of three dimensions, and that the measurement of magnitudes, such as lengths of curves, angles and areas of surfaces, is based upon Euclidean measure. Thus, when the three-dimensional space is referred to rectangular cartesian coordinates, the quadratic differential form

$$ds^2=(dx)^2+(dy)^2+(dz)^2,\qquad(1)$$

which defines the square of the distance between points (x, y, z) and $(x+dx, y+dy, z+dz)$, leads by the processes of the integral calculus to the determination of the length of a curve between two points of it. In fact, a curve is defined by two equations of the form

$$f(x, y, z)=0,\quad g(x, Y, z)=0.\qquad(2)$$

For differentials dx, dy, dz in the direction of this curve and by means of (2), equation (1) is reducible to the form $ds=F(x)dx$, and then the length of arc is given by an integration. Or any curve may be defined, in many ways, in the form

$$x=f_1(t),\quad y=f_2(t),\quad z=f_3(t),$$

where t is a parameter, and then the length of arc is given by an integral in t.

When all the points of a curve lie in one plane, it is called a

plane curve, otherwise a skew curve. If P is any point on a skew curve C, l the tangent line to C at P, and Q is any other point of the curve, the plane determined by 1 and Q assumes a limiting position as Q approaches P along the curve; it is called the osculating plane to C at P; of all the planes through 1 it lies nearest to the curve in the sense that the distance of a point of C near P from the osculating plane is of the second order and from the other planes it is of the first order. The normal to C at P in the osculating plane is called the *principal* normal, and the normal to the osculating plane at P the binormal. The manner in which the configuration consisting of the tangent, principal normal, and binormal varies in direction, as the point describes the curve, characterizes the curve. The rate of change of direction of the tangent with the arc is the curvature, and of the binormal the torsion. These are the fundamental elements in the differential geometry of curves and in any of the many treatises the reader will find extensive developments of the theory.

A surface is a locus of two dimensions. A surface in Euclidean space, or a portion of it, is defined by one relation between the coordinates as

$$f(x, y, z) = 0. \tag{3}$$

If P is an ordinary point of the surface, not a singular point such as the vertex of a cone, the tangents at P to all curves on the surface through P lie in a plane, called the tangent plane at P; its eauation is

$$\frac{\partial f}{\partial x}(X-x)+\frac{\partial f}{\partial y}(Y-y)+\frac{\partial f}{\partial z}(Z-z)=0. \tag{4}$$

When one of the three variables x, y, z is eliminated from (4) by means of (3), ordinarily the other two enter in the equation, that is, the tangent plane depends upon two parameters. When the tangent plane involves a single parameter, the surface is called developable, otherwise *non-developable;* a developable surface can be rolled out, or developed, upon a plane.

When the tangent plane at an ordinary point P of a non-developable surface is taken for the plane $z=0$, and any two orthogonal lines in this plane are taken for the x and y axes, the equation of the surface, at least in the neighbourhood of the point, can be written in the form

$$z = ax^2+2bxy+cy^2+\phi(x, y),$$

where ϕ (x, y) is a power-series in x and y of the third and higher orders, and a, b and c are constants. The ellipse or hyperbola whose equations are

$$ax^2+2bxy+cy^2=1, \quad z=0$$
$$ax^2+2bxy+cy^2=1, \quad z=0,$$

is called the *Dupin* indicatrix of the surface at P. The principal axes of the conic are called the *principal* directions at P; conjugate diameters determine conjugate directions, and the asymptotes asymptotic directions. Two one-parameter families of curves on the surface whose directions at a point of meeting are conjugate are said to form a conjugate system; a curve whose direction at every point is asymptotic is any asymptotic line; a curve whose direction at every point is principal is a line of curvature. These various curves may be defined also by properties involving the tangent plane. The tangent planes to a surface along any curve form a developable surface, and the directions of the generators are conjugate to the given curve; the tangent planes to a surface along an asymptotic line are the osculating planes of the latter; the normals to a surface along a line of curvature are tangent to a curve in space, and this is true only of a line of curvature.

If in equation (3) we put x and y each equal to a function of two parameters, u and v, and solve for z, the surface is defined by three equations

$$x=f_1(u, v), \quad y=f_2(u, v), \quad z=f_3(u, v). \tag{5}$$

Conversely, any three equations of this type define a surface. This method of definition is due to Gauss. Owing to the great arbitrariness in the choice of the parameters u and v, it is a very powerful method and has simplified the solution of many problems. When the expressions (5) are substituted in (1), we get the differential form

$$ds^2 = Edu^2+2Fdudv+Gdv^2, \tag{6}$$

where E, F and G involve the first derivatives of f_1, f_2, f_3. Any curve on the surface is defined by a relation between u and v; when this is used in connection with (6), the latter defines the length of the curve. The right-hand member of (6) is called the first *fundamental* quadratic form of *the* surface. There is another quadratic differential form of importance, called the second fundamental form and usually written

$$Ddu^2+2D'dudv+D''dv^2; \tag{7}$$

to within terms of third and higher orders it is equal to twice the distance from the point $(u+du, v+dv)$ on the surface to the tangent plane at the point (u, v). Measurement of angles between directions at a point on the surface depends only upon the first form, and conjugacy only upon the second. Since lines of curvature form an orthogonal system and also a conjugate system, their differential equation involves the coefficients of both forms.

Through each point of a surface, and in each direction, there is a curve of the surface whose principal normal at each point is normal to the surface. Although this definition involves a property of the curve as viewed from the Euclidean space in which the surface is contained, the differential equations of these curves involve only the coefficients of the first form and their first derivatives, that is, they are characterized by a property of distance alone. In fact, they are the curves for which the first variation of the integral $\int ds$ is zero; that is, they are the extremals of -this integral, to use the terminology of the calculus of variations. These curves are called the geodesics of the surface.

Let P be any point of a surface, Σ a small portion of the surface including P and C its contour. If lines be drawn through a point O parallel to the normals to the surface at points of C, these lines will meet the sphere of unit radius and centre O in a closed curve. The limit of the ratio of the area enclosed by the latter to the area of Σ as Σ approaches P in the limit is the curvature of the surface at P. It is equal to $(DD'-D'^2)/(EG-F^2)$, but it is equal also to a function of E, F, G and their first and second derivatives. Hence, when the formula for distance (6) of a surface is known, the Gaussian curvature of the surface at any point can be found without reference to the enveloping Euclidean space. In this sense properties involving geodesics and Gaussian curvature are *intrinsic.*

The foregoing are the fundamental elements which enter into the vast body of theorems concerning surfaces in a Euclidean space, which are to be found in any of the many treatises. Much of the theory involves metric properties. Since conjugate systems and asymptotic lines are invariant under projective transformations of the enveloping Euclidean space, there is a considerable theory which is projective in this sense. It is a geometrical interpretation of linear partial differential equations of the second order. This has been developed by Darboux, Guichard, Tzitzeica. Demoulin and Wilczynski. Recently Fubini and Bompiani have made further developments.

DIFFERENTIAL PARALLELISM: see TENSOR ANALYSIS.

DIFFERENTIAL PSYCHOLOGY is that branch of psychology which deals with the differences found among individuals and groups in mental traits and performances. Individual differences are attributable broadly to the two opposed, but closely interwoven, forces of nature and nurture, or heredity and environment. In the first category are the intrinsic factors such as race, sex, age, immediate ancestry, etc.; under the latter

head are the extrinsic factors, viz.—the social, educational. cultural, physical (*e.g.,* disease) and other agencies which shape and mould the developing individual from birth until death.

In a general sense, the complex and more recently acquired traits tend to be more variable than the simple, biologically more fundamental ones. The feeble-minded, for example, differ least from the normal in physical and motor abilities and most in the ability to use language, deal with "ideas," and employ abstract thought. Even among groups relatively homogeneous as to general ability, we find greater variability in those tests requiring the education of intricate verbal relations, in learning and association, than in those tests designed to measure the speed of voluntary movement, rote memory, or recognition. Individuals do not fall into sharply separated groups or "types" in mental, any more than in physical, traits. People differ widely, for example, in the vividness and kind of mental imagery which they possess. In other traits the same condition obtains; mediocrity is the status most commonly encountered, marked superiority or inferiority being relatively and equally infrequent.

The results of many careful studies of primitive peoples point to the conclusion that these races do not differ markedly from modern Europeans in general sensory equipment, such as keenness of vision and hearing, sensitivity to pain and pressure, and delicacy of the skin senses. Simple "intelligence" tests of the "form board" variety (a form board is a board containing cut out depressions into which blocks of different shapes and sizes are to be fitted) show no large differences between the whites and many primitive folk (*e.g.,* Eskimos, American Indians, etc.), although a few races, the Igorot, the Negrito and the Pygmies, do no better than low-grade and even imbecile whites. The inferiority of the negro to the white in mental capacity has often been asserted as the result of comparative studies, but it is difficult to say how much of difference found is due to native as against cultural factors. Negro high school children in New York city remain in school longer, are older on the average, and are inferior in scholastic work to whites of approximately the same social status (Mayo). The greater the admixture of white blood, the closer does the negro approach the white in performance (Ferguson). Intelligence tests given to large groups of whites and negroes in the American army place the negro below the white both in tests of the language and non-language variety. Several investigations have shown the negro to be more overtly emotional and less inhibited in his reactions than the white (Crane). The American Indian ranks consistently below the white man on tests of mental capacity; the greater the admixture of white blood, the smaller the deviation from the performance of the white. There is some recent evidence to indicate that the Indian, while slower in motor performances than the white, is more accurate and painstaking.

In comparative studies of general intelligence made in America, Chinese children have ranked slightly lower than whites in language tests (English) but better in rote memory. Japanese children do not differ significantly in intelligence from comparable groups of whites, due allowance being made for social and cultural status. The most extensive comparative data on the intellectual differences as among national groups is that obtained from the tests given in the American army during the World War. These tests indicated a superiority of those foreign-born men from northern countries of Europe (the "Nordics") over those from central and southern Europe (the "Alpines" and "Mediterranean~").Selection plus differences in language, schooling, age and culture probably account for much if not all of the difference found.

Comparative studies of men and women have indicated few differences which might be attributed to the factor of sex, apart from social and cultural influences. The differences within either sex are far greater than the differences between the two sexes. Women have been reported to have a finer sense of touch, better colour discrimination, and to be faster in verbal association; men to be superior, on the average, in the discrimination of differences in weight and visual magnitudes, and in the speed of motor response (reaction time). In general, females are superior in tests of memory and in foreign languages; males in tests of logical construction and in problems involving abstract and space relations (Thompson). Women are somewhat less stable emotionally than men. They have been asserted also to be more interested in people, more religious, more patient and more sympathetic, while men are more interested in athletic activity, have a superior sense of humour and are more independent (Pearson. Heymans and Wiersma). Girls are definitely better in school work than boys. This result has been explained as due to the slower physical development of boys, to the greater docility of girls and to native differences in ability.

The fact that men have excelled women in practically every field of endeavour is probably to be attributed to social, cultural and traditional factors, and to the greater physical strength and endurance of men, rather than to native differences in endowment One explanation is based upon the reputed greater variability within the male sex. Greater variability, *i.e.,* greater range of ability, would tend to produce more gifted men than women, even though the average man and woman ranked about the same in ability. The fact of greater variability in the male sex has been disputed, however, by competent investigators, and the question is still an open one.

Investigators are fairly well agreed that there is a regular and progressive increase in ability as measured by mental tests from infancy up to and through adolescence (14–18 years). This mental growth parallels roughly the steady increase in physical size and strength. After adolescence growth in most mental traits increases slowly, if at all, while in many cases it ceases altogether. Processes which are based upon experience, such as judgment, "reasoning ability" in practical situations, rational learning, etc., probably improve up through middle life and show no very definite losses until old age (Thorndike). There is a general loss in the speed and flexibility of mental operations in old age Sensory acuity in general — auditory, visual and tactual — is considerably reduced and there is some loss in learning ability, speed of reaction and memory. Curiosity and enthusiasm are lost as physical and mental vigour wane. A part, at least, of the fall in general intelligence score with increasing age may be attributed to the loss in speed of response, and also to the removal, by a relatively long-time interval, from school practice with the kind of operations called for by the tests. Suggestibility, or the ability to resist suggestion, is another complex trait which has been iound to differ with age and sex. Tests applied to children indicate that ability to "resist" suggestions increases progressively with age from 6 or 7 through adolescence (M. Otis). Girls are slightly more resistant than boys but the differences are not reliable.

The influence of immediate ancestry is best studied by comparing those of like ancestry and ***vice versa.*** Careful studies of twins have shown that they are more alike both mentally and physically than ordinary brothers and sisters. The fact that older twins are no more alike than younger twins argues for the greater potency of heredity in shaping mental traits. Brothers, and brothers and fathers. are more nearly alike, as measured by correlation of traits (both mental and physical) than are unrelated individuals. Brother and sister, brother and brother, and sister and sister, are also more alike in such traits as vivacity, temper, assertiveness and other character traits than unrelated persons (Pearson). No doubt a considerable part of the mental resemblance noted among those of the same family or closely related families, such as habits of speech and thought, common opinions, ideas and attitudes, is due to a common fund of environmental influences and associations. But over and above all of this, there is, in the opinion of most competent workers in the field, a large share attributable to native factors.

See W. Stern, *Differentielle Psychologie* (Leipzig, 1921); E. L. Thorndike, *Educational Psychology,* vol. iii. (New York, 1914); G. M. Whipple, *Manual of Mental and Physical Tests,* Parts I. and II. (Baltimore, 1921). (H. E. G.)

DIFFERENTIATION, a term used in biology signifying the evolutionary process, by which certain modifications of the body both structural and functional take place in plants and animals. In the vegetable kingdom the evolution of growth is usually from the simple to the complex form, the organs developing into more specialized parts of the body. (See PLANTS; EXPERI-

MENTAL EMBRYOLOGY; DEDIFFERENTIATION.) For differentiation in mathematics *see* CALCULUS.

DIFFRACTION: *see* LIGHT.

DIFFRACTION GRATING, a series of parallel straight lines spaced at equal intervals in one plane or on a concave surface. A beam of radiation after falling on such a grating, is resolved into a spectrum *(see* SPECTROSCOPY and LIGHT).

DIFFUSION, in general, a spreading out, scattering or circulation; in physics the term is applied to a special phenomenon, treated below. The word is from the Lat. *diffundere; dis-,* asunder, and *fundere,* to pour out.

1. **General** Description. — When two different substances are placed in contact with each other they sometimes remain separate, but in many cases a gradual mixing takes place. This occurs whenever there is a difference of concentration or (in the case of gases) of partial pressure between the constituents of neighbouring portions. This phenomenon is known as diffusion.

Simple cases of diffusion are easily observed qualitatively. If a solution of a coloured salt is carefully introduced by a funnel into the bottom of a jar containing water, the two portions will at first be fairly well defined, but if the mixture can exist in all proportions, the surface of separation will gradually disappear; and the rise of the colour into the upper part and its gradual weakening in the lower part, may be watched for days, weeks or even longer intervals. The diffusion of a strong aniline colouring matter into the interior of gelatine is easily observed, and is commonly seen in copying apparatus. Diffusion of gases may be shown to exist by taking glass jars containing vapours of hydrochloric acid and ammonia, and placing them in communication with the heavier gas downmost. The precipitation of ammonium chloride shows that diffusion exists, though the chemical action prevents this example from forming a typical case of diffusion. Again, when a film of Canada balsam is enclosed between glass plates, the disappearance during a few weeks of small air bubbles enclosed in the balsam can be watched under the microscope.

In fluid media, whether liquids or gases, the process of mixing is greatly accelerated by stirring or agitating the fluids, and liquids which might take years to mix if left to themselves can thus be mixed in a few seconds. It is necessary carefully to distinguish the effects of agitation from those of diffusion proper. Agitation brings together portions of the fluid between which considerable differences of concentration may exist. The interchange between such portions then proceeds much more rapidly. In many cases, especially in gases, the intermixing goes on until the concentration is uniform throughout. Thus a strong solution of $CuSO_4$ will ultimately form a uniform weaker solution if brought into contact with water. In other cases, the material remains divided into two or more regions (or phases) in each of which the relative concentration of the components is uniform, but changes in passing from one phase to the next. The passing of one or more components across the boundary between two phases is known as solution or evaporation or condensation; but the process by which the uniform distribution in each phase is set up is diffusion.

Diffusion may take place in solids, that is, in regions occupied by matter which continues to exhibit the properties of the solid state. Thus, gold and lead brought into contact begin to diffuse into one another. An interesting series of examples is afforded by the passage of gases through partitions of metal, notably the passage of hydrogen through platinum and palladium and of helium through silica ("fused" quartz) at high temperatures. When the process is considered with reference to a membrane or partition taken as a whole, the passage of a substance from one side to the other is commonly known as "osmosis" or "transpiration" *(see* SOLUTIONS) but what occurs in the material of the membrane itself is correctly described as diffusion. Agitation brings together portions of the fluid between which considerable differences of concentration may exist. The interchange between such portions then proceeds much more rapidly.

To sum up, the ultimate process by which the individual molecules of two different substances become mixed, producing finally a homogeneous mixture, is in every case diffusion.

In order to make accurate observations of diffusion in fluids it is necessary to guard against any cause which may set up currents; and in some cases this is exceedingly difficult. Thus, if gas is absorbed at the upper surface of a liquid, and if the gaseous solution is heavier than the pure liquid, currents may be set up, and a steady state of diffusion may cease to exist. This has been tested experimentally by C. G. von Hufner and W. E. Adney. The same thing may happen when a gas is evolved into a liquid at the surface of a solid even if no bubbles are formed; thus if pieces of aluminium are placed in caustic soda, the currents set up by the evolution of hydrogen are sufficient to set the aluminium pieces in motion, and it is probable that the motions of the Diatomaceae are similarly caused by the evolution of oxygen. In some pairs of substances diffusion may take place more rapidly than in others. Of course the progress of events in any experiment necessarily depends on various causes, such as the size oi the containing vessels, but it is easy to see that when experiments with different substances are carried out under similar conditions, however these "similar conditions" be defined, the rates of diffusion must be capable of numerical comparison, and the results must be expressible in terms of at least one physical quantity, which for any two substances can be called their coefficient of diffusion. How to select this quantity we shall see later.

2. Quantitative Methods of **Observing Diffusion.**—The simplest plan of determining the progress of diffusion between two liquids would be to draw off and examine portions from different strata at some stage in the process; the disturbance produced would, however, interfere with the subsequent process of diffusion, and the observations could not be continued. By placing in the liquid column hollow glass beads of different average densities, and observing at what height they remain suspended, it is possible to trace the variations of density of the liquid column at different depths, and different times. In this method, which was originally introduced by Lord Kelvin, difficulties were caused by the adherence of small air bubbles to the beads.

In general, optical methods are the most capable of giving exact results, and the following may be distinguished. (a) By *refraction in a horizontal plane.* If the containing vessel is in the form of a prism, the deviation of a horizontal ray of light in passing through the prism determines the index of refraction, and consequently the density of the stratum through which the ray passes. (b) By *refraction in a vertical plane.* Owing to the density varying with the depth, a horizontal ray entering the liquid also undergoes a small vertical deviation, being bent downwards towards the layers of greater density. The observation of this vertical deviation determines not the actual density, but its rate of variation with the depth, ie., the "density gradient" at any point. A parallel-faced vessel is employed and the incident beam falls normally upon it. (c) By *the saccharimeter.* In the cases of solutions of sugar, which cause rotation of the plane of polarized light, the density of the sugar at any depth may be determined by observing the corresponding angle of rotation; this was done originally by W. Voigt.

3. Elementary Definitions of Coefficient **of Diffusion.**— The simplest case of diffusion is that of a substance, say a gas, diffusing in the interior of a homogeneous solid medium which remains at rest, when no external forces act on the system. We may regard it as the result of experience that: (1) if the density of the diffusing substance (*i.e.,* the mass of that substance per unit volume) is everywhere the same, no diffusion takes place, and (2) if the density of the diffusing substance is differentat different points, diffusion will take place from places of greater to those of lesser density, and will not cease until the density is everywhere the same. It follows that the rate of flow of the diffusing substance at any point in any direction must depend on the density gradient at that point in that direction, *i.e.,* on the rate at which the density of the diffusing substance decreases as we move in that direction. We may define the *coefficient of diffusion* as the ratio of the total mass which flows per unit area across any small section, to the rate of decrease of the density with distance in a direction perpendicular to that section.

In the case of steady diffusion parallel to the axis of x, if p be

the density of the diffusing substance, and q the mass which flows across a unit of area in a plane perpendicular to the axis of x in unit time, then the density gradient is $-d\rho/dx$ and the ratio of q to this is called the "coefficient of diffusion." By what has been said this ratio remains finite, however small the actual gradient and flow may be; and it is natural to assume, at any rate as a first approximation, that it is constant as far as the quantities in question are concerned. Thus if the coefficient of diffusion be denoted by K we have $q=-K(d\rho/dx)$.

Further, the rate at which the quantity of substance is increasing in an element between the distances x and $x+dx$ is equal to the difference of the rates of flow in and out of the two faces, whence as in hydrodynamics, we have $d\rho/dt=-dq/dx$.

It follows that the equation of diffusion in this case assumes the form:

$$\frac{\partial\rho}{\partial t}=\frac{\partial}{\partial x}\left(K\frac{\partial\rho}{\partial x}\right),$$

which is identical with the equations representing conduction of heat, flow of electricity and other physical phenomena. For diffusion in three dimensions we have in like manner:

$$\frac{\partial\rho}{\partial t}=\frac{\partial}{\partial x}\left(K\frac{\partial\rho}{\partial x}\right)+\frac{\partial}{\partial y}\left(K\frac{\partial\rho}{\partial y}\right)+\left(\frac{\partial}{\partial z}K\frac{\partial\rho}{\partial z}\right);$$

and the corresponding equations in electricity and heat for anisotropic substances would be available to account for any parallel phenomena, which may arise, or might be conceived, to exist in connection with diffusion through a crystalline solid. The solution of such an equation can usually be expressed in terms of an expansion in an infinite series (see FOURIER'S SERIES, SPHERICAL HARMONICS, etc.).

In the case of a very dilute solution, the coefficient of diffusion of the dissolved substance can be defined in the same way as when the diffusion takes place in a solid, because the effects of diffusion will not have any perceptible influence on the solvent, and the latter may therefore be regarded as remaining practically at rest. But in most cases of diffusion between two fluids, both of the fluids are in motion, and hence there is far greater difficulty in determining the motion, and even in defining the coefficient of diffusion. It is important to notice in the first instance that it is only the relative motion of the two substances which constitutes diffusion. Thus when a current of air is blowing, under ordinary circumstances the changes which take place are purely mechanical, and do not depend on the separate diffusions of the oxygen and nitrogen of which the air is mainly composed. It is only when two gases are flowing with unequal velocity, that is, when they have a relative motion, that these changes of relative distribution, which are called diffusion, take place. The best way out of the difficulty is to investigate the separate motions of the two fluids, taking account of the mechanical actions exerted on them, and supposing that the mutual action of the fluids causes each fluid to resist the relative motion of the other.

4. The Coefficient of Resistance. — Let us call the two diffusing fluids A and B. If B were absent, the motion of the fluid A would be determined entirely by the variations of pressure of the fluid A, and by the external forces, such as that due to gravity acting on A. Similarly if A were absent, the motion of B would be determined entirely by the variations of pressure due to the fluid B, and by the external forces acting on B. When both fluids are mixed together, each fluid tends to resist the relative motion of the other, and by the law of equality of action and reaction, the resistance which A experiences from B is everywhere equal and opposite to the resistance which B experiences from A. If the amount of this resistance per unit volume be divided by the relative velocity of the two fluids, and also by the product of their densities, the quotient is called the "coefficient of resistance." If then ρ_1,ρ_2 are the densities of the two fluids, u_1, u_2 their velocities, C the coefficient of resistance. then the portion of the fluid A contained in a small element of volume v will experience from the fluid B a resistance $C\rho_1\rho_2 v(u_1-u_2)$, and the fluid B contained in the same volume element will experience from the fluid A an equal and opposite resistance, $C\rho_2\rho_1 v(u_2-u_1)$.

This definition implies the following laws of resistance to diffusion, which must be regarded as based on experience, and not as self-evident truths: (1) each fluid tends to assume, so far as diffusion is concerned, the same equilibrium distribution that it would assume if its motion were unresisted by the presence of the other fluid. (Of course, the mutual attraction of gravitation of the two fluids might affect the final distribution, but this is practically negligible. Leaving such actions as this out of account the following statement is correct.) In a state of equilibrium, the density of each fluid at any point thus depends only on the partial pressure of that fluid alone, and it is the same as if the other fluids were absent. It does not depend on the partial pressures of the other fluids. If this were not the case, the resistance to diffusion would be analogous to the friction of solids, and would contain terms which were independent of the relative velocity u_2-u_1. (2) For slow motions the resistance to diffusion is (approximately at any rate) proportional to the relative velocity. (3) The coefficient of resistance C is not necessarily always constant: it may, for example, and, in general, does, depend on the temperature.

If we form the equations of hydrodynamics for the different fluids occurring in any mixture, taking account of diffusion, but neglecting viscosity, and using suffixes 1, 2 to denote the separate fluids, these assume the form given by James Clerk hlaxwell ("Diffusion," in *Ency. Brit.*, 9th ed.):

$$\rho_1\frac{Du_1}{Dt}+\frac{\partial p_1}{\partial x}-X_1\rho_1+C_{12}\rho_1\rho_2(u_1-u_2)+\cdots=0,$$

where $$\frac{Du_1}{Dt}=\frac{\partial u_1}{\partial t}+u_1\frac{\partial u_1}{\partial x}+v_1\frac{\partial u_1}{\partial y}+w_1\frac{\partial u_1}{\partial z},$$

and these equations imply that when diffusion and other motions cease, the fluids satisfy the separate conditions of equilibrium $\partial p_1/\partial x-X_1\rho_1=0$. The assumption made in the following account is that terms such as Du_1/Dt may be neglected in the cases considered.

A further property based on experience is that the motions set up in a mixture by diffusion are very slow compared with those set up by mechanical actions, such as differences of pressure. Thus, if twc gases at equal temperature and pressure be allowed to mix by diffusion, the heavier gas being below the lighter, the process will take a long time; on the other hand, if two gases, or parts of the same gas, at different pressures be connected, equalization of *pressure* will take place almost immediately. It follows from this property that the forces required to overcome the "inertia" of the fluids in the motions due to diffusion are minute in comparison. At any stage of the process, therefore, any one of the diffusing fluids may be regarded as in equilibrium under the action of its own partial pressure, the external forces to which it is subjected and the resistance to diffusion of the other fluids.

5. Slow Diffusion of Two Gases, Relation Between the Coefficients of Resistance and of Diffusion. — llie now suppose the diffusing substances to be two gases which obey Boyle's law, and that diffusion takes place in a closed cylinder or tube of unit sectional area at constant temperature, the surfaces of equal density being perpendicular to the axis of the cylinder, so that the direction of diffusion is along the length of the cylinder, and we suppose no external forces, such as gravity, to act on the system.

The densities of the gases are denoted by ρ_1, ρ_2, their velocities of diffusion by u_1, u_2, and if their partial pressures are p_1, p_2, we have by Boyle's law $p_1=k_1\rho_1$, $p_2=k_2\rho_2$, where k_1, k_2 are constants for the two gases, the temperature being constant. The axis of the cylinder is taken as the axis of x.

From the considerations of the preceding section, the effects of inertia of the diffusing gases may be neglected, and at any instant of the process either of the gases is to be treated as kept in equilibrium by its partial pressure and the resistance to diffusion produced by the other gas. Calling this resistance per unit volume R, and putting $R=C\rho_1\rho_2(u_1-u_2)$, where C is the coefficient of resistance, the equations of equilibrium give

$$\frac{dp_1}{dx}+C\rho_1\rho_2(u_1-u_2)=0, \text{ and } \frac{dp_2}{dx}+C\rho_2\rho_1(u_2-u_1)=0. \quad (1)$$

These involve

$$\frac{dp_1}{d} + \frac{dp_2}{dr} = 0 \quad \text{or} \quad p_1 + p_2 = P, \qquad (2)$$

where P is the total pressure of the mixture, and is everywhere constant, consistently with the conditions of mechanical equilibrium.

Now dp_1/dx is the pressure-gradient of the first gas, and is, by Boyle's law, equal to k_1 times the corresponding density-gradient. Again $\rho_1 u_1$ is the mass of gas flowing across any section per unit time, and $k_1\rho_1 u_1$ or $p_1 u_1$ can be regarded as representing the flux of partial pressure produced by the motion of the gas. Since the total pressure is everywhere constant, and the ends of the cylinder are supposed fixed, the fluxes of partial pressure due to the two gases are equal and opposite, so that

$$p_1 u_1 + p_2 u_2 = 0 \quad \text{or} \quad k_1\rho_1 u_1 + k_2\rho_2 u_2 = 0. \qquad (3)$$

From (2) *(3)* we find by elementary algebra

$$u_1/p_2 = -u_2/p_1 = (u_1 - u_2)/(p_1 + p_2) = (u_1 - u_2)/P,$$

and therefore

$$p_2 u_1 = -p_2 u_2 = p_1 p_2 (u_1 - u_2)/P = k_1 k_2 \rho_1 \rho_2 (u_1 - u_2)/P.$$

Hence equations (1) *(2)* gives

$$\frac{\partial p_1}{\partial x} + \frac{CP}{k_1 k_2}(p_1 u_1) = 0, \text{ and } \frac{\partial p_2}{\partial x} + \frac{CP}{k_1 k_2}(p_2 u_2) = 0;$$

whence also substituting $p_1 = k_1\rho_1$, $p_2 = k_2\rho_2$, and by transposing

$$\rho_1 u_1 = -\frac{k_1 k_2}{CP}\frac{\partial \rho_1}{\partial x}, \text{ and } \rho_2 u_2 = -\frac{k_1 k_2}{CP}\frac{\partial \rho_2}{\partial x}.$$

We may now define the "coefficient of diffusion" of either gas as the ratio of the rate of flow of that gas to its density-gradient. With this definition, the coefficients of diffusion of both the gases in a mixture are equal, each being equal to $k_1 k_2/CP$. The ratios of the fluxes of partial pressure to the corresponding pressure-gradients are also equal to the same coefficient. Calling this coefficient K, we also observe that the equations of continuity for the two gases are

$$\frac{\partial \rho_1}{\partial t} + \frac{\partial(\rho_1 u_1)}{\partial x} = 0, \text{ and } \frac{\partial \rho_2}{\partial t} + \frac{\partial(\rho_2 u_2)}{\partial x} = 0,$$

leading to the equations of diffusion

$$\frac{\partial \rho_1}{\partial t} = \frac{\partial}{\partial x}\left(K\frac{\partial \rho_1}{\partial x}\right), \text{ and } \frac{\partial \rho_2}{\partial t} = \frac{\partial}{\partial x}\left(K\frac{\partial \rho_2}{\partial x}\right),$$

exactly as in the case of diffusion through a solid.

If we attempt to treat diffusion in liquids by a similar method, it is, in the first place, necessary to define the "partial pressure" of the components occurring in a liquid mixture. This leads to the conception of "osmotic pressure," which is dealt with in the article SOLUTIONS. For dilute solutions at constant temperature, the assumption that the osmotic pressure is proportional to the density, leads to results agreeing fairly closely with experience, and this fact may be represented by the statement that a substance occurring in a dilute solution behaves like a perfect gas. (It is to be borne in mind that the partial pressures are no longer additive. For a solution containing 1 gm. molecule of sugar per litre the osmotic pressure is about 30 atmospheres even though the total pressure is only 1 Atm.)

6. Relation of the Coefficient of Diffusion to the Units of Length and Time.—We may write the equation defining K in the form

$$u = -K \times \frac{1}{\rho}\frac{d\rho}{dx}.$$

Here $-d\rho/\rho dx$ represents the proportional rate at which the density decreases with the distance x; and we thus see that the coefficient of diffusion represents the ratio of the velocity of flow to the proportional rate at which the density decreases with the distance measured in the direction of flow. This proportional rate being of the nature of a number divided by a length, and the velocity being of the nature of a lcngtli divided by a time, we may state that K is of two dimensions in length and -1 in time, *i.e.*, of dimensions L^2/T.

Example 1. Taking K = 0·1423 for carbon dioxide and air (at temperature 0° C and pressure 76 cm. of mercury) referred to a centimetre and a second as units, we may interpret the result as follows:—Supposing in a mixture of carbon dioxide and air, the density of the carbon dioxide decreases by, say, 1, 2, or 3% of itself in a distance of 1 cm, then the corresponding velocities of the diffusing carbon dioxide will be respectively 0·01, 0·02 and 0·03 times 0·1423, that is, 0·001423, 0·002846 and 0·004269 cm. per second in the three cases.

Example 2. If we wished to take a foot and a second as our units, we should have to divide the value of the coefficient of diffusionin Example 1 by the square of the number of centimetres in 1 ft., that is, roughly speaking, by *goo*, giving the new value of K = 0·00016 roughly.

7. Numerical Values of the Coefficient of Diffusion.—The table with this article gives the values of the coefficient of diffusion of several principal pairs of gases at a pressure of 76 am. of mercury, and also of a number of other substances. In the values for gases the centimetre and second are taken as fundamental units, in other cases the centimetre and day. The numbers given must be taken as indicating the order of magnitude only since considerably different values are obtained by different observers. Thus Obermayer obtained the value 0·67 for hydrogen-oxygen.

8. Diffusion Through a Membrane or Partition. Theory of the Semi-permeable Membrane.—It has been pointed out that diffusion of gases frequently takes place in the interior of solids; moreover, different gases behave differently with respect to the same solid at the same temperature. A membrane or partition formed of such a solid can therefore be used to effect a more or less complete separation of gases from a mixture. This method is employed commercially for extracting oxygen from the atmosphere, in particular for use in projection lanterns where a high degree of purity is not required. A similar method is often applied to liquids and solutions and is known as "dialysis."

In such cases as can be tested experimentally it has been found that a gas always tends to pass through a membrane from the side where its density, and therefore its partial pressure, is greater to the side where it is less; so that for equilibrium the partial pressures on the two sides must be equal. This result is unaffected by the presence of other gases on one or both sides of the membrane. For example, if different gases at the same pressure are separated by a partition through which one gas can pass more rapidly than the other, the diffusion will give rise to a difference of pressure on the two sides, which is capable of doing mechanical work in moving the partition. In evidence of this conclusion Max Planck quotes a test experiment made by him in the Physical Institute of the University of Munich in 1883, depending on the fact that platinum foil at white heat is permeable to hydrogen but impermeable to air, so that if a platinum tube filled with hydrogen be heated the hydrogen will diffuse out, leaving a vacuum.

The details of the experiment may be quoted here:—"A glass tube of about 5 mm. internal diameter, blown out to a bulb at the middle, was provided with a stop-cock at one end. To the other a platinum tube 10 cm. long was fastened, and closed at the end. The whole tube was exhausted by a mercury pump, filled with hydrogen at ordinary atmospheric pressure. and then closed. The closed end of the platinum portion was then heated in a horizontal position by a Bunsen burner. The connection between the glass and platinum tubes, having been made by means of sealing-wax, had to be kept cool by a continuous current of water to prevent the softening of the wax. After four hours the tube was taken from the flame, cooled to the temperature of the room, and the stop-cock opened under mercury. The mercury rose rapidly, almost completely filling the tube, proving that the tube had been very nearly exhausted"

In order that diffusion through a membrane may be reversible so far as a particular gas is concerned, the process must take place so slowly that equilibrium is set up at every stage. In order to separate one gas from another consistently with this condition it is necessary that no diffusion of the latter gas should accom-

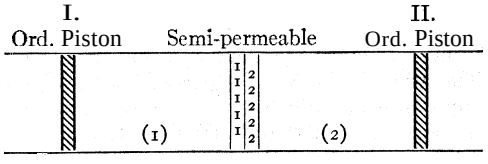
pany the process. The name "semi-permeable" is applied to an *ideal* membrane or partition through which one gas can pass, and which offers an insuperable barrier to any diffusion whatever of a second gas. By means of two semi-permeable partitions acting oppositely with respect to two different gases *A* and B these gases could be mixed or separated by reversible methods.

Most physicists admit, as Planck does, that it is impossible to obtain an ideal semi-permeable substance; indeed such a substance would necessarily have to possess an infinitely great resistance to diffusion for such gases as could not penetrate it. But in an experiment performed under actual conditions the losses of available energy arising from this cause would be attributable to the imperfect efficiency of the partitions and not to the gases themselves; moreover, these losses are, in every case, found to be completely in accordance with the laws of irreversible thermodynamics. The reasoning in this article being somewhat condensed, the reader must necessarily be referred to treatises on thermodynamics for further information on points of detail connected with the argument.

9. Work That Can Be Gained on Mixing Perfect Gases Reversibly. — In the case of perfect gases the partial pressures of the respective gases are independent of the presence of other gases. Take two separate gases, each at the same pressure, p_1+p_2, and at the same temperature; their volumes being V_1 and V_2. These can be mixed in a reversible way by means of suitable cylinders and pistons.



Place the gases in cylinders 1 and 2. The central pistons *initially in contact* must be semi-permeable, No. 1 to gas No. 1 and No. 2 to gas No. 2. By adjusting the ordinary pistons the gases may be brought to pressures p_1 and p_2 respectively. The isothermal work done by the system is

$$R_1T\log\frac{p_1+p_2}{p_1}+R_2T\log\frac{p_1+p_2}{p_2}$$

and the volumes become V'_1 and V'_2.

By suitably moving all four pistons the gases can be transferred reversibly to the space between the two inner pistons the pressure remaining at the values p_1 and p_2 while the intervening region remains throughout at constant pressure, p_1+p_2. The work done in this stage is

$$-V'_1p_1-V'_2p_2+(p_1+p_2)(V_1+V_2)$$

which, on inserting the values of V'_1 and V'_2 is seen to be zero. Hence the total work obtained is that done in the first stage and on putting $(p_1+p_2)V_1=R_1T$ and $(p_1+p_2)V_2=R2T$ it becomes

$$(p_1+p_2)V_1\log\frac{p_1+p_2}{p_1}+(p_1+p_2)V_2\log\frac{p_1+p_2}{p_2}.$$

When the two gases are mixed by diffusion in an enclosed space, the total pressure remaining constant at p_1+p_2 throughout, all this work is lost for good since the gases can only be separated again by having work performed on them at *least* equal to that which might have been gained.

10. Kinetic Models of Diffusion. — Imagine in the first instance that a very large number of red balls are distributed over one half of a billiard table, and an equal number of white balls over the other half. If the balls are set in motion with different velocities in various directions, diffusion will take place, the red balls finding their way among the white ones, and vice versa; and the process will be retarded by collisions between the balls. The simplest model of a perfect gas studied in the kinetic theory of gases (*see* KINETIC THEORY OF MATTER) differs from the above illustration in that the bodies representing the molecules move in space instead of in a plane, and, unlike billiard balls, their motion is unresisted, and they are perfectly elastic, so that no kinetic energy is lost either during their free motions, or at a collision.

The mathematical analysis connected with the application of the kinetic theory to diffusion is very long and cumbersome. We shall therefore confine our attention to regarding a medium formed of elastic spheres as a mechanical model, by which the most important features of diffusion can be illustrated. We shall assume the results of the kinetic theory, according to which: — (1) In a dynamical model of a perfect gas the mean kinetic energy of translation of the molecules represents the absolute temperature of the gas. (2) The pressure at any point is proportional to the product of the number of molecules in unit volume about that point into the mean square of the velocity. (The mean square of velocity is different from but proportional to the square of the mean velocity, and in the subsequent arguments either of these two quantities can generally be taken.) (3) In a gas mixture represented by a mixture of molecules of unequal masses. the mean

kinetic energies of the different kinds are equal.

Consider now the problem of diffusion in a region containing two kinds of molecules A and B of unequal mass. The molecules of A in the neighbourhood of any point will, by their motion, spread out in every direction until they come into collision with other molecules of either kind, and this spreading out from every point of the medium will give rise to diffusion. If we imagine the velocities of the A molecules to be equally distributed in all directions, as they would be in a homogeneous mixture, it is obvious that the process of diffusion will be greater, *ceteris paribus*, the greater the velocity of the molecules, and the greater the length of the free path before a collision takes place. If we assume consistently with this, that the coefficient of diffusion of the gas A is proportional to the mean value of $w_a l_a$, where w_a is the velocity and l_a is the length of the path of a molecule of A, this expression for the coefficient of diffusion is of the right dimensions in length and time. If, moreover, we observe that when diifusion takes place in a fixed direction, say that of the axis of x, it depends only on the resolved part of the velocity and length of path in that direction: this hypothesis readily leads to our taking the mean value of $\frac{1}{3}w_a l_a$ as the coefficient of diffusion for the gas A. This value was obtained by O. E. Meyer and others.

Unfortunately, however, it makes the coefficients of diffusion unequal for the two gases, a result inconsistent with that obtained above from considerations of the coefficient of resistance, and leading to the consequence that differences of pressure would be set up in different parts of the gas. To equalize these differences of pressure, Mever assumed that a counter current is set up, this current being, of course, very slow in practice; and J. Stefan assumed that the diffusion of one gas was not affected bv collisions between molecules of the *same gas*. When the molecules are mixed in equal proportions both hypotheses lead to the value $\frac{1}{6}([w_a l_a]+[w_b l_b])$, (square brackets denoting mean values). When one gas preponderates largely over the other, the phenomena of diffusion are too difficult of observation to allow of accurate experimental tests being made. Moreover, in this case no difference exists unless the molecules are different in size or mass.

Instead of supposing a velocity of translation added after the mathematical calculations have been performed, a better plan is to assume from the outset that the molecules of the two gases have small velocities of translation in opposite directions, superposed on the distribution of velocity, which would occur in a medium representing a gas at rest. When a collision occurs between molecules of different gases a transference of momentum takes place between them, and the quantity of momentum so transferred in one second in a unit of volume gives a dynamical measure of the resistance to diffusion. It is to be observed that, however small the relative velocity of the gases A and B, it plays an all-important part in determining the coefficient of resistance; for without such relative motion, and with the velocities evenly distributed in all directions, no transference of momentum could take place. The coefficient of resistance being found, the motion of each of the two gases may be discussed separately.

One of the most important consequences of the kinetic theory is that if the volume be kept constant the coefficient of diffusion varies as the square root of the absolute temperature. To prove this, we merely have to imagine the velocity of each molecule to be suddenly increased n fold; the subsequent processes, including diffusion, will then go on n times as fast; and the temperature T, being proportional to the kinetic energy, and therefore to the square of the velocity, will be increased n^2 fold. Thus K, the coefficient of diffusion, varies as $\sqrt{T}$.

The relation of K to the density when the temperature remains constant is more difficult to discuss, but it may be sufficient to notice that if the number of molecules is increaskd n fold, the chances of a collision are n times as great, and the distance traversed between collisions is (not *therefore* but as the result of more detailed reasoning) on the average $1/n$ of what it was before. Thus the free path, and therefore the coefficient of diffusion, varies inversely as the density, or directly as the volume. If the pressure p and temperature T be taken as variables, K varies inversely as p and directly as $\sqrt{T^3}$.

Now according to the experiments first made by J. C. Maxwell and J. Loschmidt, it appeared that with constant density K was proportional to T more nearly than to $\sqrt{T}$. The inference is that in this respect a medium formed of colliding spheres fails to give a correct mechanical model of gases. It has been found by L. Boltzmann, Maxwell and others that a system of particles whose mutual actions vary according to the inverse fifth power of the distance between them represents more correctly the relation between the coefficient of diffusion and temperature in actual gases. Other recent theories of diffusion have been advanced by M. Thiesen, P. Langevin and W. Sutherland. On the other hand, J. Thovert finds experimental evidence that the coefficient of diffusion is proportional to molecular velocity in the cases examined of non-electrolytes dissolved in water at 18° at 2·5 grams per litre.

11. Applications of Diffusion to Separating Gases.—Lord Rayleigh has applied the different *rates* at which diffusion takes place through porous partitions to the partial separation of mixed gases. Let x and y denote the quantities of the respective gases remaining at any moment in the chamber, so that $-dx$ and $-dy$ can stand for the quantities diffusing out in time dt. The values of dx/dt and dy/dt will depend upon the character of the porous partition and upon the actual pressure. Calling the relative rates of diffusionp, and v, we have

$$dy/dx=(\nu y)/\mu x. \qquad (1)$$

The integral of (1) is

$$\log \frac{y}{x} = x^{-\frac{\mu-\nu}{\mu}} + \text{constant}.$$

If the values, at any moment which we take as the initial time, are Y and X the constant can be eliminated. If we write $\frac{y}{x}\frac{X}{Y}=r$, the value of r represents the enrichment of the residue in regard to the second constituent (y) and we can write

$$\frac{x+y}{X+Y}=\frac{X}{X+Y}r^{\frac{\mu}{(\nu-\mu)}}+\frac{Y}{X+Y}r^{\frac{\nu}{(\nu-\mu)}}.$$

These equations show that the residue becomes purer *without limit*, and this is so whatever may be the original proportions. This is an outline of the theory that might be expected to apply to Graham's atmolyser in which the gaseous mixture is caused to travel along a tobacco pipe on the outside of which a vacuum is maintained. The third Lord Rayleigh applied this method to the separation of argon from air from which the oxygen had previously been removed. If an enrichment in the ratio 2 to 1 is desired the diffusion must continue until the total quantity of gas is reduced to less than 2%. In his experiments even more than this reduction was required (Rayleigh, *Phil.* Mag., xlii. 493, 1896).

BIBLIOGRAPHY.—The best introduction to the study of theories of diffusion is afforded by O. E. Meyer's *Kinetic Theory of Gases*, translated by Robert E. Baynes (London, 1899). The mathematical portion, though sufficient for ordinary purposes, is mostly of the simplest possible character. Another useful treatise is R. Ruhlmann's *Handbuch der mechanischen Wärmetheorie* (Brunswick, 1880). For a shorter sketch the reader may refer to J. C. Maxwell's *Theory of Heat*, chaps. xix. and xxii., or numerous other treatises on physics. The theory of the semi-permeable membrane is discussed by M. Planck in his *Treatise on Thermo dynamics*, Engiish translation by A. Ogg (1903), also in treatises on thermodynamics by W. Voigt and other writers. For a more detailed study of diffusion in general the following papers may be consulted:—L. Boltzmann, "Zur Integration der Diffusionsgleichung," *Sitzung. der k. bayer. A kad math.-phys. Klasse* (May 1894); T. des Coudres, "Diffusionsvorgange in einem Zylinder," *Wied. Ann.* lv. (1895), p. 213; J. Loschmidt, "Experimentaluntersuchungen iiber Diffusion," *Wien. Sitz.* lxi., lxii (1870); J. Stefan, "Gleichgewicht und . . . Diffusion von Gasmengen," *Wien. Sitz.* lxiii., "Dynamische Theorie der Diffusion, *Wien. Sitz.* lxv. (April 1872); M. Toepler, "Gas-diffusion," *Wied. Ann.* lviii. (1896), p. 599; A. Wretschko, "Experimentaluntersuchungen iiber die Diffusion von Gasmengen," *Wien. Sitz.* lxii. The mathematical theory of diffusion, according to the kinetic theory of gases, has been treated by a number of different methods, and for the study of these the reader may consult L. Boltzmann, *Vorlesungen iiber Gastheorie* (Leipzig, 1896–98); S. H. Burbury, *Kinetic Theory of Gases* (Cambridge, 1899), and papers by L. Boltzmann in *Wien. Sitz.* lxxxvi. (1882), lxxxvii. (1883); P. G. Tait, "Foundations of the Kinetic Theory of Gases," *Trans. R.S.E.* xxxiii., xxxv., xxvi., or *Scientific Papers*, ii. (Cambridge, 1900). Some of the difficulties in the

theory are discussed in a recent paper by S. Chapman, Phil. Mag. 5,630 (1928). For other work reference should be made to the current issues of *Science Abstracts* (London), and entries under the heading "Diffusion" will be found in the general index at the end of each volume. (G. H. BR.; **A.** W. Po.)

DIFFUSIVITY, the rate of propagation of *temperature,* as distinct from *heat* (*q.v.*), along a body. It depends on the thermal conductivity K, density ρ and specific heat S of the material, according to the equation: diffusity $= \frac{K}{\rho S}$.

DIGBY, GEORGE, 2nd Earl of Bristol: *see* BRISTOL, EARLS AND MARQUESSES OF.

DIGBY, SIR EVERARD (1578–1606), English conspirator, son of Everard Digby of Stoke Dry, Rutland, was born on May 16, 1578. In 1605 he joined the conspirators in the Gunpowder Plot (*q.v.*). His share in the plan was to organize a rising in the Midlands; and on the pretence of a hunting party he assembled at Danchurch, Warwickshire, on Nov. 5, a party of gentlemen who, on receiving news of the destruction of the king and the House of Lords, were to seize the person of the princess Elizabeth, who was residing in the neighbourhood. The conspirators arrived late on the evening of the 6th to tell their story of failure, and Digby was persuaded by Catesby, with a false tale that the king and Salisbury were dead, to join the small band of conspirators in their hopeless endeavour to raise the country. He went with them to Huddington, Worcs., and on the 7th to Holbeche, Staffs. On the 8th, he abandoned his companions, and, with two servants, hid in a pit, where he was discovered and captured. He was tried in Westminster Hall, on Jan. 27, 1606, and alone among the conspirators he pleaded guilty, declaring that the motives of his crime had been his friendship for Catesby and his devotion to his religion. He was condemned to death, and executed on the 31st, in St. Paul's Churchyard, with the customary brutalities.

See narrative of Father Gerard, in *Condition of the Catholics under James I.,* by J. Morris (1872), etc. A life of Digby under the title of *A Life of a Conspirator,* by a Romish recusant (Thomas Longueville) was published in 1895.

DIGBY, SIR KENELM (1603–1665), English author, diplomatist and sailor, son of Sir Everard Digby (*q.v.*), was brought up as a Roman Catholic at his mother's house at Gayhurst. On leaving Oxford in 1620 he travelled in France and Italy, and in March 1623 joined his uncle, Sir John Digby, ambassador to the court of Spain. There he met Prince Charles and the duke of Buckingham, and, joining the prince's household, returned with him to England, and was knighted by James in October. Digby was a handsome man and cut a great figure in society, but was kept out of public employment by Buckingham's jealousy of his cousin, Lord Bristol. In 162; he decided, on the latter's advice, to attempt an adventure on his own. With two ships-he set sail on a privateering expedition, captured some Spanish and Flemish ships off Gibraltar (Jan. 18, 1628), seized a Dutch ship off Majorca, and defeated the French and Venetian ships in the harbour of Scanderoon. He returned to England in Feb. 1629, and next year was made a commissioner of the navy, but his doings in the Mediterranean had to be disavowed on account of the complaints of the Venetian ambassador.

Digby had married secretly in 1625 the beautiful Venetia Hanley. She died in 1633, and was celebrated by Ben Jonson in *Eupheme.* Her husband went into retirement for two years to mourn for his wife, and changed his religion, only to return to the Roman Catholic faith immediately He wrote from France pamphlets in defence of his faith, and on his return to England appealed (1640) to Roman Catholics for money in support of the King's Scottish expedition (1641) to secure help against the parliament. He was summoned to the bar of the House of Commons (Jan. 27, 1641) to answer for his conduct. He left England, returned and was imprisoned, and was finally released and allowed to go to France (July 30, 1643), on condition that he engaged in no plots against the Government.

He became chancellor to the queen Henrietta Maria, in Paris, and was sent by her on a mission to Rome in 1646, where he promised in her name (he had no warrant from Charles) religious freedom for Roman Catholics in England and Ireland, an independent parliament for Ireland, etc. In Feb. 1649 he was asked to return to England, was again banished, and remained in exile until 1654. At that time he was engaged by Cromwell, to the scandal of both parties, in diplomatic business. At the Restoration he returned to England. He died on June 11, 1665.

While he was in Paris he had written two works famous in their day, *Of Bodies* and *Of the Immortality of Man's Soul* (1644). He dabbled in medicine, and some of his preparations are described in *Tlze Closet of the Eminently Learned Sir Kenelm Digby Knt. Opened* (1677). His *Memoirs* are composed in the high-flown fantastic manner then usual when recounting incidents of love and adventure, but the style of his more sober works is excellent.

Digby translated *A Treatise of bdhering to God written by Albert the Great, Bishop of Ratisbon* (1653); and he was the author of *Private Memoirs,* published by Sir N. H. Nicholas from *Harleiun Ms. 6758* with introduction (1827); *Journal of the Scanderoon Voyage in 1628,* printed by J. Bruce with preface (Camden Society, 1868); *Poems from Sir Kenelm Digby's Papers . . .* with preface and notes (Roxburghe Club, 1877); in the *Add. Mss.* 34,362 f. 66 is a poem *Of the Miserys of Man,* probably by Digby; *Choice of Experimental Receipts in Physick and Chirurgery . . . collected by Sir K. Digby* (1668), and *Chymical Secrets and Rare Experiments* (1683), were published by G. Hartman, who describes himself as Digby's steward and laboratory assistant.

See the *Life of Sir Kenelm Digby by one of his Descendants* (T. Longueville), 1896.

DIGBY, KENELM HENRY (1800–ISSO), English writer, youngest son of William Digby, dean of Clonfert, was born at Clonfert, Ireland. His reputation rests chiefly on his earliest publication, *The Broadstone of Honour, or Rules for the Gentlemen of England* (1822), which contains an exhaustive survey of mediaeval customs, full of quotations from varied sources. The work was subsequently enlarged and issued (1826–27) in four volumes entitled: *Godefridus, Tancredus, Morus* and *Orlandus* (numerous re-impressions, the best of which is the edition brought out by B. Quaritch in five volumes, 1876–77).

See J. Gillow's *Bibliographical Dictionary of English Catholics,* ii. 81–83, and Bernard Holland, *Memoir of Kenelm Henry Digby* (1919).

DIGENES ACRITAS, BASILIUS, Byzantine national hero, probably lived in the 10th century. He is named Digenes (of double birth) as the son of a Muslim father and a Christian mother; Acritas (ἄκρα, frontier, boundary), as one of the frontier guards of the empire. The original Digenes epic is lost, but four poems are extant, in which the different incidents of the legend have been worked up by different hands. The first of these was discovered in the latter part of the 19th century, in a 16th-century ms., at Trebizond; the other three mss. were found at Grotta Ferrata, Andros and Oxford. The poem undoubtedly contains a kernel of fact, although it cannot be regarded as in any sense an historical record. The scene of action is laid in Cappadocia and the district of the Euphrates.

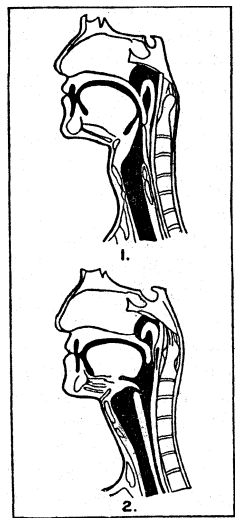
Editions of the Trebizond ms. by C. Sathas and E. Legrand in the *Collection des monuments pour servir à l'etude de la langue néo-hellénique,* new series, vi. (1875), and by S. Joannides (Constantinople, 1887). *See* monographs by A. Luber (Salzburg, 1885) and G. Wartenberg (Berlin, 1897). Full information will be found in C. Krumbacher, *Geschichte der byzantinischen Litteratur* (2nd ed., 1897); *see* also G. Schlumberger, *L'Epopée Byzantine à la fin du dixième siècle* (1897).

DIGEST, a term used generally of any digested or carefully arranged collection or compendium of written matter, but more particularly in law of a compilation in condensed form of a body of law digested in a systematic method; *e.g.,* the Digest *(Digesta)* or Pandects (Πάνδεκται) of Justinian, a collection of extracts from the opinions of earlier jurists compiled by order of the emperor Justinian. The word is also given to the compilations of the main points (marginal or head-notes) of decided cases.

DIGESTION. Most of the food substances taken by animals for nourishment require some alteration before they can be absorbed into the blood and in this way carried to all parts of the body. The conversion of foodstuffs into diffusible or assimilable substances is known as digestion and is carried out in the alimentary canal, mainly by the enzymes secreted by the various glands. The food introduced into the mouth begins its long jour-

ney 'through the alimentary canal, where it comes into contact with the digestive juices and thus undergoes chemical disintegration, the products being finally absorbed. The three chief functions of the digestive tract are (1) propulsion of food along the tract; (2) secretion of digestive juices by glands which are connected with the tract by means of ducts or situated in the walls of the tract; (3) absorption of the final products of digestion.

Salivary Secretion.—The food undergoes its first change while in the mouth; it is broken up into small pieces during the process of mastication, and is well mixed with the first digestive juice, the saliva. The normal secretion of saliva can best be studied in animals in which the natural opening of one of the salivary glands has been surgically transplanted from the inside skin of the mouth to the outside, so that the saliva flows from the gland through the diverted duct to the chin or cheek of the animal. As a result of this harmless operation, the saliva can easily be collected, measured and analyzed. This operation is known as the establishment of a salivary fistula. The results have been compared with observations on man obtained in cases where a fistula became established as the result of accidental injury. The salivary glands must be divided into two groups according to their structure and the composition of the secretion. The first group consists of the mucous glands (submaxillary and sublingual glands) which secrete viscid saliva, rich in the gluco-protein mucin. The second group comprise the serous glands (parotid gland), the juice of which contains no mucin and is therefore watery; it contains, however, some other proteins mainly of the globulin type. In man and certain other animals, both sets of glands secrete the enzyme ptyalin. Before and after the periods of intake of food, the glands are at rest, for the moisture of the mouth depends chiefly on the continuous secretion of small glands covering the mucous membrane, and not on the secretion of the salivary glands.



FROM STARLING, "PRINCIPLES OF HUMAN PHYSIOLOGY"

FIG. 1.—DIAGRAM SHOWING POSITION OF SOFT PALATE (TIGERSTEDT) 1. During rest; 2. during the act of swallowing

Function and *Composition of* Saliva.—On the administration of food, all the salivary glands begin to secrete, the amount of secretion being proportional to the length of time the food remains in the mouth. It is, however, not only food substances which evoke secretion. This power is also possessed by certain chemical substances which often are not swallowed but ejected from the mouth, as for instance acids, alkalies, salts and various irritants such as pepper, mustard, etc.; secretion is even evoked by some substances whose irritant nature is due to purely mechanical properties, as is the case with fine sand and certain powders. It is obvious that many of these irritants play a considerable rôle in our daily menu, though they cannot be regarded as nutritive substances. The main function of saliva is to soften and lubricate, in order to make the food able to pass through the comparatively narrow oesophagus tube to the stomach. In the case of irritants, the purpose of saliva is to dilute them, and to protect the mucous membrane of the mouth by covering it with a layer of viscid mucin. The primary function of the saliva is therefore physical, but in man and those animals whose saliva contains ptyalin, there is the further function of assisting in the chemical decomposition of the higher carbohydrates.

The composition of saliva secreted on administration of the two classes of stimuli (food and irritants) is very different. When food is given, the mucous glands secrete a viscid saliva, rich in mucin, but when irritants are administered, the secretion contains hardly any mucin. This differencein viscosity can be demonstrated by observing the length of time taken by different samples of saliva to flow through a capillary tube, and comparing the rates with that of water. For instance, in one experiment, 1cc. of water took 6 seconds to pass through the viscosimeter, 1cc. of saliva obtained on introduction into the mouth of 0·5% HCl took 8 seconds, of an emulsion of mustard 9 seconds, of 2·5% NaCl g seconds, while 1cc. of saliva obtained on administration of bread took 95 seconds, of meat 175 seconds, of milk 231 seconds and of dried powdered meat 255 seconds. On determining the organic and inorganic constituents of the saliva, it was found that the "alimentary" saliva from the submaxillary gland contained about 0·99% of organic matter, and about 0·4% of inorganic, while that secreted after administration of irritants contained only about 0·1–0·2% of organic matter, and about the same percentage of inorganic matter, namely from 0·35–0·45%. These peculiar differences in the composition of saliva are exhibited only by the mucous glands. The parotid saliva varies little, and with both types of substance has approximately the same composition (0·9–1·0% of organic and 0·35–0·48% of inorganic matter). The organic substances are proteins and ptyalin, and the inorganic are chiefly potassium chloride, which appears in considerably larger quantities than in the blood, sodium chloride, sodium bicarbonate and potassium sulphocyanide.

Mechanism *of* Salivary Secretion.—The amount of saliva secreted depends on the length of time any particular substance remains in the mouth, and also on the extent to which the substance can mechanically or chemically stimulate the mucous membrane of the mouth. Dry substances always evoke a far more copious secretion than liquids. The results of an actual set of observations will serve as an illustration. The following substances were administered for one minute each. Dry bread and the same soaked in water; the resulting secretion measured 3·9cc. and 1·4cc. respectively; with dry meat powder and the same soaked in water, the secretions were 4·5cc. and 1·9cc. respectively; and with dry sand and the same soaked in water, 2·8cc. and 0·4cc. It is obvious that the purely mechanical stimulation caused by the various substances is enough to bring about secretion. Pure water at body temperature evokes no secretion, but saliva is secreted on administration of both hot and cold water, and in each case the composition is the same as that obtained on administration of irritants. The concentration of the chemical stimuli is also of considerable importance. For instance, on administering HCl in concentrations of 0·1, 0.2, 0·3, 0·4 and 0·5% for one minute the total secretion was in one experiment 5.2, 7.4, 8·1, 9.2 and 9·5cc. respectively.

The movements of mastication do not evoke salivary secretion in the absence of the higher parts of the central nervous system; the well-known effect of smell and sight of food is in this case also absent. The secretory effect of these stimuli is the result of association, and will be discussed in the section on conditioned reflexes. The mechanism of salivary secretion is based on a reflex act. Foodstuffs or irritants, in virtue of their chemical or mechanical nature, stimulate the peripheral nerve endings of the sensory nerves of the mouth and tongue, namely the lingual and the glossopharyngeal nerves. The nervous impulse passes along these nerves to the salivary centre in the medulla, and is there transmitted by the efferent (secretory) nerves to the corresponding salivary glands. The higher centres are not necessary for the normal reflex salivary secretion. In dogs in which the brain has been destroyed above the medulla, all the characteristics of the salivary secretion are preserved; moreover, the composition and amount of the secretion depend on the nature of the stimulus in the usual way. After injury to the medulla or after section of both sensory nerves of the mouth, secretion cannot be evoked either by the act of eating, or by irritants.

Nerve *Connections*.—The chief secretory fibres of the two mucous glands were discovered by Ludwig in 1851. They run in the chorda tympani, which is a branch of the facial nerve. The secretory fibres of the parotid gland pass along the glossopharyngeal nerve. Electrical stimulation of these nerves evokes an immediate and copious secretion from the corresponding glands, the rate of secretion being proportional to the strength of the stimulation. All the salivary glands also receive a nerve supply from the sympathetic system, via the cervical sympathetic nerve. The saliva obtained from the mucous glands after stimulation of the cerebral nerves of the dog is more copious and less viscid than

that obtained after stimulation of the sympathetic nerve

Stimulation of the cerebral nerves produces a very considerable vasodilation and therefore increases the blood supply to the gland, while stimulation of the sympathetic nerves produces vasoconstriction to the point of almost arresting the circulation. The correlation formerly drawn was that the extent of secretion and the composition of the saliva were dependent on changes in the blood supply accompanying the stimulation of the corresponding nerves. But it is now generally accepted that the composition of the secretion depends little if at all on the blood flow. At any rate, the saliva does not become more concentrated if on stimulating the cerebral nerve the blood flow is reduced to its original level nor does it become more dilute if the blood flow is artificially increased. The differences in the composition of the saliva and the amount secreted in the normal animal during administration of various substances is certainly not dependent on changes in blood flow (as proved by direct measurements); neither is it dependent on the presence of the sympathetic fibres. After section of all the sympathetic connections, the secretion remains viscid in the case of food, and fluid in the case of irritants.

The part played by the sympathetic nerves in normal secretion is not definitely known. After section of the latter, the secretion hardly changes, while after section of the cerebral nerve it ceases. Artificial stimulation of the sympathetic nerve, however, produces a slight flow of saliva, and causes definite histological changes in the gland. Besides the secretory and vasomotor fibres, the sympathetic nerve contains fibres which stimulate some contractile elements around the secretory cells, and thus help to empty the gland of the viscid juice. The cerebral nerves have no such fibres. The secretory nerve endings of the cerebral salivary nerves are completely paralysed by atropine while the vasodilator nerves are left intact—a further proof that secretion is not due to vasodilation.

The Metabolism **of** the Gland. — The activity of the glands is accompanied by increased metabolism, and the consumption of oxygen and blood sugar may be increased during secretion tenfold. The organic substances and ptyalin which are secreted by the gland are derived from the stores laid down by the gland during the period of rest, and the inorganic substances are derived, together with the water, from the blood. In protracted secretion, as the stores are depleted, the saliva becomes progressively poorer in organic substances, and finally contains only inorganic substances and some urea. **A** gland can however excrete as much as one third of its total nitrogen, showing that the store of organic substances is considerable. As regards water, a gland may be able to secrete over 100 times its own weight in the course of a few hours. The daily secretion from all the salivary glands in man may be roughly estimated at about one litre.

Secretion is not filtration of water from the blood through the gland with a certain washing out of stored substances, but is an active process, the energy for which is derived from oxidations within the gland itself. This is most conclusively proved by the fact that during secretion the gland may develop a hydrostatic pressure in its ducts that is much greater than the blood pressure. The exact nature of the secretory process is not known, and none of the physico-chemical processes that are known to take place in the organism supplies an adequate explanation.

Deglutition.—After mastication, the food is carried to the stomach by a series of co-ordinated voluntary and involuntary movements of the muscles of the tongue, pharynx and oesophagus. The whole act of deglutition may be divided into 3 stages. During the first stage, the food, which has been collected on the surface of the tongue, is carried past the anterior pillars of the fauces; during the second stage it passes through the pharynx, past the openings of the nasal cavities and of the larynx; and during the third stage, it goes through the oesophagus into the stomach. The 3 stages actually compose one single act, and no perceptible pause can be observed between them. Just before deglutition begins, a pause takes place in mastication while the diaphragm gives a short contraction (known as the respiration of deglutition). The bolus of food is then thrown back by a sudden and vigorous contraction of the tongue, assisted by the surrounding muscles (chiefly mylohyoid, also styloglossus, palatoglossus). The contraction of the palatoglossus closes the isthmus faucium, thus preventing the return of food towards the mouth.

In the pharynx, the food passes, a region common to the respiratory and digestive system, but the respiratory passages are temporarily closed. The act of deglutition is impossible unless the larynx is free to move. The bolus is now shot rapidly into the region of the medium and lower constrictors of the pharynx, and then into the oesophagus. Liquids and semi-solids quickly pass down the oesophagus to its cardiac end. Here the passage becomes less rapid, the fluid escaping slowly in a narrow stream into the stomach. The average time for a complete act of deglutition is about 6 seconds for liquids and semi-solids, but dry food substances may take as long as 15 minutes to reach the stomach. The propulsion of liquids is mainly due to the movement of the back of the tongue, but that of solids is due to the contraction of the constrictors of the pharynx and the oesophagal muscles, which slowly push the food towards the stomach.

The passage of food along the oesophagus is assisted by a reflex inhibition of the wall, which is succeeded by a contraction. In every complete act of deglutition there are thus two waves which pass along the oesophagus, one of relaxation and the other of contraction. If however several deglutitions follow one another at short intervals, the wave of contraction has no time to develop, and the succeeding waves of relaxation fuse with one another, thus causing a relaxation of the oesophagus along its whole length. The tube therefore becomes an open passage through which large amounts of liquid can pass into the stomach by mere force of gravity. When swallowing stops, a strong wave of contraction develops. These waves of relaxation and contraction are due to a reflex. and they are not arrested by complete transverse section of the oesophagus, but are stopped by section of its nerves.

There is an important interdependence between respiration and deglutition, for every act of deglutition inhibits a respiratory movement. In the absence of this correlation, food might easily slip through the open respiratory passages into the trachea, which may actually happen in cases of paralysis of the laryngeal muscles. The arrest of respiration may last as long as 6 seconds. That deglutition is impossible in the absence of a bolus is shown by the fact that a man with an empty mouth can perform only four or five swallowings in rapid succession, after which swallowing becomes impossible for a time. The first acts of deglutition were possible because of the presence of saliva in the mouth; after rinsing the mouth with a weak solution of atropine even a single deglutition is impossible without taking some liquid.

Gastric Secretion. — Anatomically, the stomach is divided into the fundal or cardiac portion and the pylorus. Physiologically, the pylorus of the carnivorous animal resembles the intestinal tract proper rather than the rest of the stomach. As the result of an accidental wound in the stomach of a Canadian hunter, a permanent gastric fistula was established, and Beaumont was able, in 1834, to observe directly the movements and secretion of the stomach, and the effects of administering food. In 1843, Bassov, a Russian surgeon, established artificial gastric fistulae in dogs, and since that time various operations on the stomach have become a routine in physiological experimentation.

Except during the period of digestion, the gastric glands are at rest, a little mucus being secreted by the superficial epithelial layer. Within about 5 minutes of the intake of food, the gastric gland begins to secrete. The secretion gradually increases in rate, and considerably outlasts the actual period of eating.

The Reflex *Phase*.—In order to determine whether it is the act of eating or the entry of food into the stomach that brings about gastric secretion, Pavlov performed the following operation. In a dog in which a gastric fistula had been established, he made a transverse section of the oesophagus in the neck, and sutured the two ends to the skin, so that anything that was swallowed dropped out from the open end of the oesophagus and could be eaten again. The animal had of course to be fed either through the lower end of the oesophagus or through the gastric fistula. Animals operated on in this manner live as long as they would normally, and

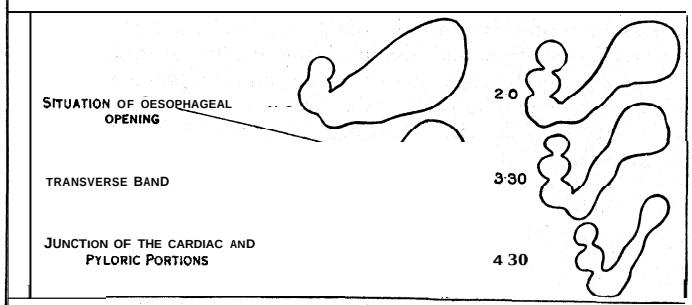
experience no discomfort whatever. When these animals are fed through the mouth (sham feeding), the gastric glands begin to secrete, exactly in the same manner and after the same latent period as in the normal act of eating. The secretion lasts for hours so long as sham feeding is continued, and after its termination the secretion gradually declines, and finally ceases within 10–20 minutes. The conclusion from these experiments is that the onset and the maintenance of the secretion is a reflex which, like that of the salivary secretion, originates in the mouth. The afferent nerves for this reflex are the same as for the salivary secretion, while the secretory fibres run along the vagus nerve. The centre for gastric secretion lies in the medulla. This reflex secretion does not involve the co-operation of the higher nervous centres, and is readily obtained in dogs whose entire fore-brain has been removed. After section of both vagi, the reflex cannot be evoked, just as happens in the case of the salivary glands after section of their respective secretory nerves.

The rate of gastric secretion, the amount of juice secreted, and the composition of the juice (see the section on Nutrition) vary little with different food substances. The juice obtained after administration of fats is deficient in pepsin. The experiments with sham feeding were repeated and confirmed in the case of a man in whom a gastric fistula had to be established on account of stricture of the oesophagus. The amount of juice secreted by an average sized dog may be as much as zoocc. after half an hour of sham feeding, but the secretion may vary considerably.

