DROSERACEAE, a family of dicotyledenous plants, remarkable in that all its members are insectivorous. There are four genera and about 90 species. *Drosera,* a cosmopolitan genus including about 85 species, has three British and seven North American representatives, known as sundews (*q.v.*). *Dionaea,* with a single species, is Venus' fly-trap (*q.v.*). *Aldrovanda,* also with only one species, is a water plant, lacking roots.

For a monographic treatment see L. **Diels, Droseraceaa** Pflanzenreich 26 (iv, 112); 1–136 fig. 1–40 (1906).

DROSOPHILA, a genus of flies (*Diptera, q.v.*). Several species, and in particular the fruit-fly, D. *melanogaster,* have become widely known on account of the exhaustive investigation of their hereditary constitution by T. H. Morgan and others. (*See* GENE; GENETICS; HEREDITY.)

DROSTE-HÜLSHOFF, ANNETTE ELISABETH, FREIIN VON (1797–1848), German poet, was born at the family seat of Hiilshoff near Munster in Westphalia on Jan. 10, 1797. Her early mental training was largely influenced by her cousin, von Droste zu Vischering, archbishop of Cologne (*see* below), and she received a liberal education. After prolonged visits among the intellectual circles at Coblenz, Bonn and Cologne she retired to the estate of Ruschhaus near Munster, belonging to her mother's family. In 1841, owing to delicate health, she went to reside in the house of her brother-in-law, the well-known scholar, Joseph, Freiherr von Lassberg (1770–1855), at Schloss Meersburg on the lake of Constance, where she met Levin Schucking (*q.v.*), and there she died on May 24, 1848. Annette von Droste-Hiilshoff is, beyond doubt, the most gifted and original of German women poets. Her verse is strong and vigorous, but often unmusical even to harshness; one looks in vain for a touch of sentimentality or melting sweetness in it. As a lyric poet she is at her best when she is able to attune her thoughts to the sober landscape of the Westphalian moorlands of her home. Her narrative poetry, and especially *Das Hospiz auf dem Grossen St. Bernard* and *Die Schlacht im Loener Bruch* (both 1838), belongs to the best German poetry of its kind. She was a strict Roman Catholic, and her religious poems, published in 1852, after her death, under the title *Das feistliche Jahr, nebst einem Anhang religioser Gedichte,* enjoyed great popularity.

Annette von Droste-Hulshoff's *Gedichte* were first published in 1844 during her lifetime. Collected editions of her works were edited by E. von Droste-Hulshoff (Munster, 1886). The *Ausgewahlte Gedichte* were edited by W. von Scholz (Leipzig, 1901). *See,* among the many monographs on Annette von Droste-Hulshoff, those by Levin Schücking (2nd ed., Hanover, 1871), by H. Hueffer (Gotha, 1871; 3rd ed. by Cardauns, 1911), Gabriele Reuter (1905), and A. Balkenhol (1916). For her correspondence *see* the *Samtliche Briefe* (edit. Cardauns, 1909), and 23 *Neue Droste-Hülshoff Briefe* (edit. M. Schneider, 1923).

DROSTE-VISCHERING, CLEMENS AUGUST, BARON VON (1773–1845), German Roman Catholic divine, was born at Munster on Jan. 21, 1773, and entered the priesthood in 1798, being elected vicar-general by the local chapter in 1807. This office he resigned in 1813 through his opposition to Napoleon, but assumed it again after the battle of Waterloo (1815) until a disagreement with the Prussian Government in 1820 led to his abdication. In 1835, he was appointed archbishop of Cologne, but a further quarrel with the Prussian Government over mixed marriages led to his imprisonment for two years. Droste was not re-installed but was obliged to accept *a* coadjutor. His chief works were: *Über die Religionsfreiheit der Katholiken* (1817), and *Vber den Frieden unter der Kirche und den Staaten* (1843).

See Herzog-Hauck, *Realencyk.,* and H. Kipper, "Droste-Vischering" in *Frankfurter Zeitgemässe Broschüren* (Hamm, 1908).

DROUAIS, JEAN GERMAIN (1763–1788), French historical painter, was born in Paris. His father, François Hubert Drouais, and his grandfather, Hubert Drouais, were well-known portrait painters; and he studied first under his father, then under Brenet, and finally under David. He accompanied David to Rome, where he was influenced by the remains of ancient art and by the works of Raphael. Goethe, who was at Rome when the picture mas finished, has recorded the deep impression made by his "Marius at Minturno." The last picture which he completed was his "Philoctetes on the Island of Lemnos."

DROUET, JEAN BAPTISTE (1763–1824), French revolutionary, was born at Ste.-Menehould, where his father was postmaster. The carriages conveying Louis XVI. and his family on their flight to the frontier stopped at his door on tbe evening of June 21, 1791; and the passengers were recognized by Drouet, who took steps which led to their arrest and detection on reaching Varennes. For this service he declined a reward. In Sept. 1792 he was elected deputy to the Convention. He voted the death of the king without appeal, showed implacable hostility to the Girondins, and proposed the slaughter of all English residents in France. He was captured at the siege of Maubeuge, and imprisoned at Spielberg till the close of 1795. He then became a member of the Council of Five Hundred, and was named secretary. Drouet was implicated in the conspiracy of Babeuf, and was imprisoned; but he made his escape into Switzerland, and thence to Teneriffe. There he took part in the successful resistance to the attempt of Nelson on the island, in 1797, and later visited India. The First Empire found in him a docile sub-prefect of Ste.-Menehould. After the second Restoration he had to leave France. Returning secretly he settled at Mâcon, under the name of Merger and a guise of piety, and died there on April 11, 1824.

See G. Lenôtre, *Le Drnme de Varennes* (Paris, 1905).

DROWNING AND LIFE SAVING. To "drown" is to suffer or inflict death by submersion in water, or figuratively to submerge entirely in water or some other liquid. As a form of capital punishment it persisted in Europe till the 18th century.

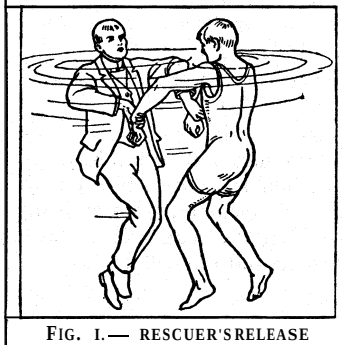

FIG. 1.— RESCUER'S RELEASE
When held by wrists, rescuer should turn both arms simultaneously against drowning person's thumbs

Death from drowning is the result of asphyxia from inhalation of water during the violent efforts to breathe. Owing to lack of oxygen and accumulation of carbonic acid gas the blood soon becomes intensely venous and by poisoning the respiratory and cardiac centres in the medulla oblongata brings them to a standstill. Sometimes death occurs from primary syncope.

When a person unable to swim falls into the water, he usually rises to the surface, throws up his arms and calls for help. This, with the water swallowed, will make him sink. Struggling will be prolonged a few seconds, and then probably cease for a time, allowing him to rise again, though perhaps not sufficiently high to get another breath of air. If still conscious, he will renew his struggle, more feebly perhaps, but with the same result. As soon as insensibility occurs, the body sinks altogether, owing to the loss of air and the filling of the stomach with water. The general belief that a drowning person must rise three times before he finally sinks is a fallacy.

FIG. 2.—RESCUER'S RELEASE
If clutched around the neck, rescuer places one hand behind drowning person's back and, with palm of other hand on chin, pushes away the head

Before diving in to rescue a drowning person the boots and heavy clothing should be discarded if possible, and where a leap has to be made from a height, or the depth of the water is unknown, it is best to drop in feet first. Where weeds abound progress should be made in the direction of the stream. The danger of being clutched by a drowning man is best avoided by approaching him from behind, but if seized, the rescuer must keep uppermost, as this makes the effort of effecting a release much easier.

If the rescuer be held by the wrists, he must turn both arms simultaneously against the drowning person's thumbs, and bring his arms at right angles to the body (fig. 1). If he be clutched round the neck he must take a deep breath, lean well over the drowning person, place one hand in the small of his back and pass the other over the drowning person's arm, pinch the nostrils and at the same time with the palm of the hand on the chin push the head away with all possible force (fig. 2). One of the most dangerous clutches is that round the body and arms or round the body only. When so tackled the rescuer should lean well over the drowning person, take a breath as before, and either withdraw both arms in an upward direction in front of his body, or else act in the same way as when releasing oneself when clutched

round the neck. In any case one hand must be placed on the drowning man's shoulder, and the palm of the other hand against his chin, and at the same time one knee should be brought up against the lower part of his chest. Then, with a strong and sudden push, the arms and legs should be stretched out straight and the whole weight of the body thrown backwards. This sudden and totally unexpected action will break the clutch (fig. 3).

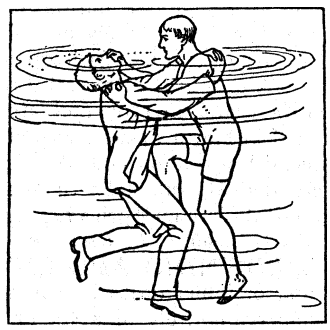

FIG. 3.—RESCUER'S RELEASE
If seized round body and arms, place one hand on drowning man's shoulder, the other on his chin, and press knee against lower part of his chest. Then push backward suddenly

There are several methods of carrying a person through the water, the easiest being that applied to a quiescent person. Then the person assisted should place his arms on the rescuer's shoulders, close to the neck, with the arms at full stretch, lie on his back perfectly still, with the head well back. The rescuer will then be uppermost, and having his arms and legs free can, with the breast stroke, make rapid progress to the shore (fig. 4).

When a drowning person is not struggling, but seems likely to do so when approached, the best method is to turn him on his back, place the hands on either side of his face and swim with the back stroke, always taking care to keep the man's face above water (fig. 5). If the man be struggling and difficult to manage, he should be turned on his back as before, and a firm hold taken of his arms just above his elbows. Then the man's arms should be drawn up at right angles to his body and the rescuer should use the back stroke (fig. 6). If the arms be difficult to grasp, or the struggling prevent a firm hold, the rescuer should slip his hands under the armpits of the drowning person, and place them on his chest or round his arms, which he should raise at right angles to his body (fig. 7). In carrying a person through the water, it is advantageous to keep his elbows well out from the sides, as this expands the chest, inflates the lungs and adds to his buoyancy. If the drowning person has sunk the rescuer should look for bubbles before diving in and remember that in running water they rise obliquely. When a drowning person is recovered on the bottom, the rescuer should seize him by the head or shoulders, place the left foot on the ground and the right knee in the small of his back, and then, with a vigorous push, come to the surface.

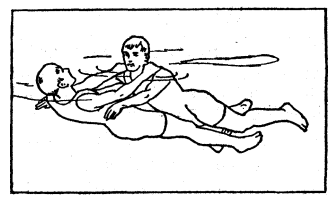

FIG. 4.— METHOD OF RESCUING A QUIESCENT PERSON
The drowning person should lie on his back, with arms on rescuer's shoulders. Rescuer is uppermost and, with arms and legs free, can use the breast stroke

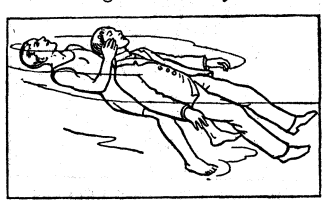

FIG. 5.—METHOD OF RESCUING PERSON LIKELY TO STRUGGLE
Turn drowning person on back and, keeping his head above water, use back stroke

When the rescuer reaches land with an insensible person, artificial respiration must be employed. The system first in vogue (1774) was inserting the pipe of a pair of bellows into one nostril and closing the other. Air was forced into the lungs and then expelled by pressing the chest, thus imitating respiration. About the middle of the 19th century came the methods of Marshall Hall, of Silvester, and of Howard. These have been superseded by the simpler and more effective method, worked out experimentally by Professor E. A. Schäfer of Edinburgh and adopted by the Royal Life Saving Society.

Professor Schafer describes the method as follows: Lay the subject face downwards on the ground, then without stopping to remove the clothing the operator should at once place himself in position astride or at one side of the subject, facing his head and kneeling upon one or both knees. He then places his hands flat over the lower part of the back (on the lowest ribs), one on each side (fig. 8), and then gradually throws the weight of his body forward onto them so as to produce firm pressure (fig. 9)—which must not be violent—upon the patient's chest. By this means the air, and water if any, are driven out of the patient's lungs. Immediately thereafter the operator raises his body slowly so as to remove the pressure, but the hands are left in position. This

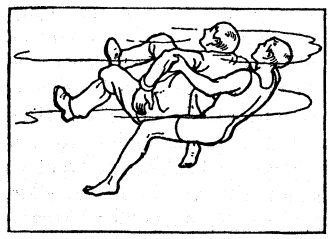

FIG. 6.—METHOD OF RESCUING PERSON WHO STRUGGLES VIOLENTLY
Turn drowning person on back and support his arms above elbow in a *lifted position*. Use back stroke

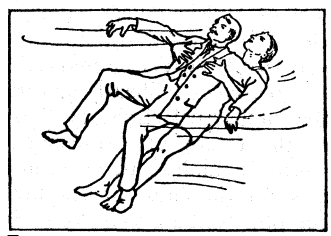

FIG. 7.—RESCUING PERSON WHO RESISTS METHOD SHOWN IN FIG. 6
Slip hands under armpits, then raise arms at right angles to body and proceed as before

forward and backward movement is repeated every four or five seconds; in other words, the body of the operator is swayed slowly forwards and backwards upon the arms from twelve to fifteen

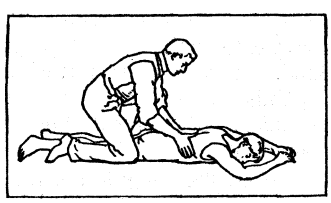

FIG. 8.—ARTIFICIAL RESPIRATION, 1ST MOVEMENT (SCHÄFER METHOD)
Straddle person, face downward and place hands on lower part of back

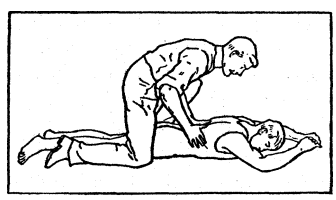

FIG. 9.—ARTIFICIAL RESPIRATION, 2ND MOVEMENT (SCHÄFER METHOD)
Throw body forward, producing firm pressure. Then resume first position

times a minute, and should be continued for at least half an hour, or until the natural respirations are resumed. Whilst one person is carrying out artificial respiration in this way, others may, if there be opportunity, busy themselves with applying hot flannels to the body and limbs, and hot bottles to the feet, but no attempt should be made to remove the wet clothing or to give any restoratives by the mouth until natural breathing has recommenced.

In his paper read before the Royal Society of Edinburgh in December, 1903, Professor Schäfer gave the following table of the relative exchanges of air under different methods:—

Mode of respiration.	Number per minute.	Amount of air exchanged per respiration.	Amount of air exchanged per minute.
		c.c.	c.c.
Natural respiration (supine)	13	489	6357
Natural respiration (prone)	12·5	422	5275
Prone (pressure), "Schafer"	13	520	6760
Supine (pressure), "Howard"	13·6	295	4012
Rolling (with pressure), "Marshall Hall"	13	254	3302
Rolling (without pressure), "Marshall Hall"	12	192	2304
Traction (with pressure), "Silvester"	12·8	178	2278

These experiments show that by far the most efficient method known of performing artificial respiration is that of intermittent pressure upon the lower ribs with the subject face downward. It is the easiest to perform, and has the further great advantage that it can be effectively carried out by one person. (*See* also ARTIFICIAL RESPIRATION.)

ing artificial respiration in man" (vol. 23, part i. *Proceedings of the Royal Society of Edinburgh)*; R. S. Bowles, *A Method for the Treatment of the Apparently Drowned* (1903); *Handbook of Instruction,* Royal Life Saving Society (1908).

DROYSEN, JOHANN GUSTAV (1808–1884), German historian, was born on July 6, 1808 at Treptow, Pomerania, son of an army chaplain. In his childhood Droysen witnessed some of the military operations during the War of Liberation, for his father was pastor at Greifenhagen, near Stettin, occupied by the French in 1813. The impressions of these early years laid the foundation of his ardent attachment to Prussia. He was educated at the gymnasium of Stettin and at the University of Berlin. Droysen occupied various positions in the schools as well as at the University of Berlin until 1840, and there his early works, on Alexander the Great and on Hellenism, were mainly written.

In 1840 Droysen succeeded F. C. Dahlmann (*q.v.*), professor of history at Kiel, and was drawn into the political movement for the defence of the rights of the Elbe duchies. In 1848 he was elected a member of the Frankfort parliament, and acted as secretary to the committee for drawing up the constitution. A determined supporter of Prussian ascendancy, he retired after the king of Prussia refused the imperial crown in 1849. In 1850, with Carl Samwer, he published a history of the dealings of Denmark with Schleswig-Holstein, *Die Herzogthümer Schleswig-Holstein und das Königreich Danemark seit dem Jahre 1806* (Hamburg, 1850; Eng. trans. 1850), a book formative of German public opinion on the rights of the duchies in their struggle with Denmark. After 1851 he had to leave Kiel, and he was appointed to a professorship at Jena; in 1859 he was called to Berlin, where he remained till his death. In 1851 he brought out his admirable biography of Count Yorck von Wartenburg (1851–52) and then began his great work on the *Geschichte der preussischen Politik* (7 vols., 1855–86). It forms a complete history of the growth of the Prussian monarchy down to the year 1756. This, like all Droysen's work, shows a strongly marked individuality, and a great power of tracing the manner in which important dynamic forces worked themselves out in history. Droysen died in Berlin on June 19, 1884. His eldest son, Gustav (1838–1908) wrote *Gustav Adolf* (Leipzig, 1869–70); *Herzog Bernhard von Weimar* (Leipzig, 1885); an admirable *Historischer Handatlas* (Leipzig, 1885), and several writings on various events of the Thirty Years' War.

See M. Duncker, *Johann Gustav Droysen, ein Nachruf (1885)*; and Dahlmann-Waitz, *Quellenkunde der deutschen Geschichte* (Leipzig, 1906).

DROZ, ANTOINE GUSTAVE (1832–1895), French man of letters, son of the sculptor J. A. Droz (1807–1872), was born in Paris. He was educated as an artist, and first exhibited in the Salon of 1857. A series of sketches dealing gaily and lightly with the intimacies of family life, published in the *Vie parisienne* and issued in book form as *Monsieur, Madame et Bébé* (1866, Eng. trans. 1887) won for the author immediate recognition and great success. *Entre nous* (1867) was built on a similar plan, and was later followed by a series of novels: *Le Cahier bleu de Mlle Cibot* (1868); *Autour d'une source* (1869); *Un Paquet de lettres* (1870); *Babolein* (1872); *Les Étangs* (1875); *L'Enfant* (1885); *Tristesses et sourires* (1884). Droz died on Oct. 22, 1895.

DROZ, FRANÇOIS-XAVIER JOSEPH (1773–1850), French writer on ethics and political science, was born at Besançon, of a legal family. He gained the Montyon prize in 1823 by his work *De la philosophie morale ou des différents systèmes sur la science de la vie.* The main doctrine inculcated in this treatise is that society will never be in a proper state till men have been educated to think of their duties and not of their rights. It was followed in 1825 by *Application de la morale à la philosophie et à la politique,* and in 1829 by *Economie politique, ou principes de la science des richesses,* which was edited by Michel Chevalier in 1854. His greatest work was a *Histoire du règne de Louis XVI* (3 vols., 1839–42). As he advanced in life Droz became more religious, and his last work was *Pensdes du Christianisme* (1842). He had been admitted to membership in the Academy some time during 1824.

See Guizot, *Discours acade'miques;* Montalembert, "Discours de réception," in *Me'moires de l'Académie française;* Sainte-Beuve, *Causeries du lundi,* t. iii.; Michel Chevalier, Notice prefixed to the *Economie politique.*

DROZ, NUMA (1844–1899), Swiss statesman, was born on Jan. 27, 1844, at La Chaux-de-Fonds. After teaching school, he became editor of *National Suisse* in 1864. Four years later he was made a member of the council of Neuchâtel, in 1875 of the Federal chamber, and in 1881 and again in 1887 was president of the Swiss Confederation. His works are *L'Instruction civique* (1886), *Essais économiques* (1895) and *Études et portraits politiques* (1895).

DRUDE, PAUL KARL LUDWIG (1863–1906), German physicist, was born at Brunswick on July 12, 1863. He studied at Gottingen, Freiburg and Berlin. Drude was extraordinary professor of physics at Leipzig (1894- goo), professor of physics at Giessen (1900–05), and finally, professor of physics at Berlin. His most important work was his application of Maxwell's electromagnetic theory, as developed by Herz, to the problems of light, and a series of papers appeared between 1896 and 1899. Some of these were on the theory of magneto-optical phenomena of iron, nickel and cobalt (1897), on the theory of anomalous dispersion (1898), on electric dispersion (1899), and on the optical constants of metals (1899). Later, Drude worked on electromagnetic oscillations. He also wrote two well-known books, which have passed through many editions and have been translated into English, *Physik des Äthers* (1894) and *Lehrbuch der Optik* (1900). In 1900 he succeeded Wiedemann as the editor of the *Annalen der Physik.* Drude committed suicide on July 5, 1906.

DRUG, a district and town of British India in the Chhattisgarh division of the Central Provinces. The district was formed in 1906 from portions of the districts of Bilaspur and Raipur (*qq.v.*). It has an area of 4,645 sq.m. and at that time the population, 676,000, showed a large decrease on the preceding census, but by 1931 it had recovered to 817,924. The district belongs to the Chhattisgarh rice plain and has the same undulating character, but contains more wheat land than its neighbours. Several irrigation storage reservoirs and the Tandula canal have been constructed by Government since the great famine of 1900. There are nine Zamindari estates in the district covering an area of 1,800 sq. miles.

Drug, the capital of the district, is the only town among 2,533 villages. Its population has greatly increased since it was made a district headquarters, namely, from 4,033 in 1901 to 13,172 in 1931. It is a station on the Bengal-Nagpur railway and a rice market has been established there, but its local industries are petty.

DRUG, any organic and inorganic substance used in the preparation of medicines, by itself or in combination with others, and either prepared by some method or used in a natural state (*see* PHARMACOLOGY and PHARMACOPOEIA). In a particular sense "drug" is often used synonymously for narcotics or poisonous substances, and hence "to drug" means to stupefy or poison.

DRUG ADDICTION may be defined as an overpowering impulse for narcotism or intoxication by any drug possessing narcotic or intoxicating properties. It is best exemplified by the overpowering influence possessed by opium and its preparations, and its alkaloids or derivatives such as morphine and heroin, and by cocaine and substances containing it. Persons who have become habituated to the continued use of these drugs find that they have become enslaved to them, and that it is with the greatest difficulty that their use can be abandoned. Addiction drugs cause very great mental and moral deterioration, usually progressive in character.

Drug addiction is by no means confined to the above-named drugs. Other examples are well known; thus, the barbituric acid derivatives (*q.v.*), the sulphonal group of hypnotics (*q.v.*), cannabis indica (Indian hemp, bhang or hashish), may give rise to addiction. It has been observed in the use of paraldehyde chloral, ether and chloroform.

It is with the first group of drugs that addiction is very dangerous and most marked, and where a habit is produced which it is most difficult to eradicate.

In Sept. 1924 a Departmental Committee was appointed by the British Minister of Health to enquire into morphine and heroin addiction, and specially to consider the circumstances under which these drugs may be supplied to persons suffering from addiction and the precautions necessary for the avoidance of abuse. This Committee took evidence and finally issued its report on Jan. 21, 1926.

Occurrence.—The universal opinion of those most competent to judge is that drug addiction is rare in Great Britain. In America special attention has been devoted to the subject during recent years and many official reports on it have been issued.

Laws and Regulations.—Drug addiction has become an international problem and the laws and regulations in Great Britain are not due to the special or peculiar needs of the country but are the reflection of international opinion and ideals.

The "opium problem" has been before the world for many years. Thus Warren Hastings, the first Governor General of India, in 1788 declared opium to be "a pernicious article of luxury which ought not to be permitted but for the purpose of foreign commerce only." The United States became directly concerned in the Far East opium problem when the Philippine Islands were ceded to them by Spain in 1898. The International Opium Commission of Shanghai was largely the result of President Roosevelt's initiative and in consequence of this the International Opium Convention at The Hague in 1911 and 1912 resulted. The recommendations of the Convention formed part of the Peace Treaty of Versailles and the consenting nations agreed to frame Acts dealing with the dangerous drugs under consideration.

As a result, in Britain "the Dangerous Drugs" Act was passed in Sept. 1920. In May 1921 regulations were passed dealing with the carrying out of the provisions of the Act and further minor regulations were made in 1921 and 1923. In May 1923 the Dangerous Drugs and Poisons Amendment Act was passed. Thus the motive factor for this legislation was the international problem and not the evil of drug addiction in Great Britain.

Legislation when once passed by Parliament in Great Britain is, as a matter of course, rigidly enforced, and in consequence of this the regulations as regards the sale of dangerous drugs are efficiently carried out in Britain. Pharmacists and medical practitioners have, it is true, experienced great difficulty and inconvenience in the carrying out of the many regulations entailed, but they have loyally complied with their requirements.

Classes of Drug Addicts.—Drug addiction occurs in two classes of persons:

(1) Those who might be called the *vicious group*, which includes those who devote their lives to so-called pleasure seeking and the search for new excitements and sensations. Cocaine, morphine and heroin employed either hypodermically or orally or inhaled as snuff, are the drugs commonly used by this type of addict. This group is found in London and the great cities. Fortunately it is small and its influence is not extensive. Addiction of this type requires to be stamped out but it is not such a serious menace to the national well-being as that affecting the main population.

(2) Members of the *general population*. The commonest cause of drug addiction in the ordinary case is undoubtedly prescription of the drug for medical purposes. This may arise from *(a)* necessity of relieving pain; (b) the necessity of inducing sleep.

The Relief of Pain.—In the former case it is necessary often after a surgical operation, particularly abdominal cases, for a hypodermic injection of morphine or heroin to be prescribed. This is a perfectly desirable and legitimate procedure but use of the narcotic drug should be limited to a few administrations. Otherwise the risk of the formation of an addiction habit is great.

Again for the relief of pain of a neuralgic type the drugs morphine and heroin often act as a charm. But should they be continuously prescribed an addiction habit is almost certain to develop. Much to be preferred therefore is the employment of other drugs such as phenacetin, pyramidon and aspirin whose use is not attended with this danger.

Employment in Insomnia Cases.—In certain conditions it may be necessary to ensure sleep at all costs and for this purpose the administration of morphine or heroin may be advisable. The frequent repetition of this is to be avoided. Too often the terrors of insomnia are impressed upon the patient and he comes to regard the administration of a hypnotic as part of his daily life. The habitual use of hypnotics is greatly to be deprecated. It is entirely unnecessary, and no instance has yet been recorded of a fatal result from insomnia in human beings. The terrors of insomnia are not to be compared with those of drug addiction, and a little sleep following natural methods of treatment is of far greater benefit than the more prolonged abnormal condition of sleep produced by narcotic drugs.

Psychological Aspects.—The psycho-neurotic factor looms largely in drug addiction. Given an exciting cause—for example the repeated daily administration of a narcotic drug—the danger of addiction is much greater in patients with a neuropathic temperament. **A** family history of insanity, neurosis or of alcoholism is usual amongst drug addicts, and they themselves previous to their addiction often present signs of nervous instability.

Often a psychological complex of a depressing type exists in patients of this group who are affected with mental worry and anxiety. There is a subconscious cry for relief from mental suffering. This is temporarily obtained by means of a narcotic drug, and as surely as this occurs so inevitably does a still deeper stage of mental agony develop which is only to be relieved by the further resort to the narcotic and so drug addiction becomes established.

Toxaemic conditions due to toxic absorption from septic teeth, or to some naso-pharyngeal infection such as septic tonsils or an infected antrum, may lead to low conditions of physical or mental health and so establish a neuropathic condition which prepares the soil for drug addiction. Such patients should be treated on general lines and their focus of infection eradicated as far as possible. The symptoms should not be masked by the administration of alcohol or addiction drugs.

One Drug Habit Leads to **Another.**—When an addiction habit has developed for one drug, *e.g.* morphine, there is a great tendency for the patient to switch off from the primary addiction drug and to take as an alternative another drug such as cocaine. Alcohol addiction is frequently combined with that of morphine or heroin or cocaine.

Symptoms.—After the daily use of an addiction drug such as morphine, heroin or cocaine for about four weeks in most cases an addiction habit develops. The patient's health becomes impaired, the complexion sallow, the tongue furred, the skin irritable, particularly in the case of cocaine where a constant sense of itching and discomfort arises. The mental and moral sense become affected. **A** constant state of deep mental depression results which is only very temporarily relieved by further and increasing doses of the drug. Appointments are not kept, all responsibilities are neglected, and no reliance can be placed on any statements made, since drug addicts usually exhibit an utter disregard for truth.

Withdrawal symptoms occur when the drug is withheld in cases of confirmed addiction; these comprise tremors, vomiting, diarrhoea and even collapse. Pains in the body and limbs may occur and mental symptoms of restlessness and apparent mental sufferingare exhibited in a marked degree. The symptoms at once disappear after a further dose of the drug but recur when its effect passes off. Withdrawal symptoms are most marked in the cases of morphine and heroin, but they occur also, although to a somewhat less degree, in the case of cocaine. Withdrawal symptoms in the case of drug addiction are now accepted as forming a definite symptom complex of characteristic type. And objective symptoms of definite type show that the symptoms are not purposely assumed by the patient with the object of obtaining further doses of the drug.

Treatment.—Drug addiction is to be regarded as a disease rather than a vice. When it has developed it requires special care and medical treatment just as would a case of organic disease such as typhoid fever. The first and most essential part of the treatment is complete and thorough supervision and care of the patient. This can only be ensured by treatment in an institution

or nursing home. In early cases sudden withdrawal of the drug may be adopted, but where the addiction has continued for long periods, such as a year or more, gradual withdrawal is advisable so that after one to three weeks no drug is being given. A long further period of treatment is still required to improve the general health of the patient and above all to educate and restore his will power. For this purpose psychotherapeutic treatment (*q.v.*) is of value. The prospect of cure depends on the extent to which the will power of the patient is restored and on the establishment of confidence and hopefulness so that he is able to resist the desire to take the drug again.

In some cases of drug addiction hyoscine treatment has been advocated. This consists in the hypodermic administration of frequently repeated small doses of hyoscine so that a condition of mild delirium lasting from 36 to 48 hours is produced. When this passes off no addiction drug is given. The hyoscine treatment is not free from risk, since some fatal cases from its use have been recorded and in general it does not appear to possess any advantages over the carefully regulated gradual withdrawal method.

Drug Addiction **of** Long Duration.— When an addiction drug such as morphine or heroin has been taken over a period of many years the prospect of cure is not good. In such cases it is probable that organic changes have resulted in the nervous system and other changes of a biochemical nature have occurred which alter the metabolic processes of the body. Where repeated attempts at cure have failed the situation has to be faced that the only way in which a person can carry on his normal avocations is to allow a minimal daily allowance of the drug to which he is addicted. The allowance should be so fixed that increase in dosage is prevented. Patients of this type are often able to carry on their daily work on a fixed allowance of the drug and to keep in fair health for years.

The Departmental Committee above referred to accepted the view that certain cases of drug addiction of long duration could only be regarded as incurable and that in such cases a daily minimal allowance of the addiction drug might wisely be permitted.

Prevention.— There is no doubt that the dangerous drugs regulations, irksome as they are to pharmacists and physicians, have done much in reducing drug addiction. Their rigid enforcement must prevent the development of fresh cases of addiction owing to the great difficulties entailed in obtaining constant supplies of the drugs in question.

The control of production of opium and of coca leaves, and the alkaloids obtained from them, strikes at the very root of the problem. An international control of the production of the "dangerous drugs" is required but has not yet been attained. There should be no surplus available for non-medicinal and non-scientific purposes.

Care on the part of medical practitioners in the prescription of drugs of addiction is a most important factor in prevention of the drug habit. and there is every reason to believe that in point of fact the utmost care is being taken in this respect.

Illegal trafficking in dangerous drugs such as morphine, heroin and cocaine undoubtedly occurs to some extent, and this must be stamped out at all costs. Fortunately the full penal powers given by The Dangerous Drugs Acts are such as to render this trafficking a most dangerous pursuit, and the number of those actually engaged in it in Great Britain is consequently very small.

In the United States, about 95% of all narcotic addicts use opium in the form of heroin or morphine. Heroin addicts are found only in a few States along the Atlantic seaboard, and morphine addicts outnumber them by about 12 to 1. Opium smoking was once fairly common, but is now confined to a few Chinese in the large cities. Cocaine is used sporadically by about 50% of the more dissipated type of morphine and heroin addicts, but continued addiction to cocaine alone is very unusual. Most normal subjects, who became addicted years ago through self-medication with opium, and many of the less unstable of the abnormal group have been cured permanently, leaving a very unstable group who constantly relapse because of the instability that was responsible for their original addiction. Many of these have been "cured" from 10 to 20 times.

A study of delinquent addicts has shown that their original psychopathic character, rather than mental and moral deterioration due to the use of narcotics, is responsible for the offences they commit; but some of them lie and steal in order to supply themselves with opium. Normal addicts do not suffer appreciable mental or moral deterioration. In hospitals for the insane only a small fraction of one per cent have psychoses attributable to the use of narcotics.

The trend of drug addiction was upward from 1860 to about 1900, at which time addicts totalled 250,000 to 300,000. The number remained practically stationary during the next decade, after which drug addiction declined to about one-third what it used to be. In 1924 the division of the Bureau of Internal Revenue having charge of narcotic law enforcement estimated the total number of addicts to be 110,000; the U S. Public Health Service set the figure as between 110,000 and 150,000. In 1926 the number was estimated at less than 95,000 and it is constantly declining. The United States enforces all the recommendations of the Hague International Opium Convention of Jan. 23, 1912. In 1909 the Federal Government forbade the importation of smoking opium, but the first restrictive legislation was the Ohio Anti-Opium Smoking Law of 1885. Practically all other anti-narcotic legislation has been enacted since 1897. By 1912 every State except Delaware had an anti-narcotic law. At present every State and Territory has such a law, but the most important one is the Federal anti-narcotic law known as the Harrison Act, which became effective in 1915. It has been amended and supplemented so that the Federal Government now traces opium and cocaine from the time a permit to import the crude drug is issued, until the finished product reaches the consumer. Violations of the narcotic laws are punished by large fines and imprisonment of from one to ten years.

(L. K.)

DRUIDISM was the faith of the Celtic inhabitants of Gaul until the time of the Romanization of their country, and of the Celtic population of the British Isles either up to the time of the Romanization of Britain, or, in parts remote from Roman influence, up to the period of the introduction of Christianity. From the standpoint of the available sources the subject presents two distinct fields for enquiry, the first being pre-Roman and Roman Gaul, and the second pre-Christian and early Christian Ireland and Pictland. In the present state of knowledge it is difficult to assess the interrelation of druidic paganism.

Gaul.— The earliest mention of druids is reported by Diogenes Laertius (Vitae, intro., 1 and 5) and was found in a lost work by a Greek, Sotion of Alexandria, written about 200 B.C., a date when the greater part of Gaul had been Celtic for over two centuries and the Greek colonies had been even longer established on the

south coast. The Gallic druids subsequently described by Caesar were an ancient order of religious officials, for when Sotion wrote they already possessed a reputation as philosophers in the outside world. Caesar's account, however, is the mainspring of our information, and it is an especially valuable document as Caesar's confidante and friend, the Aeduan noble Divitiacus, was himself a druid. Caesar's description of the druids (B.G., *vi.)* emphasizes their political and judicial functions. Although they officiated at sacrifices and taught the philosophy of their religion, they were more than priests; thus at the annual assembly of the order near Chartres, it was not to worship nor to sacrifice that the people came from afar, but to present their disputes for lawful trial. Moreover, it was not only minor quarrels that the druids decided, for their functions included the investigation of the gravest criminal charges and even inter-tribal disputes. This, together with the fact that they acknowledged the authority of an archdruid invested with supreme power, shows that their system was conceived on a national basis and was independent of ordinary inter-tribal jealousy; and if we add to this political advantage their influence over educated public opinion as the chief instructors of the young, and, finally, the formidable religious sanction behind their decrees, it is evident that before the clash with Rome the druids must very largely have controlled the civil administration of Gaul.

Of druidism itself, little is said except that the druids taught the immortality of the human soul, maintaining that it passed into other bodies after death. This belief was identified by later writers, such as Diodorus Siculus, with the Pythagorean doctrine, but probably incorrectly; for there is no evidence that the druidic belief included the notion of a chain of successive lives as a means of ethical purification, or that it was governed by a doctrine of moral retribution having the liberation of the soul as the ultimate hope, and this seems to reduce the druidic creed to the level of ordinary religious speculation. Of the theology of druidism, Caesar tells us that the Gauls, following the druidic teaching, claimed descent from a god corresponding with Dis in the Latin pantheon, and it is possible that they regarded him as a Supreme Being; he also adds that they worshipped Mercury, Apollo, Mars, Jupiter and Minerva, and had much the same notion about these deities as the rest of the world. In short, Caesar's remarks imply that there was nothing in the druidic creed, apart from the doctrine of immortality, that made their faith extraordinary, so that it may be assumed that druidism professed all the known tenets of ancient Celtic religion and that the gods of the druids were the familiar and multifarious deities of the Celtic pantheon. The philosophy of druidism does not seem to have survived the test of Roman acquaintance, and was doubtless a mixture of astrology and mythical cosmogony. Cicero *(De Divin.* i., xli., *go)* says that Divitiacus boasted a knowledge of *physiologia,* but Pliny decided eventually (N.H. xxx., *13)* that the lore of the druids was little else than a bundle of superstitions. Of the religious rites themselves, Pliny (N.H. xvi., 249) has given an impressive account of the ceremony of culling the mistletoe, and Diodorus Siculus (*Hist.,* v., 31, 2–5) describes their divinations by means of the slaughter of a human victim, Caesar having already mentioned the burning alive of men in wicker cages. It is likely that these victims were malefactors, and it is accordingly possible that such sacrifices were rather occasional national purgings than the common practice of the druids.

The advent of the Romans quickly led to the downfall of the druidic order. The rebellion of Vercingetorix must have ended their inter-tribal organization, since some of the tribes held aloof or took the Roman side; furthermore, at the beginning of the Christian era their cruel practices brought the druids into direct conflict with Rome, and led, finally, to their official suppression. At the end of the 1st century their status had sunk to that of mere magicians, and in the 2nd century there is no reference to them. A poem of Ausonius, however, shows that in the 4th century there were still people in Gaul who boasted of druidic descent.

British Isles.—There is one mention of druids in Great Britain as contemporaries of the Gallic clergy, and that is the reference to them by Tacitus *(Annals,* xiv., *30)* from which we learn that there were elders of that name in Anglesey in A.D. 61; but there is no mention of the druids in the whole of the history of Roman England, and it may be questioned whether there ever were any druids in the eastern provinces that had been subjected, before the Roman invasion, to German influence. On the other hand, there were certainly druids in Ireland and Scotland, and there is no reason to doubt that the order reaches back in antiquity at least to the 1st or 2nd century B.C.; the word *draí* (druid) can only be traced to the 8th century Irish glosses, but there is a strong tradition current in Irish literature that the druids and their lore (*druidecht*) were either of an aboriginal or Pictish origin. As to Wales, apart from the existence of druids in Anglesey, there is little to be said except that the earliest of the bards (the Cynfeirdd) very occasionally called themselves *derwyddon.*

The Irish druid was a notable person, figuring in the earliest sagas as prophet, teacher and magician; he did not possess, nevertheless, the judicial powers ascribed by Caesar to the Gallic druids, nor does he seem to have been a member of a national college with an archdruid at its head. Further, there is no mention in any of the texts of the Irish druids presiding at sacrifices, though they are said to have conducted idolatrous worship and to have celebrated funeral and baptismal rites. They are best described as seers who were, for the most part, sycophants of princes.

Origin.—Some confusion is avoided if we distinguish between the origin of the druids and the origin of druidism. Of the officials themselves, it seems most likely that their order was purely Celtic, and that it originated in Gaul, perhaps as a result of contact with the developed society of Greece; but druidism, on the other hand, is probably in its simplest terms the pre-Celtic and aboriginal faith of Gaul and the British Isles that was adopted with little modification by the migrating Celts. It is easy to understand that this faith might acquire the special distinction of antiquity in remote districts, such as Britain, and this view would explain the belief expressed to Caesar that the *disciplina* of druidism was of insular origin.

The etymology of the word *druid* is still doubtful, but the old orthodox view taking *dru* as a strengthening prefix and *uid* as meaning *knowing,* whereby the druid was a *very learned* man, has been abandoned in favour of a derivation from an oak-word. Pliny's derivation from Greek δεῦς is, however, improbable.

A great revival of interest in the druids, largely promulgated by the archaeological theories of Aubrey and Stukeley, and by Romanticism generally, took place in the 18th and 19th centuries. One outcome of this interest was the invention of *neo-druidism,* an extravagant mixture of helio-arkite theology and Welsh bardic lore, and another result is that more than one society has professed itself as inheriting the traditional knowledge and faith of the early druids. The *Ancient Order of Druids,* however, a friendly society founded in the 18th century, makes no such claim.

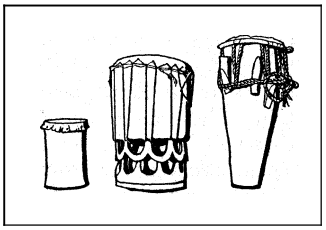
DRUMS FROM NEW MEXICO

DRUM, the name given to a well-known percussion musical instrument and also to many objects resembling it in shape. Early forms of the word are *drome* or *dromme,* a word common to many Teut. languages, *cf.* Dan. *tromme,* Ger. *Trommel;* the word is ultimately the same as "trumpet," and is probably onomatopoeic in origin; it appears late in Eng. about the middle of the 16th century. The word is used, in connection with machinery, of a revolving cylinder, round which belting is passed;

of the tympanum or cylindrically-shaped middle ear, and specially of the membrane that closes the external auditory meatus; and in architecture, of the sub-structure of a dome when raised to some height above the pendentives. The term is also applied to the circular blocks of stone employed in columns of large dimensions.

In music the drum (Fr. tambour; Ger. *Trommel;* Ital. *tamburo*) is an instrument of percussion common in some form to all nations and ages. It consists of a frame or vessel forming a resonant cavity, over one or both ends of which is stretched a skin or vellum set in vibration by direct percussion of hand or stick. Drums fall into two divisions according to the nature of their sonority:—(1) instruments producing sounds of definite musical pitch, and qualified thereby to take part in the harmony of the orchestra, such as the kettle drum (*q.v.*); (2) instruments of indefinite pitch, and therefore excluded from the harmony of the orchestra; such are the bass drum, the side or snare drum, the tenor drum, the tambourine, all used for marking the rhythm and adding tone colour.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

LEFT TO RIGHT: THE AFRICAN DRUM, HAWAIIAN DRUM AND SOUTH AMERICAN DRUM

The bass drum or Turkish drum (Fr, grosse *caisse;* Ger. Grosse *Trommel;* Ital. gran cassa or tamburo grande) consists of a short cylinder of very wide diameter covered at both ends by vellum, the tension of which is controlled by means of leather braces. It gives out no definite note, but has a place in every orchestra, although it is used but sparingly to accentuate the rhythm. Wagner did not once score for the bass drum after he composed *Rienzi.*

The side or snare drum (Fr. tambour *militaire;* Ger. *Militär-trommel;* Ital. tamburo *militare*) is an instrument consisting of a small wooden or brass cylinder with a vellum at each end. Across the lower vellum are stretched two or more catgut strings called snares, which produce a rattling sound at each stroke on the upper head, owing to the sympathetic vibration of the lower head, which jars against the snares. The presence of the snares gives the side drum its peculiar timbre, changing the nature of the vibrations, for the snares form a kind of nodal contact, inducing double the number of vibrations, and a sound approximately an octave higher than would be the case were the heads left to vibrate freely.

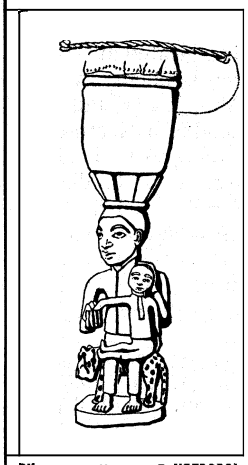
A JAVANESE DRUM

The tenor *drum* (Fr. caisse roulante; Ger. Roll- or *Rühr-trommel;* Ital. *tamburo rulante*) is similar to the side drum, but has a larger cylinder of wood and no snares; consequently its timbre lacks the brilliancy and incisiveness of the side drum.

The popularity of all kinds of drums in the most ancient civilizations is established beyond a doubt by the numerous representations of the instrument in a variety of shapes and sizes on the monuments and paintings of Egypt, Assyria, India, and Persia. The *tympanon,* under which name seem to have been included tambourines and kettle drums, as well as the dulcimer (during the middle ages), was in use among Greeks and Romans chiefly in the worship of Cybele and Bacchus; it was introduced through the medium of the Roman civilization into western Europe. It is often said that the drum was introduced by the crusaders, but it was certainly known in England long before the crusades, for Bede (*Musica practica*) mentions it in his list of instruments, and Cassiodorus (ii. p. 507) describes it. An actual drum with two curved drum-sticks belonging to the ancient Egyptians was found during the excavations at Thebes in 1823.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

FRENCH CONGO DRUM

The side drum was admitted into the orchestra in the 17th century, when Marais (1636–1728) scored for it in his opera Alcione.

DRUM, the name given to certain fishes belonging to the family Sciaenidae, so called because they make a peculiar grunting noise. The sea drum (Pogonias cromis), found along the Atlantic coasts of North and South America, attains a length of four feet. The body, which is oblong, with an elevated back, has large scales except on the breast. The throat is paved with stony teeth adapted for crushing shell-fish. In colour the sea drum is brownish-grey or brownish-red, the young being marked with broad, vertical bands of a darker shade. It is not valued for food and, as it destroys great quantities of oysters, is much dislikedby oystermen. The very similar freshwater drum (*Aplodinotus grunniens*), called also sheep-head and thunder pumper, is a greyish, silvery fish sometimes attaining $3\frac{1}{2}$ ft. in length and 50 lb. in weight. It occurs from Georgia and Texas to the Great Lakes but is especially abundant in the streams and lakes of the Mississippi valley. Its scales are thin and deep, with the larger ones on the breast. The freshwater drum is a popular food fish in the South but is little used in the North.

In architecture, a drum is a vertical wall, usually cylindrical, supporting a dome, commonly limited to walls carried at a considerable height by pendentives, or similar forms. The drum first appears in a developed form in Byzantine architecture (see BYZANTINE AND ROMANESQUE ARCHITECTURE). It later became a characteristic feature of almost all Renaissance dome design (see DOME).

DRUMMOND, HENRY (1786–1860), English banker, politician and writer, best known as one of the founders of the Catholic Apostolic or "Irvingite" Church, was born at the Grange, near Alresford, Hants., on Dec. 5, 1786, the eldest son of Henry Drummond, a prominent London banker. He was educated at Harrow and at Christ Church, Oxford. From 1847 until his death he represented West Surrey in parliament. In 1817 he met Robert Haldane at Geneva, and continued his movement against the Socinian tendencies then prevalent there. In later years he was intimately associated with the origin and spread of the Catholic Apostolic Church. Meetings of those who sympathized with the views of Edward Irving were held for the study of prophesy at Drummond's seat, Albury Park, in Surrey; he contributed very liberally to the funds of the new church; and he became one of its leading office-bearers, visiting Scotland as an "apostle" and being ordained as an "angel" for that kingdom. He died on Feb. 20, 1860. His works include Social Duties on Christian Principles (1830); Abstract *Principles* of *Revealed* Religion (1844); *The* Fate of Christendom (3rd ed. 1854); Discourses on the *true Definition* of the *Church* (1858); and Speeches in Parliament (ed. Lord Lovaine, 1860).

DRUMMOND, HENRY (1851–1897), Scottish evangelical writer and lecturer, was born in Stirling on Aug. 17, 1851. He was educated at Edinburgh university, and in 1877 became lecturer on science in the Free Church college, Glasgow. His principal work was Natural Law in the Spiritual *World* (1883), the argument of which was that the scientific principle of continuity extended from the physical world to the spiritual. In 1888 he published Tropical Africa, a valuable digest of information based on a visit to Africa in 1883. In 1890 he travelled in Australia, and in 1893

delivered the Lowell Lectures at Boston, which were printed in 1894 under the title of *The Ascent of Man*, in which he argued that the disinterested care and compassion of animals for each other played an important part in effecting "the survival of the fittest," a thesis previously maintained by Prof. John Fiske. Drummond died on March 11, 1897.

See the *Life* by Sir G. A. Smith (1898).

DRUMMOND, JAMES (1835–1918), Unitarian scholar, was born in Dublin on May 14, 1835, and was educated at Trinity college, Dublin, and Manchester New college, London. In 1860 he became pastor of Cross Street chapel, Manchester, but nine years later returned to his old college in London as lecturer in biblical and historical theology. From 1885 to 1906 he held the principalship, moving with the college to Oxford where he died on June 13, 1918. As a Unitarian, Drummond advocated doctrinal freedom. He regarded Christ as the highest revelation from God but rejected the Resurrection and the nature miracles. His acceptance of the Johannine authorship of the fourth gospel is elaborated in his *Inquiry into the Character and Authorship of the Fourth Gospel* (1903).

His other chief works ara *The Jewish Messiah* (1877); *Philo-Judaeus* (1888); *Via, Veritas, Vita* (Hibbert lectures, 1894), and *Studies in Christian Doctrine* (1908). His *Pauline Meditations*, published posthumously in 1919, has a memorial introduction.

DRUMMOND, SIR JAMES ERIC (16th EARL OF PERTH) (1876–), British statesman, first secretary-general of League of Nations, half-brother of the 15th earl of Perth, was educated at Bedford Grammar school and Eton, and entered the British Foreign Office in April 1900. Later he became private secretary to the prime minister, Mr. Asquith, to Sir Edward Grey, and to Mr. Balfour during his term of office as foreign secretary. He accompanied Balfour on his special mission to the United States in 1917 and remained with him during the first months of the Peace Conference in Paris, until, on the proposal of President Wilson, he was appointed secretary-general of the League.

The appointment lasted from the acceptance of the text of the Covenant, April 29, 1919, until 1933, when Drummond became British ambassador in Rome.

Although the treaty was not signed and did not in fact come into force until Jan. 1920, the new secretary-general began immediately to organize the Secretariat of the League. Several different systems had been suggested; but Drummond decided from the first that it must be a basic principle of the new organization that none of its members should be there as representatives of the interests of their own countries, but should form an international civil service, each member of which should consider himself as the servant of the League as a whole, and as bound to do his best to carry out its decisions with regard to national interests or desires.

Sir Eric Drummond made it his chief aim to establish the organization on a basis of unimpeachable solidarity. Following the traditions of the British Civil Service he adopted the principle that the duty of the Secretariat was to act strictly in accordance with the decisions taken by the responsible authorities, *i.e.*, by the members of the League acting through their constitutional organs, and to avoid all action which was not clearly based on authority constitutionally given. Drummond was ambassador to Rome from 1933 to 1939, and was created G.C.M.G. in 1934. He served as chief adviser on foreign publicity of the Ministry of Information in 1939–40.

He succeeded as 16th earl of Perth in 1937, and became a representative peer of Scotland in 1941.

DRUMMOND, THOMAS (1797–1840), British inventor and administrator, was born at Edinburgh, on Oct. 10, 1797, and was educated at the high school there. He was appointed to a cadetship at the Royal Military Academy, Woolwich, in 1813; and in 1815 he entered the Royal Engineers. In 1820 he received an appointment on the trigonometrical survey of Great Britain. In 1825, when he was assisting T. F. Colby in the Irish survey, his lime-light apparatus ("Drummond light") enabled observations to be completed between Divis mountain, near Belfast, and Slieve Snaght, a distance of 67 miles. About the same time he also devised an improved heliostat, and in 1829 he was employed in adapting his light for lighthouse purposes. In 1835 he was made under-secretary of State for Ireland, where he proved himself a most successful administrator. It was he who in 1838 told the Irish landlords that "property has its duties as well as its rights." In 1836 he proposed the appointment of a commission on railways in Ireland, and took a large share in its work. Drummond died at Dublin on April 15, 1840.

See J. F. M'Lennan, *Life of Thomas Drummond* (1867); *R.* Barry O'Brien, *Life and Letters of Thomas Drummond* (1889).

DRUMMOND, WILLIAM (1585–1649), called "of Hawthornden," Scottish poet, was born at Hawthornden, near Edinburgh, the son of John Drummond, first laird of Hawthornden. Drummond received his early education at the high school of Edinburgh, and graduated in July 1605 as M.A. of the recently founded university of Edinburgh. He spent two years at Bourges and Paris in the study of law; but in 1609, he was again in Scotland, where, by the death of his father in 1610, he became laird of Hawthornden. In 1612 began his correspondence with Sir William Alexander of Menstrie, afterwards earl of Stirling (*q.v.*), which ripened into a life-long friendship.

Drummond's first poem appeared in 1613, an elegy on the death of Henry, prince of Wales, called *Teares on the Death of Meliades (Moeliades*, 3rd. ed. 1616). In 1616, the year of Shakespeare's death, appeared *Poems; Amorous, Funerall, Divine, Pastorall: in Sonnets, Songs, Sextains, Madrigals*, being substantially the story of his love for Mary Cunningham of Barns, who was about to become his wife when she died in 1615. The poems bear marks of a close study of Sidney, and of the Italian poets. He sometimes translates direct from the Italian, especially from Marini. *Forth Feasting: A Panegyricke to the King's Most Excellent Majestie* (1617), a poem written in heroic couplets, celebrates James's visit to Scotland in that year. In 1618 Drummond began a correspondence with Michael Drayton. The two poets continued to write at intervals for 13 years, the last letter being dated in the year of Drayton's death. In the winter of 1618–19, Drummond had included Ben Jonson in his circle of literary friends, and at Christmas 1618 was honoured with a visit of a fortnight or more from the dramatist. The account of their conversations, long supposed to be lost, was discovered in the Advocates' Library, Edinburgh, by David Laing, and was edited for the Shakespeare Society in 1842. The publication of what was obviously intended merely for a private journal has given Jonson an undeserved reputation for harsh judgments, and has cast blame on Drummond for blackening his guest's memory.

In 1623 appeared *Flowers of Sion: By William Drummond of Hawthornedenne; to which is adjoyned his Cypresse Grove.* From 1625 till 1630 Drummond spent much of his time travelling on the Continent, but in 1627 he presented about 500 volumes to the library of the university of Edinburgh. In 1630 he again began to reside permanently at Hawthornden, and in 1632 married Elizabeth Logan, by whom he had five sons and four daughters. About 1635 he began his *History of Scotland during the Reigns of the Five Jameses*, a work which did not appear till 1655. His next work, entitled *Irene: or a Remonstrance for Concord, Amity, and Love amongst His Majesty's Subjects* (1638), embodies his political creed of submission to authority as the only logical refuge from democracy, which he hated. In 1639 he had to sign the Covenant in self-protection, but was uneasy under the burden, as several political squibs by him testify. In 1643 he published *Σκιαμαχία: or a Defence of a Petition tendered to the Lords of the Council of Scotland by certain Noblemen and Gentlemen*, a political pamphlet in support of those royalists in Scotland who wished to espouse the king's cause against the English parliament. Its burden is an invective on the intolerance of the then dominant Presbyterian clergy. His later works may be described briefly as royalist pamphlets, written with more or less caution, as the times required. Drummond took the part of Montrose; and a letter from the Royalist leader in 1646 acknowledged his services. He died on Dec. 4, 1649, and was buried in his parish church of Lasswade.

Drummond's most important works are the *Cypresse Grove* and the poems. *The Cypresse Grove* exhibits great wealth of illustra-

tion, and an extraordinary command of musical English. It is an essay on the folly of the fear of death. "This globe of the earth," says he, "which seemeth huge to us, in respect of the universe, and compared with that wide pavilion of heaven, is less than little, of no sensible quantity, and but as a point." This is one of Drummond's favourite moods; and he uses constantly in his poems such phrases as "the All," "this great All." Even in such of his poems as may be called more distinctively Christian, this philosophic conception is at work. Drummond was called "the Scottish Petrarch;" and his sonnets, which are the expression of a genuine passion, stand far above most of the contemporary Petrarcan imitations.

BIBLIOGRAPHY.—Drummond's *Poems*, with *Cypresse Grove*, the *History*, and a few of the minor tracts, were collected in 1656 and edited by Edward Phillips, Milton's nephew. *The Works of William Drummond, of Hawthornden* (1711), edited by Bishop Sage and Thomas Ruddiman, contains a life by the former, and some of the poet's letters. A handsome edition of the *Poems* was printed by the Maitland Club in 1832. Later editions are by Peter Cunningham (1833), by William R. Turnbull in "The Library of Old Authors" (1856), by W. C. Ward (1894) for "The Muses' Library," and by Prof. Kastner (Scot. Text Soc. 1913). The standard biography of Drummond is by David Masson (1873). Extracts from the Hawthornden mss. preserved in the Library of the Society of Antiquaries of Scotland were printed by David Laing in *Archaeologia Scotica*, vol. iv.

DRUMMOND, WILLIAM HENRY (1854–1907), Canadian poet, was born at Mohill in Co. Leitrim, Ireland, the son of an officer in the Royal Irish Constabulary, who emigrated with his family to Canada in about 1864. In 1869 Drummond obtained work as a telegraph operator at Bord-à-Plouffe on the Rivière des Prairies; but he afterwards studied medicine at Bishop's college, Lennoxville, where he took his degree in 1884. From 1888 he practised medicine in Montreal, where he wrote verse in his leisure time. In 1905 he left his Montreal practice to look after the Drummond mines which he owned in conjunction with his brothers. His poems, some of the best known of which are *The Habitant* (1897), Phil-0-Rum's *Canoe* (1898) and *Johnnie Courtneau* (1901) have been collected, with an introduction by Louis Fréchelte and an appreciation by Neil Munro (1912).

See J. F. Macdonald, *William Henry Drummond* (1925).

DRUMRIGHT, a city in one of the oil and gas fields of Creek county, Oklahoma, U.S.A., 60 mi. N.E. of Oklahoma City, near the Cimarron river, and served by the Santa Fe railway. The city was founded in 1912 and incorporated in 1914. By 1920 the population was 6,460 (94% native white), in 1930 it was 4,972 and in 1940, 4,303 by the federal census. The principal manufacturing industry is the refining of petroleum.

DRUNKENNESS, a state resulting from excessive drinking, usually of alcohol (see ALCOHOL, PATHOLOGICAL EFFECTS OF). It may represent either an act or a habit, the latter consisting in frequent repetitions of the former.

What appears to be "intoxication" may arise from many different causes, *e.g.*, epilepsy, fractured skull, intracranial haemorrhage, the toxaemic coma of diabetes and uraemia and intense cold. The police records supply many instances of this statement. But, as a rule, the phenomena of drunkenness are actually due to excessive consumption of intoxicants. Some individuals have a special susceptibility to alcohol, due to heredity or to one of the sequelae of sunstroke or cranial injury.

The immediate effect of all intoxicants is a cumulative production of paralysis of various parts of the nervous system, but this effect varies with the amount of the dose and also with the agent, the race and the individual. In short, from tea to haschisch we have, through hops, alcohol, ether, tobacco and opium, a graduated scale of intoxicants, which stimulate in small doses, and narcotize in larger—the narcotic dose having no stimulating properties whatever, and only appearing to possess them because the agent is gradually absorbed from the stomach, and the system comes primarily under the influence of a stimulant dose. In chloroform narcosis the stage of stimulation may be shortened or eliminated; while with tea, the narcotic stage is not readily produced.

In the case of alcoholic intoxication the senses gradually become hazy, articulation difficult, a filmy haze obscures the vision, the head seems lighter than usual, the equilibrium unstable. Soon ocular co-ordination fails, objects appear double or unstable, judgment ceases, the victim babbles with unrestrained communicativeness; becomes quarrelsome or boisterous, till at last he falls on the ground insensible—dead drunk (alcoholic coma)—a state from which, after profound slumber, he at last awakes feverish, exhausted, sick and giddy, with ringing ears, a throbbing heart and a violent headache.

The poison primarily affects the cerebral lobes, and the other parts of the cerebro-spinal system are consecutively involved, till in dead-drunkenness the only parts at work are those automatic centres in the medulla oblongata which regulate and maintain the circulation and respiration. But even these are not unaffected, the coma of drunkenness sometimes terminating in death.

The discomforts following an act of drunkenness are readily removed for the time by a repetition of the cause. Thus what has been an act may become a habit, all the more readily as the will and the judgment are progressively impaired. From this condition there is no hope of relief but in enforced abstinence; the drunkard must be regarded as temporarily insane (see INSANITY and NEUROPATHOLOGY), and ought to be placed in a home for inebriates till he regains his self-control.

For the law concerning drunkenness the reader is referred to INEBRIETY, LAW OF. Its prevalence as a vice has varied considerably according to the state of education or comfort in different classes of society and according to the mere facilities for obtaining drink. Speaking generally, it may be said that in Great Britain drunkenness appears chiefly prevalent in the seaport and mining districts.

Analysis of the prosecutions for drunkenness shows that about a quarter of the total number of offences are committed by women. But there are important local differences. Whether intemperance is increasing among women is uncertain. There is no satisfactory way of determining the point, but the opinion is widely held in the United Kingdom that drunkenness in women, as in men, is less common, but spirit drinking is commoner than formerly. There is no doubt that during the World War for a variety of reasons, including compulsory closing of taverns and restricted sale of alcohol during certain hours, prosecutions for drunkenness diminished considerably and that they have increased during the years since.

See also LIQUOR LAWS and TEMPERANCE.

DRURY, SIR WILLIAM (1527–1579), English statesman and soldier, was a son of Sir Robert Drury of Hedgerley, Bucks., and grandson of another Sir Robert Drury (d. 1536), who was speaker of the House of Commons in 1495. He was born at Hawstead, Suffolk, on Oct. 2, 1527, and was educated at Gonville hall, Cambridge. In 1559 he was sent to Edinburgh to report on the condition of Scottish politics, and five years later he became marshal and deputy-governor of Berwick. He was frequently sent on errands to Scotland, and conducted raids over the border; and he commanded the force which compelled Edinburgh castle to surrender in May 1573. In 1576 he was sent to Ireland as president of Munster, and in 1578 he became lord justice to the Irish council, taking the chief control of affairs after the departure of Sir Henry Sidney. Drury's letters to Lord Burghley and others are invaluable for the story of the relations between England and Scotland at this time.

DRUSES, the adherents of an esoteric religion founded in the 11th century after Christ by the Fatimid Caliph of Egypt, Al-hakim bi'amrillahi, the son of a Russian mother, who proclaimed himself an incarnation of God, established a reign of terror at Cairo and finally disappeared mysteriously (A.D. 1021). They take their name from his missionary, Ismail Ad-darazi, who preached the cult of Al-hakim among the Syrians. Their origin is probably mixed; their traditions derive them from Arab colonists, but some of their chief families claim Turkoman or Kurdish descent and there is an obvious North Syrian (Armenoid) infusion among some of the Druses in the Lebanon. They have always been confined to Syria, and like other small and often persecuted Near Eastern sects, such as the Yazidis and the Assyrian Christians, have preferred the relative security of the mountains to the insecure advantages of the plains. They have

three strongholds—the districts of Shuf and Metn in the Lebanon, the western slopes of Mt. Hermon, and the mountains which separate the cornlands of the Hauran from the Syrian desert. There are Druse villages on Mt. Carmel, and small outliers of no political importance in Northern Syria and in the Anti-Lebanon. French statistics estimate their numbers at 48,000 in the Hauran mountains, which are generally known as the Jabalu'd-Duruz (*i.e.*, mountain of the Druses), 7,000 in the Hermon area, and 43,000 in the Lebanon. There are about 7,000 Druses in the British mandated territory of Palestine, and an unknown number in the United States of America, where the Druse immigrant usually passes as a Syrian Christian. The permission given to a Druse to conform outwardly to the faith of the unbelievers among whom he dwells, which is an interesting feature of their religion, makes it difficult to attempt an estimate of the number of Druses living outside the Syrian strongholds of the sect.

The name Druse is first mentioned by Benjamin of Tudela (*c.* A.D. 1170) and little is known of the beginnings of the political power of the great families whose history is that of the Druse community. The Druses first appear in Arab records as mountain villagers of Lebanon, Hauran and West Hermon, yielding feudal service in return for military and political protection to various families of seigneurs (Al-umara) who quarrelled incessantly for the headship of the community. Their chief political centre lay in the southern Lebanon. Khalwatu'l-Bayadh in the Hermon was their religious centre at a very early date; the Hauran community was unimportant. Religious proselytism has been discouraged or forbidden by their spiritual chiefs in recent centuries; but the fact that Maliku 'l-Ashraf, the Mameluke sultan of Egypt compelled the Lebanese Druses to conform outwardly to Sunni Islam about A.D. 1300 suggests that their leaders, the Tnuh House, had sought more than political domination over the mixed population of "the mountain." After their defeat by the Mamelukes the power of the Tnuh waned, to the advantage of the Maan family, recent immigrants from northern Arabia who may have been proselytes.

The Maan amirs were shrewd and politic; the family threw its influence and retainers into the scale against the Mamelukes when Selim the Grim invaded Syria in 1516. The victor recognized their supremacy over the Druse, Muslim and Maronite chiefs of the Lebanon, and for three generations they throve mightily under Turkish protection. The reign of Fakru'd-din Maan II. marked the zenith of their power. By treaties, by the protection of small chiefs against great, and by successes in various baronial wars, he extended the feudal sway of his house nearly as far as Antioch in the north, built a castle at Palmyra in the eastern desert and drew a large revenue from the ports of Beirut, Saida (Sidon), Latakia and Tripoli in Syria. Success, however, turned his head; he intrigued against the Turk, and in 1614 was defeated by the pasha of Damascus and fled to Italy, where he intrigued with the rulers of Tuscany and Naples and apparently invented the propagandist myth that the Druses were descendants of a crusading count of Dreux. In 1619 he returned, recovered his power and ruled as an independent prince until 1633, when a Turkish army defeated and captured him with his sons. The bow-string terminated their lives at Constantinople.

After a welter of civil war, in which the combatants were divided into the ancient Arab factions of Yemenis and Qaisis—the Shanavests and Caravats of the Arab world—a new family, the Shehab of Mt. Hermon, became master of the mountain. They were descendants of early Arab governors of Hauran, had intermarried with the Maan family, and deserted them when they fell. But they never adopted the Druse creed and several of them appear to have become Maronite Christians in the 18th century, thus causing the dangerous suspicion of apostasy to fall on the house. From Haidar, third of the line, who defeated the Turks and Druse rivals at Ain Dara in 1711, to Beshir the last great Shehab amir, they played the old game, now rebelling against the weak sultans of the decadence, now bribing their governors, and constantly at war with the rival house of Jumblat. Beshir became amir of the mountain in 1786 and for 54 years, with two brief intervals of exile, held his own by the time-honoured expedient of aiding and betraying one rebel satrap after another. He successively supported and betrayed Ahmad Jezzar and Abdullah of Acre, and cultivated the friendship of infidel admirals; threw in his lot with Mohammed Ali of Egypt and his son Ibrahim, but deserted them in 1839 when the Powers, save France, were turning against them. But Ibrahim held Druse hostages, and so Beshir, though he promised much, gave little help to Powers or Porte. After Ibrahim's expulsion from Syria the Turks called him to account. He fled to Malta on a British ship but was induced to go to Constantinople, where he died in 1851.

Beshir may have been a crypto-Christian; his successor Beshiru'l-Qassim openly joined the Maronites, hoping to defeat Druse rivals with their aid. It was a suicidal policy; even the Druses of the Shehab faction distrusted and disliked their Christian allies; the rest became perforce pro-Muslim, and the Turkish Government, which was carrying out the centralizing policy initiated by Mahmud the Reformer, saw danger in the alliance. For the next 20 years the history of the Lebanon is a monotonous record of murder, intrigue and civil war. The Maronites rebelled once, the Druses twice, against the Turks, who half-heartedly attempted or pretended to impose reforms desired by the European Powers upon the turbulent mountain chiefs. Three constitutions were successively bestowed upon the Lebanon, which was twice "disarmed"; European interference increased the exasperation of Druses and Muslims against the Maronites, and the scandal culminated in massacres of Christians which extended to the coast and to Damascus, where some 2,500 Christians were slaughtered and foreign consulates sacked (July 9, 1860). The Powers intervened. A French army occupied the Lebanon for nearly a year, and the Porte, after appointing a Christian governor-general of the Lebanon, conferred a large measure of autonomy on the province by the Organic Statute of Sept. 6, 1864. The change made an end of the political importance of the Lebanese Druses. Beshiru'l-Qassim had been murdered; his family had lost wealth and prestige, and henceforth Druse political interests in Lebanon were mainly confined to such harmless subjects as the rivalry between a Jumblat or an Arslan for the governorship of a county. Those who found the change too distasteful migrated to the Hauran. The rest made the best of it, and till 1918 remained a conservative, rather aloof community, influential in the parish politics of the southern Lebanon.

The Hauran **Druses.**—By 1840 the influx of malcontents from the Lebanon had increased the small Druse community in the Hauran to 7,000 souls. For some time they remained independent and held out successfully in their stronghold, the lava field of the Leja, against Ibrahim Pasha's Egyptians in 1839, and Kibrisli Pasha's Turks in 1852. Their government was then theocratic under the ***Rais*** (chief) of the *'Uqqala* (initiated) in Suwayda. In 1879 Midhat, the reforming governor-general of the Damascus province, found them troublesome and formidable neighbours. Their numbers had increased to over 20,000 and their repression required an army corps. He imposed a qaimaqam (lieutenant-governor) upon them and the office after a while became vested in the house of Atrash (pl. Turshun), but the majority of the clans refused taxes and military service. In 1896 the contumacious clans were defeated and their country ravaged by a Turkish army; but the campaign was costly and the Turks agreed to a compromise whereby the Druses were to pay taxes and serve as frontier guards on the desert edge in their own territory. A governor with a small Turkish force was stationed at Sheikh Saad, outside Druse territory proper, and the clans were left to fight as they pleased with the Beduin whom they usually defeated. After the Turkish revolution of 1908 the Government decided to garrison points in Druse territory. Some of the Turshun revolted in 1910 but the rebels were defeated and their chief, Yahya, executed. (D. G. H.; G. BE.)

The French Mandate.—The Druse polity in the Hauran at the end of the World War remained feudal. The cultivated land attached to each village was communally owned and re-allotted at varying periods among the cultivators. The lords had prescriptive rights to the produce of certain demesne lands which

their peasants cultivated for them, but a peasant revolt late in the 19th century had restricted these demesnes. The ten noble families kept open house and maintained armed retainers. Clan solidarity and the sense of obligation between nobles and peasants were strong, but family jealousies usually prevented the chiefs from acting in unison.

During the World War the Druses, who had gained economic advantages by the opening of the Hejaz railway on the western edge of their territory, sat prudently on the fence and made money out of their crops until Sept. 1, 1918, when a section led by Sultan Pasha Al-Atrash assisted Feisul and Col. Lawrence during their advance on Damascus. There Sultan Pasha gave the Sherifians trouble, and Lawrence has recorded that he was well-nigh strangled during a conference by the redoubtable Auda abu-Tayyi. The Druses maintained an attitude of reserve towards the Sherifian Government and after its overthrow by the French under Gen Gouraud in July 1920, refused to join the Hauran Muslims in resisting the French mandate. Late in the year they entered into negotiations with the French, and on March 4, 1921, an agreement was signed by the acting high commissioner, M. de Caix, and sealed by a number of Druse spiritual and temporal chiefs, whereby the Druse mountain (Jabalu'd-Duruz) was granted an independent national government headed by an elected native governor under the French mandate. On May 1 an informal assembly of notables elected Salim Pasha Al-Atrash governor at Suwayda, the capital of the new state. His relatives gave trouble, and in the same year his kinsman, Sultan Pasha, exasperated by the arrest in his house of a suppliant who had attempted to murder Gen, Gouraud and was seeking asylum, revolted with his retainers. Next year he was amnestied after some skirmishing. In Sept. 1923 Salim died, and the Druse council, which had not been constitutionally elected but appointed by private understanding among the lords, could not agree concerning the election of a governor, and unconstitutionally elected Capt. Carbillet the French adviser to the Druse state as their provisional governor.