Part Played by the Higher Centres.—Like the amount of saliva, the amount of gastric juice secreted is largely dependent on appetite. A hungry animal may give, in the same period of time, 5 times more juice than an animal which recently has been fed. It is not only contact with the mucous membrane of the mouth that evokes the reflex, but also the sight and smell of food, and in fact all those' stimuli which the animal associates with food. These effects are entirely dependent on conditioned reflexes (*i.e.* on the higher centres), which in ordinary life play an extremely important part in regulating the activities of all the systems of animals and man; amongst these activities are those of the alimentary glands, which stand in close relation to the central nervous system. Administration of tasteless food, monotony in food, and gross irregularity in the time of feeding will all affect gastric secretion. If the intake of food is too rapid, the secretion will not have time to develop to its maximum, and the food will remain undigested for a considerable time. It is known that the amount of juice secreted, and therefore the digestive and nutritive properties of the food, depend in the long run not so much on the weight or calorific value of the food as on how we eat it, how it is prepared and served, and how we prepare ourselves and concentrate on its intake. However, if man's nutrition depended entirely on his wisdom, only a few would survive, and the organism has, in the case of gastric secretion, a mechanism which is controlled independently not only of the higher centres, but also of the medullary reflex mechanism.

The *Chemical* Mechanism.—This mechanism was also discovered by Pavlov. If certain food substances are introduced through a fistula directly into the stomach, secretion of the gastric juice ensues. This secretion is independent of the nervous system, and can be obtained in a stomach after section of all its nerves. The secretion is best observed in animals in which a portion of the stomach has been separated from the rest and transplanted to the outside (gastric pouch). The pouch may be made so as to preserve its innervation intact, or after section of all the nerves. In the first case, sham feeding will of course produce its usual effect, since this secretion depends on the integrity of the nerves; but in the latter case sham feeding mill have no effect. Introduction of certain food substances into the main part of the stomach will, after a latent period of 10–15 minutes, evoke secretion from the main stomach as well as from the isolated portion, regardless as to whether the nerves are cut or left intact. It is obvious that, in these experiments, since the food substance is never in contact with the transplanted part of the stomach, the secretion cannot be due to a local chemical or mechanical stimulation.

As regards the nature of the substances producing secretion on entry into the stomach, it is known that unchanged food substances, whether carbohydrates, fats or proteins, are unable to produce this secretion. The secretion is however evoked by the presence of the products of the digestion of proteins (peptones, albuminoses) and of fats (fatty acids, soaps). Substances which may be extracted from meat and vegetables on boiling (probably the albumoses) also evoke the secretion if they are introduced directly into the stomach. A most illustrative example is provided



FROM STARLING. "PRINCIPLES OF HUMAN PHYSIOLOGY" (W. B CANNON)

FIG. 2.— SHADOW SKETCHES OF THE OUTLINES OF A CAT'S STOMACH, OBTAINED BY MEANS OF X-RAY ILLUMINATION, IMMEDIATELY AFTER A MEAL CONTAINING BISMUTH SALTS FED AT 11.0, 12.0, 2.0, 3.30 AND 4.30

by the following experiment. Direct introduction of raw meat into the main part of the stomach, after a latent period of about 15 minutes, brought about a considerable secretion from the isolated pouch; a similar introduction of an equal quantity of meat which had been boiled for several hours produced no secretion at all, but the water in which the meat had been boiled caused the same secretion as raw meat. Boiled meat which had been subjected to gastric digestion in vitro produced a very large secretion. The experiment is practically duplicated with vegetables, but on a smaller scale, except that the peptic digestion of the thoroughly boiled vegetables makes no appreciable difference.

There are however proteins which do not yield any extractive substances which are capable of stimulating gastric secretion (for instance egg-white), though on digesting them with gastric juice they acquire strong stimulating properties. In general, we can say that extractive substances from proteins, the products of the digestion of proteins but not proteins themselves, and the products of the digestion of fats but not fats themselves bring about gastric secretion when introduced into the stomach, and this secretion is not under the control of the nervous system.

Two Phases.—The whole gastric secretion may thus be divided into two phases, the first reflex phase (through the vagus nerve), and the second or chemical phase. The first phase is by far the most important—it starts the digestion of proteins, and thus leads to the production of those chemical substances which will further stimulate the secretion of gastric juice. But how much more than mere custom there is in the taking of soup before a meal; in this way we administer to the stomach extractive substances derived from meat or vegetables, and thus ensure that, even in the absence of appetite, our food will meet with some gastric juice in the stomach.

The mechanism underlying the chemical phase of secretion is not yet clear. It is, however, known that the products of digestion of proteins, etc., need not come into contact with the fundal part of the stomach at all; they must, however, come into contact with the mucous membrane of the pylorus, and this is the way in which they produce their effect. There is much evidence for the view that, under the action of these stimulations, a substance (generally called gastrin [Edkins]) is liberated by the pylorus into the blood; the blood then brings this substance to the fundal glands and stimulates them to secrete the juice. That the stimulus is carried by the blood stream can be regarded as proved, at least in cases of transplantation of parts of the stomach to the thigh and chest of the animal, for extractive substances on introduction to the main stomach evoke secretion in the transplanted part.

Besides the two phases of gastric secretion, there are no other methods of evoking secretion, and in any given case the amount of gastric juice secreted, in a complete act of eating, is equal to the

sum of the effects of the nervous phase and the chemical phase. Atropine, which paralyses all secretory nerves, does not affect the second phase of secretion.

The Effect of Fats.—Neutral fats have a peculiar effect on gastric secretion. On administration of fats, the amount and strength of the gastric juice are diminished. This effect is supposed to be due to a reflex originating in the duodenum. It is certainly not due to clogging of the orifices of the gastric glands, for substances with the same viscosity have no effect. Fats when administered to the mouth quickly enter the duodenum, and there augment the pancreatic secretion and diminish the gastric secretion. Fats become digested by the pancreatic juice, and the products of their digestion are regurgitated into the stomach, where they stimulate the gastric secretion by liberating the gastrin bodies from the pylorus. The effect of fats on the gastric secretion passes through three phases, the reflex, the inhibitory and the chemical.

It is obvious that in the case of complete feeding, the production of the gastric juice, depending on the two phases of secretion and on the inhibitory effect of fats, will be typical for each of the three main food substances. In the case of carbohydrate food, the secretion is very much like that in sham feeding—rapidly rising, then falling off within an hour or so; the nervous phase predominates, the chemical phase being negligible since the carbohydrates and their products have hardly any stimulating effect on gastric secretion. In the case of proteins, the chemical phase is well pronounced and superimposes itself on the nervous phase, and the secretion is prolonged at its maximum for over two hours. Then as the food leaves the stomach the secretion gradually diminishes. In the case of fats, the nervous phase is cut short as soon as food enters the duodenum, but the secretion is again favoured by the chemical phase setting in, the net result being a considerable prolongation of the period of gastric secretion. With mixed food, secretion will be the result of a summation of all these individual factors.

Gastric secretion is not evoked by the mechanical stimulation of the gastric mucous membrane, as was supposed before the true mechanism of gastric secretion was known. Water and alcohol both cause a slight secretion. The products of the digestion of carbohydrates do not seem to have any effect on gastric secretion, but carbohydrates themselves increase the strength of the gastric juice, and if they are present in the food in sufficient amount the concentration of pepsin may be actually doubled. The mechanism of this effect is not known.

The Pyloric Secretion.—The secretion of the pylorus is strikingly different from that of the main part of the stomach. The pyloric secretion is never copious but is continuous, and is not increased by sham feeding. The pyloric juice does not contain HCl, and is very poor in pepsin. It is viscid on account of the presence of mucin. The secretion is not affected by section of all the nerves going to that part of the stomach, but it is greatly increased by local mechanical stimulation. It is immaterial whether the stimulation is caused by a food substance or something indigestible; provided that the texture is coarse, it will increase the production of the juice. Local stimulation with a glass rod may increase the secretion four- or five-fold. Local application of chemical irritants, such as 0·5% HCl, a weak solution of carbonate, a suspension of pepper, or an emulsion of mustard also causes an increased secretion. But liquid and semi-liquid food substances, being devoid of mechanical stimulus, have no effect, either on local application or on introduction to the rest of the stomach. Even the extractive substances and the products of the digestion of fat, which serve as stimuli for the fundal secretion, have no effect on the pyloric secretion. The function of the pyloric juice is to lubricate the narrow passage connecting the stomach with the intestine, and to provide a small additional amount of pepsin which helps in the gastric digestion as a whole.

The Movements of the Stomach.—The gastric movements can best be studied by Cannon's method of direct observation by means of Rontgen rays. Bismuth subnitrate or oxychloride is mixed with the food, and the animal or man is then X-rayed at different intervals. The obtained shadow of the stomach gives a good idea of the movements. This method can be checked by other experiments, such as the determination of the rate at which the food or various liquids pass from the stomach into the duodenum. which can be done in an animal with a gastric fistula. An alternative method is to introduce a small rubber balloon through the gastric fistula; the balloon is connected to some kind of registration apparatus, and in this way pressure changes occurring in the stomach at each contraction can be observed. The relaxation of the cardiac orifice, which accompanies swallowing. extends also over the whole fundus of the stomach. This relaxation lowers the pressure within the stomach and makes room for the incoming food. As soon as the gastric contents become acid, the cardiac orifice closes.

When food is taken, it accumulates in the fundus and is separated from the pylorus by a strong contraction (the transverse band or the prepyloric sphyncter). After a few minutes, waves of contraction begin to appear slightly on the fundal side of the transverse band, and travel slowly towards the pylorus. These waves gradually increase in strength so that the pylorus may present a series of constrictions. The semi-digested food is thus brought into close contact with the pylorus mucous membrane. The pylorus, however, remains closed, and the food is therefore squeezed back, and forms a reflux stream towards the fundus. The food thus becomes thoroughly mixed with the gastric juice. The fundus of the stomach is now exercising a steady pressure by the contraction of its muscular walls, so that the digested food is forced to enter the pylorus. At varying intervals, the time depending on the nature of the food, the pylorus opens, and a little of the digested food enters the duodenum. As digestion proceeds, the fundus increases its pressure on the gastric contents while the pylorus opens at more frequent intervals. The stomach thus gradually empties itself, and the whole organ acquires the shape of a curved tube. At the end of digestion, the pylorus may even open to allow the passage of undigested material.

The contractions of the stomach, and its method of emptying, are very similar in man and the carnivorous animals. The foregoing description applies to the events which succeed the taking of a considerable mixed meal. If water alone is taken, the pylorus opens within a very short time, and the fluid reaches the duodenum within a few minutes. The importance of this becomes obvious when it is remembered that practically no absorption of water takes place in the stomach, but only in the intestine.

Pylorus and *Duodenum.*—The movements of the two portions of the stomach can be observed also on anaesthetised animals, and even on a stomach which has been excised and placed in warm salt solution. They must therefore have their origin in the walls of the stomach itself. The vagus nerve supplies the muscles with fibres, the stimulation of which increases the contractions. The opening of the pylorus is more dependent on the nervous mechanism. If both vagi are cut, the emptying of the stomach becomes difficult on account of the diminution in the strength of the contractions, and also because the opening of the pylorus is not easily brought about. The iood thus remains in a semi-digested form (since the secretion of the juice is also diminished) for a long time in the stomach; it undergoes putrefaction and the animal may die of autointoxication. The opening of the pylorus does not only depend on the intragastric events but also, as shown by Pavlov, on the condition of the duodenum. The pylorus remains firmly closed so long as the contents of the duodenum remain acid. If alkaline fluid or water is introduced into the stomach, and at the same time some weak acid is injected into the duodenum by means of a duodenal fistula, no fluid passes out of the stomach until the acid is neutralised by the secretion of the pancreatic juice.

When the pylorus is open, not only do the contents of the stomach enter the duodenum, but also the contents of the duodenum regurgitate into the pyloric cavity. Such regurgitation is a normal occurrence, and takes place in the digestion of any food, but is especially conspicuous in the digestion of fats. Fats are not digested in the stomach; they pass on to the duodenum where they are converted into glycerol and fatty acids which, in the alkaline medium, form soaps. While in the duodenum, fats cause (a) an inhibitory effect on gastric secretion, and (b) a contraction

of the pylorus. As soon as the fats are digested, the pyloric sphyncter opens, and large amounts of the products of the digestion together with bile and pancreatic juice regurgitate into the pylorus, where they increase gastric secretion by chemical stimulation. We must consider the action of the sphyncter as dependent on the central nervous system and on the "acid control." Cannon's experiments have shown that "hunger pangs" are associated with and probably due to the rhythmic contractions of the stomach which occur about meal-times, especially if they are delayed.

Vomiting. — Vomiting may occur as a result of overdistension of the stomach, or the presence of irritating material, or from abnormal conditions of the brain. The first indication of vomiting is the feeling of nausea, accompanied by a profuse secretion of saliva. After a deep inspiration, the glottis is closed, and this is followed by a strong contraction of the diaphragm and of the abdominal muscles. At the same time the cardiac orifice is relaxed, and the gastric contents are passed out. The part played by the stomach itself is negligible. Vomiting is a reflex which can be excited by stimulation of the base of the pharynx, irritation of the stomach and from almost every abdominal organ. It is also evoked reflexly through the labyrinth or the eye, as in sea-sickness, and is a conspicuous symptom of various diseases of the cerebrum and cerebellum. The nerve centre of vomiting is located in the medulla, and can be excited directly by various drugs such as tartar emetic, apomorphine, etc.

Pancreatic Secretion. — The pancreas is the main digestive gland. It is the only gland which secretes a juice that contains enzymes capable of digesting all the three classes of foodstuffs. The carbohydrate-splitting enzyme (amylase or diastase) is secreted in a fully active form. The fat-splitting enzyme (lipase) is partially active when secreted, and is rendered fully active by the action of the bile salts. But when the protein-splitting enzyme (Trypsinogen) is secreted, it is completely inactive; it is converted into the active form (trypsin) by the co-enzyme enterokinase of the intestinal juice.

The secretion of pancreatic juice has been studied in animals in which a fistula of the pancreatic duct has been established (the operation is similar to that of establishing a salivary fistula). Like the salivary glands and the glands of the stomach, the pancreatic gland is at rest except during the periods of digestion. The secretion begins soon after administration of food but it lags Behind the gastric secretion, the maximum of which precedes the maximum of the pancreatic secretion by about an hour. The rate of pancreatic secretion, after a meal of proteins or carbohydrates, is on the whole very similar to that of the gastric secretion, but in the case of fats it is somewhat different. The similarity in the histological structure of the pancreas and the salivary glands has led physiologists to believe that the mechanism of secretion of these glands is the same, that is to say that the pancreatic secretion is controlled by a secretory nerve.

The Secretory *Innervation* of the *Pancreas*.—The secretory fibres were discovered by Pavlov to run in the vagus nerve. However, stimulation of the vagus never produces anything like the normal quantity of the juice, and the whole secretion is rather peculiar. The vagus nerve has to be stimulated for a very long time before the secretion will appear. The vagus produces a strong contraction of the larger ducts of the gland, and thus prevents the juice from leaving the gland. But even independently of this contraction of the ducts, the amount of juice secreted is very small (about 10cc. during a period of stimulation of 5–6 hours, as against a normal secretion of over 150cc. after entry of $\frac{1}{4}$ pound of meat).

Furthermore, the composition of the juice so obtained is not like that which is secreted under normal conditions. It is over 10 times more concentrated, both in its protein and enzyme content. When boiled. it coagulates in a lump like egg-white, while the normal juice becomes only slightly flocculent; it is also less alkaline than the normal juice, and therefore the trypsinogen of the "vagus juice" is apt to undergo spontaneous activation, and is more easily activated by enterokinase than the normal juice (the rate of activation is slower the more alkaline the juice). Nevertheless, the vagus nerve is a true secretory nerve; on stimulation, it produces very considerable histological changes in the gland, far greater changes than in the case of normal secretion, and the nerves are completely paralysed by atropine. It may be concluded that, so far as causing the output of solids and enzymes is concerned, the vagus stimulation does the same or more than the taking of food, but as regards the passage of water from the blood into the ducts it is much less effective.

We also owe to Pavlov the discovery that introduction of acid into the duodenum of animals or anaesthetised animals is followed by a profuse pancreatic secretion, which lasts as long as the acid is being absorbed. The similarity between this effect and the secretion of saliva (on administration of acid into the mouth) led Pavlov to believe that the pancreatic secretion is also based on a reflex mechanism, the efferent path from which follows the vagi. He soon found, however, that section of the vagi, or in fact destruction of the entire nervous system, does not prevent the secretion of the pancreatic juice on administration of acid into the small intestine. Administration of acid into the stomach, into the large intestine or anywhere else has no effect whatever.

Gastric *Juice*.—The discovery of the effect of acids is far more important than could be imagined at first sight. Pure gastric juice contains about 0·5% HCl but usually, on account of dilution with saliva and food, the acidity of the gastric contents is reduced to about 0·2–0·3%. The acid enters the duodenum and causes the pancreatic gland to begin to secrete. The first phase of gastric secretion becomes of outstanding importance, for it not only causes a further stimulation of gastric secretion, by giving rise to the products of digestion, but it also indirectly causes the continuation of digestion, for the acidity of the whole gastric contents leads to the secretion of the pancreatic juice.

Appetite, in that it augments the nervous phase of gastric digestion, is the trigger that sets the whole digestive tract into activity. This fact so much impressed Pavlov that he organized, next to his laboratory, a special department where the gastric juice of dogs was (and still is) obtained by sham feeding in large quantities. This material was sterilized and sold at a low price to the general public at the rate of several thousands of bottles a year. The improvement of digestion and nutrition in cases of dyspepsia, cancer, achlorhydria, loss of appetite and chronic gastritis was immense.

The *Chemical Phase* of Pancreatic *Secretion*.—The mechanism of the secretory effect of acid was discovered by Bayliss and Starling in 1902. They found that, on pounding up some scrapings of the intestinal mucous membrane with dilute acid and filtering. they obtained a filtrate that produced a copious flow of pancreatic juice when it was injected into the blood. This discovery was not only of great value. in elucidating the mechanism of pancreatic secretion, but it was also of general importance in physiology, for it was the first time it could be shown that a chemical substance, manufactured under definite conditions by one organ, could be liberated into the blood stream and conveyed to another organ, which it would excite to activity. Since this discovery, a number of other substances of the same nature have become known. Bayliss and Starling described them as chemical messengers, and gave them the name of *hormones* (*q.v.*). The hormone of the small intestine was called secretin, or pancreatic secretin, to distinguish it from other members of the same class.

Secretin can be extracted from the small intestine by various solvents, *e* g., water, alcohol, salt solutions. etc. It is not an enzyme, and is not destroyed by boiling. That secretin is normally transported by the blood stream is most convincingly shown by experiments with crossed circulation, and perfusion of the isolated pancreatic gland If two arteries of two dogs are connected in such a manner that the blood of one animal freely mixes with that of the other, and if acid is injected into the duodenum of one of the animals, the pancreatic glands of both dogs begin to secrete. Also, if a pancreas is cut out of the body and perfused with blood under pressure so as to keep it alive, and if a solution of secretin is injected into the blood, the isolated pancreas immediately responds by secretion of the juice. In this secretory mechanism, we have a very striking example of a correlation between the activities of two different parts of the body, effected

by chemical means. When the acid chyme enters the intestine, a certain amount of secretin is liberated into the blood stream. The resulting secretion of the alkaline pancreatic juice neutralizes the acid chyme, and the liberation of secretin (and therefore of pancreatic juice) comes to an end. So long as the duodenal contents are acid, the pylorus remains closed, but as soon as they are neutralised, the pylorus opens to allow another portion of the acid gastric contents to pass. In this way, the pancreatic secretion is maintained throughout the whole period of digestion.

Secretin.—The chemical composition of secretin is not known, and secretin has not yet been obtained in a pure form. The usual extracts of the mucous membrane of the small intestine contain, besides secretin, a large number of impurities, especially a substance named histamine, which has a considerable vasodilator effect on the capillaries of all organs. Thus after the injection of crude preparations of secretin, the blood pressure falls, sometimes very considerably. It has been proved that the induced pancreatic secretion is not caused by the fall of blood pressure itself. The proof rests on the following observations. The vasodilatory substances can be extracted from almost every organ, but secretin is only present in the small intestine. With certain solvents, it is possible to extract a depressor-free secretin. In slightly alkaline medium, secretin is destroyed while the vasodilatory substances remain intact. The action of secretin is not paralysed by atropine, showing that secretin acts directly on the pancreatic cells, and not on the nerve-endings of the secretory nerves. The composition of the secretion and the chemical mechanism of pancreatic secretion are apparently the same in all animals; at least, secretin extracted from the intestine of any animal will cause pancreatic secretion in any other animal. In the foetus, secretin is found in a very early stage of development.

The question now arises as to the correlation between the nervous and the chemical mechanisms of pancreatic secretion. The correlation is not yet clear, but we know of one instance in which the secretion, or rather the composition of the juice, is determined by the cooperation of the vagus nerve—that is in the case of injection of fats. Injection of neutral fats or of soaps into the duodenum evokes a secretion of very concentrated juice that is rich in enzymes. After section of the vagi, or after injection of atropine, the quantity of the secreted juice is unaltered, but it is now poor in enzymes. In many cases also sham feeding, when the entry of the gastric juice into the duodenum is prevented, will evoke a small secretion of very concentrated juice, some time before the appearance of gastric secretion; this secretion is absent after section of the vagi.

Stimulation of the vagi, superimposed upon the pancreatic secretion which has been evoked by injection sf secretin, does not modify the rate of secretion but greatly enriches the juice in enzymes. It seems that the nervous mechanism is chiefly concerned with the removal from the cells of the pre-stored enzymes, while the chemical mechanism regulates the passage of water and alkali from the blood through the gland into its system of ducts. Histological observations support this point of view since, after the considerable secretion of pancreatic juice evoked by chemical means, the pancreas looks only slightly exhausted, while after the small secretion evoked by stimulation of the vagus the gland becomes a picture of maximal exhaustion.

The Secretion of Bile.—The liver is the largest gland in the body, but its digestive function is only of secondary importance, as compared with the rôle it plays in the chemical alteration of substances after they have been absorbed into the blood, and its function as an excretory organ of various substances, amongst which the products of the decomposition of haemoglobin are the chief. The production of bile by the liver cells is continuous, but the entry of the bile into the digestive tract is intermittent, and is only to some extent related to the periods of digestion. The secreted bile accumulates in the gall bladder and in the large bile duct, the entry into the intestine being prevented by a small sphyncter at the end of the common bile duct. While the bile remains in the gall bladder, it undergoes concentration on account of absorption of water and secretion of mucin by the walls of the bladder.

From the point of view of digestion, the only important constituents of bile are the bile salts (sodium taurocholate and glycocholate). The digestive functions of bile are:—

(1) Activating the lipase of the pancreatic juice.
(2) Increasing the emulsification of fats by lowering the surface tension.
(3) Dissolving fatty acids and soaps.
(4) Increasing the peristaltic movements of the intestinal tract.
(5) Increasing the bile production on reabsorption of bile salts into the blood.

During the periods of digestion, the flow of bile is increased. This is due to two factors:—(a) the emptying of the gall bladder, and (b) an increased formation of bile.

The muscular wall of the gall bladder is under a nervous control, the vagus conveying motor, and the sympathetic inhibitory fibres. The entry of the products of gastric digestion and of the acid chyme into the duodenum sets the reflex in operation. The actual secretion of bile, however, is independent of the nervous system, and continues even after all the nerve connections of the liver have been severed. It is mainly dependent on the blood supply to the liver and, if other conditions are the same, the bile flow increases with increase of blood flow. Absorption of food substances, of acid, and especially of fats increases the production of bile. This is ascribed by some to the liberation of the pancreatic secretin.

The bile salts are reabsorbed in the intestine and conveyed via the portal vein back to the liver, which removes them from the blood, thus preventing their entry into the general circulation where they would be intensely poisonous (see JAUNDICE). The bile salts increase the production of bile, and thus a comparatively small amount of bile salts undergoes repeated resecretion during a comparatively short time. The entry of bile into the digestive tract, and therefore the stimulating effect of bile salts upon bile production, is stopped at the end of digestion by the closure of the sphyncter of the common bile duct.

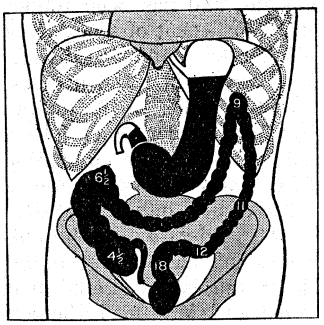
The Intestinal Juice (**Succus Entericus**).—The secretion of the intestinal juice, like that of the pyloric juice, is continuous. The secretion is studied in animals in which one or another part of the intestinal tract is transplanted so as to open to the outside of the abdominal cavity. Since the intestine hangs on the loose mesentery, the blood vessels and nerves of the transplanted part remain intact. The continuity of the rest of the tract is re-established. Animals operated on in this manner live as long as normal animals, and do not suffer in their digestion or general condition.

The intestinal juice on standing divides itself into 2 fractions, a sediment which is chiefly composed of the mucus secreted by the goblet cells of the digestive tract and desquamated epithelium, and a liquid part containing enzymes (see section on nutrition; the enzymes are enterokinase. erepsin, nuclease, amylase, invertase, lactase and lipase maltase; the Brunner's glands of the duodenum secrete an enzyme similar to pepsin). The lower down the tract, the larger is the sedimentation, until the secretion in the large intestine is composed of mucus and is devoid of enzymes.

There are no definite indications of any nervous control of intestinal secretion. Section of the nerves produces a great increase in the flow, but this is usually attributed to the hyperaemia ensuing after section of the nerves, which contain a large amount of vasoconstrictor fibres. Some physiologists regard this secretion as due to section of special inhibitory nerves.

Intravenous injections of secretin increase the secretion of intestinal juice, and Starling regarded the mechanism of intestinal secretion as identical with that of pancreatic secretion, namely that in both cases the stimulus is due to the liberation of the same agent, viz. secretin. However, experiments on animals with a transplanted loop of the intestinal tract (kept under normal conditions) make this view untenable. On feeding such an animal, the secretion of the transplanted part is not increased as it would have been if the hormone mechanism were the operative factor. Pavlov's experiments show that the stimulus for intestinal secretion is, like that of pyloric secretion, local mechanical stimulation of the mucous membrane.

Some *Experiments.*—The following experiments may serve to illustrate this point The secretion of the intestinal juice from the small isolated portion was measured before and after feeding the animal with various food substances. The juice was collected by means of a small tube inserted in the isolated loop. Before feeding, the spontaneous secretion varied between 2·0 and 2·8cc; after intake of meat, it was 2 5cc., after bread 3·0cc., after milk 1·7cc., and after mixed food 1·6cc Only in the case of feeding with fats did the secretion of the isolated portion slightly but definitely increase (from 3·0 to 5·0cc.). With these results should be compared the experiments with local mechanical and chemical stimulation of the transplanted part. The spontaneous secretion was 0·0–0·5cc. per hour; when a rubber tube was introduced into the intestinal loop, the secretion increased to 4cc.; when glass beads were placed in the intestines, it increased to 8·7cc; when 0·5% HCl was injected into the intestine and then removed, thehourly secretion increased to 20cc. The stimulation by either of the above methods of some part of the intestine has no effect on the rest of the tract, showing that the effect is mainly if not entirely local These local stimuli have hardly any effect on the secretion of the sediment; they only increase the production of the enzyme-containing liquid part of the juice.



FROM STARLING, "PRINCIPLES OF HUMAN PHY SIOLOGY"

FIG. 3.—DIAGRAM OF NORMAL POSITION OF COLON OR LARGE **INTESTINE IN MAN, SHOWING THE TIME AT** IN HOURS OF ARRIVAL OF FOOD AT VARIOUS LEVELS

Some observers have found that stimulation of the vagus nerve increases the secretion of the juice after a very long latent period. It is possible, however, that the increased flow is due to a more vigorous contraction of the intestines, for the vagus is the motor nerve of the intestinal muscles.

A very interesting correlation has been discovered as regards the concentration of enterokinase in the intestinal juice and the pancreatic juice The transplanted loop of the intestine secretes a juice which becomes progressively poorer in enterokinase, so that a few months after the operation it almost entirely loses the power to activate trypsinogen (see section on Enzymes). If however the mucous membrane is brought for a short time (2–3 minutes) into contact with the pancreatic juice (the juice may be diluted to as much as one in 1000), the concentration of enterokinase increases Alkali and boiled pancreatic juice have no such effect. The concentration of other enzymes of the intestinal juice is not affected by such treatment of the intestine with pancreatic juice.

The Movements **of** the Small Intestine.— It is known that the intestinal tract is in a state of constant movement, the analysis of which presents great difficulties because several types of contraction may occur simultaneously or in rapid succession, either at the same point or at neighbouring positions. Different authors have given different descriptions of these movements, and have used different nomenclatures but in spite of this confusion it may be said that the small intestine exhibits three kinds of contractions. These are as follows:—(a) the rhythmic segmentation (also known as pendular movements or swaying movements); (b) the peristaltic contraction (also known as the mysenteric reflex); and (c) the tonic contractions.

Rhythmic *Contractions.*—Direct observations of an exposed part of the intestine show that slight waves of contraction pass over its surface. Records by means of instruments show that both the circular and the longitudinal muscular coats take part in these contractions, which recur at the rate of 10–15 a minute. These contractions involve only short stretches of the intestine. They easily can be produced artificially by stimulating the gut either electrically or mechanically. On application of such a stimulus, the part immediately stimulated quickly contracts, the contraction spreading one or two centimetres along the intestine These rhythmic contractions may originate spontaneously in any part of the intestinal tract, especially at those parts which are subjected to some tension. The propagation of this contraction goes from muscle fibre to muscle fibre at an average rate of about 5cm. per second.

These rhythmic contractions are unaffected by section of all the nerves of the intestine, in fact they are entirely myogenic in origin. They are even independent of the local nervous network of the intestinal wall, for strips removed from the longitudinal coat of the small intestine entirely free from any remains of the nerve plexus continue their rhythmic contraction. (The nervous network of the intestine is made up of Auerbach's plexus and Meissner's plexus.)

In order to observe the rhythmical contractions, isolated portions of the intestine can be removed from an animal after its death; these portions should be kept at body temperature, surrounded with a solution containing salts in the same proportion as those in blood (Ringer's fluid), and richly supplied with oxygen In the normal animal, the rhythmic contractions cause a thorough mixing of the contents of the gut with the secretions of the various glands, but they do not help to pass the food along the intestinal tract, for each contraction squeezes the food in both directions. A column of food may thus remain at the same level in the gut for a considerable time.

Peristaltic Contractions.—The onward progress of the food is caused by true peristaltic contractions which involve contraction of the intestine above the food mass, and relaxation below This contraction and relaxation travels down the intestinal tract in the form of two waves, and in this way the food is slowly propelled towards the large intestine. The peristaltic contractions involve the co-operation of the local nervous system of the intestine, and they are absolutely abolished by painting the intestine with drugs which paralyse nerves (*e.g.,* nicotine, cocaine), but still continue after severing the nervous connection between the intestine and the brain and spinal cord. The direct irritating effect of food, or the application of an experimental stimulus, evokes an immediate contraction above and relaxation below (sometimes described as "the law of the intestines") Anti-peristalsis is not observed in the small intestine.

Tonic Contractions.—The third type of movement, which is known as the tonic contraction, is common to all plain muscles, and is determined by a state of sustained partial contraction of the muscle. Neither during the wave of relaxation observed as the forerunner of the wave of contraction in peristalsis, nor during the periods in between the rhythmic segmentation, is the intestine completely relaxed; it always maintains a certain tone, which may be greater or less Thus the two forms of contraction (already described) are superimposed upon the tonically contracted state of muscles. In some cases, the intestinal tone may be intense. It is claimed that colic pains are due to this form of contraction.

Although the mechanism of all these three forms of contraction is entirely peripheral, they can be increased or decreased by impulses from the central nervous system. The vagus nerve carries nerve fibres to the intestine which stimulate its movements, while the splanchnic nerves diminish or even abolish them The lowest ncms. of the small intestine exhibits a thickening of the circular muscular coat, the ileocolic sphincter (valve), which relaxes in front of a peristaltic wave and contracts if there is any regurgitation from the large intestine. This sphincter presents a marked contrast to the rest of the small intestine in that its innervation is reversed, the vagus being the inhibitory and the splanchnic the excitatory nerve.

The Movements **of** the **Large** Intestine.— The contents of the small intestine are gradually transferred into the large intestine. In carnivora, the digestion and absorption are both nearly completed at the ileocolic valve, but in herbivora a large part of the processes of digestion and absorption occur in the large intestine and in the caecum As regards his large intestine, man takes an intermediate position between these two groups of animals.

The movements of the large intestine can best be observed by means of the X-ray method, after feeding a meal containing some bismuth The food first fills the proximal part of the large intestine The distension brings about a wave of contraction which starts at the end portion of the ascending colon, and slowly travels

in a backward direction, passing the food towards the caecum; the ileocolic valve prevents its escape into the small intestine. These contractions are not preceded by a wave of relaxation, and therefore should not be regarded as anti-peristaltic waves. As the whole contents cannot escape into the caecum, certain portions slip back. These movements thus have the same effect as those of the pylorus; they bring the food into closer contact with the walls of the alimentary canal. In this way the intestinal movements favour the absorption of substances that escaped absorption in the small intestine.

The distension of the caecum occasionally excites a true peristaltic wave which travels in a forward direction and drives the semi-solid residue of the food towards the distal part of the colon. The intensity of the peristaltic waves and of the backward contraction vary greatly in different kinds of animals, and even in different individuals of the same species. In man they are not well pronounced, and the caecum and the ascending colon seem to be more or less passive. About 400 grammes of semi-liquid material passes the ileocolic valve daily; of this, about 250 grammes is water with some nutrient material, which is absorbed in the large intestine; the remaining 150 grammes form the faeces.

The large intestine, like the small, has a nervous system of its own in the form of a network of nerve cells and fibres lying in between the muscular layers. The movements of the large intestine are primarily dependent on this network, but they can be increased under the influence of the pelvic visceral nerve, or diminished by the inferior mesenteric nerves which belong to the sympathetic nervous system. **A** distinguishing feature of the distal colon is its complete subordination to the spinal centres. It remains inactive until, on account of distension, it is reflexly excited through the pelvic visceral nerve; it is then completely emptied. In man, the emptying of the rectum is largely assisted by contractions of voluntary muscles of the pelvis and of the abdominal wall.

In herbivora, the large intestine plays an important part in the digestion of cellulose, not because of the secretion of some special enzyme which could effect this digestion, but because of the rich bacterial flora of the large intestine. The splitting of celiulose is due to the action of bacteria, and it results in the formation of simpler carbohydrates, viz., sugars. Thus the cellulose which forms vegetable cell-walls can be utilized by the animal.

DIGESTIVE ORGANS. The digestive system comprises greater range of structure and diversity of function than any other system in the animal body. The pathological changes met with, therefore, differ widely at first glance. Essentially they are identical in all situations, the apparent differences depending on variation in prominence of the individual components. The mouth of an infant with "thrush" and the small intestine of an adult with typhoid fever show congestion, accumulations of leucocytes, death and desquamation of superficial cells, oedema of subjacent tissues because both are the seats of inflammation caused by a micro-organism, however widely different they may appear to the eye. *(See* ALIMENTARY CANAL, DISEASES OF THE, and allied articles.)

DIGGES, WEST (1720–1786), English actor, made his first stage appearance in Dublin in 1749 as Jaffier in *Venice Preserved,* and both there and in Edinburgh until 1764 he acted in many tragic rôles with success. He was the original "young Norval" in Home's *Douglas* (1756). His first London appearance was as Cato in the Haymarket in 1777, and he afterwards played Lear, Macbeth, Shylock and Wolsey. In 1781 he returned to Dublin and retired in 1784. He died in Cork on Nov. 10, 1786.

DIGIT, literally a finger or toe (Lat. *digitus,* finger), and so from counting on the fingers a single numeral, or, from measuring, a finger's breadth. In astronomy a digit is the 12th part of the diameter of the sun or moon; it is used to express the magnitude of an eclipse.

DIGITALIS. In pharmacy, the leaves of the foxglove (*q.v.*) gathered from wild plants when about two-thirds of their flowers are expanded.

Digitalis contains four important glucosides, of which three are cardiac stimulants. The most powerful is *digitoxin* $C_{34}H_{54}O_{11}$, an extremely poisonous and cumulative drug, insoluble in water. *Digitalin,* $C_{35}H_{56}O_{14}$, is crystalline and is also insoluble in water. *Digifalein* is amorphous but readily soluble in water. It can therefore be administered subcutaneously, in doses of about one-hundredth of a grain. *Digitonin,* on the other hand, is a cardiac depressant, and has been found to be identical with saponin, the chief constituent of senega root.

Taken by the mouth digitalis is apt to cause digestive disturbance, varying in different cases and sometimes severe. This action is probably due to the digitonin, which is thus a constituent in every way undesirable. The all-important property of the drug is its action on the circulation. Its first action is upon the unstriped muscle of the arteries and arterioles.

The clinical influence of digitalis upon the heart is well defined. After a moderate dose the pulse is slowed. This is due to a very definite influence upon the different portions of the cardiac cycle. The systole is not altered in length, but the diastole is very prolonged, and since this is the period not only of cardiac rest but also of cardiac "feeding"—the coronary vessels being compressed and occluded during systole—the result is greatly to benefit the nutrition of the cardiac muscle. So definite is this that, despite a great increase in the force of the contractions and despite experimental proof that the heart does more work in a given time pnder the influence of digitalis, the organ subsequently displays all the signs of having rested, its improved vigour being really due to its obtaining a larger supply of the nutrient blood. Almost equally striking is the fact that digitalis causes an irregular pulse to become regular. Added to the greater force of cardiac contraction is a permanent tonic contraction of the organ, so that its internal capacity is reduced. The bearing of this fact on cases of cardiac dilatation is evident. In larger doses a remarkable sequel to these actions may be observed. The cardiac contractions become irregular. the ventricle assumes curious shapes—"hour-glass," etc.—becomes pale and bloodless, and finally the heart stops in a state of contraction and passes into rigor-mortis. Before this final change the heart may be started again by the application of a soluble potassium salt, or by raising the fluid pressure within it. Clinically the drug is cumulative, being very slowly excreted, so that after it has been taken for some time the pulse may become irregular, the blood-pressure low, and the cardiac pulsations rapid and feeble. These symptoms with gastro-intestinal irritation and decrease in the quantity of urine passed indicate digitalis poisoning. It is by way of stimulation of the cardiac terminals of the vagus nerves that the heart's action is slowed. Thereafter follows the most important effect of the drug, which is a direct stimulation of the cardiac muscle. This can be proved to occur in a heart so embryonic that no nerves can be recognized in it, and in portions of cardiac muscle that contain neither nerve-cells nor nerve-fibres.

The action of this drug on the kidney is of importance only second to its action on the circulation. In small or moderate doses it is a powerful diuretic. It seems probable that this is due to a rise in the general blood-pressure associated with a relatively dilated condition of the renal vessels. In large doses, the renal vessels also are constricted and the amount of urine falls. In large doses it causes cerebral symptoms, such as seeing all objects blue, and various other disturbances of the special senses. It also lowers the reflex excitability of the spinal cord.

Digitalis is indicated when the heart shows itself unequal to the work it has to perform. This formula includes the vast majority of cardiac cases.

DIGNE, a small thermal spa and chief town of the department of the Basses Alpes, in S.E. France, 14 mi. by a branch line from the main railway line between Grenoble and Avignon. Pop. (1936) town, 5,689; commune, 7.623. The *Dinia* of the Romans, it was the capital of the Bodiontii. From the early 6th century at least it has been an episcopal see, which till 1790 was in the ecclesiastical province of Embrun, but since 1802 in that of Aix en Provence. It suffered much during the reliqious wars of the

16th and 17th centuries. The Ville Haute is built on a mountain spur on the left bank of the Bléone river, and above its narrow, winding streets towers the present cathedral church (late 15th cent.), largely reconstructed in modern times, and the former bishop's palace (now the prison). The fine Boulevard Gassendi separates the Ville Haute from the Ville Basse, which is of modern date. The old cathedral (Notre Dame du Bourg) (13th cent.) is now disused except for funerals. The neighbourhood of Digne is rich in orchards, which have long made the town famous in France for its preserved fruits and confections, honey and yellow wax.

DIGOIN, a town of east-central France, in the department of Saône-et-Loire, on the right bank of the Loire, 55 mi. W.N.W. of Mâcon on the Paris-Lyon railway. Pop. (1936) 5,668. It is situated at the meeting places of the Loire, the Lateral canal of the Loire and the Canal du Centre, which here crosses the Loire by a fine aqueduct. The town carries on considerable manufactures of faïence, pottery and porcelain. The port on the Canal du Centre trades in timber, sand, iron, coal and stone.

DIJON, a town of eastern France, capital of the department of CBte d'Or and formerly capital of Burgundy, 195 mi. S E. of Paris on the Paris-Lyon railway. Pop. (1936) 93,929.

Under the Romans Dijon (*Divonense castrum*) was a *vicus* in the *civitas* of Langres. In the 2nd century it was the scene of the martyrdom of St. Benignus (Bénigne, *vulg.* Berlin, Berain), the apostle of Burgundy. About 274 the emperor Aurelian surrounded it with ramparts. Gregory of Tours, in the 6th century, comments on the strength and pleasant situation of the place, expressing surprise that it does not rank as a *civitas.* The dukes of Burgundy acquired Dijon early in the 11th century. The communal privileges, conferred on the town in 1182 by Hugh III., duke of Burgundy, were confirmed by Philip Augustus in 1183, and in the 13th century the dukes took up their residence there. For the decoration of the palace and other monuments built by them, eminent artists were gathered from northern France and Flanders, and during this period the town became one of the great intellectual centres of France. The union of the duchy with the crown in 1477 deprived Dijon of the splendour of the ducal court; but to counterbalance this loss it was made the capital of the province and seat of a *parlement.* Its fidelity to the monarchy was tested in 1513, when the citizens were besieged by 50,000 Swiss and Germans. and forced to agree to a treaty so disadvantageous that Louis XII. refused to ratify it. In the wars of religion Dijon sided with the League, and opened its gates to Henry IV. only in 1595. The 18th century was a brilliant period for the city; it became the seat of a bishopric, its streets were improved, its commerce developed, and an academy of science and letters founded; while its literary salons were hardly less celebrated than those of Paris. The neighbourhood was the scene of considerable fighting during the Franco-Prussian War, which was, however, indirectly of some advantage to the city owing to the impetus given to its industries by the immigrants from Alsace.

Dijon stands on the western border of the fertile plain of Burgundy, at the foot of Mont Afrique, the north-eastern summit of the CBte d'Or range, and at the confluence of the Ouche and the Suzon; it also has a port on the canal of Burgundy. The great strategic importance of Dijon as a centre of railways and roads, and its position with reference to an invasion of France from the Rhine, led to the creation of a fortress forming part of the Langres group. There is no *enceinte,* but on the east side detached forts, 3 to 4 m. distant from the centre, command all the great roads, while the hilly ground to the west is protected by Fort Hauteville to the N.W. and the "groups" of Motte Giron and Mont Afrique to the S.W. Including a fort near Saussy (about 8 m. to the N.W.) protecting the water-supplv of Dijon, there are eight forts, besides the groups above mentioned. The old churches and historic buildings of Dijon are to be found in the irregular streets of the old town, but industrial and commercial activity has been transferred to the new quarters beyond its limits.

The cathedral of St. Bénigne, originally an abbey church, was buiit in the latter half of the 13th century on the site of a Romanesque basilica, of which the crypt remains. The west front is flanked by two towers and the crossing is surmounted by a slender timber spire. The plan consists of three naves, short transepts and a small choir, without ambulatory, terminating in three apses. In the interior there is a fine organ and a quantity of statuary, and the vaults contain the remains of Philip the Bold, duke of Burgundy, and Anne of Burgundy, daughter of John the Fearless. The site of the abbey buildings is occupied by the bishop's palace and an ecclesiastical seminary, The church of Notre-Dame, typical Burgundian Gothic (1252–1334) is distinguished for the grace of its interior and the beauty of the western façade. The portal consists of three arched openings, above which are two stages of arcades, open to the light and supported on slender columns. A row of gargoyles surmounts each storey of the facade, which is also ornamented by sculptured friezes. A turret to the right of the portal carries a clock called the Jaquemart, on which the hours are struck by two figures. The church of St. hfichel belongs to the 15th century. The west facade, the most remarkable feature of the church, is, however, Renaissance. The vaulting of the three portals is of exceptional depth owing to the projection of the lower storey of the facade. Above this storey rise two towers of five stages, the fifth stage being formed by an octagonal cupola. The columns decorating the facade represent all the four orders. The design of this facade is wrongly attributed to Hugues Sambin (*fl. c.* 1540), a native of Dijon, and pupil of Leonardo da Vinci, but the sculpture of the portals, including "The Last Judgment" on the tympanum of the main portal, is probably his work. St. Jean (11th century) and St. Étienne (11th, 16th and 17th centuries), now used as the exchange, are the other chief churches. Of the ancient palace of the dukes of Burgundy there remain two towers, the Tour de la Terrasse and the Tour de Bar, the guard-room and the kitchens; these now form part of the *hôtel de ville,* the rest of which belongs to the 17th and 18th centuries. This building contains an archaeological museum, the archives of the town, and the principal museum, which, besides paintings and other works of art, contains the magnificent tombs of Philip the Bold and John the Fearless, dukes of Burgundy. These were transferred from the Chartreuse of Dijon (or of Champmol), built by Philip the Bold as a mausoleum, now replaced by a lunatic asylum. Relics of it survive in the old Gothic entrance, the portal of the church, a tower and the well of Moses, which is adorned with statues of Moses and the prophets by Claus Sluter (*fl.* end of 14th century), the Dutch sculptor. who also designed the tomb of Philip the Bold. The Palais de Justice, which belongs to the reign of Louis XII., is of interest as the former seat of the *parlement* of Burgundy. Dijon possesses several houses of the 15th, 16th and 17th centuries, notably the Maison Richard in the Gothic, and the Hôtel Vogüé in the Renaissance style.

The town is important as the seat of a prefecture, a bishopric, a court of appeal and a court of assizes, and as centre of an académie (educational district). There are tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce, an exchange and an important branch of the Bank of France. Its educational establishments include faculties of law, of science and of letters, a preparatory school of medicine and pharmacy, a higher school of commerce, a school of fine art and a conservatoire of music.

Dijon is well known for its mustard, and for the black-currant liqueur called *cassis de Dijon;* its industries include the manufacture of machinery, automobiles, bicycles, soap, biscuits, brandy, leather, boots and shoes and hosiery. There are also flour mills, important printing works, vinegar works and, in the vicinity, nursery gardens. The state has a large tobacco manufactory in the town. Dijon has considerable trade in cereals and wool, and is the second market for the wines of Burgundy.

DIKE or DYKE, a trench dug out of the earth for defensive and other purposes (cf. Dutch *dijk,* Ger. *Teiclz).* Water naturally collects in such trenches, and hence the word is applied to natural and artificial channels filled with water, as appears in the names of many narrow waterways in East Anglia. "Dike"

is also used of the bank of earth thrown up out of the ditch, and so of any embankment, dam or causeway, particularly the defensive works in Holland, the Fen district of England, and other low-lying districts which are liable to flooding by the sea or rivers. (See HOLLAND and FENS.) In Scotland any wall, fence or even hedge, used as a boundary, is called a dyke. In geology the term is applied to wall-like masses of rock (sometimes projecting beyond the surrounding surface) which fill up vertical or highly inclined fissures in the strata.

DIKKA, in architecture, a raised tribune or platform in a hlohammedan mosque, from which the service is directed and the Koran read.

DILAPIDATION, a term meaning in general a falling into decay, but more particularly used in the plural in English law for (1) the waste committed by the incumbent of an ecclesiastical living; (2) the disrepair for which a tenant is usually liable when he has agreed to give up his premises in good repair (see EASEMENT; FLAT; LANDLORD AND TENANT; as to limited owners, *see* WASTE).

In the eye of the law an incumbent of a living is a tenant for life of his benefice, and any waste, voluntary or permissive, on his part must be made good. Under the old law, proceedings might be taken against the dilapidating incumbent in the ecclesiastical court; or an action in the courts of common law could be brought by the successor upon the custom of England against the previous incumbent or his personal representatives if he were dead. And if such a thing should happen, this law might still have to be applied in the case of bishops or cathedral dignitaries or officers. But for parochial incumbents provision was made in 1873 by the Ecclesiastical Dilapidations Act of that year, which Act however has now been superseded by the Ecclesiastical Diiapidations Measure 1923 which covers the whole ground.

By this measure, diocesan dilapidation boards are appointed who are to cause first inspections to be made of the buildings of every benefice. These first inspections are to be made within seven years of the passing of the Measure or earlier if the benefice becomes vacant or is put under sequestration. The surveyor is to report whether any and if so what repairs are needed, and to divide them into ordinary repairs and structural repairs, and to sub-divide the latter into those which do not or do admit of delay; and if there has been any mischief due to deliberate action or gross neglect, he is to state the cost of these separately and call them "wilful dilapidations." For these latter the incumbent is to be liable at once. Opportunity is given to any party interested to object to the report of the surveyor on any point, and the board is finally to determine.

If the inspection is on a vacancy, and the late incumbent is not protected by a certificate under the old Act, he or his personal representatives must pay to Queen Anne's Bounty the cost of ordinary and immediate structural repairs, as determined by the Board. If the first inspection is not on a vacancy and the incumbent or the sequestrator is not protected by a certificate under the old Act he is similarly liable, but in case of personal poverty or the benefice being less than £250 a year, there are provisions for his relief.

As to the future, Queen Anne's Bounty is to make an assessment first for a "repair rate" to cover the execution of repairs required by an order of the dilapidation board, except those already provided for and those for which the cost is spread over more than five years; secondly for an "insurance rate" to provide for reinstating the buildings in case of fire; and thirdly for an "administration rate" to cover office expenses and surveyor's fees. For repairs, the cost of which is to be spread over a longer period than five years, there is to be a "long assessment" in lieu of an ordinary assessment.

There are numerous provisions directing the application of the moneys raised and the execution of repairs and giving power to Queen Anne's Bounty to advance loans and to make grants in the case of poor livings, and concerning timber growing on the glebe. The broad effect of the Measure is to substitute annual payments in the nature of premiums of insurance in lieu of a capital liability

In the United States, the term means the neglect of necessary repairs of a building, the suffering of it to fall into a state of decay or the unauthorized pulling down of the building or any part of it. (See LANDLORD AND TENANT.)

DILATATION, a widening or enlarging; a term used in physiology, etc. In pathology the process is of great importance as it may be compatible with health or the cause of changes so severe that they menace life. In the case of blood vessels dilatation of arteries occurs in blushing and in every inflammation at some stage in its course; dilatation of the abdominal blood vessels is the cause of syncope and shock in many instances and dilatation of veins accompanies every case of passive congestion. In the case of lymphatics dilatation is the cause of elephantiasis. In the case of hollow organs like the heart, bladder, stomach or intestines dilatation, if great and of rapid onset is accompanied by severe pain (*e.g.* angina pectoris) and if continued is followed by temporary paralysis of the organ's musculature. In the case of the brain, dilatation of the lateral ventricles causes hydrocephalus (*q.v.*) dilatation of the central canal of the spinal cord causes the special symptoms depending on syringomyelia. If the dilatation of hollow muscular organs is gradual there may be time for hypertrophy to occur and compensate for the dilatation. This is typically the case with the left ventricle of the heart in cardiac disease but ultimately dilatation gains the upper hand and initiates the terminal stages of the illness. (W. S. L.–B.)

DILATORY, delaying, or slow; in law a "dilatory plea" is one made merely to delay the suit.

DILEMMA is the name of a special type of reasoning. In its commonest form its conclusion presents one with two alternatives. When employed in debate the usual aim is to present alternatives both of which are unpalatable to the opponent. Thus, *e.g.* in answer to the contention of a protectionist that protective import duties *both* increase revenue and stimulate home industry, it has been argued: "If protective duties increase revenue, they cannot also stimulate home industry; and if they stimulate home industry, they cannot also increase revenue.

"But they do either the one or the other.

"Therefore they either cannot stimulate home industry, or they cannot increase revenue." (That is they cannot do both at once) The unpalatable alternatives are called the "horns" of the dilemma. This familiar use of the dilemma has led to an extension of its meaning, and the term is applied popularly to any kind of situation in which one is confronted with unsatisfactory alternatives, as, *e.g.,* when a country, exhausted by war, finds itself in the dilemma of either impoverishing its people or repudiating its debts

Valid arguments in the form of the dilemma are not very common, hence few situations can be adequately summed up in two alternatives. The dilemma is consequently used frequently in a rather loose manner by plausible orators. Hence there is an impression abroad that dilemmas are merely sophistical tricks. But this is a mistake. Dilemmas can be, and sometimes are, quite sound. Their association with political discussions or merely captious argumentations is accidental; and the alternatives which their conclusions present need not be unpalatable. (*See* LOGIC.)

DILETTANTE, an Italian word for one who delights in the fine arts, especially in music and painting. Properly the word refers to an "amateur" as opposed to a "professional" cultivation of the arts, but is often used in a depreciatory sense of one who is only a dabbler. The Dilettanti Society, founded in 1733–34, still exists in England. A history of the society, by Lionel Cust, was published in 1898.

DILIGENCE, in common law, a term which is substantially equivalent to "care." In Scots law it is a general term for the process by which persons. lands or effects are attached on execution, or in security for debt. (See NEGLIGENCE.)

DILKE, CHARLES WENTWORTH (1789–1864), an English critic and antiquarian, was born on Dec. 8, 1789. After studying at Cambridge, he entered the navy pay office. From 1814 to 1816 he edited *Old* English Plays (6 vols.), from 1830 to 1846 the Athenaeum, and from 1846 to 1849 was manager of the *Daily* News. He then became a regular contributor to the

Athenaeum, his valuable essays for it on Elizabethan drama, on the literary history of the 17th and 18th centuries, and especially on Pope, being collected as *Papers of a Critic* (2 vols., 1875). Dilke died in Hampshire on Aug. 10, 1864.

DILKE, SIR CHARLES WENTWORTH, BART. (1810–1869), English politician, son of Charles Wentworth Dilke, proprietor and editor of *The Athenaeum*, was born in London on Feb. 18, 1810, and was educated at Westminster school and Trinity Hall, Cambridge. He studied law, and in 1834 took his degree of LL.B., but did not practise. He assisted his father in his literary work, and was for some years chairman of the council of the Society of Arts. He took a prominent part in the affairs of the Royal Horticultural Society and other bodies, including the executive committee of the Great exhibition. In 1853 Dilke was one of the English commissioners at the New York Industrial Exhibition, and in 1862 one of the five royal commissioners for the second Great Exhibition. Soon after the death of the prince consort he was created a baronet. In 1865 he entered parliament as member for Wallingford. In 1869 he was sent to Russia as representative of England at the horticultural exhibition held at St. Petersburg (Leningrad). His health, however, had been for some time failing, and he died suddenly in that city on May 10, 1869.

DILKE, SIR CHARLES WENTWORTH, BART. (1843–1911), son of the preceding, was born in London in 1843, and educated at Trinity Hall, Cambridge, where he achieved the triple distinction of being senior legalist in the law tripos, president of the Union and stroke of the boat which was head of the river. In 1866 he made a voyage round the world, beginning with the United States, and visiting New Zealand, Australia, Ceylon, India and Egypt. The impressions gained on these travels left him, he said, "with a conception, however imperfect, of the grandeur of our race, already girdling the world, which it is destined, perhaps, to overspread." The book in which he described his travels, *Greater Britain* (1868), gave a great impulse to a sane and reformed imperialism. All his life Dilke was a true imperialist. For him there was no incompatibility between imperialism and extreme radicalism. He became a prominent Liberal politician, as M P. for Chelsea (1868–86), under-secretary for foreign affairs (1880–82), and president of the local government board (1882–85). In 1871–72 Dilke represented the extreme radical party in England. There was no great love for the Crown, for the Queen's retirement of ten years was a cause of discontent, and he attacked the expense of royalty, in particular the dowries voted for the Queen's children. He was a theoretical republican, and on various occasions in public speeches put the case for republicanism. His own attitude was the reverse of revolutionary. As he said himself, "To think and even to say that monarchy in western Europe is a somewhat cumbersome fiction is not to declare oneself ready to fight against it on a barricade." During these years he says himself he was nearly subjected to physical and really subjected to moral martyrdom, and it is a fact that on one occasion at least nothing but his own imperturbable courage saved his life. Nevertheless, within a few years Disraeli could express the opinion that Sir Charles Dilke was the most powerful and influential member among quite young men that he had ever known.

During his first years in the House of Commons he maintained an independent position. Between 1876 and 1880 he became a close ally of Joseph Chamberlain. Gradually, however, he became a force within the Liberal party, and during the Beaconsfield government with Lord Hartington as leader, the task of presenting the case for the opposition fell more and more into his hands. As a result of the Liberal victory of 1880 he and Chamberlain became members of the Gladstone ministry. In 1885 Dilke was chairman at a conference on industrial remuneration attended by all the prominent trade unionists of the day and women representatives of the Protective and Provident League, afterwards to become the Women's Trade Union League. This was symptomatic of his whole attitude towards labour problems. Throughout his life he was an ardent supporter of better conditions for the workers. While he was at the Local Government Board he called attention to the problem of housing, with the result that a Royal Commission sat in 1884 to study the housing of the working classes. He was associated with the acts legalizing the position of the Trades Unions and limiting the hours of work. He was in favour of legislation to secure a minimum wage and he wished for the representation of labour in the House of Commons. When the Independent Labour Party emerged in 1894 he was asked to be its leader, but refused on the ground that he differed on certain radical points with its views. He therefore remained its candid friend and critic to the end of his life. He was largely instrumental in 1884 in bringing about the party truce enabling the Franchise Bill to become law. It was at first rejected by the Lords unless accompanied by a redistribution of seats, a principle for which Dilke had long contended. It was eventually passed at the end of 1884 and the Redistribution Bill early in 188;.

"I never knew a man of his age, hardly ever a man of any age, more powerful and admired than was Dilke during his management of the Redistribution Bill in 1885." Such was Sir George Trevelyan's verdict of a man who combined radical principles with an extraordinary authority on foreign affairs and a capacity for working with men of the most varied views when great questions were at stake. Nevertheless, when Dilke left the Local Government Board on June 24, 1885, on the defeat of the Gladstone ministry, he left official life for ever. At this point he was cited as co-respondent in a divorce suit brought by Donald Crawford, Liberal M.P. for Lanark. Mrs. Crawford was the sister-in-law of Dilke's brother Ashton and the proceedings caused great scandal. The case against Dilke was dismissed, but he determined to retire from public life. In 1884 he had become privately engaged to Emilia Frances Pattison (née Strong), the widow of Mark Pattison, herself an accomplished art critic and collector. She was in India when the blow fell. Her reply to the accusation was the publication of her engagement to Sir Charles Dilke in the *Times*, and she married him on October 3, 1885; she died in 1904. Later, Chamberlain overruled his determination to retire from politics, and he was returned for the Forest oi Dean in 1892 and for Chelsea once more in 1905. Although his knowledge of foreign affairs and his powers as a critic and writer on military and naval questions were admittedly of the highest order, his official position in public life could not again be recovered. We was marked out in 1885 as the future leader of the Liberal Party in the House of Commons, and there is little doubt that he might have become one of the great foreign ministers of Europe. He possessed a knowledge of the needs and aspirations of foreign countries rare among his contemporaries, and a definite policy to be pursued irrespective of party politics and the rise and fall of ministries. His military writings are *The British Army* (1888); *Army Reform* (1898) and, with Spenser Wilkinson, *Imperial Defence* (1892). On colonial questions he wrote with equal authority. His *Greater Britain* (2 vols., 1866–67) reached a fourth edition in 1868, and was followed by *The Present Position of European Politics* (1887), *Problems of Greater Britain* (2 vols., 1890) and *The British Empire* (1899).

Emilia Frances, Lady Dilke, his second wife, was the author of a number of books, the most important being the studies on *French Painters of the Eighteenth Century* (1899) and three subsequent volumes on the architects and sculptors, furniture and decoration, engravers and draughtsmen of the same period, the last of which appeared in 1902. A posthumous volume, *The Book of the Spiritual Life* (1905), contains a memoir of her by Sir Charles Dilke.

(E. F. M. S.)

S. Gwynn and G. M. Tuckwell, *Life of Sir Charles Dilke* (2 vols., 1917). Also published in abridged form by G. M. Tuckwell (1925).

DILL (*Anethum graveolens*), an annual or biennial herb of the family Umbelliferae, native to the south of Europe, Egypt and the Cape of Good Hope. It resembles fennel in appearance. The leaves are used in soups and sauces and, as well as the umbels, for flavouring pickles. The fruits are employed for the preparation of dill-water and oil of dill; they are largely consumed in the manufacture of gin and when ground are eaten in the East as a condiment. Aqua Anethi or dill-water (dose 1–2 oz.) and the Oleum Anethi, almost identical in composition with caraway oil, and given in doses of ½–3 minims, are sometimes used as a carminative and as a vehicle

for the exhibition of nauseous drugs.

DILLEN (DILLENIUS), **JOHANN JAKOB** (1684–1747), English botanist, was born at Darmstadt and educated at the university of Giessen, where he printed in 1719 his *Catalogus plantarum sponte circa Gissam nascentium.* In 1721 he came to England, and in **1724** published a new edition of Ray's *Synopsis stirpium Britannicarum.* In **1732** appeared *Hortus Elthamensis,* a catalogue of the rare plants growing at Eltham, Kent, for which Dillen himself executed 417 plates, and it was described by Linnaeus as *opus botanicum quo absolutius mundus non vidit.* In **1734** he became professor of botany at Oxford. Dillen, who wrote *Historia muscorum* (1741), died at Oxford on April 2, 1747.

For an account of his collections preserved at Oxford, see *The Dillenian Herbaria, by G.* Claridge Druce (Oxford, 1907).

DILL (ANETHUM GRAVEOLENS) AN AROMATIC PLANT VALUED FOR FLAVOURING AND FOR ITS MEDICINAL PROPERTIES
At left is an enlarged drawing of fruit

DILLENBURG, a town of Hesse-Nassau, Prussia, Germany, in wooded country, on the Dill, 25 m. N.W. from Giessen on the railway to Troisdorf. Population **6,470.** On an eminence above it lie the ruins of the castle of Dillenburg, founded by Count Henry the Rich of Nassau, about the year 1255, and the birthplace of Prince William of Orange (1533). It has a chamber of commerce. Its industries embrace iron-works, bronze works, colour-works, tanneries and the manufacture of cigars. Owing to its beautiful surroundings Dillenburg has become a favourite summer resort.

DILLENS, JULIEN (1849–1904), Belgian sculptor, was born at Antwerp June **8, 1849,** son of a painter, and died at St. Gilles, near Brussels, Dec. **24,** 1904. He studied under Eugène Simonis at the Brussels Academy of Fine Arts. In **1877** he received the *prix de Rome* for "A Gaulish Chief taken Prisoner by the Romans," and from that time onward executed a number of important sculptures for the principal towns of Belgium and for the Belgian Government. Perhaps the most famous of these is the group "La justice entre la clémence et le droit," in the Palais de Justice at Brussels.

DILLINGEN, a town of Germany, in the *Land* of Bavaria, on the left bank of the Danube, **25** mi. N.E. from Ulm by rail. Population **6,220.** Dillingen became the residence of the bishops of Augsburg; was taken by the Swedes in **1632** and **1648,** by the Austrians in 1702, and on June **17,** 1800 by the French. In 1803 it passed to Bavaria. Its principal buildings are an old palace of the bishops of Augsburg, now Government offices, a royal gymnasium, a Capuchin monastery and a Franciscan convent. The university, founded in 1549, was abolished in **1804.** The inhabitants are engaged chiefly in cattle-rearing and the cultivation of corn, hops and fruit. In the vicinity is the Karolinen canal, which cuts off a bend in the Danube between Lauingen and Dillingen.

DILLMANN, CHRISTIAN FRIEDRICH AUGUST (1823–1894), German orientalist and biblical scholar, was born at Illingen on April **25, 1823.** In **1853** he became professor extraordinarius (at Tiibingen), and subsequently professor of philosophy at Riel (1854), of theology at Giessen **(1864)** and Berlin **(1869).** He died on July **4,** 1894. Dillmann's chief works are the *Book of Enoch* in Ethiopian **(1851;** German, **1853);** the first part of the Ethiopic bible, *Octateuchus Aethiopicus* (1853–55); *Grammatik der äthiopischen Sprache* (1857; Eng. trans., 1907); the *Book of Jubilee* (1859); another part of the Ethiopic bible, *Libri Regum* **(1861** and 1871); *Lexicon linguae aethiopicae* **(1865);** *Chrestomathia aethiopica* **(1866).** His *Commentar zum Hiob* **(1869)** stamped him as one of the foremost Old Testament exegetes. His renown as a theologian was mainly founded by the series of commentaries on other Old Testament books including *Genesis; Exodus und Leviticus; Numeri, Deuteronomium und Josua,* and *Jesaja.* In **1877** he published the *Ascension of Isaiah* in Ethiopian and Latin, and in **1895** *Vorlesungen iiber Theologie des Alten Testamentes* appeared.

See W. Baudissin, *A. Dillmann* (Leipzig, 1895).

DILLON, ARTHUR RICHARD (1721–1807), French archbishop, was the son of Arthur Dillon (1670–1733), an Irish general in the French service. He was born at St. Germain, held many important preferments and in 1763 became archbishop of Narbonne, and in that capacity, president of the estates of Languedoc. He carried out many works of public utility, bridges, canals, roads, harbours, etc., had chairs of chemistry and of physics created at Montpellier and at Toulouse, and tried to reduce poverty. In 1787 and **1788** he was a member of the Assembly of Notables called by Louis XVI., and in 1788 presided over the assembly of the clergy. Refusing to accept the civil constitution of the clergy, Dillon emigrated to Coblenz in 1791. He lived in London until his death in 1807, never accepting the Concordat.

See L. Audibret, *Le Dernier Prtsident des États du Languedoc, Mgr. Arthur Richard Dillon, archevêque de Narbonne* (Bordeaux, *1868);* L. de Lavergne, *Les Assemblées provinciales sous Louis XVI.* (Paris, *1864).*

DILLON, JOHN (1851–1927), Irish nationalist politician, was the son of John Blake Dillon (1816–1866), who sat in parliament for Tipperary, and was one of the leaders of "Young Ireland." John Dillon was educated at University college, Dublin, and afterwards qualified as a surgeon. He entered parliament in 1880 as member for Tipperary, and was at first an ardent supporter of C. S. Parnell, whom he accompanied in his tour of the United States in that year. In August he delivered a bitter speech on the Land League at Kildare; he advocated boycotting, and was arrested in May **1881** under the Coercion Act, and again after two months of freedom in October. In **1883** he resigned his seat for reasons of health, but was returned unopposed in 1885 for East Mayo, which he continued to represent. He was one of the prime movers in the famous agrarian "plan of campaign" *(see* IRELASD, *History).* Dillon was compelled by the court of queen's bench on Dec. **14, 1886,** to find securities for good behaviour; and in June **1888** under the provisions of the new Criminal Law Procedure Bill he was condemned to six months' imprisonment. He was released in September, and in the spring of **1889** sailed for Australia and New Zealand, where he collected funds for the Nationalist Party. On his return he was again arrested, but, being allowed bail, sailed for France in a fishing-boat with W. O'Brien, and thence to America. He returned to Ireland by way of Boulogne, where he and W. O'Brien held long and indecisive conferences with Parnell. They surrendered to the police in February, and on their release from Galway gaol in July declared their opposition to Parnell. After the expulsion of T. M. Healy and others from the Irish National Federation, Dillon became the chairman (Feb. **1896).** His early friendship with O'Brien gave place to disagreement, but the various sections of the party were ostensibly reconciled in 1900 under Redmond's leadership. In the autumn of **1896** he arranged a convention of the Irish race, which included **2,000** delegates from various parts of the world. In **1897** Dillon opposed in the House the diamond jubilee address to Queen Victoria on the ground that her reign had not been a blessing to Ireland. He was suspended on March 20 for violent language addressed to Joseph Chamberlain.

In 1905 he advised Irishmen in England to vote Liberal at the general election, and now began to support the Liberal government in its Irish measures, notably the Land bill, although in his earlier days he had opposed ameliorative measures as likely to defer Home Rule. In the crisis of **1912** over the Better Government of Ireland bill Dillon urged that Nationalists should concentrate on the attack against the House of Lords. In July 1914 he was invited by King George V. to accompany Redmond to the Buckingham Palace conference which attempted to settle the Irish controversy, when his attitude is said to have been stiffer than Redmond's.

When war broke out, he immediately placed his whole influence behind the British Government, speaking in this sense at the meet-

ing in the Dublin Mansion House on Sept. 25, 1914. He took an active part in recruiting but steadily opposed the extension of conscription to Ireland which would, he was convinced, merely strengthen the Sinn Fein movement. He succeeded Redmond as leader of the Nationalist Party, and at the General Election of Dec. 1918 he shared the general obliteration which overwhelmed the Party. He died in London on Aug. 4, 1927, and was buried in Glasnevin cemetery, Dublin, by the side of his wife (d. 1907), a daughter of Justice Mathew.

DILLON, a city of south-western Montana, U.S.A., on the Beaverhead river, the Oregon Short Line railroad and Federal highway 91; the county-seat of Beaverhead county. The population in 1940 was 3,014. It has a very beautiful location on a plateau 5,200 ft. above sea level, surrounded by mountain peaks. It is the hub of an extensive livestock, seed potato, seed pea and mining (gold and silver) region. Beaverhead county leads the state in area and per capita wealth. Dillon was settled about 1880 and incorporated in 1885, and is the seat of the state normal college, which was established in 1893.

DILTHEY, WILHELM (1833–1911), German philosopher, was born on Nov. 19, 1833, at Biebrich and died on Oct. 1, 1911, at Seis, near Bolzano. He was successively professor in Basle (1866), in Kiel (1868), in Breslau (1871), and in 1882 succeeded Lotze in Berlin. As a supporter of positive Idealism, Dilthey regards the external world as a representation arising out of pure experience, will as well as thought being a factor of knowing and of self-consciousness. His empirical tendency also appears in his historical approach to philosophy. His chief writings are: *Leben Schleiermachers* (1870); *Einleitung in die Geisteswissenschaften* (1883); *Das Erlebnis und die Dichtung* (1905); *Die Jugendgeschichte Hegels* (1905); *Systematische Philosophie* (1907); *Der Aufbau der geschichtlichen Methode in den Geisteswissenschaften* (1910); *Weltansclzauung u. Analyse des Menschen seit Renaissance und Reformation,* 2 vols. (1921).

See E. Spranger; *Wilhelm* Dilthey (1912).

DILUVIUM, a term in geology for superficial deposits formed by flood-like operations of water, and so contrasted with alluvium (*q.v.*) or alluvial deposits formed by slow and steady aqueous agencies. The term (Lat. for "deluge," from *diluere,* to wash away) was formerly given to the "boulder clay" deposits, supposed to have been caused by the Noachian deluge. In this sense it still lingers on the continent of Europe, but it has disappeared from British geological literature.