War with France.—In Prof. Toynbee's words (Toynbee, *Survey* of *International* ***Affairs,*** vol. i., pp. 412–413, 1925), the new governor, while sincere, disinterested and energetic, was "tyrannical in his methods and psychologically blind . . . to a degree which made it inevitable that his well-meant efforts should end in disaster. . . ." He filled the treasury, supplied the country with roads, schools, irrigation channels, reservoirs, and justices of the peace, founded a museum, and in the autumn of 1924 gave effect to Article 4 of the de Caix Agreement by conducting elections for a new council, which promptly violated Article 3 of the agreement by electing him as the regular governor. Capt. Carbillet's policy was directed against the chiefs, notably the Turshun, but his strict imposition of forced labour and of a rigid system of passes, and his imprisonment of recalcitrants, who were occasionally incarcerated in his coal-cellar, exasperated the peasantry.

In April 1925 Druse delegates waited on Gen. Sarrail, the new French high commissioner in Syria, to complain of their governor, and to point out that his election was a violation of the de Caix Agreement. The general brusquely dismissed them, and subsequently stated in writing that he repudiated the agreement. Meanwhile the governor went on leave. His French *locum tenens* warned Sarrail of the growing excitement among the Druses and was dismissed. Druse petitions remained unheard, and another delegation was rebuffed. On July 11 Gen. Sarrail ordered his delegate at Damascus to summon the Druse "conspirators . . . on the pretext of receiving their demands" and then hold them as hostages. Three confiding notables appeared, and were exiled to Palmyra. On July 20 Sultan Pasha rebelled, and having surprised and defeated a small French force next day, invested Suwayda on July 22. Gen. Sarrail made light of the revolt, and on Aug. 2–3 a column 3.000 strong, comprising some unreliable colonial troops, was attacked near Azra' while marching to relieve Suwayda, and lost its transport, most of its guns, and more than a quarter of its men. A general Druse rising followed.

The rebels promptly established contact with the pro-Sherifian elements in Damascus and with the nationalist and anti-French "People's Party." Its leader, Dr. A. Shahbandar, and other chiefs fled to the Druses to avoid arrest, and early in September proclaimed a "National Syrian Government." The French repulsed a Druse raid on Damascus on Aug. 24 and relieved Suwayda a month later, but were unable, owing to transport difficulties, to force the Sultan to a general action. The retreats that followed their advances encouraged the hostile Muslim elements in their rear, and the revolt in Damascus and the bombardment of the city (Oct. 18–20) marked the beginning of the Syrian Nationalist revolt, the history of which is narrated elsewhere. *(See* SYRIA: History.) In the course of this unequal struggle the Druses proved themselves far better fighters than the Muslim insurgents, and they were the last to submit. At one moment they seemed likely to inflict a grave disaster upon the French. The Hermon Druses joined the revolt late in Sept. 1925; Zaydu'l Atrash son of the Sultan came to their aid, surprised Hasbayya on the night of Nov. 9–10, and prepared to invade the Lebanon, where he expected to be joined by the local Druses and the Shiah Muslims (Matawilah) of the Sidon hinterland. The heroic defence of Rashayya by a handful of troops saved the situation, and French reinforcements cleared the Hermon region in December. Thenceforward the Hauran Druses fought a losing battle. Abdu'l-Ghaffar Al-Atrash and other chiefs opened negotiations with Gen. Andrea in Oct. 1926, which ended after some months in their surrender on honourable terms. The Leja was conquered in the spring of 1927, and Sultan, who had established a camp at Qasru'l Azraq, in the British mandatory territory of Transjordan, was compelled by British armoured cars and Transjordanian police to withdraw into Ibn Sa'ud's desert dominions with the remnant of his followers, and their families. He settled at Qurayyatu'l-Milh in the Wadi Sirhan with, perhaps, 500 families, who were well received by the Wahabi king, though a lasting friendship between the "Puritans of Islam" and the non-Muslim Druses seems improbable. Col. Clément Grandcourt was appointed governor of the Hauran in 1927 and the French military chiefs, who respected Druse valour, did their best to restore good relations.

Customs.—The Hauran Druses have some of the vices and all the virtues of oriental mountaineers. They are intelligent, self-respecting, and hospitable, but cruel and, by Western standards, treacherous. The women enjoy much consideration; polygamy is forbidden, and they join the men in religious functions. Divorce may be initiated by the wife. The veil is obligatory; some Druse women, indeed, will not unveil in the presence of a foreign woman. Feminine dress is black, with red slippers. The men usually wear a black under-robe with white girdle, and a white roll round the red fez, which is now almost the sole distinguishing mark of the Lebanon Druses. (For religious observances *see* above.)

RELIGION

Druses, a term for the Muwahhidin (Unitarians), as the Druses call themselves, who believe that there is one and only one God, indefinable, incomprehensible, ineffable, passionless. He has made himself known to men by successive incarnations, of which the last was Ḥākim, the sixth Fatimite caliph. How many these incarnations have been is stated variously; but 70, one for each period of the world, seems the best-attested number. Jesus appears to be accepted as one such incarnation, but not Muḥammad. No further incarnation can now take place: in Ḥākim a final appeal was made to mankind, and after the door of mercy had stood open to all for 26 years, it was finally and for ever closed. When the tribulation of the faithful has reached its height, Ḥākim will reappear to conquer the world and render his religion supreme. Druses, believed to be dispersed in China, will return to Syria. The combined body of the Faithful will take Mecca, and finally Jerusalem, and all the world will accept the Faith. The first of the creatures of God is the Universal Intelligence or Spirit, impersonated in Ḥamza, Ḥākim's vizier. This Spirit was

the creator of all subordinate beings, and alone has immediate communion with the Deity. Next in rank, and equally supporting the throne of the Almighty, are four Ministering Spirits, the Soul, the Word, the Right Wing and the Left Wing; and beneath these again are spiritual agents of various ranks. The material world is an emanation from, and a "mirror" of, the Divine Intelligence. The number of human beings admits neither of increase nor of decrease, and a regular process of metempsychosis goes on continually. The souls of the virtuous pass after death into ever new incarnations of greater perfection, till at last they reach a point at which they can be re-absorbed into the Deity itself; those of the wicked may be degraded to the level of camels or dogs. All previous religions are mere types of the true, and their sacred books and observances are to be interpreted allegorically. The Gospel and the Qur'ān are both regarded as inspired books, but not as religious guides. The latter function is performed solely by the Druse Scriptures. As the admission of converts is no longer permitted, the faithful are enjoined to keep their doctrine secret from the profane; and in order that their allegiance may not bring them into danger, they are allowed to make outward profession of whatever religion is dominant around them. To this latter indulgence is to be attributed the apparent indifferentism which leads to their joining Muslims in prayers and ablutions, or sprinkling themselves with holy water in Msronite churches. Obedience is required to the seven commandments of Ḥamza, the first and greatest of which enjoins truth in words (but only those of Druse speaking with Druse); the second, watchfulness over the safety of the brethren; the third, absolute renunciation of every other religion; the fourth, complete separation from all who are in error; the fifth, recognition of the unity of "Our Lord" in all ages; the sixth, complete resignation to his will; and the seventh, complete obedience to his orders. Prayer, however, is regarded as an impertinent interference with the Creator; while, at the same time, instead of the fatalistic predestination of Islam the freedom of the human will is distinctly maintained Not only is the charge of secrecy rigidly obeyed in regard to the alien world, but full initiation into the deeper mysteries of the creed is permitted only to a special class designated 'Āqils (Arabic *'Aql,* intelligence), in contradistinction from whom all other members of the Druse community, whatever may be their position or attainments, are called *Jāhil,* the Ignorant. About 15% of the adult population belong to the order of 'Aqils. Admission is granted to any Druse of either sex who expresses willingness to conform to the laws of the society, and during a year of probation gives sufficient proof of sincerity and stability of purpose. There appears to be no formal distinction of rank among the various members. Exceptional influence depends upon exceptional sanctity or ability. All are required to abstain from tobacco and wine; the women used not to be allowed to wear gold or silver, or silk or brocade, but this rule is commonly broken now; and although neither celibacy nor retirement from the affairs of the world is either imperative or customary, unusual respect is shown to those who voluntarily submit themselves to ascetic discipline. The 'Āqils are distinguished by the wearing of a white turban, emblematic of the purity of their life. Their food must be purchased with money lawfully acquired; and lest they should unwittingly partake of any that is ceremonially unclean. they require those Jāhils, whose hospitality they share, to supply their wants from a store set apart for their exclusive use. The idea1 'Āqil is grave, calm and dignified, with an infinite capacity of keeping a secret, and a devotion that knows no limits to the interests of his creed. On Thursday evening, the commencement of the weekly day of rest, the members of the order meet together in the various districts, probably for the reading of their sacred books and consultation on matters of ecclesiastical or political importance. Their meeting-houses, *khalwas,* are plain, unornamented edifices, in which the women assemble at the same time as the men, a part of the space being fenced off for them by a semi-transparent black veil. It has been frequently asserted that the image of a calf is kept in a niche, and traces of phallic and gynaecocratic worship have been vaguely suspected; but there is no authentic information in support of either statement; and it is certain that the sacred books of the religion contain moral teaching of a high order on the whole.

As a formulated creed, the Druse system is not a thousand years old. In the year A.D. 996 (386 A.H.) Ḥākim Biamrillāhi (*i.e.* he who judges by the command of God), sixth of the Fatimite caliphs (third in Egypt), began to reign; he believed that he held direct intercourse with the deity, or even that he was an incarnation of the divine intelligence; and in A.D. 1016 (407 A.H.) his claims were made known in the mosque at Cairo; in 1017 (408 A.H.) the new religion found a successful apostle in the person of Hamza ibn 'Alī ibn Ahmad, a Persian mystic, who became Ḥākim's vizier, gave form and substance to his creed, and by an ingenious adaptation of its various dogmas to the prejudices of existing sects, finally enlisted an extensive body of adherents. In 1020 (411 A.H.) the caliph was assassinated; but it was given out by Hamza that he had only withdrawn for a season, and his followers were encouraged to look forward with confidence to his triumphant return.

It is possible, even probable, that the segregation of the Druses as a people dates only from the adoption of Hamza's creed. But when it is recalled that other inhabitants of the same mountain system *e.g.,* the Maronites, the Ansarieh, the Metawāli and the Isma'ilites, also profess creeds which, like the Druse system, differ from Sunni Islam in the important feature of admitting incarnations of the Deity, it is impossible not to suspect that Hamza's emissaries only gave definition and form to beliefs long established in this part of the world. Many of the fundamental ideas of Druse theology belong to a common West Asiatic stock; but the peculiar history of the Mountain is no doubt responsible for beliefs, held elsewhere by different peoples, being combined there in a single creed. Some allowance, too, must be made for the probability that Hamza's system owed something to doctrines, Christian and other, ,with which the metropolitan position of Cairo brought Fatimite society into contact.

(See *Encyclopaedia* of *Islam,* ii., 255.)

DRUSUS, MARCUS LIVIUS, Roman statesman, was colleague of Gaius Gracchus in the tribuneship, 122 B.C. The proposal of Gracchus (*q.v.*) to confer the full franchise on the Latins had been opposed not only by the senate but also by the mob, whose privileges would thereby be diminished. Drusus threatened to veto the proposal. Encouraged by this, the senatorial party put up Drusus to outbid Gracchus. Gracchus had proposed to found colonies abroad; Drusus provided twelve in Italy, to each of which 3,000 citizens were to be sent. Gracchus had proposed to distribute allotments to the poorer citizens subject to a state rent-charge'; Drusus promised that they should be free, and inalienable. In addition to the franchise, immunity from corporal punishment (even in the field) was promised the Latins. The absence of Gracchus, and the inefficiency of his representative at Rome, led to the acceptance of these proposals, which were never intended to be carried. Drusus himself declined all responsibility in connection with carrying them out. He was rewarded for his services by the consulship (112), and the title of *patronus senatus.* He received Macedonia for his province, and he was the first Roman general to reach the Danube. He is possibly the Drusus mentioned by Plutarch as having died in 109, the year of his censorship.

See Appian, *Bell. Civ.* i. 23; Plutarch, *Gaius Gracchus,* 8–11; Florus iii. 4; **A. H. J.** Greenidge, *Hist. of Rome,* vol. i. (1904).

MARCUS LIVIUS DRUSUS, son of the former, tribune of the people in 91 B.C. was a man of high integrity and recognized the need of reform. At that time an agitation was going on for the restoration of the judicial functions from the *equites* to the senate; Drusus proposed as a compromise a measure which restored to the senate the office of *iudices,* while its numbers were doubled by the admission of 300 equites. Further, a special commission was to be appointed to try all *iudices* guilty of taking bribes. But the senate was lukewarm, and the equites offered violent opposition. In order, therefore, to catch the popular votes, Drusus proposed the establishment of colonies in Italy and Sicily and an increased distribution of corn at a reduced rate. By help of these riders the bill was carried. Drusus then sought a closer alliance with the Italians, promising them the long-coveted boon of the Roman franchise.

The senate broke out into open opposition. His laws were abrogated as informal, and each party armed its adherents for the civil struggle which was inevitable. Drusus was murdered, and his assassin was never discovered.

See ROME: History; also Appian, Bell. *Civ.* i. 35; Florus iii. 17; Diod. Sic. xxxvii. 10; Livy, Epit. 70; Vell. Pat. ii. 13.

DRUSUS, NERO CLAUDIUS (38–9 B.C.), Roman general, son of Tiberius Claudius Nero and Livia Drusilla, stepson of Augustus and younger brother of the emperor Tiberius. In 13 B.C. in conjunction with Tiberius, he subdued the Raeti and Vindelici. The credit of the decisive victory, however, must be assigned to Tiberius. (See Horace, Odes IV. 4 and 14.) In 13 B.C. Drusus was sent as governor to the three Gauls, where discontent had been aroused by the exactions of the Roman governor Licinius. Drusus made a fresh assessment for taxation purposes, and summoned the Gallic representatives to a meeting at Lugdunum to discuss their grievances. It was important to pacify the Gauls, in order to have his hands free to deal with the German tribes, one of which, the Sugambri, on the right bank of the Rhine, had seized the opportunity, during the absence of Augustus, to cross the river (12). Drusus drove them back and pursued them to their own territory, which he devastated. Sailing down the Rhine, he subdued the Frisii and, in order to facilitate operations against the Chauci, dug a canal (Fossa Drusiana) leading from the Rhenus (Rhine) to the Isala (Yssel) into the lacus Flevus (Zuider Zee) and the German Ocean. Making his way along the Frisian coast, he conquered the island of Burchanis (Borkum), defeated the Bructeri in a naval engagement on the Amisia (Ems), and went on to the mouth of the Visurgis (*Weser*) to attack the Chauci. On the way back his vessels grounded on the shallows, and were only got off with the assistance of the Frisii.

In his second campaign (11), Drusus defeated the Usipetes, threw a bridge over the Luppia (*Lippe*), attacked the Sugambri and advanced to the Weser, where he defeated the Cherusci. While making his way back he fell into an ambush but managed to defeat his enemy. In view of future operations, he built two forts, one at the junction of the Luppia and Aliso (Alme), the other in the territory of the Chatti on the Taunus, near Moguntiacum (*Mainz*).

The third campaign (10) was of little importance; and, after some insignificant successes, Drusus returned to Rome, and was elected consul for the following year.

In 9 B.C. he defeated the Chatti, Suebi, Marcomanni and Cherusci, and penetrated as far as the Albis (*Elbe*). Here trophies were set up to mark the farthest point ever reached by a Roman army. To secure the conquered territory, fortresses were erected along the Elbe, Weser and Maas (*Meuse, Mosa*), a flotilla was placed upon the Rhine, and a dam built upon the right arm of its estuary to increase the flow of water into the canal mentioned above. On his return, his horse threw him, and he died thirty days after the accident (Sept. 14). The body was carried to the winter quarters of the army, whence it was escorted by Tiberius to Rome, the procession being joined by Augustus at Ticinum (Pavia). Tiberius delivered the funeral oration.

Drusus was one of the most distinguished men of his time. His agreeable manners, handsome person and brilliant military talents gained him the affection of the troops, while his liberal principles endeared him to the people. He married Antonia, the daughter of Marcus Antonius the triumvir, by whom he had three children: Germanicus, adopted by Tiberius; Claudius, afterwards emperor; and a daughter Livilla.

The chief ancient authorities for the life of Drusus are Dio Cassius, the epitomes of Livy, Suetonius (Claudius), Tacitus (Portions of the *Annals*), Florus (whose chief source is Livy), Velleius Paterculus and the *Consolatio* ad Liviam. The German campaigns were described in the last books of Livy and the lost *Bella Germaniae* of the elder Pliny. They have produced an extensive literature in Germany, J. Asbach's "Die Feldzüge des Nero Claudius Drusus" (Rhein. Jahrb. lxxxv. 14–30) being especially recommended; *see* also Mommsen's History of the Roman Provinces, i.; Merivale, History of the Romans *under the Empire*, ch. 36; A. Stein in Pauly-Wissowa's *Realencyclopädie* (1899), where other authorities are given; J. C. Tarver, Tiberius the Tyrant (1902).

DRUSUS CAESAR (c. 15 B.C.–A.D. 23), commonly called Drusus junior, to distinguish him from his uncle Nero Claudius Drusus, was the only son of the Emperor Tiberius. He was consul elect in A.D. 14, and on the accession of Tiberius was sent to put down a mutiny of the troops in Pannonia (Tacitus, Annals, i. 24–30). As governor of Illyricum (17 A.D.), he set the Germanic tribes against one another. On his return Drusus was consul a second time (21 A.D.) and in the following year received the tribunician power which indicated him as heir to the throne. Seianus, who also aspired to the supreme power, determined to remove Drusus. He seduced Drusus's wife and persuaded her to assist him in murdering her husband. A slow poison was administered, from the effects of which Drusus died after a lingering illness. Drusus was a man of violent passions, but not entirely devoid of better feelings, as is shown by his undoubtedly sincere grief at the death of Germanicus.

See Tacitus Annals, i. 76, iv. 8–11; Dio Cassius lvii. 13, 14; Suetonius *Tiberius*, 62; J. C. Tarver *Tiberius* the *Tyrant* (1902).

DRYADES (drī'ăd-ez), or HAMADRYADES, in Greek mythology, nymphs of trees and woods. It is sometimes said by late authors that a dryad is a nymph who lives among trees (Gr. δρῦς, tree, especially oak), a hamadryad the spirit of a tree, living and dying with it.

DRYANDER, JONAS (1748–1810), Swedish botanist, was educated at Gothenburg, Lund and at Uppsala under Linnaeus. He visited England in 1782 and became librarian to Sir Joseph Banks. He was librarian to the Royal Society and also to the Linnean Society, of which he was one of the founders in 1788. He was vice-president of the society till his death in London on Oct. 19, 1810. Besides various papers Dryander published Dissertatio gradualis fungos *regno* vegetabili vindicans (Lund, 1776) and Catalogus bibliothecae *historico-naturalis Josephi* Banks, Bart. (London, 1796–1800, 5 vols.), and edited Aiton's Hortus *Kewensis* and Roxburgh's Plants of the Coast of *Coromandel*.

DRY-CLEANING, sometimes termed French or chemical cleaning, is the process of removing dirt and stains from materials by organic solvents and special soaps and detergents. Greasy and resinous substances collected by wearing apparel, house furnishings and other articles are first dissolved, and then any insoluble soil is removed mechanically or by detergents. The process was first employed in France about the middle of the 19th century. The work was done by hand and the operations were simple. Elaborate machinery was gradually introduced, providing the basis for an industry which requires not only skill but much capital.

Liquids employed in dry-cleaning are inert toward textile fibres. Water, on the other hand, causes the fibres to become limp and in many cases to alter in shape and size. For this reason, carefully fitted and accurately draped upholstery and hangings can be successfully cleaned only by dry-cleaning methods. Various dry-cleaning solvents and dry-cleaning soap are supplemented by ethyl alcohol, acetone, carbon tetrachloride, acetic acid, etc., for removing spots that do not respond to the ordinary treatment. Most dry-cleaning fluids are inflammable and, unless proper precautions are observed, static electrical discharges will ignite the volatile fluid and cause serious injury to life and property. For this reason, dry-cleaning can be practised with safety only in plants designed for the purpose. The demand for a special naphtha for the industry has resulted in the adoption by the National Association of Dyers and Cleaners of the United States and Canada of specifications for a product known as Stoddard solvent, which has eliminated most of the fire hazard and simplified the process of cleaning. Non-inflammable chlorinated hydrocarbons, namely carbon tetrachloride, perchlorethylene, and trichlorethylene are also used as dry-cleaning solvents. In general the process of dry-cleaning is as follows: articles made of strong materials are placed in mechanically revolved washers with petroleum naphtha or chlorinated hydrocarbon solvent and dry-cleaning soap. This operation is followed by several rinsings in fresh diy-cleaning solvents. The articles are then freed from most of the solvent in centrifugal extractors and are dried in a current of warm air.

Delicate materials are cleaned by hand. After drying they are inspected, and any remaining spots are removed by special cleaning agents. The dry-cleaning solvent used is reclaimed and, after renovation, is used again.

The dry-cleaning industry in the United States and Canada has supported industrial fellowships in the Mellon Institute of Industrial Research and in the National Bureau of Standards. Specifications for a special dry-cleaner's naphtha have been developed, improved methods for naphtha recovery have been devised, more efficient detergents have been made available and many other advances have been made in the art. In 1927 the National Association Institute of Dyeing and Cleaning built a model plant, research laboratories and school at Silver Spring, Md., to advance the technical side of the industry. There were in 1938 approximately 9,500 power dry-cleaning plants in the United States and Canada, employing 150,000 people doing a total business for the year of about $560,000,000. European dry-cleaning practice is similar to that of the United States, except that there are fewer plants per unit of population. The plants are much larger, however, and some of them have several thousand employees.

(L. E. J.; X.)

DRYDEN, JOHN (1631–1700), English poet, born at Aldwinkle, in Northamptonshire, of a family with Puritan and antimonarchial leanings, was educated at Westminster school under Dr. Busby, and at Trinity college, Cambridge, where he took his degree in 1654. In that year his father died, leaving him a small estate worth about £60 a year, and he seems to have remained in Cambridge another three years before establishing himself in London, where he is said to have lived in the house of his publisher, Herringman, with whom he was connected until 1679, when Jacob Tonson became his publisher. He had written some elegiac and commendatory verses while he was at school, but the first work which showed the measure of his genius was the *Heroic Stanzas* (1659) to the memory of Oliver Cromwell. This is a fine tribute to the Protector, and shows Dryden as a disciple of John Donne indeed, but as a direct student of the Latin classics. With the coronation of Charles II. Dryden, the hereditary Puritan and the panegyrist of the Protector hailed the new order in his *Astraea Redux* (1660), followed by a *Panegyric on the Restoration* (1661).

For a livelihood Dryden turned to the stage. Having failed with a tragedy on the fate of Henry, duke of Guise, he turned to comedy, for which he admitted he had little taste. The age demanded comedies, and he endeavoured to supply the kind of comedy that the age demanded. His first attempt was unsuccessful. He then wrote *The Wild Gallant*, acted in Feb. 1663, by Thomas Killigrew's company in Vere street. Pepys showed good judgment in pronouncing the play "so poor a thing as ever I saw In my life." Dryden never learned moderation in his humour; but he took a lesson from the failure of *The Wild Gallant;* his next comedy *The Rival Ladies*, produced before the end of,1663, and printed in the next year, was correctly described by Pepys as "a very innocent and most pretty witty play." But he never quite conquered his tendency to extravagance. *The Assignation, or Love in a Nunnery*, produced in 1673, was another failure; and even in 1680, after 20 years' experience to guide him, *The Kind Keeper, or Mr. Limberham*, was prohibited after three representations as being too indecent for stage presentation. The undisciplined force of the man carried him to an excess from which more dexterous writers held back. After the production of *The Rival Ladies* in 1663, Dryden assisted Sir Robert Howard in the composition of a tragedy in heroic verse *The Indian Queen*, produced with great splendour in Jan. 1664. Its success, one of the greatest since the reopening of the theatres, was largely due to the magnificent scenic accessories—the battles and sacrifices on the stage, the spirits singing in the air, and the god of dreams ascending through a trap. Dryden followed it up with *The Indian Emperor, or the Conquest of Mexico by the Spaniards*, acted in 1665. Immediately after the success of *The Indian Queen*, in the preface to an edition (1664) of *The Rival Ladies*, Dryden took up the question of the propriety of rhyme in serious plays. Rhyme was not natural, some people had said; to which he answers that it is as natural as blank verse, and that much of its unnaturalness is not the fault of the rhyme but of the writer. Rhyme at once stimulates the imagination, and prevents it from being too discursive in its flights.

In 1668 he published his *Essay of Dramatick Poesie*. The essay takes the form of a dialogue between Neander (Dryden), Eugenius (Charles, Lord Buckhurst, afterwards earl of Dorset), Crites (Sir R. Howard), and Lisideius (Sir C. Sedley), who is made responsible for the definition of a play as a "just and lively image of human nature, representing its passions and humours, and the changes of fortune to which it is subject, for the delight and instruction of mankind." Dryden's form is of course borrowed from the ancients, and his main source is the critical work of Corneille in the prefaces and discourses contained in the edition of 1660, but he was well acquainted with the whole body of contemporary French and Spanish criticism. Crites maintains the superiority of the classical drama; Lisideius supports the exacting rules of French dramatic writing; Neander defends the English drama of the preceding generations, including, in a long speech, an examination of Ben Jonson's *Silent Woman*. Neander argues, however, that English drama has much to gain by the observance of exact methods of construction without abandoning entirely the liberty which English writers had always claimed. He then goes on to defend the use of rhyme in serious drama. Howard had argued against the use of rhyme in a "preface" to *Four New Plays* (1665), which had furnished the excuse for Dryden's essay. Howard replied to Dryden's essay in a preface to *The Duke of Lerma* (1668). Dryden at once replied in a masterpiece of sarcastic retort and vigorous reasoning, *A Defence of an Essay of Dramatique Poesie*, prefixed to the second edition (1668) of *The Indian Emperor*. It is the ablest and most complete statement of his views about the employment of rhymed couplets in tragedy.

Before his return to town at the end of 1666, when the theatres (which had been closed during the disasters of 1665 and 1666) were reopened, Dryden wrote a poem on the Dutch war and the Great Fire entitled *Annus Mirabilis* (ptd. 1667). The poem is in quatrains, the metre of his *Heroic Stanzas* in praise of Cromwell, which Dryden chose, he tells us, "because he had ever judged it more noble and of greater dignity both for the sound and number than any other verse in use amongst us." From the reopening of the theatres in 1666 till Nov. 1681, the date of his *Absalom and Achitophel*, Dryden produced nothing but plays. The stage was his chief source of income. *Secret Love, or the Maiden Queen*, a tragi-comedy, produced in March 1667, was based on an episode in the *Artambne, ou le Grand Cyrus* of Mlle. de Scudéry, the historical original of the "Maiden Queen" being Christina, queen of Sweden. His next play *Sir Martin Mar-all, or the Feigned Innocence*, an adaptation in prose of the duke of Newcastle's translation of Molibre's *L'Étourdi*, was produced at the Duke's theatre, without the author's name, in 1667. It was about this time that Dryden became a retained writer under contract for the King's theatre, receiving from it £300 or £400 a year, till it was burnt down in 1672, and about £200 for six years more till the beginning of 1678. His co-operation with Davenant in a new version (1667) of Shakespeare's *Tempest* (for his share in which Dryden can hardly be pardoned on the ground that the chief alterations were happy thoughts of Davenant's, seeing that he affirms he never worked at anything with more delight) must also be supposed to be anterior to the completion of his contract with the Theatre Royal. He was engaged to write three plays a year, and he contributed only 10 plays during the 10 years of his engagement, finally exhausting the patience of his partners by joining in the composition of a play for the rival house. Comedies produced by him in this period are *An Evening's Love, or the Mock Astrologer*, an adaptation from *Le Feint Astrologue* of the younger Corneille, produced at the King's theatre in 1668; *Ladies à la Mode* (1668); *Marriage à la Mode* (1672); *The Assignation, or Love in a Nunnery* (1673); *The Kind Keeper, or Mr. Limberham* (1678); but only *Marriage à la Mode* was really successful.

While Dryden met with such indifferent success in his willing efforts to supply the demand of the age for low comedy, he struck upon a really popular and profitable vein in heroic tragedy. *Tyrannic Love, or the Royal Martyr*, a Roman play dealing with the

persecution of the Christians by Maximin, was produced in 1669. It is in rhymed couplets, but the author again did not trust solely for success to them; for, besides the magic incantations, the singing angels, and the view of Paradise, he made Nell Gwyn, who had stabbed herself as Valeria, start to life again as she was being carried off the stage, and speak a riotous epilogue, in violent contrast to the serious character of the play. *Almanzor and Almalzide, or the Conquest of Granada*, a tragedy in two parts, was written in 1669 to 1670. This piece seems to have given the crowning touch of provocation to the wits, who ridiculed the popular taste for these extravagant heroic plays. *The Rehearsal* (1671) written by the duke of Buckingham, with the assistance, it was said, of Samuel Butler, Martin Clifford, Thomas Sprat and others, was a severe and just punishment for Dryden's boast in the epilogue to the second part of *The Conquest of Granada* of the superiority of Restoration comedy over that of the Elizabethan age. Davenant was originally the hero, but on his death in 1668 the satire was turned upon Dryden, who is ridiculed under the name of Bayes, the name being justified by his appointment in 1670 as poet laureate and historiographer to the king (with a pension of £300 a year and a butt of canary wine). It is said that *The Rehearsal* was begun in 1663, but this probably only means that Buckingham and his friends had resolved to burlesque the extravagant heroics of *The Indian Queen*. Later Dryden fully avenged himself on Buckingham by his portrait of Zimri in *Absalom and Achitophel*. His immediate reply is contained in the preface "Of Heroic Plays" and the "Defence of the Epilogue," printed in the first edition (1672) of his *Conquest of Granada*.

His next tragedy *Amboyna* (1673), put on the stage to inflame the public mind in view of the Dutch war, was written, with the exception of a few passages, in prose, and those passages in blank verse. An opera which he wrote in rhymed couplets, called *The State of Innocence, and Fall of Man*, an attempt to turn part of *Paradise Lost* into rhyme, as a proof of its superiority to blank verse, prefaced by an "Apology for Heroique Poetry and Poetique Licence," was entered at Stationers' Hall in 1674, and printed in 1677, but never acted. Dryden praises his original as "undoubtedly one of the greatest, most noble and most sublime poems which either this age or nation has produced." He is said to have had the elder poet's leave "to tag his verses." In *Aurengzebe*, which was Dryden's last, and also his best rhymed tragedy, he borrowed from contemporary history, for the Great Mogul was still living. In the prologue he confessed that he had grown weary of his long-loved mistress rhyme and retracted, with characteristic frankness, his disparaging contrast of the Elizabethan with his own age. But the stings of *The Rehearsal* had stimulated him to do his utmost to justify his devotion to his mistress, and he claims that *Aurengzebe* is "the most correct" of his plays. It was entered at Stationers' Hall and probably acted in 1675, and published in the following year.

After the production of *Aurengzebe* Dryden seems to have reconsidered the principles of dramatic composition, and to have made a particular study of the works of Shakespeare. The fruits of this appeared in *All for Love, or the World Well Lost*, a version of the story of Antony and Cleopatra, produced in 1678, which must be regarded as a very remarkable departure for a man of his age, and a wonderful proof of undiminished openness and plasticity of mind. In his previous writings on dramatic theory, Dryden, while admiring the rhyme of the French dramatists as an advance in art, did not give unqualified praise to the regularity of their plots; he was disposed to allow the irregular structure of the Elizabethan dramatists, as being more favourable to variety both of action and of character. But now, in frank imitation of Shakespeare, he abandoned rhyme, and, if we might judge from *All for Love*, and the precepts laid down in his "Grounds of Criticism in Tragedy," prefixed to *Troilus and Cressida* (1679), the chief point in which he aimed at excelling the Elizabethans was in giving greater unity to his plot. He upheld still the superiority of Shakespeare to the French dramatists in the delineation of character, but he thought that the scope of the action might be restricted, and the parts bound more closely together with advantage. *All for Love* and *Antony and Cleopatra* are two excellent plays for the comparison of the two methods. Dryden gave all his strength to *All for Love*, writing the play for himself, as he said, and not for the public. The action of his play takes place wholly in Alexandria, within the compass of a few days; it does not, like Shakespeare's, extend over several years, and present incessant changes of scene. Dryden chooses, as it were, a fragment of a historical action, a single moment during which motives play within a narrow circle, the culminating point in the relations between his two personages. He devotes his whole play, also, to those relations; only what bears upon them is admitted. In Shakespeare's play we get a certain historical perspective, in which the love of Antony and Cleopatra appears in its true proportions beneath the firmament that overhangs human affairs. In Dryden's play this love is our universe; all the other concerns of the world retire into a shadowy, indistinct background. If we rise from a comparison of the plays with an impression that the Elizabethan drama is a higher type of drama, taking Dryden's own definition of the word as "a just and lively image of human nature," we rise also with an impression of Dryden's power such as we get from nothing else that he had written since his *Heroic Stanzas* 20 years before.

It was 12 years before Dryden produced another tragedy worthy of the power shown in *All for Love*. *Don Sebastian* was acted and published in 1690. In the interval he wrote *Oedipus* (ptd. 1679) and *The Duke of Guise* (ptd. 1683) in conjunction with Nathaniel Lee; *Troilus and Cressida* (1679); *The Spanish Friar* (1681); *Albion and Albanius*, an opera (1685); *Amphitryon* (1690). In *Troilus and Cressida* he follows Shakespeare closely in the plot, but the dialogue is rewritten throughout, and not for the better. The versification and language of the first and the third acts of *Oedipus*, which with the general plan of the play were Dryden's contribution to the joint work, bear marked evidence of his recent study of Shakespeare. The *Duke of Guise*, in which he used one scene from his earliest dramatic attempt, provided an obvious parallel with contemporary English politics. Henry III. was identified with Charles II., and Monmouth with the duke. The lord chamberlain refused to license it until the political situation was less disturbed. The plot of *Don Sebastian* is more intricate than that of *All for Love*. It has also more of the characteristics of his heroic dramas; the extravagance of sentiment and the suddenness of impulse remind us occasionally of *The Indian Emperor;* but the characters are much more elaborately studied than in Dryden's earlier plays, and the verse is sinewy and powerful. It would be difficult to say whether *Don Sebastian* or *All for Love* is his best play; they share the palm between them. Dryden's subsequent plays are not remarkable. Their titles and dates are: *King Arthur*, an opera (1691), for which Purcell wrote the music; *Cleomenes* (1692); *Love Triumphant* (1694).

Soon after Dryden's abandonment of heroic couplets in tragedy, he found new and more congenial work for his favourite instrument in satire. As usual the idea was not original to Dryden, though he struck in with his majestic step and energy divine, and immediately took the lead. The pioneer was Mulgrave in his *Essay on Satire*, an attack on Rochester and the court, which was circulated in ms. in 1679. Dryden himself was suspected of the authorship, and he may have given some help in revising it; but it is not likely that he attacked the king on whom he was dependent for the greater part of his income, and Mulgrave in a note to his *Art of Poetry* (1717) expressly asserts Dryden's ignorance. Dryden, however, was attacked in Rose street, Covent Garden, and severely cudgelled by a company of ruffians who were generally supposed to have been hired by Rochester. Towards the close of 1681 Dryden took the field as a satirist on the side of the court, at the moment when Shaftesbury, baffled in his efforts to exclude the duke of York from the throne as a Papist, and to secure the succession of the duke of Monmouth, was waiting his trial for high treason. *Absalom and Achitophel* produced a great stir. Nine editions were sold in rapid succession in the course of a year. There was no compunction in Dryden's ridicule and invective. Delicate wit was not one of Dryden's gifts; the motions of his weapon were sweeping, and the blows hard and trenchant. The advantage he had gained by his recent studies of

character was fully used in his portraits of Shaftesbury and Buckingham, Achitophel and Zimri. In a play produced in 1681 (*The Spanish Friar)* he had written on the other side, gratifying the popular feeling by attacking the Roman Catholic priesthood.

Three other satires followed *Absalom and Achitophel,* one of them hardly inferior in point of literary power. *The Medall;* a *Satyre against Sedition* (March 1682) was written in ridicule of the medal struck to commemorate Shaftesbury's acquittal. Then Dryden had to take vengeance on the literary champions of the Whig party who had opened upon him with all their artillery. Their leader, Shadwell, had attacked him in *The Medal of John Bayes,* which Dryden answered in Oct. 1682 by *MacFlecknoe, or a Satyr upon the True-Blew Protestant Poet, T. S.* This satire, in which Shadwell filled the title-rôle, served as the model of the *Dunciad.* To the second part of *Absalom and Achitophel* (Nov. 1682), written chiefly by Nahum Tate, he contributed a long passage of invective against Robert Ferguson, one of Monmouth's chief advisers, Elkanah Settle, Shadwell and others. *Religio Laici,* which appeared in the same month, though nominally an exposition of a layman's creed, and deservedly admired as such, was not without a political purpose. It attacked the Papists, but declared the "fanatics" to be still more dangerous.

Dryden's next poem in heroic couplets was in a different strain. On the accession of James, in 1685, he became a Roman Catholic. There has been much discussion as to whether this conversion was or was not sincere; but it is worth while to notice that in his earlier defence of the English Church he exhibits a desire for the definite guidance of a presumably infallible creed, and the case for the Roman Church brought forward at the time may have appeared convincing to a mind singularly open to new impressions. At the same time nothing can be clearer than that Dryden always regarded his literary powers as a means of subsistence, and had little scruple about accepting a brief on any side. *The Hind and the Panther,* published in 1687, is an ingenious argument for Roman Catholicism, put into the mouth of "a milk-white hind, immortal and unchanged." Prior and Montagu, the future earl of Halifax, ridiculed it in *The Hind and the Panther transversed to the story of the Country Mouse and the City Mouse.* Dryden's other literary services to James were a savage reply to Stillingfleet (who had attacked two papers published by the king) and a translation of a life of Xavier in prose. He had written also a panegyric of Charles *Threnodia Augustalis* (1685), and a poem in honour of the birth of James II.'s heir, under the title of *Britannia rediviva* (1688).

Dryden did not abjure his new faith on the Revolution, and so lost his office and pension as laureate and historiographer royal. His rival Shadwell reigned in his stead. Dryden was once more thrown mainly upon his pen for support. He turned again to the stage and wrote the plays already enumerated. In the last decade of his life his translations from the classics occupied much of his attention. *Ovid's Epistles translated* appeared in 1680; and numerous translations from Virgil, Horace, Ovid, Lucretius and Theocritus appeared in the four volumes of *Miscellany Poems— Miscellany Poems* (1684), *Sylvae* (1685), *Examen poeticum* (1693), *The Annual Miscellany* (1694 by the "most eminent hands"); in 1693 was published the verse translation of the *Satires* of Juvenal and of Persius by "Mr. Dryden and several other eminent hands," which contained his "Discourse concerning the Origin and Progress of Satire"; and in 1697 Jacob Tonson published his most important translation, *The Works of Virgil.* The book, which was the result of three years' labour, was a vigorous, rather than a close, rendering of Virgil into the style of Dryden. Among other notable poems of this period are the two "Songs for St. Cecilia's Day," written for a London musical society for 1687 and 1697, and published separately. The second of these is the famous ode on "Alexander's Feast." The well-known paraphrase of *Veni, Creator Spiritus* was printed in the *Examen Poeticum,* and his "Ode to the memory of Anne Killigrew," called by Dr. Johnson the noblest ode in the language, was written in 1686.

His next work was to render some of Chaucer's and Boccaccio's tales and Ovid's *Metamorphoses* into his own verse. These translations appeared in 1700, a few months before his death, and are known by the title of *Fables, Ancient and Modern.* The preface, which is an admirable example of Dryden's prose, contains an excellent appreciation of Chaucer, and, incidentally, an answer to Jeremy Collier's attack on the stage. Thus a large portion of the closing years of Dryden's life was spent in translating for bread. Besides, his three sons held various posts in the service of the pope at Rome, and he could not well be on good terms with both courts. However, he was not molested by the government and in private he was treated with the respect due to his age and his admitted position as the greatest of living English poets. He held a small court at Wills's coffee-house, where he spent his evenings; here he had a chair by the fire in winter and by the window in summer; Congreve, Vanbrugh and Addison were among his admirers, and here Pope saw the old poet of whom he was to be the most brilliant disciple. He died at his house in Gerrard street, London, on May 1, 1700 and was buried on the 13th of the month in Westminster Abbey. Dryden's portrait, by Sir G. Kneller, is in the National Portrait gallery.

BIBLIOGRAPHY.—The *Comedies, Tragedies and Operas written by John Dryden, Esq.* (1701) was published by Tonson, who also issued the poet's *Dramatick Works* (1717), edited by Congreve. *Poems on Various Occasions and Translations from Several Authors* (1701), also published by Tonson, was very incomplete, and although other editions followed there was no satisfactory collection until the edition of the *Works* (1808, 2nd ed. 1821) by Sir Walter Scott, who supplied historical and critical notes with a life of the author. This, as revised and corrected by G. Saintsbury (1882–93), still is regarded as the standard edition, but John Sargeaunt issued an edition with introduction and textual notes in 1910. His *Critical and Miscellaneous Prose Works* (1800) were edited by Edmund Malone, who collected industriously the materials for a life of Dryden. Convenient partial modern editions are the *Poetical Works* (Globe ed. 1870), edited by W. D. Christie with an excellent "life"; *The Best Plays of John Dryden* (Mermaid series), edited by G. Saintsbury; and *Essays of John Dryden* (1900), edited by W. P. Ker. Besides the critical and biographical matter in these editions *see* Dr. Johnson's *Lives of the Poets; G.* Saintsbury, *Dryden* (English Men of Letters series, 1881); A. Beljame *Le Public et les hommes de lettres en Angleterre 1660–1744* (1897); *A. W.* Ward *History of English Dramatic Literature* (new ed. 1900); J. Churton Collins *Essays and Studies* (1895); L. N. Chase *The English Heroic Play* (1909); M. Van Doren *The Poetry of John Dryden* (1920); and Sir W. Raleigh, in *Some Authors* (1923). *(See* also ENGLISH LITERATURE.)

DRY DOCK: *see* DOCKS.

DRY-FARMING. In many parts of the world there are large tracts of land suitable for the growth of crops but in which the rainfall is deficient. They lie in a different category from actual desert areas which are, for the most part, so lacking in plant food as to require more than water to make them capable of producing vegetation. What are commonly termed "arid" or "semi-arid" districts need only an adequate supply of water to make them productive. A district is usually classed as "arid" when its annual rainfall is less than 10in. and "semi-arid" when the rainfall exceeds 10 and is less than 20 inches. These limits are elastic, as other factors of climate and of soil have to be taken into account.

Dry-farming is a system of cultivation designed to conserve and utilise to the utmost possible extent the limited amount of moisture falling upon the land in arid regions, without resorting to extraneous supplies of water. It is practised in those regions of low rainfall where, for physical or economic reasons, irrigation is not practicable. The conservation of moisture is effected by careful tillage of the surface-soil and the subsoil separately. The surface is kept loose and finely pulverised to allow the ready percolation to the subsoil of such moisture as may fall in rain or snow. The subsoil is also finely pulverised but it is made as firm and compact as possible to increase its capacity for holding water and render its condition suitable for the germination of seed and the development of plant roots.

By this system of cultivation the land is first deeply ploughed, and the subsoil consolidated by a machine termed a sub-soil packer. The surface soil is thoroughly harrowed and scarified. The best results are obtained if the land is left fallow for a year. During the winter and early spring it is covered with snow. When the snow melts, the water, instead of draining away or evaporating, is collected and stored in the packed subsoil. As soon as the surface is sufficiently dry it is harrowed over, and this operation is

repeated after every rainfall until seed-time. The seed is drilled at the right depth to place it in the packed subsoil where the moisture has been accumulated. After sowing, the land is harrowed after each rainfall until the crop is so far advanced that this cannot be done without injuring it. As soon as the crop is harvested preparation for the next seeding begins. The plough follows close on the harvester and cuts a furrow seven inches deep. The subsoil packer follows immediately after the plough. The land is then harrowed after every rainfall, but never when it is dry, until the sowing of the next crop.

Crops are grown under this system either annually or biennially, this being determined mainly by the amount of rainfall, and also by the nature and texture of the soil.

Wheat is the crop mainly grown by the dry-farming system. W. P. Rutter in *Wheat-growing in Canada, tize United States and the Argentine* (1911) states that under dry-farming the nitrogen content of the wheat is large and the grains flinty and transparent, whereas under irrigation the grain is light-coloured, opaque, starchy and soft. The yield on irrigated land is greater but the quality of the wheat is better on land which is dry-farmed.

Area of Dry-farming.— The system of dry-farming was started by a few individuals in the State of Utah in 1875 and its practice has increased rapidly since 1900. The State of Utah and other States support a number of experiment stations where new varieties of wheat are tested, especially for their drought-resisting qualities. The rapid advance in the science of plant-breeding in recent years bids fair to have an important influence on the extension of wheat and other crops to regions formerly regarded as outside the possibilities of commercial production. In arid and semi-arid regions where irrigation is not now practicable, the system of dry-farming enables the fullest possible use to be made of drought-resisting wheats in extending the area of cultivation.

The United States Department of Agriculture *(Yearbook,* 1923) estimates that 587 million acres, or nearly one-third of the total area in America available for crops, pasture and forest, are arid or semi-arid pasture and range. About 51 million acres were stated to be irrigable, of which 20 million acres had been irrigated in 1920. California, Colorado and Idaho have the largest areas of irrigated land, comprising more than half the area irrigated. Dry-farming is practised chiefly in the Great Basin, the Columbia river valley, the interior valley of California and portions of the Great Plains.

The arid or semi-arid region of the United States extends over the Canadian border, a tract of some 80,000 square miles west of the 102nd meridian and east of the Rocky mountains being subject more or less to these conditions. Here also dry-farming is practised and methods of cultivation to conserve moisture in the soil are continuously studied.

The system of dry-farming has been mainly developed in North America, but in other areas having deficient rainfall it is also practised although on a less extensive scale.

Stephens, "Experiments in Wheat Production on the Dry Lands of the Western United States," U.S. *Dept. Agvic. Bull.* No. 1173 (1923); R. A. Oakley, "Forage Crops in Relation to the Agriculture of the Semi-arid Portion of the Great Plains," *U.S. Dept. Agvic. Bull.* No. 1244 (1924). (R. H.R.)

DRY-ICE, the trade-name for solid carbon dioxide, is a dense, snow-like substance having a temperature of 109° F. below zero or lower. Carbon dioxide gas is changed to a liquid when subjected to a pressure over five times that of the ordinary atmosphere and at 70° F. below zero. When this liquid is allowed to expand rapidly from the high pressure to atmospheric pressure, carbon dioxide snow results. This snow is compressed into cakes. Instead of melting it evaporates to a dry gas that has no corrosive action if moisture free. It makes possible the shipping of perishable products (meats, ice cream) long distances. One pound of dry-ice will absorb a little less than twice as much heat as one pound of water ice. A block of dry-ice 10in. x 10in. x 10in. in size weighs about 45 lb.

DRYNESS, CHEMICAL. The majority of chemical actions take place in the presence of water or some other solvent which plays an important part in the reaction; in fact, water appears to be a substance whose presence in minute amounts is essential for the occurrence of most chemical reactions. So far back as 1794, Mrs. Fulhame, in "An Essay on Combustion with a View to a New Art of Dyeing and Painting," recognized that presence of water, either as liquid or vapour, was necessary for the reduction of salts of gold and silver by hydrogen. In 1812 Cluzel discovered that the reaction between sulphuretted hydrogen and sulphur dioxide would not take place unless liquid water was present.

In 1869 Wanklyn brought together pure chlorine gas and metallic sodium without any appreciable interaction taking place even when the sodium was molten, but he did not realize that the impurity which he had removed was water.

Some of the earliest experiments on the effect of moisture on gaseous combustion were carried out in 1880 by H. B. Dixon, who discovered that a mixture of carbon monoxide and oxygen which had been most carefully dried would not explode when an electric spark was passed through the mixture, but on addition of a drop of water a violent explosion took place on again passing the spark. In 1888 H. B. Baker showed that water exerts some influence on the combustion of charcoal, since the carefully dried substance could be heated to redness in dry oxygen without appearance of a flame and only underwent partial oxidation to carbon monoxide and dioxide. He also showed that the elements boron, sulphur and phosphorus do not burn in dried oxygen, the latter not even becoming luminous. He further showed (1902) that a well-dried mixture of hydrogen and chlorine does not explode on exposure to sunlight, as does an undried one; similarly, the gases ammonia and hydrogen chloride, if perfectly dry, do not combine when mixed at the ordinary temperature, whilst pure dry electrolytic gas may be heated to redness or exposed to ultra-violet light without any measurable amount of water being formed. The introduction of a mere trace of moisture, *e.g.,* by allowing a small bubble of ordinary moist air to enter the apparatus, causes the normal action to take place. In 1887 E. W. Morley showed that the mere passing of a gas slowly through a long tube of such a vigorous dehydrating agent as phosphoric oxide leaves in it only 3 milligrams of water vapour per million litres, and yet this is sufficient to allow chemical action to proceed.

Not only is the rate of a chemical reaction materially retarded by removal of water from the system, but in many cases the physical properties of substances are modified by intensive drying. Carefully purified liquids of such widely different constitution as nitrogen trioxide, nitrogen tetroxide, bromine, mercury, hexane, benzene, carbon bisulphide, carbon tetrachloride, ether and various aliphatic alcohols were submitted to the influence of the drying agent, phosphorus pentoxide, for a period of several years. They were then examined and their boiling points showed a very considerable rise. In the case of mercury the rise was 62°, *i.e.,* the boiling point was 420–425° C. instead of 358° C.; for benzene the rise was 38" (from 80° to 118° C.). The melting point of bromine dried for 10 years, was found to be −4·5° C., while that of bromine dried for only a few days was −7·3° C.; that of sulphur was 117·5° C., showing a rise of 5·5°. The melting point of pure, dried sulphur trioxide was found to be 61° C., compared with 50° C. for the undried sample, and the dried sulphur trioxide changed on melting into the β-modification which had a melting point of 15·5° C. compared with the normal 14° C. The vapour densities of dried ether and methyl alcohol were 81.7 and 45 respectively, *i.e.,* more than double and treble the normal values; this is in agreement with the change of surface tension for these and other intensively dried liquids.

These results point to a change, generally an increase in the complexity of the molecule, which is due to the removal of the last traces of water from the substance. In the same way that particles of water vapour collect together and condense to form droplets which in their turn coalesce to give large drops, so the single molecules of a substance may coalesce into aggregates of molecules. This aggregation of single molecules into a more complex molecule is termed association (*q.v.*) and the breaking up of complex molecules into more simple ones is dissociation. It is

obvious, then, that the effect of intensively drying a substance is to increase its molecular association to such an extent as to cause a modification of its physical properties. Since in every instance drying has produced increased association, it is evident that association is less affected by the process of desiccation than is dissociation.

Practically all gases, liquids, and solids are soluble in water, some being very soluble, whereas others dissolve to such a small extent that only the most searching examination will give any indication of their presence in water. Conversely, water is soluble to a similar extent in most substances. This fact, and also the property of water of condensing in a thin film on liquid and solid surfaces — as observed in the "sweating" of walls in wet weather — in such a way that complete removal of the liquid film of water from surfaces is very difficult, gives some idea of the difficulty of removing the last, generally invisible, traces of water from substances. A clean, dry, polished glass carries on its surface an invisible film of water.

This property of retaining liquids or gases in an invisible form on the surface of solids is known as occlusion, and it is this power, which all substances possess, of occluding water to a greater or less extent, which renders so difficult the exact determination of the part played by water, both liquid and vapour, in chemical actions.

It has been shown above that a carefully dried mixture of certain gases will not react under ordinary conditions, whereas introduction of a trace of water causes instantaneous reaction. That the presence of liquid water is essential to the reaction between sulphuretted hydrogen and sulphur dioxide is demonstrated by an experiment described by H. B. Baker. The gases in question were dried by calcium chloride before mixing. This leaves about 4 milligrams of water vapour per litre of gas. The gases were then mixed and a small, open tube introduced containing about 2 milligrams of dried radium bromide. There was no apparent change after six hours; *i.e.*, no sulphur had been deposited on the walls of the jar, and it seemed as if no reaction had taken place. On opening the jar, however, there was an inrush of air and on heating the radium tube a large quantity of water was driven off and there was a considerable sublimate of sulphur. The whole of the gaseous contents of the jar had condensed in the small tube of radium bromide, and this was due to the fact that the ions from the radium salt cause condensation of the water vapour (left after desiccation with calcium chloride), to drops of liquid water in which the chemical action takes place.

This property possessed by water of helping a chemical action without itself being changed in the process is also characteristic of other substances, and the phenomenon is known as catalysis (*q.v.*).

Desiccation, or the removal of water from a substance, may be performed either by mechanical devices such as centrifuging, freezing or evaporation, or by chemical means. The choice of agent in this case is determined by the degree of dryness required and the nature of the substance to be dried. The most generally useful substances are anhydrous calcium chloride, concentrated sulphuric acid and phosphorus pentoxide, the last being the most powerful desiccator known. By its action over varying periods of time the degree of intensive dehydration described above has been attained.

DRYOPITHECUS (drī-ō-pĭth'ē-kŭs), a genus of fossil Anthropoids which inhabited Europe, North Africa and North India in the Miocene. Seven species have been described and these, with four allied genera from the Siwalik formation of India, are believed to represent the ancestral stock of the anthropoids.

See C. F. Sonntag, *Morphology and Evolution of the Apes and Man* (1924).

DRY-POINT. Though generally classed as a variety of etching, and in practice often combined with that process, dry-point is, strictly speaking, a kind of engraving.

In etching the needle scratches only through the etching ground and exposes the surface of the plate; the latter is then placed in a bath of acid, and it is the chemical action of the acid that eats out in the copper a line of sufficient depth to hold printing ink. In dry-point, on the contrary, as in line-engraving, the lines are hollowed out by the tool itself in direct contact with the copper, as directed by the engraver's hand, without the intervention of any chemical action. Zinc can be used instead of copper, but this metal wears out quickly.

Methods. — The "dry" point, so called because no bath of acid supplements its use, is a tapering pointed instrument of steel, of stronger build than the point or needle used by the etcher and sometimes sharpened at both ends; but many modern engravers have substituted for steel a diamond point, or more rarely a ruby, fixed in a vectal handle. With one of these instruments the engraver works directly upon a plate of hard and polished copper, either shiny or blackened, ploughing up a line, shallow or deep, according to the amount of pressure used. Along one edge of this line, if the point is slanting, or along both edges if it is held upright, a raised edge of copper is turned up by the tool, and this ridge is termed the "burr." The burr, when the plate is inked for printing, becomes clothed with ink and produces in the impression the rich, soft and velvety effect which constitutes the peculiar charm of a dry-point proof. If the burr is removed (as it easily can be, should the engraver desire it, with a scraper) the somewhat thin line thus produced is less easily distinguished except by a practised eye, from the characteristic lines produced by the burin or the etching point. The burr is delicate and is easily worn out, either by too vigorous wiping when the plate is inked (experienced printers of dry-point use the palm of the hand for wiping the plate in preference to rag or muslin) or by too great pressure in the printing press. In any case the burr does not last long and the "bloom" of the early proofs of a dry-point soon wears off. The first two or three proofs, though they may be rough and uneven, often have a charm which can never be replaced by the more even printing of the bulk of the edition, and at some stage, it may be after a dozen proofs, or 20 or 50, according to the manipulation of the plate and the depth to which the lines have been sunk, deterioration inevitably becomes noticeable, unless the plate has been protected from wear by steel-facing. Some engravers assert that this precaution in no way affects the beauty of the proofs, and of some dry-point plates this may be true. But most engravers and most collectors are of opinion that there is an appreciable difference and that, according to Prof. H. W. Singer, "a trained eye can distinguish between the good, warm impressions taken from the copper and the hard, cold ones, taken from the plate after it has been steeled."

There can be no doubt that dry-points printed from the steel-faced plate for book illustration, such as André Dunozer de Segouzac's illustrations to *Les Croix de Bois* by *R.* Dorgelès (1921), can ill sustain comparison with the few artist's proofs taken before the steel-facing. In fact the process is thoroughly unsuitable for any purpose that requires the production of a large edition printed with mechanical regularity, and the dry-point only yields its essential charm in the hands of a sensitive and conscientious printer — none is better than the artist himself, if he understands the art of printing also — who knows when to stop, at the moment when the plate begins to show signs of wear, and does not feel bound to fulfil a contract by delivering a certain number of proofs, whether the plate will bear it or not. The dry-point, more than any other process of engraving, needs to be under the direct control, at every stage, of the artist who has invented the design to which he feels this process, rather than another, to be appropriate.

Corrections. — Two advantages which the dry-point process offers to the original etcher are the power which he possesses when using it of seeing exactly what he is doing with his tool upon the plate, and the comparative ease with which he can

DRY-POINTS BY ENGRAVERS AND ETCHERS FROM THE 16TH TO THE 19TH CENTURY

1. "St. Jerome seated near a Pollard Willow" (1512) by Albrecht Durer, the first of three dry-points. From the impression of the second plate in the Albertina Museum, Vienna
2. "Holy Family" by Albrecht Diirer. Undated, probably about 1512
3. "The Man of Sorrows" (1512) by Albrecht Durer. This plate and the two preceding were the only dry-points made by Durer
4. "Portrait of Himself" (1739) by Arthur Pond, one of the English painter-etchers of the 18th century who used the dry-point technique with success
5. "Spectacle des Tuileries" (1760) by Gabriel de St. Aubln. Touched up in dry-point in 1763
6. "L'Orage" (1848) by Charles Jacque, a French etcher who produced a number of dry-point landscapes with figures of horses
7. "Portrait of the Artist's Mother" (1822) by Andrew Geddes
8. Trial proof (Oct. 7, 1877) of "Windmill Hill," dry-point by Seymour Haden, one of the leading English etchers of the 19th century
9. "Sunset in Ireland" (from a very rich imprint) by Seymour Haden, 1863

EXAMPLES OF THE DRY-POINT TECHNIQUE

Dry-point is generally classed as a variety of etching though actually a kind of engraving. In dry-points no acid is used on the plate, as in pure etching, but the lines are hollowed out of the copper with a sharp pointed instrument. The raised edge of copper turned up by the tool is called the "burr." This, in the printing, produces the soft velvety effect peculiar to dry-points

1. "Weary" by James Abbott McNeill Whistler, finished in 1872
2. "Christ Healing the Sick" (the "Hundred Guilder Print") by Rembrandt. An etching of his middle period (1640–50) retouched with dry-point
3. Portrait of Arnold Tholinx by Rembrandt, 1656
4. Portrait of Victor Hugo by Auguste Rodin (1840–1917)
5. Portrait of Henry Becque by Auguste Rodin
6. portrait of Victor Hugo by Auguste Rodin
7. "Third Avenue" by C. W. R. Nevinson, British
8. "The Vista" by Rembrandt, 1652
9. "La Route d'Emmaus" by J. L. Forain (1852–1931), French

make alterations if he changes his mind or requires to correct a fault. Lines already made can be almost entirely obliterated with the burnisher or worked over with other lines, whereas in etching such alterations can only be effected by the much more difficult operation of laying a new ground. To quote E. S. Lumsden, "Corrections are very easily made in dry-point, because so little metal is *removed* from the surface, the strength depending principally upon the upturned ridges. This means that the sides of the lines are comparatively easily closed up by pushing them together with the burnisher. If the passage is to be reworked with heavy strokes, there is no difficulty at all; but if the original surface has to be recovered in order to print a clean tone from it, there is often considerable labour to erase the scratches altogether, as under heavy pressure the faintest indications of a line will show up in the proof. With care and patience anything can be done, and the freshness of the surface kept intact."

The comparative ease with which changes can be made results, in the case of some modern original artists whose work is done in dry-point, in a multiplicity of states. Of a celebrated recent dry-point by Muirhead Bone "A Spanish Good Friday," there are no less than 39 states, the engraver having repeatedly changed his mind about some detail, or thought of a fresh improvement that he could introduce, after he had begun to take proofs.

Dry-point and Etching.—Dry-point has sometimes been used by line-engravers, instead of etching to which they far more frequently resort, in the first preparatory stage (outline) of plates which are subsequently to be finished with the burin. Much more usual is the combination of dry-point with etching. Such a combination may be made either for the purpose of the general enrichment of an etched plate, in a second or subsequent state, by the addition of the dry-point burr, or for the sake of introducing small corrections, which can be made far more easily, though less permanently, by the addition of a few touches or lines with the dry-point than by an additional biting of the etched plate, which involves stopping out or the laying of a fresh ground. Dry-point additions to an etched plate can be readily distinguished by a trained eye in early impressions, but they wear away gradually till all trace of them is lost, and it is the presence of a clearly visible dry-point work, with all the richness that it was intended to impart, that confers value on early impressions of such an etching as the "Hundred Guilder Print" of Rembrandt, in its second state, or on the single state of "Christ Healing the Sick" by the same artist, though both the rich early impressions and the bare late ones from the worn plate which has lost its burr have to be described as belonging to the same state.

HISTORY

In a retrospect of the use of pure dry-point during the centuries which have elapsed since the invention of engraving, it will appear that its popularity has been intermittent, and that there have been prolonged periods during which, in one country or another, if not in all countries, it has quite fallen out of favour.

Earliest Work.—Its first appearance is earlier than that of etching, for there can be no doubt that the scarce and valuable prints of the "Master of the Hausbuch," a painter-engraver who worked in western Germany (probably on the middle Rhine) about 1480, were produced with the dry-point or possibly with the burin used in the same way, so as to scratch the surface of the copper and throw up a burr, which was not scraped away. This engraver is also called the "Master of the Amsterdam Cabinet" from the fact that the largest collection of his prints, numbering about 80 in all, is in that collection, but the name is to be deprecated, as it suggests that he was a Dutchman. He was a very original artist, and a keen observer of nature, with a technique quite unlike that of any other 15th century engraver.

Dürer.—The next engraver whom we find employing dry-point is Albrecht Dürer, who resorted to this process only in or about the year 1512, and probably abandoned the experiment when he discovered how few good proofs a plate engraved in this manner could yield. There are only three dry-points by Durer, "The Man of Sorrows" 1512 (Bartsch 21, Dodgson 65), "St. Jerome seated near a Pollard Willow," 1512 (Bartsch 59, Dodgson 66), and its companion print, the undated "Holy Family" of similar dimensions (Bartsch 43, Dodgson 67). Of the two latter dry-points very few good impressions are extant, for the burr wore off rapidly and the majority of extant specimens have been taken from the worn-out plates. Of Dürer's first work in this technique, "St. Jerome," two proofs only exist of a first state before the monogram (in the British Museum, and the Albertina, Vienna). These are of superior quality; the Albertina impression of the second plate is also very fine indeed. A fourth dry-point, "St. Veronica" (Bartsch 64), dated 1510, which figures in the older catalogues as one of the great rarities in Diirer's work, for only two impressions are known, is now discredited, for it has been proved to be a copy of an unsigned woodcut published at Nuremberg in a *Salve Animae* of 1503. Hans Sebald Beham alone of the followers of Durer used dry-point, and that but sparingly. It is hardly found again in the history of German engraving until a much later date.

Italy.—In Italy also the process was used in early times, chiefly by Andrea Schiavone, or Meldolla (1522?–82), an engraver who worked at Venice, and perhaps also by the monograminist H.E., for early impressions of his prints show signs of burr which in the usual later prints would not be suspected.

Rembrandt.—In the Netherlands dry-point was hardly used, if at all, before the 17th century. Its varied uses, as described above, for the enrichment of the etched plate by the addition of burr to the etched line as well as for the production of pure dry-points, were first discovered and exploited by the greatest of all painter-etchers, Rembrandt, who in his middle period, from about 1639 onwards, used this technique increasingly, in a thoroughly personal manner, for the sake of substituting "colour" and warmth for the drier effect of the pure etchings of his earlier period. From 1640–50 Rembrandt used dry-point extensi ely for retouching his etched plates—"The Death of the Virgin" and the "Hundred Guilder Print" are examples taken from the beginning and close of this period—while in his last period (1650–61), plates wrought wholly in dry-point became more and more frequent. Among the finest of these must be reckoned "The Goldweigher's Field" (1651); "The Vista" (1652); the two large plates, '(The Three Crosses" and "Christ Presented to the People," of 1653 and 1655 respectively and the "Portrait of Arnold Iboliux," 1656. An impression of the exceedingly rare first state of this portrait, in the Rudge collection, sold at auction in Dec. 1924, realized the large sum of 3,600 guineas, the highest price hitherto paid at an auction for an etching, if not for a print of any kind.

The 18th **Century.**—After Rembrandt, no very considerable use of the dry-point was made by any of the great engravers for a lengthy period. The 17th century was in all countries an age of line-engraving and etching, while in the Low Countries, Germany and England, the invention and development of mezzotint were claiming attention. In the 18th century dry-point was used here and there by a number of painter-etchers, amateurs in their technique as compared with the professional engravers, who found the medium congenial and probably took hints in their use of it from their study of Rembrandt. A beautiful example of such an 18th century dry-point is the portrait of himself, dated 1739, by Arthur Pond (reproduced, *Print Collectors' Quarterly,* 1922, ix. 324). One of the little subjects illustrating the destruction by fire of the Foire de Saint Germain in 1762, by Gabriel de St. Aubin, is a dry-point which seems in its modernity a precursor of the 19th century. In the period which preceded what is known as "the revival of etching," that is to say, during the first half of the 19th century, several English and Scottish etchers produced dry-points of remarkable merit. Among these were D. C Read, of Salisbury (1790–1821), E. T. Daniell, of Norwich (1804–42), and especially the two Scottish painter-etchers Andrew Geddes (1783–1844) and Sir David Wilkie (1785–1841). Of the last two, catalogues describing all the states of their plates with reproductions of five specimens, will be found in the fifth and eleventh publications of the Walpole Society, 1917 and 1923. Geddes' "Portrait of the Artist's Mother," his "Peckham Rye" and some other landscapes, and Wilkin's one pure dry-point, "The Lost

Receipt" are of conspicuous merit if compared with the dry-points of any period. The French etcher, Charles Jacque, also produced, long before 1850 a number of dry-point landscapes, with figures or horses, of great beauty.

Modern Work.—The etchers of the "revival," both in France and England soon brought the dry-point, as well as etching, into renewed favour. In the hands of Haden it yielded masterpieces like "Windmill Hill" and "Sunset in Ireland"; in those of Whistler "Finette," the "Portrait of Axenfeld," "Weary" and many more. Legros, soon after 1860, produced "La Promenade du Convalescents," "Femme se baignant les pieds," "Pecheurs d'écrevisses," and many beautiful landscapes. His pupil, Strang, half a century later, did much fine work in dry-point; so has Sir D. Y. Cameron, especially in his later work since 1903, and especially after 1910. Another master of the technique was Theodore Roussel (1847–1926). Of outstanding excellence among French dry-points of the late 19th century are those of the sculptor Auguste Rodin, whose portraits of Victor Hugo, of Henri Becque, of A. Proust, and "Allégorie du Printemps" and "La Ronde," are among the masterpieces of the medium. The French painter and etcher, J. L. Forain, produced some superb dry-points about 1909–10 and later. Among modern British engravers, Sir Muirhead Bone is pre-eminent as a master of dry-point, in which medium almost the whole of his numerous plates since 1898 have been wrought. His brother-in-law, Francis Dodd, since 1907, has done much good work in dry-point, and among later followers Henry Rushbury has come into the front rank. Another excellent engraver in dry-point is Edmund Blampied; C. R. W. Nevinson produced work of great merit in this medium during the World War.

(C. Do.)

ADVANCED TECHNIQUE

Some dry-point artists use a plate prepared or blackened as for etching, taking care to cut through the varnish to the metal surface underneath, and using the varying emphasis required by their design; for in dry-point everything must be drawn delicately or strongly by the artist himself as in ordinary drawing. The difficulty of working on the blackened plate is that it is not easy to judge exactly what emphasis has been used in making the lines, so the bare plate is more often used and a little weak black paint rubbed into the lines to mark their progress. Great care should be taken to do such inking of the lines as gently and as sparingly as possible, as the burr is easily injured during the progress of an elaborate plate with the result that the earlier portions of the work may look quite different from the later. Another difficulty will be found in the varying degrees of sharpness of the point used. A steel point requires resharpening frequently and the sharpening may not be exactly the same each time and this difference will be found reflected in the work. To obviate this, a diamond or ruby point is frequently used and works very smoothly when in good condition. It is, however, somewhat brittle and apt to flake away in strong cross-hatching or by striking the edge of the plate.

Dry-point has several striking advantages over etching: (a) The work can be more easily judged on the bare plate, being positive in character, *i.e.*, the lines appearing black (if filled in with black paint) exactly as in the print. (b) Corrections are more easily made as the lines are shallower and the metal being thrown up in furrows and not removed from the plate, can be forced back into the groove with a burnisher. Additions to the work can be easily made since the plate requires no regrounding and rebiting as in etching. (c) A trial print can be easily taken at any stage of the work, though it should be remembered that the fewer trial proofs that are taken the better, as a dry-point may easily be worn out in the course of a protracted series of trial proofs.

The point, the burnisher and the scraper are the three instruments used in dry-point: the use of the scraper is of much more importance than it is in etching, as the burr can be wholly or partly removed by it and the whole significance of the line altered. Some artists even remove the burr altogether and depend on the "nervous" character of the dry-point line for their effect.

One great disadvantage of dry-point is the difficulty of obtaining a large number of prints of equal excellence, owing to the delicate character of the work compared with etching or line-engraving. This has been largely overcome by the practice of steel-facing the plate before printing. It has led (especially in recent years) to the mixed plate, where dry-point is strengthened and stiffened by engraved lines done with the burin. The result is work obviously clearer and firmer in character than many pure dry-points, but lacking the particular charm of the best dry-point prints where spontaneity and vivacity (not characteristics of the burin) are most important assets. The best qualities of the two mediums are really incompatible. We cannot imagine a burin line introduced into the masterpieces of dry-point without fatal results. Dry-point is also used to lend to etched plates a "warmth" or "accent," or simply as the easiest method of making necessary additions. The difficulty then is that the dry-point lines wear out under the pressure of printing much earlier than the etched lines, and it becomes necessary to renew the dry-point work from time to time. From the pictorial point of view dry-point has the disadvantage of producing a picture too often "out of tone" and "spotty," owing to the somewhat accidental emphasis of the burr. From the point of view of style the dry-point needle is capable of too many different kinds of strokes; yet these difficulties only add to the fascination of trying to overcome them as they have been overcome by the great masters of the art.

Steel-facing and Printing Dry-points.—The question of steel-facing is surrounded by a prejudice in the eyes of collectors because it allows of larger editions being printed. The old steel-facing was heavy and clumsy compared with what is used to-day, and must have injured the dry-point on its application. Then, too, editions used to be printed from the copper and only after that steel-faced for a commoner kind of print. And the steel-faced plate being considered "fool-proof" was handed over to unintelligent printing—the fact not being recognized that a steel-faced plate really requires more and not less care in printing. For the delicate tones of the printing ink are more difficult to estimate with nicety on the less "sympathetic" surface of the steel. Still, it is true that for certain plates requiring delicate tones of printing-ink to supplement the line work steel-facing is not appropriate. If steel-facing is determined on, this should be done immediately the plate is completed and it should be remembered that the cleaner the plate and its lines have been kept during working the better, as the plate has to be made chemically clean before the electro-steeling and the smaller the amount of cleaning required the better for the preservation of the burr and the delicate lines.

Printing dry-points is a difficult art for the line and its burr lends itself to many different styles of printing. Care should be taken to give a clearness and purity to lines which so easily become clogged and heavy. The aim should be, while retaining the ink caught by the burr, to remove all the smudginess and heavy tone between the lines. This can best be done by repeated hand-wiping of the plate from all directions while the plate is fairly warm. Dry-point printing—or rather the preparing of the plate for the press—is thus a much slower process than etching printing, as so much more careful hand-wiping is required. "Retroussage" should be sparingly used, as the ink on the burr is easily smudged. A soft paper shows a dry-point to most advantage.