DIME, the tenth part, the tithe paid as church dues, or as tribute to a temporal power. In this sense it is obsolete, but is found in Wyclif's translation of the Bible—"He gave him dymes of alle thingis" (Gen. xiv. 20). A dime is a silver coin of the United States, in value 10 cents (English equivalent about 5d.), or one-tenth of a dollar; hence "dime-novel," a cheap sensational novel, a "penny dreadful"; also "dime-museum."

DIMENSION, a term used in geometry to denote a magnitude measured in a specified direction, as, for instance, along a diameter or a principal axis or an edge. **A** point is said to be without dimension; a line has the one dimension of length, a surface has the two dimensions of length and breadth, while a solid has the three dimensions of length, breadth and thickness. Since the lengths of lines, the areas of surfaces and the volumes of solids are represented respectively by linear, quadratic and cubic algebraic expressions, the term dimension has been carried over into algebra. Thus quadratic, cubic, biquadratic algebraic expressions or equations are said to be respectively of two, three, four dimensions. Similarly, the term dimensions is used in mechanics with reference to the units of time, length and mass and various derived units *(see* UNITS, DIMENSIONS OF), and it occurs likewise in many other parts of physics, notably in the theory of electricity and magnetism *(see* PHYSICAL **UNITS).**

The fundamental descriptive proposition concerning space, as we are accustomed to it in experience, is that space is a continuum (a continuous or unbroken distribution of points) having three dimensions. The intuitive basis of this proposition may be elucidated as follows. If on a curve (or line) we mark certain points (elements without dimension) we separate the curve into parts bounded by the points in such a way that we cannot pass along the curve from one part to another without encountering and passing over one of these marked points. Since the curve may be separated into parts by elements without dimensions it is itself said to be a figure having one dimension. But a surface cannot be thus separated into parts by marking isolated points on it; for, in going from one place to another on the surface, we can always avoid passing over these marked points by going around them. If we draw in the surface a suitable closed curve (a figure of one dimension) then the surface is separated into parts in such a way that we cannot move over the surface from one part to another without encountering and passing over a point on the curve. Since a surface can not be separated into parts by points (figures without dimension) but can be separated into parts by a suitable figure of one dimension, we say that a surface itself has two dimensions. Similarly space cannot be separated into parts by isolated points or curves or both taken together, while it can be so separated into parts by means of a closed surface (a figure of two dimensions). For this reason we say that space has three dimensions. This, according to Henri Poincaré (*Dernières Pensées, Flammarion,* Paris, 1917, pp. 61ff.), is the fundamental qualitative ground for ascribing three dimensions to the usual space of experience.

The mathematician introduces three co-ordinates to represent the points of ordinary space and much of his analysis of its properties is carried out algebraically. Now the algebraic analysis is competent to deal with sets of any number n of co-ordinates. Thus algebraic geometry leads readily to the conception of spaces of any number n of dimensions; and these have been extensively treated, though no one has a lively mental picture of spaces having more than three dimensions. Popular interest in these higher spaces (as opposed to the interest of mathematicians in them) has been centered principally around the concept of the "fourth dimension." But the number of dimensions of these higher spaces is unlimited; and, in fact, several kinds of space with an infinite number of dimensions have been investigated.

That the higher spaces may be given a concrete representation in terms of experience is shown by the fact that the totality of straight lines in our usual space of three dimensions constitutes a veritable space of four dimensions *(see* PROJECTIVE GEOMETRY). This arises from the fact that four independent co-ordinates are necessary to define completely the position in space of a line of unlimited extent. Therefore a geometry in which the elements are the lines of ordinary space is a geometry of four dimensions.

(R. D. CA.)

DIMINISHING RETURNS, in economics, represents the special application to land of the more generalized "law of diminishing productivity." This latter law may be stated as follows: "The size of the product obtained in a given productive process varies greatly according to the way in which the various agents of production are combined. If the supply of all other agents is kept constant, while the supply of one specific agent is increased, the average product per unit of this specific agent may increase to a maximum point, but, thereafter will, as a rule, diminish continuously, though often irregularly." This law is applicable to all types of production. Economists early noted the application of this law to land and called it "the law of diminishing returns." They observed that, beyond a certain point, as a greater value of labour and other agents of production are applied to a given area of land, the physical product obtained per additional unit of value invested on the land tends to diminish continually. Experience everywhere confirms the existence of this principle.

Any farmer knows that it is unprofitable to increase the intensity of use or cultivation of land beyond a certain point. It is a generally accepted fact that, when population density in a nation increases beyond an optimum point, average productivity per capita diminishes, and hence poverty increases.

(See ECONOMICS). (W. I. K.)

DIMINUENDO (It.), diminishing, *i.e.,* as used in music (abbr, *dim.*), in loudness, otherwise getting softer. *Decrescendo* and the sign have the same meaning.

DIMINUTION, a term in music applying when a given theme or passage is played in a "diminished" form, *i.e.*, in notes of shorter duration; "augmentation" signifying the converse procedure.

DIMITRIEVIĆ, DRAGUTIN (1876–1917) COLONEL, Serbian soldier and conspirator, was born on Aug. 17, 1876, and was the principal organiser of the conspiracy which ended in the murder (1903) of King Alexander Obrenovich of Serbia (*q.v.*) and his wife Draga. He was at first treated with great consideration by King Peter Karageorgević, and advanced rapidly in his profession. He became lecturer in tactics at the Military Academy of Belgrade, and contributed largely to the reorganisation of the Serbian army. In time, however, he became estranged from the dynasty, and as the semi-official "Narodna Obrana" was too lukewarm, in his opinion, he founded (May 1911) the secret society "Ujedinjenje ili Smrt" (Union or Death), a league composed mainly of officers, and known generally as "the Black Hand," which aimed at uniting all Southern Slav districts, by no matter what means. This league, and Dimitriević himself, took an active part in the comitadji warfare in Macedonia, and also in the anti-Austrian propaganda in Bosnia. In June 1913 Dimitriević was appointed chief of intelligence of the Serbian general staff. He was the prime author and organiser of the murder of Sarajevo. The "Black Hand" had quarrelled with the civilian administration and Radical party over the latter's administration in Macedonia. On Dec. 15, 1916, Dimitrievid and his principal partisans were arrested at Salonica on a charge of conspiring to deliver the Serb front to the enemy; he was condemned to death for inciting to mutiny and conspiring to assassinate the crown prince (later king) Alexander of Serbia, and shot June 1917.

Dimitrievid (commonly known as "Apis") was a man of great courage, intelligence, patriotism and energy, but ruthless and utterly unscrupulous in his methods. Personal details are given most fully in Boghichevich, *Le Procès* de *Salonique* (1927), while the evidence regarding the Sarajevo crime is best given in R. W. Seton-Watson, Sarajevo (1927).

DIMITY, derived from the Gr. δίμιτος "double thread," through the Ital. dimito, "a kind of course linzie-wolzie" (Florio, 1611); a cloth commonly employed for bed upholstery and curtains, and usually white, though sometimes a pattern is printed on it in colours. It is stout in texture, and woven in raised patterns.

DIMORPHISM, the property of assuming two forms. In crystallography (*q.v.*), two substances which are identical in chemical composition but different in crystalline form, and consequently in others of their physical properties, are *dimorphous.*

In biology the word is used when there are two distinct varieties of an organism which freely interbreed; thus, in plants, the pin-eyed and thrum-eyed varieties of primrose (Primula) are examples of dimorphism; among animals, some female mimetic butterflies show dimorphism, changing their appearance to resemble a different model (see MIMICRY); some birds, *e.g.*, certain owls, also exhibit dimorphism. In addition, many animals exhibit sexual dimorphism (see SEX) in which the two sexes are sharply differentiated from one another, *e.g.*, deer, birds of paradise, many butterflies, etc.

DINAJPUR, a town and district of British India, in the Rajshah division of Bengal. The population of the town in 1931 was 19,156. The district has an area of 3,946 sq.m. and a population of 1,755,432. It is a flat alluvial plain broken in the south by a slightly elevated tract known as the Barind, and in the north-west by low hills, along the banks of the Kulik river. The principal rivers are the Atrai and Jamuna and the Karatoya, which forms the eastern boundary for 50 m. Rice is the staple agricultural product. The district is partly traversed by the main line of the Eastern Bengal State railway and by the line to Behar. which takes off at Parbatipur. Pillars and copper-plate inscriptions have yielded numerous records of the Pala kings of Bengal. Interesting ruins exist at Devikot and Ghoraghat which were military stations under the early Mohammedan rulers of Bengal.

DINAN, a town of north-western France, capital of an arrocdisscment in the department of Côtes-du-Nord, 37 mi. E. of St. Brieuc on the Ouest-État railway. Pop. (1936) 11,711

Dinan, a stronghold of the dukes of Brittany, was besieged by the English under the duke of Lancaster in 1359, during which siege Du Guesclin and an English knight called Thomas of Canterbury engaged in single combat.

Dinan stands on a height on the left bank of the Rance (here canalized), some 17 m. above St. Malo, with which it communicates by means of small steamers. It is united to the village of Lanvallay on the right bank of the river by a granite viaduct 130 ft. in height. The town is almost entirely encircled by the mediaeval ramparts, strengthened with towers and, on the south, a castle of the late 14th century, now a prison. Three old gateways also remain. The church of St. Malo is late Gothic, that of St. Sauveur, Romanesque and Gothic intermingled. In the latter church a granite monument contains the heart of Bertrand Du Guesclin. The quaint winding streets of Dinan are often bordered by mediaeval houses. It is a tourist centre. Near the town are the ruins of the château and the Benedictine abbey at Léhon; and not far off is the now dismantled chbteau of La Garaye. Dinan is the seat of a sub-prefect. There is trade in grain, cider, wax, honey, butter and other agricultural products. Leather is manufactured.

DINANT, an ancient town in the province of Namur, Belgium, on the Meuse, with the station and the suburb of St. Medard. Pop. (1930) 7,003. As early as the 7th century it was a dependency of the bishopric of Tongres. From the 10th century to the French revolution it was a fief of the prince-bishopric of Liége. In 1040 a castle was built on a rock dominating the town In the 15th century, with a population of 60,000, and 8.000 workers in copper, Dinant was one of the most flourishing cities in Walloon Belgium until it incurred the wrath of Charles the Bold. In 1466 Charles, in his father's name, laid siege to Dinant, and carried the place by storm, killing most of the combatants. In 167j Dinant was taken by Louis XIV., and remained in French hands for nearly 30 years. The citadel on the cliff, 300 ft. or 408 steps above the town, was fortified by the Dutch in 1818, but was dismantled later. Half way up the cliff is the grotto of Montfat, 13th century.

The church of Notre Dame (13th century) stood immediately under the citadel, flanking the bridge, and was a remarkably complete illustration of Gothic architecture with a curious slate-covered spire shaped like a long pumpkin.

Dinant was practically destroyed in August 1914 during the German invasion, and 670 of its inhabitants were shot, but after 1918 it was largely restored. It again suffered heavily in the May 1940 campaign.

Dinant is a summer resort and also a convenient central point for excursions into the Ardennes.

DINAPORE, a subdivisional town and cantonment of British India, in the Patna district of Behar and Orissa, on the right bank of the Ganges. Pop. (1931) 81 367. In 1857 the sepoy regiments here who had been allowed to retain their arms broke into open mutiny when an attempt was made to disarm them. The majority crossed over the Son into Shahabad where they joined the rebels under Kuar Singh and laid siege to Arrah.

DINAR. The monetary unit of Serbia, and since the war of Yugoslavia, divided into 100 paras. At par, the dinar is equivalent to 2.982 cents in the currency of the United States.

Gold coins are of 20 and 10 dinars in denomination, and silver is coined into pieces of 5, 2, 1 and ½ dinars, respectively. Nickel coins circulate, in the form of 20, 10 and 5 paras, while bronze is struck into coins of 2 paras. With the dinar equivalent to 1.76 cents or about three-farthings, 2 paras would be only 1/100th of a penny.

National bank notes circulate in Yugoslavia. In 1920, 3,344 million dinars were outstanding, and by 1924 the volume had risen to 6,000 millions. Concurrently, the dollar exchange fell from 2 95 to 1.49 cents.

The world depression of the 1930s and the outbreak of World War II in 1939 caused further violent fluctuations in the exchange value of this and other currencies.

(See also CURRENCY.)

DENARD, a seaside town of north-western France. in the department of Ille-et-Vilaine. Pop. (1936) 6,541. The town, the chief watering place of Brittany, stands on a rocky promontory at the mouth of the Rance opposite St. Malo, which is about 1 mi distant. It is a favourite resort of English and Americans, as well as of the French, its attractions being the beauty of its situation, a famous grotto, the mildness of the climate and the good bathing. It has two casinos and numerous luxurious hotels and elegant villas. The adjoining watering places of St. Enogat, St. Lunaire and St. Briac are increasing in importance.

DINDIGUL, a town of British India, in the Madura district of Madras, 880 ft. above the sea, 40 m. from Madura by rail. Pop. (1931) 43,617. Dindigul is a trade centre, and has a considerable manufacture of tobacco, a large cotton ginning and pressing factory, and tanneries. The town has manufactures of cloth and safe-locks and an export trade in cotton, coffee, grain and cardamoms. Approximately one-ninth of the population is Christian. There is an industrial school. The ancient fort, well preserved, stands 350 ft. above the town; this was formerly a position of great strategic importance, commanding passes into Madura from Coimbatore, and figured prominently in the military operations of the Mahrattas in the 17th and 18th centuries, and of Hyder Ali in 1755 and the years which followed. After being thrice captured by the British it was eventually ceded to the East India Company.

DINDORF, KARL WILHELM (1802–1883), German classical scholar, was born at Leipzig. After completing F. Invernizi's edition of Aristophanes (1826), and editing several grammarians and rhetoricians, he was, in 1828, appointed extraordinary professor at Leipzig, a post which he resigned in 1883. He edited Athenaeus (1827) and the Greek dramatists, both separately and combined in his *Poetae scenici Graeci* (1830 and later editions). He also wrote a work on the metres of the Greek dramatic poets, and compiled special lexicons to Aeschylus and Sophocles. He edited Procopius for Niebuhr's *Corpus* of the Byzantine writers, and between 1846 and 1851 brought out at Oxford an important edition of Demosthenes; he also edited Lucian and Josephus for the Didot classics. His last important editorial labour was his *Eusebius of Caesarea* (1867–71). Much of his attention was occupied by the republication of Stephanus's *Thesaurus* (Paris, 1831–65), chiefly executed by him and his brother Ludwig, a work of prodigious labour and utility.

His brother LUDWIG (1805–1871) led so secluded a life that many doubted his existence, and declared that he was a mere pseudonym. The important share which he took in the edition of the *Thesaurus* is nevertheless authenticated by his own signature to his contributions. He also published valuable editions of Polybius, Dio Cassius and other Greek historians.

D'INDY, PAUL MARIE THÉODORE VINCENT (1851–1931), French musical composer, was born in Paris on March 27, 1851. He studied composition and the organ at the Paris Conservatoire under César Franck, and obtained the grand prize offered by the city of Paris in 1887 with *Le Chant de la Cloche,* a dramatic legend after Schiller. His principal works include the symphonic trilogy *Wallenstein,* the symphonic works entitled *Saugefleurie, La Forêt enchantke, Istar, Symphonie sur un air montagnard français;* overture to *Anthony and Cleopatra; Ste. Marie Magdeleine,* a cantata; *Attendez-moi sous l'orme,* a one-act opera; *Fervaal,* a music drama in three acts; and *La Légende de Saint-Christophe,* a hybrid work, part oratorio, part opera, part symphony, containing some of his finest music. Vincent d'Indy was perhaps the most prominent among the disciples of César Franck. He was guided by the loftiest ideals and few musicians laboured more strenuously or disinterestedly in the service of art. His opera *Fervaal,* which is styled "action musicale," is constructed upon the leading motive system. Its legendary subject recalls both *Parsifal* and *Tristan,* and the music is also suggestive of Wagnerian influences. As founder and director of the Schola Cantorum d'Indy did magnificent work as a teacher. and the briefest record of his activities would be incomplete which omitted reference to his indefatigable propagandist labours on behalf of his master, César Franck.

DINEIR, also DINAR or GEYIKLER, a kaza in the vilayet of Afiun Qarahisar in Turkey, built amidst the ruins of Celaenae-Apamea, near the sources of the Maeander. Population, 36,117. It lies on the Smyrna-Egerdir railway *(see* APAMEA).

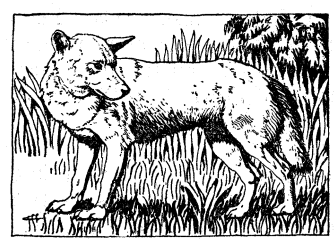
DINGAAN: *see* ZULULAND.

DINGELSTEDT, FRANZ VON (1814–1881), German poet and dramatist, was born at Halsdorf, in Hesse Cassel, on June 30, 1814. He studied at Marburg, became schoolmaster at Cassel (1836) and at Fulda (1838). In 1839 he produced a novel, *Unter der Erde,* and in 1841 the book by which he is best remembered, the *Lieder eines kosmopolitischen Nachtwächters* These poems, which expressed the liberal aspirations of his time, determined his career, and in 1841 he joined the staff of the *Augsburger allgemeine Zeitung.* In 1843 the satirist of German princes accepted, to the general surprise, the appointment of private librarian to the king of Wiirttemberg, and in the same year he married the Bohemian opera singer, Jenny Lutzer. After the production of his tragedy, *Das Haus der Barneveldt* (1850), he became intendant at the court theatre at Munich, but in 1856 was suddenly dismissed on the most frivolous charges, the real authors of his disgrace being the ultramontane clique at court., Through the influence of Liszt he became intendant of the court theatre at Weimar, where he remained until 1867; under his management there all Shakespeare's historical plays were presented in an unbroken cycle. In 1867 he became director of the court opera house in Vienna, and in 1872 of the Hofburg theatre, a position he held until his death on May 1;, 1881. Among his other works may be noticed an autobiographical sketch of his Munich career, entitled *Münchener Bilderbogen* (1879), *Die Amazone,* a society novel (1869), translations of several of Shakespeare's comedies, and several writings dealing with questions of practical dramaturgy. He was ennobled in 1867 by the king of Bavaria, and in 1876 was created *Freiherr* by the emperor of Austria. Dingelstedt was one of the founders of the German Shakespeare Society.

Dingelstedt's *Sämtliche Werke* (12 vols., 1877–78), is incomplete. On his life *see,* besides the autobiography mentioned above, J. Rodenberg, *Heimaterinnerungen an* F. *Dingelstedt* (1882), and *F. Dingelstedt, Blatter aus seinem Nachlass* (2 vols., 1891).

DINGHY, a boat of greatly varying size and shape, used on the rivers of India; the term is applied also, in certain districts, to a larger boat used for coasting purposes. The name was adopted by the merchantmen trading with India, and is now generally used to designate the small extra boat kept for, general purposes on a man-of-war or merchant vessel, and also, on the Thames, for small pleasure boats built for one or two pairs of sculls.

DINGLE, a seaport and market town of Co. Kerry, Eire, on the fine natural harbour of Dingle bay. Pop. (1936) 1,800. The town, a mackerel-fishing centre, was important in the 16th century as a seaport, and had also a noted manufacture of linen. It was incorporated by Queen Elizabeth and returned two members to the Irish parliament until the Union.



BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

DINGO, THE NATIVE AUSTRALIAN DOG, IS THE ONLY LARGE PLACENTAL MAMMAL WHICH INHABITED AUSTRALIA PREVIOUS TO EUROPEAN COLONIZATION

DINGO (*Canis dingo),* the native Australian dog, a stoutly-built, short-legged animal, intermediate in size between a jackal and a wolf. It is very similar in appearance to the pariah dogs of India and Egypt, from which it is probably derived. The dingo occurs both wild and tame, and is the only large placental mammal which inhabited Australia previous to European colonization. There is strong evidence, however, that the dingo is not indigenous to the continent, but was brought from Asia by the aborigines. In colour it is sandy-brown often marked on the back with black.

Owing to the introduction of the rabbit, which affords it a staple food-supply, the dingo has recently increased in numbers to such an extent as to become a serious menace to the sheep-

farmers in many parts of Australia. It hunts singly or in pairs, more rarely in small packs of five or six.

Fossil remains of the dingo are found in the Australian Pleistocene mixed with bones of giant marsupials.

DINGWALL, royal burgh, county town and parish, shire of Ross and Cromarty, Scotland. Pop (1938) 2,828. It is near the head of Cromarty Firth where the valley of the Peffery unites with the alluvial lands at the mouth of the Conon, 18½ m. N.W. of Inverness by the L.M.S.R. Its name, derived from the Scandinavian *Thingvöllr,* "field or meeting-place of the *thing,"* or local assembly, preserves the Norse origin of the town; its Gaelic designation is Inverpefferon, "the mouth of the Peffery." The 18th-century town house (largely rebuilt in 1905) and some remains of the ancient mansion of the once powerful earls of Ross still exist. A tower has been built on Mitchell hill to the south of the town in memory of Brig. General Sir Hector Macdonald, who was born near Dingwall. The town has an important corn market and auction marts, and a distillery. Some shipping is carried on at the harbour at the mouth of the Peffery, about a mile below the burgh. Branch railways run to Strathpeffer and to Strome Ferry and Kyle of Lochalsh (for Skye). Alexander II. created Dingwall a royal burgh in 1226, and its charter was renewed by James IV. On the top of Knockfarrel, a hill about 3 m. to the west, is a large and very complete vitrified fort with ramparts.

DINIZULU: *see* CETYWAYO and *s.v.* ZULULAND.

DINKA: *see* NILOTES.

DINKELSBÜHL, a town of Germany, in the *Land* of Bavaria, on the Wörnitz, 16 mi. N. from Nordlingen by rail. Population 5,180. Fortified by the emperor Henry I., Dinkelsbuhl received in 1305 the same municipal rights as Ulm, and obtained in 1351 the position of a free imperial city, which it retained till 1802, when it passed to Bavaria. Its municipal code, the *Dinkelsbühler Recht,* published in 1536, and revised in 1738, contained a very extensive collection of public and private laws. It is still surrounded by old walls and towers. The *Deutsches Haus,* the ancestral home of the counts of Drechsel-Deufstetten, is of the German renaissance style of wooden architecture. Brushes, gloves, stockings and gingerbread are the chief manufactures.

DINNER, the chief meal of the day, eaten either in the middle of the day or in the evening. The word "dine" comes through Fr. from Med. Lat. *disnare,* for *disjejunare,* to break one's fast (*jejunium*); it is, therefore, the same word as Fr. *déjeuner,* to breakfast, in modern France, to take the midday meal, *diner* being used for the later repast.

DINOFLAGELLATA, single-celled organisms (class Flagellata), with plant-like metabolism, which are present as part of the floating fauna (plankton) of pools, lakes and the sea. They form a certain part of the food-supply of other animals (*e.g.,* of fish larvae). (*See* PROTOZOA.)

DINORNPTHIDAE: *see* MOA.

DINOSAURIA, a sub-class or order of Mesozoic reptiles. The term dinosaur is in current use for the members of two groups of extinct reptiles, most members of which are characterized by their gigantic size.

The first group, the Saurischia, first appears in the Trias, the earliest known remains being found in the Middle Trias, although the evidence of foot-prints suggests that they already existed in the Lower Trias. These Triassic forms are very variable in size, ranging from animals no bigger than a hen to creatures some 15ft. or more in length. All of them are bipedal, walking on the clongated hind legs and scarcely ever if at all touching the ground with their small hands during ordinary progress. In the main these animals were carnivorous, and some of their descendants continued to feed on flesh until their disappearance at the top of the Cretaceous. One other group, however, of very heavily built, more quadri-pedal animals, apparently adopted herbivorous habits and developed into the great group of Sauropoda. The truly carnivorous Jurassic and Cretaceous forms fall into many families differing very considerably from one another. The most important end-forms, *i.e.,* those which represent the climax of the evolution of a line, are *Struthiomimus* and *Tyrannosaurus.*

Struthiomimus is a bipedal animal probably capable of running at a great speed, its legs and particularly its feet, strongly recalling those of such struthious birds as the emu and rhea There are three toes, the middle much the longest, the others forming a symmetrical pair; and they correspond to the second, third and fourth of the full pentadactyl foot. The fore-limb is also three toed, but is peculiar in structure. Its bones and the muscles which move them are slender, whilst the digits are of nearly the same length, each of the three ending in a large curved and sharp-pointed claw. These fingers could not be opposed to one another, the hand could merely be shut and opened like that of a sloth: it can have served only as an organ for grasping boughs. The neck is long, slender and freely movable, whilst the head is relatively very small and the jaws are covered with a horny beak like that of an ostrich. The eye is large. It seems most probable that the animal used its slender arms for pulling down the boughs of trees, in order that their leaves might be plucked by the beak, but it is possible that the animal was capable of digging up shrubs with its hands. It is about 12ft. in length and stands about 4ft. high at the pelvis.

Tyrannosaurus, which is of slightly more recent date, presents a remarkable contrast to *Struthiomimus.* The animal stands about 18ft. high and has a length of some 38ft.; the skull alone is more than 4ft. in length. The animal walked entirely on its hind legs, only the toes resting on the ground; the fore limbs are absurdly small and feeble, and can scarcely have been of much use to the animal in feeding. The body is narrow from side to side, but very deep and must have been immensely heavy; in order to balance its weight the thick tail is nearly twice as long as the anterior part of the body. *Tyrannosaurus* has teeth nearly 1ft. in length and is by far the largest land-living carnivorous animal known. It is a descendant of the somewhat smaller *Gorgonosaurus* from the Middle Cretaceous of Alberta, Canada, in which the fore-legs are somewhat larger and the tail shorter; not dissimilar are *Megalosaurus* from the Lower Jurassic of England and *Allosaurus* from somewhat later rocks in North America. In these forms, however, the neck is relatively longer and the fore limbs are still more so.

A great contrast to *Tyrannosaurus* is afforded by *Compsognathus.* This animal was no bigger than a pigeon, and had a foot with a grasping big toe very like that of a bird. Its very delicate skull was provided with small very sharp teeth. The only known specimen, which comes from the Solenhofen slate of Bavaria, contains within its ribs the remains of a skeleton; this has sometimes been interpreted as that of an unborn individual of the same form, but it is more probably the remains of a small lizard-like reptile which was its last meal.

The other great group of Saurischia, the Sauropoda, is composed of large reptiles, many of which attained gigantic dimensions. The smallest and one of the most recent, *Titanosazrrus,* is little more than 5ft. high at the shoulder and about 25ft. in length, more than half of it being tail. The largest form, *Brachiosaurus,* has a humerus about 6ft. in length. These animals walked on all four legs and the fore-leg was not disproportionately shorter than the hind one. The fore-foot usually bears a single large claw on the thumb, the second and third fingers retain some phalanges, and the fourth and fifth are usually reduced to mere stumps. The hind-foot is similar, but usually the first three digits have claws. The animal walks on the ends of its metacarpals and tarsals, that is, the palm of the hand and the sole of the foot were not placed on the ground; the limbs were rather elephant-like. The trunk is short and the neck long and flexible. The tail is extraordinarily long, and often ends in a whip-like extremity. The head is very small with the nostrils opening on its upper surface; the teeth are never large, and form a uniform series which may be restricted to the front of the mouth. In *Diplodocus* (which has *a* total length of 65ft.), the dentition is reduced to some 20 teeth in each jaw, each tooth about as big as the stump of a thin pencil. It is clear that these animals were not carnivorous, and it is exceedingly

difficult to discover any food soft enough to be eaten with such a dentition, and sufficiently abundant to maintain an animal weighing some 35 tons. As the remains of these animals are not uncommonly found in shallow water marine deposits, it is probable that they were mainly aquatic in their habits, walking on the bottom of shallow estuaries, reaching the air by raising their long necks, and feeding on water plants. The skin, in the only case in which it is known, was covered with small horny scales about half an inch in diameter. The oldest known Sauropod is *Cetiosaurus* from the Great Oolite of Oxford, England, but the best known forms are *Diplodocus* and *Apatosaurus* from the top of the Jurassic of Colorado. The most widely distributed was *Titanosaurus* found in the Cretaceous rocks of England, Hungary, India, Madagascar and Patagonia.

The other great division of the dinosaurs, the Ornithischia, contains only herbivorous animals. The oldest member of the group comes from the Upper Trias of South Africa and the group becomes extinct at the extreme top of the Cretaceous. The most familiar forms are animals with the shape of a gigantic kangaroo, the hind legs being very long and the animal balanced about them by the great tail. The fore-limbs are shorter than the hind ones and may perhaps have been used for grasping food. *Iguanodon* (about 28ft. long and 14ft. high) is the most familiar European form, whilst the Cretaceous of North America and of central Asia yields the remains of many animals similar in appearance, but in many cases diversified by the presence of a crest rising from the top of the head. These animals, the Trachodonts, are sometimes so perfectly preserved that the impression of the skin still covers the entire skeleton, and shows that during life the animals were covered with small horny scales often arranged in little groups forming a pattern. These animals appear to have been predominantly aquatic.

Another very different group, is represented by the armoured dinosaurs: they are the oldest known forms, and are characterized by the possession of at least two rows of bony scutes set in the skin of the back. These scutes may be relatively small, but in larger forms such as *Stegosaurus* from the Jurassic of North America and England, they are enlarged so as to stand up as a wall of bony plates 3ft. high by 3ft. wide, on each side of the mid-line of the back of the animal, the plates in the two rows alternating with one another. The largest plates are over the base of the tail, whose extremity bears two pairs of sharp pointed spines, each one sometimes 3ft. in length, projecting laterally. *Stegosaurus* is flat from side to side and its legs are straight and rather elephant-like.

A widely different form is *Palaeoscincus* and its allies, from the Middle Cretaceous of Alberta, Canada. This animal, with a total length of some 15ft. was only 4ft. high, but had a width across the middle of its back of some 6 feet. The head is short and rounded, the neck is also short and is covered with pairs of bony plates lying in the skin; in the region of the shoulder these plates are tall, very sharp-pointed spines, and a similar group of them lies on the elbow. In the middle of the back the spines disappear and are replaced by flat but keeled small bony plates, forming four rows along the animal's back; these extend over the hip region and swell out on the tail so as to form nearly complete rings. Finally, in some cases at any rate, there is an unarmoured but quite stiff region terminating at the end of the tail in an enormous mass of bone composed of numerous bony scutes.

The last group, the Ceratopsia, begins with *Protoceratops*, an animal whose remains are abundant on a certain horizon in the Middle Cretaceous of Mongolia. This animal was quite small; the head of the adult, although developed backwards into a great frill overhanging the neck, was little more than 1ft. in length, whilst the whole animal was only some 5ft. long. This creature had long hind and short fore legs and was probably capable of running on the former like an *Iguanodon*, but it is clear that it was habitually quadripedal. In later rocks in North America there occur a whole series of animals which become progressively larger until they end in such forms as *Triceratops*, with a head 6ft. long. In these later animals the frill becomes more and more extensive and massive and three horns appear, one over each eye and one on the end of the nose. The fore and hind legs become nearly equal in size and the animal walked entirely on all fours.

Protoceratops is the animal which laid the dinosaur eggs discovered by the American Museum of Natural History expedition in Mongolia. On the whole these recall the eggs of birds; they are large, about 7in. long and 5in. in diameter, covered with a calcareous shell, differing in the detail of its structure from that of a bird, although superficially recalling an ostrich egg-shell. These eggs were laid in clutches of 13 or more, and were neatly arranged in a nest, a mere hollow scooped out of the sand on which the animal was walking. The arrangement is a systematic one, the eggs being so arranged that they radiate from the centre and are in two rings overlying one another. The whole appearance of this nest suggests that the animal actually sat on the eggs as does a bird, and that they were not left untended to hatch by the heat of the sun. Fragments of eggs presumed to have been laid by a Dinosaur had been found much earlier in the south of France.

The brain of a dinosaur was always small and in some species it was extremely tiny. For example that of *Diplodocus* is only 4in. in length, 2in. high, and a little more than 1in. in width, whereas the animal as a whole is some 65ft. in length. The most massive part of the whole central nervous system lay in a swelling in the sacrum. It has to be remembered that an impulse takes an appreciable amount of time to travel down a nerve, and that in *Diplodocus* it might take nearly a second to transmit an impulse from the end of the tail to the brain and back again. (*See* REPTILES.) (*D.* M. S. W.)

DINOSAUR NATIONAL MONUMENT, a reservation (80 ac. in area) in Uintah county, Utah, U.S.A., about 12 m. east by north of Vernal. The reservation, created Oct. 4, 1915, contains deposits of fossil remains of prehistoric animal life of great scientific interest.

DINOTHERIUM, an extinct mammal, fossil remains of which occur in the Miocene beds of France, Germany, Greece and northern India. An entire skull, obtained from the Lower Pliocene beds of Eppelsheim, Hesse-Darmstadt, measured 4½ft. in length and 3ft. in breadth, and indicates an animal exceeding the elephant in size. The upper jaw is destitute of incisor and canine teeth, but possesses five molars on each side, with a corresponding number in the jaw beneath. The most remarkable feature, however, consists in the front part of the lower jaw being bent downwards and bearing two tusk-like incisors also directed downwards and backwards. *Dinotherium* is a member of the group Proboscidea (*q.v.*).

DINTER, GUSTAV FRIEDRICH (1760–1831), German divine and educator, was born on Feb. 29, 1760, at Borna, Saxony. He was educated at Leipzig university, and while pastor of a village near Borna, became interested in the training of teachers. From 1797 to 1807 he was principal of the Dresden normal school, and after founding a progymnasium at Gornitz, in 1816 was appointed inspector of schools of the province of Prussia and shortly afterwards professor of theology at Konigsberg university In education, Dinter introduced the methods of Pestalozzi and in his famous *Schullehrer-bibel* (1826–30) advocated the use of the Bible as an authority in religion only, not in science. He died at Konigsberg on May 29, 1831.

See *Sämtliche Schriften*, 42 Bde. (Neustadt, 1840–51), and his autobiography (Neustadt, 1829).

DINWIDDIE, ROBERT (1693–1770), British colonial governor of Virginia, was born near Glasgow, Scotland, in 1693 From the position of customs clerk in Bermuda, which he held in 1727–38, he was promoted to be surveyor-general of the customs "of the southern ports of the continent of America," as a reward for having exposed the corruption in the West Indian customs service. In 1751–58 he was lieutenant-governor of Virginia. He was energetic in the discharge of his duties, but aroused much animosity among the colonists by exacting heavy fees. It was his chief concern to prevent the French from building in the Ohio valley a chain of forts connecting their settlements in the north with those on the Gulf of Mexico; and in the autumn of 1753 he sent George Washington to Ft. Le Boeuf, a newly established French post at what is now Waterford, P a with a message

demanding the withdrawal of the French from English territory. As the French refused to comply, Dinwiddie in the spring of 1754 sent Washington with an armed force toward the forks of the Ohio river "to prevent the intentions of the French in settling those lands." In May Washington encountered a French force at Great Meadows, in what is now southwestern Pennsylvania, and a skirmish followed which precipitated the French and Indian War. Dinwiddie's appeals to the home government, however, resulted in the sending of General Edward Braddock to Virginia with two regiments of regular troops; and at Braddock's call Dinwiddia and other colonial governors met at Alexandria, Va., in April 1755, and planned the initial operations of the war. Dinwiddie's administration was marked by a constant wrangle with the assembly over money matters; and its obstinate resistance to military appropriations caused him in 1754 and 1755 to urge the home government to secure an act of parliament compelling the colonies to raise money for their protection. In Jan. 1758 he left Virginia and lived in England until his death at Clifton, Bristol, July 27, 1770.

The Official Records of Robert Dinwiddie, Lieutenant-Governor of Virginia (1751–58), published in two volumes, at Richmond, Va., in 1883–84, by the Virginia Historical Society, and edit. by R. A. Brock, are of great value for the political history of the colonies in this period.

DIO CASSIUS (more correctly CASSIUS DIO) **COCCEIANUS** (c. A.D. 150–23j), Roman historian, born at Nicaea in Bithynia. His father was Cassius Apronianus, governor of Dalmatia and Cilicia under Marcus Aurelius, and on his mother's side he was the grandson of Dio Chrysostom. After his father's death Dio Cassius went to Rome (180) and became a member of the senate. During the reign of Commodus, Dio practised as an advocate and held the offices of aedile and quaester. He was raised to the praetorship by Pertinax (193) but did not assume office till the reign of Septimius Severus, with whom he was for a long time on intimate terms. By Macrinus he was entrusted with the administration of Pergamum and Smyrna, and on his return to Rome he was made consul (c. 220). After this he obtained the proconsulship of Africa, and again on his return was sent as legate successively to Dalmatia and Pannonia. He was granted a second consulship by Alexander Severus, in 229, but soon afterwards retired to Nicaea, where he died. Before writing his history of Rome (*Romaika*), Dio Cassius had dedicated to Severus an account of various prodigies which had presaged his elevation to the throne (perhaps the Ἐνόδια attributed to Dio by Suidas), and had also written a biography of his fellow-countryman Arrian. The history of Rome, which is written in Greek, consisted of 80 books, beginning with the landing of Aeneas in Italy and ending with the reign of Alexander Severus (222–23j). We possess books 36–60 (68 B.C.—A.D. 47); books 36 and 55–60 are imperfect. We also have part of 35 and 36–80 in the epitome of John Xiphilinus, an 11th-century Byzantine monk. For the earlier period the loss of Dio's work is partly supplied by the history of Zonaras, who followed him closely. Numerous fragments are also contained in the excerpts of Constantine Porphyrogenitus. Dio's work is a most important authority for the history of the last years of the republic and the early empire. His industry was great and the various offices he held gave him opportunities for historical investigation. His narrative shows the hand of the practised soldier and politician; the language is correct and free from affectation. But his work, although far more than a mere compilation, is not remarkable for impartiality, vigour of judgment, or critical historical faculty.

The best edition with notes is that of H. S. Reimar (1750–52), new ed. by F. G. Sturz (1824–36); text by I. Melber (1890 foll.), with account of previous editions, and U. P. Boissevain (1895–1926); translations by H. B. Foster (Troy, New York, 1905 foll.), with full bibliography, and E. Cary (Loeb series, 1912); *see* also *W.* Christ, *Geschichte der Griechischen Literatur* (1898), p. 675; E. Schwartz in Pauly-Wissowa's *Realencyklopadie,* iii. pt. 2 (1899); C. Wachsmuth, *Einleitung in das Studium der alten Geschichte* (1895).

DIOCESE, the sphere of a bishop's jurisdiction (from Gr. *διοίκησις,* "house-keeping," "administration"). In this, its sole modern sense, the word diocese (dioecesis) has only been regularly used since the 9th century. The Greek word *διοίκησις,* from meaning "administration," came to be applied to the territorial circumscription in which administration was exercised. The word is equivalent to "assize-districts." But in the reorganization of the empire, begun by Diocletian and completed by Constantine, the word "diocese" acquired a more important meaning, the empire being divided into twelve dioceses, of which the largest—Oriens—embraced sixteen provinces, and the smallest—Britain—four (see ROME: Ancient History; and W. T. Arnold, *Roman Provincial* Administration, pp. 187, 194–196, which gives a list of the dioceses and their subdivisions). The organization of the Christian church in the Roman empire following very closely the lines of the civil administration (see CHURCH HISTORY), the word diocese, in its ecclesiastical sense, was at first applied to the sphere of jurisdiction, not of a bishop, but of a metropolitan. For exceptions see Hinschius ii. p. 39, note 1. The word, however, survived in its general sense of "office" or "administration," and it was even used during the middle ages for "parish" *(see* Du Cange, Glossarium, s. "Dioecesis" 2).

The practice, under the Roman empire, of making the areas of ecclesiastical administration very exactly coincide with those of the civil administration, was continued in the organization of the church beyond the borders of the empire, and many dioceses to this day preserve the limits of long vanished political divisions. The process is well illustrated in the case of English bishoprics. But this practice was based on convenience, not principle; and the limits of the dioceses, once fixed, did not usually change with the changing political boundaries. Thus Hincmar, archbishop of Reims, complains that not only his metropolitanate (dioecesis) but his bishopric (*parochia*) is divided between two realms under two kings; and this inconvenient overlapping of jurisdictions remained, in fact, very common in Europe until the readjustments of national boundaries by the territorial settlements of the 19th century. In principle, however, the subdivision of a diocese, in the event of the work becoming too heavy for one bishop, was very early admitted, *e.g.,* by the first council at Lugo in Spain (569), which erected Lugo into a metropolitanate, the consequent division of diocese being confirmed by the king of the second council, held in 572. Another reason for dividing a diocese, and establishing a new see, has been recognized by the church as duly existing "if the sovereign should think fit to endow some principal village or town with the rank and privileges of a city" (Bingham, lib. xvii. c. 5). But there are canons for the punishment of such as might induce the sovereign so to erect any town into a city, solely with the view of becoming bishop thereof. Nor could any diocese be divided without the consent of the primate.

In England an act of parliament is necessary for the creation of new dioceses. In the reign of Henry VIII. six new dioceses were thus created (under an act of 1539); but from that time onward until the 19th century they remained practically unchanged.

By the ancient custom of the church the bishop takes his title, not from his diocese, but from his see, *i.e.,* the place where his cathedral is established. Thus the old episcopal titles are all derived from cities.

See Hinschius, *Kirchenrecht,* ii. 38, etc.; Joseph Bingham, *Origines ecclesiasticae,* 9 vols. (1840); Du Cange, *Glossarium,* s. "Dioecesis"; *New English Dictionary* (Oxford, 1897), s. "Diocese."

DIO CHRYSOSTOM (the "golden-mouthed"), (c. A.D. 40–115), Greek sophist and rhetorician, was born at Prusa (mod. Brusa), a town at the foot of Mount Olympus in Bithynia. Although he did much to promote the welfare of his native place, he became so unpopular there that he migrated to Rome, but, having incurred the suspicion of Domitian, he was banished from Italy. He wandered about in Thrace, Mysia, Scythia and the land of the Getae. He returned to Rome on the accession of Nerva, with whom and his successor Trajan he was on intimate terms. During this period he paid a visit to Prusa, but, disgusted at his reception, he went back to Rome. The place and date of his death are unknown; it is certain, however, that he was alive in 112, when the younger Pliny was governor of Bithynia.

Eighty orations have come down to us under his name; the *Corinthiaca,* however, is generally regarded as spurious, and is probably the work of Favorinus of Arelate. Of the extant ora-

tions the following are the most important: *Borysthenitica* (xxxvi.), on the advantages of monarchy, addressed to the people of Olbia, and containing information about the Greek colonies on the Black sea; *Olympica* (xii.), in which Pheidias is represented as setting forth the principles which he had followed in his statue of Zeus. one passage being supposed by some to have suggested Lessing's *Laocoon; Rhodiaca* (xxxi.), an attack on the Rhodians for altering the names on their statues to those of famous men of the day; *De regno* (i.-iv.) addressed to Trajan and describing the stoic ideal kingship; *De Aeschylo et Sophocle et Euripide* (lii.), a comparison of the treatment of the story of Philoctetes by the three tragedians; and *Philoctetes* (lix.), a summary of the prologue to the lost play by Euripides. In his later life, Dio, who had originally attacked the philosophers, himself became a convert to Stoicism. To this period belong the essays on moral subjects, such as the denunciation of various cities (Tarsus, Alexandria) for their immorality. Most pleasing of all is the *Euboica* (vii.), a description of the simple life of the herdsmen and huntsmen of Euboea. Amongst his lost works were attacks on philosophers and Domitian, and *Getica,* an account of the manners and customs of the Getae.

Mahaffy in *The Greek World under Roman Sway* (1890), and there is a translation of *Select Essays* by Gilbert Wakefield (1800).

DIOCLETIAN (GAIUS AURELIUS VALERIUS DIOCLETIANUS) (A.D. 245–313), Roman emperor 284–305, is said to have been born at Dioclea, near Salona, in Dalmatia. His original name was Diocles. Of humble origin, he held important military commands under the emperors Probus and Aurelian, and accompanied Carus to the Persian War. After the death of Numerianus he was chosen emperor by the troops at Chalcedon, on Sept. 17, 284, and slew with his own hands Arrius Aper, the praefect of the praetorians. Having been installed at Nicomedia, he received general acknowledgment after the murder of Carinus. In consequence of the rising of the Bagaudae in Gaul, and the threatening attitude of the German peoples on the Rhine, he appointed Maximian Augustus in 286; and, in view of further dangers and disturbances in the empire, proclaimed Constantius Chlorus and Galerius Caesars in 293. Each of the four rulers was placed at a separate capital — Nicomedia, Mediolanum (Milan), Augusta Trevirorum (Trier), Sirmium. This amounted to an entirely new organization of the empire, on a plan commensurate with the work of government which it now had to carry on. Diocletian abdicated his sovereignty on May 1, 305, and retired to Salona, where he died eight years afterwards (others give 316 as the year of his death). The end of his reign was memorable for the persecution of the Christians. He hoped to strengthen the empire by reviving the old religion, and the church as an independent State appeared to be a standing menace to his authority.

Under Diocletian the senate became a political nonentity, the last traces of republican institutions disappeared, and were replaced by an absolute monarchy. He wore the royal diadem, assumed the title of lord, and introduced the whole ceremonial of Eastern monarchy. His first work was the reform of the administration of the empire; this is partly dealt with under ROME: *History,* and a brief summary is all that can be attempted here. The titular supremacy of Italy disappears, and a uniform system of administration comes into play throughout the empire. Beginning with Diocletian, local autonomy gradually disappears, and the empire is administered by a huge bureaucracy, entirely dependent on the emperor. The empire was sick of civil war and continual insecurity. and Diocletian and his successors saved it at the price of practically destroying its economic and political life. The old, regular, intricate system of taxation was abolished, and a simplified, but oppressive and inelastic system substituted, which was really a systematization of the practice of exacting forced contributions of produce and labour, based on acreage, which resulted in the country people becoming compulsorily tied to their land The responsibility for the city taxes was put on the members of the municipal councils. In the military sphere Diocletian only laid the foundations of the new system, which was the work of Constantine, but he took the first steps by largely increasing the numbers of the army. His attempted stabilization of prices *(see* DIOCLETIAN, EDICT OF) was a failure. In addition, he adorned the city with numerous buildings, such as the thermae, of which extensive remains are still standing *(see* AURELIUS VICTOR, *de Caesaribus* 39; Eutropius ix. 13; Zonaras xii., 31). The problem before Diocletian was much the same as that before Augustus but the conditions were much more unfavourable. "By his genius Augustus succeeded in restoring not only the State but also the prosperity of the people. Diocletian and Constantine sacrificed the interests of the people to the preservation of the State."

See M. Rostovtzev, *Social and Economic History of the Roman Empire* (1926); and ROME, *History.*

DIOCLETIAN, EDICT OF, an imperial edict (A.D. 301) fixing a maximum price for provisions and other articles, and a maximum rate of wages. Incomplete copies of it have been discovered, the first (in Greek and Latin) in 1709, at Stratonicea in Caria, containing the preamble and the beginning of the tables down to No. 403. A second fragment (now in the museum at Aix, in Provence) was brought from Egypt in 1809; it adds the titles of the emperors and Caesars, and the number of times they had held them, whereby the date can be determined. Other fragments have been found, *e.g.,* at Elatea, Plataea, and Megalopolis. Latin being the oflicial language all over the empire, there was no official Greek translation. All the fragments come from the provinces which were under the jurisdiction of Diocletian, *i.e.,* the eastern portion of the empire. No traces have been found in the western empire. The articles mentioned in the edict, giving their relative values at the time, include cereals, wine, oil, meat, vegetables, fruits, skins, leather, furs, foot-gear, timber, carpets, and articles of dress, and the wages range from those of the ordinary labourer to those of the professional advocate. The unit of money was a copper coin introduced by Diocletian, of which the value has been fixed at one-fifth of a penny. The punishment for exceeding the prices fixed was death or deportation. The edict was a well-intended but abortive attempt to meet the distress caused by several bad harvests and commercial speculation. The actual effect was disastrous, and the edict soon fell into abeyance.

See *Corpus Inscriptionum Latinarum;* Lactantius, *De mortibus persecutorum,* a contemporary who, as a Christian, writes with natural bias against Diocletian; J. E. Sandys, *Companion to Latin Studies* (1921), with useful bibliography. There is an edition of the whole edict by Mommsen, with notes by H. Blümner (1893).

DIODATI, GIOVANNI (1576–1649), Swiss Calvinist, was born in Geneva on June 6, 1576, of a refugee Protestant family from Lucca. In 1606 he became professor of theology, in 1608 pastor at Geneva, and in 1609 succeeded Beza as professor of theology. Diodati is chiefly famous for his Italian translation of the Bible (1603, edited with notes, 1607). He died at Geneva on Oct. 3, 1649.

Among his other works are his *Annotationes in Biblia* (1607, Eng. trans., 1648) and polemical treatises, such as *De fictitio Pontificiorum Purgatorio* (1619); *De iusta secessione Reformatorum ab Ecclesia Romana* (1628); *De Antichristo,* etc. He also published a French translation of his friend Sarpi's *History of the Council of Trent.*

DIODE, in radio, a type of vacuum tube containing two electrodes, which passes current wholly or predominantly in one direction, and which, therefore, may be used as a rectifier.

DIODORUS CRONUS (4th century B.C.), Greek philosopher'of the Megarian school. Practically nothing is known of his life. Diogenes Laertius (ii. 111) tells a story that, while staying at the court of Ptolemy Soter, Diodorus was asked to solve a dialectical subtlety by Stilpo. Not being able to answer on the spur of the moment, he was nicknamed ὁ Κρόνος (Father Time) by Ptolemy. The story goes that he died of shame at his failure. Strabo, however, says (xiv. 658; xvii. 838) that he took the name

from Apollonius, his master. He belonged to the Megarian school. His was the famous sophism known as the Κυριεύων. The impossible cannot result from the possible; a past event cannot become other than it is; but if an event, at a given moment, had been possible, from this possible would result something impossible; therefore the original event was impossible. From his great dialectical skill he earned the title ὁ διαλεκτικός or διαλεκτικώτατος.

See Cicero *De Fato*, 6, 7, 9; Aristotle *Metaphysica*, § 3; Sext. Empiric. *adv. Math.* x. 85; Ritter and Preller *Hist. philos. Gr. et Rom.* chap. v. §§ 234–236 (ed. 1869).

DIODORUS SICULUS, Greek historian, born at Agyrium in Sicily, lived in the times of Julius Caesar and Augustus. From his own statements we learn that he travelled in Egypt between 60–57 B.C. and that he spent several years in Rome. The latest event mentioned by him belongs to the year 21 B.C. His history, *Bibliotheca historica*, "Historical Library" consisted of forty books, and was divided into three parts. The first treats of the mythic history of the non-Hellenic, and afterwards of the Hellenic tribes, to the destruction of Troy; the second section ends with Alexander's death; and the third continues the history as far as the beginning of Caesar's Gallic War. Of this extensive work there are still extant only the first five books, treating of the mythic history of the Egyptians, Assyrians, Ethiopians and Greeks; and also the 11th to the 20th books inclusive, beginning with the second Persian War, and ending with the history of the successors of Alexander, previous to the partition of the Macedonian empire (302). The rest exists only in fragments preserved in Photius and the excerpts of Constantine Porphyrogenitus. The faults of Diodorus arise partly from the nature of the undertaking, and the annalistic form which he adopts. He lacks the critical faculty; he repeats and contradicts himself, and his simple diction, intermediate between pure Attic and the colloquial Greek of his time, enables us to detect the undigested fragments of the materials which he employed. Yet the *Bibliotlzeca* is of considerable value as supplying to some extent the loss of the works of older authors, from which it is compiled. Unfortunately, Diodorus does not always quote his authorities, but his general sources of information were in history and chronology, Castor, Ephorus and Apollodorus; in geography, Agatharchides and Artemidorus. In special sections he followed special authorities, *e.g.*, in the history of Sicily, Philistus and Timaeus.

Editio princeps, by *H.* Stephanus (1559); of other editions the best are: P. Wesseling (1746) not yet superseded; L. Dindorf (1828–31); (test) L. Dindorf (1866–68) (revised by F. Vogel, 1888–93 and C. T. Fischer, 1903–06). The standard works on the sources of Diodorus are C. G. Heyne, *De fontibus et auctoribus historiarum Diodori*, printed in Dindorf's edition, and C. A. Volquardsen, *Die Quellen der griechischen und sicilischen Geschichten bei Diodor* (1868); A. von Mess, *Rkeinisches Museum* (1906); see also L. O. Brocker, *Untersuchungen über Diodor* (1879), short, but containing much information; O. Maass, *Kleitarch und Diodor* (1894 etc.); G. J. Schneider, *De Diodori fontibus*, i.–iv. (1880); C. Wachsmuth, *Einleitung in das Studium der alten Geschichte* (1895); **GREECE:** *Ancient History*, "Authorities."

DIODOTUS, Seleucid satrap of Bactria, who rebelled against Antiochus II. (about 255) and became the founder of the Graeco-Bactrian kingdom (Trogus *Prol.* 41; Justin xli. 4, 5, where he is wrongly called Theodotus; Strabo xi. 515). His power seems to have extended over the neighbouring provinces. Arsaces, the chieftain of the nomadic (Dahan) tribe of the Parni, fled before him into Parthia and here became the founder of the Parthian kingdom (Strabo *l.c.*). When Seleucus II. in 239 attempted to subjugate the rebels in the east he seems to have united with him against the Parthians (Justin xli. 4, 9). Soon afterwards he died and was succeeded by his son Diodotus II., who concluded a peace with the Parthians (Justin *l.c.*). Diodotus II. was killed by another usurper, Euthydemus (Polyb. xi. 34, 2). Of Diodotus I. we possess gold and silver coins, which imitate the coins of Antiochus II.; on these he sometimes calls himself Soter, "the saviour." As the power of the Seleucids was weak and continually attacked by Ptolemy II., the eastern provinces and their Greek cities were exposed to the invasion of the nomadic barbarians and threatened with destruction (Polyb. xi. 34, 5); thus the erection of an independent kingdom may have been a necessity and indeed an advantage to the Greeks, and this epithet well deserved. Diodotus Soter appears also on coins struck in his memory by the later Graeco-Bactrian kings Agathocles and Antimachus. *Cf.* A. v. Sallet *Die Nachfolger Alexanders d. Gr. in Baktrien und Indien;* Percy Gardner *Catal. of the Coins of the Greek and Scythian Kings of Bactria and India* (Brit. Mus.); *see* also BACTRIA. (ED. M.)

DIOGENES, "the Cynic," Greek philosopher, was born at Sinope about 412 B.C., and died in 323 at Corinth, according to Diogenes Laertius, on the day on which Alexander the Great died at Babylon. When his father was exiled Diogenes was included in the charge and went to Athens. Attracted by the zscetic teaching of Antisthenes, he became his pupil, and rapidly excelled his master both in reputation and in the austerity of his life. The stories which are told of him are probably true; in my case, they serve to illustrate the logical consistency of his character. He inured himself to the vicissitudes of weather by living in a tub belonging to the temple of Cybele. The single wooden bowl he possessed he destroyed on seeing a peasant boy drink from the hollow of his hands. On a voyage to Aegina he was captured by pirates and sold as a slave in Crete to a Corinthian named Xeniades. Being asked his trade, he replied that he knew no trade but that of governing men, and that he wished to be sold to a man who needed a master. As tutor to the two sons of Xeniades, he lived in Corinth for the rest of his life, which he devoted entirely to preaching the doctrines of self-control. It was, probably, at the Isthmian games, during which he used to lecture, that he craved from Alexander the single boon that he would not stand between him and the sun, to which Alexander replied "If I were not Alexander, I would be Diogenes." On his death the Corinthians erected to his memory a pillar on which there rested a dog of Parian marble. His ethical teaching will be found in the article CYNICS (*q.v.*). It may suffice to say here that virtue, for him, consisted in the avoidance of all physical pleasure; that pain and hunger were positively helpful in the pursuit of goodness; that morality implies a return to nature and simplicity. Both in ancient and in modern times, his personality has appealed strongly to sculptors and to painters. Ancient busts exist in the museums of the Vatican, the Louvre and the Capitol. The interview between Diogenes and Alexander is represented in an ancient marble bas-relief found in the Villa Albani.

The chief ancient authority for his life is Diogenes Laertius vi. 20; *see* also Mayor's notes on Juvenal, *Satires*, xiv. 308–314; *Quellen-Untersuchungen z. Leben u. Philosophie des Diogenes von Sinope* (*Philolojus*, Supplementband 18, 1926).

DIOGENES APOLLONIATES (c. 460 B.C.), Greek natural philosopher, was a native of Apollonia in Crete. Although of Dorian stock, he wrote in the Ionic dialect, like all the *physiologi* (physical philosophers). He moved to Athens, where his opinions once endangered his life. It is his theories that are ridiculed as those of Socrates in the Clouds (264 ff.). An eclectic in doctrine, he drew his views from many sources but his main position is a reconciliation of the theories of Anaximenes and Anaxagoras, which he achieved by taking Anaximenes' theory that air is the one source of being and attributing intelligence to it as well. His most important work was Περὶ φύσεως (*De natura*), of which considerable fragments are extant (chiefly in Simplicius); it is possible that he wrote also *Against the Sophists* and *On the Nature of Man,* to which the well-known fragment about the veins would belong; possibly these discussions were subdivisions of his great work.

Fragments in F. Mullach, *Fragmenta philosophorum Graecorum*, i. (1860); F. Panzerbieter, *Diogenes Apolloniates* (1830), with philosophical dissertation; J. Burnet, *Early Greek Philosophy* (1892); *H.* Ritter and L. Preller, *Historia Phitosophiae* (4th ed., 1869), §§ 59–68; E. Krause, *Diogenes von Apollonia* (1909).

DIOGENES LAËRTIUS (or LAËRTIUS DIOGENES), the biographer of the Greek philosophers, is supposed by some to have received his surname from the town of Laertc in Cilicia, and by others from the Roman family of the Laertii. Of the circum-

stances of his life we know nothing. It is probable that he flourished during the reign of Alexander Severus (A.D. 222–235) and his successors. His own opinions are equally uncertain. By some he was regarded as a Christian; but it seems more probable that he was an Epicurean. The work by which he is known deals with the lives and sayings of the Greek philosophers. Of no philosophical value itself, its interest lies in the glimpses given of the private life of the philosophers. He treats his subject in two divisions which he describes as the Ionian and the Italian schools. The biographies of the former begin with Anaximander, and end with Cleitomachus, Theophrastus and Chrysippus; the latter begins with Pythagoras, and ends with Epicurus. The Socratic school, with its various branches, is classed with the Ionic; while the Eleatics and sceptics are treated under the Italic. The whole of the last book is devoted to Epicurus, and contains three most interesting letters addressed to Herodotus, Pythocles and Menoeceus. The text seems once to have been much fuller than that now in existence. In addition to the *Lives*, Diogenes was the author of a work in verse on famous men, in various metres.

BIBLIOGRAPHY.—*Editio princeps* (1533); H. Hübner and C. Jacobitz with commentary (1828–33); C. G. Cobet (1850), text only. *See* F. Nietzsche, "De Diogenis Laertii fontibus" in Rheinisches *Museum*, xxiii., xxiv. (1868–69); J. Freudenthal, "Zu Quellenkunde Diog. Laert.," in *Hellenistische Studien*, iii. (1879); O. Maass, De biographis Graecis (1880); V. Egger De fontibus Diog. Laet. (1881). There is an English trans. by C. D. Yonge in Bohn's Class. Lib.

DIOGENIANUS, of Heraclea on the Pontus (or in Caria), Greek grammarian, flourished during the reign of Hadrian. He was the author of a lexicon (sometimes known as περιεργοπένητες for "industrious poor students") which was perhaps abridged from the great lexicon of Pamphilus of Alexandria (*fl.* A.D. 50) and other similar works. It formed the basis of the lexicon of Hesychius of Alexandria, described in the preface as a new edition of the works of Diogenianus. We still possess a collection of proverbs under his name (ed. by E. Leutsch and F. W. Schneidewin in *Paroemiographi Graeci*, i. 1830). Diogenianus was also the author of an anthology of epigrams; of geographical treatises; and of a list (with map) of all the towns in the world.

See H. Weber, *Philol. Suppl.* III., 454 f. (1878); Bursian's Jahresb. xvii., 125 (1881).

DIOGNETUS, EPISTLE TO, one of the early Christian apologies. Diognetus, of whom nothing is known, has expressed a desire to know what Christianity really means—"What is this new race" of men who are neither pagans nor Jews? "What is this new interest which has entered into men's lives now and not before?" The anonymous writer, after attacking idolatry and the ceremonials of Judaism in the usual way, proceeds in a passage of great eloquence to show that Christians have no obvious peculiarities that mark them off as a separate race. In spite of blameless lives they are hated. Their home is in heaven, while they live on earth. "In a word, what the soul is in a body, this the Christians are in the world. . . . The soul is enclosed in the body, and yet itself holdeth the body together: so Christians are kept in the world as in a prison-house, and yet they themselves hold the world together." This strange life is inspired in them by the almighty and invisible God, who sent no angel or subordinate messenger to teach them, but His own Son by whom He created the universe. No man could have known God, had He not thus declared Himself. "If thou too wouldst have this faith, learn first the knowledge of the Father. For God loved men, for whose sake He made the world. . . . Knowing Him, thou wilt love Him and imitate His goodness; and marvel not if a man can imitate God: he can, if God will." By kindness to the needy, by giving them what God has given to him, a man can become "a god of them that receive, an imitator of God." No early Christian writing outside the New Testament appeals so much to modern readers. The best edition is that of Otto, *Corpus Apologeticum*, vol. iii. (3rd ed. 1879), based on accurate collations of the one ms. which contained this letter and which perished by fire at Strasbourg in 1870

See also Lightfoot, Apostolic Fathers (shorter edition), and (very conveniently) Kirsopp Lake, Apostolic Fathers, vol. ii. (in Loeb Classical Library).

DIOMEDEIDAE: *see* ALBATROSS.

DIOMEDE ISLANDS, two small adjacent islands in the Bering strait. The larger, Big Diomede, belongs to the U.S.S.R.; the other, Little Diomede, is a part of Alaska. They were sighted by Vitus Bering Aug. 16, 1728.

DIOMEDES, Latin grammarian, flourished at the end of the 4th century A.D., author of an extant *Ars grammatica* in three books. The third book is the most important, as containing extracts from Suetonius' *De poetis*. Diomedes wrote about the same time as Charisius (*q.v.*) and used the same sources independently.

The best edition is in H. Keil's *Grammatici* Latini, i.; see also C. von Paucker, Kleinere *Studien*, i. (1883), on the Latinity of Diomedes.

DIOMEDES, in Greek legend, son of Tydeus (*q.v.*); in Homer one of the bravest of the heroes of the Trojan War. In the post-Homeric story, he and Odysseus steal the Palladium, the presence of which within the walls secured Troy against capture (Virgil, *Aeneid*, ii. 164). On his return to Argos, finding that his wife had been unfaithful, he removed to Aetolia, and thence to Daunia (Apulia), where he married the daughter of King Daunus. He was buried or mysteriously disappeared on one of the islands in the Adriatic called after him Diomedeae, where his companions were turned into birds (Ovid, *Metam.* xiv. 457 ff.). He was worshipped as a hero in Greece, and on the coast of the Adriatic.

DION (408–353 B.C.), tyrant of Syracuse, the son of Hipparinus, and brother-in-law of Dionysius the Elder. He was a friend of Plato, who had visited the court of the elder Dionysius, and whom Dion now summoned to teach the theory of government to Dionysius' son. But the historian Philistus set Dion at variance with the tyrant, and procured his banishment on a charge of intriguing with the Carthaginians. Dion remained awhile at Athens, but in 357, assembling a small force at Zacynthus, he sailed to Sicily and was received with demonstrations of joy. Dionysius, who was in Italy, returned to Sicily, but was defeated and obliged to flee. Dion himself was soon after banished through the intrigues of Heracleides (356). But the incompetence of the new leader soon led to Dion's recall; Heracleides submitted, and soon afterwards the supporters of Dionysius surrendered. Dion retained the tyranny, but in 353 he was assassinated by Callippus, an Athenian who had accompanied him in his expedition.

See *Lives* by Plutarch and Cornelius Nepos (cf. Diod. Sic. xvi. 6–20) and in modern times by T. Lau (1860); Freeman, History of Sicily (vol. iv.) (1894); and *Camb. Anc. Hist.*, vol. vi., ch. x. with bibliography; see also SYRACUSE and SICILY: History.

DIONAEA: *see* VENUS'S FLY-TRAP.

DIONE, cult-partner of Zeus of Dodona (Strabo vii, 329). As the partner and wife of Zeus is normally Hera, Dione was variously described: in the *Iliad* (v. 370) as mother by Zeus of Aphrodite; in Hesiod (Theog. 353) as a daughter of Oceanus

DIONNE, NARCISSE EUTROPE (1848–1917), Canadian author and librarian, was born at Saint-Denis de la Bouteillerie. He studied at St. Anne's college, at the Quebec grand seminary and at Laval university, where he graduated in medicine. He became editor of *Le Courrier du Canada* and then of *Le Journal de Québec*, and in 1892 chief librarian of the Quebec legislature. He has published *Jacques Cartier* (1889); *La Vie de C. F. Painchaud* (1894); *Les ecclésiastiques et les royalistes français réfugiés au Canada à l'époque de la révolution, 1791–1802* (1905); *Champlain* (1905); *Québec et Nouvelle France. Bibliographie* (4 tom., 1905–12); and in the *Galerie Historique* series of 1910 his chief studies are *Chouart et Radisson; J. Richard, Sulpicien; Mgr. de Forbin-Jamon; Sainte-Anne de la Pocatière* and *Pierre Bédard*.

DIONNE QUINTUPLETS, five phenomenal daughters of Oliva and Elzire Dionne, born near Callander, Ontario, May 28th, 1934. The attending physician was Dr. Allan Dafoe. These children, weighing collectively but 11½ pounds six days after their premature birth, were rescued from the hazards and handicaps of freak exploitation by the Government of Ontario, which made them King's wards. Against all precedent, the five continued to thrive through childhood. *See* plate, TWINS AND TWINNING

DIONYSIA, festivals of Dionysus (*q.v.*). These were numerous and widespread, the most famous being those of Attica, which were (1) the Little or Rustic Dionysia, a festival held in various country places in the month Poseideon (December), characterized by simple, old-fashioned rites; (2) the Lenaea ("festival of Maenads"), in the following month, Gamelion, held at Athens; the chief rites were a festal procession and dramatic performances at the theatre of Dionysus; (3) the Anthesteria (*q.v.*), in the next month, Anthesterion; (4) The Great or City Dionysia, in Elaphebolion (about the end of March), also accompanied by dramatic performances (see DRAMA), and the most famous of all; (5) the Oschophoria ("Carrying of Grape-clusters"), in Pyanepsion (about the end of October). The times and what we know of the ritual of these festivals show them to have been originally rites of a kind common in the worship of gods of fertility.

See A. Mommsen, Feste d. Stadt *Athen* (1898); L. R. Farnell, Cults of *the* Greek States (1896–1919) v., ch. vi.

DIONYSIUS, pope from 259 to 268. To Dionysius fell the task of reorganizing the Church after the persecution of Valerian. At the protest of some of the faithful at Alexandria, he demanded from their bishop (also called Dionysius) explanations touching his doctrine. He died on Dec. 26, 268.

DIONYSIUS (c. 432–367 B.C.), tyrant of Syracuse, began life as a clerk in a public office, but took advantage of war with Carthage to seize the tyranny (405). The next eight years were spent in strengthening his power. He fortified Epipolae (402), defeated his political opponents, and removed the Greek citizens of Naxos, Catana, and Leontini, handing the cities over to foreign mercenaries and Sikels. His first Punic War (397–396), during which the Greeks besieged Motya, and the Carthaginians Syracuse, ended with a notable victory, and Carthage's power in Sicily was confined to the north-west. His second war in 392 was ended by a treaty greatly in his favour. In 391 he led an expedition against Rhegium and its allied cities in Magna Graecia. In one campaign in which he was joined by the Lucanians, he devastated the territories of Thurii, Croton, and Locri. After a protracted siege he took Rhegium (386), thus making himself the chief power in Greek Italy. At the next Olympic festival (384), whither he sent a splendid embassy, the Athenian Lysias attacked him in a speech (Or. 33) and the crowd pillaged the tents of his envoys.

His third Punic War (383–378) proved disastrous; he suffered a crushing defeat and was obliged to pay an indemnity of 1,000 talents and cede to Carthage the territory west of the River Halykas. He was engaged in another war against Carthage when he died. He had friendly relations with the Spartans, whom he assisted more than once with mercenaries, and two inscriptions record his alliance with Athens (369–367). The success of his tragedy at the Lenaea (367) is probably to be connected with this friendship; though he had frequently competed at Athens he had never till now won a first prize. Dionysius reigned 38 years, and was succeeded by his son. Freeman says of him: "He had destroyed the freedom of his native city, but he had made it both the greatest city and the greatest power in Europe." (See SICILY and SYRACUSE.)

See Diod. Sic. xiii, xiv., xv. (the earlier part based on Philistos, Dionysius' friend and contemporary); Freeman *Hist.* of Sicily (Vols. iii. and iv.) (Oxford, 1894); Camb. *Anc. Hist.* Vol. vi. ch. v., with bibliography; J. Bass Dionysius *I.* von *Syrakus* (Vienna, 1881), with full refs. to authorities.

His son DIONYSIUS, known as "the Younger," succeeded in 367 B.C. He mas driven from the kingdom by Dion (356) and fled to Locri; but during the commotions which followed Dion's assassination, he managed to make himself master of Syracuse. On the arrival of Timoleon he was compelled to surrender and retire to Corinth (343). (Diodorus Siculus. xvi.; Plutarch, Timoleon.)

See SYRACUSE and TIMOLEON; and, on both the Dionysii, arts. by B. Niese in Pauly-Wissowa's *Realencyklopädie,* v. pt. I. (1905).

DIONYSIUS AREBPAGITICUS (or "The Areopagite"), named in Acts xvii 34 as one of those Athenians who believed when they had heard Paul preach on Mars Hill. Beyond this mention our only knowledge of him is the statement of Dionysius, bishop of Corinth (*fl.* 171), recorded by Eusebius (Church *Hist.* iii. 4; iv. 23), that this same Dionysius the Areopagite was the first "bishop" of Athens. Some hundreds of years afterwards his name was attached to a number of anonymous theological writings of unknown origin. These were destined to exert enormous influence on mediaeval thought, and their form led to a great development of the personal legend of the original Dionysius (see for example, "The Life and Passion of the Most Holy Dionysius," by Hildwin, abbot of St. Denys, printed in Migne, *Patrologia* Latina, vol. 106).