Because of its very simplicity, dry-point is a peculiarly "autographic" medium, very sensitive to the display of the temperament of the artist. All etched work bears a strong family resemblance, and still more so work with the burin. But a collection of the best dry-points shows an astonishing difference in the mere appearance of the lines. This is the great fascination of the craft, as a peculiarly personal style has been attained in it again and again. It is as capable of as many styles as drawing itself, to which indeed it is the nearest of all methods of making prints. There is no chemistry to overcome—no accidentals—the old gibe, levelled at etching, of "a blundering art" does not apply. If the student studies carefully the dry-points of Rembrandt, Whistler, Haden and Rodin, the immense range and possibilities of the medium should be clearly grasped. The inimitably natural stroke of the first, the sweeping "silky" line of the second, the abrupt strokes so suggestive of painters' colour of the third, the chisel-

like cutting of the fourth—there is no range comparable to this in any other system of making prints, and new triumphs of individual method in dry-point may yet have to be recorded. (See ETCHING, ENGRAVING.)

(Mu. B.)

DRY **QUENCHING** is a process of cooling a hot solid substance without using a liquid in direct contact with the substance to be quenched. The sensible heat in most of the cases can thereby economically be converted into useful energy and the quality of the product improved. This process has been applied and developed primarily for the quenching of coke as it is discharged from coke ovens at temperatures of 1,800° to 2,000° F. It was for a long time common practice to sprinkle this hot coke with water or to submerge it in water to reduce its temperature sufficiently to prevent it from re-igniting and to facilitate handling and transportation. This method, however, has several disadvantages. The coke takes up water, thereby considerably reducing its heating value. The wet quenching vapours are corrosive and affect steel and concrete construction, thereby largely increasing maintenance costs. They also carry coke dust high into the air and scatter it widely over the plant and the community.

Methods.—In the Sulzer system, the process of dry quenching of the hot coke is accomplished by circulating an inert mixture of gases in a closed cycle, first through the hot coke mass where the gases extract the sensible heat, thence through a steam boiler where the hot gases transfer the heat to the water in the boiler and convert it into steam. The cooled gases leaving the boiler are conducted back to the fan and again forced through the coke.

The hot coke is conveyed to the dry quencher in more or less regular intervals depending upon the schedule of discharge of the coke ovens. It is introduced through the top door of the coke container which holds a number of loads Before a new load of coke is charged, an equal amount of cooled coke is withdrawn from the bottom of the apparatus. The coke, therefore, is allcwed to remain in the container for several hours gradually reaching lower cooling zones. The cooling gas is circulated by means of a fan continuously operating and flows through the coke mass in an upward direction, thereby performing the cooling in accordance with the counterflow principle.

The inert mixture of gas is formed when starting up the plant. A small portion of coke is converted into a mixture of carbon monoxide and carbon dioxide whereby the oxygen of the air within the system is completely consumed. The cooling gas therefore consists mainly of these products of combustion and nitrogen. Care must be taken that two doors are never open at the same time in order to prevent air entering the system causing combustion of coke. As long as only one door is open at a time, the pressure in the system adjusts itself to atmospheric pressure at that point, but no gas is pushed out nor air sucked in. However, on discharging cooled coke an equal volume of air enters the system.

Advantages.—The principal benefit in dry quenching is the production of 400 to 500 lb. of steam per 1,000 lb. of coke quenched, this representing a saving that equals 25 to 40% of the fuel required to carbonize the coal. The steam may be used in the by-product plant or for generating of power which may either cover the needs of the plant or be fed into the lines of a power company.

The specific heat of coke has been determined by many investigators and can be considered as sufficiently established for practical use. It depends upon the temperature, the ash content and the amount of volatile matter still contained in the coke. The thermal efficiency of a dry quenching plant taking the inlet and outlet temperatures of the coke as limits is about 90 to 95%; there is no loss due to combustible matter in the ash, stack waste gases, etc., as is the case in direct fired boilers; the only loss is through radiation. Dry quenched coke has a higher thermal value than wet quenched coke owing to absence of water. Considerable improvement in operation of gas-producers, water-gas plants, blast furnaces, foundry cupolas and domestic furnaces is the benefit resulting from the use of dry quenched coke. Breeze from this coke can still be considered as a high quality fuel, while wet quenched coke breeze due to high moisture is very likely to cause trouble in furnace operation. The dry-quenching process may also be adapted for the purpose of cooling other hot products of the chemical industry such as calcium carbide, lime, cement clinker, etc., saving the sensible heat and improving the quality of the product.

(H. D. S.)

DRY ROT, a term applied to the decay of wood caused by various kinds of fungi. Frequently the term is applied solely to such decay as takes place in timber that has been worked or is in actual use: the present article deals solely with dry rot in this restricted sense. The fungi feed upon the wood, and thus cause it to become lighter in weight, weaker, more brittle and less elastic, so that when struck the wood emits a muffled sound and readily snaps. In more advanced stages of rot the wood is apt to warp, and may show cracks ("cross-shakes") at right angles to the grain and can greedily absorb liquids, *e.g.,* water, and, comparatively early, the wood may show discolourations and lose any characteristic scent.

The fungi causing dry rot belong to the great class that includes the familiar toadstools and mushroom. They are composed of very slender, hollow, jointed, closed tubes (hyphae) which grow in length and emit branches. These tubes permeate the wood, and outside this may also produce loose mould-like coatings, or by interweaving can give rise to denser sheets, nets, strings or more massive fruit-bodies shaped like cakes, brackets or mushrooms.

The fruit-bodies, which are easily visible to the naked eye, eject myriads of microscopic infectious germs, termed spores. But spores are likewise produced by certain species of these fungi quite apart from the fruit-bodies.

Infection of wood may also take place by means other than by spores. Certain species of fungi, including the most malignant causal agent of dry rot in houses in Europe, *Merulius* lacrymans (*domesticus*), not only grow inside the wood but can more rapidly spread over its surface, and advance over non-wooden surfaces, and, in the form of strings penetrate or perforate brick walls, attacking wood that they reach. Contrasting with such *contagious* species are other merely *infectious* species that usually live only in the interior of the wood until they thrust their fruit-bodies outside it; such internal decay is often difficult to detect, as the superficial wood may be quite sound and normal in appearance.

Wood may be protected against dry rot by one or both of two methods: (1) sanitation; (2) antiseptic (fungicidal) treatment.

Sanitation.—Sanitation is the cheapest method of preventing, and sometimes of arresting, dry rot. One essential condition for activity is a sufficient supply of air, as these fungi absorb oxygen and give out carbonic acid and water. Although they can grow in the absence of oxygen, they are readily killed by an accumulation of carbon dioxide. During respiration certain species of fungi can produce water so vigorously that dry wood is thoroughly moistened and drops of water appear on the fungus itself (hence the specific name of *Merulius* lacrymans).

An adequate supply of water is required by the fungus, which owes the main part of its weight to water and cannot take in food unless this be dissolved in water. So far as dry rot in temperate regions is concerned, in the dry air of deep coal pits and of warmed rooms wood may last for decades or centuries; whereas dry rot is common in moist, shallower coal-pits, in moist cellars and damp ground-floors; especially can it appear near escapes of water from water pipes or steam pipes, and in stuffy, feebly ventilated places; for instance under floors covered with linoleum. In a house fungus causing dry rot may be luxuriant on the hidden faces of floor-boards, panels and skirting-boards, but be entirely lacking on the visible faces of these in contact with drier air of rooms; so that dry rot may be widespread through a building although no fungus be visible until the wood-work is disturbed.

Fungi causing dry rot cannot attack wood that is either too wet or too dry. Some species demand much moisture: among such

are *Coniophora* cerebella (whose slender black threads are common on the surface of damp wood in houses) and a number of fungi that do not grow over the surface of the wood. These species are probably largely responsible for "wet rot," a popular term apparently applied to discoloured wood showing to the naked eye no fungus inside or outside the wood, no external cross-shakes, but giving evidence of weakness and possibly former or present wetness (which caused the death and disappearance of any fungus formerly outside the wood).

Other fungi, including Merulius lacrymans, produce considerable amounts of water and, transporting this, can thus moisten distant wood; thus they can feed on drier wood.

Where dry rot in a building is caused by fungi demanding much moisture, it may be arrested by merely cutting off the excessive supply of water; this will not suffice when *Merulius* lacrymans is the causal agent. Moreover cutting off the excess of moisture does not necessarily cause death of the fungus inside the wood: when wood attacked by *Merulius* or when certain internal feeders have been thoroughly dried for months, the fungus inside the wood may awaken into activity if the wood be remoistened.

Arrangements to secure a house against excess of dampness include: erection on a light pervious soil, provision of efficient dampcourses; care against absorption or condensation of water by and on the walls; under the ground floor, adequate ventilation and provision of a water-tight coating over the concrete; obviation of leakage or overflow from rain-water pipes and gutters outside the house, and water pipes and steam pipes indoors; proper construction of window casements to allow water to flow properly away from them; renewal of paint on external woodwork; and adequate maintenance of the roofing.

Fungi causing dry rot are active only within certain ranges of temperature; but inasmuch as the temperatures prevailing in all parts of a building, from cellar to roof, in temperate regions at times enable these fungi to be active, temperature from the practical point of view intervenes only as a means of eradication. Low temperatures (for instance the freezing point of water) at least in the case of *Merulius* lacrymans do not suffice to kill fungus or spores. Higher temperatures (over 50° C.) are much more effective, so that infected wood can be sterilized by heat, especially by steam, at temperatures below the boiling point of water. A painter's lamp suffices to sterilize infected surfaces, but an oxy-acetylene flame, or some equivalent, is required for rapid sterilization of walls permeated with fungi causing dry rot.

Antiseptic (Fungicidal) Treatment.— The decay of wood can be combated by the application of disinfectants and especially by substances that are powerful fungicides.

Among organic wood-preservatives the most familiar is so-called coal-tar "creosote oil," which is very widely used out of doors to preserve railway-sleepers, paving blocks, telegraph-poles, etc. Its scent is too powerful and persistent to permit of its use indoors, so that in houses, etc., "creosote" is often replaced by somewhat similar preservatives from which the more volatile and strong-scented oils have been removed. Extremely powerful organic fungicides suitable for use on wood are dinitrophenol and sodium dinitrophenate, to which are added other substances, such as sodium fluoride, designed to render the mixture non-explosive. On the other hand carbolic acid and formalin are too evanescent; and many other disinfectants used to destroy bacteria causing disease are too weak in action on fungi to act as timber preservatives.

Among aqueous solutions of *inorganic* salts used to preserve wood are copper sulphate (which attacks iron), zinc chloride (which easily washes out and when too warm or strong destroys wood), corrosive sublimate (very poisonous), sodium fluoride, and acid (commercial) magnesium silico-fluoride (which attacks metals and glass). Of these inorganic salts the last two may be generally regarded as the best for use in houses.

It is generally true that with increasing depth of penetration of the preservative into the wood the greater is the durability conferred, but the more costly is the process of treatment. Out of doors the preservative (usually "creosote") is driven deep into thick pieces of timber (such as sleepers, poles or paving-blocks) by pneumatic pressure or by immersion in hot tanks. Whereas wood-work in buildings is usually merely coated with the preservative, reliance being more economically based upon sanitation including proper methods of construction. (P. GM.)

DRY TOWTUGAS, a group of 10 coral islets or keys 65 m. west of Key West, Florida. The largest are East Key, Bird Key and Loggerhead. Fort Jefferson, the site of a military prison during the Civil War, is a quarantine station. Loggerhead has a Carnegie laboratory of marine biology. The group forms a Federal bird reservation.

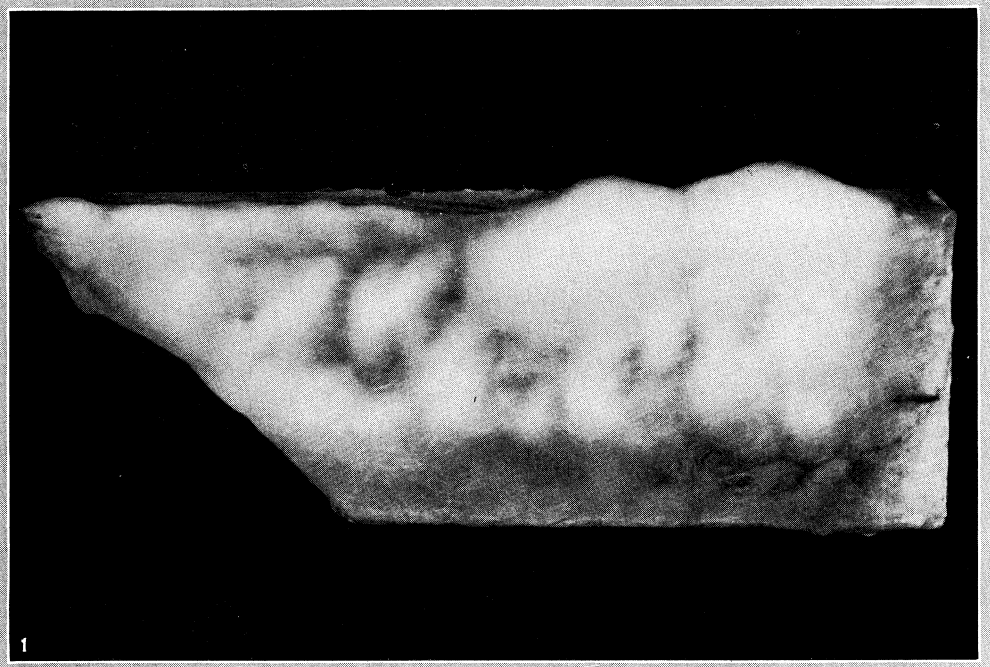
DUAL IGNITION: see INTERNAL COMBUSTION ENGINES.

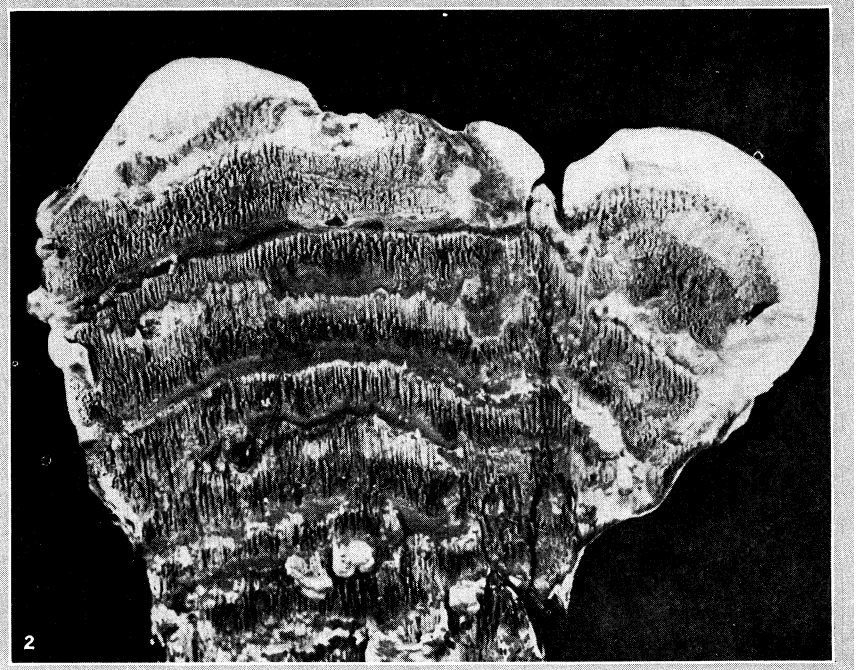
DUALISM. In metaphysics, dualism postulates the eternal coexistence of mind and matter, as opposed to monism both idealistic and materialistic. Two forms of this dualism are held. It is said that (1) mind and matter are absolutely heterogeneous, thus making any causal relation between them ex *hypothesi* impossible, (2) there is a hypothetical dualism, so that mind cannot bridge over the chasm so far as to *know* matter in itself, though it is compelled by its own laws of cause and effect to postulate matter as the origin, if not the cause, of its sensations. It follows that, for the thinking mind, matter is a necessary hypothesis. Hence the theory is a kind of monism, inasmuch as it confessedly does not assert the existence of matter save as an intellectual postulate for the thinking mind. Matter, in other words, must be assumed to exist, though mind cannot know it in itself. From this question there emerges a second and more difficult problem. Consciousness, it is held, is of two main kinds, sensation and reason. Sensation alone is insufficient to explain all our intellectual phenomena; all sensation is momentary and individual (cf. EMPIRICISM). HOW then are we to account for memory and the principles of necessity, similarity, universality? It is argued that there must be in the mind an enduring, primary faculty whereby we retain, compare and group the presentations of sense. This faculty is a priori, transcendental, and entirely separate from all the data of experience and sense-perception. Here then we have a dualism within experience. The mind is not to be regarded as a sensitized film which automatically records the impressions of the senses. It contains within itself this co-ordinating power which reacts upon and arranges the sense-given presentations.

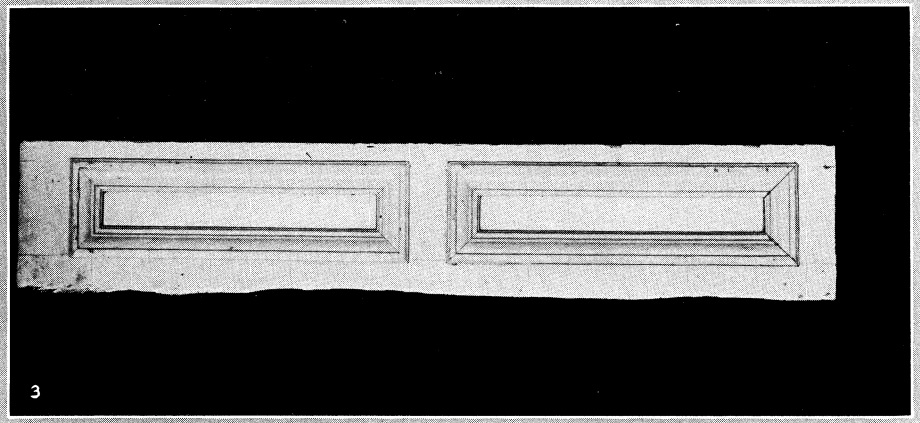
In Ethics and Theology.— In the domain of morals, dualism postulates the separate existence of Good and Evil, as principles of existence. In theology the appearance of dualism is sporadic and has not the fundamental, determining importance which it has in metaphysics. It is a result rather than a starting-point. The old Zoroastrianism, and those Christian sects (*e.g.,* Manichaeism) which were influenced by it, postulate two contending deities Ormuzd and Ahriman (Good and Evil), which war against one another in influencing the conduct of men. So, in Christianity, the existence of Satan as an evil influence, antagonistic to God, involves a kind of dualism. But generally speaking this dualism is permissive, inasmuch as it is always held that God will triumph over Satan in His own time. So, in Zoroastrianism, the dualism is not ultimate, for Ahriman and Ormuzd are represented as the twin sons of Zervana Akarana, *i.e.,* limitless time, wherein both will be finally absorbed. The postulate of an Evil Being arises from the difficulty, at all times acutely felt by a certain type of mind, of reconciling the existence of evil with the divine attributes of perfect goodness, full knowledge and infinite power. John Stuart Mill (Essay on Religion) preferred to disbelieve in the omnipotence of God rather than forgo the belief in His goodness. It follows from such a view that Satan is not the creation of God, but rather a power coeval in origin, over whose activity God has no absolute control.

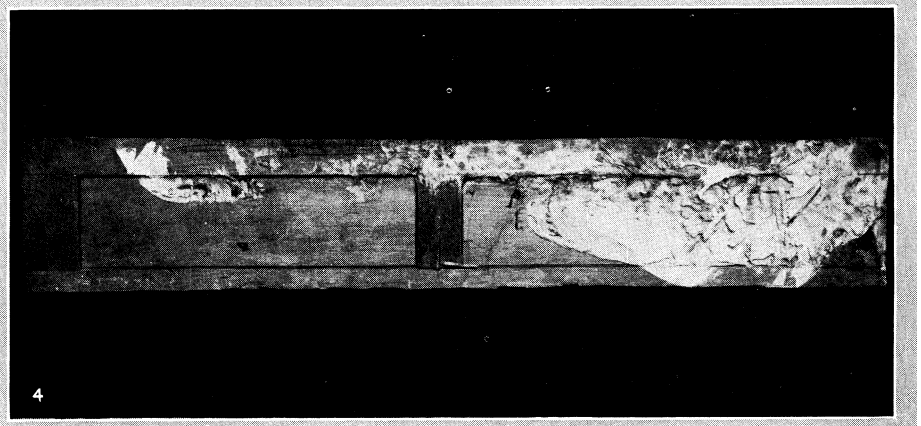
In Christology.—Dualism is also used in a special theological sense to describe a doctrine of the Nestorian heresy. According to this doctrine the personality of Christ is twofold; the Divine Logos dwells as a distinct personality in the man Jesus Christ, the union of the two natures being analogous to the relation between the believer and the indwelling Holy Spirit.

History of Metaphysical Dualism.— The earliest European thinkers (see IONIAN SCHOOL OF PHILOSOPHY) endeavoured to









FORMS OF DRY ROT (MERULIUS LACRYMANS)

1. Cushion-like growth of *Merulius lacrymans*, so called because it is covered with drops of water. During the process of respiration this fungus produces a considerable amount of water with which it moistens dry wood
2. Bracket-like fruit-body of *Merulius lacrymans*, a form of this fungus easily visible to the naked eye. It ejects myriads of microscopic germs called spores, which infect the surrounding wood
3. The sound exposed face of a panel infected with *Merulius lacrymans*. The visible faces of woodwork which are in contact with the comparatively dry air of rooms often appear sound, although the hidden faces of the same woodwork may be covered with fungous growth
4. The reverse of the panel in figure 3, showing infection with *Merulius lacrymans*

reduce all the facts of the universe to a single material origin, such as Fire, Water, Air. It is only gradually that there appears any recognition of a spiritual principle exercising a modifying or causal influence over inert matter. Anaxagoras was the first to postulate the existence of Reason (*νοῦς*) as the source of change and progress. Yet even he did not conceive this Reason as incorporeal; it was in reality only the most highly rarefied form of matter in existence. In Plato for the first time we find a truly dualistic conception of the universe. Asserting that Ideas alone really exist, he yet found it necessary to postulate a second principle of not-being, the groundwork of sensuous existence and of imperfection and evil. Herein he identified metaphysics and ethics, combining the good with the truly existent and evil with the non-existent. Aristotle rebels against this conception and substitutes the idea of *πρώτη ὕλη* and development. Nevertheless he does not escape from the dualism of Form and Matter, *νοῦς* and *ὕλη*. The scholastic philosophers naturally held dualistic views resulting from their extreme devotion to formalism. This blind dualism found its natural consequence in the revolt of the Renaissance thinkers, Bruno and Paracelsus, who asserted the unity of mind and matter in all existence and were the precursors of the more intelligent monism of Leibniz and the scientific metaphysics of his successors. The birth of modern physical science on the other hand in the investigations of Bacon and Descartes obscured the metaphysical issue by the predominance of the mechanical principles of natural philosophy. They attempted to explain the fundamental problems of existence by the unaided evidence of the new natural science. Thus Descartes maintained the absolute dualism of the *res cogitans* and the *res extensa*. Spinoza realized the flaw in the division and preferred to postulate a single substance *(unica substantia)* of which mind and matter are ultimate attributes, while Leibniz explained the universe as a harmony of spiritual or semispiritual principles. Kant practically abandons the problem. He never really establishes a relation between pure reason and things-in-themselves *(Dinge an sich)*, but rather seeks refuge in a dualism within consciousness, the transcendental and the empirical. Since Kant there are, therefore, two streams of dualism, dealing, one with the radical problem of the relation between mind and matter, the other with the relation between the purely rational and the empirical elements within consciousness. To the first problem one answer commonly given is that matter in itself is inherently unthinkable and comes within the vision of the mind only as an intellectual presentation, so that philosophy is in a sense both dualist and monist; it is a cosmic dualism inasmuch as it admits the possible existence of matter as a hypothesis, though it denies the possibility of any true knowledge of it, and is hence with regard to the only possible knowledge an idealistic monism. It is a self-destructive dualism, a confessedly one-sided monism, agnostic as to the fundamental problem. To the second problem there are two main answers, that of Associationism which denies to the mind any *a priori* powers and asserts that sensation is the only source of knowledge, and that which admits the existence of both transcendental and empirical knowledge.

DUALITY. A statement capable of two different meanings, both of them true, one obtained from the other, by simply interchanging two words, is an illustration of the principle of duality. An important application of the principle is found in projective geometry. In the plane this is accomplished by interchanging the words "point" and "line"; it is well illustrated by the theorem of Pappus, which may be stated as follows:

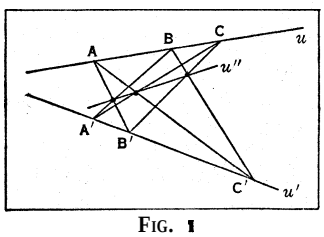


FIG. 1

Given any two straight lines u, u' in the plane; choose any three points A, B, C on u, and any three points A', B', C', on u'. The three points of intersection AB', $A'B$; AC', $A'C$; BC', $B'C$ lie on a straight line u''. The dual theorem is:

Given any two points U, U'; draw any three lines a, b, c through U and a', b', c' through U'. The three lines joining the points ab', $a'b$; ac', $a'c$; bc', $b'c$ all pass through a point U''. If the first proof has been established, the second follows by duality, since the determining elements of lines in terms of points are identical with those of points in terms of lines. The principle was first recognized by Poncelet in the *Journal für Mathematik* (1829), and by Gergonne in the *Annales de Mathématiques pures et appliquées* (1825–27), and first generally applied by Steiner in his *Systematische Entwickelungen*, (1832).

In geometry of three dimensions there is a corresponding duality between points and planes. In this case the line is self dual, as it is determined by any two distinct points on it or by any two distinct planes through it.

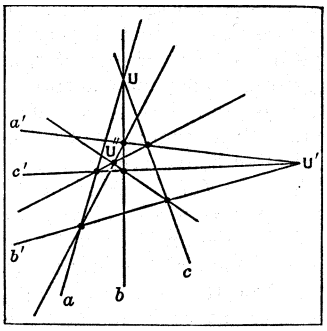

FIG. 2

Many other illustrations of the principle can be given. A geometry can be constructed in the plane by replacing the word "line" wherever it occurs in a proposition by the word "circle," if the circle associated with any given line is constructed as follows:

Given a fixed circle C with centre O. Let a given line meet it in A, B. Draw the circle through A, B, O. After this has been done for every line, think of the point O being removed from the plane. The resulting system of incomplete circles furnishes a non-euclidean interpretation of plane geometry. The line-sphere transformation of Lie is an illustration of a complete duality between lines and spheres in space. Much of higher geometry is concerned with the principal of duality; every new application practically doubles the extent of existing knowledge.

DUALLA, one of the principal negro peoples of Cameroon estuary, west Africa. *(See* CAMEROONS.)

DUAL ORGANIZATION. A distinctive feature in the social structure of certain simple communities is their division into two complementary sections which have important functions in the social and ceremonial life of the people. This system of dual organization occurs most typically in many parts of Australia, Melanesia and N. America, and has been recorded from India and Assam; its existence elsewhere has not been definitely established. The two sections, usually termed moieties or phratries, are unilateral in character, membership being determined by descent through either the father or the mother. In Melanesia matrilineal descent predominates, elsewhere both matrilineal and patrilineal descent are common. An exceptional case is found among the Fox and Kickapoo of N. America, where the father usually, but not always, determines which moiety his child shall enter, so that often the first-born child will belong to one moiety and the next child to the other. The structure of the moieties also varies: in some communities they are simple undivided groups; in others they are each composed of a number of smaller sub-divisions or clans, *e.g.*, among the Winnebago of N. America, where the one moiety consists of 28 clans and the other of *26*.

Functions.— The dual organization is very frequently connected with the regulation of marriage. In most communities the moieties are exogamous, and consequently a man belonging to one moiety must always marry a woman belonging to the other. This feature is sometimes regarded as the distinctive characteristic of the dual organization, but although it is of most frequent occurrence there are several exceptions. Among certain N. American tribes, *e.g.* the Hidatsa, Yuchi, Western Mono and Iroquois, marriage between members of the same moiety is not prohibited. When the moieties are exogamous a man is never permitted to marry any woman he chooses in the opposite moiety. The form of marriage is always dependent upon other factors, such as age, status and kinship, where certain relatives are prescribed as eligible mates while marriage between others is not permitted. Thus the form of marriage most frequently found with the dual organization is that between cross-cousics; and, where the moieties are exogamous, it follows (whether descent be patrilineal or matrilineal) that cross-cousins belong to different moieties, while parallel cousins between whom marriage is not permitted, become mem-

bers of the same moiety. The dual organization in such cases does not determine but merely systematizes the form of marriage. Only under exceptional circumstances can cross-cousin marriage result from the division of the community into moieties (see COUSIN MARRIAGE).

Other functions of the dual organization vary according to the community in which it is found. .In the daily life of the people, the members of the two moieties are very commonly separated at games, feasts, contests, etc., and may even inhabit different parts of the settlement. Often there is also a striking development of reciprocal services between the two moieties, so that they assist each other, *e.g.*, at the initiation and burial of their members, at the building of houses and in various other economic enterprises, while communal ceremonies are usually so arranged that one moiety is conceived as giving them to the other. The symmetry of structure characteristic of the dual organization here serves as the indispensable basis of reciprocal obligations (cf. B. Malinowski, Crime and *Custom* in Savage Society, chap. iv.). Thus among the Iroquois of N. America, the two moieties are always represented at the great annual festivals and at the ceremonial meetings of the medicine or religious societies, and in the ceremonial Long House they are spatially separated, the speakers on each side addressing the other in the course of the ceremony; games, such as ball and lacrosse, are also played between the two moieties; they have the obligation of burying each other's members; and they also exercise political functions, each moiety, *e.g.*, having the right of veto over the choice of the other in the election of chiefs (cf. L. H. Morgan, *The* League of the Iroquois).

Again, there is sometimes to be found a theoretical dichotomy of the universe whereby all natural phenomena are divided between the two moieties; and, especially where the moieties are subdivided into clans, this system of classification is frequently accompanied by totemism (*q.v.*). Thus the Wotjobaluk of S.E. Australia have two moieties called Rrokitch and Gamutch, each of which is sub-divided into a number of clans. Associated with each moiety in rather arbitrary fashion is a long list of animals, plants, etc.; in fact, the native concept is that everything in the world is either Krokitch or Gamutch. This classification is carried still further, so that objects regarded as belonging say to Krokitch are sub-divided among the clans composing that moiety. Moreover, suppose a man is a member of a certain clan in the Krokitch moiety to which the white cockatoo also belongs, then the white cockatoo is his totem, and he has a series of special observances to fulfil towards it, while he also has a general ritual relation towards all the other objects belonging to his moiety (cf. A. W. Howitt, Native Tribes of S.E. Australia).

Frequently also the dual division of the community seems to stimulate a tendency to emphasize contrasts between the two moieties. One moiety, *e.g.*, is believed to be of local origin, the other to have come from elsewhere; or they are supposed to have different physical and mental characters; or their mythologies and traditions differ; or the one is regarded as superior to the other; or their names are antithetical, *e.g.*, the widespread Australian names "Eaglehawk" (white) and "Crow" (black).

Sometimes, as in Melanesia, the moieties are apparently even hostile, and each regards the other with dislike and suspicion. All such distinctions bring out the fundamental significance of the dual organization in the structure of the community.

Theories **of** Origin. — The dual organization is ascribed sometimes to a process of fission whereby a single group came to be divided into two moieties. On the other hand, Rivers (The History of Melanesian Society, chap. xxxviii.), emphasizing the ideas of contrast between the two moieties as found in Melanesia, believed that the dual organization there developed as the result of the intermixture of two distinct peoples, one of which migrated into the region and set up a social system in co-operation with the communities it found there. This idea is carried still further, by not restricting the term "dual organization" to the moiety system, to which alone it applies, but extending it to dualism of every form—economic, political, religious, mythological, etc.—regarded as having originated in Egypt as the result of a process whereby a duality of ruling groups became completely superposed on a duality of a territorial nature (Upper and Lower Egypt), and as having spread with these characteristics to all parts of the world where it is now found (cf. W. J. Perry, The Children of the Sun.) This theory however, suffers from defects which render it unacceptable.

All theories which attempt to find a single origin for the dual organization are inadequate. This mode of social structure cannot be regarded either as the invention of one people or as the result of one particular social process. It is a recurring institution that has arisen many times in different places — now by the reduction of clans, now by the fusion of two inter-marrying groups, and again by other processes. No one theory of origin can be laid down as conclusive: each occurrence must receive special investigation. (I. S.)

Lowie, *Primitive Society* (1921, bibl.); A. A. Goldenweiser, *Early Civilization* (1922); W. H. R. Rivers, *Social Organization* (1924).

DUARS, a tract of country in north-east India consisting of the Western and the Eastern Duars, both of which belonged to Bhutan prior to the Bhutan War of 1864–65; as a result of this they passed into possession of the British, when the Eastern Duars were assigned to Assam and the Western to Bengal. The Eastern Duars, 1,570 sq.m., are in the Goalpara district of Assam, forming a strip of flat country lying beneath the Bhutan mountains. It is but slightly developed and sparsely populated. The Western Duars, 1,862 sq.m., lie at the foot of the Himalayas in the north-east of the Jalpaiguri district of Bengal. They are traversed by the Bengal-Duars railway and are an important centre of the tea-planting industry.

DU BARRY, MARIE JEANNE BECU, COMTESSE (1746–1793), French adventuress, mistress of Louis XV., was born at Vaucouleurs on Aug. 19, 1746, the illegitimate daughter of a tax collector. She lived as a courtesan in Paris under the name of Mdlle. Lange, and Jean, comte du Barry, took her into his house to make it more attractive to the dupes whose money he won by gambling. Through Lebel, valet de chambre of Louis XV., and the duc de Richelieu, he succeeded in installing her, in 1769, as official mistress of the king, after a nominal marriage with Guillaume du Barry. The duc de Choiseul, who refused to acknowledge her, was disgraced in 1771; and the duc d'Aiguillon, who had the reputation of being her lover, took his place, and in concert with her governed the monarch. Louis XV. built for her the mansion of Luciennes. At his death in 1774 an order of his successor banished her for a brief period to the abbey of Pont-aux-Dames, near Meaux. She led a retired life at Luciennes with the comte de Cossé-Brissac. Having gone to England in 1792 to endeavour to raise money on her jewels, she was on her return accused before the Revolutionary Tribunal of having conspired against the republic. She was condemned to death on Dec. 7, 1793, and guillotined the same evening. Her contemporaries, scorning her low birth rather than her vices, attributed to her a malicious political rôle of which she was at heart incapable, and have done scant justice to her quick wit, her frank but gracious manners and her seductive beauty. The volume of Lettrcs et Anecdotes (1779) which bears her name was not written by her.

See E. and *J.* de Goncourt, *La du Barry* (Paris, 1880); C. Vatel, *Histoire de Madame du Barry* (1882–83), based on sources; R. Douglas, *The Life and Times* of *Madame du Barry* (1896); Saint-André, *Madame du Barry* (1908).

DU BARTAS, GUILLAUME DE SALLUSTE, SEIGNEUR (1544–1590), French poet, was born near Auch. He was employed by Henry IV. of France in England, Denmark and Scotland; and he commanded a troop of horse in Gascony, under the marshal de Martingan. He was a convinced Huguenot, and cherished the idea of writing a great religious epic in which biblical characters and Christian sentiment were to supplant the pagan mise *en scène* then in fashion. His first epic, Judith, appeared in a volume entitled La Muse *chrétienne* (Bordeaux, 1573). This was followed five years later by his principal work, La *Sepmaine,* a poem on the creation of the world. This work was held by admirers of du Bartas to put him on a level with Ronsard, and

30 editions of it were printed within six years after its appearance. Its religious tone and fanciful style made it a great favourite in England, where the author was called the "divine" du Bartas, and placed on an equality with Ariosto. Spenser, Hall and Ben Jonson all speak of it in the highest terms. King James VI. of Scotland tried his "prentice hand" at the translation of du Bartas's poem *L'Uranie,* and the compliment was returned by the French writer, who translated, as La *Lepanthe,* James's poem on the battle of Lepanto. Du Bartas began the publication of the Seconde *Sepmaine* in 1584. He aimed at a great epic, never completed, which should stretch from the story of the creation to the coming of the Messiah. Du Bartas died in July 1590 in Paris from wounds received at the battle of Ivry. He maintained a reputation abroad long after he had ceased to be read, except by students, in France, where his prolixity proved fatal to his fame.