The author, date and place of composition of these writings are alike unknown. External evidence precludes a date later than 500; the internal evidence from the writings themselves precludes any date prior to 4th-century phases of Neo-platonism, while the first certain dated reference to them is at the Council of Constantinople in 533. The extant writings of the Pseudo-Areopagite are: (a) Περὶ τῆς οὐρανίας ἱεραρχίας, *Concerning* the Celestial Hierarchy, in 15 chapters; (b) Περὶ τῆς ἐκκλησιαστικῆς ἱεραρχίας, Concerning the Ecclesiastical Hierarchy, in 7 chapters; (c) Περὶ θείων ὀνομάτων, Concerning Divine Names, in 13 chapters; (d) Περὶ Μυστικῆς θεολογίας, Concerning Mystic Theology, in five chapters; (e) ten letters addressed to various worthies of the apostolic period. They are all of great interest, first as a striking presentation of the heterogeneous elements that might unite in the mind of a gifted man in the 5th century, and secondly, because of their enormous influence upon subsequent Christian theology and art. Their ingredients—Christian, Greek, Oriental and Jewish—are united into an organic system, not crudely mingled. Perhaps theological philosophic fantasy has never constructed anything more remarkable. The system of Dionysius was a proper product of its time—lofty, and apparently complete.

His constructive principles the writer owed to Hellenism in its last great philosophical creation, Neo-platonism, since the general principle of the transmission of life from the ultimate Source downward through orders of mediating beings unto men might readily be adapted to the Christian God and his ministering angels. Pseudo-Dionysius had lofty thoughts of the sublime transcendence of the ultimate divine Source. That Source was not remote or inert; but a veritable Source from which life streamed to all lower orders of existence,—in part directly, and in part indirectly as power and guidance through the higher orders to the lower. Life, creation, every good gift, is from God directly; but his flaming ministers also intervene to guide and aid the life of man; and the life which through love floods forth from God has its counterflow whereby it draws its own creations to itself. God is at once absolutely transcendent and universally immanent. To live is to be united with God; evil is the non-existent, that is, severance from God.

The transcendent Source, as well as the universal immanence, is the Triune God. Between that and men are ranged the three triads of the celestial hierarchy: Seraphim, Cherubim and Thrones; Dominations, Virtues, Powers; Principalities, Archangels, Angels. Collectively their general office is to raise mankind to God through purification, illumination and perfection; and to all may be applied the term angel. The highest triad, which is nearest God, contemplates the divine effulgence, and reflects it onward to the second; the third, and more specifically angelic triad, immediately ministers to men. The sources of these names are evident: seraphim and cherubim are from the Old Testament; later Jewish writings gave names to archangels and angels, who also fill important functions in the New Testament. The other names are from Paul (Eph. i. 21; Col. i. 16).

Such is the system of Pseudo-Dionysius, as presented mainly in The Celestial Hierarchy. That work is followed by *The* Ecclesiastical Hierarchy, its counterpart on earth. What the primal Triune Godhead is to the former, Jesus is to the latter. The ecclesiastical hierarchy likewise is composed of triads. The first includes the symbolic sacraments: Baptism, Communion, Consecration of the Holy Chrism. Baptism signifies purification; Communion signifies enlightening; the Holy Chrism signifies perfecting. The second is made up of the three orders of Bishops, Presbyters and

Deacons, or rather, as the Areopagite names them: Hierarchs, Light-bearers, Servitors. The third triad consists of monks, who are in a state of perfection, the initiated laity, who are in a state of illumination, and the catechumens, in a state of purification. All worship, in this treatise, is a celebration of mysteries, and the pagan mysteries are continually suggested.

Concerning the Divine Names is a noble discussion of the qualities which may be predicated of God, according to the warrant of the terms applied to him in Scripture. *Concerning Mystic Theology* explains the function of symbols, and shows that he who would know God truly must rise above them.

The works of Pseudo-Dionysius began to influence theological thought in the West from the time of their translation into Latin by Erigena (*q.v.*). Their use may be followed through the writings of scholastic philosophers, *e.g.*, Peter Lombard, Albertus Magnus, Thomas Aquinas and many others. The fifteenth chapter of *The Celestial Hierarchy* constituted the canon of symbolical angelic lore for the literature and art of the middle ages.

BIBLIOGRAPHY.—There is an enormous literature on Pseudo-Dionysius. The reader may be first referred to the articles in Smith's *Dictionary of Christian Biography* and Herzog-Hauck *Realencyklopädie fiür protestantische Theologie.* The bibliography in the latter is very full. Some other references, especially upon the later influence of these works, are given in H. O. Taylor's *Classical Heritage of the Middle Ages* (1903). The works themselves are in Migne's *Patrologia Graeca,* tomes 3 and 4, with a Latin version. Erigena's version is in Migne, *Patrol. Lat.* t. 122.

DIONYSIUS EXIGUUS, a scholar of the 6th century, was, according to the statement of his friend Cassiodorus, a Scythian by birth. He was living at Rome in the first half of the 6th century, and is usually spoken of as abbot of a Roman monastery though Cassiodorus calls him simply "monk." He was in high repute as a theologian, was profoundly versed in the Holy Scriptures and in canon law, and was also an accomplished mathematician and astronomer. We owe to him a collection of 401 ecclesiastical canons, including the apostolical canons and the decrees of the Councils of Nicaea, Constantinople, Chalcedon and Sardis, and also a collection of the decretals of the popes from Siricius (385) to Anastasius II. (498) These collections, which had great authority in the West *(see* CANON LAW), were published by Justel in 1628. Dionysius translated many Greek works now lost, including *Life of St. Pachomius,* and the *Instruction of St. Proclus of Constantinople.* He introduced the method of reckoning the Christian era which we now use *(see* CHRONOLOGY). He died at Rome, some time before A.D. 550.

His works have been published in Migne, *Patrol. Lat.* v. 67; *see* A. Tardif, *Histoire des sources du droit canonique* (1887); D. Pitra, *Analecta novissima, Spicilegii Solesmesis continuatio,* vol. i. p. 36 (1885); Bardenhewer; *Gesch. der Altkirch. Lit.* (Freiburg, 1902).

DIONYSIUS HALICARNASSENSIS ("of Halicarnassus"), Greek historian and teacher of rhetoric, flourished during the reign of Augustus. He went to Rome after the end of the civil wars and spent 22 years in studying Latin and preparing materials for his history. The date of his death is unknown. His great work, entitled Ῥωμαϊκὴ ἀρχαιολογία (Roman Antiquities), embraced the history of Rome from the mythical period to the beginning of the first Punic War. It was divided into 20 books, of which the first nine remain entire, the tenth and eleventh are nearly complete, and the remainder exist in fragments in the excerpts of Constantine Porphyrogenitus and an epitome discovered by Angelo Mai in a Milan ms. The first three books of Appian and Plutarch's *Life of Camillus* also embody much of Dionysius. His chief object was to reconcile the Greeks to the rule of Rome by dilating upon the good qualities of their conquerors. He has carefully consulted the best authorities, and his work and that of Livy are the only connected and detailed extant accounts of early Roman history.

Dionysius was also the author of several critical treatises: *The Arrangement of Words; On Imitation,* on the best models in the different kinds of literature—a fragmentary work; *Commentaries on the Attic Orators,* dealing with Lysias, Isaeus, Isocrates and (by way of supplement), Deinarchus; *On the admirable Style of Demosthenes; On Thucydides,* a detailed but rather unfair criticism of his treatment of subject matter and his style and two *letters to Ammaeus* dealing with Demosthenes and Thucydides, and the *Letter to Cn. Pompeius,* dealing with Plato.

BIBLIOGRAPHY.—Complete edition by J. J. Reiske (1774–77); of the *Archaeologia* by A. Kiessling and V. Prou (1886) and C. Jacoby (1885–91); Opuscula by Usener and Radermacher (1899); Eng. translation by E. Spelman (1758). A full bibliography of the rhetorical works is given in W. Rhys Roberts's edition of the Three Literary Letters (1901); the same author published an edition of the *De compositione verborum* (1910, with trans.); *see* also M. Egger, *Denys d'Halicarnasse* (1902), a very useful treatise. On the sources of Dionysius *see* 0. Bocksch, "De fontibus Dion. Halicarnassensis" in *Leipziger Studien,* xvii. (1895). Cf. also J. E. Sandys, *Hist. of Class. Schol.* i. (1906).

DIONYSIUS OF ALEXANDRIA (*c.* 190–265), bishop of Alexandria, called "Dionysius the Great," became a Christian when young and studied under Origen. In 231 he was made head of the Catechetical school of Alexandria, and in 247 bishop of that city. During the Decian persecution in 251 he fled to the Libyan desert, while under Valerian he was banished to Cephro in 257, returning when toleration was decreed by Gallienus in 260. He was engaged in controversy over the restoration of Christians who had lapsed during the persecution, and over the iteration of baptism by heretics. In opposing the bishops of Upper Libya who supported Sabellianism, Dionysius overemphasized the unity of the Godhead. He had to express his orthodoxy in *Refutation and Defence.* Eusebius in *Hist. Eccl.* often cites him, and in *Praep. Evang.* xiv. quotes some fragments of the On *Nature.* The fragments were edited by Simon De Magistris, S. *Diony. Alex. Opera Omnia* (Rome, 1796), by Migne, *Pat. Graeca,* x., and C. L. Feltoe, *Letters and other Remains of Dionysius* of *Alexandria* (Cambridge, 1904; Eng trans. 1918). *See* also Dittrich, *Dionysius der Grosse* (Frieburg i. B., 1867) and J. Burel, *Denys d'Alexandrie* (1910).

DIONYSIUS PERIEGETES, author of a Περιήγησις τῆς οἰκουμένης, a description of the habitable world in Greek hexameters. There is some reason for believing that the author was an Alexandrian, who wrote in the time of Hadrian (some put him as late as the end of the 3rd century). The work was popular in ancient times as a school-book; it was translated into Latin by Rufus Festus Avienus, and by the grammarian Priscian. The commentary of Eustathius is valuable.

The best editions are by G. Bernhardy (1828) and C. Muller (1861) in their *Geographici Graeci minores; see* also E. *H.* Bunbury, *Ancient Geography* (ii. p. 480), who regards the author as flourishing from the reign of Nero to that of Trajan, and U. Bernays, *Studien zu Dion. Perieg.* (1905). There are two old English translations: T. Twine (1572, black letter), J. Free (1789, blank verse).

DIONYSIUS TELMAHARENSIS ("of Tell-Maḥrē") d. 848, patriarch or supreme head of the Syrian Jacobite Church during 818–848, was born at Tell-Maḥrē near Rakka (ar-Rakkah) on the Balikh. He was the author of an important historical work, which has perished except for some passages quoted by Barhebraeus and an extract found by Assemani in Cod. *Vat.* 144 and published by him in the *Bibliotheca orientalis* (ii. 72–77). He spent his earlier years as a monk at the convent of Ken-neshrē on the upper Euphrates, and later moved to that of Kaisūm in the district of Samosāta. At the death of the Jacobite patriarch Cyriacus in 817, the Church was disputing the phrase "heavenly bread" in connection with the Eucharist. An anti-patriarch had been appointed in the person of Abraham Kartamin, who insisted on the use of the phrase in opposition to the recognized authorities of the Church. The council of bishops at Raḳḳa in 818 elected Dionysius to the patriarchal chair, but the ecclesiastical schism continued unhealed during the 30 years of his patriarchate. The details of this contest, of his relations with the caliph Ma'mūn, and of his many travels—including a journey to Egypt—are to be found in the *Ecclesiastical Chronicle* of Barhebraeus. He died in 848, his last days having been especially embittered by Mohammedan oppression.

In addition to the lost *Annals,* covering the years from the accession of the emperor Maurice (582–583) lo the death of Theophilus (842–843), Dionysius was credited with the authorship

of a *Chronicle* narrating the history of the world from the creation to the year A.D. 774–775, but on the completion of its publication by M. Chabot in 1895, Noldeke (Vienna *Oriental Journal*, x. 160–170), and Nau (*Bulletin critique*, xvii. 321–327), clearly proved that the chronicle was the work not of Dionysius but of an earlier writer, a monk of the convent of Zuknin near Amid (Diarbekr) on the upper Tigris. Though the author had limited intelligence and little historical skill, the last part of his work has considerable value as a contemporary account of events during the middle of the 8th century.

See W. Wright, *Hist.* of Syriac Literature (1894), and Chabot's introduction to his translation of pt. iv. of the Chronicle.

DIONYSIUS THRAX (so called because his father was a Thracian), the author of the first Greek grammar, flourished about 100 B.C. He was a native of Alexandria, where he attended the lectures of Aristarchus, and afterwards taught rhetoric in Rhodes and Rome. His grammar, which we possess (though probably not in its original form), begins with the definition of grammar and its functions. Dealing next with accent, punctuation marks, sounds and syllables, it goes on to the eight parts of speech and their inflections. No rules of syntax are given, and nothing is said about style. The authorship of Dionysius was doubted in the middle ages, and in modern times its origin has been attributed to the oecumenical college founded by Constantine the Great, which existed till 730. But there seems no reason for doubt; the great grammarians of imperial times (Apollonius Dyscolus and Herodian) knew the work in its present form, although additions and alterations may have been made later. Dionysius also wrote commentaries on Homer and Hesiod and various other works, including an account of Rhodes, and a collection of Μελέται (literary studies), to which the considerable fragment in the *Stromata* (v. 8) of Clement of-Alexandria probably belongs. The grammar, first edited by J. A. Fabricius from a Hamburg ms., was published in his *Bibliotheca* Graeca, vi. (ed. Harles). An Armenian translation, belonging to the 4th or 5th century, containing five additional chapters, was published with the Greek text and a French version, by M. Cirbied (1530).

Editions, with scholia, by I. Bekker in *Anecdota Graeca*, ii. and G. Uhlig (1884), reviewed exhaustively by P. Egenolff in Bursian's *Jahresbericht*, vol. xlvi. (1888); Scholia, ed. A. Hilgard (1901); Eng. trans. J. Davidson, 1874; see also W. Horschelmann, De Dionysii *Thracis interpretibus veteribus* (1874); J. E. Sandys, *Hist.* of Classical Scholarship, i. (1906).

DIONYSUS, in Greek mythology originally a nature god of fruitfulness and vegetation, especially of the vine; hence, distinctively, the god of wine. [Gr. Διόνυσος, Διώνυσος; Thracian, Zōnnyxos; Phrygian, Diounsis: etymology doubtful; *?dio-*, name of Thraco-Phrygian sky-god resembling Zeus; *nys-*, possibly akin to Lat. *nurus*, Gr. νυός, and may mean "child" or "son"; hence perhaps "son of God." The names Bacchus (Βάκχος, in use among the Greeks from the 5th century), Sabazius, and Bassareus, are also Thracian names of the god. All are of doubtful significance; for various interpretations of these and other cult-titles *see* O. Gruppe, Griechische *Mythologie*, ii. pp. 1408, 1532, especially the notes.]

There seems little doubt that he is a Thraco-Phrygian deity, introduced into Greece from Thrace or possibly from both Thrace and Phrygia, and, blending with native gods of similar character, *e.g.*, Iacchus at Eleusis. In Homer, notwithstanding the frequent mention of the use of wine, Dionysus is never mentioned as its inventor or introducer, nor does he appear in Olympus; Hesiod is the first who calls wine the gift of Dionysus. On the other hand, he is spoken of in the Iliad (vi. 130 foll.), as "raging," an epithet that indicates that already the orgiastic character of his worship was recognized. In his native country his worshippers sought to become possessed by or assimilated to him by wild dancing and perhaps the use of intoxicants; in Greece this was much toned down. According to the usual tradition, he was born at Thebes and was the son of Zeus and Semele, the daughter of Cadmus. Before the child was mature, Zeus appeared to Semele, whose name is simply the Phrygian for "earth" (*Zemelo*), at her request in his majesty as god of lightning, by which she was killed, but the infant was saved from the flames by Zeus (or Hermes). Zeus took him up, enclosed him within his own thigh till he came to maturity, and then brought him to the light, so that he was twice born; an allusion to this was found in the word dithyrambos, a name of the god and of a hymn in his honour, which perhaps is really to be connected with Phrygian *dithrera*, a tomb. (See Calder in Class. Rev., xxxvi., p. 11. ff. xli. p. 161 ff.) Dionysus was then conveyed by Hermes to be brought up by the nymphs of Nysa, a purely imaginary spot. As soon as Dionysus was grown up, he started on a journey through the world, to teach the cultivation of the vine and spread his worship among men. While so engaged he met with opposition, even in his own country, as in the case of Pentheus, king of Thebes, who opposed the orgiastic rites introduced by Dionysus among the women of Thebes, and, having been discovered watching one of these ceremonies, was mistaken for some animal of the chase, and slain by his own mother. A similar instance is that of Lycurgus, a Thracian king, from whose attack Dionysus saved himself by leaping into the sea, where he was kindly received by Thetis. Lycurgus was blinded by Zeus and soon died, or became frantic and hewed down his own son, mistaking him for a vine. At Orchomenus, the three daughters of Minyas refused to join the other women in their nocturnal orgies, and for this were transformed into birds. (*See* AGRIONIA.) These and similar stories may point to the vigorous resistance offered to the introduction of the mystic rites of Dionysus or to some ceremony in which the god, or a priest representing him, was killed and probably brought to life again. *See* below. On the other hand, when the god was received hospitably he repaid the kindness by the gift of the vine, as in the case of Icarius of Attica (see ERIGONE).

The worship of Dionysus continued to flourish in Asia Minor, particularly in Phrygia and Lydia. His cult is closely associated with that of numerous Asiatic deities, as Sabazius (*q.v.*), and from the time of Alexander, he appears as conqueror of India. The other incidents in which he appears in a purely triumphal character are his transforming into dolphins the Tyrrhene pirates who attacked him, and his part in the war of the gods against the giants. The adventure with the pirates occurred on his voyage to Naxos, where he found Ariadne abandoned by Theseus. At Naxos Ariadne (probably a Cretan mother-goddess', was associated with Dionysus as his wife, and their marriage was annually celebrated by a festival. Having compelled all the world to recognize his divinity, he descended to the underworld to bring up his mother. Like most deities connected with vegetation, Dionysus, at least in Thrace, died and rose again. This is reflected principally in Orphic mythology, not in normal Greek belief. Zeus had by Persephone a wonderful child Zagreus. He was brought up secretly, watched over by Curetes; but the jealous Hera discovered where he was, and sent Titans to the spot, who, finding him at play, tore him to pieces and cooked and ate his limbs, while Athena gave his heart to Zeus. This myth is probably to be connected with the savage rite of *omophagia* (eating of raw flesh) in the worship of Dionysus, in which a victim, perhaps originally human in some cases, incarnating the god, was torn in pieces and sacramentally eaten raw. It is variously reconciled with the tale of Semele. (*See* also TITANS.)

Dionysus further possessed the prophetic gift, and at Delphi was received by the priesthood of Apollo on almost equal terms. His followers included spirits of fertility, as the satyrs, and in his ritual the phallus was prominent. He often takes bestial shape, and is associated with the panther, the lion, the snake, the tiger, the ass, the goat, and sometimes also the dolphin. His personal attributes are an ivy wreath, the thyrsus (*q.v.*), and the kantharos, a large two-handled goblet. His later representations in art show a youth of soft, nearly feminine form, occasionally an infant, but the earlier type is a bearded man. His title Dendrites ("he of the tree") arises most probably from his functions as a god of the productivity of nature; not of the vine only. For the connection of Dionysus with Greek tragedy *see* DRAMA.

DIOPHANTINE EQUATIONS. About the middle of the third century, A.D., the Greek mathematician Diophantus wrote an epoch-making book entitled Arithmetica. It was important in at least three respects:—Essentially an algebra rather than an arithmetic, it was the first book to be recognized as an algebra; it contained problems requiring rational solutions which have proved to be too difficult for all mathematicians from the time of Diophantus to the present; it exhibited very ingenious methods of attacking many difficult problems of which it gave only a partial solution. The efforts of Pierre De Fermat, Leonhard Euler and other mathematicians to solve completely the difficult problems of Diophantus and other similar ones have given rise to a large part of what is called the analytic theory of numbers. For this reason, all indeterminate equations, with rational coefficients, for which a rational solution is required are called Diophantine *equations.*

Diophantine Equations, in Practical Problems.—If a banker wishes to change a dollar by means of five-cent coins (nickels) and twenty-five-cent coins (quarters) by including in the change at least one coin of each kind, he may ask himself in how many ways this can be done, and, by mental arithmetic, he may discover that the answer is three; that is, he can select 5 nickels and 3 quarters, 10 nickels and 2 quarters, or 1 j nickels and 1 quarter. In Diophantine form, this problem is to *find* all positive integral solutions of the equation $5x+25y=100$, or its equivalent $x+5y=20$, where x and y represent the numbers of nickels and quarters, respectively. Applying to $x+5y=20$ the known theory of the equation $ax+by=c$ (see NUMBER, THEORY), one finds that all solutions of $x+5y=20$, and only these solutions, are given by the formulae $x=5+5t$, $y=3-t$, t being an arbitrary constant commonly called a parameter. As (x, y) are both positive only when $t=0$, 1, or 2, the solutions sought are as stated above (5, 3), (10, 2) and (15, 1). This problem not only suggests that an indeterminate equation of the first degree may he useful, but it also exemplifies two important facts in the theory of such equations; viz., if a system of Diophantine equations of the first degree with specified coefficients has a solution, it can be found directly by use of known theory; and, when one solution of such a system is known, general formulae can be obtained which give without repetition all solutions of the system, and only these solutions, in terms of the known solution and certain parameters that appear only to the first degree.

Diophantine Equations of Higher Degree.—Nearly all Diophantine equations of degree higher than the first are difficult to solve, the difficulty increasing with the degree of the equations. On account of this fact and because of the practical and mathematical importance of solving indeterminate equations of the second degree, these equations have received more attention than have any other types of Diophantine equations. Consequently, the literature of indeterminate quadratics is extensive; it and the associated theory of third and fourth degree equations constitute the most important part of the classical Diophantine theory of to-day, which is one of the great treasures of number theorists.

One regrettable feature of this theory, however, is that it contains scarcely a principle that can be applied to more than one type of problem. Mathematicians still have to follow the example of Diophantus and devise a special mode of attack for nearly every Diophantine problem. There is a difference, however, between the procedure of Diophantus and that of mathematicians of to-day. For example, in Problem 8, Book II., of his Arithmetica (see T. L. Heath, Diophantus of Alexandria, 1910), Diophantus solves the problem of dividing a given square number into the, sum of two squares essentially as follows. Let the given square number be 16 and let x^2 be one of the required squares. Then $16-x^2$ must be equal to a square. Take a square of the form $(mx-4)^2$, where m is an arbitrary integer and 4 is the number which is the square root of 16; for example, take $(2x-4)^2$ and equate it to $16-x^2$. One thus obtains $4x^2-16x+16=16-x^2$, so that $x=16/5$. Hence the required squares are $256/25$ and $144/25$. The customary treatment of this problem at present would be to let N^2 be the given square number and to write $(mx-N)^2=N^2-x^2$. Since x is not zero, this equation implies that $x=2mN/(1+m^2)$, so that

$$x^2=4m^2N^2/(1+m^2)^2,$$

and the other required square is

$$N^2-x^2=N^2(1-m^2)^2/(1+m^2)^2.$$

As m is an arbitrary integer, the formulae just written give infinitely many solutions of the problem. This example not only illustrates one of Diophantus's processes, namely that of introducing an arbitrary parameter as a direct tneans to a desired solution, but it also shows how mathematicians since the time of Fermat have generalized both the statements and the solutions of many Diophantine problems. Indeed it was to the above problem that Fermat himself appended the famous theorem: $x^n+y^n=z^n$ has no solution *in positive* integers when n is an integer greater than two. No rigorous proof of this theorem has yet been published; nor has it been disproved.

In vivid contrast with Diophantus's desire for a single rational solution, is the modern mathematician's search for all solutions of the type that he seeks, which may be, for example, the rational solutions, the integral solutions, or the positive integral solutions. Indeed a single solution of a Diophantine equation is no longer of interest unless it has some special significance; *e.g.,* that of containing the largest integer that can appear in any positive integral solution of a given equation. The present tendency is to make as complete an analysis of Diophantine equations as is possible. Thus, in a given problem, one desires first to find all rational solutions, next all integral solutions, then all positive integral solutions, and the final touch is to discover any special properties which individual solutions possess.

The following well-known. theorems may increase one's understanding of the nature of the results that have been obtained in classical Diophantine theory:—

All solutions of the equation $x^2+y^2=z^2$ in relatively prime positive integers x, y, z are given by the formulae, $x=2mn$, $y=m^2-n^2$, $z=m^2+n^2$, where m and n are relatively prime positive integers and m is greater than n; furthermore, every set of numbers x, y, z defined by these formulae, when m and n are as just described, is a solution in positive integers of $x^2+y^2=z^2$.

The equation $x^2+y^2+z^2+w^2=u$, where u is a positive integer, has a solution in which x, y, z, w are non-negative integers.

The simultaneous equations $x^2+y^2=z^2$, $y^2+z^2=t^2$ have no solution in integers, x, y, z, t all being different from zero.

The equation $x^3+y^3=z^3$ has no solution in which x, y, z are all positive integers.

Every prime number of the form $8n+1$ or $8n+3$ is representable in the form x^2+2y^2; n, x and y being positive integers.

BIBLIOGRAPHY.—T. L. Heath, *Diophantus* of Alexandria (2nd ed. 1910), containing a discussion of Diophantus's works, the *Arithmetica,* the Porisms, and On Polygonal Numbers, besides a supplement "Notes, Theorems, and Problems by Fermat" and "Some Solutions by Euler"; E. Cahen, The'orie Des Nombres (1914); R. D. Carmichael, *Diophantine* Analysis (1915); L. E. Dickson, *History* of the *Theory* of Numbers (1920). (H. A. SI.)

DIOPHANTUS, of Alexandria, Greek algebraist, probably flourished about the middle of the 3rd century. Not that this date rests on positive evidence. But we gather from a passage of Michael Psellus (*Diophantus,* ed. P. Tannery, ii. p. 38) that he was not later than Anatolius, bishop of Laodicea from A.D. 270, while he is not quoted by Nicomachus (fl. *c.* A.D. 100), nor by Theon of Smyrna (c. A.D. 130), nor does Greek arithmetic as represented by these authors and by Iamblichus (early 4th century) show any trace of his influence, facts which can only be accounted for by his being later than those arithmeticians at least who would have been capable of understanding him fully. On the other hand he is quoted by Theon of Alexandria (who observed an eclipse at Alexandria in A.D. 365), and his work was the subject of a commentary by Theon's daughter Hypatia (d. 415). The Arithmetica, the great treatise on which the fame of

Diophantus rests, purports to be in 13 books, but none of the Greek mss. which have survived contain more than six (though one has the same text in seven books). They contain, however, a fragment of a separate tract on *Polygonal Numbers.* The missing books were apparently lost early, for there is no reason to suppose that the Arabs who translated or commented on Diophantus ever had access to more of the work than we now have. The difference in form and content suggests that the *Polygonal Numbers* was not part of the larger work. On the other hand the *Porisms,* to which Diophantus makes three references ("we have it in the Porisms that . . . "), were probably not a separate book, but were embodied in the *Arithmetica* itself, whether placed all together or spread over the work in appropriate places. The "Porisms" quoted are interesting propositions in the theory of numbers, one of which was clearly that *the difference between two cubes can be resolved into the sum of two cubes.*

Among the great variety of problems solved are problems leading to determinate equations of the first degree, in one, two, three or four variables, to determinate quadratic equations, and to indeterminate equations of the first degree in one or more variables, which are, however, transformed into determinate equations by arbitrarily assuming a value for one of the required numbers, Diophantus being always satisfied with a rational, even if fractional, result, and not requiring a solution in integers. But the bulk of the work consists of problems leading to indeterminate equations of the second degree, and these universally take the form that ohe or two (and never more) linear or quadratic functions of one variable x are to be made rational square numbers by finding a suitable value for x. A few problems lead to indeterminate equations of the third and fourth degrees, an easy indeterminate equation of the sixth degree being also found. The general type of problem is to find, two, three or four numbers such that different expressions involving them in the first and second, and sometimes the third, degree are squares, cubes, partly squares and partly cubes, etc., *e.g., to find three numbers such that the product of any two added to the sum of those two gives a square* (III. 15); *to find four numbers such that, if we take the square of tkeir sum* + *or* − *any one of them singly, all the resulting numbers are squares* (III. 19); *to find two numbers such that their product* + *or* − *tkeir sum gives a cube* (IV. 28); *to find three squares such that their continued product added to any one of them gives a square* (V. 21). Book VI. contains problems of finding *rational right-angled triangles* such that different functions of the parts (the sides and the area) are squares. A word is necessary on Diophantus' notation. He has only one symbol (written somewhat like a final sigma) for an unknown quantity, which he calls ἀριθμός (defined as "an undefined number of units"); the symbol may be a contraction of the initial letters αρ, as A^{Y}, K^{Y}, $A^{Y}A$ etc., are for the powers of the unknown (δύναμις square; κύβος, cube; δυναμοδύναμις, fourth power, etc.). The only other algebraical symbol is ⅄ for *minus,* plus being expressed by merely writing terms one after another. With one symbol for an unknown, it will easily be understood what scope there is for adroit assumptions, for the required numbers, of expressions in the one unknown which are at once seen to satisfy some of the conditions, leaving only one or two to be satisfied by the particular value of x to be determined. Often assumptions are made which lead to equations in x which cannot be solved "rationally," *i.e.,* would give negative, surd or imaginary values; Diophantus then traces how each element of the equation has arisen, and formulates the auxiliary problem of determining how the assumptions must be corrected so as to lead to an equation (in place of the "impossible" one) which can be solved rationally. Sometimes his x has to do duty twice, for different unknowns, in one problem. In general his object is to reduce the final equation to a simple one by making such an assumption for the side of the square or cube to which the expression in x is to be equal as will make the necessary number of coefficients vanish. The book is valuable also for the propositions in the theory of numbers, other than the "porisms," stated or assumed in it. Thus Diophantus knew that *no number of the form* $8n + 7$ *can be the sum of three squares.* He also says that, if $2n + 1$ is to be the sum of two squares, "n must not be odd" (i.e., *no number of the form* $4n + 3$, *or* $4n - 1$, *can be the sum of two squares),* and goes on to add, practically, the condition stated by Fermat, "and the double of it increased by one, when divided by the greatest square which measures it, must not be divisible by a prime number of the form $4n - 1$," except for the omission of the words "when divided . . . measures it."

BIBLIOGRAPHY.—The first to publish anything on Diophantus in Europe was Rafael Bombelli, who embodied in his Algebra (1572) all the problems of Books I.–IV. and some from Book V., interspersing them with his own problems. Next Xylander (Wilhelm Holzmann) published a Latin translation (Basle, 1575), an altogether meritorious work, especially having regard to the difficulties he had with the text of his ms. The Greek text was first edited by C. G. Bachet *(Diophanti Alexandrini arithmeticorurn libri sex, et de numeris multangulis liber unus, nunc primum graece et latine editi atque absolutissimis commentariis illustrati . . .* Lutetiae Parisiorum . . . MDCXXI.). A reprint of 1670 is valuable because it contains Fermat's famous notes; so far as the Greek test is concerned it is much inferior to the other. There are two German translations, one by Otto Schulz (1822) and the other by G. Wertheim (Leipzig, 1890), and an English edition in modern notation (T. L. Heath, *Diophantus* of *Alexandria: A Study in the History of Greek Algebra)* (Cambridge 1885; second edition 1910). The Greek text has now been definitively edited (with Latin translation, scholia, etc.) by Tannery (Teubner, vol. i. 1893; vol. ii. 1895). General accounts of Diophantus' work are to be found in the histories of mathematics and in Pauly-Wissowa; more elaborate analyses are those of Nesselmann (*Die Algebra der Griechen,* 1842), and G. Loria *(Le scienze esatte nell' antica Grecia,* 1914, pp. 845–919). (T. L. H.)

DIOPSIDE, an important member of the pyroxene group of rock-forming minerals. It is colourless, white, pale green to dark green or nearly black in colour, the depth of the colour depending on the amount of iron present, and is a calcium-magnesium metasilicate, $CaMg(SiO_3)_2$, crystallizing in the monoclinic system. Usually some iron is present, replacing magnesium, and when this predominates there is a passage to hedenbergite, $CaFe(SiO_3)_2$, a closely allied variety of monoclinic pyroxene; these are distinguished from augite by containing little or no aluminium. The specific gravity and optical constants also vary with the chemical composition; the specific gravity of diopside is 3·2, increasing to 3.6 in hedenbergite, and the angle of optical extinction in the plane of symmetry varies between 38° and 47° in the two extremes of the series. Crystals are usually prismatic in habit, with a rectangular cross-section, the angle between the prism faces *m,* parallel to which there are perfect cleavages, being 92° 50′. The name magnesium diopside is given to the solid solutions of diopside and enstatite commonly found in quartz-dolerites They are distinguished from diopside by smaller extinction angles and smaller angles between the optic axes.

Belonging to the same series with diopside and hedenbergite is a manganese pyroxene, known as schefferite, which has the composition $(Ca,Mg)(Fe,Mn)(SiO_3)_2$.

Diopside is easily prepared synthetically from a melt of its component oxides. The artificial crystals melt sharply at 1,391° C., and this temperature is used as a fixed point on the thermometer scale. (C. E. T.)

DIOPTASE, a rare mineral species consisting of acid copper orthosilicate, H_2CuSiO_4, that has occasionally been used as a gem-stone, especially in Russia and Persia. It has a fine colour, but a low degree of hardness and the transparency is imperfect, and it crystallizes in the parallel-faced hemihedral class of the rhombohedra1 system, in which there is only an axis of triad symmetry and a centre of symmetry. The crystals have the form of a hexagonal prism terminated by a rhombohedron. There are perfect cleavages truncating the polar edges of the primary rhombohedron. From these cleavage cracks internal reflections are often to be seen in the crystal, and it was on account of this that the mineral was named dioptase, by R. J. Hauy in 1797, from διοπτεύειν, "to see into." The crystals vary from transparent to translucent with a vitreous lustre, and are bright emerald-green in colour; they thus have a certain resemblance to emerald, hence the early name emerald-copper (German, *Kupfersmaragd).* Hardness 5; sp.gr. 3·3. The fine crystals from Mount Altyn-Tube on the western slopes of the Altai mountains, Asiatic Russia, line cavities in a compact limestone; they were first

brought to Europe in 1785. Excellent crystals have also come from the copper mines in the French and Belgian Congos and from South-West Africa.

DIOPTER. A unit of measurement used in optics to measure the power of a lens or lens system. The power of a lens is the reciprocal of its focal length, and when the focal length is expressed in metres the power of the lens is in diopters. Thus a lens whose focal length is one metre has a power of one diopter, a lens of focal length 50 cm. ($\frac{1}{2}$ metre) a power of 2 diopters, a lens of focal length 2 metres $\frac{1}{2}$ diopter and so on. (*See* LENS.)

DIORITE, the name given by Haüy to a family of rocks of granitic texture, composed of plagioclase felspar and hornblende. As they are richer in the dark coloured ferromagnesian minerals they are usually grey or dark grey, and have a higher specific gravity than granite. They also rarely show visible quartz. But there are diorites of many kinds, as the name applies rather to a family of rocks than to a single species. Some contain biotite, others augite or hypersthene; many have a small amount of quartz. Orthoclase is rarely entirely absent, and when it is common the rock becomes a monzonite. It is rare to find the pure types of "hornblende-diorite," "augite-diorite," etc., but in most cases the rocks contain two or more ferromagnesian silicates, and such combinations as "hornblende-biotite-diorite" are commonest in nature.

The felspar of the diorites ranges in composition from oligoclase to labradorite and is often remarkably zonal, the external layers being more alkaline than the internal. Small fluid enclosures and black grains, probably iron oxides, often occur in it in great numbers. Weathering produces epidote, calcite, sericite and kaolin. The biotite is always brown or yellow; the hornblende usually green, but sometimes brown or yellowish brown in those diorites which have affinities to lamprophyres. The augite is nearly always green, but sometimes has a reddish tinge; bronzite and hypersthene have their usual green and brown shades. Apatite, iron oxides and zircon are almost invariably present; sphere garnet and orthite are occasionally observed; calcite, chlorite, muscovite, kaolin, epidote and bastite are secondary. The structure is not essentially different from that of granite. The ferromagnesian minerals crystallize comparatively early and have some idiomorphism; the felspar usually follows and only in part shows good crystalline outlines. Orthoclase and quartz, if present, are last to separate out, and fill the spaces between the other minerals; often they interpenetrate to form micropegmatite. In many diorites the plagioclase felspar has crystallized before the hornblende, which consequently has less perfect outlines and forms irregular plates which enclose sharply formed individuals of felspar; this produces the ophitic structure (very common also in the dolerites). More rarely biotite and augite exhibit the same relations to the plagioclase. Orbicular structure also occasionally appears in these rocks; in fact the orbicular diorite of Corsica (also called "napoleonite" (*q.v.*) or "corsite") was for a long time the best-known example of this structure. Occasionally diorites have a parallel banded or foliated structure, but these must not be in any manner confounded with the epidiorites, which are metamorphic rocks without conspicuous foliation.

Diorites must also be distinguished from hornblendic gabbros, which contain more basic felspars, rarely quartz and occasionally olivine; but the boundary lines between diorites and gabbros are admittedly somewhat vague, e *g.*, some authors would call rocks gabbro which others would regard as augite-diorite. The hornblendites differ from the diorites in containing little felspar, and consist principally of hornblende. Among varietal designations given to rocks of the diorite family are "hanatite" for an augite-diorite with or without quartz (from the Schemnitz district), "granodiorite" for a quartz-hornblende-diorite (essentially the same as tonalite) from California, etc., "ornoite" for a hornblende-diorite rich in felspar, from Sweden. (J. S. F.)

DIOSCOREACEAE, a family of monocotyledonous plants which includes the yam (*q.v.*), the black bryony (*Tamus communis*), and the elephant's-foot (*q.v.*). There are nine genera and about 650 species, all climbing herbs or shrubs with tubers or rhizomes. The flowers are small, usually inconspicuous, unisexual or perfect, usually regular, the parts in threes. The fruits are for the most part a three-winged capsule, the seeds mostly winged. The family is economically important, as many species of Dioscorea are cultivated for their edible tubers, those of the greater yam (D. ulata) sometimes attaining a weight of 40 lb. Other cultivated species are D. *batatas*, D. *esculenta*, D. *cayenensis*, D. *bulbifera*, *D. pentaphylla* and D. *triloba*.

For a monographic treatment see R. Knuth, Dioscoreaceae. Pflanzenreich 87 (iv, 43): 1–278, fig. 1–69 (1924).

DIOSCORIDES, PEDANIOS (*fl. c.* A.D. 50), Greek medical man, served in the army of Nero. He is known through his *Materia Medica* which was very popular in the middle ages. It details the properties of about 600 medicinal plants and describes animal products of dietetic and medicinal value.

A Graeco-Latin text by K. Sprengel appeared at Leipzig (1829) and a German trans. by J. Berendes (Stuttgart, 1902).

DIP, in magnetism (see TERRESTRIAL MAGNETISM), the angle made by the direction of the earth's magnetic field and the horizontal is the angle of dip, commonly called the dip. In astronomy (*q.v.*) and surveying (*q.v.*) the dip of the horizon is the angular distance between the true horizon and the apparent horizon, due to the observer's elevation. In geology (*q.v.*) the angle which the line of maximum slope of a stratum makes with the horizontal.

DĪPAVAṂSA, a poem ("History of the Island") composed in Ceylon in the Pāli language, relating the history of Buddhism in India and its propagation in Ceylon. It belongs to the 4th century A.D., and is the earliest example of a purely historical compositicn relating to India. It contains 22 chapters, and begins with the Enlightenment of Buddha, the immediately following events, and his three legendary visits to Ceylon. Then follows the genealogy of the kings of Buddha's ancestry from the first king of this cycle (*kalpa*) down to Buddha himself and his son Rāhula. The really historical portion begins with chapter 4, the history of Buddhism in the Magadha kingdom down to the 3rd council in the reign of Asoka. From this point it continues with the history of Ceylon, the settlement of the island by king Vijaya, the subsequent kings down to Devānampiya Tissa, under whom Buddhism was introduced by Asoka's son Mahinda, with a continuation of the history of the island ending with king Mahāsena at the beginning of the 4th century A.D.

As the *Dīpavaṃsa* is the oldest connected account of Buddhism and of contemporary secular events in India for the first three centuries of its history, it is important to determine if possible in what sense it can be called historical. There are two circumstances to be first considered, the fact that its record of events (apart from purely local Sinhalese history) was compiled in India, and consequently cannot be treated as the composition or invention of a Sinhalese author, and secondly that it corresponds in important features with the Puriinas. The Purānas, like the *Dīpavaṃsa,* contain genealogies of kings which are traced up to the purely legendary beginnings of the cycle, and recent study has not only shown that the Puriinas contain genealogies belonging to actual lines of kings, but further that in the case of the Magadha kings between Buddha and Asoka both the Purānas and the *Dīpavaṃsa* rest on a common historical basis. This is further corroborated by the lists found in Jain works. What we possess is not a historical record in the modern sense, for the chroniclers recorded events uncritically, and accepted legends about quite historical persons. This is very different from free invention. What we have to guard against is not deliberate romancing, but faults due to the very defective means of transmitting and recording events, and the unhistorical attitude of the compilers. The probable mode of composition has been most closely studied by Oldenberg, who first edited the Dipavamsa, and by Geiger, who has edited the later chronicle, the *Mahāvaṃsa.* A native commentary (*ṭīkā*) on the *Mahāvaṃsa,* was compiled about A.D. 1000. References in it show that at that time there was in existence a Sinhalese historical work, which formed part of the great Sinhalese commentary on the Buddhist Scriptures. The existence of this Sinhalese commentary at least as early as the 4th century A.D. is known from frequent references found in the existing Pāli commentaries. It was on the basis of this work in Sinhalese that the *Dīpavaṃsa* was compiled, and its repetitions and the disjointed arrangement of various passages show that it must have been compiled from just such a source. The main details of the work correspond so closely with those in the Indian records (the Purānas and Buddhist Sanskrit works) that it is clear that they are of Indian origin. This Sinhalese work must have at first ended with the introduction of Buddhism into Ceylon by Mahinda, but it appears to have been later on extended to the reign of Mahāsena. This is the period

covered by the *Dīpavaṃsa,* and this work is probably a recension and adaptation of the whole of the Sinhalese work. These conclusions are essentially the views of Geiger, who has summarized his results about both the *Dīpavaṃsa* and the *Mahāvaṃsa* in his translation of the latter work. References will also be found here to the criticisms of R. O. Franke, whose attitude on the historical value of the chronicles is one of complete scepticism. (See MAHĀVAMSA.)

DIP-CIRCLE. An instrument used for measuring the magnetic dip. It consists essentially of a magnetic needle pivoted at the centre of a graduated metal circle. The circle is mounted with its plane vertical and the axis about which the needle turns horizontal. If such an instrument is placed with the plane of the circle in the magnetic meridian the needle will lie in the direction of the earth's magnetic field. See TERRESTRIAL MAGNETISM.

DIPHENYL (phenylbenzene), an aromatic hydrocarbon found in that fraction of the coal-tar distillate boiling between 240°–300°C., from which it may be obtained by warming with sulphuric acid, separating the acid layer and strongly cooling the undissolved oil. It crystallizes in plates (from alcohol) melting at 70–71° C. and boiling at 254° C. It is sometimes called phenyl benzene, having the structure $C_6H_5{\cdot}C_6H_5$. It may be prepared by passing benzene vapour through a red-hot tube; by the action of sodium on brombenzene dissolved in ether; by the action of stannous chloride on phenyldiazonium chloride; by the decomposition of phenyldiazonium sulphate with warm benzene or with alcohol and copper powder, or a yield of 82% of diphenyl is obtained by heating iodobenzene with copper powder at 230° C.

See BENZIDINE for the industrially important derivative, diparadiaminodiphenyl.

DIPHILUS, of Sinope, poet of the new Attic Comedy and contemporary of Menander (342–291 B.C.). Most of his plays were written and acted at Athens, but he led a wandering life, and died at Smyrna (Athenaeus xiii. pp. 579, 583). He is said to have written 100 comedies, the titles of fifty of which are preserved. He sometimes acted himself. To judge from the imitations of Plautus (Casina from the Κληρούμενα, *Asinaria* from the Ὄναγός, Rudens from some other play), he was very skilful in the construction of his plots. Terence also tells us that he introduced into the *Adelphi* (ii. 1.) a scene from the Συναποθνήσκοντες, which had been omitted by Plautus in his adaptation (Commorientes) of the same play. The ancients were undecided whether to class him among the writers of the New or Middle comedy.

Fragments in H. Koch, *Comicorum Atticorum fragmenta,* ii.; *see* J. Denis, *La Comédie grecque* (1886), ii. p. 414; R. W. Bond in *Classical Review* (Feb. 1910, with trans. of *Emporos* fragm.).

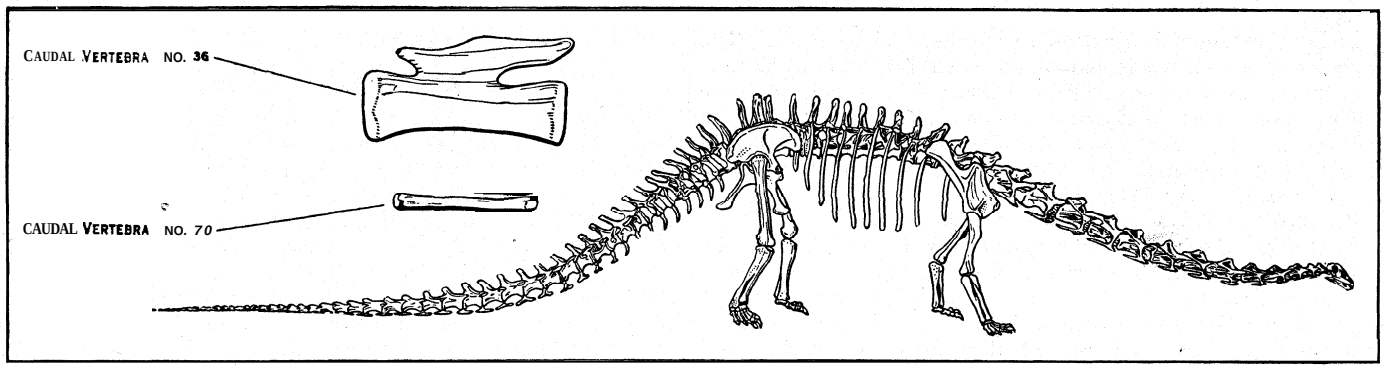
DIPHTHERIA, an acute infectious disease, accompanied by a membranous exudation on a mucous surface, generally the tonsils and back of the throat or pharynx.

As a rule, early symptoms are comparatively slight, viz., chilliness and depression. A slight feeling of uneasiness in the throat is experienced along with some stiffness of the back of the neck. The throat is reddened and somewhat swollen, particularly in the neighbourhood of the tonsils, the soft palate and upper part of pharynx, and there is tenderness and swelling of the glands at the angles of the jaws. The affection of the throat spreads rapidly, and soon the characteristic exudation appears on the inflamed surface as greyish-white specks or patches, increasing in extent and thickness until, in a well developed case, a yellowish-looking false membrane is formed, firmly adherent to the mucous membrane and if removed soon reproduced upon the raw, bleeding, ulcerated surface so left. It may cover the whole of the back of the throat, and the posterior nares, and spread downwards into the air-passages. Portions may be detached spontaneously, and expelled by coughing. There is pain and difficulty in swallowing, but unless the disease has affected the larynx no affection of the breathing. The voice acquires a snuffling character. When the disease invades the posterior nares an acrid, foetid discharge, and sometimes also copious bleeding, takes place from the nostrils. Along with these local phenomena there is in cases severe constitutional disturbance. While there may be no great amount of fever, there is marked depression and loss of strength. The pulse becomes small and frequent, the countenance pale, the swelling of the glands of the neck increases, and albumen appears in the urine. Unless favourable symptoms emerge death takes place within three or four days or sooner, either from the rapid extension of the false membrane into the air-passage, giving rise to asphyxia, or from a condition of general collapse, which is sometimes remarkably sudden. In cases of recovery the change for the better is marked by an arrest in the extension of the false membrane, the detachment and expectoration of that already formed, and the healing of the ulcerated mucous membrane beneath. Recovery, however, is slow, and it is many weeks before full convalescence is established. Even, however, where diphtheria ends favourably, a few weeks later paralysis of the soft palate and pharynx may occur, causing difficulty in swallowing and regurgitation of food through the nose, and giving a peculiar nasal character to the voice. Other forms of paralysis occurring after diphtheria are those affecting the muscles of the eye, which produce a loss of the power of accommodation and consequent impairment of vision, paralysis of both legs, and occasionally also of one side of the body (hemiplegia). These symptoms, after continuing for a variable length of time, almost always ultimately disappear.

Causation. — The exciting cause of diphtheria is a micro-organism, identified by Klebs and Loffler in 1883 (see BACTERIA AND DISEASE). It has been shown by experiment that the symptoms of diphtheria, including the after-effects, are produced by a toxin derived from the micro-organisms which lodge in the air-passages and multiply in a susceptible subject (see IMMUNITY). Cats and cows are susceptible to the diphtheritic bacillus, but actual cases among them are very rare; and fowls, turkeys and other birds have been known to suffer from a diphtheria-like disease, not due however, to the diphtheria bacillus; other domestic animals appear to be more or less resistant or immune. Children are far more susceptible than adults, but even children may have the Klebs-Löffler bacillus in their throats without showing any symptoms of illness, though such children are "carriers" (*q.v.*). Altogether there are many obscure points about this micro-organism, which is apt to assume a puzzling variety of forms.

Prevalence. — Diphtheria is endemic in all European and American countries, and the incidence varies greatly in different countries and, from year to year, even in the same country. In other words, diphtheria, though always endemic, exhibits at times a great increase of activity, and becomes epidemic or even pandemic.

Dissemination. — The contagion is spread by means which are in constant operation, whether the general amount of disease is great or small. Water, so important in some epidemic diseases, is believed not to be one of them. On the other hand, outbreaks of an almost explosive character, besides minor extensions of disease from one place to another have been traced to milk; but several cases have been ascribed to infection from cows with a diphtheritic affection of the udder. Human intercourse is the most important means of dissemination. the contagion passing either by actual contact, as in kissing, or by the use of the same utensils and articles, or by mere proximity. In the last case the germs must be supposed to be air-borne for short distances, and to enter with the breath. In the act of talking, tiny infected droplets are expelled into the air. It has been held that diphtheria is a rural rather than an urban disease, but this view is negatived when sufficiently numerous data over a long period of years are analysed. Diphtheria appears to creep about very slowly, as a rule, from place to place, and from one part of a large town to another; it forsakes one district and appears in another; occasionally it attacks a fresh locality with great energy, presumably because of the susceptibility of the inhabitants. who are, so to speak, virgin ground. But through it all personal infection is the chief means of spread.



FROM "MEMOIRS OF THE CARNEGIE MUSEUM"

SKELETON OF DIPLODOCUS CARNEGIEI, ABOUT ONE ONE-HUNDREDTH NATURAL SIZE. RECONSTRUCTED FROM FOSSIL REMAINS FOUND IN THE ROCKY MOUNTAINS. THE FEET ARE INCORRECTLY RESTORED

The acceptance of this doctrine has directed great attention to the practical question of school influence. There is no doubt whatever that it plays a very considerable part in spreading diphtheria. The incidence of the disease is chiefly on children, and nothing furnishes such constant and extensive opportunities for personal infection as school attendance. Many outbreaks have definitely been traced to schools. From a practical point of view the problem is a difficult one, but has been simplified by discovery of the Schick reaction and the prophylactic antitoxin treatment of those exposed to infection in whom the reaction is positive (see MEDICAL RESEARCH). All these considerations imply the necessity of segregating the sick in isolation hospitals. Of late years this preventive measure has been carried out with increasing efficiency, but, unfortunately, the complete segregation of infected persons is hardly possible, because of the mild symptoms, and even absence of symptoms, exhibited by some individuals. A further difficulty arises with reference to the discharge of patients. It has been proved that the bacillus may persist almost indefinitely in the air-passages in certain cases, and in a considerable proportion it does persist for several weeks after convalescence. On returning home such cases may, and often do, infect others. The method usually adopted is to retain the patient until the throat has been found free from B. diphtheria on each of three consecutive weekly bacteriological tests. These tests are generally started 12 days after the onset of the disease and made every two days. This still leaves the problem of dealing with persistent carriers unsolved.

Treatment.— Since the antitoxin treatment was introduced in 1894 it has overshadowed all other methods We owe this drug originally to the Berlin school of bacteriologists, and particularly to Dr. Behring. (*See* BACTERIA AND DISEASE; IMMUNITY; SERUM THERAPY.) Since then an enormous mass of facts has accumulated from all quarters of the globe, all testifying to the value of antitoxin in the treatment of diphtheria. The experience of the hospitals of the London Metropolitan Asylums Board for five years before and after antitoxin may be given as a particularly instructive illustration; and the subsequent reduction in the rate of mortality (12% in 1900, 11·3 in 1901, 10·8 in 1902, 9.3 in 1903, and an average of 9 in 1904–8) added further confirmation. Since then a further reduction has taken place. During 1923–26 the case mortality (annual reports of the chief medical officer of the Ministry of Health) was: 1923, 6·83%; 1924, 5.95; 1925, 5·81; 1926, 5.86.

Annual Case Mortality in Metropolitan Asylums Board's Hospitals.

Before Antitoxin		After Antitoxin.	
Year.	Mortality %	Year.	Mortality %
1890	33·55	1895	22·85
1891	30·61	1896	21.20
1892	29 51	1897	17·79
1893	30·42	1898	15·37
1894	29·29	1899	13·95

The number of cases dealt with in these five antitoxin years was 32,835, or an average of 6,567 a year, and the broad result is the reduction of mortality by about one-half. It is a fair inference that the treatment saved the lives of about 1,000 children each year in London alone. This refers to all cases. Those which occur in the hospitals as a sequel to scarlet fever, and consequently come under treatment from the commencement, show very much more striking results. The case mortality, which was 46·8% in 1892 and 58·8% in 1893, has been reduced to 3·6% since the introduction of antitoxin. This is a special example of the general law that the efficacy of antitoxin treatment varies inversely as the length of time that the disease has existed prior to administration of antitoxin. The following table (compiled from the annual reports of the Metropolitan Asylums Board), gives the case mortality of diphtheria on this basis:—

Day of disease on which antitoxin treatment was begun.	Case mortality %
1	1.62
2	4·73
3	10·37
4	14.60
5 and later	15·51

But the evidence is not from statistics alone. The beneficial effect of the treatment is equally attested by clinical observation. Adult patients have described the relief afforded by inoculation; it acts like a charm, and lifts the deadly feeling of oppression off like a cloud in the course of a few hours. Finally, the counteracting effect of antitoxin in preventing the disintegrating action of the diphtheritic toxin on the nervous tissues has been demonstrated pathologically. It has been said that diphtheritic paralyses are commoner since the introduction of antitoxin, but obviously the modern greater survival of diphtheria patients implies the existence of persons in whom these paralyses can be observed, who, formerly, would have died too early to manifest them.

DIPLODOCUS, a gigantic extinct reptile, about 60ft. long, found in the Upper Jurassic rocks along the east side of the Rocky mountains. It is a member of the Sauropoda, a division of the Dinosaurs (*q.v.*). See Illustration above.

DIPLOMACY, the art of conducting international negotiations. The word is derived ultimately, through the French *diplomatie,* from the Greek word *diploma, i.e.,* the duplicate or copy of an act emanating from the sovereign of which the original is retained. Diplomacy has thus been defined as "the science of external relations, which has for its basis *diplômes* or written acts

of the sovereign." According to the *New Engtish Dictionary*, the word was first used in England so late as 1796 by Burke. The need for such a term was, indeed, only then beginning to be felt; for, though in a sense as old as history, it was only in quite modern times, even in Europe, that diplomacy developed into a uniform system, based upon generally recognized rules and directed by a diplomatic hierarchy having a fixed international status. (See *History*, below.)

Principles and Functions. — Though diplomacy is usually treated under the head of international law, it would perhaps be more consonant with the facts to place international law under diplomacy. The principles and rules governing the intercourse of states, defined by a succession of international lawyers, have no sanction except the consensus of the powers, established and maintained by diplomacy; in so far as they have become, by international agreement, more than mere pious opinions of theorists, they are working rules, established for mutual convenience, which it is the function of diplomatists to apply. The greater mass of diplomatic work, indeed, consists in giving particular application to rules generally admitted. This presents no special difficulty, though it demands technical knowledge. The rest of the work, however, is disproportionately harder, since it consists in adjusting disputes about matters to which the application of existing rules is doubtful, or to which they admittedly do not apply, or which stand beyond all rules as questions of high policy. In such debates, as Mr. Denys P. Myers has pointed out, the diplomatist is naturally an advocate; his object is not justice, but the advantage of the country he represents. In this aspect of its activities diplomacy must continue to be frank advocacy of particular interests, even though the dispute be heard before the high court of the League of Nations.

In the 18th century this would have been admitted without qualification. It is true that Frederick de Marselaer had declared in his *Legatus* (1626) that it was the function of an ambassador not only to study the interests of his sovereign, but "to work for the common peace and to study the convenience of foreign princes"; that writers like François de Callières (1716) and Vattel (1756) spoke of Europe as a kind of republic which it was the function of diplomacy to preserve; and that idealists, like the abbé de St. Pierre, had visions of the League of Nations; but in practice sovereigns regarded their dominions as so much real property, which it was the function of their "agents" to protect or to enlarge. Diplomacy thus resolved itself into a process of exalted haggling, conducted with an amazing disregard for the ordinary standards of morality, but with the most exquisite politeness, and in accordance with ever more and more elaborate rules. Much of the outcome of these dead debates became stereotyped in the conventions of the diplomatic service; but the spirit and methods of diplomacy have undergone a great change.

The change was due to two main causes: (1) the new sense of European solidarity, which was the outcome of the French revolutionary wars, and found expression in the series of congresses from 1814 onward, and (2) the growth of democracy. The process of change was gradual, as was to be expected; for diplomacy is not a thing apart, as some seem to imagine, but is intimately bound up with the organic life of states; it can only be effective if it speaks with authority; it can only speak with authority when, both in its personnel and its methods, it represents the ultimate sovereignty, whether this reside in an autocrat or in the people. With the changing constitution of states, then, there has been a constant adjustment of the methods of diplomacy. The process has, of course, not been uniform. George Canning, for instance, could appeal to public opinion in support of his foreign policy at a time when Metternich was suppressing all expressions of public opinion; but Canning represented a parliamentary government, Metternich an autocrat. But in spite of survivals of the old spirit, the 19th century witnessed an immense advance in the ethics of diplomacy. In 1853 the comte de Garden could speak of diplomacy as deriving its principles from "the common law of the European peoples," and define it as "the art of reconciling the interests of the peoples one with another." At the close of the century The Hague Conferences revived in a more promising form the ideal of international co-operation which, in 1815, had inspired Alexander I.'s Holy Alliance.

EFFECTS OF THE WORLD WAR

The failure of diplomacy to avert the awful disaster of the World War naturally strengthened the agitation, which had begun before the war, against the personnel and methods of the traditional diplomacy. Diplomatists were accused of being in league with capitalists and munition-makers, out of touch with the people, and habitually using language that was "false-friendly and circumlocutory." The cry went up for "open diplomacy" and "democratic control," and was strengthened by President Wilson's announcement (in the first of his Fourteen Points) that henceforth "diplomacy shall proceed always frankly and in the public view."

Open Diplomacy and Democratic Control. — In a democratic state the control of foreign policy must always ultimately rest with the representatives of the people, who hold the purse-strings. But the public conduct of negotiations is another matter. "How is the task of peace-maker to be pursued," asked Mr. Arthur (later, Lord) Balfour, in the House of Commons, "if you are to shout your grievances from the house-tops whenever they occur? The only result is that you embitter public feeling, that the differences between the two states suddenly attain a magnitude they ought never to be allowed to approach, that the newspapers of the two countries agitate themselves, that the parliaments of the two countries have their passions set on fire, and great crises arise, which may end, have ended sometimes, in international catastrophes." Mirabeau said much the same thing in the French National Assembly in 1790, and subsequent events bore out its wisdom; it was not the diplomatists, but the oratorical heat of the Assembly that plunged Europe into the wars of the Revolution. The world remembers the wars that diplomacy failed to avert; it has forgotten, or has never known of those — and they are many more — which diplomacy has averted by a conspiracy of silence.

So far as the practice of diplomacy is concerned, the war and the negotiations which followed have led to only three developments of any outstanding importance. The first, which needs no further discussion, is the provision of the covenant that all international agreements, to be generally recognized as valid, must be registered in the secretariat of the League of Nations. This is intended to ensure the publication of the result of negotiations. Its effectiveness is limited to the membership of the league; and accusations have been made from time to time of the continued existence of secret treaties even between league members. The second is the growth of the practice of diplomacy by conference. The third is the adoption of the principle that no important treaty can be considered to be concluded until it has been ratified by the legislatures of the chief signatory states.

Ratification of Treaties. — This last development was due, not to the desire to secure democratic control so much as to the uncertainty created by the rejection by the United States Senate of the Treaty of Versailles. In most states ratification had hitherto been the prerogative of the sovereign and was regarded as a mere formality, since treaties were negotiated and concluded by representatives armed by the sovereign with full powers. Whether the new rule will make for peace or not is an open question. Wherever the minister responsible for foreign policy can rely on a parliamentary majority, ratification is likely to remain a mere formality; but it is easy to see the confusion and delay that would arise if a treaty signed by several powers really had to run the gauntlet of the criticism and amendments of several popular assemblies. In this respect the example of the Cnited States has not been encouraging; for the fact that the treaty-making power is vested by the Federal Constitution in the President and Senate concurrently has often made the conclusion of treaties with the United States a very long and difficult process. In the foreign relations committee of the Senate democratic control has often resolved itself into party opposition

Diplomacy by Conference, — Just as after the Napoleonic wars personal meetings of sovereigns and their principal ministers

were found of service in clearing up misunderstandings and expediting business—so for a while during and after the World War the substitution for the ordinary diplomatic channels of direct personal correspondence and meetings between foreign ministers, was justified by the greatness and urgency of the problems to be discussed. With the establishment of more settled conditions, however, diplomatic intercourse has tended to revert to the normal channels, though the attendance of foreign ministers at the periodical meetings of the Council and Assembly of the League of Nations seems now to be an established custom.

This direct influence of foreign ministers on the conduct of negotiations has been increased by modern means of communication. But it would be easy to exaggerate the importance of this change as affecting the character and status of diplomatic agents. Foreign ministers must still depend for information and advice on the "man on the spot," and the success of their policy largely depends upon his qualities of discretion and judgment. The growth of democracy, moreover, has given to the ambassador a new importance; for he represents not only the sovereign to the sovereign, but the nation to the nation; and he may by his personal qualities do a large **amount** to remove the prejudices and ignorances which stand as a barrier between the nations.

The Personnel of the Diplomatic Service.—The great part played by ambassadors and diplomatists generally in the intercourse between nations makes the question of their qualifications of supreme importance. With the growth of democracy a demand arose in Britain for the "democratization" of the diplomatic service. This demand was reasonable enough, in so far as it aimed at making this service more perfectly representative. It had, too, some basis in history. In the early days of diplomacy princes, in choosing their agents. paid more attention to their skill as negotiators than to their rank, and ambassadors were not drawn from any particular class; they might be clerics, or soldiers, or lawyers, or even simple merchants. Louis XI. of France even sent his barber, Olivier le Daim, on diplomatic missions. It was not till the 18th century that a diplomatic service, in the modern sense, came into existence. The elaboration of court ceremonial, for which Versailles had set the fashion, made it desirable that diplomatists should be courtiers, and young men of rank began to be attached to missions, in order to learn the art of diplomacy. Thus arose that aristocratic diplomatic class which survived from the 18th century into the 19th.

The example set by France was not followed in Britain till after the Napoleonic wars. By his circular of Jan. 1, 1816, Castlereagh announced that "in order to provide a suitable succession of diplomatic servants, properly qualified etc.," the Prince Regent intended to nominate from time to time "to such of the Ambassadors or Envoys, as the emergency of the service might point out, one, or at the utmost two, attachés to be domesticated in his family." (F.O. 115. 25. archives No. 2). This was the beginning in Britain of the trained diplomatic service. When, some years later, the service was thrown open to competition, precautions were still taken to ensure that it should be manned by gentlemen, that is to say, by those who had "at least had the opportunity of mixing in society where good manners are to be expected." Thus candidates for examination had to have an income of at least £400 a year, and were nominated by the foreign secretary on the recommendation of persons of position.

This system was modified as the result of a report issued in 1914, by the royal commission on the civil service. One of its recommendations was that the diplomatic establishment of the Foreign Office and the diplomatic corps abroad should be amalgamated up to and including the grades of assistant under-secretary of state and minister of the lowest grade. This involved the abolition of the property qualification, which did not apply to the Foreign Office; and it was recommended that members of the service employed abroad should receive a suitable foreign allowance. After the publication of the findings of the commission the recommendation of the foreign secretary was made dependent on the report of a board of selection composed of members of the Foreign Office and of the diplomatic service. In this there was nothing revolutionary; and the effect of the putting in force of these recommendations has been to widen the area of selection for the service.

HISTORY

In its widest sense the history of diplomacy is that of the intercourse between nations, in so far as this has not been a mere brute struggle for the mastery; in a narrower sense, with which the present article is alone concerned, it is that of the methods and spirit of diplomatic intercourse and of the character and status of diplomatic agents. Whatever the influence of earlier practice, modern diplomacy dates from the rise of permanent missions, and the consequent development of the diplomatic hierarchy as an international institution. Of this the first beginnings are traceable to the 15th century and to Italy. There had, of course, during the middle ages been embassies and negotiations; but the embassies had been no more than temporary missions directed to a particular end, and conducted by ecclesiastics or nobles of a dignity appropriate to each occasion; there were neither permanent diplomatic agents nor a professional diplomatic class. To the evolution of such a class the Italy of the Renaissance, the nursing-ground of modern statecraft, gave the first impetus. This was but natural; for in Italy, with its numerous independent states, between which there existed a lively intercourse, and a yet livelier rivalry, diplomacy early played a part as great as, or greater than, war. Where all were struggling for the mastery, the existence of each depended upon alliances and counter-alliances, of which the object was the maintenance of the balance of power. In this school there was trained a notable succession of men of affairs. Thus, in the 13th and 14th centuries Florence counted among her envoys Dante, Petrarch and Boccaccio, and later on could boast of agents such as Capponi, Vettori, Guicciardini and Machiavelli. Papal Rome, too, as was to be expected, had always been a fruitful nursing-mother of diplomatists; and some authorities have traced the beginnings of modern diplomacy to a conscious imitation of her legatine system. *(See* Hinschius, *Kirchenrecht*, i. p. 498.)

It is, however, in Venice, that the origins of modern diplomacy are to be sought. The Venetians, in their turn, doubtless learned their diplomacy originally from the Byzantines, with whom their trade expansion in the Levant early brought them into close contact. (For Byzantine diplomacy *see* ROMAN EMPIRE, LATER.) So early as the 13th century the republic began to lay down rules for the conduct of its ambassadors. Thus in 1268, ambassadors were commanded to surrender on their return any gifts they had received, and about the same time it was decided that they were to hand in a written account of their mission; in 1288 this was somewhat expanded by a law decreeing that ambassadors were to deposit, within 15 days of their return, a written account of the replies made to them during their mission, together with anything they might have seen or heard to the honour or in the interests of the republic. These provisions, which were several times renewed, are the origin of the famous reports of the Venetian ambassadors to the senate, which are at once a monument to the genius of Venetian statesmen and a mine of historical material. *(See* Eugenio Albèri, *Le Relazioni degli ambasciatori Veneti al senato,* 15 vols. Florence, 1839–63.)

The origin of the change from temporary to permanent missions has been the subject of much controversy. The theory that it was due to the evolution of the Venetian consulates (*bajulats*) in the Levant into permanent diplomatic posts, and that the idea was thence transferred to the West, is disproved by the fact that Venice had established other permanent embassies before the *baylo* (*q.v.*) at Constantinople was transformed into a diplomatic agent of the first rank. Nor is the first known instance of the appointment of a permanent ambassador Venetian. The earliest record[1] is contained in the announcement by Francesco Sforza,

[1] The *apocrisiarii* (ἀποκρισιάριοι) or *responsales* should perhaps be mentioned, though they certainly did not set the precedent for the modern permanent missions. They were resident agents, practically legates, of the popes at the court of Constantinople. They were established by Pope Leo I., and continued until the Iconoclastic controversy brake the intimate ties between East and West. *See* Luxardo, *Das vordekretalische Gesandtschaftsrecht der Päpste* (Innsbruck, *1878)*; also Hinschius, *Kirchenrecht*, i. 501.

duke of Milan, in 1455, of his intention to maintain a permanent embassy at Genoa, and in 1460 the duke of Savoy sent Eusebio Margaria, archdeacon of Vercelli, as his permanent representative to the Curia[1]. Though, however, the early records of such appointments are rare, the practice was probably common among the Italian states. Its extension to countries outside Italy was a somewhat later development. In 1494 Milan is already represented in France by a permanent ambassador. In 1495 Zacharia Contarini, Venetian ambassador to the emperor Maximilian, is described by Sanuto (*Diarii*, i. 294) as stato ambasciatore; and from the time of Charles V. onwards the succession of ambassadors of the republic at the imperial court is fairly traceable. In 1496 "as the way to the British Isles is very long and very dangerous," two merchants resident in London, Pietro Contarini and Luca Valaressa, were appointed by the republic *subambasciatores;* and in June of the same year Andrea Trevisano arrived in London as permanent ambassador at the court of Henry VII[2]. Florence, too, from 1498 onwards, was represented at the courts of Charles V. and of France by permanent ambassadors.

During the same period the practice had been growing up among the other European powers. Spain led the way in 1487 by the appointment of Dr. Roderigo Gondesalvi de Puebla as ambassador in England. As he was still there in 1500, the Spanish embassy in London may be regarded as the oldest still surviving post of the new permanent diplomacy. Other states followed suit, but it was not till late in the 16th century that permanent embassies were regarded as the norm. The precarious relations between the European Powers during the 16th century, indeed, naturally retarded the development of the system. Thus it was not till after good relations had been established with France by the Treaty of London that, in 1519, Sir Thomas Boleyn and Dr. West were sent to Paris as resident English ambassadors, and, after the renewed breach between the two countries, no others were appointed till the reign of Elizabeth. Nine years before, Sir Robert Wingfield, whose simplicity earned him the nickname of "Summer-shall-be-green," had been sent as ambassador to the court of Charles V., where he remained from 1510 to 1517; and in 1520 the mutual appointment of resident ambassadors was made a condition of the treaty between Henry VIII. and Charles V. In 1517 Thomas Spinelly, an Italian, who had for some years represented England at the court of the Netherlands, was appointed "resident ambassador to the court of Spain," where he remained till his death in 1522. These are the most important early instances of the new system. Alone of the Great Powers, the emperor remained unrepresented at foreign courts. In theory this was the result of his unique dignity, which made him superior to all other potentates; actually it was because, as emperor, he could not speak for the practically independent princes nominally his vassals. It served all practical purposes if he were represented abroad by his agents as king of Spain or archduke of Austria.

All the evidence goes to prove that the establishment of permanent diplomatic agencies was deliberately adopted as an obvious convenience. But, while all the powers were agreed as to the convenience of maintaining such agencies abroad, all were equally agreed in viewing the representatives accredited to them by foreign states with extreme suspicion. This was justified by the peculiar ethics displayed by the new diplomacy. Machiavelli had gathered in The Prince and *The* Discourses on ***Livy,*** the principles underlying the practice of his day in Italy; Francis I., the first monarch to establish a completely organized diplomatic machinery, did most to give these principles a European extension. By the close of the 16th century diplomacy had become frankly "Machiavellian," and the ordinary rules of morality were held not to apply to the intercourse between nations. This was admitted in theory as well as in practice[3]. The situation is summed up in the famous definition of Sir Henry Wotton, which, though excused by himself as a jest, was held to be an indiscreet revelation of the truth: "An ambassador is an honest man sent to lie abroad for the good of his country." (See Pearsall Smith, Sir Henry *Wotton,* pp. 49, 126 et seq.) So universally was this principle adopted that, in the end, no diplomatist even expected to be believed; and—as Bismarck cynically avowed—the best way to deceive was to tell the truth.

But, in addition to being a liar ex *officio,* the ambassador was also "an honourable spy." "The principal functions of an envoy," says François de Callibres, himself an ex-ambassador of Louis XIV., "are two; the first is to look after the affairs of his own prince; the second is to discover the affairs of the other." A clever minister, he maintains, will know how to keep himself informed of all that goes on in the mind of the sovereign, in the councils of ministers, or in the country; and for this end "good cheer and the warming effect of wine" are excellent allies[1]. This being so, it is hardly to be wondered at that foreign ambassadors were commonly regarded as unwelcome guests. The views of Philippe de Commines were shared by theoretical writers as well as by men of affairs. Gentilis is all but alone in his protest against the view that all ambassadors were exploratores *magis quam* oratores, and to be treated as such. So early as 1481 the government of Venice had decreed the penalty of banishment and a heavy fine for any one who should talk of affairs of state with a foreign envoy, and though the more civilized princes did not follow the example of the sultan, who by way of precaution locked the ambassador of Ferdinand II., Jerome Laski, into "a dark and stinking place without windows," they took the most minute precautions to prevent the ambassadors of friendly powers from penetrating into their secrets. Charles V. thought it safest to keep them as far away as possible from his court, and so did Francis I. Henry VII. forbade his subjects to hold any intercourse with them, and, later on, set spies upon them and examined their correspondence—a practice by no means confined to England alone. To Paschalius the permanent embassies were "a miserable outgrowth of a miserable age[2]." Grotius himself condemned them as not only harmful, but useless, the proof of the latter being that they were unknown to antiquity. (De *jure* belli et *pacis,* Amsterdam, 1621, ii. c. 18, § 3. n. 2.)

Development of the Diplomatic Hierarchy.—The term corps *diplomatique* originated about the middle of the 18th century. "The Chancellor Fürst," says Ranke (xxx. 47, note), "does not use it as yet in his report (1754) but he knows it," and it would appear that it had just been invented at Vienna. "Corps diplomatique, nom qu'une dame donna un jour a ce corps nombreux de ministres étrangers à Vienne." The middle ages, however, knew no classification of diplomatic agents; the person sent on mission is described indifferently as *legatus,* orator, *nuntius, ablegatus* commissarius, procurator, *mandatarius, agens* or ambaxator (ambassator, etc.). In Gundissalvus, De legato (1485), the oldest printed work on the subject, the word ambasiator, first found in a Venetian decree of 1268, is applied to any diplomatist. Florence was the first to make a distinction; the orator was appointed by the council of the republic; the mandatorio, with inferior powers, by the Council of Ten. In 1500 Machiavelli, who held only the latter rank, wrote from France urging the Signoria to send ambasiadori. This was, however, rather a question of powers than of dignity. But the causes which ultimately led to the elaborate differentiation of diplomatic ranks were rather questions of dignity than of functions. The breakdown of feudalism, with the consequent rise of a series of sovereign states, or of states claiming to be sovereign, of very various size and importance, led to a certain confusion in the ceremonial relations between them, which had been unknown to the comparatively clearly defined system of the middle ages. The smaller states were eager to assert their dignity; the greater powers were equally

[1] François de Callières, *De la manière de négocier avec les souverains* (Brussels, 1716). *See* also A. Sorel, *Recueil des instructions données aux ambassadeurs et ministres de France* (Paris, 1884), *e.g.,* vol. *Autriche,* pp. 77, 88, 102, 112.

[2] Paschalius, *Legatus* (1598), p. 447. So too Félix de la Mothe Le Vayer (1547–1625), in his *Legatus* (Paris, 1579).

bent on "keeping them in their place." If the emperor, as has been stated above, was too exalted to send ambassadors, certain states were soon esteemed too humble to be represented at the courts of the Great Powers save by agents of an inferior rank. By the second half of the 16th century, then, there are two classes of diplomatists, ambassadors and residents or agents, the latter being accounted ambassadors of the second class. At the first the difference of rank was determined by the status of the sovereign by whom or to whom the agent was accredited; but early in the 16th century it became fairly common for powers of the first rank to send agents of the second class to represent them at courts of an equal status. The reasons were various, and not unamusing. First and foremost came the question of expense. The ambassador, as representing the person of his sovereign, was bound by the sentiment of the age to display an exaggerated magnificence. His journeys were like royal progresses, his state entries surrounded with every circumstance of pomp, and it was held to be his duty to advertise the munificence of his prince by boundless largesses. Had this munificence been as unlimited in fact as in theory, all might have been well, but, in that age of vaulting ambitions, depleted exchequers were the rule rather than the exception in Europe; the records are full of pitiful appeals from ambassadors for arrears of pay, and appointment to an embassy often meant ruin, even to a man of substance. But the dignity of ambassador carried another drawback; his function of "honourable spy" was seriously hampered by the trammels of his position. He was unable to move freely in society, but lived a ceremonial existence in the midst of a crowd of retainers, through whom alone it was proper for him to communicate with the world outside. It followed that, though the office of ambassador was more dignified, that of agent was more useful.

Yet a third cause encouraged the growth of the lesser diplomatic ranks; the question of precedence among powers theoretically equal. Modern diplomacy has settled a difficulty which caused at one time much heart-burning, and even bloodshed, by a simple appeal to the alphabet. Great Britain feels no humiliation in signing after France, if the reason be that her name begins with G; had she not been Great, she would sign before. The vexed question of the precedence of ambassadors, too, has been settled by the rule as to seniority of appointment. But while the question remained unsettled it was obviously best to evade it by sending an agent of inferior rank to a court where the precedence claimed for an ambassador would have been refused.

Thus set in motion, the process of differentiation continues until the system is stereotyped in the 19th century. It is mainly a question of names. The ambassador extraordinary had originally been one sent on an extraordinary mission during which his authority superseded that of the resident ambassador. But by the middle of the 17th century the custom had grown up of calling all ambassadors "extraordinary," in order to place them on an equality with the others. The same process was extended to diplomatists of the second rank; and envoys (*envoyé* for *ablegatus*) were always "extraordinary," and as such took precedence over mere "residents," who in their day had asserted the same claim against the agents — all three terms having at one time been synonymous. Similarly a "minister plenipotentiary" had originally meant an agent armed with full powers (*plein-pouvoir*); but, by a like process, the combination came to mean as little as "envoy extraordinary" — though a plenipotentiary *tout* simple is still an agent, of no ceremonially defined dignity, despatched with full powers to treat and conclude. Finally, the evolution of the title of a diplomatist of the second rank is crowned by the high-sounding combination, now almost exclusively used, of "envoy extraordinary and minister plenipotentiary." The ultimate fate of the simple title "resident" was the same as that of "agent." Both had been freely sold by needy sovereigns to all and sundry who were prepared to pay for what gave them a certain social status. The "agent" fell thus into utter discredit, and those "residents" who were still actual diplomatic agents became "ministers resident" to distinguish them from the common herd.

The classification of diplomatic agents was for the first time definitively included in the general body of international law by the *Règlement*, March 10, 1815, at Vienna, and the whole question was finally settled at the congress of Aix-la-Chapelle (Nov. 21, 1818) when, the proposal to establish precedence by the status of the accrediting powers having wisely been rejected, diplomatic agents were divided into four classes: (1) ambassadors, legates, nuncios; (2) envoys extraordinary and ministers plenipotentiary, and other ministers accredited direct to the sovereign; (3) ministers resident; (4) chargés d'affaires. With a few exceptions (*e.g.*, Turkey), this settlement was accepted by all states, including the United States of America.

Rights **and** Privileges of Diplomatic Agents. — These are partly founded upon immemorial custom, and the result of negotiations embodied in international law. The most important, as it is the most ancient, is the right of personal inviolability extended to the diplomatic agent and the members of his suite. This inviolability is maintained after a rupture between the two governments concerned, and even after the outbreak of war. The habit of the Ottoman government of imprisoning in the Seven Towers the ambassador of a power with which it quarrelled was but an exception which proved the rule. The second important right is that of exterritoriality (*q.v.*), a convenient fiction by which the house and equipages of the diplomatic agent are regarded as the territory of the power by whom he is accredited. This involves the further principle that the agent is in no way subject to the receiving government. He is exempt from taxation and from the payment at least of certain local rates. He also enjoys immunity (1) from civil jurisdiction, *e.g.*, he cannot be sued, nor can his goods be seized, for debt; (2) from criminal jurisdiction, *e.g.*, he cannot be arrested and tried for a criminal offence. For a crime of violence, however, or for plotting against the State, he can be placed under the necessary restraint and expelled the country. The right of granting asylum claimed by diplomatic agents in virtue of that of exterritoriality, at one time much abused, is now strictly limited. A political or criminal offender may seek asylum in a foreign embassy; but if, after a formal request for his surrender, the ambassador refuses to deliver him up, the authorities may take the measures necessary to effect his arrest, and even force an entrance for the purpose. The "right of chapel" (droit de *chapelle*, or droit de *culte*), enjoyed by envoys in reference to their exterritoriality, *i.e.*, the right of free exercise of religious worship within their house, formerly of great importance, has been rendered superfluous by the spread of religious toleration.

During the World War certain questions were raised by the activities of the representatives of the belligerents in neutral states. In all neutral countries it was the duty of these representatives to obtain information useful to their governments, and to act as centres for an active propaganda of their views and aims. So long as this propaganda did not pass certain bounds no violence was done to the traditional principles of diplomacy. It was otherwise when diplomatic privileges and immunities were used to cover indirect attacks on the enemy through neutral interests. This was the case with the efforts of the Central Powers to interrupt the supply of munitions to the Allies from the United States. The discovery, in Sept., 1915, that Dr. Dumba, the Austrian ambassador, was proposing to finance strike movements on a large scale in the United States in order to hamper the manufacture of munitions led to his recall. Even more serious, however, was the subsequent discovery (October) that Capt. Boy-Ed and Capt. von Papen, the naval and military attaches to the German embassy, had been active in a plot to destroy American munition factories and American ships carrying munitions. Their subordinates, who were not covered by diplomatic immunity, were imprisoned; the two attaches were recalled at the instance of the United States Government. The same fate befell Count Luxburg, German minister in Buenos Aires, the author of the famous advice that ships carrying food from the Argentine to the Allies should be "spurlos versenkt" (sunk without leaving a trace). These notorious cases, characteristic of many others, were clearly condemned by the traditional standards of diplomacy. "The ambassador," Callières had written in the 18th century, "may suborn the prince's subjects for the purpose of obtaining information, but

not for the purpose of plotting against their master." Equally clear was the principle condemning the practice of the German diplomatists, especially in the United States, of plotting attacks on enemy states (*e.g.,* Canada, Ireland) under cover of their immunities. This was an abuse of diplomatic privilege, since it injured the State in which the plots were hatched by imperilling its neutrality.

BIBLIOGRAPHY.—Besides general works on international law (*q.v.*), a vast mass of treatises on diplomatic agents exists. The earliest printed work is the *Tractatus de legato* (Rome, 1485) of Gundissalvus (Gonsalvo de Villadiego), professor of law at Salamanca, auditor for Spain at the Roman court of the Rota, and bishop of Oviedo; but the first really systematic writer on the subject was Albericus Gentilis, *De legationibus libri iii.* (London, 1583, 1585, Hanover 1596, 1607, 1612). For a full bibliography of works on ambassadors *see* Baron Diedrich *H.* L. von Ompteda, *Litteratur des gesanzmten sowohl natürlichen als positiven Volkerrechts* (Regensburg, 1785), p. 534, etc., which was completed and continued by the Prussian minister Karl Albert von Kamptz, in *Neue Literatur des Volkerrechts sezt dem Jahre 1784* (Berlin, 1817), p. 231. A list of writers, with critical and bibliographical remarks, is also given in Ernest Nys's "Les Commencements de la diplomatie et le droit d'ambassade jusqu'à Grotius," in the *Revue de droit international,* vol. xvi. p. 167. Other useiul modern works on the history of diplomacy are: E. C. Grenville-Murray, *Embassies and Foreign Courts, a History of Diplomacy* (2nd ed. 1856); J. Zeller, *La Diplomatie française vers le milieu du XVIe siècle* (1881); A. O. Meyer, *Die englische Diplomatie in Deutschland zur Zeit Eduards VI. und Mariens* (Breslau, 1900); and, above all, Otto Rrauske, *Die Entwickelung der standigen Diplomatie vom fünfzehnten Jahrhundert bis zu den Beschlüssen von 1815 und 1818,* in Gustav Schmoller's *Staats-und socialwissenschaftliche Forschungen,* vol. v. (Leipzig, 1885). To these may be added, as admirably illustrating in detail the early developments of modern diplomacy, Logan Pearsall Smith's *Life and Letters of Sir Henry Wotton* (Oxford, 1907). For modern diplomacy *see* the *Guide diplomatique* of Baron Charles de Martens, new edit. revised by F. H. Geffcken, (Leipzig, 1866); P. Pradier-Fodéré, *Cours de droit diplomatique* (1881); Sir Ernest Satow, *A Guide to Diplomatic Practice* (1917); Denys P. Myers, "Notes on the Control of Foreign Relations," in part iii. of the *Recueil de Rapports* of the Organisation Centrale pour une Paix durable (The Hague, 1917), pp. 285–382, an invaluable study of the essential conditions under which diplomacy works; Edward S. Corwin, *The President's Control of Foreign Relations* (1917); Sir Maurice Hankey, *Diplomacy by Conference* (1921). A. Ponsonby, *Democracy and Diplomacy* (1915), puts the case for "democratic control", and contains the findings of the Royal Commission. (W. A. P.)

DIPLOMATIC is the science of the critical study of official as opposed to literary sources of history; that is to say, of charters, acts, treaties, contracts, judicial records, rolls, chartularies, registers and kindred documents. The employment of the word "diploma" as a general term to designate an historical document is of comparatively recent date. It is a Greek word, meaning literally a doubled or folded sheet, and was used by the Romans to denote, first, a passport or licence to travel by the public post and, later, any imperial grant of privileges. It was applied by the humanists of the Renaissance to important deeds and acts of sovereign authority, to privileges granted by kings and by great personages and by degrees its significance became extended to embrace the documents of the middle ages in general. The study of such documents, when Latin was the universal language of scholarship, was called *res diplomatica,* which, when learned books began to be written in the vernacular, was translated into "diplomatic."

History.—The first great text-book, the *De re diplomatica,* issued in 1681 by the learned Benedictine Dom Jean Mabillon, of the abbey of St. Germain-des-PrCs, was called forth by an earlier work by Daniel van Papenbroeck, the editor of the *Acta Sanctorum* of the Bollandists, who, with no great knowledge of archives, undertook to criticize the historical value of ancient records and monastic documents, and cast wholesale doubt on their authenticity. Mabillon's refutation of Papenbroeck's criticisms was complete, and was accepted by Papenbroeck himself. The *De re diplomatica* established the science on a secure basis; and, though its immediate result was a flood of controversy between the Benedictines and the Jesuits, it has been the foundation of all subsequent works on the subject

In Spain the Benedictine Perez published, in 1688, a series of dissertations following the line of Mabillon's work. In England Madox's *Formulare Anglicanum* (1702) and Hickes's *Linguarum septentrionalium thesaurus* (1703) both endorsed the principles laid down by the learned Frenchman. In Italy Maffei appeared with his *Istoria diplomatica* in 1727, and Muratori, in 1740, introduced dissertations on diplomatic into his great work, the *Antiquitates Italicae.* In Germany, the first diplomatic work of importance was that by Bessel, entitled *Chronicon Gotwicense* and issued in 1732.

France, however, the cradle of the science, has continued to be the home of its development. Mabillon had not taken cognizance of documents later than the 13th century, but a more comprehensive work was compiled by two later Benedictines. Dom Toustain and Dom Tassin; viz, the *Nouveau Traitk de diplomatique,* in six volumes, 1750–65, which embraced more than diplomatic proper and extended to all branches of Latin palaeography. Although the arrangement of this book is faulty, it contains a mass of valuable material, and more modern compilers have made extensive use of it.

As a result of the Revolution, the archives of the middle ages lost in France their juridical and legal value; but this rather tended to enhance their historical importance. The taste for historical literature revived. The Académie des Inscriptions fostered it. In 1821 the Ecole des Chartes was founded; and, though at first it did little, it received a further impetus in 1829 by the issue of a royal ordinance re-establishing it. Thenceforth it has been an active centre for the teaching and encouragement of the study of diplomatic throughout the country, and has produced results which other nations may envy. In Germany and Austria there has also been a systematic study of diplomatic archives, more or less with the support of the state; nor has the science been neglected in Italy. In England a late start was made, but much has been done within recent years to make up for lost time. The publications of the Public Record Office and of the department of mss. in the British Museum are now very numerous and are issued more regularly than in former times. The publication and criticism of documents are functions of various learned societies; and there are lectureships in palaeography and diplomatic at several universities.

Classification of Documents.—Documents may be classified under the two main heads of public and private deeds. In the former category are the legislative, administrative, judicial and diplomatic documents emanating from public authority in public form: laws, constitutions, ordinances, privileges. grants and concessions, proclamations, decrees, judicial records, pleas, treaties; in a word, every kind of deed necessary for the orderly government of a civilized state In early times many of these were comprised under the general term of "letters," *litterae,* and to the large number of them which were issued in open form and addressed to the community the specific title of "letters patent," *litterae patentes,* was given. Those which were issued in closed form under seal on the other hand were known as "close letters," *litterae clausae.*

Under the category of private documents are included not only the deeds of individuals, but also those of corporate bodies representing private interests, such as municipal bodies and monastic foundations. The largest class of documents of this character is composed of conveyances of real property and other title deeds. These are commonly described by the generic name of "charters," and are to be found in thousands, not only in the great public repositories, but also in the archives of municipal and other corporate bodies throughout the country and in the muniment rooms of old families. There are also the records of the manorial courts preserved in countless court-rolls and registers; while many scattered muniments of the dissolved monasteries represented by collections of charters and chartularies, or registers of charters, have fortunately survived and exist both in public and in private keeping.

The formalities observed by the different chanceries of mediaeval Europe, which are to be learned from a study of the documents issued by them, are so varied and often so minute that it is impossible to give a full account of them within the limits of the present article We can only state some of the results of the investigations of students of diplomatic.

Papal Chancery. — First and foremost stands the papal chancery, which has served as a model for all others. Organized in remote times, it adopted for the structure of its letters a number of formulae and rules which became more and more precise from century to century. The apostolic court being organized from the first on the model of the Roman imperial court, the early pontiffs naturally collected their archives, as the emperors had done, into *scrinia* (boxes). Pope Julius I., A.D. 337–353, reorganized the papal archives and Pope Damasus, A.D. 366–384, built a record office at the Lateran. The collection and orderly arrangement of the archives provided material for the establishment of regular diplomatic usages, and the science of formulae naturally followed.

For the study of papal documents four periods have been defined, each being distinguished by some particular development of forms and procedure. The first period is reckoned from the earliest times to the accession of Leo IX., A.D. 1048. For almost the whole of the first eight centuries no original papal documents have survived. But copies are found in canonical works and registers, many of them false, and others probably not transcribed in full or in the original words, but still of use, as showing the growth of formulae. The earliest original document is a fragment of a letter of Adrian I., A.D. 788. From that date there is a series, but documents are rare before the beginning of the 11th century, all of which exist, being written on papyrus. The latest existing papyrus document is dated A.D. 1022, the earliest on vellum A.D. 1005. The nomenclature of papal documents even at an early period is rather wide. In their earliest form they are letters, called in the documents themselves *litterae,* epistola, *pagina, scriptum,* sometimes *decretum.* A classification, generally accepted, divides them into: (1) Letters or Epistles: the ordinary acts of correspondence with persons of all ranks and orders; including constitutions (a later term) or decisions in matters of faith and discipline, and encyclicals giving directions to bishops of the whole church or of individual countries; (2) Decrees, being letters promulgated by the popes of their own motion; (3) Decretals, decisions on points of ecclesiastical administration or discipline; (4) Rescripts (called in the originals *preceptum,* auctoritas, *privilegium*), granting requests to petitioners. The comprehensive term "bull" (the name of the leaden papal seal, *bulla,* being transferred to the document) did not come into use until the 13th century.

The second period of papal documents extends from Leo IX. to to the accession of Innocent III., A.D. 1048–1198. At the beginning of the period formulae tended to take more definite shape and to become fixed; but it was under Urban II., A.D. 1088–99, that the principal formulae became stereotyped. The distinction between documents of lasting and those of transitory value became more exactly defined; the former class being known as greater bulls, bullae *majores* (also called *privilegia*), the latter lesser bulls, bullae *minores.* The introduction of subscriptions of cardinals as witnesses to greater bulls had gradually become a practice. Under Victor II., A.D. 1055–57, the practice became more confirmed, and after the time of Innocent II., A.D. 1130–45, the subscriptions of the three orders were arranged according to rank, those of the cardinal-bishops being placed in the centre under the papal subscription, those of the priests on the left, and those of the deacons on the right.

By degrees the use of the lesser bulls almost entirely superseded that of the greater bulls, which became exceptional in the 13th century and almost ceased after the migration to Avignon in 1309. In modern times the greater bulls occasionally reappear for very solemn acts, as bullae consistoriales, executed in the consistory.

The third period of papal documents extends from Innocent III. to Eugenius IV., A.D. 1198–1431. The pontificate of Innocent III. was a most important epoch in the history of the development of the papal chancery. Formulae became more exactly fixed, definitions more precise, the observation of rules and precedents more constant. The staff of the chancery was reorganized. The existing series of registers of papal documents was then commenced. The growing use of lesser bulls for the business of the papal court led to a further development in the 13th century. They were now divided into two classes, *tituli* and *mandamenta.* The former conferred favours, promulgated precepts, judgments, decisions, etc.; the latter comprised ordinances, commissions, etc., and were executive documents.

In the fourth period, extending from 1431 to the present time, the *tituli* and mandamenta have continued to be the ordinary documents in use; but certain other kinds have also arisen. Briefs (brevia), or apostolic letters, concerning the personal affairs of the Pope or the administration of the temporal dominion, or conceding indulgences, came into general use in the 13th century in the pontificate of Eugenius IV. They are written in the italic hand on thin white vellum, and the name of the Pope with his style as papa is written at the head of the sheet; *e.g.,* Eugenius papa iiii. They are closed and sealed with the Seal of the Fisherman, *sub anulo* Piscatoris. Briefs have almost superseded the mandamenta.

Merovingian Chancery. — Of the chancery of the Merovingian line of kings of France as many as 90 authentic diplomas are known, and of these 37 are originals, the earliest being of the year 625. The most ancient examples were written on papyrus, vellum superseding that material towards the end of the 7th century. All these diplomas are technically letters and were authenticated by the king's subscription, that of the referendarius (the official charged with the custody of the royal seal), the impression of the seal, and exceptionally by subscriptions of prelates and great personages. The royal subscription was usually autograph; but, if the sovereign were too young or too illiterate to write, a monogram was traced by the scribe. They are of two classes: (1) Precepts, conferring gifts, favours, immunities, and confirmations, entitled in the documents themselves *praeceptum, praeceptio, auctoritas;* some drawn up in full form, with preamble and ample final clauses; others less precise and formal; (2) Judgments (judicia), which required no preamble or final clauses as they were records of the sovereign's judicial decisions; they were subscribed by the referendary and were sealed with the royal seal.

Carolingian Chancery. — The diplomas of the early Carolingians differed but little from those of their predecessors. The royal subscription was in form of a sign-manual or mark, but Charlemagne elaborated this into a monogram of the letters of his name built up on a cross. Most of his diplomas were authenticated by the subscription of the chancellor and impression of the seal. A novelty in the form of dating was also introduced, two words, datum (for time) and *actum* (for place), being then employed. The character of the writing of the diplomas, founded on the Roman cursive hand, which had become very intricate under the Merovingians, improved under their successors, yet the reform which was introduced into the literary script hardly affected the cursive writing of diplomatic until the latter part of Charlemagne's reign. The archaic style was particularly maintained in judgments, which were issued by the private chancery of the palace, a department more conservative in its methods than the imperial chancery. It was in the reign of Louis Debonair, A.D. 814–840, that the Carolingian diploma took its final shape. A variation then appears in the monogram, that monarch's sign-manual being built up, not on a cross as previously, but on the letter H, the initial of his name Hludovicus, and serving as the pattern for successive monarchs of the name of Louis.

In the Carolingian chancery the staff was exclusively ecclesiastical; at its head was the chancellor, whose title it traced back to the *cancellarius,* or petty officer under the Roman Empire, stationed at the bar or lattice (*cancelli*) of the basilica or other law court and serving as usher. As keeper of the royal archives his subscription was indispensable for royal acts. The diplomas were drawn up by the notaries, an important body, upon whom devolved the duty of maintaining the formulae and traditions of the office. It has been observed that in the 9th century the documents were drawn carefully, but that in the 10th century there was a great degeneration in this respect. Under the early Capetian kings there was great confusion and want of uniformity in their diplomas, and it was not until the reign of Louis VI., A.D. 1108, that the formulae were again reduced to rules. The acts of

the imperial chancery of Germany followed the patterns of the Carolingian diplomas, with little variation down to the reign of Frederick Barbarossa, A.D. 1152–1190.

England. — For the study of diplomatic in England material exists in two distinct series of documents, those of the Anglo-Saxon period and those subsequent to the Norman Conquest. The Anglo-Saxon kings appear to have borrowed, partially, the style of their diplomas from the chanceries of their Frankish neighbours, introducing at the same time modifications which give those documents a particular character marking their nationality. In some of the earlier examples the lines of the foreign style are followed more or less closely; but very soon a simpler model was adopted which lasted in general construction down to the time of the Norman Conquest. The royal charters were usually drawn up in Latin, sometimes in Anglo-Saxon, and began with a preamble or exordium, in the early times of a simple character, but later drawn out not infrequently to great length in involved and bombastic periods. Then immediately followed the disposing or granting clause, often accompanied with a few words explaining the motive, such as for the good of the soul of the grantor; and the text was closed with final clauses of varying extent, protecting the deed against infringement, etc.

In early examples the dating clause gave the day and month (often according to the Roman calendar) and the year of the indiction; but the year of the Incarnation was also immediately adopted, and later the regnal year also. The subscriptions of the king and of the personages witnessing the deed, each preceded by a cross, but all written by the hand of the scribe, usually closed the charter. A peculiarity was the introduction in many instances, either in the body of the charter or in a separate paragraph at the end, of the boundaries of the land granted, written in the native tongue. The sovereigns of the several kingdoms of the Heptarchy, as well as those of the United Kingdom, usually styled themselves *rex*. But from the time of Aethelstan, A.D. 825–840, they also assumed fantastic titles in the text of their charters, such as: *rex et primicerius, rex et rector, gubernator et rector, monarchus* and particularly the Greek *basileus* and *basileus industrius*. At the same time the name of Albion was also frequently used for Britain.

A large number of documents of the Anglo-Saxon period, dating from the 7th century, has survived, both original and copies entered in chartularies. Of distinct documents there are nearly two hundred; but a large proportion of these must be set aside as copies (both contemporary and later) or as spurious deeds.

Although there is evidence of the use of seals by certain of the Mercian kings, the method of authentication of diplomas by seal impression was practically unknown to the Anglo-Saxon sovereigns, save only to Edward the Confessor, who, copying the custom which obtained upon the Continent, adopted the use of a great seal.

Immediately after the Norman Conquest of England the old tradition of the Anglo-Saxons. disappeared. The Conqueror brought with him the practice of the Roman chancery, which naturally followed the Capetian model; and his diplomas of English origin differed only from those of Normandy by the addition of his new title, *rex Anglorum,* in the superscription. But even from the first there was a tendency to simplicity in the new English chancery, not improbably suggested by the brief formalities of Anglo-Saxon charters, and, side by side with the more formal royal diplomas, others of shorter form and less ceremony were issued, which by the reign of Henry II. had quite superseded the more solemn documents. By the reign of John these simpler forms had taken final shape, and from this time the acts of the kings of England have been classified under three heads; viz.: (1) Charters, generally of the pattern described above; (2) letters patent, in which the address is general, the king himself is his own witness, and the great seal is appended; (3) close letters, administrative documents conveying orders, the king witnessing.

The style of the English kings down to John was, with few exceptions, *Rex Anglorum;* thenceforward, *Rex Angliae.* Henry II. added the feudal titles, *dux Normannorum* et *Aquitanorum et comes Andegavorum,* which Henry III. curtailed to *dux Aquitaniae.* John added the title *dominus Hiberniae;* Edward III., on claiming the crown of France, styled himself *rex Angliae et Franciae,* this title being borne by successive kings down to the year 1801; and Henry VIII., in 1521, assumed the title of *fidei dejensor.* The formula *Dei gratia* does not consistently accompany the royal title until the reign of Henry II., who adopted it in 1173.

The forms adopted in the royal chanceries were imitated in the composition of private deeds, which in all countries form the mass of material for historical and diplomatic research. The student of English diplomatic will soon remark how readily the private charters, especially conveyances of real property, fall into classes, and how stereotyped the phraseology and formulae of each class become, only modified from time to time by particular acts of legislation. The brevity of the early conveyances was maintained with only moderate growth through the 12th, 13th and 14th centuries. The different kinds of deeds must be learned by the student from the text-books, but a particular form of document which was especially in favour in England should be mentioned. This was the chirograph (Gr. χείρ, a hand, γράφειν, to write), which is found even in the Anglo-Saxon period, and which got its name from the word *chirographum, cirographum* or *cyrographum* being written in large letters at the head of the deed. At first the word was written, presumably, at the head of each of the two authentic copies which the two parties to a transaction would require. Then it became the habit to use the word as a tally, the two copies of the deed being written on one sheet, head to head, with the word between them, which was then cut through longitudinally in a straight, or more commonly waved or indented line, each of the two copies thus having half of the word at the head. Any other word, or a series of letters, might thus be employed for the same purpose. The chirograph was the precursor of the modern indenture, the commonest form of English deeds, though no longer a tally. In other countries, the notarial instrument has performed the functions which the chirograph and indenture have discharged for us.

of Anglo-Saxon Manuscripts (charters), (1878–84); G. F. Warner and H. J. Ellis, Facsimiles of Royal and other Charters in the *British* Museum (1903). (E. M. T.; F. B.)

DIPLOPIA, seeing a single object as double, occurs whenever one of the two eyes leaves the correct position of fixation, *i.e.,* when one eye cannot focus on an object simultaneously with the other eye. An object clearly seen by the normal eye gives rise to an image in the deviated eye to one side of the macula, and is referred by the mind to a position different from that which it really occupies. Thus there seem to be two objects, one clearly seen with the normal eye, and one indistinctly seen by the deviated eye. Causes of deviation of one eye are (1) disturbances in the motor apparatus of the eye, (2) tumor or abscess in the orbit, (3) limitation of motion of the eyeball from without. Paralysis, or weakness of one or more of the eye muscles, is by far the commonest cause of ocular deviation, and it is in those cases which come on suddenly that diplopia is a striking feature. It occurs frequently in alcoholic intoxication and in encephalitis lethargica and less often in poisoning by lead or carbon monoxide, and in certain acute infections such as diphtheria and polioencephalitis.

DIPNOI: see LUNG-FISH; FISHES.

DIPOENUS and **SCYLLIS,** early Greek sculptors, who worked together, and are said to have been pupils of Daedalus. Pliny assigns to them the date 580 B.C., and says that they worked at Sicyon, which city from their time onwards became one of the great schools of sculpture. They also made statues for Cleonae and Argos. They worked in wood, ebony and ivory, and apparently also in marble. It is curious that no inscription bearing their names has come to light.

DIPPEL, JOMANN KONRAD (1673–1734), German theologian and alchemist, son of a Lutheran pastor, was born near Darmstadt on Aug. 10, 1673. He studied theology at Giessen, and then pharmacy and medicine, taking his M.D. degree at Leyden in 1711. He discovered Prussian blue, and by the destructive distillation of bones prepared Dippel's animal oil. Dippel was one of the most learned men of his time. He died near Berleburg on April 25, 1734 having practised at Amsterdam as a physician and afterwards at the Court of Sweden.

Dippel's works (mostly written under the pseudonym of Christianus Democritus) were published at Berleburg (1743). See W. Bender: J. K. *Dippel* (Bonn, 1882).

DIPPER or WATER-OUSEL, a bird about the size of a thrush, squatly built and of an active disposition. The dipper (*Cinclus* cinclus) haunts the rocky streams of Europe and North Asia. The dipper, belonging to a small family of its own, the Cinclidae, feeds upon small fresh-water molluscs and crustacea, which it captures under the water, walking along the bottom of the stream and aiding its progress with its wings. It can also swim on the surface of the water, despite the fact that its feet are not webbed. The upper parts are dark, the throat and breast white, and the belly has a chestnut band. Its ringing song may be heard even in winter. The white eggs, four to seven in number, are laid in a cup-shaped nest of grass, lined with dead leaves, and completely encased and domed with moss, except for a small hole to admit the bird. There are many Old World forms.

In North America, this species is replaced by C. *mexicanus* in the mountains of the west. The American bird lacks the white throat of the European form, which it otherwise resembles closely. The Costa Rican dipper (C. *ardesiacus*) of the highlands of Costa Rica and Chiriqui is similar, with the general colour a lighter gray.

DIPSACACEAE, a family of dicotyledonous plants, the best-known member of which is the teasel (*q.v.*). The family includes ten genera and 150 species. The scabiouses (Scabiosa Knautia) also belong to this family.

DIPSOMANIA, a term formerly applied to the attacks of delirium (*q.v.*) caused by alcoholic poisoning. It is now sometimes loosely used as equivalent to the condition of incurable inebriates, but strictly should be confined to the pathological and insatiable desire for alcohol, sometimes occurring in paroxysms.

DIPTERA, the term used in zoological classification for the two-winged or true flies which form one of the largest orders of insects. Their chief character is expressed in the name of the order (Gr. δίς double, and πτερά wing) and, with certain aberrant exceptions, flies possess a single pair of membranous wings corresponding with the anterior pair in other winged insects: hind wings are absent and are represented by a pair of small knobbed organs termed halteres or balancers. The mouth parts are always adapted for sucking and sometimes for piercing also, and the various organs combined form a proboscis. Flies undergo complete metamorphosis and their larvae are always devoid of legs and most often have a much reduced head: the pupae are either free or enclosed in a hardened shell or puparium. The foregoing definition embraces over 50,000 described species and, of this number, about 3,000 kinds inhabit the British Isles, but new species are continually being found in almost all countries. As a rule, flies are of small or moderate size: some species are even minute, measuring one millimetre long. while some Australian robber flies exceed three inches in wing-expanse with a body length of one and three-quarters inches. The majority of flies are diurnal and frequent flowers for their nectar or haunt decaying organic matter of diverse kinds. Some species, however, are predaceous upon smaller insects, while a number of others, including mosquitoes and horse flies, have acquired blood-sucking habits, chiefly in the female. It is in virtue of this latter propensity that the order has acquired great significance in relation to medicine and public health. The pathogenic organisms of malaria, sleeping sickness, elephantiasis, yellow fever and other diseases are transmitted to man through the intermediary of blood-sucking flies. Diptera are generally of sombre coloration, but some species (hover flies) are conspicuously banded, others (the green-bottles, etc.) are metallic green or blue, while several kinds are densely hairy and coloured like bees. The sexes are generally closely alike, but in some flies with long antennae those organs are densely plumose in the males, and in many species the compound eyes are placed much closer together in the male than in the female, sometimes nearly meeting. Linnaeus first used the term "diptera" in its modern sense.

General Structure. — The head is generally a somewhat spherical capsule, with much of its surface often occupied by the compound eyes and the antennae exhibit diverse forms (fig. 1) of important significance in classification. The mouth-parts (fig. 2, 3) are highly modified for sucking: mandibles are only present in those flies that feed by piercing, and are lancet-like: the maxillae in such flies are of similar form but usually they are reduced, partly fused with the head and chiefly represented by their palpi: the labium is membranous and forms the greater part of the proboscis, and its apex is expanded to form two sucking lobes or labella. The thorax is fused into a single mass chiefly formed by the large mesothorax, and the legs have five-jointed tarsi. The membranous wings (fig. g) frequently have the venation reduced and there are but few cross-veins: in certain parasitic and other flies wings are absent. In the female the abdomen often has its terminal segments tubular and retractile, forming an ovipositor. The tracheae are frequently expanded to form large air-sacs, while the digestive system usually has a special food-reservoir opening into it by a narrow duct. In many flies the ganglia of the ventral chain are fused into a single mass and, in some cases, the female reproductive organs are adapted to retain the larvae for a variable period after developing from the eggs.

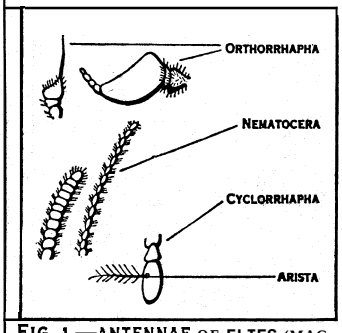

FIG. 1.—ANTENNAE OF FLIES (MAGNIFIED)

Classification. — The classification of flies is of a very technical character and is somewhat simplified in the following scheme. There are two main sub-orders which embrace a large number of families, only the more important of which are noted below.

SUB-ORDER I. NEMATOCERA

Mostly slender flies with elongate antennae of seven or more joints: maxillary palpi four or five jointed. Wings with median cell usually absent. Larvae with an evident head, pupae free.

The Nematocera include 13 families; the most important are the following:

The *Tipulidae* include the crane-flies or "daddy-long-legs" which

FIG. 3.— HEAD AND MOUTH PARTS OF AN ANOPHELES MOSQUITO, SHOWING PIERCING AND SUCKING APPARATUS

roots. Crane-flies include many species and are found all over the world.

The *Culicidae* (fig. 4) are known as gnats or mosquitoes (*q.v.*): the body and wings are invested with scales and the mouth-parts are stylet-like and used for sucking blood. Their larvae and pupae live in water and are very active. More than 1,500 species are known and at least 25 kinds occur in Great Britain. The common gnats are species of the genus *Culex* while members of the genus *Anopheles* are concerned with the transmission of the malaria organism.

The *Chironomidae* or midges resemble mosquitoes in form, but scales are wanting and the mouth-parts are usually degenerate. Their larvae and pupae are mostly aquatic and red or green in colour, the red larvae being known as blood-worms.

The *Cecidomyidae* or gall midges (fig. 5) are minute flies with very few veins to the wings and the antennae bead-like and adorned with circlets of long hairs. Their larvae are often orange in colour, with a minute head: they live in plant-tissues, forming galls of various types.

Mention should also be made of the *Mycetophilidae* or fungus midges and the tiny hairy *Psychodidae* which comprise the moth-flies, sand-flies and the *Simuliidae*, or buffalo gnats.

SUB-ORDER II. BRACHYCERA

Mostly stoutly built flies whose antennae are three to six jointed and maxillary palpi one or two jointed. Wings usually with a median cell. Larvae generally with a much reduced head, (fig. 8) pupae free or enclosed in puparium.

This large sub-order is divisible into two series as follows:

Series I. ORTHORRHAPHA.—*Head without a frontal suture: antennae with a terminal bristle or prolongation* (fig. 1). *Larvae with a reduced head; pupae free and splitting by means of a dorsal fracture.*

There are 14 families in this series, of which five are mentioned below.

The *Stratiomyidae* are more or less flattened flies usually with white, yellow or green markings, while some are metallic. The scutellum is often spiny and the last antennal joint is generally ringed. More than 1,000 species are known and their larvae live in water or damp earth; the pupae are loosely enclosed in the last larval skin.

The *Tabanidae* (fig. 6) or horse-flies have a broad head, piercing mouth-parts and brilliantly coloured eyes. The costal vein is prolonged right round the wing and the halteres are hidden by a membranous scale or squama. The various species of *Tabanus* and the clegs *(Haematopota)* are troublesome blood-suckers, attacking man, horses and cattle. Their larvae frequent damp earth and bear circlets of papillae around many of the segments. The family is widely distributed, none of the species is very small and over 2,000 kinds are known.

The *Asilidae*, or robber flies, are large insects with long, hairy bodies and elongate, bristly, prehensile legs. They prey upon other insects, extracting their body-fluids by means of their piercing mouth-parts. Their larvae live in soil and rotting wood.

The *Empidae* have similar habits but are not hairy and are less robustly built; a tuft of hairs, forming a mouth-beard, present in *Asilidae*, is absent in this family. Both families are widely distributed and include many species.

The *Bombyliidae*, or bee-flies (fig. 7), are usually densely pubescent and bee-like with a long projecting proboscis, slender stiff legs and often marbled wings. The flies suck nectar from flowers, and their larvae are chiefly parasitic upon those of solitary bees. Although only nine species occur in Britain, at least 2,000 kinds are known from various parts of the world. None of the above types are remarkable for brilliancy of colouring.

Series II. CYCLORRHAPHA. *Head usually with a fronfal suture with a small hard plate or lunule* (fig. 2) *above it: antennae with*

a dorsal bristle or arista (fig. 1). *Larvae with only a vestige of a head: pupae enclosed in the hardened larval skin or puparium* (fig. 8) *which ruptures by means of a circular fracture.*

In these flies a kind of bladder (the ptilinum) is protruded through the frontal suture in order to force open the puparium, thus allowing the insect to emerge: the bladder is then withdrawn into the head.

Superfamily I. Syrphoidea.—*Frontal suture rudimentary or absent: lunule prerent.*

Three families belong here, the most important being the *Syrphidae*, or hover flies, distinguished by the spurious vein, which crosses the wing without reaching the outer margin, and by the presence of an inner vein running parallel with the apical wing-margin (fig. 9). Many of these flies are banded like wasps, while others are hairy and resemble bumble bees. The drone fly (*Eristalis tenax*) is a familiar example and, like most of the other species, hovers in the air with rapidly vibrating wings. The larvae exhibit diverse habits; many are predaceous upon aphids, etc, while others are scavengers in decaying matter or in the nests of bees and wasps.

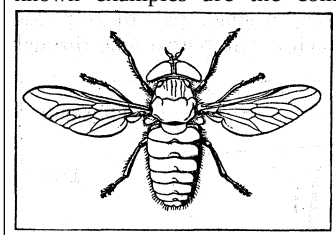
FIG. 5.—THE LIFE HISTORY OF THE ROSE MIDGE (DASYNEURA RHODOPHAGA), A NATIVE OF THE UNITED STATES

Superfamily **II. Muscoidea.**—*Frontal suture and lunule present.*

This is an immense group containing many families, some of which are ill-defined and difficult to separate. The fruit-flies (fam. *Trypaneidae*) usually have prettily marked wings and their larvae attack various fruits, mine leaves (as in the celery fly) or form galls. The gout-fly of barley and the frit-fly of oats are well-known members of the family *Oscinidae*. The *Agromyzidae* include many flies whose larvae mine the leaves and other tissues of plants. The *Muscidae* are a very important family most of whose larvae are scavengers, or prey upon other fly larvae. Well-known examples are the common house-fly, *Mwca domestica* (*q.v.*), the blue-bottles (*Calliphora*) and the Tsetse flies, *Glossina* (*q.v.*). The *Tachinidae* include a great number of bristly flies, bearing a general resemblance to the house-fly. Most of their larvae are internal parasites, especially of caterpillars, and are important natural agents in restraining the abundance of other insect life. The *Oestridae* are seldom found as flies, but their larvae live as parasites of domestic and other animals and are more commonly met with. The Ox warble flies (*Hypoderma*) live as larvae beneath the hide of cattle, and larvae of the bot flies (*Gastrophilus*) are troublesome intestinal parasites of horses *Muscidae* fly parasites have been found in Australia.



FROM DR. IMMS, GENERAL TEAT-BOOK OF ENTOMOLOGY (METHUEN & CO.)

FIG. 6.—THE BRITISH HORSE-FLY, (TABANUS MACULICORNIS)

Superfamily **III. Hippoboscoidea** (*or* **Pupipara**).—*Frontal suture and lunule present. Flattened leathery flies living parasitically upon mammals and birds: the larvae are retained within the bodies of the females until about to pupate.*

Three families belong here, the most important being the *Hippoboscidae* which include the forest-fly (*Hippobosca equina*) and its allies: the wingless sheep ked or tick (*Melophagus ovinus*) and the genus *Ornithomyia*, which infests birds, are also included. The families *Nycteribiidae* and *Streblidae* include highly aberrant insects found in many parts of the world living on bats. The members of the first-mentioned family are all wingless creatures of spider-like form.

Reproduction and Development.— *The* eggs of flies are of diverse forms and are usually laid in large numbers: thus, a single house-fly in warm countries may deposit over 2,000 eggs during her life. By this insect they are deposited in masses of 100–150, while by *Culex* mosquitoes they are laid in compact groups forming rafts which float on the surface of water. Many other flies deposit their eggs separately wherever there is sufficient food to nourish the larvae. Most flies pass through more than one generation in a season and in the presence of abundant larval food and a high temperature, generation after generation may result. As a rule only a few days are spent in the egg, and in some flies the eggs are retained within the female until they have developed into larvae. In the Tsetse flies and the *Hippoboscoidae* the whole larval life is passed in this manner, and under such circumstances the larvae are nourished on a special secretion provided by the female fly. When fully grown, these larvae are "born" one at a time, at long intervals, and they quickly change into pupae. Dipterous larvae never bear legs (fig. 8), they are commonly elongate and somewhat vermiform in shape, and only in certain families is the head fully formed. In most cases, they bear only an anterior and a posterior pair of spiracles, or the latter pair alone may be present. Owing to their legless condition, fly larvae pass a concealed life in the tissues of plants, burrowing in soil or in decaying refuse and dung, in the bodies of insects or other animals, or in water. Perhaps the most remarkable life is that spent by an American fly whose larvae inhabit petroleum pools in California; certain midge larvae occur in the sea and other dipterous larvae

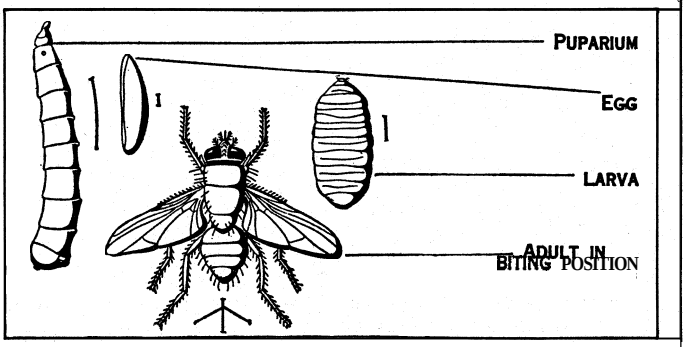
FIG. 7.—THE BRITISH BEE-FLY (BOMBYLIUS MAJOR), WHICH HAS EXTERNAL RESEMBLANCE TO A BEE

frequent hot springs. With this diversity of habitat there is found a wide range of food preference. Probably more fly larvae feed on decaying organic matter than on anything else; only in a comparatively small number of families do we find exclusively plant-feeders, but a considerable number of families have larvae that are predaceous or parasitic in habit. There are many structural adaptations which fit the larvae to their mode of life. Thus, most of the parasitic forms have only a single pair of spiracles, situated at the caudal extremity. Such larvae bore a hole through



BY COURTESY OF THE U S. DEPARTMENT OF AGRICULTURE

FIG. 8.— THE EUROPEAN HORN-FLY (HAEMATOBIA SERRATA), A BLOOD-SUCKING FLY BREEDING IN COW DUNG, NOW FOUND IN AMERICA

their host's skin, and insert their tail-end therein in order to breathe the outer air. Some Tachinid larvae work their spiracular extremity into a main trachea of the host insect and breathe the contained air. Mosquito larvae have a similar disposition of the spiracles and keep their tail extremity above the water when taking in air. When about to pupate, fly larvae do not usually form cocoons, the pupae being protected by the medium in which the larvae lived. Among the more primitive groups of flies the pupae are free, but in the Cyclorrhapha the final larval skin persists around the pupa and hardens into a barrel-like puparium (fig. 8).

Geographical Distribution. — It may be said briefly that all the important families of flies are very widely distributed but certain of the smaller groups are more restricted in their range. As a rule the largest and most striking members occur in the tropics where some of the most exaggerated developments of form are also found. Generally, however, the members of a given family have a very constant facies, whether they come from the tropics or from temperate regions. The house-fly is practically cosmopolitan and is found wherever man has established himself; many other flies such as *Lucilia* (green-bottles), *Calliphora* (blow flies) and Stomoxys (stable fly) have also become very widely distributed through human agencies, while some of the curious bat-parasites (Nycteribiidae) have a wide distribution dependent upon that of their hosts. On the other hand, the Tsetse flies (Glossina) are confined to Africa south of the Sahara, and the small family *Acanthomeridae* belongs to tropical America and the West Indies. Flies are also met with in very isolated situations. The curious wingless crane-fly, Chionea, is found in Europe and North America on the surface of snow, while other wingless or semi-wingless Diptera are found on the shores of Kerguelen and other far-distant ocean islands.

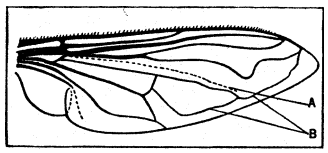


FIG. 9.— WING OF THE DRONE-FLY (ERISTALIS TENAX)
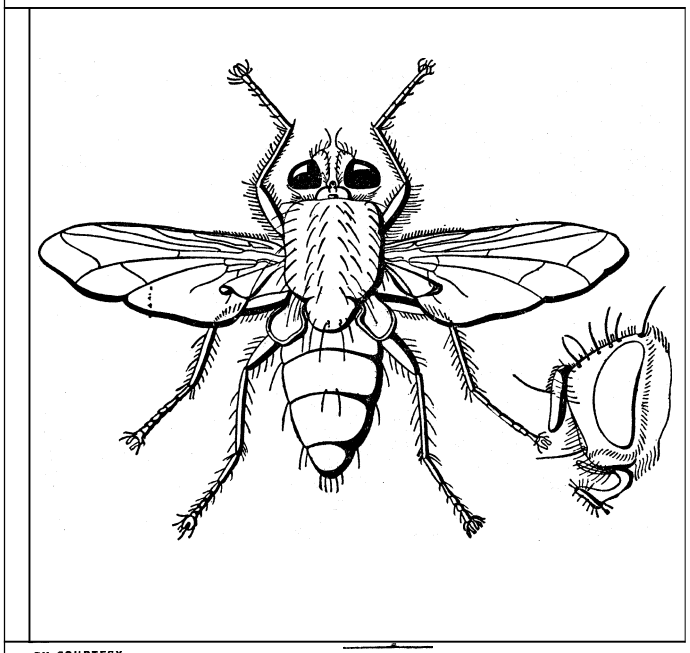
A. Spurious vein; B. branches of median

Geological Distribution. — Diptera is one of the latest orders of insects to appear in geological time and is not met with until the Upper Lias of Europe, where certain Nematocera occur. There appears to be no certain evidence of the existence of the higher families until the Tertiary period. In Baltic amber and in the beds at Florissant, Colorado, numerous fossil flies occur.

Economic Importance. — No order of insects exceeds the Diptera in economic importance. A large number of flies in their larval stages are destructive to cultivated plants. Among the most important of these is the frit fly (Oscinella frit) of Europe and North America, which is destructive to growing oats, while the closely allied gout fly (Cltlorops *taeniopus*) produces swollen deformations of the ear-bearing shoots of barley. Leather-jackets, or larvae of certain crane-flies, cause much damage to the roots of cereals and other crops, while the cabbage root-fly (*Chortophila* brassicae) and the onion fly (*Hylemyia antiqua*) entail losses to growers of those vegetables. The Hessian fly (Mayetiola destructor) is also a severe pest of cereals, both in Europe and North America. Mention must also be made of the Mediterranean fruit-fly (Ceratitis capitata) which attacks almost all kinds of succulent fruits in many tropical and warm regions, including south Europe.

There are other flies whose larvae are injurious to man and domestic animals, and the affections induced by their presence are included under the general term of *myiasis*. Included in this category are the Oestridae, especially the warble flies (Hypoderma) of Europe and North America, which cause immense losses through perforating the hides of cattle; the larvae of bot-flies (*Gastrophilus*) are parasites that attach themselves to the alimentary canal of horses and mules. The related sheep bot-fly (*Oestrus* ovis) troubles sheep, its larvae burrowing in the cranial sinuses. The screw-worm, or larva of Clzrysomyia *macellaria* (allied to the house-fly), occurs from Canada to Patagonia and infests sores and wounds in animals and even the nasal cavities of man. The sheep-maggot flies of Australia and other countries include several species which cause immense losses on sheep farms: their larvae often puncture the skin, causing horrible-infestations, accompanied by bacterial infection of the parts concerned.

There are also numerous flies of blood-sucking habits, whose larvae are not directly injurious. Certain kinds are irritating pests of man and domestic animals, while others of similar habits convey the pathogenic organisms of certain virulent diseases from one animal, or human being, to another. Thus, many species of



BY COURTESY OF THE U.S. DEPARTMENT OF AGRICULTURE

FIG. 10.—TACHINID FLY (TACHINA LARVARUM): FEMALE AND HEAD IN PROFILE, MAGNIFIED

Anopheles mosquitoes are the direct carriers of malaria parasites from man to man. Yellow fever is only contracted when the mosquito Aedes *aegypti* (formerly known as Stegomyia fasciata) sucks the blood of man after having previously fed upon an infected person (fig. 3). Another mosquito, *Culex* fatigans, is a carrier of the filaria worm which induces the disfiguring disease of elephantiasis, while the Tsetse fly (Glossina) is a carrier of the pathogenic organisms (Trypanosomes) of sleeping sickness in man and of nagana in domestic animals. The minute moth flies (fam. Psychodidae) include the blood-sucking genus *Phleboto-*

mus, the members of which are small enough to pass through the meshes of mosquito curtains. Sand-fever or pappataci fever of Southern Europe, North Africa, etc., is transmitted from man to man by a member of this genus. Mention must also be made of the horse-flies (fam. Tabanidae) a species of which (*Tabanus striatus*) has been shown to transmit the pathogenic organism of surra among horses and other animals in the Orient.

The house-fly (*Musca domestica*), although innocent of blood-sucking habits, is a dangerous carrier of the germs of typhoid, infantile diarrhoea and other diseases. Being attracted to excrementous matter, often containing disease germs, the insect's mouth-parts and body thus become contaminated and its faeces include ingested bacilli. Flies infected in this way readily contaminate food which consequently becomes a source of infection to human beings.

The economic importance of Diptera is not confined to their injurious activities: on the other hand, there are many species which are valuable auxiliaries to man. The majority of the predaceous and parasitic forms are beneficial: many larvae of the hover flies (fam. *Syrphidae*), for example, are important agents in reducing the excessive multiplication of plant lice, while the parasitic larvae of the Tachinidae destroy vast numbers of other insects. The rôle of the latter flies as natural controlling agents has led to their practical utilization in several parts of the world. Thus, the sugar cane borer beetle (*Rhabocnemis* obscura) in the Hawaiian Islands is so successfully parasitized by the Tachinid *Ceromasia sphenophori,* introduced into those islands from New Guinea, that it is now largely under control. Other Tachinidae have been introduced from Europe and Japan into North America to assist in the control of the gypsy moth, and quite recently conspicuous success has attended the importation of the fly *Ptychomyia* rentota from Malaysia into Fiji, where it is now parasitizing the caterpillars of the coco-nut moth.

BIBLIOGRAPHY.—A useful handbook of the order is S. W. Williston, Manual of *N.* American Diptera (New Haven, 1908). No general work exists on the British species and the analytical tables given by W. J. Wingate, "A Preliminary List of Durham Diptera" (in Trans. *Nat. Hist. Soc.* Northumb. Durham and Newcastle, ii., 1906) form the only comprehensive paper; references to the more important literature on British Diptera are given by P. H. Grimshaw in *Proc.* Roy. Physical *Soc.* Edin., xx., 1917. The Diptera *Danica* by W. J. Lunbeck, being written in English, will be found of assistance, and also the various fascicles of the Faune de France; the two volumes of British Flies by G. H. Verrall deal exhaustively with the Syrphidae and certain families of the Orthorrhapha. As a modern comprehensive work, E. Lindner, Die *Fliegen der Palaeartischen* Region (Stuttgart) is important. The British species are catalogued by G. H. Verrall, A List of British Diptera (1901), while the Katalog der Palaeartischen Diptera (Budapest, 1903–05) covers a wider field; for the American species J. M. Aldrich, Catalogue of N. American Diptera (Smithsonian *Misc.* Coll. 46, 1905) contains useful bibliographical references.

Among special works on individual subjects, L. *C.* Miall and A. Hammond, The Harlequin *Fly* (1900); C. G. Hewitt, The House Fly (1914); E. E. Austen, British Blood-sucking Flies (1906); E. E. Austen and E. Hegh, Tsetse Flies (1922); H. *C.* Lang, Handbook of British *Mosquitoes* (1920); and two volumes, Flies and Disease, by E. Hindle and G. S. Graham-Smith, respectively, may be mentioned. Among the few books of a popular character are L. C. Miall, Natural History of *Aquatic* Insects (1902) and J. H. Fabre, The Life of *the* Fly (English trans. from Souvenirs *Entomologiques* (1913).

(A. D. I.)

DIPTERAL, the term applied to temples that have a double range of columns in the peristyle, as in the temple of Diana at Ephesus.

DIPTYCH, (1) Two writing-tablets hinged or strung together, used in the Roman empire for letters and documents, especially (made of bronze) for the discharge of time-expired soldiers; also (made of wood or ivory, sometimes of gold or silver, and containing the sender's name and portrait) for a token of a consul's, praetor's or aedile's entrance into office, which he issued to his friends and the public generally (Gr. δίπτυχος, two folding).

(2) In the early Christian Church the names of eminent members and benefactors, living or dead, were recorded on diptychs and read aloud from the ambo or from the altar, thereby securing the prayers of the church; especially. in each church, were the names of those who had been its bishops recorded. The reading of these names during the canon of the mass gave rise to the term *canonization.*

The diptych formed the germ of the elaborate system of festologies, martyrologies and calendars which developed in the church. It went by various names in the early church—mystical tablets, anniversary books, ecclesiastical matriculation registers or books of the living. According to the names inscribed a diptych might be a *diptycha episcoporum, diptycha mortuorum* or diptycha vivorum.

The richly ornamented outsides of consular diptychs sometimes found their way into church treasuries, where they were eventually used as covers for copies of the Gospels, or for liturgical prayers; and their tradition was continued in the use of the diptych or triptych form for works of Christian devotional art.

(R. A. S. M.)

DIR, an independent state in the North-West Frontier Province of India, lying to the north-east of Swat. It commands the greater part of the route between Chitral and the Peshawar frontier. The trouble between the khan of Dir and Umra Khan of Jandol were factors that led up to the Chitral Campaign of 1895. During that expedition the khan made an agreement with the British Government to keep the road to Chitral open in return for a subsidy. Including the Bashkars. an aboriginal tribe allied to the Torwals and Garhuis, who inhabit Panjkora Kohistan, the population is estimated at about 100,000.

DIRCE, in Greek legend, daughter of Helios the sun-god, the second wife of Lycus, king of Thebes. After her death (see ANTIOPE) her body was cast into a spring near Thebes afterwards called by her name.

DIRECT ACTION. The use of trade union action for political ends, a theory imported into Britain from French syndicalist sources. Theoretically, trade union action for political ends can include other methods than the strike, and was originally intended to do so—as, for example, sabotage (*q.v.*) on a large scale, the boycott and use of the trade union label. But none of these, except perhaps the first, can be effective for political pressure, and "direct action" in fact has been confined to the strike. Since the object of direct action is to bring pressure upon the whole political system, only a large strike is of use, and "direct action" invariabiy has meant either a general strike or a strike affecting so many vital industries that it might as well be general.

The idea was taken to England in the early years of the 20th century from the writings of Lagardelle, Griffuelhes and Sorel, the propagandists of the French C.G.T. (Confederation General du Travail, General Confederation of Labour, see SYNDICALISM). Political action of the ordinary kind was opposed by syndicalists, but pressure by trade union action on a Government was held to be permissible, as being the one means which did not injure but strengthened working class solidarity through the trade unions. "Useful laws can be won by direct action," said M. Sorel—a remarkable concession to politicalism—and added that "the determining factor in politics is the poltroonery of the Government."

"Direct action" strikes may be divided into three classes according to their object: (1) Strikes against war, (2) social general strikes, or revolutionary strikes, (3) strikes to force a Government to enact or refrain from enacting certain legislative or administrative measures. Not all general strikes are "direct action": the famous Swedish general strike of 1909, for example, was a purely industrial battle between the employers and employed.

Direct Action Against War.—(I) An actual strike against a war has never yet been effectively carried out, although it has been, of the three, the proposal which has secured most enthusiasm. J. Keir Hardie (Britain) and Edouard Vaillant (France) were most active before the World War in pressing for its adoption by the Socialist International (see INTERNATIONAL), and the motion to this end is generally known by their combined names. It was received with coolness, particularly by the German delegates who were on principle opposed to general strikes and further argued that an explicit statement of this kind would make the German Social Democratic Party illegal. The proposal was eventually referred to the Bureau to ascertain the opinion of the various national parties and their industrial organizations. By August 1914 only a trivial number of these had answered. The

policy of the Socialist International in August 1914 was therefore defined by a compromise resolution drafted by Jean Jaurès, "Should war break out it is their (the Socialist Parties) duty to bring it promptly to an end and with all their energies to use the political and economic crisis created by the war to rouse the masses of the people and to hasten the fall of capitalist domination."

This resolution, literally taken, would have meant revolution as a reply to the declaration of war; it was, however, not applied by any but the Russian section (in March 1917). Since the war the idea of direct action against war has been much more powerfully supported. In this connection the intervention of the "Council of Action" in 1920, whose strike threat removed the possibility of war with Russia, must be cited.

Revolutionary Direct Action:—(a) The "social general strike," has figured on the programmes of many syndicalist groups, especially of the Industrial Workers of the World (*q.v.*). But it has never, in western Europe, actually been called, unless we count upheavals in Spain (and especially Catalonia) before the war, which were directed by political elements. The "Communalist" insurrections of 1873, for example, were accompanied by extensive cessations of work, and in one or two towns juntas of the International were for a short while actually in power. The only important cases of direct action with the object of subverting the whole political constitution of a state took place in Russia in 1905. The first strike took place on Oct. 17 and lasted till Nov. 1; many middle class elements (doctors, lawyers, etc.) in Moscow and St. Petersburg took part and the Government was severely shaken. Extended suffrage and an effective constitution were granted. The Tsarist Government, however, quickly recovered and began to withdraw its concessions and, as a first step, excluded Poland from the provisions of its decree. In reply the St. Petersburg Soviet, or Council of Workers and Peasants' deputies, which had become the recognized revolutionary authority, called a second political general strike (Nov. 14). The Government, however, learning from its previous experience, merely stood aside and allowed the workers to feel the full brunt of the consequent hunger and disorganization. As the Soviet had no troops, nor was able to seduce the garrison, it had to call off the strike on Nov. 19 without securing concessions. On Dec. 20, as a result of the arrest of the whole Soviet, another general strike was called, which in Moscow turned into an insurrection, which was suppressed.

Limited Direct Action:—(3) Direct action to force a Government to take or refrain from a certain measure has, contrary to a general impression, frequently been practised. As a political instrument, however, it has been much discredited by the levity with which the French C.G.T. has called general strikes without adequate preparation. In 1909 and in 1919 complete fiascoes resulted, and since the division of French trade unions into "C.G.T. U.," "C.G.T." and "C.G.T. autonome," general strike calls have been issued with even less reflection, especially by the first-named body (*e.g.* the "Sacco-Vanzetti strike" of 1927).

In earlier years, even in France, considerable victories were achieved. Direct action was taken in 1902–03 to secure the closing of the private Labour exchanges, in 1903 to secure state technical education and in 1905–06 for the eight-hour day. In the first case the success was complete, in the second some advantages were secured and in the third none. In 1902 the Swedish trade unions called a limited three-day general strike to destroy a reactionary Government franchise bill, which was withdrawn. In 1893 a Belgian general strike secured universal suffrage, but general strike calls in 1902 and 1913 for further suffrage reform, though punctually obeyed, secured no advantages. Pre-war experience of limited direct action indicated that the object desired must be one that the Government would rather voluntarily concede than face the dislocation of industry, but at the same time must be sufficiently far-reaching to secure the enthusiasm of the workers and the neutrality of sections of the middle class. Thus the Dutch general strike of 1903 (to secure trade union rights for civil servants) met with scarcely any response.

The most famous cases of limited direct action are, of course, the threatened British general strike of 1925 and the actual general strike of 1926 (see GENERAL STRIKE). An unusual but startlingly successful form of direct action is the strike in defence of a threatened form of Government. In Germany, in 1920, the "Kapp putsch," by which a group of monarchist officers had overturned the Republican government, was expeditiously ended by a general strike called with the assent of the fallen rulers.

See G. D. H. Cole, *The World of* ***Labour*** (1913); R. W. Postgate, *The Bolshevik Theory* (1920); *W.* Mellor, *Direct Action* (1920).

(R. W. P.)

DIRECT ADVERTISING, a type of advertising distinguished by the fact that it is conducted by delivering by post (mail), by person or otherwise the announcement of an advertiser directly to specific individuals instead of by publishing it in a newspaper or magazine to the public in general. Direct advertising commonly takes such forms as catalogues, sales letters, folders, circulars, broadsides, pamphlets, booklets, post-cards, novelty pieces, house organs and package inserts. If any of such material is sent to individuals through the post, such advertising is called direct-mail advertising.

BIBLIOGRAPHY.—R. E. Ramsay, *Effective Direct Advertising* (1922); *S.* R. Hall, *Mail-Order and Direct-Mail Selling* (1928); *V.* E. Pratt, *Selling By Mail* (1924); *J.* H. Picken, *Princzples of Selling By Mazl* (1927).

DIRECTIONAL ANTENNA. An antenna having the property of radiating or receiving radio waves in larger proportion along some directions than others. A directional antenna used as a transmitting antenna Is sometimes called a "directive antenna." If the angle within which the radiation is substantially confined is a small one, the antenna may appropriately be described as a "beam antenna." A type of antenna known as a "coil antenna" consisting of one or more complete turns of wire has directional characteristics and has the property of radiating or receiving radio waves in larger proportion in angular regions 180° apart than in other directions. One type of directional receiving antenna used particularly at low radio frequencies consists of a comparatively low horizontal aerial having a physical length of the same order of magnitude as that of the signaling waves to be received. Such an antenna is known as a "wave antenna."

DIRECTOIRE STYLE, a loose term designating, in architecture, furniture, etc., the transitional work between the restrained classicism of the Louis XVI. style (see LOUIS STYLES) and the Roman heaviness of the Empire style (*q.v.*); so-called from the French Directory which was in power 1795–99. The style is characterized by a gradual loss of the delicacy and grace of Louis XVI. forms and a growing enthusiasm for purely Roman motives.

DIRECTOR, NAVAL: see GUNNERY, NAVAL.

DIRECTORS: see COMPANY LAW.

DIRECTORY, literally, that which guides or directs, and hence a book giving directions for public worship, *e.g.*, the *directorium* or *ordo* of the Roman Church. The term now usually signifies a book containing the names, addresses and occupations, etc., of the inhabitants of a town or district, a list of the users of a telephone system, or of the members of a particular profession or trade. The name Directoire or Directory was given to the body which held the executive power in France from Oct. 1795 until Nov. 1799. (See FRENCH REVOLUTION.)

DIRGE, a song sung at funerals or in commemoration of the dead; derived from the antiphon, Dirige, *Domine,* Deus *meus,* in conspectu tuo *viam meam* (adapted from Ps. v. 9), of the opening psalm in matins for the dead in the Roman Catholic Church.

DIRICHLET, PETER GUSTAV LEJEUNE (1805–1859), German mathematician, was born at Diiren on Feb. 13, 1805. He was educated at Cologne, and later held professorships at Breslau and Berlin, and in 1855 he succeeded Gauss at Göttingen. He became a member of the Berlin Academy in 1832 and a foreign member of the Paris academy in 1854. Dirichlet's chief work was on the theory of numbers; he was the first to lecture on this subject at a German university. His researches on complex numbers were published in the *Berichte* der Berliner Akademie in 1841, 1842 and 1846; they were edited by Dedekind in 1863. Dirichlet also wrote on the theory of potential, on equations of the

fifth degree and on definite integrals. In addition he wrote a number of memoirs on the work of Gauss, in order to make it more intelligible, but he did not live long enough to complete this work. Dirichlet died at Gottingen on May 5, 1859.

DIRIGIBLE: see AIRSHIP.

DIRIGIBLE BALLOON: see AIRSHIP.

DIRK, a dagger, particularly the heavy dagger carried by the Highlanders of Scotland. The dirk as worn in full Highland costume is an elaborately ornamented weapon, with cairngorms or other stones set in the head of the handle, which has no guard. Inserted in the sheath there may be two small knives. The dirk, in the shape of a straight blade, with a small guard, some 18in. long, is worn by midshipmen in the British navy. The origin of the word is doubtful. The earlier forms were dork and durk, and the spelling dirk, adopted by Johnson, represents the pronunciation of the second form. The name seems to have been early applied to the daggers of the Highlanders, but the Gaelic word is biodag, and the Irish *duirc,* often stated to be the origin, is only an adaptation of the English word. It may be a corruption of the German *Dolch,* a dagger. The suggestion that it is an application of the Christian name "Dirk,.' the short form of "Dieterich," is not borne out, according to the New *English* Dictionary, by any use of this name for a dagger, and is further disproved by the earlier English spelling. In Highland full dress, the skean *dhu,* a small dirk, is carried in the stocking.

DIRSCHAU: see TCZEW.

DISABILITY, a term used in law to denote an incapacity in certain persons or classes of persons for the full enjoyment of duties or privileges. Thus, persons under age, insane persons, convicted felons are under disability to do certain legal acts. This disability may be absolute or relative. In the latter case (*e.g.,* drunken or insane persons) the incapable person cannot rely on his condition if it was unknown to his co-contractor at the time the alleged obligation was contracted.

D'ISALGUIER, ANSELME (*fl.* 1380–1420), a French traveller, as far as is known the first European to see the river Niger. He was a nobleman of Languedoc and had a château near Toulouse. He was fond of travel and natural history and was a man of letters. He had made various journeys before in 1402 he set out on his principal expedition, which brought him in 1405 to Gao, then a flourishing city on the Niger 400m. below Timbuktu. There he married Salam Casais, a Songhai princess—a Muslim negress. In 1413 he returned to Toulouse, having crossed the Sahara to Tunisia and in the Mediterranean narrowly escaped capture by pirates. With him he brought his wife, a daughter (Marthe) six years old and half a dozen attendants. One of these attendants was skilled in the knowledge of herbs and in 1419 cured the Dauphin (afterwards Charles VII. of France) of an illness. D'Isalguier wrote an account of his travels and produced a dictionary in Arabic, Tuareg and Songhai, with Latin and French equivalents. These books are now lost. They were in the library of the Jesuits' college at Lyons at the end of the 17th century, where they were consulted by the Abbé Tricaud, who refers to them in his *Essais* de *littérature* pour la connaissance des *livres* (Paris, 1702) though the Abbé shows no interest in the light d'Isalguier's narrative must have thrown on a puzzling problem of African geography—the course of the great river Niger. Memories of d'Isalguier and his black household—he had a grandson known as "The Moor"—long lingered at Toulouse and in a still existing 15th-century ms., *Historie* chronologique des *Parlements* de Languedoc, written by a suitor for Marthe's hand, an account of d'Isalguier's travels is inserted.