Joshua Sylvester translated the *Sepmaine* in 1598; other English translations from du Bartas are *The Historie of Judith* . . . (1584), by Thomas Hudson; of portions of the "Weeks" (162j) by William Lisle (1569–1637), the Anglo-Saxon scholar; *Urania* (1589), by Robert Ashley (1565–1641); and Sir Philip Sidney *(see* Florio's dedication of the second book of his translation of Montaigne to Lady Rich) wrote a translation of the first "Week," which is lost. The *Oeuvres complètes* of du Bartas were printed at Paris (1579), Paris and Bordeaux (1611); a selection, *Choix de poésies,* was edited by Benetric and de Gourcutt in 1890. *See* also G. Pellissier, *La Vie et les oeuvres de du Bartas* (1883); H. Ashton, *Du Bartas en Angleterre* (1908).

DUBAWNT or **DOOBAUNT** (Indian Toobaung, *i.e.,* turbid), a river of Mackenzie and Keewatin districts, Canada. It rises in Wholdaia (or Daly) Lake, in 104° 20′ W. and 60° 15′ N., and flows northward to its confluence with the Thelon river, and thence eastward to Chesterfield Inlet, an arm of Hudson Bay.

DUBBO, a municipal town of Lincoln county, Mew South Wales, Australia, on the Macquarie river, a flourishing manufacturing town in a pastoral district with coal and copper in the neighbourhood.

DU BELLAY, GUILLAUME, SIEUR DE LANGEY (1491–1543), French soldier and diplomat, was born at the chbteau of Glatigny, near Montmirail in 1491, of the Angevin family which gave many soldiers to France. Guillaume, the eldest of six brothers, was a soldier, humanist, historian, and the most able diplomat at the command of Francis I. He was taken prisoner at Pavia (1525) and shared the captivity of Francis I. He was sent three times to England in 1529–1530, was occupied with the execution of the treaty of Cambrai and also with the question of Henry VIII.'s divorce. With the help of his brother Jean, then bishop of Paris, he obtained a decision favourable to Henry VIII. from the Sorbonne (July 2, 1530). From 1532 to 1536, though he went three times to England, he was principally employed in uniting the German princes against Charles V.; in May 1532 he signed the treaty of Scheyern with the dukes of Bavaria, the landgrave of Hesse, and the elector of Saxony, and in Jan. 1534 the treaty of Augsburg. During the war of 1537 Francis I. sent him on missions to Piedmont; he was governor of Turin from Dec. 1537 till the end of 1539, and subsequently replacing Marshal d'Annebaut as governor of the whole of Piedmont, he displayed great capacity in organization. But at the end of 1542, overwhelmed by work, he was compelled to return to France, and died near Lyons on Jan. 9, 1543. Rabelais, an eye-witness, has left a moving story of his death (Pantagruel, iii. ch. 21, and iv. ch. 27). Charles V. is said to have remarked that Langey, by his own unaided efforts, did more mischief and thwarted more schemes than all the French together.

Without actually joining the reformers Guillaume du Bellay defended the innovators against their fanatical opponents. In 1534–35 he even tried, unsuccessfully, to bring about a meeting between Francis I. and Melanchthon; and in 1541 he intervened in favour of the Vaudois. Rabelais was the most famous of his clients, and followed him to Piedmont from 1540 to 1542. Guillaume was himself a clear and precise writer. He imitated Livy in his Ogdoades, a history of the rivalry between Francis I. and the emperor from 1521, of which fragments were inserted by his brother Martin du Bellay (d. 1559) in his *Mémoires* (1569). The celebrated *Instructions,* reprinted as Trait6 de la discipline *militaire* in 1554 and 1592 and translated into Italian, Spanish and German, are not his (see Bayle, *Dict. Hist.,* i. 502, and Jahns, *Geschichte* der Kriegswissenschaf ten, i. 498 seq.).

See also the edition of Martin du Bellay's *Mémoires* by Michaud and Poujoulat (1838), and Bourrilly's *Fragments de la première Ogdoade* (Paris, 1905). There is an excellent study of Guillaume du Bellay by V. L. Bourrilly (Paris, 1905).

DU BELLAY, JEAN (c. 1493–1560), French cardinal and diplomat, younger brother of Guillaume du Bellay, appears as bishop of Bayonne in 1526, member of the privy council in 1530, and bishop of Paris in 1532. He carried out several missions in England (1527–34) and Rome (1534–36). In 1535 he received his cardinal's hat; in 1536–37 he was nominated "lieutenant-general" to the king at Paris and in the Île de France, and was entrusted with the organization of the defence against the imperialists. When Guillaume du Bellay went to Piedmont, Jean was put in charge of the negotiations with the German Protestants, principally through the humanist Johann Sturm and the historian Johann Sleidan. In the last years of the reign of Francis I., Cardinal du Bellay was in favour with the duchesse d'Étampes, and received many benefices. Under Henry II., being involved in the disgrace of all the servants of Francis I, he was sent to Rome (1547), and he obtained eight votes in the conclave which followed the death of Pope Paul III. After three quiet years passed in retirement in France (1550–53), he was charged with a new mission to Pope Julius III. and took with him to Rome his young cousin the poet Joachim du Bellay (q v.). In 1555 he was nominated bishop of Ostia and dean of the Sacred College. He died at Rome on Feb. 16, 1560. The cardinal had brilliant qualities, was on the side of toleration and protected the reformers. Budaeus was his friend, Rabelais his faithful secretary and doctor; men of letters, like Étienne Dolet, and the poet Salmon Macrin, were indebted to him for assistance. He left three books of graceful Latin poems (printed with Salmon Macrin's Odes, 1546, by R. Estienne), and some other compositions, including Francisci *Francorum regis epistola apologetica* (1542).

BIBLIOGRAPHY.—The Bibliothèque Nationale at Paris has numerous unpublished letters of Jean du Bellay. *See* also Ribier, *Lettres et mémoires d'estat* (Paris, 1666); V. L. Bourrilly and P. de Vaissière, *Ambassade de Jean du Bellay en Angleterre,* vol. i. (Paris, 1905); marquis de la Jonquière, *Le Cardinal du Bellay* (Alençon, 1887); Heulhard, *Rabelais, ses voyages en Italie* (Paris, 1891); Chamard, *Joachim du Bellay* (Lille, 1900); V. L. DU BELLAY, JOACHIM (c. 1522–1560), French poet and critic, member of the Pléiade, was born at the chbteau of La Turmelikre, not far from Liré, near Angers, being the son of Jean du Bellay, seigneur de Gonnor, cousin-german of the cardinal Jean du Bellay and of Guillaume du Bellay. Both his parents died while he was still a child, and he was left to the guardianship of his elder brother, René du Bellay, who neglected his education, leaving him to run wild at La Turmelière. When he was 23, however, he went to Poitiers to study law, no doubt with a view to obtaining preferment through his kinsman the cardinal. At Poitiers he came in contact with the humanist Marc Antoine Muret. and with Jean Salmon Macrin (1490–1557), a Latin poet famous in his day. There too he probably met Jacques Peletier, who had published a translation of the Ars *poëtica* of Horace, with a preface in which much of the programme advocated later by the Pléiade is to be found in outline.

It was probably in 1548 that du Bellay met Ronsard in an inn on the way to Poitiers, an event which may justly be regarded as the starting-point of the French school of Renaissance poetry. The two immediately became fast friends. Du Bellay returned with Ronsard to Paris to join the circle of students of the humanities attached to Jean Daurat (*q.v.*) at the Collkge de Coqueret. While Ronsard and Antoine de Baïf were most influenced by Greek models, du Bellay was more especially a Latinist, and perhaps his preference for a language so nearly connected with his own nad some part in determining the more national and familiar note of his poetry. In 1548 appeared the Art *poétique* of Thomas Sibilet, who championed the cause of Clément Marot and his disciples, and poured scorn on the sonnet and on new-fangled ideas.

The famous manifesto of the Pléiade, the *Dkfense et Illustration de la langue française* (1549), was at once a complement and a refutation of Sibilet's treatise. This book was the expression of the literary principles of the Pléiade as a whole, but although Ronsard was the chosen leader, its redaction was entrusted to du Bellay. To obtain a clear view of the reforms aimed at by the Pléiade, the *Deffense* should be further considered in connection with Ronsard's *Abrégé d'art poétique* and his preface to the *Franciade.* Du Bellay maintained that the French language as it was then constituted was too poor to serve as a medium for the higher forms of poetry, but he contended that by proper cultivation it might be brought on a level with the classical tongues. He condemned those who despaired of their mother tongue and used Latin for their more serious and ambitious work. For translations from the ancients he would substitute imitations. Not only were the forms of classical poetry to be imitated, but a separate poetic language and style, distinct from those employed in prose, were to be used. The French language was to be enriched by a development of its internal resources and by discreet borrowing from the Latin and Greek. Both du Bellay and Ronsard laid stress on the necessity of prudence in these borrowings, and both repudiated the charge of wishing to latinize their mother tongue. The book was a spirited defence of poetry and of the possibilities of the French language; it was also a declaration of war on those writers who held less heroic views.

The violent attacks made by du Bellay on Marot and his followers, and on Sibilet, did not go unanswered. Sibilet replied in the preface to his translation (1549) of the *Iphigenia* of Euripides; Guillaume des Autels, a Lyonnese poet, reproached du Bellay with ingratitude to his predecessors, and showed the weakness of his argument for imitation as opposed to translation in a digression in his *Réplique aux furieuses dkfenses de Louis Meigret* (Lyons, 1550); Barthélemy Aneau, regent of the Collège de la Trinité at Lyons, attacked him in his *Quintil Horatian* (Lyons, 1551), the authorship of which was commonly attributed to Charles Fontaine. Aneau pointed out the obvious inconsistency of inculcating imitation of the ancients and depreciating native poets in a work professing to be a defence of the French language. Du Bellay replied to his various assailants in a preface to the second edition (1550) of his sonnet sequence *Olive,* with which he also published two polemical poems, the *Musagnaeomachie,* and an ode addressed to Ronsard, *Contre les envieux poktes. Olive,* a collection of love-sonnets written in close imitation of Petrarch, first appeared in 1549. With it were printed 13 odes entitled *Vers lyriques.* Du Bellay did not actually introduce the sonnet into French poetry, but he acclimatized it.

About this time du Bellay had a serious illness of two years' duration, from which dates the beginning of his deafness. He had further anxieties in the guardianship of his nephew. The boy died in 1553, and Joachim, who had up to this time borne the title of sieur de Liré, became seigneur of Gonnor. In 1549 he had published a *Recueil de poësies* dedicated to the Princess Marguerite. This was followed in 1552 by a version of the fourth book of the *Aeneid,* with other translations and some occasional poems. In the next year he went to Rome as one of the secretaries of Cardinal du Bellay. To the beginning of his four and a half years' residence in Italy belong the 47 sonnets of his *Antiquités de Rome,* which were rendered into English by Edmund Spenser (*The Ruins of Rome,* 1591). These sonnets were more personal and less imitative than the *Olive* sequence, and struck a note which was revived in later French literature by Volney and Chateaubriand. His stay in Rome was, however, a real exile. His duties were those of an intendant. He had to meet the cardinal's creditors and to find money for the expenses of the household. Nevertheless he found many iriends among Italian scholars, and formed a close friendship with another exiled poet whose circumstances were similar to his own, Olivier de Magny. Towards the end of his sojourn in Rome he fell violently in love with a Roman lady called Faustine, who appears in his poetry as Columba and Columbelle. This passion finds its clearest expression in the Latin poems. Faustine was guarded by an old and jealous husband, and du Bellay's eventual conquest may have had something to do with his departure for Paris at the end of Aug. 1557. In the next year he published the poems he had brought back with him from Rome, the Latin *Poemata,* the *Antiquités de Rome,* the *Jeux rustiques,* and the 191 sonnets of the *Regrets,* the greater number of which were written in Italy. The *Regrets* show that he had advanced far beyond the theories of the *Deffense.* The simplicity and tenderness specially characteristic of du Bellay appear in the sonnets telling of his unlucky passion for Faustine, and of his nostalgia for the banks of the Loire. Among them are some satirical sonnets describing Roman manners, and the later ones written after his return to Paris are often appeals for patronage. His intimate relations with Ronsard were not renewed; but he formed a close friendship with the scholar Jean de Morel, whose house was the centre of a learned society. In 1559 du Bellay published at Poitiers *La Nouvelle Manière de faire son profit des lettres,* a satirical epistle translated from the Latin of Adrien Turnèbe, and with it *Le Pokte courtisan,* which introduced the formal satire into French poetry. These were published under the pseudonym of J. Quintil du Trousay, and the courtier-poet was generally supposed to be Melin de Saint-Gelais, with whom du Bellay had always, however, been on friendly terms.

A long and elequent *Discours au roi* (detailing the duties of a prince, and translated from a Latin original written by Michel d l'Hôpital, now lost) was dedicated to Francis II. in 1559, and is said to have secured for the poet a tardy pension. In Paris he was still in the employ of the cardinal, who delegated to him the lay patronage which he still retained in the diocese. In the exercise of these functions Joachim quarrelled with Eustache du Bellay, bishop of Paris, who prejudiced his relations with the cardinal, less cordial since the publication of the outspoken *Regrets.* His chief patron, Marguerite de Valois, to whom he was sincerely attached, had gone to Savoy. Du Bellay's health was weak; his deafness seriously hindered his official duties; and on Jan. 1, 1560, he died. There is no evidence that he was in priests' orders, but he was a clerk, and as such held various preferments.

BIBLIOGRAPHY.—The best edition of the works of J. du Bellay is *Oeuvres françaises* (2 vols., 1866–67), edited with introduction and notes by C. Marty-Laveaux in his *Pléiade française.* His *Oeuvres choisies* were published by L. Becq de Fouquières in 1876. The chief source of his biography is his own poetry, especially the Latin elegy addressed to Jean de Morel, *"Elegia ad Janum Morellum Ebredunensem, Pyladem suum,"* printed with a volume of *Xenia* (1569). A study of his life and writings by H. Chamard, forming vol. viii. of the *Travaux et mémoires de l'université de Lille* (Lille, 1900), contains all the available information and corrects many common errors. *See* also Sainte-Beuve, *Tableau de la poésie française au XVIe siècle (1828)*; *La Défense et illust. de la langue française* (1905), with biographical and critical introduction by Léon Séché, who also wrote *Joachim du Bellay, documents nouveaux et inédits* (1880), and published in 1903 the first volume of a new edition of the *Oeuvres; Lettres de Joachim du Bellay* (1884), edited by P. de Nolhac; A. Tilley, *The Literature of the French Renaissance* (2 vols., 1904); H. Belloc, *Avril* (1905); G. Wyndham, *Ronsard and La Pléiade* (1906).

DUBLIN, a county of Eire, in the province of Leinster, bounded north by Co. Meath, east by the Irish sea, south by Wicklow, and west by Kildare and Meath. The area is 355.9 sq.mi. and the population (1936) 118,822, apart from Dublin city. Of the population over 70% are Roman Catholics. The county is divided into 100 parishes and its towns include Rathmines, Rathgar, Pembroke, Blackrock. The central and northern portions of the county are low-lying and composed chiefly of carboniferous limestone, with some millstone grit to the north and north-west, and some Silurian and Ordovician rocks behind Balbriggan. The peninsula of Howth, connected by a raised beach with the mainland, is formed of old quartzites and shales, crushed and folded, and probably of Cambrian age. The rocks of the county show many signs of ice-action.

The mountains which occupy the southern border of the county are the extremities of the great group belonging to the adjacent Co. Wicklow (*q.v.*). The principal summits are the group containing Glendoo (1,919 ft.) and Two Rock (1,699 ft.) within the county, and the border group of Kippure, reaching in that summit a height of 2,473 feet.

The mountains are chiefly covered with heath, except where a

subsidence in the ground affords a nucleus for the formation of bog, with which about 2,000 ac. are covered. There are also a few small tracts of bog in the northern part of the county. The mountain district is well adapted for timber. The northern coast of the county from Balbriggan to Howth has generally a sandy shore, and affords only the small harbours of Balbriggan and Skerries. In the promontory of Howth, the coast suddenly assumes a bolder aspect; and between the town of Howth and the rocky islet of Ireland's Eye an unsuccessful artificial harbour was constructed. Kingstown harbour on the south side of Dublin bay superseded this, and is by far the best in the county. The chief river is the Liffey, which rises in the Wicklow mountains about 12 m. S.W. of Dublin, and empties itself into Dublin bay. The course of the river is so tortuous that 40 m. may be traversed and only ten gained in direction.

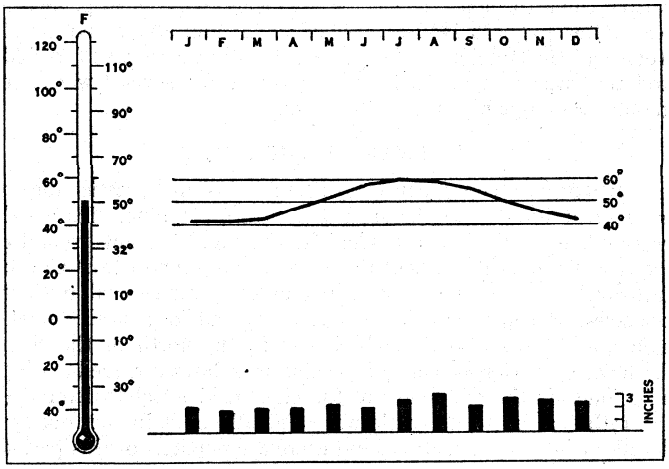
Dublin is among the counties generally considered to have been formed by King John, and comprised the chief portion of country within the English pale. The limits of the county, however, were uncertain. and underwent many changes before they were fixed. As late as the 17th century the mountainous country south of Dublin offered a retreat to the lawless, and it was not until 1606 that the boundaries of the county received definition in this direction, along with the formation of county Wicklow. Although so near the seat of government much land was forfeited in the Rebellion of 1641 and in the Revolution of 1688. In 1867 the most formidable of the Fenian risings took place near the village of Tallaght, about 7 m. from the city. Raths or encampments are frequent, and there are also dolmens and round towers.

The extension of Dublin city and its suburbs has no doubt had its influence on the decrease of acreage under both tillage and pasture. Oats and potatoes are the principal crops, but live stock, especially cattle, receives greater attention. A large proportion of the land holdings are smaller than one acre. The manufactures of the county are mainly confined to the city and suburbs, but there is manufacture of cotton hosiery at Balbriggan. Fisheries, both deep-sea and coastal, are important, and Kingstown is the headquarters of the fishery district. The salmon fishery district of Dublin also affords considerable employment. The communications of the county are good, several important railways and two canals converging upon the city of Dublin, under the head of which they are considered. Co. Dublin returns five members to Dáil Eireann.

DUBLIN, county borough and seaport, and the metropolis of Eire. It lies at the head of a bay of the Irish Sea, to which it gives name, about midway on the eastern coast of the island, and 70 mi. W. of Holyhead. The Gaelic name, Baile Atha Cliath, "Town of the Ford of the Hurdles," is now used by the Post Office. Pop. (1936) 468,103. (For map, *see* IRELAND.)

History.—The name of Dublin signifies the "Black pool." It is recorded that the inhabitants of Leinster were defeated by the people of Dublin in the year 291. Christianity was introduced by St. Patrick about 450. In the 9th century the Danes took Dublin. The first Norse king was Thorkel I. (832), though the Danes had appeared in the country as early as the close of the previous century. Thorkel established himself strongly at Armagh. In 1014 Brian Boroihme, king of Munster, fought the battle of Clontarf against the Danes, and he and his son and 11,000 of his followers fell. The Irish, however, won the battle, but the Danes reoccupied the city. Constant struggles with the Irish resulted in intermissions of the Danish supremacy from 1052 to 1072, at various intervals between 1075 and 1118 and from 1124 to 1136. The Danes were finally ousted by the Anglo-Normans in 1171. In 1172 Henry II. came to Dublin and held his court there. Previous to his departure for England, Henry bestowed the government on Hugh de Lacy, having granted by charter "to his subjects of Bristol his city of Dublin to inhabit, and to hold of him and his heirs for ever, with all the liberties and free customs which his subjects of Bristol then enjoyed at Bristol and through all England." In 1176 Strongbow, earl of Pembroke, died in Dublin and was buried in Christ Church cathedral. A fresh charter was granted in 1207 by King John to the inhabitants of Dublin, who were at constant feud with the native Irish. In 1216 Magna Carta was granted to the Irish by Henry III. In 1217 the fee farm of the city was granted to the citizens at a rent of 200 marks per annum; and about this period many monastic buildings were founded. In 1227 the same monarch confirmed the charter of John fixing the city boundaries and the jurisdiction of its magistrates.

During the invasion of Ireland by Edward Bruce in 1315 some of the suburbs of Dublin were burnt to prevent their falling into



GRAPH OF THE AVERAGE TEMPERATURE IN DUBLIN THROUGH THE YEAR
The mercury in the thermometer stands at the normal annual mean temperature. The curve shows the normal monthly mean temperature through the year. The columns below indicate the normal precipitation for each month

his hands. The inroad of Bruce had been countenanced by native Irish ecclesiastics, whose sentiments were recorded in a statement to Pope John XXII.

Richard II. erected Dublin into a marquisate in favour of Robert de Vere, whom he also created duke of Ireland. The same monarch entered Dublin in 1394, and after holding a parliament and making much courtly display before the native chieftains, returned to England. Five years later Richard returned to Ireland and visited Dublin, where he remained a fortnight.

In 1534 Lord Thomas Fitzgerald, son of the Lord Deputy Kildare, organized a rebellion against the English Government and attacked the city of Dublin itself, but raised the siege on certain conditions. After many vicissitudes, Lord Thomas and others were executed at Tyburn in 1536.

At the outbreak of civil war in 1641, a conspiracy to seize Dublin Castle was disclosed, and the city was thus preserved for the king's party; but the Irish outside began an indiscriminate extermination of the Protestant population. In 1646 Dublin was besieged unsuccessfully by the Irish. The city had been put in an efficient state of defence by the marquess of Ormonde, then lord-lieutenant; but in the following year, to prevent its falling into the hands of the Irish, he surrendered it on conditions to Colonel Jones, commander of the Parliamentary forces. In 1649 Ormonde was totally defeated at the battle of Baggotrath, near Old Rathmines, in an attempt to recover possession. The same year Cromwell landed in Dublin, as commander-in-chief under the parliament.

When James II. landed in Ireland in 1689 to assert his right to the British throne, he held a parliament in Dublin, which passed acts of attainder against upwards of 3,000 Protestants. The governor of the city, Colonel Luttrell, at the same time issued a proclamation ordering all Protestants not housekeepers, excepting those following some trade, to depart from the city within 24 hours, under pain of death or imprisonment, and in various ways restricting those who were allowed to remain. In the hope of relieving his financial difficulties, the king depreciated the coinage. After his defeat at the battle of the Boyne, James returned to Dublin for a few hours. William III. on the following day proceeded in state to St. Patrick's cathedral to return thanks for his victory.

In 1783 a convention of delegates from all the volunteer corps in Ireland assembled in Dublin for the purpose of procuring a

reform in parliament; but the House of Commons refused to entertain the proposition. In May 1798 a conspiracy planned by the United Irishmen to seize the city was frustrated. In 1803 an insurrection broke out, but was immediately quelled, with the loss of some lives in the tumult, and the death of its leaders on the scaffold. In 1848 the lower classes in Dublin were greatly agitated, but the city was saved from much bloodshed. In 1867 the most serious of modern conspiracies, that known as the Fenian organization, came to light. The Habeas Corpus Act was suspended at one sitting by both Houses of Parliament and about 960 arrests were made in Dublin in a few hours. Dublin Castle was fortified; and the citizens lived in a state of terror for several weeks together. For later history, see IRELAND.

GROWTH OF THE CITY

Buildings.— The expansion of Dublin from a castle nucleus is of great interest to the student of town-planning. The castle was built on a ridge overlooking the river and the low ground to the east. Within the limits of the old walls are found Christ Church cathedral, the city hall, municipal offices, and several business premises. Speed's map of 1610 gives a good idea of this settlement and shows also some buildings to the north of the river. With the exception of some of the churches, however, the buildings now found in the old centre of the city are themselves later than the 17th century. The castle was originally built in the first two decades of the 13th century, and there are portions of this period, but nearly the whole is of the 16th century and later.

The cathedral of Christ Church, or Holy Trinity, was founded by Sigtryg, a Christianized king of the Danes of Dublin, in 1038, but dates its elevation to a deanery and chapter from 1541. It was restored in 1870–77 by G. E. Street, who rebuilt the choir and south side of the nave, but the model of the ancient building was followed with great care. The crypt embodies remains of the founder's work; the rest is Transitional Norman and Early English in style. Among the monuments is that of Strongbow, the invader of Ireland, to whom the earlier part of the superstructure (1170) is due. Here the tenants of the church lands were accustomed to pay their rents. Synods were occasionally held in this church, and parliaments also, before the Commons' Hall was destroyed in 1566. Here also the pretender Lambert Simnel was crowned.

The portions of the city immediately around the castle nucleus represent the development up to the first half of the 19th century. There was considerable growth to the north of the river where Sackville (O'Connell) street is one of the principal thoroughfares, although it was badly damaged in 1922. In it is the Nelson pillar, 134 ft. in height with a statue of the admiral on the top. Farther to the east are the docks. The customs house was destroyed in 1922 but was rebuilt. The most interesting buildings, however, are to the south of the river.

A short distance south from Christ Church, through the squalid quarter of Nicholas and Patrick streets, stands the cathedral dedicated to St. Patrick, the foundation of which was an attempt to supersede the older foundation of Christ Church, owing to jealousies, both ecclesiastical and political, arising out of the Anglo-Norman invasion. It was founded about 1190 by John Comyn. archbishop of Dublin; but there was a church dedicated to the same saint before. It was burnt about 200 years later, but was rebuilt. At the Reformation it was deprived of its status as a cathedral, and the building was used for some of the purposes of the courts of justice. Edward VI. contemplated its change into a university, but the project was defeated. In the succeeding reign of Mary, St. Patrick's was restored to its original purpose. The installations of the knights of St. Patrick were originally held here. This cathedral contains the monument of Dean Swift. Attached to the cathedral is Marsh's library, incorporated in 1707, by a request of Primate Marsh, archbishop of Armagh.

Westmoreland street is a continuation to the south of Sackville street and, where it meets Dame street, which leads up to the castle, are situated the Bank of Ireland and Trinity college. The Bank of Ireland was formerly the House of Parliament. There are three fronts; the principal, towards College Green, is a colonnade of the Ionic order, with facade and two projecting wings; it connects with the western portico by a colonnade of the same order, forming the quadrant of a circle. The eastern front, which was the entrance of the House of Lords, is of the Corinthian order. The House of Lords contains tapestry dating from 1733, and remains in its original condition, but the octagonal House of Commons was demolished by the bank directors. The building was begun in 1729, but the fronts date from the end of the century; the remodelling took place in 1803.

Trinity College.— Trinity college, or the University of Dublin, founded in 1591, has a Palladian façade (1759), with two statues by Foley, of Goldsmith and Burke. Above the gateway is a hall called the Regent House. The first quadrangle, Parliament square, contains the chapel (1798), with a Corinthian portico, the public theatre or examination hall (1787), containing portraits of Queen Elizabeth, Molyneux, Burke, Bishop Berkeley and other celebrities, and the wainscoted dining-hall, also containing portraits. A beautiful campanile (1853) occupies the centre of the square. The library is one of those scheduled in the Copyright Act as entitled to receive a copy of every volume published in the United Kingdom. There is a notable collection of early Irish manuscripts, including the ornamented Book of Kells, containing the gospels. The building was begun in 1712. In this square are the oldest buildings of the foundation, dating in part from the close of the 17th century, and the modern Graduates' Memorial buildings (1904). These contain a theatre, library and reading-room, the rooms of the college societies and others. The schools form a fine modern pile (1856), and other buildings are the provost's house (1760), printing house (1760), museum (1857) and the medical school buildings, in three blocks, one of the best schools in the kingdom. Other buildings of the 20th century include chemical laboratories. The college (recreation) park and fellows' garden are of considerable beauty. The college observatory is at Dunsink, about 5 m. N.W. of Dublin. It was erected in 1785, and in 1791 was placed by statute under the management of the royal astronomer of Ireland, whose official residence is here. The magnetic observatory of Dublin was erected in the years 1837–38 in the gardens attached to Trinity college, at the expense of the university. A normal climatological station was established in the fellows' garden in 1904. The botanic garden is at Ball's Bridge, 1 m. S.E. of the college.

The outer portions of the city extending as far as the circular road which skirts the periphery date from the second half of the 19th century, whilst beyond this boundary has been some more recent development. The congestion in the tenements of the older quarter has to some extent been relieved, although much remains to be done. Near St. Stephen's Green is University college, which occupies the site of the International Exhibition of 1865. University college is one of the constituent colleges, with Cork and Galway, of the National University of Ireland.

COMMERCE AND TRANSPORTATION

Trade.— Dublin was for long stigmatized as lacking, for so large a city, in the proper signs of commercial enterprise. About the time of the Revolution, the woollen trade flourished in Dublin, and the produce attained great celebrity. The cheapness of labour attracted capitalists, who started extensive factories in that quarter of the town known even now as the Liberties. This quarter was inhabited altogether by workers in wool. About 1700 the English legislature prevailed on William III. to assent to laws which directly crushed the Irish trade. All exportation except to England was forbidden, and the woollen manufacture soon decayed. But at the close of the 18th century there were 5,000 persons at work in the looms of the Liberties. About 1715 parliament favoured the manufacture of linen, and the Linen Hall was built. The cotton trade was soon afterwards introduced; and silk manufacture was begun by the Huguenots, who had settled in Dublin in considerable numbers after the revocation of the edict of Nantes. Acts favourable to these enterprises were passed, and they flourished apace. But the old jealousy arose in the reign of George I., and in the reign of George III. an Act was passed which tended directly to the ruin of the manufacture. The linen shared the same fate. Dublin poplins, however, keep their reputa-

tion. However adverse influences may have been combated, Dublin yet produces little for export save whisky and porter; but a considerable export trade, principally in agricultural produce, passes through Dublin from the country. To the manufacturing industries of the city there should be added mineral water works, biscuit-making, glass-making, cigarette-making, foundries and shipbuilding.

By continual dredging a great depth of water is kept available in the harbour. The Dublin Port and Docks Board, which was created in 1898, undertook considerable works of improvement at the beginning of the 20th century. These improvements, *inter alia*, enabled vessels drawing up to 23 ft. to lie alongside the extensive quays which border the Liffey, at low tide. The extensive Alexandra tidal basin, on the north side of the Liffey, admits vessels of similar capacity. The Custom House Works on the north side have about 17 ft. of water. With docks named after them are connected the Royal and Grand canals, passing respectively to north and south of the city, the one penetrating the great central plain of Ireland on the north, the other following the course of the Liffey, doing the same on the south, and both joining the river Shannon. The docks attached to the canals, and certain other smaller docks, are owned by companies. Vessels entering these pay tolls, but not those entering docks under the Board.

The direct route to Dublin from London and other parts of England is by the Holyhead route, controlled by the L.M.S.R. with steamers to the port of Dublin itself, while the company also works in conjunction with the mail steamers of the City of Dublin Steam Packet Company to the outlying port of Kingstown, 7 mi. S.E. Passenger steamers, however, also serve Liverpool, Heysham, Bristol, the south coast ports of England and London; Edinburgh and Glasgow, and other ports of Great Britain. The railways leaving Dublin are the following: the Great Northern, with suburban lines and a main line running north to Drogheda, Dundalk and Belfast, with ramifications through the northern counties; the Great Southern to Kilkenny, Athlone and Cork; the Midland Great Western to Cavan, Sligo and Galway; and there is the North Wall station of the L.M.S.R., with the line known as the North Wall extension, connecting with the other main lines. The internal communications of the city are excellent, electric tramways which connect all the principal suburbs. The county borough of Dublin is divided into four constituencies—Dublin North-East returning three members, Dublin North-West returning five, Dublin South returning seven, and Dublin Townships three to Dáil Eireann. Dublin is governed by an elected council and a manager. The council's powers are restricted to imposing rates, raising loans and making by-laws. Other functions are performed by the manager, a paid official who has power over all municipal officers and whose own removal is subject to central authority.

See W. Harris, *History and Antiquities of the City of Dublin* (1766); Sir J. T. Gilbert, *History of the City of Dublin* (1859); L. J. Vogt, *Dublin som Norsk By* (Christiania, *1896*); *The Dublin Civic Survey*, vol. ii. of the publications of the Civics Institute of Ireland (1925).

DUBLIN, a city of Georgia, U.S.A., on the Oconee river, 125m. S.E. of Atlanta; the county seat of Laurens county. It is on Federal highway 80, and is served by the Central of Georgia, the Macon, Dublin and Savannah and the Wrightsville and Tennille railways. The population was 6,681 in 1930 (46% Negroes) and it was 7,814 in 1940 by the federal census. It is a shipping point for various agricultural products, lumber and naval stores, and has cotton compresses, cottonseed-oil mills, fertilizer plants and wood-working industries. The city was incorporated in 1812.

DUBNER, JOHANN FRIEDRICH (1802–1867), German classical scholar (naturalized a Frenchman), was born in Horselgau, near Gotha. In 1832 he was invited by the brothers Didot to Paris, to co-operate in a new edition of H. Etienne's Greek *Thesaurus*, and edited many volumes in Didot's *Bibliotheca Graeca*. He received the Legion of Honour for his edition of Caesar, undertaken by command of Napoleon III. His editions did much to raise the standard of classical scholarship in France. He violently attacked Burnouf's method of teaching Greek, but without result. Dübner may have gone too far in his zeal for reform, but time has shown him to be right. The old text-books have been discarded, and a great improvement in classical teaching has taken place.

See F. Godefroy, *Notice sur J. J. Dübner* (1867); Sainte-Beuve, *Discours à la mtmoire de Dubner* (1868); article in *Allgemeine Deutsche Biographie.*

DUBOC, JULIUS (1829–1903), German author and philosopher, was born on Oct. 10, 1829, at Hamburg, and died on June 11, 1903, at Dresden. He studied at both Leipzig and Berlin and became a disciple of Feuerbach. Evolutionary monism, atheism, and the doctrine that pleasure is the end of all human activity find expression in his works, which include *Soziale Briefe* (3rd ed. 1873); *Die Psychologie der Liebe* (1874); *Das Leben ohne Gott* (1875); *Hundert Jahre Zeitgeist in Deutschland* (1889); and *Die Lust als sozialethisches Entwicklungsprinzip* (1900).

DUBOIS, FRANÇOIS CLEMENT THEODORE (1837–1924), French musical composer, was born at Rosney (Marne) on Aug. 24, 1837. He studied at the Conservatoire under Ambroise Thomas, and won the Grand Prix de Rome in 1861 with his cantata *Atala*. On his return to Paris he was appointed "maitre de Chapelle" at the church of Ste. Clotilde. where César Franck was organist. Here he produced *Les Sept Paroles du Christ* (1867), a work which has become well known in France. In 1868 he became "maitre de Chapelle" at the Madeleine, and nine years later succeeded Camille Saint-Saens there as organist. He became professor of harmony at the Conservatoire in 1871, and was appointed professor of composition in succession to Leo Delibes in 1891. At the death of Ambroise Thomas in 1896 he became director of the Conservatoire; he retired in 1905. Dubois was an extremely prolific composer and wrote in a variety of forms. His sacred works include four masses, a requiem, a large number of motets and pieces for organ. For the theatre he composed a light opera, *La Guzla de l'Émir*, (Athenée, April *30*, 1873); a one-act piece, *Le Pain bis* (Opéra Comique, Feb. 26, 1879); a ballet, *La Farandole* (Grand Opera, Dec. 14, 1883); *Aben-Hamet*, a four-act opera (Théâtre Italien, Dec. 16, 1884); *Xavidre*, a dramatic idyll in three acts (Opéra Comique, Nov. 26, 1895). His orchestral works include two concert overtures, the overture to *Fritio* (1880), several suites, *Marche héroïque de Jeanne d'Arc* (1888), etc. He was also the author of various sacred works and in addition he composed much for the piano and voice, Dubois died in Paris on June 11, 1924.

DUBOIS, GUILLAUME (1656–1723), French cardinal and statesman, was born at Brive, Corrèze, on Sept. 6, 1656. He received the tonsure at the age of 13, was educated at the college of St. Michel at Paris, and became tutor to the young duke of Chartres, afterwards duke of Orleans. When his pupil became regent (1715) Dubois, who had for some years acted as his secretary, was made councillor of state and the chief power passed into his hands.