See Ch. *de* la Roncière, La *Découverte de l'Afrique* du *Moyen Age,* vol. iii. (Cairo, 1927).

DISARMAMENT. The word disarmament is used to cover two distinct conceptions: first, the complete abolition of all military armament, desired by a certain school of advanced thinkers; second, the reduction and limitation of national armaments by a general international agreement accepted by all, or almost all, States. In the former sense of the word, disarmament cannot yet be said to be practical politics. In the second sense it is one of the great problems of the day.

Partial Disarmament by Treaty.—Some attempts to achieve a concrete reduction and limitation of armaments were made before the World War of 1914–18. In isolated instances, where agreements were made between countries geographically remote from the rest of the world, a measure of success was obtained. Thus some South American republics reduced their armaments in accordance with arrangements made by treaty, while in a number of cases two countries agreed to the demilitarization and sometimes to the actual neutralization of the zone surrounding the frontier between them. The most striking example of disarmament by friendly agreement is that of the 3,000-m. land frontier between Canada and the United States. which has been demilitarized since 1818. Another is the frontier between Norway and Sweden, which was neutralized when the two countries separated in 1905. But whenever any attempt was made to reach a general agreement on disarmament, as for example, at The Hague Conferences (*q.v.*) of 1899 and 1907, failure was immediate and complete, and in the 20 years preceding 1914 all the more powerful governments spent an ever-increasing proportion of their national wealth and resources in building up greater fleets and armies.

Since the War great armaments, almost on the 1914 scale, have been maintained, but nevertheless disarmament in the second sense has become a matter of practical politics.

Disarmament under the Peace Treaties of 1919.—In the first place, the principle of disarmament was effectively applied to the States defeated in the War. Under the treaties of peace, Germany, Austria, Hungary and Bulgaria accepted an immense reduction and a rigid limitation of the armed forces which they respectively maintained. The treaty clauses relating to these armed forces were worked out in the greatest possible detail and laid down the number of men, the equipment, transport and armament which each of the four States was allowed to maintain, Germany's army being fixed at a total of 100,000 long-term volunteers and all heavy artillery, tanks, aircraft, poison gas, etc., being absolutely forbidden.

Although it was one-sided, this disarmament of the former enemy powers was nevertheless a considerable factor in the general post-War situation and in itself did much to make general disarmament practically important. For, apart from its obvious political effect, the preamble to Part V. of the Treaty of Versailles contains an express obligation: "In order to render possible the initiation of a general limitation of the armaments of all nations, Germany undertakes strictly to observe the military, naval and air clauses which follow."

Provisions of the Covenant.—In the second place, specific obligations with regard to disarmament were imposed upon all the members of the League of Nations by Article 8 of the Covenant. In this article, recognized by the authors of the Covenant to be fundamental to the successful working of the League, the members "recognize that the maintenance of peace requires the reduction of national armaments to the lowest point consistent with national safety and the enforcement by common action of international obligations." The article goes on to provide that the Council of the League "shall formulate plans for such reduction for the consideration and action of the several governments." To this must also be added the final act of the Conference of Locarno in 1925, in which new undertakings to carry out Article 8 were made by the Great Powers there assembled.

Third, these obligations have been supported by the personal pledges of statesmen of all parties and countries. Thus among British statesmen Lord Grey, Lord Cecil, Mr. Macdonald, Mr. Baldwin, Sir Austen Chamberlain and others have declared that both in the interests of the British empire and of the world at large it is necessary to secure a general and mutual reduction of armaments without delay. Lord Grey summed up their arguments in a single sentence by saying that "if civilization cannot destroy armaments, armaments will destroy civilization."

Article 8 of the Covenant is an undertaking by the members of the League to co-operate in preparing a plan of disarmament and in making the treaty required to bring that plan into effect.

In the fulfilment of this task the principal rôle is assigned to the council, which has first to prepare a plan for the "consideration and action of the several governments," and which is subsequently to control its observance.

The Temporary Mixed Commission.— It was not the council, however, but the Assembly of the League which took the first important step towards executing Article 8. At the first Assembly in 1920 a resolution was adopted calling for the creation (by the council) of a special committee of experts of various kinds to study disarmament and to draft a scheme. On this committee, the "Temporary Mixed Commission," there were appointed military, naval, air, economic and financial experts, and to them were added also some persons of political experience. It first met in 1921 and early in its discussions Lord Esher produced a scheme, restricted to the limitation of the land-armaments of Europe.

But the European members of the Commission almost unanimously rejected this scheme. They contended that reduction of armaments could not come alone but must be accompanied by arrangements, supplementary to those of the Covenant, for ensuring the security of members of the League against aggressive attack. This conclusion was summarized in four resolutions drafted by Lord Robert (now Viscount) Cecil and adopted by the Temporary Mixed Commission and subsequently by the third Assembly in 1922, the gist of which was that disarmament to be effective must be general, and that "security" and disarmament must go together.

Security Negotiations.— On the foundation of these four important resolutions the Temporary Mixed Commission proceeded in the following year to draw up the Draft Treaty of Mutual Assistance. The purpose of this draft treaty was to provide a system of general security which would permit the calling of a disarmament conference. Disarmament was intimately linked to the general scheme by the provision that none of its undertakings of mutual guarantee would come into effect until a plan of disarmament had been actually adopted and carried out. The treaty of mutual assistance was not, in fact, adopted by the succeeding Assembly, but the fifth Assembly in 1924 elaborated the Geneva protocol, which was founded on the same principles and which again was conditional upon disarmament. (See SECURITY.)

The Geneva protocol, in its turn, failed to secure sufficient acceptance by leading governments to bring it into force, and instead, the method of regional pacts was attempted in the Locarno treaties. This again failed to produce a general sense of security and so at the eighth Assembly in 1927 the whole question of security as the basis for disarmament was again raised, and the Assembly unanimously adopted resolutions which restated the two fundamental principles upon which the earlier negotiations of the Temporary Mixed Commission and the fifth Assembly had been conducted. These principles were: First, that "every state should be sure of not having to provide unaided for its security by means of its own armaments, but should be able to rely also on the organized collective action of the League of Nations." Second, that "there should be systematic preparation of the machinery to be employed by the organs of the League with a view to enabling the members of the League to perform their obligations" by joint action against an aggressor.

Thus the whole course of the discussions and negotiations on the subject between 1919 and 1927 proved conclusively the essential connexion between security and disarmament. On the problem of security those years witnessed much progress, though generally acceptable results were not definitely obtained. In other respects, however, less progress was made. Quite apart from the problem of security, disarmament itself in its technical and technical-political aspects is an extremely intricate matter. It can hardly be expected that other governments will accept freely the simple but drastic system imposed on Germany and her allies, desirable though it might be that they should do so.

Technical Difficulties.— But the technical difficulties of a more elastic system are great. The success of the Washington naval conference *(see* WASHINGTON TREATY) did not give any indication of the lines on which they could be solved, for not only is naval disarmament infinitely simpler than military and air disarmament, but even among naval units the Washington treaties dealt with only two categories of fighting ships.

The failure of the conference convened by President Coolidge in 1927, on the other hand, showed how greatly technical difficulties may complicate the political. problem of finding agreement about armaments, unless adequate technical solutions for them have been prepared and adopted in advance. Happily, even before the Coolidge conference met, the sixth Assembly of the League in 1925 recognized the importance of this side of the matter and decided that its study should be begun in order that, when security had been obtained, the work of the disarmament conference might be rapidly carried through. On the proposal of the sixth Assembly, the council set up the so-called preparatory commission, which through two technical sub-committees (one military and one economic) made an exhaustive study of all the technical problems involved in a general disarmament treaty. On the basis of the reports of these sub-committees the preparatory commission began, March 1927, to draw up a draft general treaty into which the Disarmament Conference could fit the scales of armament on which it might agree. At its session in March 1927 the commission made some progress with its draft treaty, agreeing on methods for limitation of man-power in armies, navies and air forces, and for the limitation of military aircraft. It could reach no agreement on naval questions, however, and its draft scheme is still most imperfect. The eighth Assembly, however, urged that its work should be rapidly completed, and perhaps under this stimulus definite results may be obtained. The prospect of definite results has been strengthened by the movement of opinion created by the resignation of Lord Cecil from the British Cabinet in Aug. 1927. The ground for his resignation was that the British government might have avoided the failure of the Coolidge conference had they attached sufficient weight to the making of a naval agreement with the United States. It is also necessary to mention the proposals of the U.S.S.R. for total disarmament within four years put forward in the Preparatory Commission in Nov. 1927 by the Russian delegate, Litvinoff. Litvinoff offered on behalf of his government to accept any reasonable compromise that would mean a real reduction of armament. In conclusion, it may be said that the negotiations on disarmament which have so far taken place have been based on the following generally accepted principles:

1.—That general security is a necessary condition of general disarmament;

2.—That the organization of a system of "sanctions" through League of Nations machinery is the only road to security;

3.—That to this end the "gap" in the Covenant, by which recourse to aggressive war is in certain cases legitimate, must be abolished, and aggressive war in all cases made an international crime;

4.—That no scheme of disarmament can succeed unless it is accepted by all or almost all governments and unless it covers every kind of weapon and military preparation;

5.—That only through the permanent machinery of the League can the necessary preliminary preparation for a disarmament conference be carried out;

6.—That no plan for general disarmament will give confidence to governments and peoples unless it is supported by an international system of control and supervision, which again can only be organized through the machinery of the League; and

7.—That in a first disarmament treaty only small reductions will probably be made, but that there must be successive subsequent revisions and reductions at regular intervals of time.

DISCANT: see **DESCANT.**

DISCHARGE, a word meaning relief from a load or burden, hence applied to the unloading of a ship, the firing of a weapon, the passage of electricity from an electrified body, the issue from a wound, etc. From the sense of relief from an obligation, "dis-

charge" is also applied to the release of a soldier or sailor from military or naval service, or of the crew of a merchant vessel, or to dismissal from an office or situation. In law, it is used of a document or other evidence that can be accepted as proof of the release from an obligation, of the legal release of a person in custody on a criminal charge, and of the legal release of a bankrupt from debts provable in the bankruptcy with certain exceptions. It is also applied to the reversal of certain judicial orders. In divorce, where the order *nisi* is not made absolute, it is said to be discharged.

DISCHARGING ARCH, in architecture, an arch (*q.v.*) built over a lintel or square-headed opening, so as to take the weight of the wall above off the horizontal head of the opening. In the great pyramid of Giza (c. 3000 B.C.), the entrance passage is roofed with slabs of stone, but above these, great blocks, set leaning against each other at the top so as to leave a triangular space beneath, form what is probably the earliest discharging arch extant. Discharging arches of circular or segmental shape are frequent in Roman buildings, and by the time of Diocletian, the custom of decorating these arches with an architrave had arisen. This usage, which apparently was of Syrian origin, became rather common during a considerable part of the Byzantine period of architecture.

DISCIPLES OF CHRIST or **CHRISTIANS,** an American Protestant denomination, founded by Thomas Campbell, his son Alexander Campbell (*q.v.*) and Barton Warren Stone (1772–1844). Stone had been a Presbyterian minister prominent in the Kentucky revival of 1801, but had revolted because the synod had condemned Richard McNemar, one of his colleagues, for preaching (as Stone had done) counter to the Westminster Confession, on faith and the work of the Holy Spirit in conversion. He had organized the Springfield Presbytery, but in 1804 with his five fellow ministers signed "The Last Will and Testament of the Springfield Presbytery," giving up that name and calling themselves "Christians." Like Stone, Alexander Campbell had adopted (in 1812) immersion, and, like him, his two great desires were for Christian unity and the restoration of the ancient order of things. But the Campbellite doctrines differed widely from the hyper-Calvinism of the Baptists whom they had joined in 1813, especially on the points on which Stone had quarrelled with the Presbyterians; and after various local breaks in 1825–30 the Reformers were practically all ruled out of the Baptist communion (1832). The Campbells gradually lost sight of Christian unity, owing to the unfortunate experience with the Baptists and to the tone taken by those clergymen who had met them in debates; and for the sake of Christian union it was peculiarly fortunate that in Jan. 1832 at Lexington, Kentucky, the followers of the Campbells and those of Stone (who had stressed union more than primitive Christianity) united. Campbell objected to the name "Christians" as sectarianized by Stone, but "Disciples" never drove the name out of use.

During the Civil War the denomination escaped an actual scission by following the neutral views of Campbell, who opposed slavery, war and abolition. In 1849 the American Christian Missionary Society was formed; it was immediately attacked as a "human innovation," unwarranted by the New Testament, by literalists led in later years by Benjamin Franklin (secretary of the missionary society in 1857), who opposed all church music also. Isaac Errett (1820–88) was the most prominent leader of the progressive party, which was considered corrupt and worldly by the literalists, many of whom, in spite of his strenuous efforts, broke off from the main body, especially in that territory embraced by the states of Indiana, Kentucky, Tennessee, Arkansas and Texas.

The main body appointed in 1890 a standing committee on Christian union; their aim was not for absorption, as was clearly shown by their answer in 1887 to overtures from the Protestant Episcopal Church regarding Christian unity. The credal position of the Disciples is simple: great stress is put upon the phrase "the Christ, the Son of the living God," and upon the recognition by Jesus of this confession as the foundation of His church; agreement with Baptists is only as to immersion, which is considered "the primitive confession of Christ and a gracious token of salvation" and as being "for the remission of sins"; they deny the authority over Christians of the Old Covenant, and Alexander Campbell held this view so forcibly that he was accused by Baptists of "throwing away the Old Testament." The Lord's Supper is celebrated every Sunday, the bread being broken by the communicants. The Disciples are not Unitarian, but they urge the use of simple New Testament phraseology as to the Godhead. The church government of the Disciples of Christ is congregational in character.

See Errett Gate's *History of the Disciples of Christ* (N.Y. 1905), in "The Story of the Churches" series, and his *Early Relation and Separation of Baptists and Disciples* (Chicago, 1904); B. B. Tyler's *History of the Disciples of Christ* in vol. xii. of "The American Church History Series" (N.Y., 1894); and article "Disciples of Christ" by H. L. Willett in Hastings, *Encyclopaedia of Religion and Ethics,* vol. iv.

(P. AT.)

DISCLAIMER, a renunciation or disavowal. In law the term is used more particularly in the following senses: (1) in the law of landlord and tenant, the direct repudiation of that relation by the tenant setting up a distinct title either in himself or some third party; (2) in the law of bankruptcy, where the trustee may "disclaim" onerous property (see BANKRUPTCY); (3) in the law of trusts, the refusal or renunciation of the office or duties of a trustee; (4) in the law of patents, the renunciation, by amendment of specifications, of a portion of an inventor's claim to protection.

DISCONTINUANCE: see PRACTICE AND PROCEDURE.

DISCONTO-GESELLSCHAFT, BERLIN, established in 1851 as a cooperative credit-association, carries on since 1856 in the form of a Commandit joint stock company all lines of commercial and issuing banking business. By its promoting and issue activities its name is prominently connected with the home and colonial economic development. Numerous important German and foreign loans have in the past been floated under its auspices.

Since 1901 the Disconto-Gesellschaft extended its technical organisations beyond Berlin throughout Germany. The taking over of the Norddeutsche Bank in Hamburg and of the A. Schaaffhausen'scher Bankverein in Cologne carried its sphere of business also to oversea countries and the Rhenish Westphalian district. Since the absorption of the Stahl and Federer A.G. in Stuttgart (Wurttemberg) and the Bank fur Thuringen vorm. B. M. Strupp in Meiningen (Thuringen) the Disconto-Gesellschaft owns 127 branches and branch offices covering the whole of Germany. Participations are furthermore held in the Süddeutsche Disconto-Gesellschaft A.G., Mannheim, and in the banking firm of L. Pfeiffer, Cassel.

The expansion of the business of the Disconto-Gesellschaft led to the establishment of subsidiary banks abroad and participation in other European banks: the Handelmaatschappij H. Albert de Bary and Company in Amsterdam, Kreditbank in Sofia and the bank's interest in the banking firm of Ephrussi and Company in Vienna. In oversea countries the Disconto-Gesellschaft founded in conjunction with the Norddeutsche Bank in Hamburg the Brasilianische Bank für Deutschland, now Banco Brasileiro Allemao in Rio de Janeiro with branches in Sao Paulo, Santos, Porto Alegre, Recife, Bahia, further the Banco de Chile y Alemania in Valparaiso with branches in Santiago, Concepcion, Temuco, and Valdivia. In addition to the foregoing the bank also took an active and leading part in the foundation of the Deutsche-Asiatische Bank in Shanghai. In Oct. 1929 a merger was arranged with the Deutsche Bank (*q.v.*), the capital and reserves of the Disconto-Gesellschaft then standing at about 186,000,000 Reichsmark.

(H. Fu.)

DISCOUNT AND DISCOUNT HOUSES. In trade a deduction from the price of an article, allowed to a buyer who pays cash, is called a discount. In the money market, the word usually means the rate allowed to the buyer for cash of a bill of exchange due at some future date. For example, if the rate of discount for six months' bills is 4% per annum, the buyer on Jan. 1 of a bill for £1,000 due on July 1 will give £980 for it. The market rate of discount is, to a great extent, regulated by the rate officially

announced by the Bank of England, or by the central bank in other financial capitals.

Discount houses are companies and firms which specialize on the business of buying and selling the bills drawn on English banks, accepting houses, merchants and others. They make their profit by working with a capital which is small in relation to their total commitments and borrowing large sums from banks and other lenders, employing these sums in the purchase of bills which they either hold until maturity, or, more usually, sell later to the banks or to any other buyer who wants a short and liquid investment. Weir rate of profit thus depends on the difference between the rate of interest that they have to pay for the money that they borrow and the rate of discount that they are able to charge to those from whom they buy bills, of which they normally have a large stock in hand. The balance sheet of the National Discount Company, dated Dec. 31, 1927, showed bills discounted—that is, bought—£50,000,000 and bills rediscounted—that is, resold—£24,000,000, leaving a net holding of £26,000,000. It also held £5,000,000 in investments and loans and more than £500,000 in cash. Its paid-up capital was only £1,000,000 and it had borrowed over £29,000,000 in the form of "deposits and sundry balances." Before the war, the bills handled in the money market consisted almost entirely of those created in the course of trade and private financial operations, but now owing to the enormously increased amount of Treasury bills outstanding, and also to the increased extent to which trade is financed by bank advances, an important part of the business of the discount houses is in Treasury bills issued weekly by tender. In other centres, where monetary specialization has not been carried so far as in London, discount companies and firms are generally non-existent or unimportant; but they have been successfully developed in New York, since the establishment of the Federal Reserve system. (See MONEY MARKET.)

DISCOVERY: see PRACTICE AND PROCEDURE.

DISCOVERIES AND INVENTIONS: see INVENTIONS AND DISCOVERIES.

DISCRIMINATION, SENSIBLE, the awareness by a person or an animal of a difference between two very similar sensations or sensory excitations. The capacity for sensible discrimination is called differential sensitivity. The sensory difference discriminated may be one of quality, as the hue of colours or the pitch of tones, or of the intensity, extent or, less often, duration or some other aspect of the sensory impression. The just noticeable difference, often called the "j.n.d.," between the stimuli of two sensations, when statistically determined by the methods of psychophysics (*q.v.*), is the differential threshold (limen). The corresponding sensed difference was thought by Fechner to constitute a unit for the measurement of sensation, but scientific psychology has rejected this view on the ground that all j.n.d.'s cannot be proved to be equal. It was believed for a time that a sensory scale varied by discrete steps, each quantum of sensation being a j.n.d., but it is now thought that sensation is a continuous function of its stimulus for the following reason. If we begin with a tonal pitch corresponding to 435 vibrations per second, we may have to increase the frequency to 435.5 before a difference in pitch is sensed. In such a case the differential limen is 0·5 vibrations per second. However, if we begin with a stimulus of 435·3 then the sensed difference would be expected to occur at 435.8. It thus appears that there are no fixed critical points in the tonal scale, and the conclusion is that there is an infinite number of sensations in the scale, but that two very similar sensations given together can not be discriminated from each other unless they differ by an amount that is, more often than not, greater than the limen.

On the side of quality there has been a great deal of interest in determining how many different sensations can be discriminated from one another under favourable conditions. Approximate results indicate that the normal human eye can discriminate about 150 hues in the psychological spectrum from red to yellow to green to blue and back, through the purples, to red again; that it can discriminate about 800 greys between black and white; and that, for the intermediate illuminations, there are perhaps an odd hundred discriminable saturations in the fading out of the best saturated colours into grey. Light and dark colours give fewer discriminable degrees of saturation, but the total tale of discriminably different visual sensations is probably as great as two million. Between the highest and the lowest audible tone there would seem to be about 10,000 discriminably different pitches, of which music seldom uses more than 400.

The iacts of the sensible discrimination of intensity are the basis of Weber's Law, which states that the least discriminable difference, in terms of the stimulus, is always proportional to the total magnitude of the stimulus. Thus it is possible, in as far as Weber's Law holds, to state the differential intensive limen as a fraction. For illumination it is thought to be about $\frac{1}{100}$, that is, to say, a sensed difference is created when the illumination is increased by & of its amount; *e.g.,* from 100 to 101. For the sensible discrimination of lifted weights the fraction is about $\frac{1}{40}$; for light pressure upon the skin it is about $\frac{1}{20}$; for tone it is about $\frac{1}{10}$ and for intensity of smell of the order of $\frac{1}{4}$ to $\frac{1}{3}$.

(E. G. BOR.)

DISCUS THROWING. The art of throwing from a circle 8ft. 2½in. diameter to the greatest distance, and so that it falls within a 90° sector marked on the ground, an implement weighing 4 lb. 6.4 oz. known as a discus. The sport was common in the days of Homer, who mentions it repeatedly. It formed part of the pentathlon, or quintuple games, in the ancient Olympic games and is fully described by Statius (*Thebais,* 646–721). Judging by specimens found by excavators, the ancient discus was a circular plate of stone, later of metal, some 8in. or gin. in diameter, and weighed from 4 lb. to 5 lb., although one of bronze, probably a trophy, preserved in the British Museum weighs over 8 pounds. To the Greeks discus throwing was a splendid builder-up.

Throwing the discus was introduced as an event in modern athletics at the revived Olympic games first held at Athens in 1896, and in the same year was instituted as a Swedish championship. The Olympic victor at Athens was Garrett, U.S.A., 95ft. 7½in., and the first Swedish champion, Helgesson, 97ft. 5½in. Since then throwing the discus has become a recognized event in the athletic championship meetings of all nations. America adopted the event in 1897, champion C. H. Henneman, 118ft. gin., and England in 1911, champion W. E. B. Henderson, 106ft. 11in. Since the war the records have improved considerably. World's record, Willi Schröder, Germany, Magdeburg, Germany, April 28, 1935, 174ft. 2½in.; Olympic record, Kenneth Carpenter, U.S.A., Berlin, Germany, August 5, 1936, 165ft. 5·39in.; U.S.A. record, Paul Jessup, Pittsburgh, Pa., August 23, 1930, 160ft. 8⅞in.; English record, D. R. Bell, Achilles Club, 1936, 142ft. 10½in. The recent advance in records is due to an increasing number of competitors employing improved technique. The Olympic contests which set the world's standard and enable us to trace the progress that has been made, have resulted as follow:—1896, Garrett (U.S.A.), 95ft. 7½in.; 1900, Bauer (Hungary), 118ft. 2$\frac{9}{10}$in.; 1904, M. Sheridan (U.S.A.), 128ft. 10½in.; 1908, M. Sheridan (U.S.A.), 134ft. 2in.; 1912, A. R. Taipale (Finland), 148ft. 1in.; 1920, E. Nicklander (Finland), 146ft. 7$\frac{3}{10}$in.; 1924, C. Houser (U.S.A.), 151ft. 5$\frac{1}{16}$in.; 1928, C. Houser (U.S.A.), 155ft. gin., 1932, J. Anderson (U.S.A.), 162ft. 4⅞in.; 1936, Kenneth Carpenter (U.S.A.), 165ft. 5·39in.

A great deal of discussion has taken place as to the method of throwing the discus employed by the ancient Greeks. Theories have been based upon the description of the sport as given by Statius and upon a reconstruction of Myron's statue of a discus thrower (*discobolos*) which may be seen in the British Museum. This statue portrays the thrower in the act of hurling the missile, and Norman Gardiner holds that a wrong attitude has been adopted by the restorer. Dr. R. Tait McKenzie calls the "Greek style," insisted upon at the first modern Olympic games, "absurd and ridiculous," and says it "could never have been in use among the ancient Greeks" (see Exercise in *Education* and Medicine, 1924). F. A. M. Webster (see *Athletics* of To-Day), however, contends that the reconstruction is substantially correct and that the discus thrower is correctly posed in the attitude from which commences the turning movement that precedes the delivery of

the missile in all modern forms of discus throwing.

The so-called "Greek style" of discus throwing was included at the Athenian Celebration, 1906 (Jaervinen, Finland, 115ft. 4in.), and at the London Olympiad, 1908 (Sheridan, U.S.A., 124ft. 8in.), but without any great success, so that the event has since been abandoned. In the Greek style the thrower places himself upon an inclined pedestal, stretches the arms above the head with the discus held between the hands. He then turns the trunk to the right, bends the body at the waist, allows the right hand holding the discus to swing up behind and places the left hand on the right knee, as in Myron's *Discobolos*. From this position the thrower straightens out his body, hurls the discus forward and leaves the pedestal in the instant of making the throw.

The modern style, which has now entirely superseded the Greek style, provides a more graceiul and a more natural series of movements. The essence of this style is that the discus must be slung out and not really thrown at all; the athlete's difficulty lies in controlling an implement which can be retained under and against the hand and wrist only by centrifugal force and such slight pressure as the tips of the fingers are able to exert.

The discus, as used in modern competitions, is composed of a smooth metal rim, permanently attached to a wood body, brass plates set flush into the sides of the wood body, and, in the exact centre of the discus, a means for securing the correct weight, which must be not less than 4 lb. 6.4 oz. The brass plates, circular in form, may not be less than zin. nor more than $2\frac{1}{2}$in. in diameter. The sides taper in a straight line from the beginning of the curve of the rim to a line at a distance of 1in. from the centre of the discus. The largest dimension comprises a circle not less than $8\frac{5}{8}$in., the thickness through the centre is not less than $1\frac{3}{4}$in., and $\frac{1}{4}$in. from the edge, not less than $\frac{1}{2}$in.

Method **of** Throwing the Discus.—Preparatory to making a throw the athlete holds the discus in the right (best) hand so that the edge rests against the joints of the fingers nearest to the tips. He takes up his position in the rear half of an 8ft. $2\frac{1}{2}$in. circle with the feet about 18in. apart and his left side turned in the direction in which the throw is to be made. The discus is swung up above the head, where it is met and supported by the fingers of the left hand. The right arm next swings back until it reaches a point behind and higher than the right shoulder. From this position, after two or three preliminary swings have been made and the right hand is at its highest point, the athlete commences a $1\frac{1}{4}$ turn in a kind of dancing time with the right arm hanging loosely down. The first pivotal movement is upon the left foot; when a half turn has been made the weight is transferred to the right foot, upon which the turning movement continues. As the left foot again takes the ground, at the front edge of the circle, the right leg begins to push the body forward and there is a violent turn of the right shoulder, but the arm is still kept trailing behind and the actual throwing movement does not commence until the right arm is well off the right shoulder. The left leg forms a point of resistance as the throw is made and the discus departs through the air mounting upwards but flying gyroscopically flat. It is a curious phenomenon that a well-thrown discus will mount tilted to the right until it reaches the highest point in the trajectory, thereafter travelling perfectly flat for a short distance, before beginning to fall earthwards tilted to the left.

DISINFECTANTS, substances employed to neutralize the action of pathogenic organisms and prevent the spread of infectious disease. Putting on one side sunlight, perhaps the best of all disinfectants, these agents may be divided into three classes:—1st, volatile or vaporizable substances, which attack impurities in the air; 2nd, chemical agents, for acting on the diseased body or on the infectious discharges therefrom; and 3rd, the physical agencies of heat and cold. Among the first class, formic aldehyde takes foremost place. It acts more rapidly than equal quantities of sulphurous acid, and does not affect colours. It is non-poisonous, though irritating to the eyes and throat. With the exception of iron and steel it does not attack metals. For destroying vermin sulphurous acid is more powerful than formic aldehyde. Camphor and some volatile oils have been employed as air disinfectants, but mask and do not destroy bad odours. In the second class all antiseptic substances may be reckoned; but the substances chiefly employed are oxidizing agents, as potassium permanganate ("Condy's fluid") and solutions of the so-called "chlorides of lime," soda and potash, with the chlorides of aluminium and zinc, soluble sulphates and sulphites, solutions of sulphurous acid, and the tar products—carbolic, cresylic and salicylic acids. Of the physical agents cold is not practically available by artificial means; heat is used for purifying and disinfecting clothes, bedding and textile substances generally, a temperature of about 250° being employed in the form of steam under pressure. For the thorough disinfection of a sick-room all three classes of disinfectants may be required.

DISINTEGRATOR. A term rather loosely used, but generally applied to a machine which breaks up and reduces materials by impact, as distinct from one which grinds between rollers, or amongst a mass of loose balls in a rotating drum. There are two

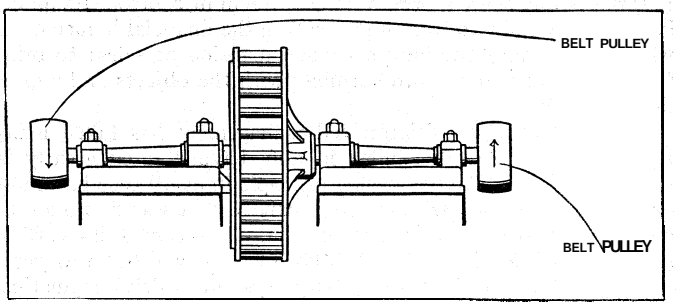

FIG. 1.—CAGE TYPE DISINTEGRATOR. IN WHICH A CAGE OF STEEL BARS REVOLVES WITHIN A CAGE TURNING IN THE OPPOSITE DIRECTION
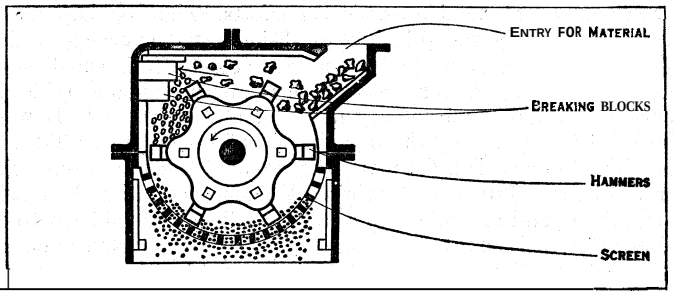
The cages are enclosed in a steel plate casting (not shown) so that material thrown in is violently hurled about between the bars and broken up into the desired state of fineness

main classes of disintegrators: the cage or reel and the hammer types, the latter being the more powerful. Among the substances broken up and ground more or less finely in disintegrators are coal, coke, slag, sand, shale, chalk, limestone, pitch, plaster, starch, clay, shells, gypsum, barytes, rock salt, glue, bark, soap, bones, fertilizers, cattle foods, brick-bats, stone, limestone, iron oxide, linoleum colours, printer's ink and other products. The more fibrous materials such as bark, rubber, asbestos, leather, herbs, etc., may be shredded up by a machine consisting of a set of revolving knives flying past a set of stationary ones, but in other cases pure



BY COURTESY OF MESSRS. EDGAR ALLEN AND COMPANY, LIMITED
FIG. 2.—HAMMER TYPE DISINTEGRATOR. WHICH SMASHES THE MATERIAL INTO SMALL PIECES AGAINST THE BREAKING BLOCKS. ANY LARGE CHUNKS UNABLE TO PASS THROUGH THE SCREEN ARE PICKED UP BY THE HAMMERS AND THROWN ONCE MORE AGAINST THE BLOCKS

impact is the disintegrating medium. The cage machines have a couple of cages, one within the other, composed of steel bars or beaters, which revolve in opposite directions (fig. 1.). The figure shows the machine with the casing removed; when the stuff is fed through a hopper, it is thrown with great violence amongst the bars and broken up. The speed of revolution ranges in various machines from 300 to 2,000 revolutions per niinute. For fine disintegration a machine with duplicated sets of cages is employed.

Hammer or beater machines consist of a revolving set of swing-hammers which beat the material small within the casing. The disintegrating action may occur while the material is "in the air," or when it is smashed against steel blocks within the strongly built casing. Fig. 2 shows the latter action; as the hammers whirl round at about a thousand revolutions a minute they catch the stuff fed into the hopper and hurl it against the blocks, the rebound being caught by succeeding hammers; and the material is finally reduced to the fineness required before it can pass through the screen. The inside of the machine is lined with steel plates which can be renewed when worn through. Some machines are built with a pocket into which fall any odd pikces of iron (termed tramp iron) which accidentally get in with the material. This safety device prevents serious damage to the various parts of the mill. A big crusher will break up 700 tons of limestone in the hour.

DISINTERESTED MANAGEMENT. A term historically associated with the regulation and control of the liquor trade; describing a system of management which has for its distinctive object the removal of private profit interest from the sale (in some cases from the manufacture also) of alcoholic beverages. It is not in any sense a prohibitionist system of control. Its object is rather to eliminate from liquor selling the financial inducements which in ordinary trading press for expansion of sales; to bring the motives of trading into harmony with the objects and aim of licensing laws.

In actual practice disinterested management has taken many forms which, although similar in aim, have diifered greatly in scope and effect. The underlying principle in every case has, however, been the same. Disinterested management was first adopted on an extensive scale in Scandinavia. It received its earliest statutory sanction in the Swedish law of 1855, which, a few years later, gave birth to the "Gothenburg" system of drink regulation, which may be said to have inspired most of the schemes of disinterested management which have since been adopted in different parts of the world. The growth of the system was rapid and the example of Sweden was quickly followed by Norway and Finland. In 1920 the latter country adopted statutory prohibition, but in Sweden and Norway (both spirit drinking countries) disinterested management is now legally established as the sole method of sale for both spirits and wine. The principle has also received statutory recognition in a permissive form in the Danish law of 1924, and in Estonia.

In Great Britain the principle of disinterested management, although lacking explicit statutory sanction (save only in the case of the State management schemes which were organized during the World War), has been variously applied. The earliest experiments date from the late '70s of last century. They were isolated experiments, but notable as pioneer efforts. The first important attempt to apply the principle of disinterested management in Great Britain, was made by the People's Refreshment-House Association Ltd., which has now some 175 licensed houses (chiefly village inns and small country hotels) under its control. It was followed (1900–01) by the organization of Public House Trusts, of which the late Earl Grey was the founder. There are some 14 or 15 of these Trusts in the United Kingdom, of which three are in Scotland and one in Ireland. Most of them are affiliated to a Central Association but operate as separate companies on a county basis. These Trusts have 92 licensed houses under their management and control. In addition there is Trust Houses Ltd. —a separate and independent company which is not now organized on a county basis and has 180 houses under its control. All of these Trust houses—272 in number (exclusive of the 175 houses controlled by P.R.H.A.)—are managed on the principle of disinterested management.

There are, also, in the mining districts of Fifeshire and in one or two other Scottish areas, a number of so-called "Gothenburg" houses, controlled by local registered companies, in which the principle of disinterested management is applied.

The **Carlisle** Experiment. — The most complete and important practical application of the principle in Great Britain is, however, represented by the three State management areas in Carlisle and District, Gretna and Cromarty Firth. In these three areas the liquor trade is under direct Government control and the undertakings have statutory authorization. The Carlisle undertaking is far the most important of the three. It has (save for two hotels and one restaurant) a complete monopoly of the sale of alcoholic liquors in the city of Carlisle and in a large adjacent area, and a partial monopoly in other districts. It also owns and operates the breweries. The undertaking, established in 1916, is directed by a central advisory council, responsible to the Home Secretary, and assisted by a local advisory committee which includes representatives of the local authorities, licensing justices, magistrates, trades council, etc., in the management area. The undertaking is in a sound financial position. By March, 1917, it had repaid, with interest, the whole of the capital liabilities and charges (some £900,000) incurred in the acquisition and development of the properties, and is now a valuable revenue-producing asset, the property of the State, which receives the whole of its profits.

Elsewhere the principle of disinterested management in the form of State control has been adopted on a large scale. In Russia, the State vodka monopoly, founded by M. Witte in 1894, and repealed in 1914 by the late tsar's edict establishing prohibition, has been re-established by the Soviet Government; while in Canada, seven of the nine provinces have substituted Government sale for prohibition. In Poland the State monopoly principle was adopted for spirits in 1924. It applies in the main at present to the production and wholesale distribution of spirits, but includes sale arrangements also. Until 1934 spirits will be sold both in State premises and in private licensed premises. After that date in State premises only. In Germany there has long been a State spirit monopoly, but it is concerned only with the production and wholesale distribution of spirits. (See TEMPERANCE; PROHIBITION; GOTHENBURG LICENSING SYSTEM; LOCAL OPTION.) (A. SH.)

DISMAL SWAMP, a large marshland lying partly in south-central Virginia and partly in north-central North Carolina. Now somewhat reduced by drainage, the original area was about 40 m. long and from 15 to 25 m. wide. The region in which the swamp lies is a slightly undulating plain, with an elevation of from 10 to 20 ft. above sea-level. The maximum elevation is in the heart of the swamp, whither the slope grades toward sea-level. Along the western margin a well-defined ancient sea beach, the Nansemond escarpment, rises from 5 to 50 ft. to constitute a natural boundary. Numerous waterways, most having their source in or near Dismal Swamp, traverse the region.

Drummond lake, the interior pool, is about seven m. long, and five wide, and 15 ft. deep. Dismal Swamp is the major north-eastern extension of the great palustrine forest which once dominated the landscape of much of the Coastal plain of the United States and of the lower flood plains of its southern streams, a forest characterized by cypress (*Taxodium distichum*), black gums (Nyssa *biflora* and N. *aquatica*), "juniper" (Chamaecyparis *thyoides*), swamp cotton gum (N. *uniflora*) and water ash (*Fraxinus caroliniana*). Not all the area is forest-covered, however, there being extensive bands and patches of marsh grassland as well. The whole area of the swamp may be drained, but the cost of reclamation would probably make it an unprofitable venture. The forest cover has been in large measure removed.

DISORDERLY HOUSE, a house of prostitution; more generally, in law, a house in which the conduct of its inmates is such as to become a public nuisance, or a house where persons congregate to the commission of crime. In England, by the Disorderly Houses Act, 1751, the term includes common bawdy houses or brothels, common gaming houses, common betting houses and disorderly places of entertainment. Under that statutc unlicensed places of public entertainment were deemed to be disorderly houses if within 20m. of the cities of London and Westminster. Brothels are now dealt with by the Criminal Law

Amendment Acts, 1885 to 1922, and charges can be dealt with summarily, but for a second or subsequent offence the accused can demand trial by a jury. The letting out for gain for indiscriminate prostitution of a room or rooms in a house will make it as much a brothel in law as if the whole house were let out for the purpose. Where, however, a woman occupies a house or room which is frequented by men for the purpose of committing fornication with her she cannot be convicted of keeping a disorderly house (see PROSTITUTION). Gaming and betting houses are prohibited and penalties are imposed by two Gaming Acts, 1845 and 1854, and the Betting Act, 1853.

DISPENSATION, a term with two main applications, (1) to the action of administering, arranging or dealing out, and (2) to the action of allowing certain things, rules, etc., to be done away with, relaxed. Of these two meanings the first is to be derived from the classical Latin use of dispensare, literally, to weigh out, hence to distribute, especially of the orderly arrangement of a household by a steward; thus *dispensatio* mas, in theology, the word chosen to translate the Greek οἰκονομία, economy, *i.e.,* divine or religious systems, as in the Jewish, Mosaic, Christian dispensations. Dispensation in law is, strictly speaking, the suspension by competent authority of general rules of law in particular cases. Its object is to modify the hardships often arising from the rigorous application of general laws to particular cases, and its essence is to preserve the law by suspending its operation, *i.e.,* making it non-existent, in such cases. It follows, then, that dispensation, in its strict sense, is anticipative, *i.e.,* it does not absolve from the consequences of a legal obligation already contracted, but avoids a breach of the law by suspending the obligation to conform to it, *e.g.,* a dispensation or licence to marry within the prohibited degrees, or to hold benefices in plurality.

1. Ecclesiastical Law.—In the theory of the canon law the dispensing power is the corollary of the legislative, the authority that makes laws, and no other, having power to suspend them. The dispensing power, like the legislative authority, was formerly invested in general councils and even in provincial synods; but in the West, with the gradual centralization of authority at Rome, it became ultimately vested in the pope as the supreme lawgiver of the Church. Subject, however, to the supreme jurisdiction of the pope, the power of dispensation continued to reside in the other organs of the Church in exact proportion to their legislative capacities, *i.e.,* in provincial synods in respect of regional rules laid down by them, and in bishops in respect of rules laid down by them for their dioceses. In the earlier periods of the papacy the tendency was to disclaim all authority to make concessions and grant relief from traditional rules; but as time went on and the Church expanded, this rigid attitude proved impossible to maintain, and the principle of "tempering" the law when forced to do so "by the exigencies of affairs or of the times" (*rerum* vel *temporum* angustia), as laid down by Gelasius (494), was adopted into the canon law itself. The principle was, of course, singularly open to abuse. In theory it was laid down from the first that dispensations were only to be granted in cases of urgent necessity and in the highest interests of the Church; in practice, from the 11th century onwards, the power of dispensation was used by the popes as one of the most potent instruments for extending their influence. Dispensations to hold benefices in plurality formed, with provisions and the papal claim to the right of direct appointment, a powerful means for extending the patronage of the Holy See and therefore its hold over the clergy, and from the 13th century onwards this abuse assumed vast proportions (Hinschius, *Kirchenrecht*, iii. p. 250). Even more scandalous was the almost unrestrained traffic in licences and dispensations at Rome, which grew up, at least as early as the 14th century, owing to the fees charged for such dispensations having come to be regarded by the Curia as a regular source of revenue (Woker, Das *kirchliche Finanzwesen* der *Päpste*, Nördlingen, 1878, pp. 75, 160). Loud complaints of these abuses were raised in the reforming councils of Constance and Basel in the 15th century, but nothing was done effectually to check them.

The actual practice of the Church is based upon the decisions of the council of Trent, which left the mediaeval theory intact while endeavouring to guard against its abuses. The proposal put forward by the Gallican and Spanish bishops to subordinate the papal power of dispensation to the consent of the Church in general council was rejected, and even the canons of the council of Trent itself, in so far as they affected reformation of morals or ecclesiastical discipline, were decreed "saving the authority of the Holy See" (Sess. xxv. cap. 21, de ref.). At the same time it was laid down in respect of all dispensations, whether papal or other, that they were to be granted only for just and urgent causes, or in view of some decided benefit to the Church (urgens *justaque causa et* major *quandoque utilitas*), and in all cases gratis. The payment of money for a dispensation was ipso facto to make the dispensation void (*Sess.* xxv. cap. 18, de ref.).

Church of England.—By an Act of Henry VIII. (1534), it was enacted that neither the king, his successors, nor any of his subjects should henceforth sue for licences, dispensations, etc., to the see of Rome, and that the power to issue such licences, dispensations, etc., "for causes not being contrary or repugnant to the Holy Scriptures and laws of God," should be vested in the archbishop of Canterbury for the time being, who at his own discretion was to issue such dispensations, etc., under his seal, to the king and his subjects. The power of dispensation thus vested in the archbishops partly fell obsolete, partly has been curtailed by subsequent statutes, *e.g.,* the Pluralities Act of 1838. It is now confined to granting dispensations for holding two benefices at once, to issuing licences for non-residence, and in matrimonial cases to the issuing of special licences. The dispensing power of bishops in the Church of England survives only in the right to grant marriage licences, *i* e., dispensations from the obligation to publish the banns. Though, however, these licences and dispensations are given under the archiepiscopal and episcopal seals, they are actually issued by the commissaries of faculties and vicars-general (chancellors), independently, in virtue of the powers conferred on them by their patents. This has led, since the passing of the Divorce Acts and the Marriage with a Deceased Wife's Sister Act, to a curiously anomalous position, licences for the remarriage of divorced persons having been issued under the bishop's seal, while the bishop himself publicly protested that such marriages were contrary to "the law of God," but that he himself had no power to prevent his chancellor licensing them.

See article "Dispensation" and kindred topics in the Catholic Encyclopaedia; in Herzog-Hauck, Realencyclopadie (by Hinschius); Wetzer and Welte's Kirchenlexikon (2nd ed.); also F. Lichtenberger, *Encyclopédie* des sciences *religieuses* (Paris, 1878), *s.v.* "Dispense"; and Phillimore, Ecclesiastical *Law*.

2. *Constitutional* Law.—The power of dispensation from the operation of the ordinary law in particular cases is, of course, everywhere inherent in the supreme legislative authority, however rarely it may be exercised. Divorce (in Ireland) by act of parliament may be taken as an example which still actually occurs. On the other hand, the dispensing power once vested in the crown in England is now merely of historical interest, though of great importance in the constitutional struggles of the past. This power possessed by the crown of dispensing with the statute law is said to have been copied from the dispensations or *non* obstante clauses granted by the popes in matters of canon law; the parallel between them is certainly very striking, and there can be no doubt that the principles of the canon law influenced the decisions of the courts in the matter. It was, for instance, very generally laid down that the king could by dispensation make it lawful to do what was *malum prohibitum* but not to do what was *malum in* se, a principle of the canon law, but one difficult to reconcile with English legal principles, since no act is legally *malum* unless forbidden by law. This was pointed out by Chief Justice Vaughan in the celebrated judgment in the case of Thomas v. *Sorrell,* when he rejected the distinction between *mala* in se and *mala prohibita* as confusing, and attempted to define the dispensing power of the crown by limiting it to cases of individual breaches of penal statutes where no third party loses a right of action, and where the breach is not continuous, at the same time denying the power of the crown to dispense with any general penal law. This judgment, as Sir William Anson points out, only

showed the extreme difficulty of limiting the power ascribed to the crown, a standing grievance from the time that parliament had risen to be a constituent part of the state. So long as the legal principle by which the law was "the king's law" survived there was in fact no theoretical basis for such limitation, and the matter resolved itself into one of the great constitutional questions between crown and parliament which issued in the Revolution of 1688. The supreme crisis came owing to the use made by James II. of the dispensing power. His action in dispensing with the Test Act, in order to enable Roman Catholics to hold office under the crown, was supported by the courts in the test case of *Godden* v. *Hales,* but it made the Revolution inevitable. By the Bill of Rights the exercise of the dispensing power was forbidden, except as might be permitted by statute. At the same time the legality of its exercise was admitted by the clause maintaining the validity of dispensations granted in a certain form before Oct. 23, 1689.

See Anson, *Law and Custom of the Constitution,* pt. i. "Parliament," 3rd ed., pp. 311–319; F. W. Maitland, *Const. Hist. of England* (Cambridge, 1908), pp. 302, etc.; Stubbs, *Const. Hist.* ss. 290, 291.

(W. A. P.)

DISPERSION: *see* LIGHT.

DISPLACEMENT TONNAGE. In shipping, a term used to describe the actual weight of the water displaced by a ship. It is measured by ascertaining the cubic space occupied by that part of the ship which is immersed and dividing this by 35, a ton of sea water measuring 35 cubic feet. The term is employed to describe the tonnage of warships. (See SHIPPING: TONNAGE.)

DISPOSAL BOARD. The conclusion of the World War found the British Government engaged in gigantic preparations for a decisive campaign in 1919. The consequent problems of liquidation of war commitments and disposal of surpluses which faced Great Britain on the conclusion of the war were far more complicated and difficult of solution than those facing any other nation, allied or enemy. These problems divided themselves into two main heads, viz., the liquidation of war contracts, and the disposal of property and stores surplus to peace requirements.

In January 1919 His Majesty's Government decided to entrust the liquidation of Ministry of Munitions contracts, and the sale of war surpluses belonging to all Government departments, to the Minister of Munitions, Lord Inverforth, who, as Surveyor General of Supply at the War Office, had controlled many of the purchases. The organization set up by Lord Inverforth was controlled in the main by eminent business men who gave their services to the State in a voluntary capacity. On the Ministry of Munitions ceasing to exist in March 1921, this policy was continued by the Disposal and Liquidation Commission of which Sir Howard Frank was chairman, the Commission in turn being succeeded by a Treasury Advisory Committee under the chairmanship of Sir Charles Barrie.

At the Armistice, the Ministry of Munitions had contracts outstanding to the number of 34,862 and their value was approximately £355,000,000, including contracts for aircraft engines and materials amounting to £154,000,000, and for guns, arms, tanks and ammunition amounting to over £99,000,000. Of the outstanding contracts, 3,722 of a value of approximately £17,000,000 were in respect of supplies still definitely required, leaving nearly 31,000 contracts valued at about £338,000,000 for immediate liquidation.

The settlement of these contracts necessitated the scrutiny of 750,000 separate claims. This not only involved the examination of the bills of each contractor for work, but also for the recovery by the Ministry of any sums due from him for raw material supplied on debit, the accounting for material issued to him without charge, the adjustment of subsidies, the recovery of loans in respect of capital expenditure, the agreement of inventories of Government plant remaining on hand, the settlement of disputes in regard to defective material and the fixing of prices regarding supplies to and by the contractor by means of cost investigation.

In spite of these complications, the great majority of these contracts were disposed of by the end of 1920 at comparatively small expense to the State.

Disposal **of** Surpluses.—The problem of selling to the best advantage public assets becoming surplus owing to the termination of the War was, it will be realized, one of extraordinary magnitude and complexity. The property to be disposed of was lying all over the world, much of it in regions that had been recently wasted by war, where its handling was extremely difficult and its disposal *in situ* almost impossible. The surplus property not only comprised vast quantities of raw materials, such as wool, flax and hides, enormous quantities of unwrought metals—platinum, copper, brass, zinc, steel and iron—railway lines in France, Egypt, Palestine and Macedonia, tugs, barges and other seagoing craft at home and abroad, harbour installations such as those at Richborough, Calais, Dunkirk, Dieppe and Taranto, whole towns such as Gretna, factories and housing estates, but also over 350,000 different types of stores, which had been used for war purposes.

Initially the Ministry was confronted with the difficult task of locating and listing the huge quantities of stocks, particularly those in war areas. For disposal purposes it was essential that the stocks should be properly sorted and classified.

Nor was the disposal of these stocks a mere matter of selling at the highest prices. Many other considerations were involved, for example, the necessities of British trade and manufacture, the avoidance as far as possible of labour dislocation at home, the obtaining of transport facilities at reasonable cost, the release of army personnel guarding property and stores in war areas, etc. Subject to these considerations, the policy adopted throughout was to dispose of the property and stores by public tender, auction or private treaty as rapidly as the market could absorb them, and at highest prices obtainable.

So energetically were sales pushed forward that before the severe slump in prices took place in the late summer of 1920, over three-quarters of the surpluses had been sold. There is little doubt that the sales of articles of general utility early in 1919 proved a death blow to the worst forms of post-war profiteering.

Many of the surpluses were by their nature quite unsuitable for disposal in their existing forms, *e.g.,* shells and ammunition, of which approximately 5,000,000 tons were broken down at home and abroad and their residuals—steel, brass, copper, resin, etc.,—sold for commercial purposes. **A** considerable quantity of ammunition proved unsafe to break down and was at suitable points dumped in the sea. The same course had to be followed with enormous quantities of poison gas, the cylinders containing it being dumped many miles out at sea. In this work and the dumping of ammunition a fleet of sea-going barges and tugs were employed for nearly two years after the Armistice.

As regards other warlike stores, while it would not be true literally to say that swords were turned into ploughshares, all possible steps were taken to secure the utilization for commercial purposes of such stores, and with a great measure of success.

The total sales of surplus stores and properties (excluding raw materials on trading accounts—wool, flax, leather, etc.) amounted to £350,000,000. The principal groups of sales at home were, in round figures, as follows:—

Lands, buildings and factories	£15,000,000
Timber, huts and building materials, etc.	16,000,000
Plant and machinery, railway material and dock equipment	25,000,000
Textile, leather and equipment	34,000,000
Ferrous metals	21,000,000
Non-ferrous metals	51,000,000
Chemicals and explosives	29,000,000
Mechanical and horse transport	20,000,000
Food	8,000,000
River and canal craft	3,000,000

In addition to the sales at home there were large sales of surpluses abroad, including:—

France and Belgium	£40,000,000
Army of the Rhine	3,000,000
Italy	3,000,000
Egypt	9,000,000
Army of the Black Sea	3,500,000
'Iraq	10,000,000
India	10,000,000
United States and Canada	4,000,000

The sales on the Continent of Europe were made where possible in sterling, but the depreciation of Continental exchanges following the war had an adverse effect on Continental sales.

Sales of raw materials (wool, flax, leather, etc.) were over £330,000,000, a net profit of £78,000,000, of which £44,000,000 accrued to the British Exchequer, £34,000,000 going to various Dominions under profit sharing schemes. Sales, including raw materials, were over £680,000,000. (D. N.)

DISPOSITION, a term used in psychology to characterize the manner in which instinctive tendencies operate in the human organism. The total pattern of instinctive mechanisms *is* a person's disposition. The great variety of human dispositions is due to the innumerable combinations of relative intensities with which instinctive impulses may assert themselves in different individuals. One person may be very irascible or pugnacious, another timid, another meek and docile, etc. The quality of these dispositions depends upon the relative strengths of the underlying instincts. Excessive preponderance of any one instinctive tendency makes for an unbalanced personality. The term *disposition* is also used in psychology to characterize the total personality as modified by past experience. In this sense disposition would include the effect of habits and acquired attitudes as well as instinctive tendencies.

DISRAELI, BENJAMIN: *see* BEACONSFIELD, BENJAMIN DISRAELI, EARL OF.

D'ISRAELI (or DISRAELI), **ISAAC** (1766–1848), English man of letters, father of the earl of Beaconsfield (*q.v.*), was born at Enfield in May, 1766. His father, Benjamin D'Israeli, migrated from Venice to London in 1748 and belonged to the London congregation of Spanish and Portuguese Jews.

When Isaac D'Israeli was about 14 his father sent him to live with his agent at Amsterdam, where he worked under a tutor for four or five years. Here he studied Bayle and Voltaire, and became an ardent disciple of Rousseau. Here also he wrote a long poem against commerce, which he produced as an exposition of his opinions when, on his return to England, his father announced his intention of placing him in a commercial house at Bordeaux. Young D'Israeli was sent to travel in France, and spent some time in literary circles in Paris, returning to London in 1788. A poem printed in *The Gentleman's Magazine,* attacking Peter Pindar (John Wolcot) brought him the friendship of his opponent and of H. J. Pye, who helped to persuade his father that it would be a mistake to force him into a business career. D'Israeli dedicated his first book, *A Defence of Poetry,* to Pye in 1790. Henceforth his life was passed in the way he best liked—in quiet and almost uninterrupted study. In 1802 he married Maria Basevi, by whom he had five children, of whom Benjamin (afterwards Lord Beaconsfield and Prime Minister of England) was the second. He died at his seat at Bradenham house, Buckinghamshire, on Jan. 19, 1848.

Isaac D'Israeli is the author of the *Curiosities of Literature* (1791, subsequent volumes in 1793, 1817, 1823 and 1834). It is a miscellany of literary and historical anecdotes, of original critical remarks, and of interesting and curious information of all kinds, animated by genuine literary feeling, taste and enthusiasm. He also wrote *Miscellanies, or Literary Recreations* (1796), the *Calamities of Autlzors* (1812–13), and the *Quarrels of Authors* (1814). Towards the close of his life D'Israeli projected a continuous history of English literature, three volumes of which appeared in 1841 under the title of the *Amenities of Literature.* But of all his works the most delightful is his *Essay on the Literary Clzaracter* (1793), which, like most of his writings, abounds in illustrative anecdotes. In the famous "Pope controversy" he supported Byron and Campbell against Bowles and Hazlitt by a defence of Pope in the form of a criticism of Joseph Spence's *Anecdotes* contributed to the *Quarterly Review* (July 1820). In 1797 D'Israeli published three novels; one of these, *Mejnoun and Leila, the Arabian Petrarch and Laura,* was said to be the first oriental romance in English. His last novel *Despotism, or the Fall of the Jesuits,* appeared in 1811, but none of his romances was popular. He also published a slight sketch of Jewish history, and especially of the growth of the Talmud, entitled the *Genius of Judaism* (1833). He was the author of two historical works—a brief defence of the literary merit and personal and political character of James I. (1816), and a learned *Commentary on the Life and Reign of King Charles I.* (1828–31).

Of the amiable personal character and the placid life of Isaac D'Israeli a charming picture is to be found in the brief memoir prefixed to the 1849 edition of *Curiosities of Literature,* by his son Lord Beaconsfield.

DISS, a market town in the Southern parliamentary division of Norfolk, England; near the river Waveney (the boundary with Suffolk), 95 mi. N.E. by N. from London by the L.N.E. railway. Pop. of urban district (1938) 3,297. The town lies pleasantly upon a hill rising above a mere, which drains to the Waveney, having its banks laid out as public gardens. The church of St. Mary exhibits Decorated and Perpendicular stone and flint work. There is a corn exchange and the agricultural trade is considerable; agricultural implements are manufactured. The poet and satirist, John Skelton (d. 1529), was rector there in the later part of his life, and is doubtfully considered a native of Diss. Area 3,674 acres.

DISSECTION, the separation into parts by cutting, particularly the cutting of an animal or plant into parts for the purpose of examination.

DISSEMINATION, of seeds, *see* ANGIOSPERMS: *Dissemination.*

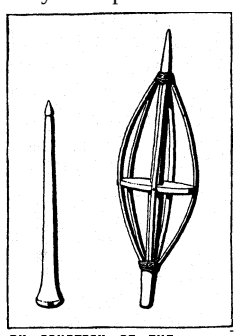
DISSENTER, one who dissents or disagrees in matters of opinion, belief, etc. The term, from Lat. *dis-sentire,* to disagree, is, however, practically restricted to the special sense of a member of a religious body in England which has separated from the Established Church; and while it has included English Roman Catholics, who in the original draft of the Relief Act of 1791 were styled "Protesting Catholic Dissenters," it is in practice restricted to the "Protestant Dissenters" referred to in sec. ii. of the Toleration Act of 1688. The term is not applied to those bodies who dissent from the Established Church of Scotland; and in speaking of members of religious bodies which have seceded from established churches abroad it is usual to employ the term "dissidents" (Lat. *dissidere,* to dissent). In this connotation the terms "dissenter" and "dissenting," which had acquired a somewhat contemptuous flavour, have tended since the middle of the 19th century to be replaced by "nonconformist," a term which did not originally imply secession, but only refusal to conform in certain particulars (*e.g.,* the wearing of the surplice) with the authorized usages of the Established Church. Still more recently the term "nonconformist" has in its turn, as the political attack on the principle of a State establishment of religion developed, tended to give place to the style of "Free Churches" and "Free Churchman." All three terms are now in use. (*See* BAPTISTS; CONGREGATIONALISM; METHODISM, etc.)

DISSOCIATION, a separation or dispersal, the opposite of association but of wider application (*see* ASSOCIATION). In chemistry the term is given to chemical reactions in which a substance decomposes into two or more substances, and particularly to cases in which associated molecules break down into simpler molecules. Thus the reactions $NH_4Cl \rightleftarrows NH_3 + HCl$, and $PCl_5 \rightleftarrows PCl_3 + Cl_2$ are instances of the first type; $N_2O_4 \rightleftarrows 2NO_2$, of the second. When this breakdown is effected by heating, the process is termed "thermal dissociation." Electrolytic or, as it is termed, ionic dissociation is the separation of a substance in solution into ions (*see* ELECTROLYSIS; CHEMICAL ACTION: *Ionic Theory*).

In psychology dissociation is an abnormal condition of the mind wherein the usual connection between various mental elements is lost. Ordinary lapses of memory represent dissociations, in normal minds, between the idea or object which cannot be called to mind and the clue or stimulus idea which formerly sufficed to recall the thing desired. Abrupt changes of mood, or change of interest from one subject to another, in normal people may represent emotional dissociation. When large, combined groups of ideas and emotions (complexes) become dissociated from other similar groups, the resulting condition is known as dissociation of personality. Such dissociation is held accountable for many insane conditions. (*See* DEFENCE MECHANISMS.) In this condition a successful lawyer has been known to draw all his money from the bank, disappear without reason and subsequently open a small shop in a distant city without memory of his former life.

DISSOLUTION, the act of dissolving or reducing to constituent parts, especially of the bringing to an end an association such as a partnership or building society. A dissolution of parliament in England is the end of its existence (see PARLIAMENT).

DISTAFF, in the early forms of spinning, the "rock" or short stick round one end of which the flax, cotton, or wool is loosely wound, and from which it is spun off by the spindle. The "distaff" or "spindle" side of a family refers to the female branch, as opposed to the "spear" or male branch. Jan. 7, the day after Epiphany, was formerly known as St. Distaff's day, as women then began work again after the Christmas holiday.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, NEW YORK
FLAX WHEEL DISTAFFS USED IN A COLONIAL HOUSEHOLD

DISTANCE. The length in a straight line between two objects, or the interval in time between two periods or events. In military language distance means the space between men or bodies of troops measured from front to rear.

DISTEMPER. A distemper in its simplest form consists of whiting, glue (size) and water, and is sometimes called whitewash. The glue acts as a binder, preventing the coatings from rubbing off. Distempers so made are exceedingly cheap, cover well, and are quickly and easily applied with large brushes, but they will not stand washing. They are largely used for whitening ceilings and cheap interior decorative work. When, in course of time the coatings become dirty, it is quite an easy and inexpensive matter to wash them off and apply a fresh coating.

Distempers are sold in the form of a thick paste or jelly, or as a dry powder, and only require mixing with cold or warm water to make them ready for use. A good distemper can be made according to the following recipe: Take 14 lb. of gilders' whiting and cover with water. Allow it to stand overnight. Next morning pour off the excess of water and work up well. **A** small amount of ultramarine blue mixed with water should be added to the whiting to improve the colour. Add about 5 lb. of hot jelly size to the whiting and mix well. Strain through a sieve and it is then ready for use. If it is desired to keep the distemper for any length of time before use, a small amount—about 1 oz.—of alum or borax should be added as a preservative.

Coloured Distempers.—By the addition of coloured pigments to the white distemper a large variety of beautiful shades may be obtained. The pigments used for tinting distempers must be permanent to light and perfectly fast to lime and alkalies. Since they are used largely on cement and plaster walls which contain free lime and alkali, such colours as Prussian blue, chrome yellow, Brunswick green, vermilionette, etc., cannot be used, as the alkali would quickly act on them and destroy their colour. In their place permanent pigments, which are fast to light and alkali, such as ultramarine blue, zinc chrome, Hansa yellow, lime green, Venetian red, etc., must be substituted. The following lime-proof colours should, when mixed with 14 lb. of white distemper, produce approximately the shades given in the right hand column:—

Colours.	***Tint** Produced.*
602. Pale French ochre	Cream.
6oz. Lime yellow	Primrose.
1lb. Venetian red	Salmon pink.
1lb. Venetian red 3lb. Yellow ochre	Terra cotta.
1lb. Venetian red 1lb. Lime blue	French grey.
2oz. Bright lime red 2oz. Lime blue	Lavender.
4oz. Pale lime blue	Bluebell.
8oz. Lime blue	Light blue.
1lb. Lime green 4oz. Yellow ochre	Sage green.
4lb. Lime green 8oz. Lime yellow	Apple green.
5lb. Bright lime red	Pompeian red.

Water Paint or Washable Distemper.—Although the terms "distemper" and "water paint" are often used synonymously, it is generally accepted that the word "distemper" should be limited to the non-washable compositions made according to the directions indicated. These simple distempers contain sufficient binder to prevent their rubbing off, but not enough to enable them to stand washing.

The term "water-paint," on the other hand, denotes a superior type of modern distemper which contains—in addition to the usual distemper ingredients—a proportion of oil or varnish, which acts as an additional binding agent. With these additional ingredients a good water paint should give insoluble coatings on drying, and the coatings should adhere so firmly that they can be washed a few days after application. This property is very valuable, as walls coated with these washable sanitary distempers, which have become dirty in course of time, can be easily cleaned and freshened up by simply sponging over with clean cold water.

Water-paints have also much better covering and hiding power than the ordinary distempers, because, in addition to whiting, a proportion of lithopone, zinc white or other strong pigment is incorporated, which increases their body or opacity, and gives more solid coatings.

Since they contain oils, varnishes, etc., these water paints are sold in paste form only. The paste is of a soft jelly-like consistency which only requires mixing with cold or warm water to thin it to a suitable consistency for use.

Water paints are largely used as flat wall paints for interior decoration. They are comparatively cheap and can be obtained in a large variety of beautiful shades. They dry very quickly after application, with a pleasing mat or flat finish; and on account of the firmness of adhesion and insolubility of these paints it is possible to apply a second coat a few hours after the first coat has dried, without working up the first coat. This property is very useful in those cases where two or more coats are necessary in order completely to hide the surface which is being painted, and give what is known as a "solid" effect.

Flat distempered surfaces are often "stippled" or dabbed whilst still wet with a special flat soft hair brush known as the "stippler." By this process all brush marks that might otherwise be in evidence are removed, and the surface is given a beautiful mat velvet-like finish.

When painting large wall areas, as in town halls, council chambers, schools and so on, these water paints are often applied by means of a spraying machine; in this way very large areas can be quickly and successfully covered with the distemper.

Water paints are manufactured as follows:—About 10 lb. of strong glue or size powder are put in a steam-pan, covered with 10 gal. of water and left to soak overnight; steam is then passed through till all the glue has gone into solution. The steam is turned off and about 1 gal. of linseed oil, copal varnish or mixtures of these is then added, and the whole well beaten up until an emulsion is formed. A small proportion of carbolic acid, formaldehyde, or other preservative is added to the emulsion, otherwise it would go mouldy if kept for any long period. This medium—usually known as petrifying liquid—is then mixed while hot with roughly its own weight of white base consisting of whiting, lithopone, blanc-fixe, or mixtures of these, and ground through stone-mills. The resultant thin paste is then packed in kegs or tins where it sets on cooling to a soft jelly-like consistency. The coloured distempers are obtained by adding the necessary quantity of lime-fast colour to the white base during the grinding process. There are some paste distempers on the market which are made by using casein—an insoluble white product obtained from skimmed milk—in place of glue or size. In these varieties the casein is dissolved in water with the aid of some alkali, such as carbonate of soda, ammonia or borax, which is added to the water in order to render the casein soluble. The procedure is then carried on in the way already described.

Outside **Distempers.**—For outdoor use only those distempers should be employed which have been specially made for the purpose Even when so manufactured these outside distempers. although largely used, will not last more than a year or two, and they do not possess the same durability and wearing properties as an ordinary paint.

Outside quality distempers contain more oil than is generally used in the preparation of distempers for indoor use. This helps to bind them better, and serves as a protective agent against weathering influences. They should be thinned ready for use with a medium—known as petrifying liquid—which is specially made for this purpose, and is of a similar composition to the medium in which the pigments are ground in making the paste distemper.

Powder Distemper.—Dry distempers (called calcimines in America) consist of whiting or carbonate of lime with either finely powdered glue or casein as their binding agent. They are manufactured by grinding the whiting and powdered glue or casein in special grinding and sifting machinery in order to get a thorough incorporation of all the ingredients. Great care must be taken to see that all the materials are thoroughly dry before mixing, as even a small amount of moisture present would make the powder cake and set up hard, and of course render it useless. A little borax, salicylic acid, alum or other dry preservative is added to keep the dry powder sweet and prevent any decomposition that might take place on standing.

In the case of coloured distempers, sufficient lime-fast pigments are incorporated during the mixing process in order to give the desired shade.

These dry distempers are now very largely used both in this country and America on account of their comparative cheapness. The following recipes will give a general idea as to their composition:—

(1.)	Whiting	100lb.
	Fine powdered size	8lb.
	Powderedalum	2oz.
(2.)	Whiting	100lb.
	Dry slaked lime	5lb.
	Sodacarbonate	2lb.
	Casein	5lb.
(3.)	Whiting	100lb.
	Dry slaked lime	14lb.
	Powdered borax	1½lb.
	Casein	12lb.

These white dry distempers may be tinted to any desired shade by adding lime-fast colours. (J. G. Be.)

DISTEMPER IN ART

Distemper is one of the earliest known mediums of painting. It was used extensively by the Greeks and Egyptians. It consists of a mixture of powdered colour with size and it differs from tempera in which process egg is the medium used. The French call all such mixtures *détrempe* but in England the egg mixture is known as *tempera* and the size mixture as *distemper*.

The colours are first ground in water and then mixed at the moment of use with size kept liquid in a *bain-marie*. This practise is necessitated by the fact that the proportion of the size required varies according to the nature of the powder used.

The method is useful for quick work as it is fluid and dries rapidly. It is durable though soluble in water. At the present day it is used chiefly by scene-painters but certain French artists, such as Degas and Vuillard, have made good use of it.

DISTEMPER: *see* CANINE DISTEMPER.

DISTICH, a couplet, consisting originally of a hexameter and pentameter line, containing a single idea, as exemplified in the Greek Anthology. Modern examples are to be found in the works of Goethe and Schiller. *See* VERSE.

DISTILLATION, an operation involving the conversion of a substance into vapour which is subsequently condensed to the liquid form. The process is exemplified at its simplest when steam from a kettle plays upon a cold surface, producing drops of *distilled* water. The term, which was originally applied to the separation of spirituous liquors from fermentation processes, now has a far wider application, and distillation is an integral part of many manufacturing processes. It has for its object the separation of liquids from solids, as pure water from sea water, or the separation of two or more liquids, petrol, or gasolene, and paraffin, or kerosene, from crude petroleum.

The simplest distillation apparatus consists of three parts: the *still* or *retort* in which the liquid is heated, the *condenser*, to cool the vapours, and the *receiver*, to collect the *distillate*. This is satisfactory for the purification of liquids containing solids. For the separation of several liquids, of which the components, in normal cases, distil in the order of their boiling points, the apparatus requires elaboration. These components do not usually distil exactly at their boiling points, but over a range of temperature, so that some overlapping of the boiling ranges is usual. To overcome this difficulty the vapours are led through a *still head* or *column* in which a sorting out of the components occurs. In this way the distillate may be collected in *fractions* (technically *cuts*), and the operation is termed *fractional* distillation.

FIG. 1.—DISTILLATION APPARATUS OF ABOUT A D. 1556. IN THE FOREGROUND RETORTS ARE BEING HEATED IN A VESSEL OF WATER, ATTACHED TO RECEIVING FLASKS BY ALEMBICS OR HEADS

Some substances decompose when heated to their boiling points. This may often be avoided by taking advantage of the fact that a lowering of pressure over the surface of the liquid lowers the temperature at which that liquid boils. This may be achieved by *vacuum* distillation, or by *steam* distillation, when steam is passed into the substance, which then volatilizes with the steam at a much lower temperature. When solid substances are heated to give gaseous or liquid products the operation is termed *dry* distillation. If the procedure involves a breakdown of complex materials into simpler substances (elementary or compound) the process is described as *destructive* distillation. (*See* COAL TAR and TARS, LOW-TEMPERATURE CARBONIZATION.) Finally, there is *sublimation*, in which a solid distils to give a solid without the intervention of a liquid phase.

Historical **Note.**—Distillation appears to have been used by the earliest experimentalists. Aristotle (384–322 B.C.) mentions that pure water is made by the evaporation of sea-water. Pliny the elder (A.D. 23–79) describes a primitive method of condensation, in which the oil obtained by heating rosin is collected on wool placed in the upper part of the still. The Alexandrians added a head or cover to the still, and prepared oil of turpentine by distilling pine resin.

The Arabians improved the apparatus by cooling the tube leading from the head, or *alembic*, with water, and discovered a number of essential oils by distilling plants and plant juices, alcohols from wine, and distilled water. By its use, the alchemists were enabled to study hydrochloric, nitric and sulphuric acids in a relatively pure state.

Modern laboratory practice owes much to the introduction, since 1850, of the condenser named after Liebig (fig. 2), and of the *reflux* condenser by Kolbe and Frankland. The latter is a condenser arranged vertically so that the condensed vapours return continually to the distilling vessel, and allows of the continued boiling of a liquid without loss. Dittmar and Anschütz introduced, independently, *reduced pressure* distillation, and fractional distillation was aided by the advent of the still-heads of Wurtz (1855), Linnemann (1871), and le Bel and Henninger (1874).

Distillation will now be dealt with in more detail under the headings:—(I) simple distillation, (2) fractional distillation, (3) reduced-pressure distillation, (4) high-vacuum distillation, (5) steam distillation, (6) dry distillation, (7) theory of distillation, (8) distillation in technology, and (9) distillation of water.

(1) Simple **Distillation.**—*Retorts* are now rarely used. Laboratory distillation in its simplest form is carried out in the apparatus depicted in fig. 2.

The diagram is self-explanatory, but it may be remarked that laboratory ware is usually constructed in glass, and connected together by means of corks or rubber bungs. When the materials to be distilled are corrosive to cork or rubber, the distilling flask,

condenser and receiver are connected by ground-glass joints, or they may be fused together with the blow-pipe, thus giving an all-glass apparatus. Heating of the *distilling flask* is effected in a variety of ways depending upon the volatility and inflammability of the substance to be distilled. It may be by direct gas flame, or indirectly through a sand-tray or wire gauze, by electric hot plate, by internal heating of the liquid by platinum wire, or by

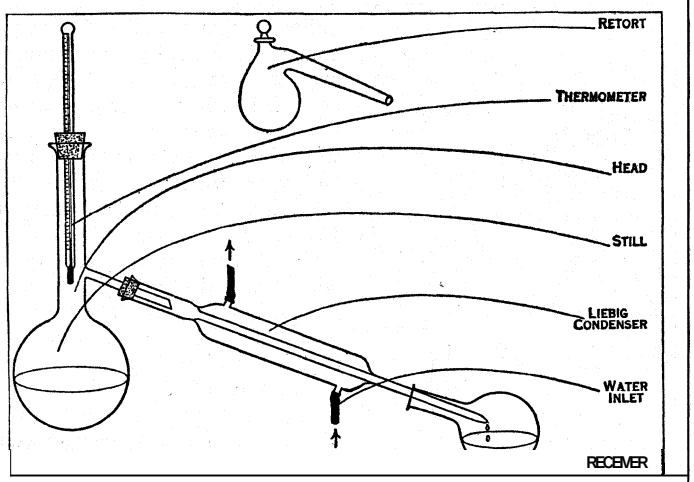


FIG. 2.— TYPICAL LABORATORY DISTILLATION APPARATUS
The vapour passes from the still to the Liebig Condenser, where it is condensed by cold water circulating in the water jacket, the distillate being collected in the receiver

immersion in a steam, oil or fusible metal bath. Some liquids boil explosively when heated and the phenomenon is known as *bumping*. This may be prevented by placing small pieces of porcelain, pumice, capillary tubing or other porous material in the still. In distilling substances likely to decompose when heated in air, an inert gas is led through the apparatus during the operation,

It will be seen from figs. 1 and 2 that the modern still is similar in principle to that of the alchemists, but a thermometer is added to facilitate control of the process. This is usually placed so that its bulb is near the point at which vapour leaves the still. Consequently a part of the mercury in the thermometer may be at

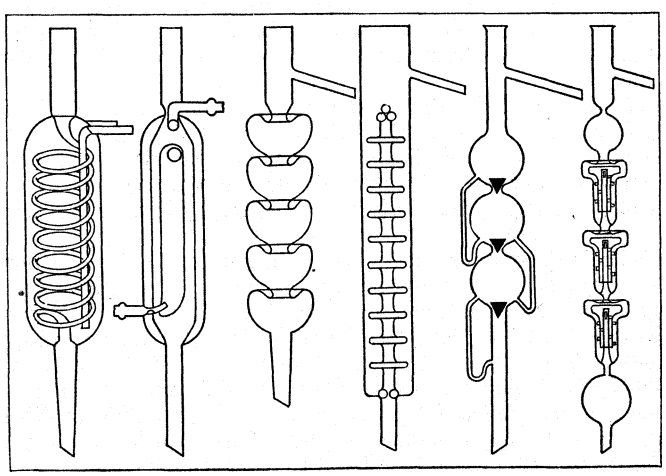

FIG. 3 — EXAMPLES OF LABORATORY CONDENSERS AND COLUMNS
From left to right: Inland Revenue Condenser; Double Surface Condenser; Pear Column: Rod and Disc Column; Le Bel-Henninger Column; Young Evaporator Column

a lower temperature than that in the bulb. To obtain the true temperature a correction for "exposed stem" is applied to the observed reading.

The choice of condenser in any given case is governed by the volatility of the substance to be distilled. With substances boiling above 170° C, air cooling of an elongated side tube is generally sufficient, but for ordinary work the Liebig *single surface* condenser (fig. 2) is used. For very volatile organic liquids the double *surface* (fig. 3) is necessary. Numerous types arc available, but the difference lies mainly in the ingenuity with which the internal members are designed to give the maximum cooling surface. The *spiral* or *worm* condenser is a compact form of the Liebig, an example being the British Inland Revenue pattern.

(2) Fractional Distillation.— Fractional distillation implies the separation of mixtures of substances of different boiling point. The nearer these boiling points are to one another, the more difficult is the operation. It is facilitated by elongation of the distilling flask neck, or by adding what is known as a *fractionating* column.

Numerous columns have been devised, but all work on the principle of allowing the more volatile portion of the vapour to proceed to the condenser whilst returning the less volatile to the still. Of the three main types, the plain column, of which the Wurtz *bulb* and the Young *pear* columns are modifications, is the least efficient. The second class of column is maintained at the temperature at which the most volatile constituent of the vapour distils. The third type, better known as the *dephlegmator* type, is the most widely used. In this the ascending vapours from the still bubble through portions of the already condensed vapour. The Linnemann modification passes the vapour through condensate temporarily collected on platinum gauzes at constrictions in the column. The le Bel–Henninger embodies a further development of the idea, and successive bulbs are connected by syphons (fig. 3). The Young *rod* and *disc*, the Hempel *glass bead*, the Raschig and the Lessing *rings* and the Young *evaporator* columns are all extensions of the same principle. Dufton (1919) has devised a very simple column which consists of a wire wound spirally in the annular space between a closed centre member and the outer column body. It is simple to construct, efficient in operation and is essentially a laboratory adaptation of the commercial column due to Foucar.

(3) **Reduced-pressure Distillation.**—Distillation under reduced pressure is adopted when dealing with substances which normally boil at inconveniently high temperatures, or with decom-

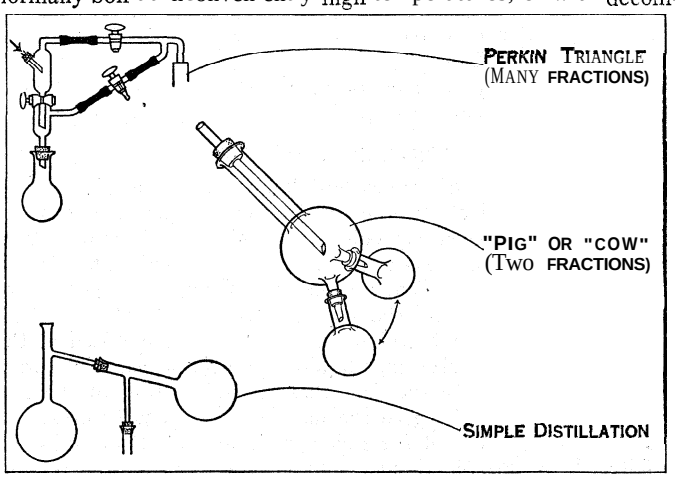

FIG 4.— LABORATORY RECEIVERS FOR DISTILLATION WORK UNDER REDUCED PRESSURE, THE TYPE USED DEPENDING ON THE NUMBER OF FRACTIONS TO BE COLLECTED

position under atmospheric pressure. The apparatus used differs but little from that already described. The receiver is connected by thick-walled rubber tubing to a manometer, for determining pressure, and to some form of vacuum pump. To avoid bumping the usual method is to introduce a fine stream of gas bubbles through the liquid by means of a capillary tube reaching to the bottom of the still. A very common form of apparatus for this work is the Claisen flask, which has two necks, one holding the capillary tube, and the second the thermometer.

If it is required to collect fractions under reduced pressure, some special form of receiver is necessary. A Bredt ***pig*** (fig. 4) is used for two or three fractions, the Perkin *triangle* is useful for a series of fractions where the distillate is fairly mobile, whilst the Brühl apparatus is most suitable for the distillation of solids, as fatty acids or waxes.

(4) **High-vacuum Distillation.**—Whereas reduced pressure distillation implies distillation at pressures of 5–15 mm of mer-

cury, it is an advantage for some purposes to go much lower, from 1 mm. down to X-ray vacuum conditions. Krafft used a cathode vacuum for distilling paraffin waxes, and to-day high-vacuum distillation is being used for purification of various gland extracts for medicinal purposes. Ordinarily, a typical high-vacuum distillation set, embodies a distillation flask with Wurtz head, which may be further improved by the insertion of a Dufton column. The distiilate is delivered into a Briihl multiple receiver having special glands to stand up to extreme vacuum conditions. The vacuum in this case is maintained by a Kaye annular-jet mercury vapour pump, backed by a Cenco Hyvac rotary oil pump. Such an apparatus is capable of maintaining a working vacuum of 0·0001 mm. of mercury at the receiver when distilling paraffin waxes.

(5) Steam Distillation.— In this operation steam, generated as a rule but not invariably in separate apparatus, is passed into the still, and the resulting mixed vapours are condensed in the usual manner. The process is equivalent to reduced pressure distillation, for Dalton's "Law of Partial Pressures" is applicable, and the substance distilled with steam only attains the temperature corresponding to its partial pressure. Thus benzaldehyde, which boils at 178·3° C at 760 mm, distils with steam at 97·9° C, corresponding to its partial pressure of 56.5 millimetres. This is, in effect, a reduction in pressure of 703·5 millimetres. Familiar instances of the use of this method are the separations of ortho- and para-nitrophenols, and of aniline and nitrobenzene, of which the first in each pair is volatile in steam. Liquids other than water can be used in analogous operations. Alcohol is used to remove phenol from the condensation product of phenol and formaldehyde. (See RESINS, SYNTHETIC.)

(6) Destructive and Dry **Distillation.**—These processes refer to operations on solid materials. The dry distillation of calcium acetate gives acetone. The destructive distillation of wood gives acetone, acetic acid and methyl alcohol; and of coal, coal gas, benzene and a multitude of other chemical products. Dry distillation is best carried out in shallow stills with small batches of material. Caking may be partially prevented by mixing the charge with sand or pumice.

(7) Theory of Distillation.— The general observation that under constant pressure a pure substance boils at constant temperature leads to the conclusion that the distillate which comes over while the thermometer records only a small variation is of practically constant composition. On this depends all *rectification* or separation by distillation. The theory of distillation is complex, and we shall confine ourselves to mixtures of two components, A and B, of which three cases are to be recognized, according as the two are: (1) quite insoluble in each other, (2) miscible only within limits, and (3) miscible in all proportions.

When the components are completely immiscible the vapour pressure of one is not influenced by the other, and the mixture distils at the temperature at which the sum of the partial pressures equals that of the atmosphere. Both components distil in constant proportion until one disappears, when the residue distils if the temperature is raised. The composition of the distillate is determinate if the molecular weights of the components and the vapour pressures at the temperature of distillation are known. It is not proposed to enter into this in detail, but it may be noted that in steam distillation the low volatility of a substance may be off-set by its high molecular weight.

When distilling a mixture of partly miscible components a distillate of constant composition is obtained so long as two layers are present; *i.e.*, A dissolved in B and B in A, since, in accordance with the second law of thermodynamics, these solutions emit vapours of the same composition. The composition of the vapour is not, however, the same as that of either layer. As the distillation proceeds one layer diminishes more rapidly than the other until one remains, which then distils as a completely miscible mixture.

The distillation of completely miscible mixtures is the most common practically, and the most complex theoretically. Such mixtures are of three kinds, depending upon the relative solubilities of the vapours in the liquids.

(i.) If the vapour of A is readily soluble in the liquid B, and the vapour of B in A, there will exist a mixture of A and B having a lower vapour pressure than any other mixture. The vapour pressure-composition curve is convex to the axis of composition, the maximum vapour pressures corresponding to pure A and B, and the minimum to some mixture of A and B. On distilling such a mixture two components, in varying amounts, come over until the still contains the mixture of minimum vapour pressure, which then distils at constant temperature. Nitric acid of boiling point 86" C, forms a mixture with water, boiling point 100° C, which boils at a constant temperature of 120·5° C, and contains 68% of acid.

(ii.) If the vapours are sparingly soluble in the liquids, there will exist a mixture having a maximum vapour pressure. The vapour pressure-composition curve is concave, the minima corresponding to the pure components. On distilling this mixture a mixed vapour of constant composition distils, leaving one or other of the components. Propyl alcohol and water furnish an example.

(iii.) If the vapour of A is readily soluble in B, and the vapour of B sparingly so in A, and if the vapour pressure of A is greater than that of B, then the vapour pressure of mixtures of A and B approximates to a linear function of the composition. On distilling this mixture, pure A comes over first, followed by mixtures in which the quantity of B continually increases. As a consequence A and B can be completely separated by a sufficient number of distillations. As an example we have methyl alcohol and water.

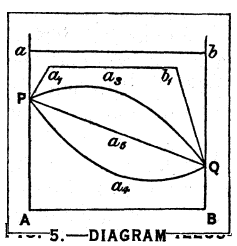

FIG. 5.—DIAGRAM ILLUSTRATING THEORY OF DISTILLATION OF IMMISCIBLE, PARTLY MISCIBLE AND MISCIBLE MIXTURES

These five cases have been illustrated in one diagram by van't Hoff. In fig. 5, AB is the axis of composition, AP the vapour pressure of A, BQ of B. For immiscible liquids the vapour pressure curve is the horizontal line ab, where $aP = QB$, and $bQ = AP$. For partially miscible liquids the curve is Pa_1b_1Q. The horizontal line a_1b_1 corresponds to the two layers of liquid, and the inclined lines Pa_1, Qb_1, to the solutions of B in A and A in B. The curves Pa_4Q, having a minimum at a_4, Pa_3Q, with a maximum at a_3, and the straight line Pa_5Q correspond to the types (i.), (ii.) and (iii.), of the completely miscible mixtures

(8) Distillation in Technology.— Distillation in all its forms is used in chemical technology. The type of apparatus in any particular process is conditioned by various factors, such as the nature of the original mixture and the available means of heating. The simplest still consists of a closed cylinder of cast or wrought iron, provided with a tubular neck. If horizontal, the ends are usually convex, but if vertical, the base may be either concave or convex. The convex bottom has the advantage of increased heating area and ease of cleaning, but the disadvantage that the run-off is at the point of maximum heat. In the concave type the run-off comes at the edge, but the still is difficult to clean. Tar stills are often of the vertical type, whilst horizontal ones are popular in the petroleum industry. Pipe stills in which the charge is pumped continuously through a heated coil are used to some extent.

A complete still is provided with a hemispherical head, and, in addition to the large opening to carry away vapours, may be fitted with: (1) bearings for stirring gear, (2) pressure or vacuum gauge, (3) inlet and outlet for closed steam coil, (4) a tube reaching to the bottom of the still to introduce live steam, (5) closed tubes to carry thermometers, (6) man holes for charging, (7) inspection windows, and (8) a safety valve. Such stills are made in a large variety of materials—cast and wrought iron, copper, mild steel, nickel and aluminium are common. Lead-lined stills are used, and for food products or fine chemicals enamelled or even glass-lined stills are particularly useful. Fused silica is used for nitric acid distillation, and glass and stoneware for bromine and iodine.

Stills may be heated by solid combustible, as coal, coke or anthracite, or gas fired. Steam may be used either as open steam, actual steam distillation, or closed, in which steam is the heating medium only. Indirect heating has the advantage over direct

firing that there is no tendency to local overheating or burning, and it is subject to closer control. Steam-heated stills can be regulated by ingenious devices which automatically ensure that the concentration of the distillate is unaffected by change in steam pressure.

Mention should here be made of an important modern development in distillation technique. In the T.I.C. method of tar distillation molten lead is commonly used as the medium for the transfer of heat from the furnace to the actual charge. A continuous stream of tar is introduced on to the surface of molten lead in a labyrinth shaped like an Archimedian spiral. The method has the important advantage that any coke or pitch formed is readily removed from the surface of the lead, and the process becomes perfectly continuous. Since only a small amount of tar is in the still at any one time the plant is particularly flexible.

In commercial practice three main types of column are used, the *packed* column, based on the laboratory Hempel, the *perforated plate,* and the *bubbler hood* or *bell* columns. In recent types of packed column special fillings are used, such as those of Raschig, Lessing, Goodwin and Prym. The Raschig filling consists of open cylinders of any suitable material, varying in size according to the operation. In plate columns, the fractionating effect is obtained by bubbling the vapour through films of liquid on perforated plates. Since efficiency depends upon the relation between the rate of evaporation and the size of hole, the apparatus is not very flexible. The bubbler hood or bell type column is extensively used in the rectification of alcohol. In these columns condensed liquid is maintained at constant level in each section, and the ascending vapour forced, as streams of fine bubbles, through the liquid by means of slotted bells placed over the up-going vapour tubes.

Of condensers, the *worm, tubular* and *open surface* may be mentioned. An example of the popular worm type is shown without water jacket in Plate II. In the tubular condenser a counter-current effect is obtained and the cooling water flows rapidly past the vapour tubes, whilst in the open surface type, the vapour passes through a bank of tubes cooled by trickling water and is thus condensed.

There is one important operation, primarily of distillation, where the product left in the still is the first consideration. This is known as *evaporation,* and may be applied to operations as various as those for obtaining salts from sea water, to concentration of milk or tomato juice to give edible products.

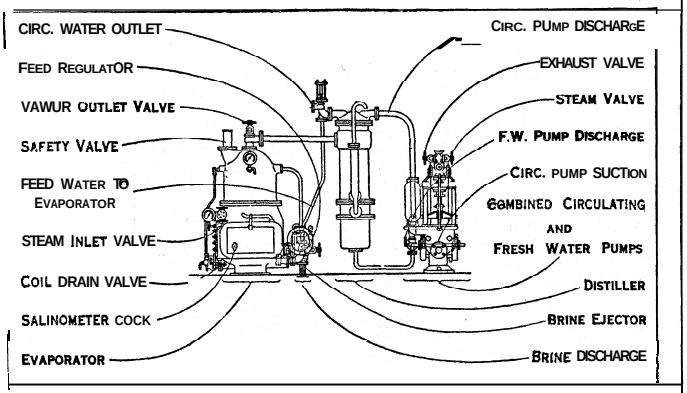

FIG. 6.— SECTION OF WEIR ADMIRALTY TYPE OF EVAPORATING AND DISTILLING UNIT. EXTENSIVELY USED IN THE BRITISH NAVY, AS IT IS COMPACT, EFFICIENT AND ECONOMICAL

(9) Distillation of Water.—Water free from dissolved gases and salts is indispensable in many scientific and industrial operations. The laboratory still for the purpose is very simple. The boiler, fed by warm water from the condenser, is usually of copper, and the head and worm of copper or tin.

The problem of the economic production of potable water from sea water is very old. In 1683, Fitzgerald patented a process for "the sweetening of sea water." Hales (1739) gives a history of the earlier attempts in his book, *Philosophical Experiments.*

Early forms of the modern apparatus were invented by Chaplin of Glasgow, Rocher of Nantes, and by Gallé and Mazeline of Havre. The Normandy apparatus was effective and economical. and extensively used in the British navy, but owing to its expensive and complicated structure it has largely given place to the Weir type of plant (fig. 6).

The modern plant consists of three main parts, the evaporator, distiller and condenser. In some types of condenser the tubes are of oval section, as in the German Pape-Henneberg, or crescent-shaped as in the Quiggins. Royles' plant uses the Row patent tube consisting of tubes indented alternately at right angles. An important feature of such tubes is that they are self-scaling in use. In distilling plant for ship-board use compactness is the first essential, whilst for terrestrial work the more elaborate form of apparatus such as the Mirlees-Watson *sextuple effect* evaporator (Plate *V.)* gives strikingly economical results.

BIBLIOGRAPHY.—Laboratory distillation is discussed in all books on practical organic chemistry, and its theory in treatises on physical chemistry. S. Young and Collaborators' *Distillation Principles and Processes* (London, 1922), and C. Mariller's *Distillation et Rectification des Liquides Industriels* (Paris, 1925) are both excellent general books combining treatment of the theory and practice of industrial distillation. In addition, the former gives a detailed analysis of laboratory column performances. C. Elliot's *Distillation Principles* and *Distillation in Practice* (London, 1925) treat the problem from the view-point of a chemical engineer. C. S. Robinson's *Element of Fractional Distillation* (New York, 1922) should also be included for reference. (E. Ho.)

DISTOMUM: *see* TREMATODES; PLATYHELMINTHES.

DISTORTION, in radio, a term denoting change in wave form which takes place as a wave passes through a circuit or transmission medium. Wave form distortion may consist of: (1) The presence in an output wave of a circuit of components having frequencies not present in the original wave due to circuit elements having non-linear characteristics; (2) a change in the relative amplitude of the component frequencies of a wave due to variation in the transmission efficiency of the circuit or transmission path for different frequencies included in the range involved; (3) a change in the relative phases of the component frequencies. Two or more of these forms of distortion may be present simultaneously.

DISTRESS, pressure, especially of sorrow, pain or ill-fortune. As a legal term, the action of distraining or distraint, the right of a landlord to seize cattle or goods of his tenant for non-payment of rent, or the right of a person upon whose land cattle stray to seize the cattle "damage feasant" (doing damage). The cattle or goods so seized are taken without legal process as a pledge to compel the satisfaction of a demand or the redress of an injury. They can only be retained until the owner makes satisfaction. "Distress damage feasant" is also applicable to inanimate things on the land, if doing damage thereto, or to its produce. Such distress must be made during the actual trespass, and by the person aggrieved by the damage. Distress for rent however is the sense in which the term is most frequently used in its legal signification. The power of distress appears to have been derived from the feudal law and to have been substituted for a forfeiture of the tenant's holding. Until the statute 2 and 3 Will. and M. sess. 1 c. 5 the chattels distrained remained only as a pledge in the hands of the landlord and could not be sold.

Rents at common law are of three kinds, rent-service, rent-charge and rent-seck and at common law distress was incident to rent-service and by special reservation to a rent charge. A rent reserved by a lease is rent-service. Distress was not incident to rent-seck until the Landlord and Tenant Act 1730. That statute also extended the remedy of distress to rents of assize and chief rents and thereby in effect abolished the most material distinction between them. But a right of distress is not incident to an obligation to pay provided for in an agreement, which is only a licence and does not create the relationship of landlord and tenant between the parties.

All personal chattels are distrainable with the following exceptions:— (i.) *goods absolutely privileged:* (a) things in actual use; (b) fixtures (*q.v.*); (c) goods delivered to a person in the way of his trade; (d) perishable goods; (e) goods in the custody of the law; *e.g.,* goods already taken in execution by the sheriff;

(f) animals ferae *naturae* (dogs and tame deer and deer in an enclosed park may be distrained); (g) Crown property; (h) goods of an ambassador or his servants on the premises of an embassy; (i) certain articles exempted by special acts of parliament; *e.g.*, gas or water meters; (j) hired agricultural machinery and breeding stock in circumstances coming within the provisions of the Agricultural Holdings Act 1923; (k) goods of an under-tenant or lodger (Law of Distress Amendment Act 1908); (l) wearing apparel and bedding of the tenant or his family, and the tools and implements of his trade to the value of £5 (Law of Distress Amendment Act 1858); (ii.) goods conditionally *privileged, i.e.*, privileged if there are sufficient goods of other kinds on the premises to satisfy the distress: (a) implements of trade not in actual use; (b) beasts of the plough and sheep; (c) agisted stock if the Agricultural Holdings Act 1923 applies.

In order to obtain the protection afforded by the Law of Distress Amendment Act 1908, it is necessary for the under-tenant or lodger, who seeks protection, to make a declaration in writing and serve it on the landlord, his bailiff or agent employed to levy the distress after (not before) the landlord has levied the distress or authorized it to be levied. The declaration must be set out (i.) that the tenant has no interest in the goods in question and that they are the property of the person making the declaration, (ii.) the rent then due by the under-tenant or lodger, (iii.) the rent payable in future, and (iv.) an undertaking to pay all such rent to the landlord until the arrears then distrained for have been paid off. An inventory of the goods in question must be annexed.

A distress for rent may not be made after sunset and before sunrise, nor on a Sunday. It may not be made till rent is in arrear. At common law a distress could not be made after the expiration of the lease, but since the Landlord and Tenant Act 1709 it may be made at any time within six months of the termination. By the National Health Insurance Act 1924 s. 102, where an insured person is receiving sickness benefit under that act and a medical practitioner certifies that the levying of a distress would endanger the insured's life, the levy must be postponed during the currency of the certificate. The certificate is of no effect until it has been sent to the insurance committee and recorded in a special register. It operates for one week but may be renewed weekly for three months but not longer. The register may be inspected without fee. In the cases of premises to which the Rent and Mortgage Interest Restrictions Acts apply distress cannot be levied without leave of the court.

Six years' arrears are recoverable in ordinary cases, but if the Agricultural Holdings Act applies only one year's arrears are recoverable.

If the tenant become bankrupt the right of distress is limited to six months' rent prior to the adjudication. If more be due that must be proved for in the bankruptcy (Bankruptcy Act 1914 s. 35). If a company is being wound up its goods cannot be distrained without leave of the court (Companies [Consolidation] Act 1908 ss. 142 and 211).

The distress for rent must be made on the land demised except in the case of the king or queen regnant and except in the case of fraudulent removals and certain rents for quarries in the Forest of Dean. Chattels clandestinely or fraudulently removed from the premises may be followed within 30 days after their removal, unless in the meantime they have been sold *bonâ fide* and for valuable consideration. Again if a landlord or his agent come to distrain cattle which he sees upon the land, and the tenant or any other person drive the cattle off the land the landlord or his agent may follow them; but this does not hold if the landlord or his agent does not see the cattle on the land or the cattle stray from the land of their own volition.

A distress may be made by the landlord himself or a certified bailiff (Law of Distress Amendment Act 1888 s. 7). This certificate is granted by a county court judge. He may be removed by the judge for extortion or misconduct. He should have an authority in writing from his employer called a "distress warrant." This warrant does not require a stamp. The outer door of the tenant's house cannot lawfully be broken open in order to make a distress but if the outer door be open an inner door may be broken open if necessary.

The chattels distrained must be impounded. By the Protection of Animals Act 1911 s. 7 a person impounding any animal must supply it with a sufficient quantity of wholesome and suitable food and water. The landlord cannot sell the chattels distrained to himself. Before any sale takes place enquiry should be made at the county court registrar's office to ascertain whether the goods have been replevied (see REPLEVIN); if that is not so and the rent due and charges for the distress remain unpaid at the end of five days (which must be extended at the request in writing of the tenant to 15 days) the goods should be sold for the best price which can be obtained for them (see AUCTION). The overplus, if any, must be repaid to the tenant.

Duties and penalties imposed by act of parliament (*e.g.*, payment of rates and taxes) are also sometimes enforceable by distress. (A. SD.)

In the United States, the process is recognized by most of the states for the taking of a personal chattel from the person to secure satisfaction for a demand.

DISTRESS, RELIEF OF. Public relief of the destitute in Great Britain is dealt with in the article POOR LAW; here we are concerned only with aspects arising out of unemployment. For relief of unemployment in the U.S.A., see RELIEF: Federal *Relief*.

The first serious attempt to treat this problem as separate from Poor Law procedure was made by the Unemployed Workmen Act, 1905, which removed these men from the pauper class. Under it were established distress committees of the councils of boroughs and urban districts with a population of not less than 50,000 (with certain special arrangements in the case of London), and central committees in the counties. The members of the distress committees were drawn from the councils, the boards of guardians, and co-opted persons (one at least of whom had to be a woman), and the central bodies comprised representatives of the committees and of the county councils, with co-opted members and persons nominated by the Local Government Board (after 1919 the Ministry of Health); their expenses were met by a fund supplied by voluntary contributions and by moneys raised from the rates, the latter being limited to a rate of ½d in the £ or, with the sanction of the minister, 1d., rate aid being confined to establishment charges, the cost of emigration or removal and the acquisition of land.

It was the duty of the distress committees to make themselves acquainted with the conditions of labour in their area and, if so required by the central body, to receive, inquire into, and discriminate between applications from unemployed persons; in suitable cases they might endeavour to find work for an applicant, but they could not themselves provide or contribute towards the provision of work for such. The central bodies superintended and, as far as possible, co-ordinated the action and aided the efforts of the distress committees, and could provide temporary work with the object of fitting the recipient for work of a regular character.

For many reasons—*e.g.*, the failure of the alliance between voluntary charity and rate aid, the burdening of the distressed area itself with the cost of its unemployed, and the unwieldy method of appointing the committees—the Act was never a success; its repeal was advised in 1909 by the Royal Commission on the Poor Law, and many times subsequently; in 1910 an important part of the work of the committees was transferred to the newly formed Labour Exchanges; and in 1929 the Act was finally repealed by the Local Government Act.

The Local Government Act, inter *alia*, abolished the boards of guardians and transferred their functions, with most of those of the Poor Law authorities, to the county and borough councils. which were empowered to set up "Public Assistance Committees" charged with the carrying out of these duties, and local sub-committees known as Guardian's Committees. The former are made up of councillors or aldermen and co-opted members; the latter of nominees of the district council, members of the county council for the area divisions. and co-opted members. In both cases co-opted members may not number more than one third of the total membership and must include some women; among them are usually ex-members of the former Poor Law authorities and frequently members of such bodies as the Voluntary Hospitals Asso-

ciation and the Personal Service League. There is no statutory limit to the numbers serving on the public assistance committees, but the guardian's committees may not comprise less than 12 nor more than 36 members.

The public assistance committee administers the Poor Law in the area over which it has control and is responsible for the supervision and management and all the various Poor Law Institutions as well as for general relief. It may delegate certain of its functions to other committees but its work in connection with the relief of distress is done through its own guardians' committee and other committees (as "Welfare", "Outdoor Relief", etc.) appointed for special purposes.

Pt. 11 of the Poor Law Act, 1930, gave the public assistance committees further powers, especially in the matter of the recovery of the cost relief; and in 1931 the Unemployment Insurance (National Economy) (No. 2) Order laid upon them the duty of investigating applications for relief from unemployed persons of 18 years or over claiming, under the Unemployment Act, 1927, that they are in need of assistance by way of transitional payments (the "needs test"). Relief, when awarded must not exceed the amount the applicant would obtain through insurance, and must be given in cash, not in kind. By 1933, when unemployment in Great Britain had passed its height, the Ministry of Health admitted that the relief of distress among the able-bodied unemployed was a State responsibility, and in 1934 a further Unemployment Act was passed upon this principle.

DISTRIBUTION. In economics, the manner in which the income of a community, won by its own production or gained in fruitful exchanges with other communities, is divided up among its members. The national output, or aggregate of services and material goods produced by the capital and labour of a nation, is a continuous stream, which is always flowing, and which is divided up among the agents of production in certain shares. The lenders of physical goods take rent; the lenders of capital take interest; management takes profit; labour takes wages or salaries. The national and local governments levy taxes upon all these for the expenses of government, and in so doing change to some extent. large or small, the nature of the distribution, among private claimants, as when the taxation of the well-to-do is used to pay an old-age pension.

The manner of the distribution of the national dividend is determined by the law of supply and demand. Each contributor to the national product brings to market his goods or his services, his property, or his labour, for sale or hire. If he owns physical property he offers it for hire and obtains whatever rent the condition of the property market affords. If he possesses money, he may lend it at the highest rate of interest he can get at the risk he is willing to hazard. If lie is a captain of industry, he sells his managing power, and if he is a man of consummate ability he can obtain a high price for his services, for the supply of such men is always relatively small. If he is a workman, he brings his skill and strength to market, bargaining either individually or collectively for the best reward he can get. In each of these matters, the law of supply and demand operates, modified by powers of monopoly or quasi-monopoly.

The subject of distribution is thus of paramount interest, and its consideration has engaged the close attention of economists of all schools, of political parties, of statesmen framing industrial and social legislation, and of finance ministers levying taxation. In these pages, the economic issue is discerned under ECONOMICS, CAPITAL, MONOPOLY and INHERITANCE; socialistic views under COLLECTIVISM, SOCIALISM, GUILD SOCIALISM and ANARCHISM; the practical industrial issues under INDUSTRIAL RELATIONS, TRADE UNIONS, CO-OPERATION, CO-PARTNERSHIP, PROFIT-SHARING and EMPLOYEE STOCK OWNERSHIP; the actual distribution of wealth and the national product under WEALTH AND INCOME, DISTRIBUTION OF; and ESTATE DUTIES.

DISTRIBUTION, IN TRADE: see MARKETING.

DISTRIBUTION OF ANIMALS. A solution of the problems of zoogeography, which attempts to explain the distribution of animals on the earth, may be sought in two directions. We may investigate the distribution of related groups of animals in the separate regions of sea and land. and from this seek to draw conclusions as to former connections betueen the present habitats of related forms. the historical aspect. or we may inquire what animal forms dwell together in places showing certain conditions of environment, and by what characters they are adapted to existence under these conditions, the oecological aspect, which is considered here.

For animal life to succeed at all, certain general conditions must be fulfilled; if but one is lacking, animal life also is absent. One of these primary conditions is water. In places such as extremely arid deserts, where water-supply and dewfall fail completely for long periods, no animal can live

To many animals light is not immediately necessary. In subterranean caverns, and in the great depths of the ocean (1,700m.), light is absent, yet animals live in these places provided they can find food Light is indispensable, however, to green plants since it supplies the energy for the manufacture of organic substances. Animals are dependent on organic food, and so ultimately, upon plants Light, therefore, is indirectly necessary to animals.

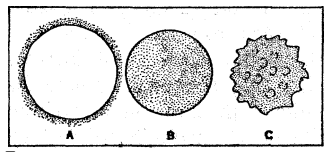

FIG 1.—MAMMALIAN RED BLOOD CORPUSCLES IN SALT SOLUTIONS: A 0.2%; B. 0.75%: C. 1.0%

All life is confined within certain limits of temperature. Albumin, the chief constituent of protoplasm, coagulates at about 70° C. Protoplasm, too, cannot live if its fluid content is frozen, *i.e.*, at temperatures below about -1° C. Thus animal life is absent in the hottest springs (some lower animals, such as Protozoa, rotifers, snails, can live in hot springs of 45°–50° C); while no animals are present in the perpetual snows of mountains.

Food is absolutely essential to all animals. In addition to organic materials (albumin, carbohydrates, fats), oxygen is needed, to combine with the products of the breaking-down of organic food, and thus liberate energy. There are some places where oxygen and therefore animal life is absent; in the depths of scme parts of the ocean and in volcanic places where carbon dioxide (CO_2) escapes from the ground, *e.g.*, the floor of the Grotto del Cane at Pozzuoli, near Naples.

The quantity of moisture, warmth and oxygen, required by an animal varies in different species; some are able to manage with little, others need much, while others again are indifferent to the amount Animals requiring amounts of moisture, warmth or oxygen (whether great or small) not varying beyond narrow limits are termed stenohygrous, stenothermic or stenoxybiont, respectively; those having wide limits, euryhygrous, eurythermic or euroxybiont; animals in all respects indifferent are euryoekous, those requiring definite quantities stenoekous. Euryoekous animals generally have a wider distribution than stenoekous.

The different regions of the earth occupied by living beings, the sea, fresh water and dry land, are fundamentally different in the conditions they offer and in the demands they make.

Sea.—The sea is the home of life. In it are represented all the structural types in which animal life manifests itself. Echinoderms, Tunicates, Cephalopoda, many groups of worms, Radiolaria and Foraminifera are confined to the sea Myriapoda and Amphibia only are not represented there. Salt water of the concentration of sea-water is the true medium for protoplasm Seawater has the same osmotic pressure as the fluid in protoplasm For that reason it withdraws no materials from the protoplasm, neither does it give up any to it. If human blood is examined in salt solutions of strengths such as 0·2%, 0·75% and 1%, the fate of the red corpuscles differs greatly in each cace (fig 1. A–C.) In 0·75% NaCl they remain unchanged; this solution is isotonic with the fluid they contain. In 0·2% NaCl the corpuscles give up colouring matter to the salt solution, swell and ultimately burst (a). In 1% NaCl they shrivel *(c)*, water having been withdrawn from them. Animals living in the sea are situated similarly to the corpuscles in the 0·75% salt solution; they need not isolate their inner medium from the environment.

In the sea, too, the conditions of life undergo least change. All seas communicate with one another, and their waters are con-

6. Queen Moray (*Lycodontis funebris*)
7. Sea Fan (*Gorgonia flabellum*)
8. Buffalo Trunkfish (*Lactophrys trigonus*)
9. Cowfish (*Lactophrys tricornis*)
10. Squirrel Fish (*Holocentrus ascensionis*)
11. Pork Fish (*Anisotremus virginicus*)

tinually mingled. The salinity, therefore, is about the same in all regions, the temperatures are similar, and vary much less than in fresh water, or in the atmosphere. The amount of oxygen present is very constant. Exceptions are secondary seas having only a narrow connection with the ocean, such as the Mediterranean and Baltic.

Fresh Water.—Fresh water, on the contrary, is dangerous to living organisms on account of the small amount of salts contained in solution. As in the red corpuscles in 0·2% NaCl, water is continually passing into the protoplasm. The inward permeation of water may be prevented either by strong armour, as in water insects, the animal body shutting itself off from the environment; or, more frequently, the water which passes in is constantly discharged. Thus all fresh-water Protozoa possess a contractile vacuole (fig. 2), which contracts rythmically, and discharges water to the exterior. In multicellular fresh-water animals the same result is reached by the action of the kidneys. Fresh-water animals, however, have less competition, for only relatively few marine animals are able to counteract the ill-effects of fresh water. Fresh water offers a rich food supply, but this must be earned.

Land.—Terrestrial life offers a number of favourable conditions. Oxygen is present in much greater quantities than in water. Further, dry land, in contrast to the sea, offers abundant vascular plants as food. These advantages, however, are not easily obtained. The amount of moisture in the air is generally far from saturation point, and puts the animals in danger of desiccation. The outer skin, and, above all, the respiratory organs, with their large, permeable surfaces, must be protected from excessive evaporation. Only members of three groups of animals can survive life in a dry atmosphere, gastropods, arthropods and vertebrates. Gastropods have in their shells a protection against desiccation; they emerge only when there is sufficient moisture. Terrestrial arthropods have their chitinous armour. Among the vertebrates, the horny epidermis lessens evaporation. In all three groups the respiratory organs have been removed to the interior of the body. Snails have a pulmonary cavity; millipedes, insects and spiders have internal air-tubes (tracheae); air-breathing vertebrates have lungs. In all these animals life takes place in the inner albuminous salt solution, not in the atmosphere.

The air also offers a new condition in its lesser density. Water supports the animal body, leaving little work for muscles and supporting organs. In the air, on the contrary, the body must be supported and compact to retain its form. All terrestrial animals, therefore, have skeletons; snails their shells, arthropods their chitinous armour and vertebrates their bony skeletons. Further, water supports, or retards the sinking of, much floating matter, such as small plants or animals, and the disintegration products of organisms (detritus), and this is carried as food to the animal population. For this reason, fixed animals may be present in water in great numbers. In terrestrial life, animals must search for their food, and fixed forms, except some parasites (*e.g.*, cochineal insects), do not occur.

Most terrestrial plants cannot be utilized by animals without undergoing further processes because the albumin, fat and starch are all enclosed in a cellulose envelope. Animals, except some snails (*e.g.*, Helix *pomatia*), possess no ferment in their gastric juice which will dissolve this substance. The cellulose membrane must therefore be broken up to liberate the food. Thus snails tear the cells to small pieces by their radulae; arthropods fragment vegetable food with their jaws; mammals chew with their teeth; and birds grind up food in their gizzards. The numerous herbivores render possible the existence of carnivores; many insects, almost all amphibians and reptiles, and many birds and mammals are insectivorous or predatory.

One particular difficulty to which terrestrial animals are generally exposed is the great variations of temperature. In the sea, the temperature of the water over large areas is subjected only to slight and gradual variations. The daily variations are also slight. In fresh water the temperature does not sink below zero; in deep water it is unusual for it to sink below 4° C. Only in summer, in the smallest basins, does it reach 25°–30° C. On land also there are regions with only slight diurnal and seasonal temperature variations, *e.g.*, tropical forests. The difference between diurnal and nocturnal temperatures, however, is usually considerable. The difference between the extreme temperatures of different seasons at certain places is very large. In Central Europe it amounts to 90° F, in Werchojansk (Eastern Siberia) it even reaches 180° F. During the winter, life in the sea and in fresh water goes on unchecked, although isolated species hibernate. On land, in the temperate and frigid zones, all life becomes torpid under the influence of winter cold; even the nightly cooling of the air makes many animals sluggish. The organization of terrestrial animals is profoundly influenced by variations of temperature; muscles become stiff, glandular activity ceases. If, however, an animal can produce inside itself by metabolic processes a favourable temperature, and can maintain this through nervous control, it is freed from these temperature variations. Such animals are termed homoiothermal (warm-blooded animals). Homoiothermal animals have, nevertheless, to pay a price for this advantage; they become slaves to their increased food-requirements. Poikilothermal (cold-blooded) animals can fast for long periods; a snake or frog can go without food for six months, and aestivating snails for four or five years. Homoiothermal animals, on the contrary, quickly succumb to lack of food.

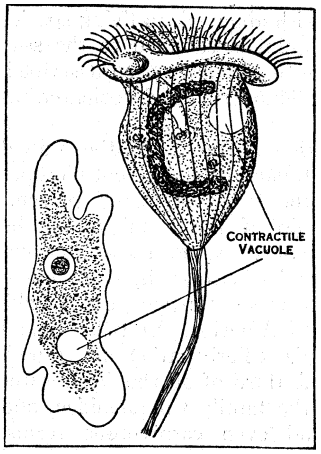

FIG. 2.—AT LEFT, AMOEBA, AND AT RIGHT, VORTICELLA (CILIATE INFUSORIAN)

The Conditions **of** Dispersal.—In the various regions inhabited by living organisms, the sea, fresh water, and dry land, animal dispersal is influenced in different ways, and the barriers opposed to it differ. The seas are in communication with one another in all parts of the earth; though the present connections between the Indo-Pacific and the Atlantic are in polar and sub-polar regions and, on that account, are impassable for warm-stenothermal animals. For most marine animals, however, dispersal depends on their powers of migration. Sedentary animals can extend their range only during the short, free-living, larval life, but powerful swimmers like sharks and mackerel are found in all warm seas. Isolation, however, is an important factor in transformation of species. The great variety of marine animals is therefore astonishing, when we consider the similarity of conditions of life in the various seas.

In inland waters conditions are quite different. This region is divided into innumerable small sections, such as streams, rivers, lakes and ponds separated by insurmountable obstacles in seas and land, Standing waters in particular are very varied in the materials they hold in solution, in conditions of light and temperature, in the fertilizing matter they receive, and therefore in their plant life. This wide-spread isolation under the influence of environment might give rise to the development of numerous different species, and to great variability within the limits of each species. but actually the fauna of fresh water is very rich in cosmopolitan genera and species, and, over the whole earth, shows great similarity. The origin of this is the transitory nature of fresh waters. Even in historic times, rivers have changed their courses, dwindled and dried up. Small standing waters are also apt to dry up. Lakes gradually become filled up. The existence of enclosed basins is not of sufficient duration for a thorough transformation of the species dwelling in them. Newly-arisen waters become populated from those already in existence by organisms which can either fly from one basin to the other, or be carried as spores by winds or water-birds. It is only in deep, and therefore ancient, basins that a characteristic fauna has been able to develop, as in Lake Baikal (1,373m. deep), and Lake Tanganyika (590m.).

Dry land is divided into many small, more or less isolated,

sections by seas, mountains, deserts and rivers. But terrestrial animals have very variously developed organs of locomotion, and therefore the effect of isolation varies. The great environmental differences have a similarly isolating effect. The transformation of species is thus exceedingly vigorous on dry land, but is confined to those animals able to live there (gastropod molluscs, arthropods and vertebrates). The sea is a much more extensive arena for iiving organisms. Nevertheless, $\frac{4}{5}$ of all animal species are terrestrial. We are acquainted with about 3,000 living species of Coelenterata and Echinoderma, animals confined to the sea; on the other hand, 400,000 species of insects have been described. But the range of variation among echinoderms and coelenterates is much greater than in the insects.

Prolonged isolation gives a striking character to the animal life of a district. The variety of the fauna in the different biotopes arises through transformation of the stock originally present. For that reason the interrelationship of the members of the fauna is much greater than in districts where continual intermixture is possible with forms which wander in from the surrounding regions. Such differentiation is found in the Caspian sea, in Lake Baikal, in Madagascar and in South America. In Lake Baikal 79 species of fresh-water Tricladida (Turbellaria) are found, more than half the known species. A third of all the fresh-water fishes in South America belong to the family Characinidae, and include mud- and plant-eating, and even carnivorous forms. Among mammals, the numerous adaptations shown by rodents of the family Hystricomorpha is most remarkable.

Area of Distribution. — The region occupied by a species is known as its area of distribution. The size of the area varies in the different species; it depends on the presence of suitable dwelling places, on the barriers limiting dispersal, on the powers of migration of the species and the facility with which it may be transported, on its oecological value, and on its history.

Species with restricted range are termed stenotopic, those with wide range, eurytopic. Species becoming extinct, or newly-arisen, often have a restricted range; examples of the former are the primitive lungfish, Neoceratodus (Murray river, Australia), and the lizard, Sphenodon (New Zealand); of the latter, the moth *Cymatophora* or var. *albigensis* in the industrial districts of England and Hamburg. **A** closely confined habitat also hinders dispersal; such are Lake Baikal and the Hawaiian islands, with their many endemic species. Changes in the area of a species may take place before our eyes; the jigger flea (*Sarcopsylla penetrans*) first arrived in Africa in 1872, and since that time has spread from the west coast to the east. The inner limit of size of an area varies with the size of the animal and the nature of its food. Carnivores require a larger range than herbivores of the same size. For this reason beasts of prey cannot exist on small islands. Cosmopolitan species are those present generally over the whole earth wherever they can find suitable dwelling places. (A cosmopolite, however, is not found in all the regions supporting life, *i.e.*, the sea, fresh water and dry land.) As examples may be mentioned the edible mussel (*Mytilus* edulis), found in all the seas of the world, the brine shrimp (Artemia salina) universally present in salt marshes.

Small districts are generally poor in species, large districts having the same conditions are richer. Thus the number of species of fishes decreases in proportion to the size of the river plus its tributaries: —

	Million sq km.	*Species*
Amazon	7	700
Congo	3.7	380
Mississippi	3.3	2j6
Rio de la Plata (with the Uruguay)	3·1	359
Ganges and Brahmaputra	1·75	170
Indus	0 965	113

Biotope and **Biocoenosis.**—A district showing uniformity in environmental conditions is uniform also in animal population; it is called a biotope (habitat). A small birch mood, a cavern or a rocky coast is a biotope. A biotope may often be subdivided into areas having particular conditions, and, therefore, a particular kind of fauna; *e.g.*, a pool in a cavern. These are termed facies. Similar biotopes are included in larger units termed biochores; the biotope "green forest" is included in the biochore "forest." Biochores are grouped in larger units, termed biocycles. These are sea, fresh water and dry land. These divisions are independent of the zoological distributions, which have to do with the systematic relationship of the animal population.

The animal population of a biotope is not a haphazard collection; the members are in close association one with another, and, together with the plant life, form a unit of a distinctive kind, an association of forms of life, or biocoenosis. To the biocoenosis belong all organisms, plant or animal, present in the biotope. They influence one another mutually, and are in many ways dependent on each other. Producers (chiefly plants), and consumers (animals), dwell beside one another, but the products of animal metabolism are food for the plants, and animals are often necessary for the fertilization of flowering plants. Among the animals themselves there are bonds, such as hunter and prey, host and parasite; they may live in symbiosis or compete as rivals. Should one kind of organism become eliminated, or get the upper hand, many members are affected, favourably, or otherwise —the balance of the biocoenosis is disturbed.

FIG. 3.—A. MARINE, AND B. FRESH-WATER ISOPODS, THE BLACK SQUARES SHOWING THE RELATIVE SIZES OF THE NEPHRIDIA (MAXILLARY GLANDS)

Every biotope has a population of characteristic constitution. Not all members of a biocoenosis are characterized in similar ways, or confined to one particular biotope. There are animals present only in certain biotopes, *e.g.*, the brine shrimp (*Artemia*), in salt inland waters; they are the predominant forms in this biotope, and in its biocoenosis, and are termed eucoenic. Animals always present in a biotope, but also constantly found in other localities, are termed tychocoenic; thus, the wolf and eagle are found on the steppes, but are also characteristic of mountainous and forest regions. Xenocoenic animals are chance members of the biocoenosis, into which they may have been forced from the surrounding district, or through which they may be passing.

The inhabitants of the same biotope are subject to the same environmental conditions, and must be in harmony with them. Thus they may resemble one another in certain respects without being related. Necessity brings about quite definite adaptations through selection. The stricter the selection, the more marked are the common characteristics. Organisms dwelling in the moss on rocks, trees or walls, are often completely dried up by the sun; they can all endure desiccation and almost entirely discontinue their vital functions without suffering injury.

ANIMAL DISTRIBUTION IN THE SEA

The distribution of life in the sea is dependent on factors partly physical, partly chemical. Density and viscosity are the primary factors governing the floating of organisms in the water. (See PLANKTON.) The pressure of the water increases with the depth. A column of sea water of average density measuring 10·07 metres exerts a pressure of one atmosphere per sq m. of surface, so that in the greatest known depths of the ocean (10,793 metres), a pressure of almost 1,072 atmospheres prevails. The pressure of the water, however, has no perceptible influence on the distribution of the animals Animal life is present at great depths, and the plankton and fishes of the open sea may undertake, in one night, vertical migrations of 300 metres and more without being injured by alteration of the pressure by about 30 atmospheres.

The brittle star *Ophiocten sericeum,* is present in depths varying from 6 to 4,370 metres; it is eurybathic. Species confined to particular depths are termed stenobathic; *e.g.,* the reef-building corals, which flourish only to a depth of 30 metres.

Waves.—The movements of the water, which at different times and places undergo many changes, are of particular importance to animal life. Waves reach to depths of several hundred metres. Currents may reach similar depths. The breakers make a heavy demand on the coastal dwellers; in the North sea the strength of their impact averages 15 tons per sq. metre. Animals dwelling on rocky coasts within the region of the breakers must protect themselves from injury. This is accomplished either by the animals attaching themselves to the substratum, or by the formation of strong shells. As examples of fixed animals the acorn-shells *(Balanus)* may be mentioned; others which adhere by a strong foot are the gastropods *(Patella, Littorina)*; the mussel *Mytilus* anchors itself by its byssus threads. In the deeper layers where movements are felt, sessile animals are able to bend, and have some elasticity of movement; in still waters they are rigid; *e.g.,* the Bryozoon, *Caberea boryi,* in the North sea. Marine currents are very important for the distribution of fixed animals, since they serve as means of transport for the free-living larvae.

Temperature.—Temperature is very important. The temperature of the surface water decreases, in general, towards the poles, but this is modified by warm and cold currents. The temperature decreases, also, with depth, and at the bottom is down to about zero. Owing to the great surface currents, more water is carried towards the poles than away from them, and, as the cold water at the poles is heavier than the water of the equatorial regions, there is a steady shifting of the deeper layers towards the equator. These cold, deep currents cannot penetrate secondary seas separated from the main ocean by ledges not far below the surface.

Related animals show marked variations under the influence of differences of temperature. Frequently the size of individuals of the same species increases with decreasing temperature towards the poles and in deep water layers. The shell of the gastropod *Nassa clausa* reaches a height of 12·7mm. in the Skagerak; at Spitzbergen it measures 38mm. Similarly, the Isopod, *Serolis bromleyana,* measures 16mm. at depths of 730 metres, and at 3,600 metres, 54mm. Giant species, *i.e.,* species which greatly exceed in size related forms, are found comparatively frequently in polar seas and in deep water. This may be ascribed to the influence of temperature. The hydropolyp, *Branchiocerianthus imperator,* which attains a height of 2 metres in depths of more than 3,000 metres, is an example. Other effects of low temperature are the greater amount of yolk in the eggs, and the frequent occurrence of brood-nursing. The multitude of brood-nursing forms in all classes of echinoderms in the Arctic and Antarctic is remarkable. It is noteworthy that the annelid *Cirratulus cirratus,* which in temperate seas deposits its eggs, at the Falkland islands practises brood-nursing.

The cold waters of the Arctic and the Antarctic are sharply divided from one another by warmer seas. To many cold-stenothermal animals this barrier is insuperable. Eurythermal animals may, indeed, be distributed through all seas, notwithstanding the variety of temperature. The fact that many species present at both poles are absent in the intervening regions has attracted particular attention. Since, in general, the area of a species is continuous, this bi-polarity requires explanation. Bi-polarity of species is by no means common. Some apparently bi-polar species are found in the intervening regions in the cold deep strata, *e.g., Calanus finmarchicus.* In other instances the two polar forms are also related to a species found in the intermediate region. Thus, the bi-polar Foraminiferan *Globigerina pachyderma* is related to *G. dutertrei* of warm seas. Bi-polar species, therefore, are derived from cosmopolitan through parallel modification of peripheral forms under the influence of environment.

Chemical Composition.—The chemical composition of the sea is very uniform, in consequence of the general mingling of the waters. The salinity at a depth of 300 metres is about 35, but is lower in surface water in estuaries, and in polar regions when the ice is melting. Considerable variations in salinity are found only in secondary seas shut off from the general mixture of the waters. These have a higher or lower salinity according to the ratio between the amount of river-water received and the amount of evaporation taking place. The Red sea has a high salinity (over 40%), so has the Mediterranean (38%); the Baltic has a low salinity. In the Baltic the influence on the animal population of the decrease in salinity is very striking. The number of species decreases, in proportion to the decrease in salinity, in an easterly direction *(see* Table).

Salinity		Marine fishes	Ascidians	Lamelli-branch molluscs	Gastropods	Opistho-branchs	Amphipods	Decapods
20%	Kattegatt	..	20	88	85	..	113	55
12%	Kiel Bay	75	5	23	17	23	18	9
7%	Middle Baltic	40	..	6	3	2	11	2
4%	Gulf of Bothnia	23	..	4	1	..	5	..

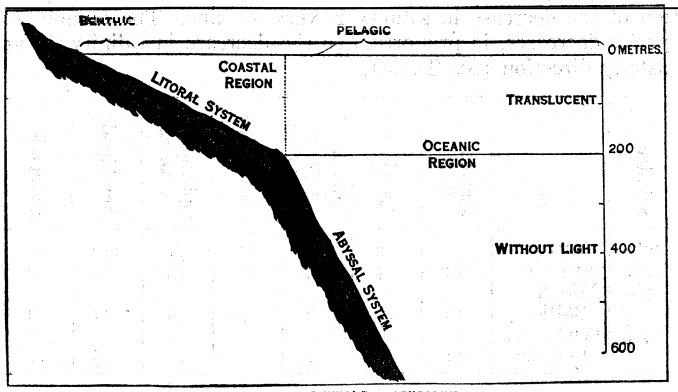
The size of the species also decreases in the same direction. The edible mussel *(Mytilus edulis)* at Kiel, attains a length of 110mm., further in the Baltic, it measures over 50mm., in the Gulf of Finland 27mm., in the Gulf of Bothnia, 21mm.

The quantity of carbon dioxide, nitrogenous salts and other materials necessary to plants in the water of any region is particularly important in determining the amount of life. If these materials are abundant, plant life flourishes and consequently animals find plenty of food. The sources of this food are, first, the products of animal metabolism and of the disintegration of dead organisms. Carbon dioxide and nitrogenous salts are only of use, however, in the upper, illuminated strata of the water, where the light is sufficient to supply energy for the assimilation processes of plants. The dead bodies of organisms which inhabit the open sea sink to the bottom, and, in great depths of the ocean, are withdrawn from the metabolic cycle. Their disintegration products can be used only in shallow seas where mixture of the water takes place right down to the bottom. In deep seas they may be of use in places where rising currents bring water from the depths to the surface. It happens, therefore, that coastal regions, shallow seas like the North sea, and banks such as the Dogger, show great wealth of life. Rising currents are found chiefly on the west coasts of continents where, owing to prevailing winds off the land, the surface water is driven away from the coast, and a compensating current from the depths flows towards it. No sea water is so teeming with life as those currents which set in towards the land in tropical regions, *e.g.,* off the coasts of Portugal and Chili. A quantity of fertilizing matter for plants is brought down to the sea, particularly by rivers. The region most richly supplied with river-water is the Atlantic-Arctic, into which more than half the earth's surface is drained. The Pacific is the poorest in this respect, particularly in its eastern portion. This, with its great depth, accounts for the poverty of its life compared with other oceans.

Oxygen is present everywhere in sufficient quantity in the surface waters of the open sea. In the depths, the influx of currents of polar surface water brings sufficient oxygen, and, since the disintegration of dead organisms goes on very slowly in the cold water of these depths, this oxygen is not used up in the process. In secondary seas where such currents are absent matters are different. In the eastern Mediterranean, the deeper layers of the water lack oxygen, and have a large quantity of carbon dioxide; on this account they contain hardly any life. This also applies to the greatest depths of the Baltic. In the Black sea, some Norwegian fjords, and in Walfisch bay on the west coast of Africa, the bottom water contains sulphuretted hydrogen produced by the disintegration of organic remains.

The Zones of Life in the Sea.—In the biocycle "the sea" two principal regions may be distinguished. These differ completely in their conditions of life, and, therefore, in their animal popula-

tion also (fig. 4). They are the "benthic region" (floor of the sea), and the "pelagic region" (open sea). The benthic fauna consists of animals attached to the sea bottom. Pelagic animals are not attached to the bottom, and maintain themselves floating or swimming in the water. Benthic and pelagic regions can be subdivided into two areas, that penetrated by light (on an average from the surface down to 200 metres), and a dark or abyssal



FROM PRUVOT, "ANNEE BIOLOGIQUE" (C REINWALD COPYRIGHT H BONNAIRE)

FIG. 4.—ZOOLOGICAL DIVISIONS OF THE SEA

region. The illuminated portion of the benthic region is termed the "littoral zone."

Littoral Zone.—In the littoral zone the bottom may be firm or shifting. A shifting bottom shows a flat surface, and varies according to its constituents, gravel, sand or mud. Rocks form a hard bottom, and the coast in such places is generally precipitous. The Binds of animals found in the littoral are determined by the type of bottom and by the movements of the water. The littoral is divided into three zones according to the movements of the water; (r) the tidal zone, between high and low tide marks, (2) the shallow water zone, or region affected by the waves, (3) the still water zone, which extends from the shallow water zone to the upper limit of the abyssal region.

A stony shore in the tidal zone is almost entirely without life, all organisms being killed by friction of the stones against one another. In shallow water, sandy bottoms which are often disturbed are not inhabitable for many animals. In places, however, where plants (Zostera, Posidonia) flourish, the sand is bound together, and animals find hiding places under the leaves and among the roots; sessile animals can find places for attachment; food (mud, detritus) is present, so that here a characteristic fauna is established. In deeper water, and in the shelter of projecting islands and sandbanks, a rich fauna may develop also near the surface, on sand and ooze. Sessile animals, certainlv, are not often found on shifting bottoms, owing to the danger of being buried; but oysters settle on the shells of molluscs, or on stones, and the edible mussel (Mytilus) attaches itself by its byssus to the floating branches of *Fucus*. On the other hand, shifting bottoms teem with animals which burrow under the surface, and so render themselves invisible to enemies. Such are the lob-worm (*Arenicola*), and other annelids, *Balanoglossus*, the heart urchin (*Echinocardium*), and numerous bivalves, which usually have smooth, flat shells for digging, and which obtain food and oxygen from the surface by siphons (fig. 5). These are followed into the sand by the starfish *Astropecten aurantiacus* and the predatory snail *Natica*. Crustaceans, amphipods, shrimps and the lancelet, *Amphioxus*, also burrow in the sand. Flat fishes, the star-gazer (*Uranoscopus*), weever (*Trachinus*) and blenny (*Blennius*) work themselves in just beneath the surface, gazing upwards with eyes situated on the upper surface of the head. The sand shelters also

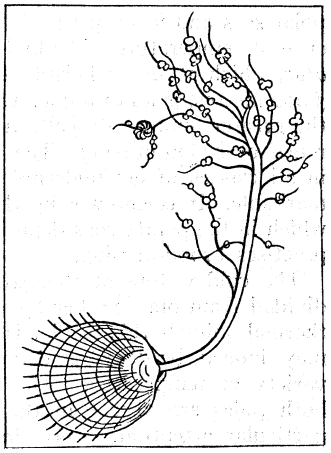
minute animals which find room for movement between the sand-grains:—acoelous Turbellarians, Archi-Annelida, Tardigrada and Gasterotricha. The principal animals found on the sand are the ophiuroids, some gastropods (*Turritella*, Aporrkais), annelids and crabs.

Rocky coasts, in contrast to flat, shifting bottoms, offer a firm substratum for plants (particularly Laminaria and *Fucus*), and for sessile animals. Clefts, holes and caves offer shelter from the force of the waves. Sessile animals fix themselves by preference to the kelp, and to its places of attachment. Some construct hiding-places by boring holes in the rocks, *e.g.*, the boring sponge, Vioa, the boring bivalves *Pholas* and *Lithodomus*, and sea urchins such as *Strongylocentrotus*. Those animals, however, which dwell upon the rock surface, are armoured and protected against attack by hard shells or by weapons, Sponges have sharp spicules of silica, polyps and Anthozoa stinging-cells (cnidoblasts), echinoderms spiny armour, snails and bivalves strong, often spiny shells. Many crustaceans on rocky bottoms have spiny cuticles; some, however, hide themselves by placing algae, sponges, or polyps on their backs, while some of the fishes have poisonous spines (*Scorpaena*). Animals dwelling within the region of the breakers require protection against the battering of the waves, and so are firmly attached (see above). This region exercises a keen selective influence; only a few species can withstand the force of the waves, but this affords them protection from enemies. Thus the edible mussel (*Mytilus*) has a wide distribution in the littoral region, but usually is represented by solitary individuals; in the region of the breakers, however, where they are not exposed to attack, mussels are packed together in large numbers.

Coral reefs may be compared to rocky coasts. They consist of the dwellings of the reef-building corals, which attach themselves to the firm substratum, and offer dwellings and hiding places for many kinds of animals. These reefs are confined to a belt in the tropical seas, extending from 30° N. to 27° S., since the coral polyps require a temperature of at least 20·5° C. This accounts for their absence on the west coasts of Africa and America, where cold currents set in towards the shore. Calcareous algae, Bryozoa, some gastropods and other organisms take part with the corals in the formation of the reef. Reef-building corals cannot live below a depth of about 30 metres, since they live in symbiosis with algae (*Zooxanthella*), which inhabit the walls of the enteron of the polyp, and require light for assimilation. The delicate colours of corals are obtained from the algae. All reef-dwelling animals have vivid colours (Plate I.). The numerous species of corals of which a reef is composed are so arranged that in the zone of the breakers, strong, resistant forms are found. In deeper water, and in places where there is shelter from the waves, the delicately tinted, branching forms occur. Many kinds of animals find retreats in the numerous holes and cavities of the reefs, among them worms, crustaceans, gastropods and fishes. Some fishes feed on the coral polyps, and bite the ends of the branches with their beak-like jaws (Pomacentridae and Plectognathse).



FROM CHUN, "WISSENSCHAFTLICHE ERGEBNISSE DER DEUTSCHEN TIEF-SEE EXPEDITION"

FIG. 6.—DEEP-SEA BRACHIOPOD: STALK WITH OUTGROWTHS TO WHICH FORAMINIFERA ADHERE

Pelagic Zone.—The inhabitants of the open water or pelagic region have common peculiarities connected with floating. Living matter is somewhat heavier than sea-water; therefore, to float, animals must possess special adaptations. The rapidity with which a body sinks varies in proportion to its weight. It decreases with increased form-resistance (such as expansion of the under-surface): The weight of a living organism is lessened by the sparing use of skeletal material (lime, silica), and by the accumulation of lighter

substances (fat, air) in the body. The shells of floating animals, therefore, are small and thin, as in pelagic Foraminifera. The phosphorescent animal *Noctiluca,* many free-swimming crustaceans, the eggs of pelagic fish (*e.g.,* cod, flat fishes) contain fat-globules; further, the accumulation of fat in the liver of many fishes, and the blubber of penguins, seals and whales lessens the effective weight. Air-bladders are the most effective means of diminishing weight, and are found in many Siphonophora and in bony fishes (Teleosteans). Form-resistance is increased by enlargement of the under-surface. The most usual way is by absorption of sea-water into the body. This does not increase the weight, but distributes it over a greater area. Thus arises the gelatinous tissue frequent in pelagic animals. Water forms 96% of the jelly-fish, *Aurelia* aurita. In small animals, the under-surface may be increased by flattening the body, or by horizontally disposed processes which serve as floats; *e.g.,* pelagic nemertines (flattened like cakes), the Plzyllosoma-larvae of crustaceans, copepods (*Sapphirina*). If such means do not suffice, movements are made to assist in the prevention of sinking, as the lashing of the cilia of pelagic larvae and turbellarians, the beating of the ciliated plates of Ctenopliora, the muscular movements of annelids, and crustaceans. Swimming occurs when the muscular movements are sufficiently strong to render the animal's path independent of the movements of the water. Swimming is almost entirely confined to fishes, some cuttlefishes, and animals not primarily marine, such as turtles, penguins, whales and seals.

Those living organisms which float free in the water are termed the plankton (*q.v.*). The constitution of the plankton of the open sea differs from that of the coastal regions, or of shallow seas. The oceanic plankton consists entirely of forms which pass their whole life floating in the water (holoplanktonic). Examples are Siphonophora, Ctenophora, Chaetognatha, some crustaceans and gastropods, salps, and the ascidian, Pyrosoma. In coastal regions, in addition to such holoplanktonic forms, there are numerous animals pelagic only at some period of their life (meroplanktonic), in particular, the larval forms of benthic animals. The composition of the coastal plankton is therefore much more changeable than that of the oceanic plankton. The coastal plankton has its lower limit at a depth of 200 metres, but it may be driven beyond this by storms or currents. Coastal waters are much richer in life than oceanic. In the open ocean, however, the amount of life is not the same in all parts. In the Atlantic, the polar regions are much richer than the tropical. The poorest catch in the tropical Atlantic contained 763 organisms per litre of water, the richest catch in cold waters 76,915. There are, however, stretches of tropical seas which have a rich plankton, such as parts of the Indian ocean. The plankton forms the food of many fishes, such as herrings.

Abyssal Region. — The deep, unilluminated, abyssal region of the ocean is not without inhabitants, but plants naturally are absent. Since no building-up of organic substances can take place, the basic food of abyssal animals consists of the dead organisms which sink from the surface. The greater the depth, the less food reaches it. The number of species of the various groups of animals decreases with the depth; the following examples are taken from the crabs in the collective tow-nettings of the "Challenger" Expedition:—

Depth, in metres	0-36	36–180	180–360	360–900	900–1800	1800
Number of species	190	75	28	21	3	2

Benthos: — The benthos is composed partly of those animals which, by setting up eddies in the water, waft food towards themselves, and partly of those feeding on ooze. Echinoderms are particularly numerous among the latter. The soft ooze of the deep sea, which is about the consistency of soft butter, forms a very unstable substratum. For this reason, sessile animals have either long stalks (glass-rope sponges), or their basal end spreads out into root-like processes (horny corals, crinoids, branchiopods) (fig. 6). Deep water sea-urchins and sea-cucumbers (Holothuria) are frequently flattened. Bottom-dwelling crustaceans have elongated legs, the lower surface of which is often broadened by rows of bristles (setae). The power of emitting light is frequently found in animals inhabiting the dark abysses, though it occurs also in the illuminated water-layers. Sea-pens, horny corals, starfishes and many others emit diffuse light. More than 40% of the fishes from depths of over 900 metres possess light-organs. Nevertheless, light in the depths is scanty. For this reason, the eyes of deep-sea crustaceans and fishes are often enlarged. Deep-sea animals are of one colour (monotonic), usually dark brown or red. The uniformity of temperature conditions and the slight degree of movement of the water favour wide distribution of animals in the deep sea. Many are cosmopolitan, but there are also local species.

THE DISTRIBUTION OF ANIMALS IN INLAND WATERS

While in many respects conditions of life in the ocean are equable, owing to the general intermingling of the waters, those in inland waters show great differences in the various regions. This is due to the splitting up of these waters into many larger or smaller sections, and is reflected in the variety of their populations.

The chemical composition of inland waters is very changeable, particularly as regards lime salts. In granite and porphyry regions it may be as little as 24mg. per litre, while in limestone regions it may rise to 420mg. per litre. Some animals, such as the water-flea *Holopedium* gibberum, and the pearl mussel (*Margaritana margaritifera*) dislike them. Others require them, *e.g.,* most molluscs. The salinity also is very varied. In the Rhine, the water contains 0·14g. NaCl per litre. When the salinity rises above 0·3g. we speak of "salt" water. In the salt marshes of Lorraine, the water contains between 50 and 110g. NaCl per litre; in the Dead sea, as much as 237·5g. No living organism can exist in such a high salinity. In bog-water, the large quantity of humus is unfavourable to life.

The amount of oxygen in inland waters varies with time and place. It is highest in the eddying waters of mountain torrents, and in shallow ponds with dense plant growth when exposed to the sun, as this causes the plants to give off much oxygen, On the other hand, in late summer, the oxygen at the bottom of some lakes is completely used up, so that animals particularly requiring it, such as some fishes (Coregonus), cannot live there.