His policy was steadily directed towards maintaining the peace of Utrecht. To counteract Alberoni's intrigues for the aggrandizement of Spain, he suggested an alliance with England, and succeeded in negotiating the Triple Alliance (1717). In 1719 he sent an army into Spain, and forced Philip V. to dismiss Alberoni. Otherwise his policy remained that of peace. Dubois's success strengthened him against the bitter opposition of a large section of the court. In spite of his dissolute life he asked the regent to give him the archbishopric of Cambray. His demand was supported by George I., and the regent yielded. In one day all the usual orders were conferred on him, and even Massillon consented to take part in the ceremonies. After long and most profitable negotiations on the part of Pope Clement XI., the red hat was given to him by Innocent XIII. (1721), whose election was largely due to the bribes of Dubois. This cardinalate cost France about 8,000,000 francs. In the following year he was named first minister of France (August).

When Louis XV. attained his majority in 1723 Dubois remained chief minister. He had accumulated an immense private fortune, possessing in addition to his see the revenues of seven abbeys. He died at Versailles on Aug. 10, 1723. His portrait was thus

drawn by the duc de St. Simon: — "He was a little, pitiful, wizened, herring-gutted man, in a flaxen wig, with a weasel's face, brightened by some intellect. All the vices — perfidy, avarice, debauchery, ambition, flattery — fought within him for the mastery. He was so consummate a liar that, when taken in the fact, he could brazenly deny it." This famous picture is certainly biased. Dubois, in spite of his vices, gave France peace after the disastrous wars of Louis XIV.

In 1789 appeared *Vie privée du Cardinal Dubois*, attributed to one of his secretaries, Mongez, and in 1815 his *Mémoires secrets et correspondance ine'dite*, edited by *L.* de Sevelinges. *See* also *A.* Cheruel, *Saint-Simon et E'abbk Dubois; L.* Wiesener, *Le Re'gent, L'abbk Dubois et les Anglais* (1891); and memoirs of the time.

DUBOIS, JEAN ANTOINE (1765–1848), French Cathplic missionary in India, was ordained in the diocese of Viviers in 1792, and sailed for India in the same year under the *Missions Etrangbres.* He at first worked in the southern districts of the present Madras presidency. On the fall of Seringapatam in 1799 he went to Mysore to reorganize the Christian community shattered by Tipu Sultan. He benefited his impoverished flock by founding agricultural colonies and introducing vaccination as a preventive of smallpox. By his fervent desire to understand Hindu life, he gained an extraordinary welcome amongst all castes, and is still spoken of in many parts of south India with affection and esteem as "the prince's son, the noblest of Europeans." His great work, *Hindu Manners, Customs and Ceremonies* (3rd ed., Oxford, 1906) gives a shrewd, clear-sighted, candid account of the manners and customs of the Hindus. Dubois left India in Jan. 1823, and on reaching Paris was appointed director of the *Missions Etrangbres,* of which he afterwards became superior (1836–39). He translated into French the famous book of Hindu fables called *Panchatantra,* and also a work called *The Exploits of the Guru Paramarta.* He died on Feb. 17, 1848.

DUBOIS, LOUIS ERNEST (1856–1929), French ecclesiastic, was born at Saint Calais, France, Sept. 1, 1856. In 1901 he became bishop of Verdun, in 1909 Archbishop of Bourges, and in 1916 of Rouen. He was made cardinal of Santa Maria in Aquino, Rome, by Pope Benedict XV. in Dec. 1916. On the death of Cardinal Amette in 1920, Cardinal Dubois was made Cardinal Archbishop of Paris. He died at Paris on Sept. 23, 1929.

See his *Memoirs* published in 1929.

DUBOIS, PAUL (1829–1905), French sculptor and painter, was born at Nogent-sur-Seine on July 18, 1829, and died on March 22, 1905. After studying at the Ecole des Beaux-Arts, Dubois went to Rome. His first contributions to the Paris Salon (1860) were busts of "The Countess de B." and "A Child." "A Florentine Singer of the Fifteenth Century" was shown in 1865; "The Virgin and Child" appeared in the Paris Universal Exhibition in 1867; from 1873 onwards date the busts of Henner, Dr. Parrot, Paul Baudry, Pasteur, Gounod and Bonnat, remarkable alike for vivacity, likeness, refinement and subtle handling. The chief work of Paul Dubois was "The Tomb of General Lamoricière" in the cathedral of Nantes, a brilliant masterpiece conceived in the Renaissance spirit, with allegorical figures and groups representing Warlike Courage, Charity, Faith and Meditation, with basreliefs and enrichments. The statue of the "Constable Anne de Montmorency" was executed for Chantilly, and that of "Joan of Arc" (1889) for the town of Reims. In 1873 Dubois was appointed keeper of the Luxemburg museum. He succeeded Guillaume as director of the École des Beaux-Arts, 1878, and Perraud as member of the Académie des Beaux-Arts.

DUBOIS, PIERRE (*c.* 1250–*c.* 1312), French publicist in the reign of Philip the Fair, was educated at the university of Paris. In 1300, he wrote his anonymous *Summaria, brevis et compendiosa doctrina felicis expedicionis et abbreviationis guerrarum et litium regni Francorum,* which is extant in a unique ms., but is analysed by N. de Wailly in the *Bibliothbque de l'École des Chartes* (2nd series, vol. iii.). In the contest between Philip the Fair and Boniface VIII. Dubois identified himself with the secularizing policy of Philip. His *Supplication du pueble de France au roy contre le pape Boniface le VIII^e^,* printed in 1614 in *Acta infer Bonifacium VIII. et Philippum Pulchrum,* dates from 1304, and is a heated indictment of the temporal power. He represented Coutances in the states-general of 1302, but in 1306 he was serving Edward I. as an advocate in Guienne, without apparently abandoning his Norman practice by which he had become a rich man. His treatise *De recuperatione terrae sanctae,* outlining the conditions for a successful crusade, was written in 1306, and dedicated in its extant form to Edward I., though it is certainly addressed to Philip. Dubois's ideas on education, on the celibacy of the clergy, and his schemes for the codification of French law, were far in advance of his time. He was an early and violent "Gallican," and the first of the great French lawyers who occupied themselves with high politics. In 1308 he attended the states-general at Tours. He is generally credited with *Quaedam proposita papae a rege super facto Templariorum,* a draft epistle supposed to be addressed to Clement by Philip.

See an article by E. Renan in *Hist. litt. de la France,* vol. xxvi. pp. 471–536; P. Dupuy, *Hist. de la condamnation . . . des Templiers* (Brussels, 1713), and *Hist. du différend entre le pape Boniface VIII. et Philippe le Bel* (Paris, 1655); and *Notices et extraits de manuscrits,* vol. xx. *E.* Zeck, *Pierre Dubois,* etc. (1911).

DUBOIS, a city of Clearfield county, Pa., U.S.A., on Sandy Lick creek, 85 mi. N.E. of Pittsburgh. It is on federal highways 119, 219 and 322, and is served by the Baltimore and Ohio and the Pennsylvania railways. The population in 1920 was 13,681; in 1930 it was 11,595; in 1940, 12,080 by federal census. The city is built on a small plateau surrounded by hills, on the western slope of the Allegheny mountains, nearly 1,400 ft. above sea level It is an important coal and lumber centre, and has various manufacturing industries, including large coal-car shops, foundry and machine shops, flour and lumber mills, wood-working plants, tanneries and others, with an aggregate output in 1937 valued at $1,938,514. The city was founded in 1872 by John DuBois, and was incorporated in 1881.

DUBOIS-CRANCE, EDMOND LOUIS ALEXIS (1747–1814), French revolutionary, born at Charleville, was elected deputy to the states-general in 1789 by the third estate of Vitry-le-Franqois. At the Constituent assembly, of which he was named secretary in Nov. 1789, he worked for the replacement of the old military system, with its caste distinctions and its mercenaries, by national guards open to all citizens. In his report on Dec. 12, 1789, he adumbrated the idea of *conscription.* He secured the Assembly's vote that any slave who touched French soil should become free. Elected to the Convention by the department of the Ardennes, he sat among the *Montagnards.* In the trial of Louis XVI. he voted for death without delay or appeal. On Feb. 21, 1793, he was named president of the Convention. He composed a remarkable report on the army, recommending the rapid advancement of the lower officers, and the fusion of the volunteers with the veteran troops. In Aug. 1793 Dubois-Crancé was designated "representative on mission" to the army of the Alps, to direct the siege of Lyons. Accused of lack of energy, he was replaced by G. Couthon (*q.v.*). On his return he was excluded from the Jacobin club at the instance of Robespierre. He took part in the revolution of 9th Thermidor of the year II., directed against Robespierre. He was one of the committee of five which had to oppose the Royalist insurrection of Vendémiaire (*see* FRENCH REVOLUTION), and was named a member of the committee of public safety, then much reduced in importance. After the Convention, under the Directory, Dubois-Crancé was a member of the council of the Five Hundred, and was appointed inspector general of infantry; then, in 1799, minister of war. Opposed to the *coup d'état* of the 18th Brumaire, he lived in retirement during the consulate and the empire. He died at Rethel on June 29, 1814.

Among the numerous writings of Dubois-Crancé may be noticed his *Observations sur la constitution militaire, ou bases du travail proposé au comitk militaire. See H. F. T.* Jung, *Dubois de Crancé. L'armke et la Révolution, 1789–1794* (2 vols. 1884).

DU BOIS-REYMOND, EMIL (1818–1896), German physiologist, was born in Berlin on Nov. 7, 1818. His father belonged to Neuchâtel, his mother was of Huguenot descent, and he spoke of himself as "being of pure Celtic blood." He studied geology at Bonn, then anatomy and physiology at Berlin under Johannes Müller. Du Bois-Reymond's graduation thesis on "Electric Fishes," was the beginning of a long series of investigations

on animal electricity. The results of these inquiries were published in his *Untersuchungen über tierische Elektrizität* (2 vols. 1848–84).

This great work may be regarded under two aspects On the one hand, it is a record of the exact determination and approximative analysis of the electric phenomena presented by living beings. On the other hand it contains an exposition of a theory. Du Bois-Reymond developed the view that a living tissue, such as muscle, might be regarded as composed of a number of electric molecules, of molecules having certain electric properties, and that the electric behaviour of the muscle as a whole in varying circumstances was the outcome of the behaviour of these native electric molecules. This theory has perhaps not stood the test of time so well as have Du Bois-Reymond's more simple deductions from observed facts It was early attacked by Ludimar Hermann, who maintained that a living untouched tissue is not the subject of electric currents so long as it is at rest, is isoelectric in substance, and therefore need not be supposed to be made up of electric molecules, all the electric phenomena which it manifests being due to internal molecular changes associated with activity or injury Although most subsequent observers ranged themselves on Hermann's side, Du Bois-Reymond's theory was of great value if only as a working hypothesis, and as such it greatly helped in the advance of science.

For many years, Du Bois-Reymond exerted a great influence as a teacher. In 1858, upon the death of Johannes Müller, he was given the new chair of physiology at Berlin. In 1851 he was elected to the Academy of Sciences of Berlin, and in 1867 became its perpetual secretary. From 1857 to 1877, he was co-editor of the *Archiv fur Anatomie* His principal work, other than the one on electricity, is *Gesammelte Abhandlungen zur allgemeinen Muskelund Nervenphysik* (2 vols., 1875–77) He died Nov. 26, 1896.

See J. Burdon Sanderson in *Nature* (vol. iv, 1897).

DUBROVNIK (Ital *Ragusa*), a port of Dalmatia, Yugoslavia. Pop. 18,767 Dubrovnik was known as Ragusa from before the 10th century, but upon its incorporation in the newly-formed state of Yugoslavia in 1918, its name was officially changed to Dubrovnik. The name is commonly thought to be derived from the Slavonic *dubrava,* "woody," though this derivation has been questioned.

It is by far the most picturesque city on the Dalmatian coast, occupying a promontory jutting out into the sea under the bare limestone mass of Mt. Sergio. The seaward fortifications rise directly from the water's edge, while a massive round tower dominates the city on the landward side. Beyond the walls, mostly a double line, which have always been the pride of Dubrovnik, are many villas, surrounded by gardens. The Stradone, or main street, runs along a narrow valley, which until the 13th century was a marshy channel, dividing the Latin island of Ragusa from the forest settlement of Dubrovnik.

Dubrovnik first became prominent during the 7th century In 639 and 6j6 the flourishing Latin communities of Salona and Epidaurus were destroyed by the Avars, and the island rock of Ragusa was colonized by the survivors. A colony of Slavs soon joined the Latin settlers at Ragusa, and thus, from an early date, the city formed a link between two great civilizations *(see* VLACHS). During the 9th, 10th, 11th and 12th centuries, Ragusa defended itself against attacks by foreign powers, but from 1205 to 1358 it acknowledged Venetian suzerainty. Ragusan policy during this period was usually peaceful. To refugees of all nations the city afforded asylum; and by means of treaty and tribute it worked its way to a position of great mercantile power. It was conveniently situated at the seaward end of a great trade route, which bifurcated at Plevlje to Byzantium and the Danube. Ragusan trade flourished, both by land throughout the Balkans; and by sea in the Mediterranean region, in northern Europe, and in the 16th century, even as far as America and India From 1358 to 1526, Ragusa was a vassal state of Hungary, but the downfall of Hungary in 1526 left the city free. About this time a great development of art and literature, begun in the 1 jth century and continued into the 17th, earned for the city its title of the "South Slavonic Athens." After this period, however, the importance of Ragusa declined. The conquest of the Balkans by the Turks and the misrule of Hungary in Dalmatia ruined its commerce, and the discovery of America reduced the importance of the Mediterranean ports. In 1667 an earthquake destroyed a considerable portion of the city and about one-fifth of the inhabitants. Only during the Napoleonic wars did the republic regain its prosperity. From 1800 to 1805 it was the sole Mediterranean state remaining neutral, and thus it secured a large share of the carrying trade. In 1805, however, it was seized by the French. Napoleon deprived it of independence and in 1814 it was annexed to Austria In 1918 it became a part of Yugoslavia and in 1941 it was seized by Italy.

Despite the havoc wrought by the earthquake in 1667, the city is rich in antiquarian interest One church, of the Byzantine period, is mentioned in 13th century documents as being, even then, of great age. Two 14th century convents stand at the ends of the city; for the Franciscans were set to guard the western gate against the hostile Slavs, while the Dominicans kept the eastern one The Rector's palace is one of the masterpieces of Dalmatian architecture. It has a fine façade of six arches. and the capitals of the supporting pillars are curiously carved. One of them bears the figure of Aesculapius, whose traditional birthplace was nearby Epidaurus, whence the Latins migrated in the 7th century to found Ragusa.

The harbour being too small for modern needs and also difficult of approach, Gravosa (Gruz), a village to the N with a good natural harbour became the steamship station and was connected by rail with Dubrovnik. Dubrovnik's industries include the manufacture of liqueurs, cheeses, silk, leather, drawn thread work, metalwork and soap, oil-refining and slate mining. Dates. figs, olives, etc. are cultivated. Malmsey, formerly its most famous wine, was not produced after the vine disease of 1852. There is a secondary school and a naval college. The Grotto of Aesculapius is famous for its stalactites.

LACROMA (Serbo-Croatian Lokrum), an island ½ mi. to the S. is remarkable for the beauty of its vegetation. It was a favourite resort of the Austrian crown prince Rudolph (1857–89), and of the archduke Maximilian, afterwards emperor of Mexico (1832–67), who restored the chateau and park, in which are the ruins of an 11th century Benedictine monastery and a church, locally ascribed to Richard I (1188–99).

See *Lacroma,* by the crown princess Stephanie, afterwards Countess Lonyay (Vienna, 1892).

DUBS, JAKOB (1822–1879), Swiss statesman, was born on July 26, 1822, at Affoltern,and studied law at Heidelberg, Berne and Zürich. After holding various offices in his native canton, he was elected a member and, in 1857, president of the federal court He was president of the Swiss confederation in 1864 and in 1868. He died at Lausanne on Jan. 13, 1879. He published *Die Schweizer Demokratie* (1866) and *Das öffentliche Recht der schweizerischen Eidgenossenschaft* (1877).

DUBUQUE, a city of Iowa, U.S.A., on the Mississippi river, opposite the boundary line between Wisconsin and Illinois; a port of entry and the county seat of Dubuque county. It is served by the Burlington, the Chicago Great Western, the Chicago, Milwaukee, St. Paul and Pacific and the Illinois Central railaays, and by river steamers and barges. Pop. 1930, 41,679; 1940, 43,892.

The business section of the city lies on the lowlands along the river, but most of the residential sections are on the slopes and tops of bluffs, which command extensive and picturesque views. Dubuque has a large traffic by rail and by water, and is winter quarters for the boats operating on the upper Mississippi. It is the centre of the state's lead and zinc mines, which were, however, abandoned because of water in 1918. There is a variety of manufacturing industries (107 plants, producing 371 commodities), with an output valued at $21,980,038 in 1937. A city-manager government was put into operation in 1920. Dubuque is the see of a Roman Catholic archbishop, and is the seat of Loras college for men, formerly Columbia college (established in 1873) and Clarke college for women, formerly Mt. St. Joseph college (established as an academy in 1843), both Roman Catholic institutions, the University of Dubuque (Presbyterian), the outgrowth

of a school started in 1852 by a Presbyterian minister, known especially as a German theological seminary from 1864 to 1905, and organized as a university in 1920, and Wartburg seminary (Lutheran). Twelve miles southwest of the city is a monastery of Trappist monks. Dubuque is the oldest town of Iowa, and until after the Civil War was the largest. In 1788 Julien Dubuque (1765–1810) settled there, attracted by the lead deposits, which were crudely worked by the Sac and Fox Indians, and which he mined until his death. In June 1829, miners from Galena, Ill., attempted to make a settlement, in direct violation of treaties with the Indians, but were driven away by U.S. troops, under orders from Col. Zachary Taylor. White settlers began to come in immediately after the Black Hawk War. A town was laid out under authority of an act of congress (approved July 2, 1836) and in 1841 it was incorporated.

DU CAMP, MAXIME (1822–1894), French writer, was born in Paris. Between 1844 and 1845, and again, in company with Gustave Flaubert, between 1849 and 1851, he travelled in Europe and the East, and made excellent use of his experiences in books published after his return. In 1851 he was one of the founders of the *Revue de Paris* (suppressed in 1858), and he was a frequent contributor to the *Revue des deux mondes*. He served as a volunteer with Garibaldi in 1860, and gave a vivid account of his experiences in his *Expédition des deux Siciles* (1861). Du Camp's *Souvenirs littéraires* (2 vols., 1882–83) contain much information about contemporary writers, especially Gustave Flaubert, of whom he was an early and intimate friend. Du Camp was one of the earliest amateur photographers, and his many books of travel were among the first photographically illustrated.

DU CANGE, CHARLES DU FRESNE, SIEUR (1610–1688), one of the lay members of the great 17th century group of French critics and scholars who laid the foundations of modern historical criticism, was born at Amiens on Dec. 18, 1610. He was educated at the Jesuits' college at Amiens, studied law at Orleans, and afterwards went to Paris, where in 1631 he was received as an advocate before the *parlement*. He had no success at the bar, and soon returned to his native city, where he married and settled. In 1647 he purchased the office of treasurer from his father-in-law. Forced to leave Amiens in 1668 in consequence of a plague, he settled in Paris, where he died Oct. 23, 1688. Of his numerous works the most important are the *Glossarium ad scriptores mediae et infimae latinitatis* (Paris, 1678), and the *Glossarium ad scriptores mediae et infimae graecitatis* (Lyons, 1688), which are indispensable aids to the student of the history and literature of the middle ages.

Du Cange studied the history of the later Roman empire, and wrote *Historia Byzantina duplici commentario illustrata* (Paris 1680), and an introduction to his edition and translation into modern French of Geoffrey de Villehardouin's *Histoire de l'empire de Constantinople sous les empereurs français* (1657). He also brought out editions (1670 and 1686) of the Byzantine historians, John Cinnamus and John Zonaras. His autograph manuscripts in addition to his large and valuable library passed through the hands of many persons before the French Government secured the greater portion of the manuscripts, which were preserved in the imperial library in Paris. Some of these were subsequently published, and the manuscripts are now found in various libraries.

To the three original volumes of the Latin *Glossarium*, three supplementary volumes were added by the Benedictines of St. Maur (Paris, 1733–36), and a further addition of four volumes (1766) by a Benedictine, Pierre Carpentier (1697–1767). There were other editions, and an abridgment with some corrections was brought out by J. C. Adelung (Halle, 1772–84). The edition in seven volumes edited by G. A. L. Henschel (Paris, 1840-50) includes these supplements and also further additions by the editor, and this has been improved and published in ten volumes by Léopold Favre (Niort, 1883–87). An edition of the Greek *Glossarium* was published at Breslau in 1889.

See H. Hardouin, *Essai sur la vie et sur les ouvrages de Ducange* (Amiens, 1849); and L. J. Feugère, in the *Journal de l'instruction publique* (1852).

DUCANGE, VICTOR HENRI JOSEPH BRAHAIN (1783–1833), French novelist and dramatist, was born on Nov. 24, 1783, at The Hague, where his father was secretary to the French embassy. Dismissed from the civil service at the Restoration, Victor Ducange became one of the favourite authors of the Liberal party, and owed some part of his popularity to the fact that he was fined and imprisoned more than once for his outspokenness. He was twice imprisoned for seditious articles in his journal *Le Diable rose, ou le petit courrier de Lucifer* (1822); after the publication of *Hélène ou l'amour et la guerre* (1823), he took refuge in Belgium. Ducange wrote numerous plays and melodramas, including *Marco Loricot, ou le petit Chouan de 1830* (1836), and *Trente ans, ou la vie d'un joueur* (1827). Many of his books were prohibited, ostensibly for their coarseness, but perhaps rather for their political tendencies. He died in Paris on Oct. 15, 1833.

DUCAS, DUKAS or **DOUKAS,** the name of a Byzantine family which supplied several rulers to the Eastern empire. The family first came into prominence during the 9th century, but was ruined when Constantine Ducas, a son of the general Andronicus Ducas, lost his life in his effort to obtain the imperial crown in 913. Towards the end of the 10th century there appeared another family of Ducas, which was perhaps connected with the earlier family through the female line. A member of this family became emperor as Constantine X. in 1059, and Constantine's son Michael VII. ruled, nominally in conjunction with his younger brothers, Andronicus and Constantine, from 1071 to 1078. Michael left a son, Constantine, who married into the family, which was also allied by marriage with other great Byzantine houses, and its members continued to take an active part in public affairs. In 1204 Alexius Ducas, called Mourzoufle, deposed the emperor Isaac Angelus and his son Alexius, and vainly tried to defend Constantinople against the attacks of the Latin crusaders. Nearly a century and a half later one Michael Ducas took a leading part in the civil war between the emperors John V. Palaeologus and John VI. Cantacuzenus, and Michael's grandson was the historian Ducas (*see* below). Many of the petty sovereigns who arose after the destruction of the Eastern empire sought to gain prestige by adding the famous name of Ducas to their own.

DUCAS (15th cent.), Byzantine historian, flourished under Constantine XIII. (XI.) Dragases, the last emperor of the East, about 1450. The dates of his birth and death are unknown. He was the grandson of Michael Ducas (*see* above). After the fall of Constantinople, he was employed in various diplomatic missions by Dorino and Domenico Gateluzzi, princes of Lesbos, where he had taken refuge. He survived the annexation of Lesbos in 1462, but no more is known of him. He was the author of a history of the period 1341–1462. Although barbarous in style, it is both judicious and trustworthy, and it is the most valuable source for the closing years of the Greek empire and the capture of Constantinople. Ducas was a strong supporter of the union of the Greek and Latin churches, and is very bitter against those who rejected even the idea of appealing to the West for assistance against the Turks.

The history, preserved (without a title) in a single Paris MS., was first edited by I. Bullialdus (Bulliaud) (Paris, 1649); later editions are in the Bonn *Corpus scriptorum Hist. Byz.*, by I. Bekker (1834) and Migne, *Patrologia Graeca*, clvii. The Bonn edition contains a 15th century Italian translation by an unknown author, found by L. Ranke in one of the libraries of Venice, and sent by him to Bekker.

DUCASSE, PIERRE EMMANUEL ALBERT, BARON (1813–1893), French historian, was born at Bourges on Nov. 16, 1813. In 1849 he became aide-de-camp to Prince Jerome Bonaparte, ex-king of Westphalia, then governor of the Invalides. He was attaché to Jerome's son, Prince Napoleon, during the Crimean War. He was employed by Prince Napoleon on the *Correspondance* of Napoleon I., and afterwards published certain letters, purposely omitted there, in the *Revue historique*. These documents, subsequently collected in *Les Rois frères de Napoléon* (1883), as well as the *Journal de la reine Catherine de Westphalie* (1893), were edited with little care and are not entirely trustworthy, but their publication threw much light on Napoleon I. and his entourage. Ducasse was also employed by Jerome Bonaparte and his son in the cornpilation of historical accounts of the affairs in which they were concerned.

DUCAT (dŭk'ạt), **a** coin, generally of gold, and of varying value, formerly in use in many European countries. It was first struck by Roger II. of Sicily as duke of Apulia, and bore an

inscription *"Sit tibi, Christe, datus, quem tu regis, iste ducatus"* (Lord, thou rulest this duchy, to thee be it dedicated); hence, it is said, the name. Between **1280** and **1284** Venice also struck a gold coin, known first as the ducat, afterwards as the zecchino or sequin, the ducat becoming merely a money of account. The ducat was also current in Holland, Austria, the Netherlands, Spain and Denmark *(see* NUMISMATICS). A gold coin termed a ducat was current in Hanover during the reigns of George I. and George III. A pattern gold coin was also struck by the English mint in **1887** for a proposed decimal coinage. On the reverse was the inscription "one ducat" within an oak wreath; above "one hundred pence," and below the date between two small roses.

DUCCIO DI BUONINSEGNA *(c.* 1255–1319), Italian painter of the Sienese School. His father's name was Buoninsegna. We learn some facts regarding Duccio's work from the records of the exchequer of the city of Siena *(Libri d'entrata e uscita* of the Biccherna). In **1278** he was employed as a painter by the commune to decorate *cassoni* in which public documents were kept. From **128j** to **1295** he received five commissions to decorate book-covers of the Biccherna. He seems therefore to have been a craftsman at the beginning of his career, and his work on book covers may have brought him in touch with Byzantine illuminations.

According to a document in the state archives at Florence (Milanesi, *Documenti* etc., vol. i. pp. 158–160) he was asked in 1285 to paint a large Madonna for the church of Sta. Maria Novella at Florence. This picture has been identified with the celebrated Ruccellai Madonna, long regarded as the work of Cimabue. In **1295** Duccio was consulted as to the site of the Fonte Nova, a Gothic fountain outside the Porta Ovile of Siena, showing that his knowledge was not confined to painting. In 1302 he was paid for a "Madonna enthroned" in the Palazzo Pubblico of Siena, a picture now lost. In **1308** he began work on the great altarpiece for the Siena cathedral, which he undertook to carry out with his own hand. When the work was completed on June **9,** 1311, a public holiday was proclaimed, and amid the rejoicing crowds the picture was carried in procession to the cathedral, accompanied by the principal men of the city, and placed over the high altar underneath the cupola. This was the climax of Duccio's career. He died eight years later, on Aug. **3,** 1319. His great masterpiece is now preserved in the Opera del Duomo (Cathedral Museum). It adorned a double altar and was painted on both sides. The front represents the "Majestas," the Virgin Enthroned surrounded by angels and saints. The back is made up of small panels representing the life of Christ. Below was a predella, also made up of small panels. Several of these small pictures have found their way to England. Three are in the National Gallery, London. The four of the Benson Collection were acquired by Duveen; and one of these is now in the Frick Collection, New York. The altarpiece is the one fully authenticated work of the master extant, and represents his later style. The following works are attributed to Duccio for stylistic reasons. To his early period belong, besides the Ruccellai Madonna mentioned above, three smaller pictures: the little Madonna with three Franciscans in the Siena Gallery, the Madonna from Count Stroganoff's Collection, and the triptych in the National Gallery representing the Madonna and two saints. These paintings adhere closely to the Byzantine type. In the National Gallery triptych, however, a new influence makes itself felt. Here the gesture of childlike love contrasting with the sad expression in the mother's face is an innovation in Byzantine as well as in Italian art, and marks the direction in which Duccio was to develop. A triptych representing "the Crucifixion" in Buckingham Palace is ascribed to the master's second period. A very fine example of the artist's later period is the Crucifixion in Lord Crawford's collection; this work is contemporary with the altarpiece in the Opera del Duomo. When comparing his later with his early work, we find a marked advance in the expression of emotion. The figures are inspired with virile energy. Moreover, Gothic features are introduced in the architecture and in the rendering of drapery, trees and animals. Nevertheless the Byzantine formulae are closely adhered to as regards the composition of figures. The harmoniously coloured shapes are arranged in an expressive two-dimensioned design, contrasting with the plastic conception of form in the work of Giotto, his younger contemporary. We do not know where Duccio learned his art. Both Vasari and Ghiberti agree that he painted in the "Maniera greca," and it is thought that he may have derived his training directly from Byzantine sources. He may have aimed at a revival of Byzantine painting at a time when the art of Central Italy was hopelessly degenerated. Though his influence was felt in the general development of Sienese art, he had but one or two direct followers: Segna di Buonaventura and Ugolino da Siena. Meanwhile Giotto carried the whole of Italy with him. Duccio may therefore be called the last and greatest representative of the Byzantine tradition.

See A. Lisini, "Notizie di Duccio Pittore" in the *Bullettino Senese di Storia Patria* (Sienna, 1898); J. P. Richter, *Lectures on the National Gallery* (1858); Langton Douglas, *History of Siena* (1902); J. A. Crowe and G. B. Cavalcaselle, *History of Painting in Italy*, ed. L. Douglas (2nd ed., 1903–14); C. H. Weigelt, *Duccio di Buoninsegna* (1911). *(I. A.* R.)

DU CHAILLU, PAUL BELLONI (1835–1903), traveller and anthropologist, was born, probably in Paris, on July **31,** 1835. In his youth he accompanied his father, who was in the African trade, to the west coast of Africa. In **18jj** he settled in America, and was commissioned by the Academy of Natural Sciences at Philadelphia to explore the delta of the Ogowé river and the estuary of the Gabun. During his travels he saw numbers of the anthropoid apes, then known to scientists only by a few skeletons. A subsequent expedition, from **1863** to **186j,** enabled him to confirm the accounts given by the ancients of a pygmy people inhabiting the African forests. His *Explorations and Adventures in Equatorial Africa* **(1861)** and *A Journey to Ashangoland* **(1867)** excited much controversy. Du Chaillu's later works are concerned with travel in Sweden and Lapland. He died on April 29, 1903, at St. Petersburg (Leningrad)

DUCHCOV or Dux, a town of Bohemia, situated in the fertile Eger valley near the centre of the Briix-Teplitz lignite field. It has flourishing glass and ceramic industries using local raw materials. Pop. (1930) **12,877,** 50% German.

DUCHENNE, GUILLAUME BENJAMIN AMAND (1806–1875), French physician, was born on Sept. **17, 1806,** at Boulogne, the son of a sea-captain. He was educated at Douai, and then studied medicine in Paris until **1831,** when he returned to his native town to practise his profession. Two years later he first tried the effect of electro-puncture of the muscles on a patient under his care, and from this time on devoted himself to electro-physiology and neurology, thereby laying the foundation of the modern science of electro-therapeutics. In **1842** he removed to Paris where he worked until his death. His greatest work. *L'Électrisation localiske* (1855), passed through three editions during his lifetime, though by many his *Physiologie des mouvements* **(1867)** is considered his masterpiece. He published over **50** volumes containing his researches on muscular and nervous diseases, and on the applications of electricity both for diagnostic purposes and for treatment. His name is especially connected with the first description of locomotor ataxy, progressive muscular atrophy, pseudo-hypertrophic paralysis, glosso-labio laryngeal paralysis, and other nervous troubles. He died in Paris on Sept. **17,** 1875.

For a detailed life see *Archives générales de médicine* (Dec. 1875), and for a list of his works the 3rd ed. of *L'Électrisation localisée* (1872).

DUCHESNE (Latinized DUCHENIUS, *QUERNEUS,* or QUERCETANUS), **ANDRÉ** (1 584–1640), French geographer and historian, generally styled the father of French history. Through the influence of Richelieu, he was appointed historiographer and geographer to the king. He died in Paris on May **30, 1640.** Duchesne left behind him more than 100 folio volumes of manuscript extracts now preserved in the Bibliothèque Nationale (L. Delisle, *Le Cabinet des manuscrits de la bibliothkque impkriale,* t. L, 333–334). Several of his larger works were continued by his only son François du Chesne (1616–93), who succeeded him in the office of historiographer to the king. The principal works of André Duchesne are *Historiae Normannorum scriptores antiqui* **(1619,** now the only source for some of the texts), and his *Historiae Francorum*

scriptores (5 vols. 1636–49). This last was intended to comprise 24 volumes, and to contain all the narrative sources for French history in the middle ages; only two volumes were published by the author, his son François published three more, and the work remained unfinished. Duchesne's other works include *Les antiquite's . . . des rois de France* (1639); *Les antiquités . . . de toute la France* (1609); *Histoires des Papes jusqu'à Paul V.* (1619).

DUCWESNE, LOUIS MARIE OLIVIER (1843–1922), French scholar and ecclesiastic, was born at St. Servan, Brittany, on Sept. 13, 1843. He was educated at the seminary of St. Brieuc and at Rome and was ordained priest in 1867. In 1874 he went on a scientific expedition to Mt. Athos and in 1876 to Asia Minor; but his interest in the history of the Western Church appeared in 1877 when he received the degree of *docteur ès lettres* with two remarkable theses, a dissertation *De Macario magnete,* and an *Étude sur le Liber pontificalis,* an acute critical study of the origin and editions of that celebrated chronicle. Immediately afterwards he was appointed professor at the Catholic Institute in Paris, and for eight years presented the example, then rare in France, of a priest teaching church history according to the rules of scientific criticism. His course, bold even to the point of rashness in the eyes of the traditionalists, was at length suspended. In Nov. 1885 he was appointed lecturer at the École Pratique des Hautes Btudes. In 1886 he published vol. i. of his learned edition of the *Liber pontificalis* (completed in 1892 by vol. ii.). In 1888 he was elected member of the Académie des Inscriptions et Belles-Lettres, and was afterwards appointed director of the French school of archaeology at Rome. Much light is thrown upon the Christian origins, especially those of France, by his *Origines du culte chre'tien, étude sur la liturgie latine avant Charlemagne* (1889; Eng. trans. by M. L. McClure, *Christian Worship: its Origin and Evolution,* London, 5th ed. 1919); *Mémoire sur l'origine des diocbses épiscopaux dans l'ancienne Gaule* (1890), the preliminary sketch of a more detailed work, *Fastes e'piscopaux dans l'ancienne Gaule* (1894–99); and *Catalogues épiscopaux de la province de Tours* (1898). His *Autonomies ecclésiastiques; églises séparées* (1897; Eng. trans. by H. H. Mathew, 1907), in which he speaks of the origin of the Anglican Church, but treats especially of the origin of the Greek Churches of the East, was received with scant favour in certain narrow circles of the pontifical court. In the *Histoire ancienne de l'église,* 4th ed. (1908; Eng. trans. by C. Jenkins, 1909–24). Duchesne touches cleverly upon the most delicate problems, and, without any elaborate display of erudition, presents notable conclusions. *L'Église at4 VI^e siècle* was published posthumously in 1925. His incisive style, his fearless and often ruthless criticism, and his wide and penetrating erudition, make him a redoubtable adversary in the field of polemic. The *Bulletin critique,* a review of history, philology and theology, founded by him in 1880, has contributed powerfully to spread the principles of the historical method among the French clergy.

Duchesne received an honorary Litt.D. from Cambridge and D.Litt. from Oxford, and in 1910 was elected to the French Academy. He died on April 21, 1922.

See C. D. 'Habloville, *Grandes Figures de l'Église contemporaine— Mgr. Duchesne* (1925).