The temperature of inland waters undergoes much greater variations than that of the sea. Inland waters are usually shallow; they are seldom more than 300 metres deep, while the majority are not deeper than 10 metres. In ponds and pools, the depth is considerably less. There is, therefore, a high ratio of surface to volume; heating and cooling take place rapidly. In temperate regions, a constant temperature is found only in springs welling up from great depths, in deep parts of lakes and in waters in caves; cold-stenothermal animals are found only in such places.

Light does not penetrate so deeply in inland waters as in the sea, on account of their more turbid condition, Usually, it penetrates only 30–40 metres; the lower limit of plant life is often at only 7 metres or less. In general, shallow waters have more plant life and therefore more animal life than deep ones.

The movements of the water are particularly important to aquatic animals. Flowing water and standing water make quite different demands on their inhabitants, and have therefore different types of population. They differ in chemical composition, thermal conditions, depth and extent. Rivers are almost always fresh, the flow preventing accumulation of matter in solution. Flowing water takes longer to warm, and cools more rapidly than standing water, and the difference of temperature between the surface and the depths is less on account of intermingling. There are, however, intermediate conditions. The rapidity of the current depends on the fall of the land. The Rhine, at its source, has a fall of 2·5% (2·5 metres in 100); the Upper Rhine from Basle to Bingen about 0·05%, the Lower Rhine, 0·012%. The Volga, in its whole course, has a fall of only 0·007%, and the Lower Amazon only 0·0019%; they show conditions resembling those of standing water.

Flowing Water. — Flowing waters are almost always connected with the sea. Their animal life, apart from forms not primarily aquatic such as insects and pulmonate gastropods, was originally derived thence. A continual immigration still takes place, particularly in the tropical region of the Indies. Some fishes ascend rivers from the sea only at spawning time (anadromous fishes),

e.g., the sturgeon (Acipenser) and salmon (Salmo salar); others ascend the rivers as young animals and descend to the sea to spawn, *e.g.*, the eel (*Anguilla anguilla*). These are katadromous fishes. Euryhaline, marine invertebrates (*e.g.*, copepods, amphipods, oysters) penetrate estuaries, and there mingle with the fresh-water inhabitants.

The velocity of river currents may be classed as "below average," "average" and "above average," according to the degree of the fall. In sluggish rivers (below average) erosion is minimal, and deposition of sediment maximal. Fine mud sinks down and forms a nutritious ooze on the bottom. This supports many detritus-eaters, such as worms, molluscs and insect larvae. At the average rate of flow, erosion and sedimentation maintain a balance, and the bottom is covered with gravel. In rapid streams (above average) erosion prevails, and deposition of sediment is minimal; the bottom is formed of large stones, which, by their movements, would crush to pieces any living organisms among them. The inhabitants must be adapted to this movement of the water. The different stretches of rivers harbour different animal populations. As regards fishes, rivers, from mouth to source, have been divided into the region of bream, of barbel, of grayling and of trout. Sharp delimitation, however, is not possible. In slowly flowing waters various kinds of fishes may be present, good swimmers and poor, with rounded bodies or with flat, provided the temperature and amount of oxygen are suitable. The stronger the current, the greater the swimming powers a fish must possess to resist it. In such places, we find fishes predominating which are round in transverse section, and so are not spun round on their axis by the whirling of the waters (fig. 7). For this reason, the number of species of fish decreases as we approach the source; the continually increasing demands made by currents and falling temperature have a selective influence. Fishes of 49 species are found in the Rhine; of these 41 are found in Holland, 33 in the Upper Rhine below the Falls, 25 above the Falls; at 700 metres above sea-level 11 species are found, at 1900 metres three species, the trout (Salnzo fario), minnow (Phoxinus laevis), and loach (*Cobitis* barbatula). Above 1900 metres the shallow alpine streams contain no fish.

FIG. 7.—DIAGRAM OF SECTIONS THROUGH FISHES

A. Brown Trout, B. Minnow, C. Loach, D. Miller's Thumb, E. Bream, F. Prussian Carp, G. Common Carp, H. Bitterling, I. Rudd

The mountain stream aifords the best instance of a characteristic fauna. The animals here take on a certain general stamp, since none can live except those able to accommodate themselves to the severe conditions of temperature and current. All have adaptations which prevent them being swept away by the current. Some are flat, and creep under stones (*Gammarus*, insect larvae), others adhere firmly by a broad sole or sucker (turbellarian worms, gastropods), or with special kinds of suckers (larvae of the gnat Blepharocera, fishes and tadpoles of tropical mountain streams), others spin threads which form a strong attachment to the bottom (larvae of the sandfly *Melusina*, pupae of mayflies). They are often flat and depressed to offer the least possible hold to the current. Since they are not strong swimmers, their power of movement is limited compared with that of related forms; *e.g.*, the water-mites of mountain streams do not swim and have limbs without swimming-bristles (fig. 8). The inhabitants of mountain brooks are generally eurythermal, or cold-stemthermal. Animal communities which require a constant low temperature are found chiefly in springs (the turbellarian *Planaria alpina*, the gastropod Bythinella *dunkeri*).

Standing Inland Waters.—In these regions the absence of currents gives rise to special conditions. An inland basin becomes rich in food material for animals, and in fertilizing matter for plants, brought down by winds and rain. Thus lakes having no outlet are richer in life than those which possess one; in the latter the quantity of plankton is in inverse ratio to the force of the outflow. In shallow basins, where the bottom is greater in proportion to the water-mass than in deep ones, and where, in all parts, light penetrates from top to bottom and permits plant-life, the mass of living organisms is generally greater than in larger and deeper basins. Of 20 Swedish lakes in which this has been studied, the smallest has the largest proportion of fish (113 K g per Ha), the largest (Lakes Wener and Maelar) only 2.7 Kg. per Ha.

In shallow basins circulation of the water takes place through winds, and thus the lower layers are aerated; as in Lake Balaton in Hungary. In deeper lakes, where no such complete mingling of the water is possible, the lower layers are aerated by convection currents set up by the cooling of the surface water in the cold season. In summer in lakes rich in organic life much oxygen is used up in the disintegration of the dead organisms which sink to the bottom, so that the amount of oxygen in the deep layers may be scanty, or absent. This excludes many animals from such depths, and gives a definite character to the composition of the fauna.

Larger basins of such depth that the greater part of the bottom is free from vegetation are described as lakes; in contrast to these are the ponds, pools and puddles, termed collectively small water basins. In lakes we distinguish a shore region (littoral), a deep water zone and a region of open water.

FIG. 8.—LEGS OF WATER-MITES, GENUS LEBERTIA

A. Bachform (*L. complexa*), B. Teichforrn (*L. insignis*)

The outer portion of the littoral, which in summer is occasionally left dry, is poor in life. On the other hand, the deeper littoral region where there are plants for food and hiding places is the richest in living organisms.

The open water is populated by plankton, and by fishes which feed on it, *e.g.*, *Alburnus, Coregonus*. The bottom fauna is varied. Three types of lakes are distinguished, eutrophic, oligotrophic and dystrophic. The eutrophic type, with flat shores overgrown with vegetation, and with a rich plankton, has its deep layers filled up with putrifying ooze composed of the disintegrating bodies of plankton organisms or detritus. Only animals able to make use of the smallest quantities of oxygen are able to live there, *e.g.*, oligochaetes (Tubificidae), larvae of the harlequin-fly *Chironomus*. Both these have haemoglobin in their blood, apparently enabling them to use fully whatever oxygen is present. In oligotrophic lakes, with steep banks and little vegetation, the plankton is scanty, and the bottom therefore has less ooze; other insect larvae are found here (*Tanytarsus* larvae). In spite of the greater supply of oxygen, the number of organisms is less because of the smaller amount of food. Dystrophic lakes are those with bog-water, in which the acidity caused by humus is unfavourable, and the deficiency in lime also excludes many animals. The plankton here is chiefly animal, and consists mainly of rotifers and small crustaceans, which feed on colloidal matter in the humus.

In ponds and pools the fauna is similar to that of the overgrown littoral zone of eutrophic lakes. Decaying vegetable matter is present in sufficient quantity to provide food and oxygen for the growth of plants and only the great variations in temperature are unfavourable. In pools and puddles there is often a rich fauna of small rotifers, crustaceans and insect larvae. In waters liable to dry up periodically a particularly characteristic fauna is found. In temperate regions these waters are small, but in subtropical steppe areas (South African pans) they are sometimes of much greater extent. In such places animals must pass through stages of development quickly, and therefore must be small; and they need some protection against desiccation. Many produce hard-shelled resting ova (Hydra, rotifers, Cladocera) or spores (gemmules of sponges, statoblasts of Bryozoa), others are able to sur-

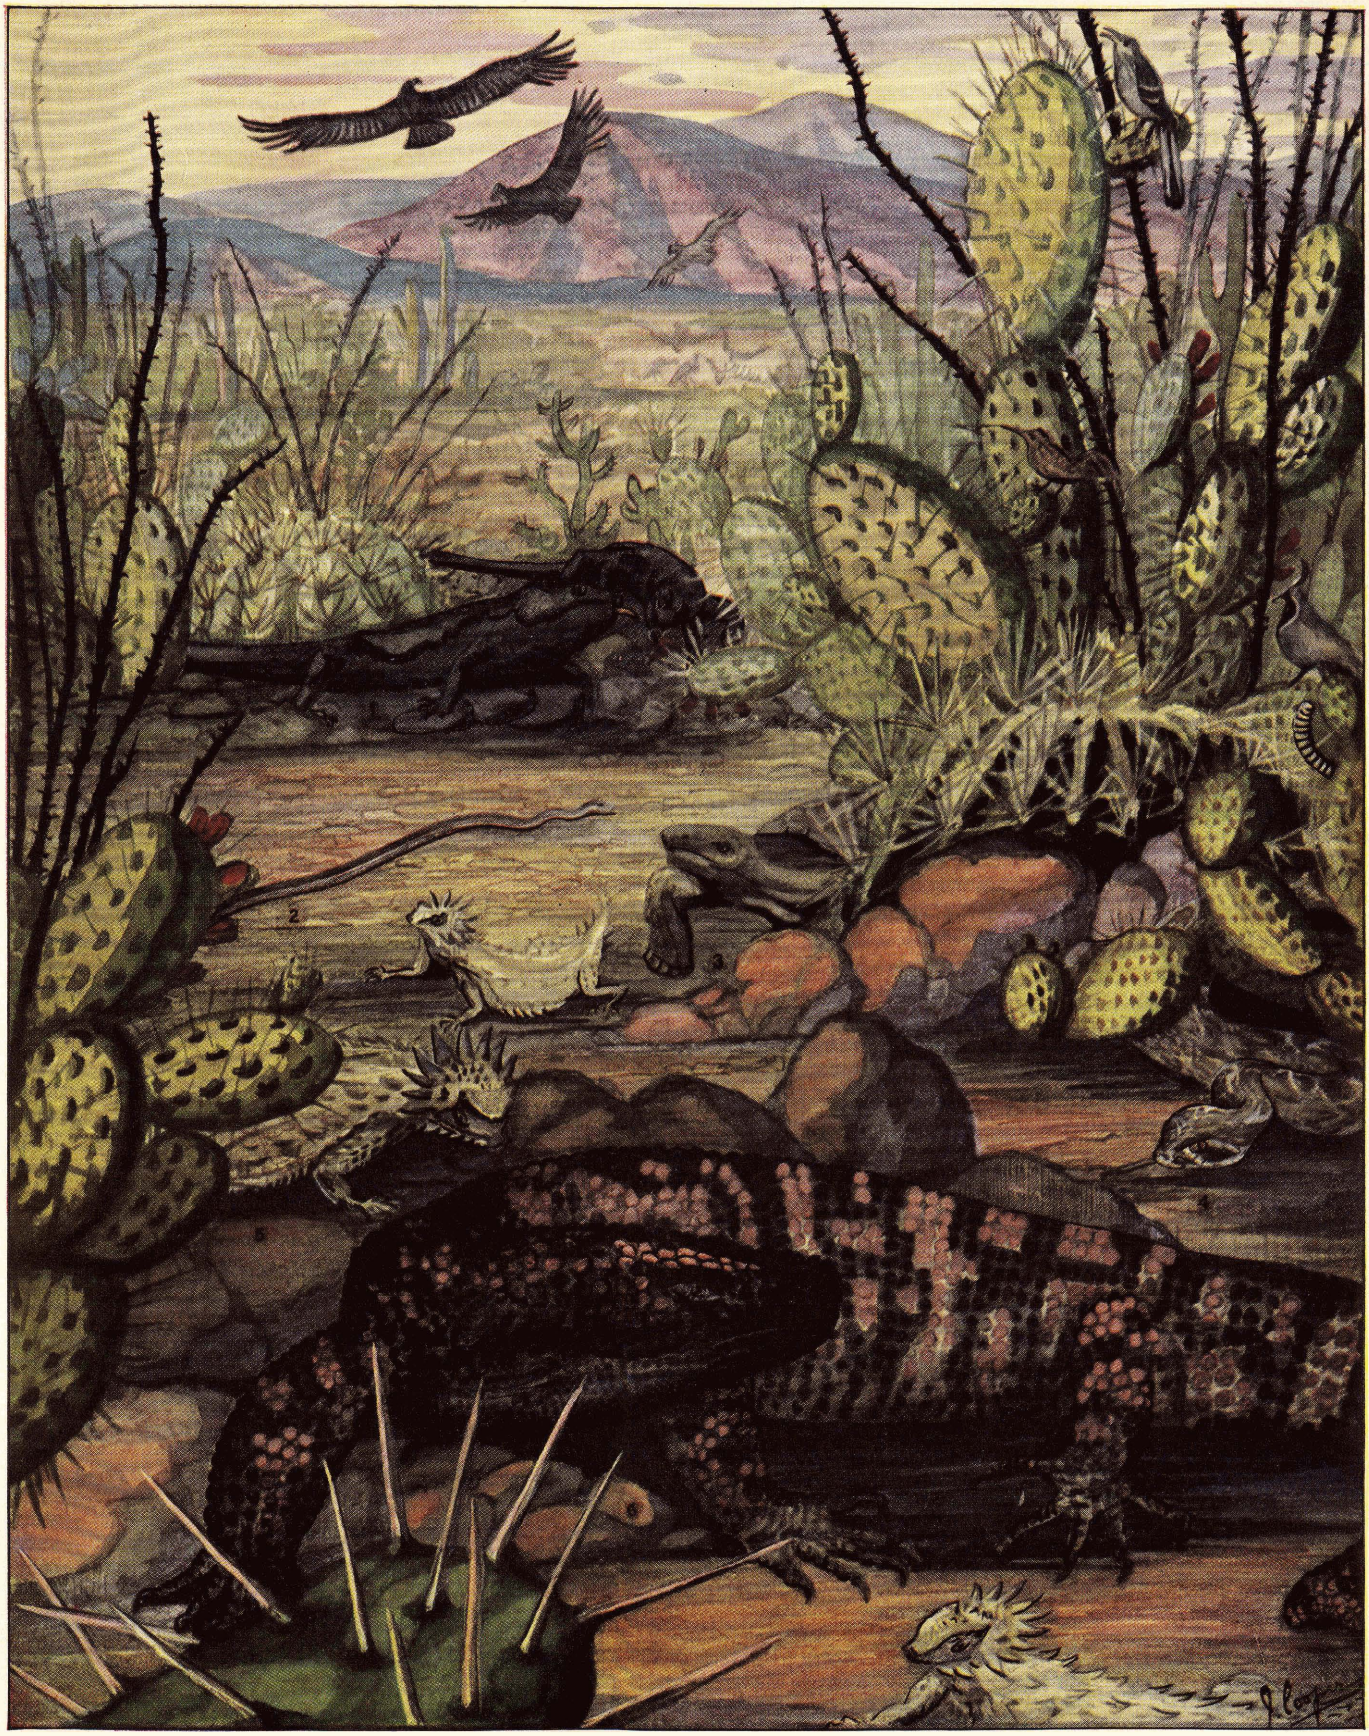
FIG. 9.—HEADS OF (A) ARCTIC FOX (VULPES LAGOPUS), (B) COMMON FOX (VULPES VULPES) AND DESERT FOX (VULPES CERDO)



PAINTED FOR THE ENCYCLOPEDIA BRITANNICA BY ISABEL COOPER AFTER HABITAT GROUPS IN THE AMERICAN MUSEUM OF NATURAL HISTORY

REPTILES INHABITING THE DESERT REGION OF THE SOUTH-WESTERN UNITED STATES

1. Chuckwalla *(Sauromalus obesus),* the largest lizard in the United States. It is herbivorous and is considered edible by the Indians
2. Sonoran racer *(Masticophis semilineatus),* a small harmless snake
3. The desert tortoise *(Gopherus agassizii),* a terrestrial member of the turtle family that makes its home in holes in the ground
4. Texas rattlesnake (*Crotalus atrox),* the most dangerous of all south-western snakes because of the great amount of poison it can inject into its victims. It feeds largely upon mammals
5. The regal horned toad *(Phrynsoma solare),* a small, harmless lizard
6. Gila monster *(Heloderma suspectum),* the only poisonous lizard in the world. It inhabits Arizona and New Mexico and sometimes attains a length of two feet

round themselves by a capsule formed by a glandular secretion (the small annelid Aeolosoma, some copepods), and some burrow into the ooze and form a capsule of mud around themselves (phyllopod crustaceans, fishes such as *Protopterus*). Lastly, there are animals which can dry up into a cyst without losing their power of living, such as many rotifers (Philodina) and Nematoda (thread worms). These groups can live also in the mossy growth on rocks and tree trunks.

In salt lakes and pools the number of species decreases with increasing salinity. Those able to endure the greatest salinity are the brine-shrimp (Artemia salina), and a number of fly larvae, but even the brine-shrimp suffers changes with increasing salinity, the bristles become stunted, the size of the animal decreases, it becomes enfeebled, and finally disappears. In the Dead sea, in Palestine, the salinity is so high that all life is absent.

THE DISTRIBUTION OF TERRESTRIAL ANIMALS

The environmental conditions which influence the distribution of terrestrial animals are much more complicated than those brought to bear on aquatic animals. The chemical composition of the air is not important, as complete intermixture can take place very quickly. Only in a few places where carbon dioxide is present does this accumulate in limited areas, by reason of its weight, and render them uninhabitable by animals, as in the Grotto del Cane, at Pozzuoli. More important is the physical condition of the atmosphere, that combination of conditions called climate, and which is not present in water in such complexity. Such climatic factors are atmospheric moisture, temperature, atmospheric movements and solar radiation, some of which change periodically.

Moisture. — The amount of atmospheric moisture varies with time and place. Where the air is saturated, as in tropical rain-forests, even soft-skinned animals (planarians, leeches) can live out of water without danger of drying up. In such places a rich fauna and flora is found. Life is scarcest in regions where atmospheric moisture periodically fails completely, as in desert regions far from the sea. There are animals, however, which can live in a moderately dry atmosphere, as they can limit their evaporation of water as required. Air-breathing animals may be divided into moist-air breathers and dry-air breathers. To the former belong snails, many insects, such as ephemerids and mosquitos, all amphibians, buffaloes, hippopotami and some South American monkeys. These are characterized by the possession of numerous skin glands, liquid urine and watery excrement. Dry-air breathers include most insects, reptiles and birds; they have no skin glands, and excrete uric acid; among mammals, many rodents, some antelopes, roe-deer and camels; these have few skin glands, dry excrement and concentrated urine.

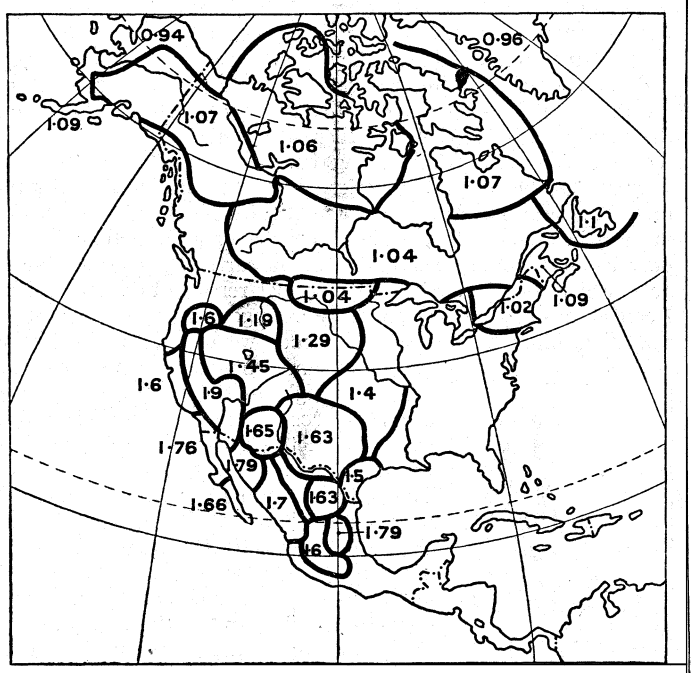


FIG. 10. — MAPSHOWING THE VARIATIONS DUE TO TEMPERATURE IN THE LENGTH OF EARS IN COMPARISON WITH LENGTH OF SKULL IN NORTH AMERICAN HARES (LEPUS)

Temperature. — Although the quantity of atmospheric moisture in many ways influences the distribution of air-breathing animals, the effects of temperature are still greater. The temperature of air varies to a much greater degree than that of water, and does so more rapidly and more extensively. Whilst in water the lower limit of temperature is 0° C (+32° F), in air it may sink to −67·8° C (−80° F) (at Werchojansk); on the other hand, it may, in instances, rise to 56·6° C (101·7° F). The greatest difference between the highest and lowest mean monthly temperatures in any place is at Werchojansk, where it amounts to 66·3° C; daily variations at 22° C occur in elevated steppes.

The distribution of animals, therefore, is determined by the degree of warmth they require. Animals limited to a uniformly high temperature, *i.e.*, warm-stenothermal animals, in temperate regions live only in particularly warm localities, especially on chalk soil. As examples may be mentioned the green lizard (Lacerta *viridis*), and the praying mantis (Mantis religiosa), when found north of the Alps. Cold-stenothermal animals, on the other hand, inhabit places with a lower temperature; *e.g.*, snails of the genus *Vitrina* are found on the summits of the Alps, on Mt. Kilimanjaro and in the Cameroons, but are absent in warm parts.

Homoiothermal (warm-blooded) animals are not immediately influenced by their surrounding temperature. The temperature of the surroundings, however, by its variations renders difficult the regulation of internal heat. The problem of the limitation of the amount of heat given off is solved in various ways. Thick coverings of hair or feathers, or the deposition of fat beneath the skin are the most important; in many birds air-sacs assist in maintaining a protective warmth round the internal organs. It is important, also, that the surface-area of the body, where heat radiation takes place, should be lessened. Birds, as compared with mammals, have a very small surface in proportion to mass. Among mammals the external ear and the tail are parts where much heat is given off, and for this reason they are smaller in animals dwelling in cold regions than in their relatives in warmer parts. For instance, the ears of the Arctic fox are small, those of the European fox are larger and those of the desert fox largest (fig. 9). The length of the ears in comparison with that of the skull in North American hares (Lepus), is shown in fig. 10.

Since large animals have a relatively smaller surface-area than small ones, this implies in them a diminution of the giving-off of heat. Of two dogs weighing 20kg. and 3·2kg., having surface-areas of 7,500 and 2,423 sq.cm. respectively, the larger had a surface-area of 375 sq.cm. per kg. of body-weight, the smaller 757 sq.cm., *i.e.*, about double the area; the larger produced in 1 unit of time from 1kg. of mass 45 calories, the smaller 88 calories; the amount of heat given off, therefore, rises in proportion to the surface-area. It is worthy of note that warm-blooded animals in cool regions usually attain a larger size than the corresponding species in warmer climates (Bergmann's rule). Fig. 11 shows the increase in size, corresponding to decrease in temperature, in the Great Horned or American eagle owl. The coldest parts of a faunal region are therefore centres of maximal forms, while the warmest parts are centres of minimal forms. In the Palaearctic region warm-blooded species have a minimum size on the south coast of the Mediterranean, while in northern Siberia they reach their maximum size. In North America Alaska is a centre of maximum size, for example: — among mammals the bear (*Ursus* gyas), the fox and the moose (*Alce gigas*); among birds, the eagle-owl (Bubo *virginianus*), the Alpine lark (Otocoris *alpestris*) and the pine grosbeak (Pinicola *enucleator*), all being larger than normal. Smaller forms are in Florida and Lower California.

Peculiarities of Tropical Fauna. — A uniform climate is found chiefly in some tropical regions of America, Africa and India, particularly in tropical forest areas. These are distinguished by the absence of seasonal changes, and by offering optimum conditions of moisture, warmth and light. The abundant

vegetation permits rich development of animal life. Poikilothermal animals enjoy almost the same favourable conditions as have been established internally as the optimum in homoiothermal animals. Homoiothermal animals require considerably less food than in temperate regions. Many classes of animals attain a considerable size in the tropics, *e.g.*, numerous insects, millipedes, spiders, snails. Here amphibians and reptiles attain maximum size.

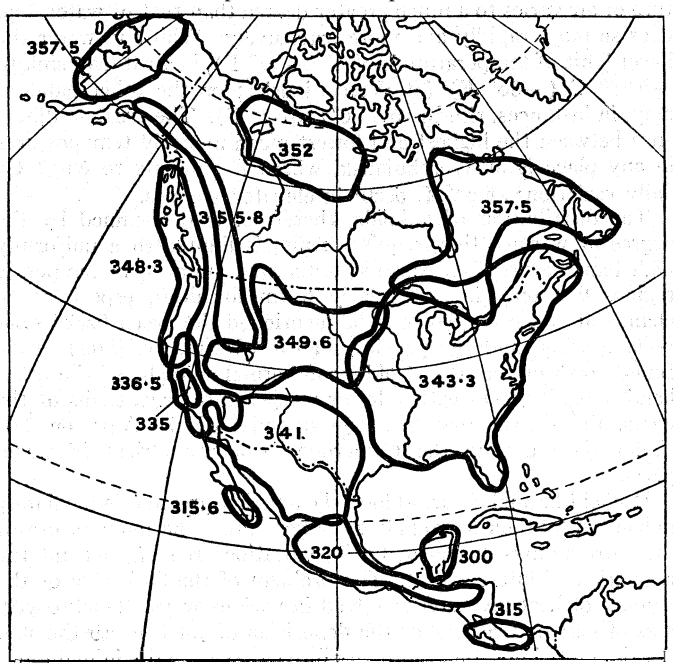

FIG. 11.— MAP SHOWING VARIATIONS IN THE SIZE OF THE GREAT HORNED OWL (BUBO VIRGINIANUS) OF NORTH AMERICA. THE NUMBERS INDICATE THE WING-LENGTHS IN MILLIMETRES

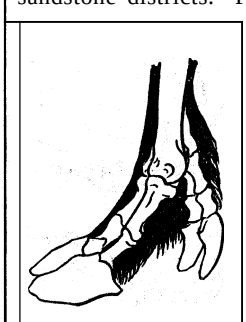
Brilliant colours and clearly defined markings are characteristic of tropical animals. The number of living organisms is enormous. Development takes place quickly, generation following generation in rapid succession. The butterfly *Danaus chrysippus* in the northern parts of its area of distribution is represented by one generation a year, but in the Philippines it requires only 23 days for complete development. Among mammals also development is accelerated, as puberty is reached much sooner (in the 12th year in man). The number of species is astonishing. South America has 4,560 species of Lepidoptera, while the whole of the Palaearctic region (Asia north of the Himalayas, Europe and north Africa) has only 716. The Brazilian states of Para and Amazonas have 1,117 species of birds, *i.e.*, almost as many as the whole Palaearctic region (1,218). The number of individuals of a single species, however, is usually limited; of insects and spiders it is often easier to collect 100 different species than 100 individuals of one species. The absence of seasons causes reproduction to go on during the whole year; one may find at any time of the year eggs, larvae, pupae and fully developed animals.

Temperate **Regions.**—On the other hand, in regions where periodical changes of temperature give rise to seasons, animals are subjected to conditions varying from times of plenty to times of need. It is immaterial whether the changes be between summer and winter, or between rainy season and dry. Summer and the rainy season bring the most favourable conditions, winter and drought the least favourable. Animal life languishes under unfavourable conditions, lack of warmth in one place bringing about a state similar to lack of moisture in another. When, however, the bonds are loosed, the awakening of the animal world is the more effectual owing to the simultaneous appearance of many species. Most species immediately set about reproduction; the chirping of crickets, the croaking of frogs, and particularly the songs of birds, together with the awakening of plant-life, is in sharp, refreshing contrast to the desolation of winter and the dry season. In winter, or the dry season, many terrestrial animals cease their vital activities. Aestivation in time of drought is common among insects, spiders and snails; frogs and toads creep into holes in the earth or other hiding-places, and remain there in a death-like sleep. Crocodiles dig themselves into the mud of pools which are drying up, and rest beneath the hardened crust. This habit of sleeping through the dry season is also found among mammals; *e.g.*, the aardvark (Orycteropus) in Africa. In winter, poikilothermal animals hibernate in a similar way; this may also occur in warm-blooded animals, which undergo a drastic fall of temperature and a slowing-down of the rate of metabolism. Such are hedgehogs, bats, dormice and marmots. Among birds, however, we find neither hibernation nor aestivation; they withdraw from the reach of unfavourable seasons by migrating, Migration (*q.v.*) occurs also among mammals, brought about by seasonal changes of weather. It occurs among South African antelopes, reindeer and bats. Among birds of temperate regions, we may distinguish a general resident population, which dwells the whole year in the same locality; migratory birds present only for the breeding season (summer visitors) or only in the non-breeding season (winter visitors) or occurring on passage between their summer and winter habitats. According to the climate of the habitat the same species may be resident in one locality and migratory in another. Thus in England birds such as starlings and song-thrushes remain throughout the winter; in central Europe they migrate. Some birds travel great distances; the summer and winter quarters of *Sterna paradisea* are 17,700km. apart. The change from rainy season to dry causes migration, as in Africa.

The nature of the soil of a locality is important in determining the composition of its population, particularly as regards the higher forms of life. Among mammals the two-legged jumping animals require a hard substratum, which offers a firm foothold. These are found in all the steppe regions of the earth. Such are jerboas, the jumping hare *pedetes*, and the kangaroo group of marsupials. Running animals, such as carnivores which go upon their toes, and ungulates, which place only the tips of the toes on the ground, favour a hard soil, where there is least friction. Ungulates living on sand, bog or snow, have the surface of the hoof expanded to prevent sinking; they have three or four toes (pigs and tapirs), or two toes bearing elongated hooves, which can diverge widely, as in *Gazella loderi*, the marsh antelope, and the reindeer (fig. 12). In reptiles which live on loose sand the toes sometimes have fringes along the sides.

Soil.—Of the chemical constituents of the soil, chalk merits the first consideration. Animals which require much lime for building up their bodies thrive better on chalky ground than on soil poor in lime. Among mammals this is particularly noticeable in deer, which require lime for the annual renewal of their antlers. Roebuck in limestone regions have stronger antlers than those in sandstone districts. Further, the body-weight of the roedeer is greater in limestone districts. In Württemberg the weight of the carcase of the roedeer in limestone regions exceeds 14kg, but in districts with little lime in the soil (sandstone, moorland) it is below 14kg. The amount of lime in the soil, and, therefore in the drinking water, affects mankind also; this shows itself particularly plainly in the teeth. The number of decayed teeth in school-children is much higher in regions poor in chalk than in those rich in it. Snails are more numerous in limestone regions, both in species and in individuals, owing to the number of hiding places present, to the chemical composition of the soil and to thewarmthof thechalk.



FROM CUVIER, "LE REGNE ANIMAL"

FIG. 12.— TOES OF FOREFOOT OF REINDEER (RANGIFER)

Other animals require a large amount of salt in the soil, and are widely distributed on sea-coasts; inland, they are found only on salt ground, as at Stassfurt and in similar localities. This applies particularly to the small beetles (Staphylinidae, Carabidae) and other insects. Salt is sought after by mammals also, particularly by herbivores; places where it crops up are much resorted to by ruminants, and in primaeval forests they have paths converging to them from all directions.

The Fauna **of** Forests. — Large forests are found only in regions where, during the four months vegetative season, a minimum temperature of 10° C prevails, a minimum rainfall of 50cm. and an atmospheric humidity of more than 50% saturation. The dense covering of the tree-tops hinders penetration of heat-rays, evaporation of moisture and air-currents. For this reason, temperature, humidity and air-currents vary much less than in open country. The density of forests, moreover, varies greatly; all grades are found from the tali, hot, impenetrable, dripping rain-forests of the tropics, to the Bght pine forests near the tree limit on mountain slopes and in the sub-arctic region. The peculiarities of forest animals are seen most plainly in the tropical rain-forests, which form an immense zone round the earth at the equator, and include the Congo forest region, the forests of southern Asia and the islands of that region and the selvas of the Amazon.

Orientation is possible only for short distances, eyes and organs of smell are not much use; the sense of hearing is the most useful. The gregarious forest animals, therefore, such as birds and monkeys, are noisy, in contrast to those of open country. The light is subdued and much reflected; brilliant colours do not show up; protective coloration is rendered unnecessary by the restriction of the outlook. Flying and running are hampered; the true forest birds are usually poor fliers, but are good at gliding and climbing. Some forest animals, such as elephants and large swine, are able to force their way through; others are small and slender, stand lower in front than behind, carry the head low, and are able to squeeze through narrow places, *e.g.*, forest antelopes (*Cephalolophus, Tragelaphus*), forest deer (muntjac) and agutis (*Dasyprocta*). Many birds and mammals are equipped with sharp claws (woodpeckers, squirrels, martens); others have gripping-feet (parrots, monkeys, arboreal marsupials), some have prehensile tails (many South American monkeys, the porcupine *Erethizon,* the anteater, various marsupials).

Climbing animals in forest regions include also many reptiles and amphibians, such as the laterally-compressed tree Agamidae of the Old World, and the tree-iguanas of the New World, the long, slender tree-snakes and numerous tree-frogs. Parachuting animals, which can prolong their leaps from tree to tree by their expanded under-surface, are confined to forests; such are frogs of the genus *Rhacophorus,* the flying dragon (Draco *volans*), the flying phalangers (Petaurus, Petauroides, Acrobates), the flying squirrels (*Anomalurus,* Petaurista), and the flying lemurs (*Galeopithecus*). Some tree-frogs have become so adapted to arboreal life that they have forsaken the ground even for reproduction; laying their eggs in the collections of water on the epiphytic Bromliaceae; or the eggs are carried until they hatch in dorsal pouches, in gular sacs or in the mouth. A number of active animals use the forest only as a dwelling place, and seek their food in open country; *e.g.,* birds of prey, wolf, fox, buffalo and stag. The conditions of the forest are uniform; the food supply is poor and therefore the population is sparse; on the other hand, the borders of forests and forest glades where there is plenty of light swarm with life, since there is room for free movement and an abundance of vegetable food combined with protective shelter.

The more a forest departs from the extreme type of the tropical rain-forest, the more the characteristic peculiarities of its inhabitants are effaced. In the forests of temperate regions the characteristics of the fauna are mostly determined by the nature of the forest; entirely green forests have a different animal population from entirely coniferous forests, while mixed forests have an intermediate type of population. In green forests gastropods are represented by many species, in pine forests they are almost absent. Many forest insects are restricted in diet either to green or to coniferous trees. Green forests are preferred by the black grouse (Tetrao *tetrix*), the pheasant, song-thrush, blackbird and whitethroat; and by the dormouse (*Muscardinus avellanarius*) among mammals. Coniferous forests are preferred by the capercaillie (Tetrao urogallus), great black woodpecker (*Picus* martius), nutcracker (Nucifraga), crossbill (*Loxia*), siskin (*Carduelis spinus*) and gold-crest (Regulus).

Fauna of Open Country.--Open country is in every respect in contrast to forest regions. Forests ate not found where moisture and warmth are insufficient; in such places only grass and shrubs are present. Such lack of moisture is often found in great plains, both elevated and low-lying. But there are numerous grades of open country, from savannahs and steppes to pre-desert (shrub steppe), and desert. The gradations depend on the degree of precipitation; this is greatest in subxerophilous grasslands; in arid steppes it is confined to the rainy season, and in waterless deserts it may be absent for years. In the rainy season, such regions show very diverse appearances, but in the dry season they are much more alike. All have an absence of protective foliage, and, on this account, variations of temperature and humidity are great, and atmospheric currents are strong.

In general only animals which can endure a dry atmosphere are able to exist in open country; those requiring moisture in the air, such as gastropods and amphibians, are rare. An extraordinary number of animals seek shelter in holes and burrows in the ground from storms, enemies and variations of temperature. Here **we** find ants and other brood-nursing Hymenoptera, and termites. Among burrowing reptiles are the Caspian tortoise (Clemmys *caspica*), skunks and many snakes (*Typhlopidae, Eryx, Psammophis*). Among mammals, rodents show the greatest number of burrowing forms, such as the marmots (Marmotta), prairie-dogs (*Cynomys*), sousliks (Spermophilus), rats, voles, hamsters (Cricetus), jerboas, porcupines, the South American Hystricomorpha (*Ctenomys, Dolichotis, Viscacia*), and rabbits (*Lepus cuniculus*); they often live in large communities, and undermine extensive areas. Armadillos (*Dasypus*), ant-bears (*Orycteropus*), wart-hogs (*Phacochoerus*), and predatory animals (*e.g., Canis* cerdo in Africa) dig holes for themselves in open country. The birds are ground-breeding forms, but others such as eagles, which usually nest in trees, occasionally breed on the ground in such regions. Others again make their nests in the holes of rodents, *e.g.,* the burrowing owl (Speotyto). In such regions, where there is little cover, the colouration of the animals is frequently adapted to that of the surroundings; the less cover present, the greater the degree of adaptation. This is found to the greatest degree in deserts, where the most varied kinds of animals have coloration similar to that of the ground (Plate II.). A few insects which have special protection in their hard cuticle (some Tenebrionidae), or which eject a poisonous fluid against attackers (the locust Eugaster *guyoni*), have a striking black colouration.

Agile animals are particularly characteristic of open country, Here are found running birds such as the ostrich, partridge, desert jay (Podoces) and larks. The solipeds and two-legged jumping animals are inhabitants of open country. Visual and olfactory organs assist orientation, as the outlook is wide and the winds carry scents. Animals of open country, in contrast to those of forests, make little noise. Gregarious animals are particularly common. The subxerophilous grasslands are the richest game regions of the world; the North American prairies formerly harboured enormous herds of bison; the South African plains swarm with herds of ungulates.

Plains where winter is the dry season and those covered with snow at this season differ in several respects. In the dry season the former offer food in dry grass and its seeds, which keeps life from dying out. In regions where the grass in winter is covered by snow, vegetation decays and is useless as food; all animals hibernate or migrate. When the dry season is past and the first rains begin, life awakens suddenly, but where there is snow, plants and animals awaken gradually at the end of the winter. All these peculiarities are most marked in desert regions with their extreme conditions of life; the scarcity of animal life and the sharp competition, the frequency of protective coloration, the paler coloration of the animals, are all direct effects of climate.

Fauna **of** Mountain Regions. — In mountain regions there is generally sufficient moisture for the growth of forests, but, with the decrease of temperature in proportion to increase of altitude, the forests are confined to a zone, higher or lower according to latitude. In the Colombian Andes the limit of trees is 3,300 metres above sea level, in the Swiss Alps, on an average 1,800 metres. The forest fauna extends to this limit; above, and adjoining it from the lower limit of the region of snow, a characteristic

alpine fauna is found. As the height above sea-level increases, atmospheric pressure and temperature decrease. The low atmospheric pressure, *i.e.,* the small quantity of oxygen in the air, causes an increase in the number of red blood corpuscles in homoiothermal animals. Plain-dwelling mammals suffer from lack of oxygen if they ascend high ("mountain sickness"). Nevertheless, mammals are able to dwell at heights of more than 6,000 metres; *e.g.,* the rodent Ochotona wollastoni at 6,125 metres on Mt. Everest. More important is the decrease in temperature, and the shortening of the warmer season in alpine regions. For these reasons the number of species decreases rapidly with increasing altitude. In Switzerland up to 700 metres there are 178 species of birds, up to 1,800 metres 178 species (partly other kinds), in the Alpine region (up to 2,700 metres) go species, in the region of the snows only 8 species. The species of gastropods, insects and mammals show a similar decrease. The special conditions of temperature at ground-level lessen, for small animals, the unfavourable climate of mountain regions. In consequence of the strength of the sun's rays, the surface layers of the ground, and the air in the tussock-growth of plants which covers them, is rapidly heated; on summer days with an air temperature of 23° C, the temperature at the surface of the ground may rise to 40–50°. Insects, mites, gastropods, salamanders and lizards are able, therefore, to move about in search of food; at night they find shelter from the cold in the surface layers of the earth and under stones. Flying insects are comparatively scarce; at sunset, all of them settle on the ground. The steepness of the mountain slopes facilitates the removal of loose earth by rain and torrents. In many places the rock is exposed and harbours a peculiar fauna; birds, such as the Alpine creeper (*Tichodroma*), those which nest in cliffs, such as the Alpine chough (*Pyrrhocorax-graculus*) and the Alpine swift (*Apus* melba), and ruminants such as the chamois, ibex, musk-deer and yak, which have broadly expanded hooves, enabling them to get foothold. Among insects, those with complete metamorphosis preponderate; in particular, beetles, Lepidoptera, Diptera; Orthoptera and Hemiptera, which require more warmth, are poorly represented. On the other hand, springtails are numerous. Among Hymenoptera the most numerous are humble-bees, with a hairy covering to the body, which retains the heat generated by their movements. The shorter time amphibians require for development, the higher they ascend the mountain slopes, for the higher a pool, the shorter the time it remains free of ice. In Rana fusca, Hyla, Bufo, Alytes, Bombinator, the tadpole stage lasts from 85 days increasing to 134 days; their upper limit is from 2,600 metres decreasing to 1,500 metres. The upper limit of reptiles is connected with their manner of reproduction, viviparous species ascending highest. In the Alps, the common lizard Lacerta vivipara ascends to more than 3,000 metres, the common viper (*Vipera* berus) to 2,750 metres, the slow-worm (*Auguis fragilis*) to 2,000 metres. Oviparous reptiles inhabit the lower slopes. Viviparous forms and therefore their embryos, are constantly exposed to the sun, while deposited eggs are usually in the shade, and are only warmed by the sun from time to time. Homoiothermal animals are more independent of temperature, but are very dependent on food; to obtain it, they often migrate down towards the valleys in winter. Most alpine birds are non-migratory; migratory species are relatively scarce. Homoiothermal animals in high mountains are often larger than their relatives in the plains; *e.g.,* the tree-creeper (Certhia familiaris) and the hedge-shrew (Mus sylvaticus) of the Swiss Alps. Many specifically mountain dwellers cannot live in the plains; they are isolated in the mountain ranges by the surrounding lowland, and have been transformed into geographical races; *e.g.,* the ibex (Capra ibex) of the Alps, Caucasus, Taurus mountains, Mt. Sinai and Abyssinia.

Fauna of Polar Regions.—Varieties similar to those in the fauna of the lower slopes of mountains are present in regions approaching the North Pole. Organisms in the Arctic and in the Antarctic regions are very different, owing to the difference in the climate. In Arctic regions there is a short summer, with sunshine and higher temperatures, which awakens plant and animal life; in the Antarctic, although the winter is not quite so cold, the summer is cooler, and the sky is constantly overcast, and therefore little life develops on land. Arctic and the highest alpine regions have many species in common, which are absent in the intervening areas; such are the Alpine hare (Lepus timidus), the ptarmigan (*Lagopus* mutus), the gastropod *Acanthinula harpa,* and some lepidopterans, which traversed the warmer intervening areas during the Glacial Period. The number of arctic insects is not great; Diptera and Lepidoptera are most abundant, Orthoptera and Hemiptera are rare. Among Hymenoptera, bumble-bees are relatively numerous, and are strikingly large, thus having proportionately smaller surface to give off heat. The few species of gastropods are small. Amphibians and reptiles are found only in the southern portion and these species are the same as those ascending highest in mountain regions. Homoiothermal animals are characterized by adaptations for conservation of heat; they are sturdy, have short appendages (ears and tail) and a thick covering of fur or feathers. The white colour of so many polar birds and mammals is important in reducing heat radiation. Experiments have shown that the proportion of heat given off by light-coloured and black guinea-pigs is as 100:124. Polar mammals do not hibernate, as the frozen ground provides no protection from temperatures below freezing point. The number of birds and mammals is small, apart from those which find their food in the sea. In eastern Greenland, besides polar bears and seals, only seven kinds of mammals are found (the hare, lemming, musk-ox, reindeer, ermine, arctic fox and wolf). In Spitsbergen, there are only two kinds, the reindeer and arctic fox. In the Antarctic terrestrial birds and mammals are absent; all homoiothermal animals are confined to the sea.

Animals of Islands.—The characteristic peculiarities many island faunas have in common are due chiefly to isolation. Animals of islands are originally derived from those of continents, and the sea forms a barrier preventing the influx of the parent-species. This barrier, however, is not insuperable. In many cases land connections were formerly present. Such islands are termed "continental," in contrast to "oceanic" islands, which have arisen in the sea by volcanic agency, or as coral reefs, and were originally devoid of terrestrial animals. Isolation brings about differentiation of species, each form developing its peculiarities undisturbed by intercrossing with the original stock. This process being continued, races are produced confined to certain localities. In all islands the length of the time of separation, and the degree of isolation, *i.e.,* the distance from the mainland, is important; the longer and more complete the isolation, the greater the degree of differentiationof the species. Madagascar has long been isolated; forms of Ethiopian origin are here so greatly differentiated that, for example, all non-volant mammals except a few later immigrants belong to endemic genera, and, usually, also to sub-families and families not found elsewhere. On the other hand, the British Isles, which have been separated only since the end of the Glacial Period, have only one peculiar vertebrate (the red grouse).

In ancient oceanic islands, the number of endemic species increases with the distance from the mainland. While the Azores, in addition to endemic species, have many in common with Europe and Africa, most of the fauna of St. Helena is endemic, and in that of the Hawaiian islands (more than 3,000km. from the mainland) there are numerous genera, and among gastropods and birds, families also, which are not found elsewhere.

The isolation of oceanic islands by the sea implies selection in the fauna. Mammals, amphibians and freshwater fishes are unable to overcome this obstacle, and are therefore absent. Reptiles can seldom reach such islands, but birds can do so much more frequently. Flying insects may be carried to them by winds, and some even reach them unassisted. Terrestrial gastropods and wood-boring insects (*e.g.,* weevils) reach them on driftwood.

Isolated regions offer shelter from rivals and enemies. Thus, in Tasmania, the carnivorous marsupials *Thylacinus* and Sarcophilus can hold their own, but on the Australian continent they succumb to the imported dingo. Loss of the power of flight, which often occurs in birds inhabiting islands, is connected with the absence of mammals; in the Galapagos Islands there is a flightless cormorant (*Nannopterus*), in New Zealand the kiwi (Apteryx). On other islands, flightless birds have become extinct in historical

times, as in Mauritius. The large size of the birds found on islands may be connected with the loss of flying powers; the limit of size imposed by flight disappeared when this was abandoned. On the other hand, we frequently find dwarf varieties of mammals on islands; on the islands of the Red sea *Gazella arabica* does not exceed a third the normal weight of the species.

Some of the peculiarities of animals of islands are explained by the climate. On small islands feeble fliers are in danger of being carried out to sea by strong winds. For this reason most insects on the Polynesian islands take shelter from wind; in the East Frisian island few flying insects are found. Animals which feed on these insects (flycatchers, swallows, small bats, etc.) are also absent. On the storm-swept islands of the Subantarctic, numerous insects have vestigial wings (of eight species of flies in Kerguelen one only has normal wings).

DISTRIBUTION OF PLANTS: *see* PLANTS: *Distribution and Ecology*.

DISTRIBUTION OF TERMS. In logic a term is said to be distributed in a proposition when explicit reference is made to its whole extent or extension. Otherwise (that is, not only when reference is made explicitly to a part only of the extension of the term, but when explicit reference is simply not made to its whole extension) it is said to be undistributed. Thus, in a proposition of the form *No S is P* both the subject and the predicate are distributed. In the form *Some S is P*, neither *S* nor *P* is distributed. In *All S is P*, *S* is distributed, but P is not. Lastly, in *Some S is not P*, *S* is not distributed, but *P* is. Briefly, only universal propositions distribute the subject term (S), and only negative propositions distribute their predicate *(P)*. Naturally, singular terms (including proper names used as singular terms) are always distributed, for they only refer to one object, and cannot refer to less. The importance of the distribution of terms arises from the fact that it is a principle of formal inference that no term may be distributed in this conclusion unless it was distributed in the premises. That is why, *e.g.*, All *S is P* can only be converted into *Some P is S* (not into *All P is* S), and *Some S is not P* cannot be converted at all.

See A. Wolf, *Essentials of Logic* (1928).

DISTRIBUTION OF WEALTH. This expression has been applied both to the distribution of wealth and to the distribution of income. To a considerable extent. the distribution of income is bound up with the distribution of wealth and capital. and for convenience of reference the two subjects are treated in this work in the article WEALTH AND INCOME, DISTRIBUTION OF.

DISTRIBUTIVE LAW, in algebra the law which asserts that $a(b+c+d) = ab+ac+ad$, one of two factors *(a)* being distributed, as it were, among the parts *(b*, c and *d)* of the other factor *(b+c+d)*. Stated in words, the result of first adding several numbers and then multiplying the sum by another number is the same as the result of first multiplying each of the several numbers separately by the other number and then adding the products. For example, $2(5+3)=2\times8=16$; and $2\times5+2\times3=10+6=16$. The law is equally valid for negative, fractional, irrational, and complex numbers.

DISTRIBUTOR, in electrical engineering, a form of switch, generally rotary, arranged so that it transmits successive electrical impulses to definite points in a given order *(see* HIGH-TENSION MAGNETO).

DISTRICT, a word denoting in its more general sense, a tract or extent of a country, town, etc., marked off for administrative or other purposes, or having some special and distinguishing characteristics *(see* LOCAL GOVERNMENT, etc.). In mediaeval Latin the word *districtus* is defined by Du Cange as *Territorium feudi, seu tractus, in quo Dominus vassallos et tenentes suos distringere potest;* and as *justitiae exercendae in eo tract~facultas.* It was also used of the territory over which the feudal lord exercised his jurisdiction generally. In British India the word is used to represent the *zillah,* an administrative subdivision of a province or presidency.

In the United States of America the word has many administrative, judicial and other applications. In South Carolina it was used instead of "county" for the chief division of the State other than in the coast region. In the Virginias, Tennessee, Georgia, Kentucky and Maryland it answers to "township" or precinct, elsewhere the principal subdivision of a county. It is used for an electoral "division," each State being divided into Congressional and State legislatorial districts; and also for a political subdivision either of an unorganized or an organized Territory.

DISTRICT OF COLUMBIA: *see* WASHINGTON, D.C.

DISTYLE, the term given to a portico of two columns, especially in the phrase "distyle in antis," when the columns are between antae. *(See* ANTAE and TEMPLE.)

DITA BARK, the bark of a fruit tree *(Alstonia scholaris)* growing in the Philippines and elsewhere, and containing valuable medicinal properties.

DITHMARSCHEN or **DITMARSH** (in the oldest form of the name *Thiatmaresgaho,* Dietmar's Gau), a territory between the Eider, the Elbe and the North sea, forming the western part of the old duchy of Holstein. It contains about 550sq.m., half of which consists of good pasture land, preserved from inroads of the sea by banks and dams, the other half being mostly waste. The district was subjugated and Christianized by Charlemagne, and ranked as a separate *Gau,* probably included in the countship of Stade. Ultimately the archbishops of Bremen claimed supremacy over the land; but the inhabitants, who had developed and consolidated a systematic organism for self-government, made obstinate resistance, and rather attached themselves to the bishop of Schleswig. Ditmarsh continued part of the Danish dominions till the disastrous battle of Bornhoved in 1227, when its former independence was regained. The claims of the archbishop of Bremen were now so far recognized that he exercised the royal rights of *Heerbann* and *Blutbann,* and was represented first by a single *advocatus,* or *Vogt,* and afterwards by one for each of the five Döffts, or marks, into which the land was divided after the establishment of Meldorf. The community was governed by a *Landrath* of 48 elective consuls, being 12 from each of the four marks. In 1319 and 1404 the inhabitants defeated the invasions of the Holstein nobles; and though in 1474 the land was nominally incorporated with the duchy by the emperor Frederick III., the attempt of the Danish king Hans and the duke of Gottorp to enforce the decree in 1500 resulted only in their complete rout in the marshes of the Dussend-Diiwels-Warf. During the early part of the following century Ditmarsh was the scene of violent religious conflict; and, thus weakened, it was obliged in 1559 to submit to partition among its three conquerors—King Frederick II. of Denmark and Dukes John and Adolphus. A new division took place on Duke John's death in 1581, by which Frederick obtained South Ditmarsh, with its chief town of Meldorf, and Adolphus obtained North Ditmarsh, with its chief town of Heide; and this arrangement continued till 1773, when all the Gottorp possessions were incorporated with the Danish Crown.

R. Dahlmanns Vorlesungen* (1873).

DITHYRAMBIC POETRY, the description of poetry in which the character of the dithyramb is preserved. It remains quite uncertain what the derivation or even the primitive meaning of the Greek word διθύραμβος is. It was, however, connected from earliest times with the choral worship of Dionysus. The earliest dithyrambic poetry was probably improvised by priests of Dionysus at solemn feasts and expressed, in disordered numbers, the excitement and frenzy felt by the worshippers. The dithyramb was traditionally first practised in Naxos; it spread to other islands, to Boeotia and finally to Athens. Arion is said to have introduced it at Corinth, and to have allied it to the worship of Pan. It was thus "merged," as Professor Gilbert Murray says, "into the Satyr-choir of wild mountain-goats" out of which sprang the earliest form of tragedy. It flourished in Athens until

after the age of Aristotle. So far as we can distinguish the form of the ancient Greek dithyramb, it must have been a kind of irregular wild poetry, not divided into strophes or constructed with any evolution of the theme. It was accompanied on some occasions by flutes, on others by the lyre. Pindar, in whose hands the ode took such magnificent completeness, is said to have been trained in the elements of dithyrambic poetry by Lasus of Hermione. In the opinion of antiquity, pure dithyrambic poetry reached its climax in a lost poem, *The Cyclops*, by Philoxenus of Cythera, a poet of the 4th century B.C. In modern literature, although the adjective "dithyrambic" is often used to describe an enthusiastic movement in lyric language, and particularly in the ode, pure dithyrambs have been extremely rare. The *Baccho in Toscana* of Francesco Redi (1626–98), which was translated from the Italian, with admirable skill, by Leigh Hunt, is a piece of genuine dithyrambic poetry. *Alexander's Feast* (1698), by Dryden, is the best example in English. But perhaps more remarkable, and more genuinely dithyrambic than either, are the astonishing improvisations of Karl Mikael Bellman (1740–95), whose Bacchic songs form one of the most remarkable bodies of lyrical poetry in the literature of Sweden.

DITTERSBACH, a town of Germany, in the Prussian province of Silesia, 3 m. by rail S.E. from Waldenburg and 50 m. S.W. from Breslau. It has coal-mines, bleach-fields and match, chemical and benzole works. Population (1933) 15,392.

DITTERSDORF, KARL DITTERS VON (1739–1799), Austrian composer and violinist, was born in Vienna on Nov. 2, 1739, his father's name being Ditters. He took the name of Dittersdorf on his ennoblement in 1773. The boy Ditters was a brilliant violinist and attracted the attention of Prince Joseph Frederick of Hildburghausen (1702–1787), who gave the boy, now eleven years old, a place in his private orchestra—the first of the kind established in Vienna. Later he obtained a place in the Vienna opera; and subsequently in 1761 he accompanied Gluck to Italy where his violin-playing won him great renown. He became conductor of the orchestra of the bishop of Grosswardein, a Hungarian magnate, at Pressburg. He set up a private stage in the episcopal palace, and wrote for it his first "opera buffa," *Amore in musica.* His first oratorio, *Isacco figura del Redentore,* was also written during this time; but the scandal of performances of light opera by the bishop's company, even on fast days and during Advent, outweighed this pious effort; the Empress Maria Theresa sharply called the bishop to order; and he, in a huff, dismissed his orchestra (1769). After a short interlude, Ditters was again in the service of an ecclesiastical patron, Count von Schafgotsch, prince bishop of Breslau, at his estate of Johannisberg in Silesia. At Johannisberg Ditters also produced a comic opera, *Il Viaggiatore americano* and an oratorio, *Davide.* The title rôle of Davide was taken by Signora Nicolini, whom Ditters married. In 1773 his oratorio *Ester* was produced in Vienna. After the peace of Teschen (1779) he again became conductor of the reconstituted orchestra of the bishop of Breslau. From this time forward his output was enormous. In 1780 ten months sufficed for the production of his *Giobbe* (Job) and four operas, three of which, *Doktor und Apotheke* (1786), *Das Rotkäppchen* (1788) and *Hieronymus Knicker* (1789) had a great success. But when the bishop died in 1795 his successor dismissed the composer with a small money gift. Poor and broken in health, he accepted the asylum offered to him by Ignaz Freiherr von Stillfried, on his estate near Neuhaus in Bohemia, where he continued to write operas, symphonies and pianoforte pieces. He died on Oct. 1, 1799, praying "God's reward" for whoever should save his family from starvation. On his death-bed he dictated to his son his *Selbstbiographie* (autobiography).

While in the work of Boccherini we trace the influence of Haydn as a force tending to disintegrate the polyphonic suite-forms of instrumental music, in Dittersdorf on the other hand we see the popular conception of the modern sonata and dramatic style. Six of Dittersdorf's symphonies on the *Metamorphoses* of Ovid were republished in 1899 (ed. J. Liebeskind, Leipzig), the centenary of his death. The end of the representation of the conversion of the Lycian peasants into frogs is prophetically and ridiculously Wagnerian in its ingenious expansion of rhythm and eminently expert orchestration.

See his *Selbstbiographie,* published at Leipzig, 1801 (English translation by A. D. Coleridge, 1896); an article in the *Rivista musicale,* vi. 727; the article "Dittersdorf" in Grove's *Dictionary of Music and Musicians; K.* Kalbs *Dittersdorfiana* (1900), with bibliography; and L. Riedinger, *Karl von Dittersdorf als Opernkomponist* (1914).

DITTO, that which has been said before, the same thing (from the Lat. *dictum,* something said, Ital. *detto,* aforesaid), frequently abbreviated into "do."

DIU, an island and town of India, belonging to Portugal, and situated at the southern extremity of the peninsula of Kathiawar. The district (area 20 sq.m.), which inciudes the village of Goala on the mainland and the fortress of Simbor, j m. W., is subject to the governor-general of Goa. Pop. of the island (1921) 13,844. The anchorage is protected from the sea, but the depth of water is only about 2 fathoms. The channel between island and mainland is navigable only by small craft. The town is surrounded by a wall with towers at regular intervals. Its trade is decayed. There are remains of several fine ancient buildings. The cathedral of Sé Matriz, dating from 1601, was formerly a Jesuit college. The Portuguese under treaty with Bahadur Shah of Gujarat, built a fort here in 1535, but were besieged in 1538 and 1545. The second siege is one of the most famous in Indo-Portuguese history.

DIURETICS, the name given to remedies which, under certain conditions, stimulate an increased flow of urine. Some are absorbed into the blood and stimulate the kidneys directly, causing an increased flow of blood; others act through the nervous system. A second class act in congested conditions of the kidneys by diminishing the congestion. Another class (saline diuretics) are effectual by virtue of their osmotic action. A fourth class are diuretic by increasing the blood pressure within the vessels in general, and the Malpighian tufts in particular,—some, as digitalis, by increasing the strength of the heart's contractions, and others, as water, by increasing the amount of fluid circulating in the vessels. Some remedies, as mercury, although not diuretic themselves, when prescribed along with those which have this action, increase their effect. The same substance may act in more than one way; *e.g.,* alcohol, besides stimulating the secretory organs directly, is a stimulant to the circulation, and thus increases the pressure within the vessels. Caffeine acts in nearly every way mentioned above. Together with digitalis it is the most efficient remedy for cardiac dropsy. A famous diuretic pill, known as Guy's pill, consists of a grain each of mercurial pill, digitalis leaves and squill, made up with extract of henbane. Digitalis, producing its diuretic effect by its action on heart, vessels and kidneys, is much used in the oedema of mitral disease, but must be avoided in chronic Bright's disease, as it increases the tension of the pulse, already often dangerously high. Turpentine and cantharides are not now used as diuretics, as they are too irritating to the kidneys.

DIURNAL MOTION, the apparent motion of the heavens from east to west resulting from the earth's rotation on its axis from west to east. The axis of this apparent motion passes through the celestial poles (coincident in direction with the earth's axis) so that the stars appear to describe circles around the pole star.

DIURNAL VARIATION. The small daily change in value of the magnetic quantities, dip, declination and the horizontal component of the earth's magnetic force. *(See* TERRESTRIAL MAGNETISM.)

DIUSHAMBE (now STALINABAD), a small town in Turkistan, capital of the Tadzhik S.S.R., situated south of the Hissar Mountains, but north of the town of Hissar, on the Diushambe river, a tributary of the Kafirnigan river which flows into the Amu-Darya. Pop. (1935) 60,000. It is the centre of a fertile loess area, producing grains (including rice), cotton, melons, grapes, apricots and other fruits. The town itself is built on a loess cliff and its streets and gardens and water tank are shaded by poplar trees. Formerly of little importance, for its main link with the U.S.S.R. was a caravan route to Samarkand, Stalinobad has developed rapidly since its connection by rail with Termez (124 miles) and the establishment of air communications with Termez and Kagan.

It is also a base for the All-Union Academy of Science.

DIVAN (dē-vahn′ or dī-văn′), Persian word, probably from Aramaic, meaning a "counting-house, bureau, tribunal"; thence, on one side, the "account-books and registers" of such an office, and on another, the "room where the office or tribunal sits"; thence again, from "account-book, register," a "book containing the poems of an author," arranged in a definite order (alphabetical according to the rhyme-words), perhaps because of the saying, "Poetry is the register (*dīwān*) of the Arabs," and from "bureau, tribunal," "a long seat, formed of a mattress laid against the side of the room, upon the floor or upon a raised structure or frame, with cushions to lean against" (Lane, Lexicon, 930 *et* seq.). All these meanings existed and exist, especially "bureau. tribunal," "book of poems," and "seat"; but the order of derivation may have been slightly different. The word first appears under the caliphate of Omar (A.D. 634–644). Later, as the state became more complicated, the term was extended over all the government bureaux. The divan of the Sublime Porte was for long the council of the empire, presided over by the grand vizier. (See DEWAN; also Von Kremer, *Culturgeschichte* des Orients, i. 64, 198.)

DIVER, a name applied to many birds, but properly restricted to the family Colymbidne, containing the single genus Colynzbus. They are sea-birds, strong swimmers, and feed mainly on fish. Their legs are set far back on the body, so that they cannot walk more than a few steps at a time; sometimes they progress on land by a series of bounds. They fly well when once on the wing, and usually resort to fresh water for breeding purposes. The red-throated diver (C. stellatus) has a patch of bay on the throat in summer dress. This is replaced by black in the beautifully striped black-throated diver (C. *arcticus*). The Pacific loon (*Colymbus,* or ***Gavia*** *pacifica*) resembles the black-throated diver.

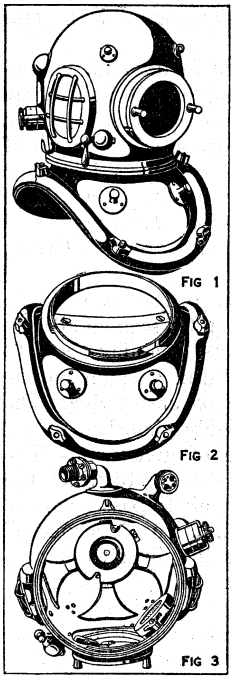
The largest form is the great northern diver (*C. immer*) which has a black back, marked with white spots, a black head and neck, and two semi-collars of black and white vertical stripes. These birds inhabit the Arctic seas of both New and Old Worlds. They breed in the Hebrides, Scandinavia, Canada, Iceland and other suitable places in the North. The American form is usually called loon (q.v.). There is a remarkable mutual courtship, in which the birds may run erect over the surface of the water (see J. S. Huxley, Journ. *Linn. Soc.,* 1923).

DIVERS, EDWARD (1837–1912) English chemist, was born in London on Nov. 27. 1837. He was educated at the City of London school and the Royal College of Chemistry and then studied medicine at Queen's college, Galway, where he also acted as assistant and demonstrator. Between 1853 and 1873 he held a number of posts at the medical schools of several London hospitals where he lectured on materia medica, on medical jurisprudence, and on physics and chemistry. In 1873 he accepted the post of professor of chemistry to the Imperial Government of Japan and stayed in Japan until he retired in 1899. Divers supervised the building and equipment of his own laboratories at the newly built engineering college. In 1886 the college was incorporated in the newly organized imperial university and Divers was transferred to the college of science of that university. After his retirement he lived in London, where he died on April 8, 1912.

It is remarkable that Divers was a great experimental chemist, although he had very bad eyesight and after an accident in the laboratory in Japan, became practically blind. His early work in Japan included an examination of Japanese minerals, which led to some fruitful work on tellurium and selenium. This was followed by work on the compounds of nitrogen and sulphur and on the composition of Japanese bird lime, the manufacture of calomel in Japan and Japanese meteorites and springs.

DIVERS AND DIVING APPARATUS. The earliest reference to the practice of diving occurs in the Iliad, 16, 745–750, where Patroclus compares the fall of Hector's charioteer to the action of a diver diving for oysters. Thucydides mentions the employment of divers during the siege of Syracuse to saw down the barriers which had been constructed below the surface of the water with the object of obstructing and damaging any Grecian war vessels which might attempt to enter the harbour. At the siege of Tyre, divers were ordered by Alexander the Great to impede or destroy the submarine defences of the besieged as they were erected. Livy records that in the reign of Perseus considerable treasure was recovered by divers from the sea. By a law of the Rhodians, their divers were allowed a proportion of the value recovered.

Early Diving Appliances.— The earliest mention of any appliance for assisting divers is by Aristotle, who says that divers were sometimes provided with instruments for drawing air from above the water and thus they were able to remain a long time under the sea (*De* Part. *Anim.* 2, 16), and also that divers breathed by letting down a metallic vessel which did not get filled with water but retained the air within it (Problem. 32, 5). It is also recorded that Alexander the Great made a descent into the sea in a machine called a *Colimpha,* which had the power of keeping a man dry, and at the same time of admitting light. Pliny also speaks of divers engaged in the strategy of ancient warfare, who drew air through a tube, one end of which they carried in their mouths, whilst the other end was made to float on the surface of the water. Roger Bacon in 1240, too, is supposed to have invented a contrivance for enabling men to work under water; and in Vegetius's De Re *Militari* (editions of 1511 and 1532, the latter in the British Museum) is an engraving representing a diver wearing a tight-fitting helmet to which is attached a long leathern pipe leading to the surface where its open end is kept afloat by means of a bladder.



BY COURTESY OF SIEBE, GORMAN AND CO , LTD.

FIGS. 1 TO 3.—HELMET
Fig. 1.—A diver's helmet complete with corselet
Fig. 2.—Corselet
Fig. 3.—Interior of helmet showing valves and telephone connections

Repton invented "water armour" in the year 1617, but when tried it was found to be useless. G. A. Borelli in the year 1679 invented an apparatus which enabled persons to go to a certain depth. It embodied means for altering the specific gravity of the diver, but was not practical. John Lethbridge, a Devonshire man, in the year 1715 contrived "a watertight leather case for enclosing the person." This leather case held about half a hogshead of air, and mas so adapted as to give free play to arms and legs, so that the wearer could walk on the sea bottom, examine a sunken vessel and salve her cargo, returning to the surface when his supply of air was getting exhausted. It is said that Lethbridge made a considerable fortune by his invention. The next contrivance worthy of mention and most nearly resembling the modern diving-dress was an apparatus invented by Kleingert, of Breslau, in 1798. This consisted of an egg-ended metallic cylinder enveloping the head and the body to the hips. The diver was encased first of all in a leather jacket having tight-fitting arms, and in leather drawers with tight-fitting legs. To these the cylinder was fastened in such a way as to render the whole equipment airtight. The air supply was drawn through a pipe which was connected with the mouth of the diver by an ivory mouthpiece, the surface end being held above water after the manner mentioned in Vegetius, viz. by means of a floating bladder attached to it.

In 1819, Augustus Siebe invented his "open" diving dress worked in conjunction with an air force pump. The dress consisted of a metal helmet formed with a shoulder-plate attached to a jacket of waterproof leather. The helmet was fitted with an air inlet valve to which one end of a flexible tube was attached, the other end being connected to the air pump. The air, which kept the water down below the diver's chin, found its outlet at the edge of the jacket, exactly as it does in the case of the diving bell. Excellent work was accomplished with this dress—work which could not have been attempted before its introduction—but it was still far from perfect. It was absolutely necessary for the diver to

maintain an upright, or but very slightly stooping, position whilst under water; if he stumbled and fell, the water filled his dress, and, unless brought quickly to the surface, he was in danger of being drowned. To overcome this and other defects, Siebe carried out a great many experiments, extending over several years, which culminated, in the year 1830, in the introduction of his "close" dress in combination with a helmet fitted with air inlet and regulating outlet valves. Though, of course, many great improvements have been introduced since Siebe's death, in 1872, the fact remains that his principle is in universal use to this day. The submarine work which it has been instrumental in accomplishing is incalculable.

Modern Apparatus.—A set of ordinary modern diving apparatus consists essentially of seven parts, viz:—(*a*) An air pump, (b) an incompressible helmet with breastplate, or corselet, (c) a compressible, or flexible, waterproof diving dress, (d) a length of flexible non-collapsible air tube, with metal couplings joining it to pump and helmet, (e) a pair of weighted boots, (f) a pair of lead weights for breast and back, (g) a life-line. Most apparatus is fitted with a telephone, and submarine lamps are also largely used.

Helnzet (figs. 1, 2 and 3).—The helmet proper is separate from the corselet, and is secured to the latter by segmental'neck rings which are provided on both these parts, enabling them to be connected together by one-eighth of a turn, a catch on the back of the helmet preventing any chance of unscrewing. The helmet and corselet are usually made of highly planished tinned copper, the valves and other fittings being of gun metal. The helmet is provided with a non-return air inlet valve to which the air supply pipe is attached. This valve allows air to pass from the pump to the helmet, but not in the reverse direction. A regulating air outlet valve fitted to the helmet enables the diver to control the amount of air in the dress, and hence his buoyancy. By screwing up the valve, he retains the air in the dress, and so maintains or increases his buoyancy; by unscrewing it he allows the air to escape, thus causing the dress to become deflated, with a consequent loss of buoyancy. On reaching the bottom and starting work, the diver will adjust his valve so as to maintain himself comfortably in equilibrium, altering the adjustment only when he wishes to ascend; that is, of course, assuming, as should be the case, that air is pumped to him at a uniform rate. Thick plate glass windows are fitted to the helmet. The front window is detachable from the helmet, usually by unscrewing, though some helmets are fitted with hinged windows similar to those used for ships' scuttles.