DUCIS, JEAN FRANÇOIS (1733–1816), French dramatist and adapter of Shakespeare, succeeded to the fauteuil of Voltaire at the Academy in 1779. His father, originally from Savoy, was a linen-draper at Versailles. In 1768 he produced his first tragedy, *Amélise.* The failure of this first attempt was compensated by the success of his Shakespearian adaptations: *Hamlet* (1769), *Roméo et Juliette* (1772), *Le Roi Lear* (1783), *Macbeth* (1783) and *Othello* (1792), which last, supported by the acting of Talma, obtained immense applause, Though actuated by honest admiration of the great English dramatist, Ducis is not Shakespearian. His ignorance of the English language left him at the mercy of the translations of Pierre Letourneur (1736–88) and of Pierre de la Place (1707–93); and even this modified Shakespeare had still to undergo a process of purification and correction before he could be presented to the fastidious criticism of French taste. He did not pretend to reproduce, but to excerpt and refashion; and consequently the French play sometimes differs from its English namesake in everything almost but the name. The plot is different, the characters are different, the *motif* different, and the scenic arrangement different. To *Othello,* for instance, he wrote two endings. In one of them Othello was enlightened in time and Desdemona escaped her tragic fate. Of his original works the best were *Oedipe chez Admète* (1778), and *Abufar* (1795).

An edition of his works in three volumes appeared in 1813; *Oeuvres posthumes* were edited by Campenon in 1826; and *Hamlet, Oedipe chez Admète, Macbeth* and *Abufar* are reprinted in vol. ii. of Didot's *Chefs-d'oeuvrs tragiques. See* Onésime Leroy, *Etude sur la personne et les écrits de Ducis* (1832), based on Ducis' own memoirs preserved in the library at Versailles; Sainte-Beuve, *Causeries du lundi,* t. vi., and *Nouveaux lundis,* t. iv.; Villemain, *Tableau de la litt. au XVIII^e siècle.*

DUCK, the English name for birds forming five of the eleven sub-families of the family *Anatidae.* Technically, duck is restricted to the female, the male being called "drake," and, in one species, "mallard."

Ducks comprise: (1) the *Anatinae* or fresh-water ducks; (2) the *Fuligulinae* or sea-ducks *(see* EIDER; POCHARD; SCAUP; SCOTER); (3) the *Erismaturinae* or spiny-tailed ducks; (4) the *Merganettinae* or torrent ducks; (5) the *Merginae* or mergansers (q.v.).

The *Anatinae* are the typical group and the only ones here considered. The mallard (*Anas platyrhynchos*) is the most plentiful and best-known species, and is the origin of the domestic breeds of Europe and U.S.A. It inhabits the Northern Hemisphere, reaching Panama, Egypt and N.W. India in winter, and the Arctic Circle in summer. The nest may be on the ground or in a hole in a tree; g to 11 pale green eggs are laid on a lining of down which the mother pulls from her breast. As soon as the young hatch out, the mother takes them to the nearest piece of water. The male may guard the nest before hatching, but takes no interest in the brood and, indeed, is incapable of rendering active assistance by reason of an additional moult that deprives him of power of flight until the autumn. In hard weather, the ducks resort to tidal waters. For the domestic breeds of duck, *see* POULTRY AND POULTRY FARMING. It is an interesting point that, whereas the male wild duck is monogamous, the domesticated drake is polygamous.

Numerous allied species occur in various parts of the world, in some of which, e.g., *A. obscura* of America, there is little difference in plumage between the sexes. Among other genera are the groups represented by the shoveller (q.v.), garganey (q.v.), gadwall (q.v.), teal (q.v.), pintail, and widgeon (q.v.). The genus *Aix* includes the beautiful American wood-duck *(A. sponsa)* and the mandarin duck *(A. galericulata)* from East Asia. The sheldrakes (q.v.), the musk-duck *(Cairina)* of South America, and the tropical tree-ducks (*Dendrocygna*) are other groups.

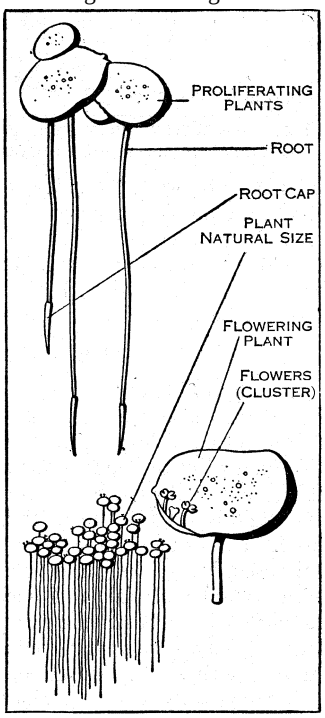
DUCK, a plain fabric, made originally from tow yarns. The cloth is lighter than canvas or sailcloth, and differs from these in that it is almost invariably single in both warp and weft. The term is also used to indicate the colour obtained'at a certain stage in the bleaching of flax yarns; it is a colour between half-white and cream. Most of the flax ducks (tow yarns) appear in this colour, although quantities are bleached or dyed. Some of the ducks are made from long flax, dyed black, and used for kit-bags, while the dyed tow ducks may be used for inferior purposes. The fabric, in its various qualities and colours, is used for an enormous variety of purposes, including tents, wagon and motor hoods, light sails, clothing, workmen's overalls, bicycle tubes, mail and other bags and pocketings. *Russian duck* is a fine white linen canvas. The term is probably derived from the Dutch *doeck,* a coarse linen material.

DUCKING and **CUCKING STOOLS,** chairs used for the punishment of scolds, witches and prostitutes in bygone days. The two have been confused, but are distinct. The earlier, the cucking-stool or stool of repentance, is of very ancient date, and was used by the Saxons, who, called it the *Scealding* or *Scolding Stool.* Seated on this stool the woman, her head and feet bare, was publicly exposed at her door or paraded through the streets amidst the. jeers of the crowd. The cucking-stool was used for

both sexes, and was specially the punishment for dishonest brewers and bakers. The earliest record of the use of the ducking-stool is towards the beginning of the 17th century. It was a strongly made wooden armchair in which the culprit was seated, an iron band being placed around her so that she should not fall out during her immersion. The chair was fastened to a long wooden beam fixed as a seesaw on the edge of a pond or river. Sometimes, however, the ducking-stool was not a fixture, but was mounted on a pair of wooden wheels so that it could be wheeled through the streets. In sentencing a woman the magistrates ordered the number of duckings she should have. Yet another type of ducking-stool was a chair on two wheels with two long shafts fixed to the axles. This was pushed into the pond and the shafts released, thus tipping the chair up backwards. Ducking-stools were used in England as late as the beginning of the 19th century.

See W. Andrews, *Old Time Punishments* (Hull, 1890); *A.* M. Earle, *Curious Punishments of Bygone Days* (Chicago, 1896); W. C. Hazlitt, *Faithr and Folklore* (London, 1905); Llewellynn Jewitt in *The Reliquary,* vols. i. and ii. (1860–62); *Gentleman's Magazine* for 1732.

DUCKWEED, the common botanical name for species of lemna (family *Lemnaceae)* which form a green coating on fresh-water ponds and ditches. The plants are of extremely simple structure and are the smallest and least differentiated of flowering plants. They consist of a so-called "frond"—a flattened green more or less oval structure which emits branches similar to itself from lateral pockets at or near the base. From the under surface a root with a well-developed sheath grows downwards into the water. The flowers, which are rarely found in Britain, are developed in one of the lateral pockets. The inflorescence is very simple, consisting of one or two male flowers each comprising a single stamen, and a female flower comprising a flask-shaped pistil. The family to which they belong is regarded as representing a very reduced type perhaps allied to the Aroids.



DUCKWEED (LEMNA MINOR), OR DUCK MEAT, SHOWING THE FLAT BLADE-LIKE FROND AND FLOWER, WHICH FLOAT ON THE WATER, ALLOWING THE ROOTS TO HANG LOOSELY

Besides *Lemna,* other genera kepresentative of the family are *Spirodela,* with several roots, and *Wolfia* and *Wolffiella,* with no roots. In Great Britain three species of *Lemna* occur; the lesser duckweed (*L. minor*), the gibbous duckweed (L. *gibba),* and the ivy-leaved duckweed (L. *trisulca*); the greater duckweed (*Spirodela polyrrhiza*) is also found. All the foregoing are distributed widely throughout the world. In Great Britain the family is further represented by *Wolffia arrhiza,* in which the rootless fronds are only $\frac{1}{20}$ in. long; it is the smallest of British flowering plants. In North America eight duckweeds occur, including all those found in Great Britain; there are also three species each of *Wolfia* and *Wolffiella. Wolfia punctata,* with fronds only $\frac{1}{50}$ in. to $\frac{1}{35}$ in. long, is one of the most minute of all flowering plants.

DUCKWORTH, SIR JOHN THOMAS (1748–1817), British admiral, was born at Leatherhead, Surrey, on Feb. 28, 1748, and entered the navy in 1759. He shared in the three days' naval engagement in which the Brest fleet was defeated (June 1, 1794), and received a gold medal and the thanks of parliament. In March 1801 he was the naval commander of the combined force which reduced the islands of St. Bartholomew and St. Martin, a service for which he was rewarded with the Order of the Bath and a pension of £1,000 a year. Promoted to be vice-admiral of the blue, he was appointed in 1804 to the Jamaica station. Two years later, while cruising off Cadiz with Lord Collingwood, he was detached with his squadron to pursue a French fleet that had been sent to the relief of Santo Domingo. He came up with the enemy on Feb. 6, 1806, and, after two hours' fighting, inflicted a signal defeat, capturing three of their five vessels and stranding the other two. In 1807 he was again sent to the Mediterranean to watch the movements of the Turks. In command of the "Royal George" he forced the passage of the Dardanelles, but sustained considerable loss on his return. In 1815 he was appointed to the chief command at Plymouth, which he held until his death on April 14, 1817.

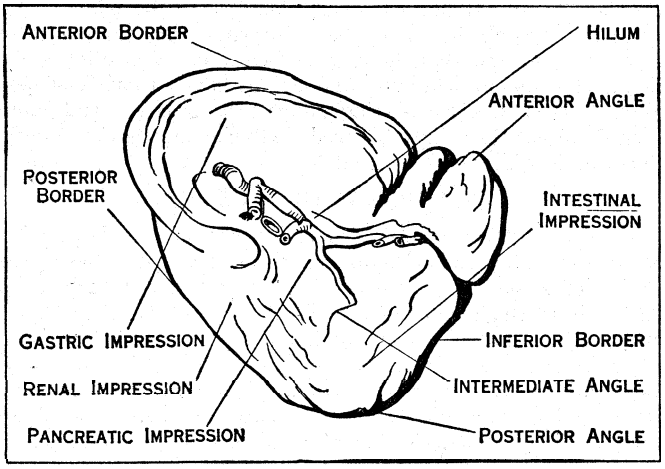
See *Naval Chronicle,* xviii.; Ralfe's *Naval Biography,* ii.

DUCLAUX, AGNES MARY FRANCES (1857–), English poet and critic (*née* Robinson), was born at Leamington on Feb. 27, 1857. In 1888 she married James Darmesteter (*q.v.*), and in 1901, after his death, Émile Duclaux, director of the Pasteur institute. She published several volumes of poetry, including *A Handful of Honeysuckle* (1878); *The New Arcadia and other Poems* (1884); *An Italian Garden* (1886); *Collected Poems, Lyrical and Narrative* (1902), and *The Return to Nature, Songs and Symbols* (1904).

Madame Duclaux's best known prose works are a monograph on *Emily Brontë* (1883); the *Life of Ernest Renan* (1897); *The End of the Middle Ages* (1888); "Froissart" (1894) in the *Grands écrivains français; Vie d'Émile Duclaux* (1907); *Madame de Sévigné* (1914); *La Pensée de Robert Browning* (1922) and *A Portrait of Pascal* (1927).

DUCOS, PIERRE ROGER (1747–1816), French politician, was born at Dax. Despite his lack of ability, he ascended the highest rungs of the political ladder from the day when he became member of the council of the Five Hundred, serving successively as a director, consul and vice-president of the Senate. He abandoned Napoleon in 1814, but was himself exiled in 1816. He died at Ulm in March 1816.

DUCTLESS GLANDS, in anatomy, glands in the body having no *ducts* or canals for conveying away their products, which, known as internal secretions, pass directly into the veins or lymphatics. Among these structures are the *spleen, adrenals, thyroid gland, parathyroids, thymus* and the *carotid* and *coccygeal* bodies. In addition lymphatic glands are described under lymphatic system (*q.v.*), and pineal and pituitary bodies under brain (*q.v.*).



FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY" BY PERMISSION OF OXFORD MEDICAL PUBLICATIONS

FIG. 1.—THE SPLEEN, VISCERAL ASPECT

THE SPLEEN

The human *spleen* is an oval, flattened gland, of a dull purple colour, and about 5in. long by three broad, situated in the upper and back part of the left side of the abdominal cavity. The external surface is convex to adapt it to the concavity of the diaphragm, against the posterior part of which it lies; external to the diaphragm is the pleural cavity, and more externally still, the ninth, tenth and eleventh ribs. The internal surface is divided by

a prominent ridge into a gastric or anterior and a renal or posterior surface. Probably, the shape of the spleen varies somewhat from time to time. The gastric surface is concave to fit the fundus of the stomach, while just in front of the ridge separating the gastric and renal surface is the hilum, where the vessels enter and leave the organ. The renal surface is moulded on to the upper part of the outer border of the left kidney and just reaches the left adrenal body. The borders of the spleen usually show two or more notches. The whole spleen is surrounded by peritoneum, which is reflected off on to the stomach and the kidney. Small accessory spleens are fairly often found in the neighbourhood, though, possibly, some of these may be haemo-lymph glands (see LYMPHATIC SYSTEM).

Microscopically the spleen has a fibro-elastic coat in which involuntary muscle is found (fig. 2). This coat sends fine trabeculae into the organ, subdividing it into minute compartments, in which the red, highly vascular, spleen pulp is contained. This pulp contains small spherical masses of adenoid tissue (Malpighian corpuscles), situated on the terminal branches of the splenic blood-vessels, numerous red blood corpuscles, lymphocytes and endothelial cells, the last often containing pigment granules or fat. The arteries in large part open into spaces, which give origin to the veins.

Embryology.— The spleen is developed in the dorsal mesogastrium (see COELOM AND SEROUS MEMBRANES) from the mesenchyme, or that portion of the mesoderm, the cells of which lie scattered in a matrix. Large lymphoid cells are early seen among those of the mesenchyme, probably being derived from the coelomic epithelium. The network of the spleen seems certainly to be derived from cells of the mesenchyme which lose their nuclei.

Comparative Anatomy.— The spleen is regarded as the remains of a mass of lymphoid tissue which, in a generalized type of vertebrate, stretched all along the alimentary canal. It is absent as a distinct gland in the Acrania and Cyclostomata. In the fishes it is closely applied to the U-shaped stomach, and in some of the Elasmobranchs, *e.g.,* the basking and porbeagle sharks, it is divided into small lobules. In Protopterus (Dipnoi) it is enclosed within the walls of the stomach. In frogs and toads (Amphibia) it is a spherical mass close to the rectum, and is derived from a different part of the original mass, already mentioned, to that which persists in other vertebrates. In the Iguana (Reptilia) the organ has many notches, each corresponding to the point of entrance of a vessel. In mammals the notches, when present, also frequently correspond to the points of entrance of arteries at the hilum. The Monotremata and Marsupialia have curious Y-shaped spleens. As a rule flesh-eating animals have larger and more notched spleens than vegetable feeders, though among the Cetacea the spleen is relatively very small.

ADRENAL GLANDS

The adrenal glands or suprarenal capsules are two conical bodies, flattened from before backward, resting on the upper poles of the kidneys close to the sides of the vertebral column; each has a concave base which is in contact with the kidney. On the anterior surface is a transverse sulcus or hilum from which a large vein emerges. The arteries are less constant in their points of entry. The glands are entirely retro-peritoneal. In a vertical transverse section each gland is seen to consist of two parts, cortical (yellow) and medullary (red). The cortical substance is composed of columns of cells, separated by a stroma. The medullary part consists of small islets of cells, which resemble columnar epithelium lying among venous sinuses; these cells are in close connection with the sympathetic nerve filaments from the great solar plexus.

Embryology.— The generally accepted view is that the cortical substance is derived fom the coelomic epithelium covering the mesoderm of the upper (cephalic) portion of the Wolffian body, and corresponds to the nephrostomes of mesonephridial tubules (see URINARY SYSTEM), while the medullary part grows out from the sympathetic ganglia and so is probably ectodermal in origin. In the early human embryo the adrenals are larger than the kidneys, and at birth they are proportionately much larger than in the adult.

Comparative Anatomy.— Adrenals are unknown in Amphioxus and the Dipnoi. In the Cyclostomata (hags and lampreys) they are said by some to arise in connection with the cephalic part of the pronephros, though other writers deny their presence altogether. In the Elasmobranchs and Holocephali the medullary and cortical parts are apparently distinct, the former being represented by a series of organs situated close to the intercostal arteries, while the latter may be either median or paired, and, being placed between the kidneys, are often spoken of as interrenals. In the Amphibia the glands are sunk into the surface of the kidney. In reptiles and birds they are long lobulated bodies lying close to the testis or ovary. In the lower mammals they are not as closely connected with the kidneys as they are in man, and their shape is usually oval or spherical.

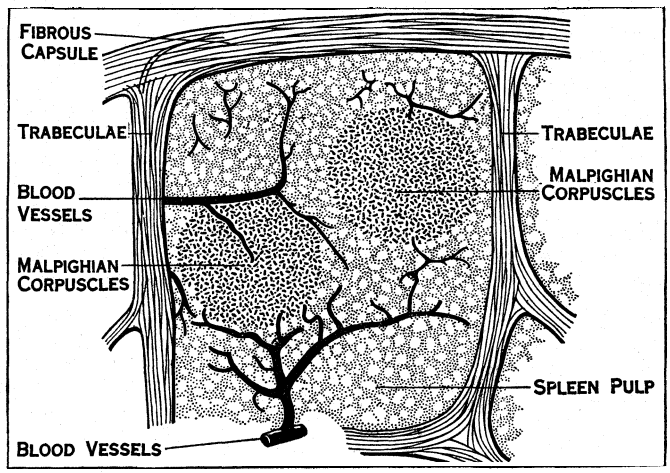


FIG. 2.— SECTION OF SPLEEN. UNDER LOW MAGNIFICATION. SHOWING FIBRO-ELASTIC COVERING. BLOOD VESSELS AND VARIOUS CORPUSCLES

THE THYROID GLAND

The thyroid body or gland is a deep red glandular mass consisting of two lobes which lie one on each side of the upper part of the trachea and lower part of the larynx; these are joined across the middle line by the isthmus which lies in front of the second and third rings of the trachea. The gland is relatively larger in women and children than in men. It is enclosed in a capsule of cervical fascia and is supplied by the superior and inferior thyroid arteries. Microscopically, the gland consists of closed tubular alveoli filled with colloid material, and lined by cuboidal epithelial cells, unsupported by a basement membrane. The lymphatic vessels are large and numerous, and contain the same colloid as the alveoli. Accessory thyroids, close to the main gland, are often found.

Embryology.— The median part of the gland is developed from the thyro-glossal duct which grows down in the middle line from the junction of the buccal and pharyngeal parts of the tongue (*q.v.*), between the first and second branchial arches. The development of the hyoid bone obliterates the middle part of the duct, leaving its upper part as the foramen caecum of the tongue, while its lower part bifurcates. The lateral parts of the gland are developed from the entoderm of the fourth visceral clefts, and, joining the median part, lose their pharyngeal connection.

Comparative Anatomy.— The endostyle or hypobranchial groove of Tunicata and Acrania is regarded as the first appearance of the median thyroid; this is a median entodermal groove in the floor of the pharynx, secreting a glairy fluid in which food particles become entangled and so pass into the intestine. In the larval lamprey the connection with the pharynx is present, but in the adult as in all adult vertebrates, this connection is lost. In Elasmobranchs, the single median thyroid lies close to the mandibular symphysis, but in Teleostei it is paired. In Dipnoi there is also an indication of a division into two lobes. In Amphibia the thyroid forms numerous vesicles close to the anterior end of the pericardium. In Reptilia it lies close to the trachea, and in Chelonia and Crocodilia is paired. In birds it is also paired and lies near the origin of the carotid arteries. In Mammalia the lateral

lobes make their first appearance. In the lower orders of this class the isthmus is often absent.

PARATHYROID GLANDS

These little oval bodies are two on each side. The upper pair is embedded in the thyroid at the level of the lower border of the cricoid cartilage, while the lower pair may be embedded in the lateral lobes of the thyroid or lie below in relation to the inferior thyroid veins. They are often very difficult to find in the adult. Microscopically they consist of solid masses of epithelioid cells with numerous blood-vessels, while, embedded in their periphery, are often masses of thymic tissue including the concentric corpuscles of Hassall. They are developed from the entoderm of the third and fourth branchial grooves.

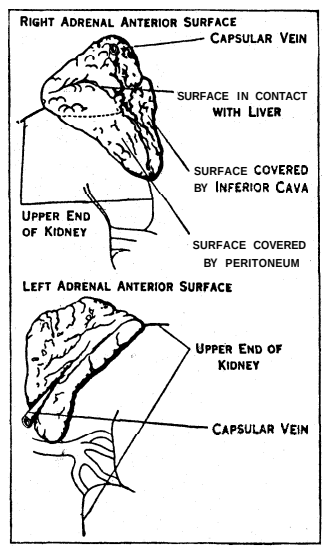
Parathyroids have been found in the orders of Primates, Cheiroptera, Carnivora, Ungulata and Rodentia among the Mammalia, and also in birds. In the other classes of vertebrates little is known of them.

THE THYMUS GLAND

The thymus is a light pink gland, consisting of two unequal lobes, which lies in front of the pericardium and great vessels; it also extends up into the root of the neck to within a short distance of the thyroid gland. It continues to grow until the second year of life, after which it remains stationary until puberty, when it usually atrophies and is represented by a mass of fat. Each lobe is divided up by areolar tissue, and, microscopically, the lobules consist of a cortical and medullary part. The cortex resembles in structure a lymphatic gland (see LYMPHATIC SYSTEM). In the medulla the lymphoid cells are fewer, and nests of epithelial cells are found (concentric corpuscles of Hassall). The vascular supply is derived from all the vessels in the neighbourhood, the lymphatics are very large and numerous, but the nerves, which come from the sympathetic and vagus, are few and small.

Embryology. — The thymus is formed from a diverticulum, on each side, from the entoderm lining the third branchial groove, but the connection with the pharynx is soon lost. The lymphoid cells and concentric corpuscles are probably derived from the original cells lining the diverticulum.

Comparative Anatomy.— The thymus is always a paired gland. In most fishes it rises from the dorsal part of all five branchial clefts; in Lepidosiren (Dipnoi), from all except the first; in Urodela from third, fourth and fifth, and in Anura from the second only. In all fishes, including the Dipnoi, it is placed dorsally to the gill arches on each side. In Amphibia it is close to the articulation of the mandible. In Reptilia it lies along the carotid artery; but in young crocodiles it is lobulated and extends all along the neck, as it does in birds, lying close to the side of the oesophagus. In mammals the Marsupials are remarkable for having a well-developed cervical as well as thoracic thymus. In some of the lower mammals the gland does not disappear as early as it does in man.



FROM CUNNINGHAM, "TEXTBOOK OF ANATOMY" (OXFORD UNIVERSITY PRESS)

FIG. 3.—RIGHT AND LEFT SUPRARENAL BODIES SHOWING THE ANTERIOR SURFACES

CAROTID BODIES

These are two small bodies situated between the origins of the external and internal carotid arteries. Microscopically they are divided into nodules or cell balls by connective tissue, and these closely resemble the structure of the parathyroids, but are without any thymic tissue. The blood-vessels in their interior are large and numerous. It is believed that they are part of the sympathetic system.

COCCYGEAL BODY

This is a median body. the size of a oea. situated in front of the apex of the coccyx and between the insertions of the levatores ani muscles. It resembles the carotid body in its microscopical structure, but is not so vascular. Concentric corpuscles, like those of the thymus, have been recorded in it. Of its embryology and comparative anatomy little is known. Probably it is sympathetic in origin. (For further information see ENDOCRINOLOGY.)

BIBLIOGRAPHY.—Quain's ***Anatomy***, vol. 1 (1908); McMurrich's ***Development*** of ***the Human Body*** (1906); Wiedersheim's ***Vergleich. Anat. der Wirbeltiere*** (Jena, **1898**).

DUDDELL, WILLIAM DU BOIS (1872–1917), British electrical engineer, was born in 1872. Because of his delicate health Duddell was educated at Cannes, and as a child he showed signs of great mechanical ingenuity. He served his apprenticeship as an engineer at Colchester. In 1893 he went to the City and Guilds Institute, where he stayed for some years because of the facilities for experimental work. Later he had an office of his own in Victoria street, London. Duddell showed an extraordinary gift for designing and constructing apparatus. His first, and probably his most notable instrument was the Duddell galvanometer or oscillograph. (See INSTRUMENTS, ELECTRICAL.) While carrying out observations on the resistance of the electric arc, the results of which were published in the *Proceedings of* the Royal Society (1901), he discovered the "singing arc," which led eventually to the development of the Poulsen arc. In connection with this work he designed and constructed a mechanical high frequency alternator giving 120,000 cycles per sec. Duddell also designed a thermo-ammeter (see INSTRUMENTS, ELECTRICAL), which he used in his work on radio-telegraphy. He was F.R.S. and held office in several learned societies. Duddell died on Nov. 4, 1917.

DUDERSTADT, town, Prussian province of Hanover, Germany, situated in a beautiful and fertile valley (formerly called Goldene Mark) watered by the Hahle, and on the railway Wulften-Leinefelde. Population 6,950. Duderstadt was founded by Henry I. (the Fowler) in 929, passed later to the monastery of Quedlinburg, and then to Brunswick. It was a member of the Hanseatic League, and during the Thirty Years' War became a stronghold of the Imperialists. It was taken by Duke William of Weimar in 1632; in 1761 its walls were dismantled, and it passed finally in 1866 with Hanover to Prussia. It is an interesting mediaeval town with many ancient buildings. There are two beautiful Gothic churches of the 14th century. It makes gloves, hats, paper, cigars and bricks; it has also a trade in singing-birds.

DUDEVANT, A. L. A.: see SAND, GEORGE.

DUDLEY, BARONS AND EARLS OF. The holders of these English titles are descended from John de Sutton (c. 1310–59) of Dudley Castle, Staffordshire, who was summoned to parliament as a baron in 1342. Sutton was the son of another John de Sutton, who had inherited Dudley Castle through his marriage with Margaret, sister and heiress of John de Somery (d. 1321); he was called Lord Dudley, or Lord Sutton of Dudley, the latter being doubtless the correct form. However, his descendants, the Suttons, were often called by the name of Dudley; and from John Dudley of Atherington, Sussex, a younger son of John Sutton, the 5th baron, the earls of Warwick and the earl of Leicester of the Dudley family are descended.

John Sutton or Dudley (*c.* 1400–87), the 5th baron, was first summoned to parliament in 1440, having been viceroy of Ireland from 1428 to 1430. He died on Sept. 30. 1487. He was succeeded as 6th baron by his grandson Edward (c. 1459–1532), and one of his sons, William Dudley, was bishop of Durham from 1476 until his death in 1483. His descendant Edward Sutton or Dudley, the 9th baron (1567–1643), had several illegitimate sons. Among them was Dud Dudley (1599–1684), who in 1665 published *Metallum Martis,* describing a process of making iron with "pit-coale, sea-coale, etc.," which was put in operation at his father's ironworks at Pensnet, Worcestershire, of which he was manager. During the Civil War he was a colonel in the army of Charles I.

Dying without lawful male issue in June 1643, the 9th baron was succeeded in the barony by his grand-daughter, Frances

(1611–97); she married Humble Ward (*c.* 1614–70), the son of a London goldsmith, who was created Baron Ward of Birmingham in 1644. Their son Edward (1631–1701) succeeded both to the barony of Dudley and to that of Ward, but these were separated when his grandson William died unmarried in May 1740. The barony of Dudley passed to a nephew, Ferdinando Dudley Lea, falling into abeyance on his death in Oct. 1757; that of Ward passed to the heir male, John Ward (d. 1774), a descendant of Humble Ward. In 1763 Ward was created Viscount Dudley, and in April 1823 his grandson, John William Ward (1781–1833), foreign minister in 1827–28, became the 4th viscount. He was created Viscount Ednam and earl of Dudley in 1827, and when he died unmarried on March 6, 1833, these titles became extinct. His barony of Ward, however, passed to William Humble Ward (1781–1833), whose son, William (1817–85) was created Viscount Ednam and earl of Dudley in 1860. The 2nd earl of Dudley in this creation was the latter's son William Humble (b. 1866), who was lord-lieutenant of Ireland from 1902 to 1906, and governor-general of Australia from 1908 to 1911. He died in 1932.

See H. S. Grazebrook in the *Herald and Genealogist*, vols. ii., v. and vi.; in *Notes and Queries*, 2nd series, vol. xi.; and in vol. ix. of the publications of the William Salt Society (1888).

DUDLEY, EDMUND (c. 1462–1510), minister of Henry VII. of England, was a son of John Dudley of Atherington, Sussex, and a member of the great baronial family of Sutton or Dudley. After studying at Oxford and at Gray's Inn, Dudley came under the notice of Henry VII. He and his colleague Sir Richard Empson (*q.v.*) are called *fiscales iudices* by Polydore Vergil, and their extortions made them bitterly hated. Dudley, who was speaker of the House of Commons in 1504, amassed a great amount of wealth for himself, and possessed large estates in Sussex, Dorset and Lincolnshire. When Henry VII. died in April 1509, he was thrown into prison by order of Henry VIII. and charged with the crime of constructive treason, being found guilty and attainted. He was executed on Aug. 17 or 18, 1510. Dudley's nominal crime was that during the last illness of Henry VII. he had ordered his friends to assemble in arms in case the king died, but the real reason for his death was the unpopularity caused by his avarice. During his imprisonment he sought to gain the favour of Henry VIII. by writing a treatise in support of absolute monarchy called The Tree of *Commonwealth* (printed privately, in Manchester 1859).

See Francis Bacon, *History of Henry VII.* edit. *J. R.* Lumby (1881); and J. S. Brewer, *The Reign of Henry VIII.*, edit. *J.* Gairdner (1884).

DUDLEY, SIR ROBERT (1573–1649), titular duke of Northumberland and earl of Warwick, English explorer, engineer and author, was the son of Robert Dudley, earl of Leicester (*q.v.*), the favourite of Queen Elizabeth. His mother was Lady Douglas Sheffield, daughter of Thomas, first Baron Howard of Effingham. Leicester, who deserted Lady Douglas Sheffield for Lettice Knollys, widow of the first earl of Essex, denied that they were married. Her son Robert was born in May 1573, was recognized by Leicester, and sent to Christ Church, Oxford, in 1587. He inherited all Leicester's property under the earl's will at his death in 1588, and in the following year the property of Ambrose Dudley, earl of Warwick. In 1594 he made a voyage to the West Indies, and in 1596 he took part in the expedition to Cadiz and was knighted. After the death of Elizabeth he endeavoured to secure recognition of his legitimacy, and of his right to inherit the titles of his father and uncle. The proceedings were quashed by the Star Chamber. In 1605 he obtained leave to travel abroad, and went to Italy accompanied by the beautiful Miss Elizabeth Southwell, daughter of Sir Robert Southwell of Woodrising, in the dress of a page. When ordered to return home and to provide for his deserted wife and family, he refused, was outlawed, and his property was confiscated. On the continent he avowed himself a Roman Catholic, married Elizabeth Southwell at Lyons, and entered the service of Cosimo II., grand duke of Tuscany. He was employed in draining the marshes behind Leghorn, and in the construction of the port. In Italy Dudley was known as Duca di Nortombria and Conte di Warwick. He died near Florence on Sept. 6, 1649. His deserted wife, Alicia, was created duchess of Dudley by Charles I. in 1644, and died in 1670, when the title became extinct. Dudley's chief claim to remembrance is the magnificent *Arcano del mare* (Florence, 3 vols. 1645–1646, reprinted 2 vols. 1661), a collection of all the naval knowledge of the age, remarkable for a scheme for t e construction of a navy in five rates which Dudley designed and described.

See G. L. Craik, *Romance of the Peerage* (London, 1848–1850), vol. iii.; Sir N. H. Nicolas, *Report of Proceedings on the Claim to the Barony of L'Isle* (London, 1829); and *The Italian Biography of Sir R. Dudley*, by Doctor Vaughan Thomas.

DUDLEY, THOMAS (1576–1653), British colonial governor of Massachusetts, was born in Northampton, England, in 1576, possibly a member of the elder branch of the family to which Robert Dudley, earl of Leicester, belonged. He was the son of a country gentleman of some means and high standing, was captain of an English company in the French expedition of 1597, serving under Henry of Navarre, and eventually became the steward of the earl of Lincoln's estates, which he managed with great success for many years. Having been converted to Puritanism, he became an advocate of its strictest tenets. About 1627 he associated himself with other Lincolnshire gentlemen who in 1629 entered into an agreement to settle in New England provided they were allowed to take the charter with them. This proposal the general court of the Plymouth Company agreed to, and in April 1630 Dudley sailed to America in the same ship with John Winthrop, the newly appointed governor, Dudley himself at the last moment being chosen deputy-governor in place of John Humphrey (or Humfrey), the earl of Lincoln's son-in-law, whose departure was delayed. Dudley was for many years the most influential man in the Massachusetts Bay Colony, save Winthrop, with whose policy he was more often opposed than in agreement. He was deputy-governor in 1629–34, in 1637–40, in 1646–50 and in 1651–53, and was governor four times, in 1634, 1640, 1645 and 1650. Soon after his arrival in the colony he settled at Newton (Cambridge), of which he was one of the founders; he was also one of the earliest promoters of the plan for the establishment of Harvard college. Winthrop's decision to make Boston the capital instead of Newton precipitated the first of the many quarrels between the two, Dudley's sterner and harsher Puritanism, being in strong contrast to Winthrop's more tolerant and liberal views. He was an earnest and persistent heresy-hunter — not only the Antinomians, but even such a good Puritan as John Cotton, against whom he brought charges, feeling the weight of his stern and remorseless hand. His position he himself best expressed in the following brief verse found among his papers: —

> Let men of God in courts and churches watch
> O'er such as do a Toleration hatch,
> Lest that ill egg bring forth a Cockatrice
> To poison all with heresy and vice.

He died at Roxbury, Mass., on July 31, 1653.

See Augustine Jones, *Life and Work of Thomas Dudley, the Second Governor of Massachusetts* (1899); and the *Life of Mr. Thomas Dudley, several times Governor of the Colony of Massachusetts, written as is supposed by Cotton Mather*, edited by Charles Deane (1870). Dudley's interesting and valuable "Letter to the Countess of Lincoln," is reprinted in Alexander Young's *Chronicles of the Planters of the Colony of Massachusetts Bay* (1846), and in the New Hampshire Historical Society *Collections*, vol. iv. (1834); G. K. Koues, *Thomas Dudley, Governor of Massachusetts* (Boston, 1914).

His son JOSEPH DUDLEY (1647–1720), colonial governor of Massachusetts, was born in Roxbury, Mass., on Sept. 23, 1647. He graduated at Harvard college in 1665, became a member of the general court, and in 1682 was sent by Massachusetts to London to prevent the threatened revocation of her charter by Charles II. There, with an eye to his personal advancement, he secretly advised the king to annul the charter; this was done, and Dudley, by royal appointment, became president of the provisional council. With the advent of the new governor, Sir Edmund Andros, Dudley became a judge of the superior court and censor of the press. Upon the deposition of Andros, Dudley was imprisoned and sent with him to England, but was soon set free. In 1691–92 he was chief-justice of New York, presiding

over the court that condemned Leisler and Milburn. Returning to England in 1693, he was lieutenant-governor of the Isle of Wight and a member of parliament, and in 1702, after a long intrigue, secured from Queen Anne a commission as governor of Massachusetts, serving until 1715. His administration was marked, particularly in the earlier years, by ceaseless conflict with the general court, from which he demanded a regular fixed salary instead of an annual grant. He was active in raising volunteers for the so-called Queen Anne's War. He was accused by the Boston merchants, who petitioned for his removal, of being in league with smugglers and illicit traders, and in 1708 a bitter attack on his administration was published in London, entitled The Deplorable State of New England by reason of a Covetous and Treacherous Governor and Pusillanimous *Counsellors*. His character may be best summed up in the words of one of his successors, Thomas Hutchinson, that "he had as many virtues as can consist with so great a thirst for honour and power." He died at Roxbury on April 2, 1720.

See Everett Kimball, *The Public Life of Joseph Dudley* (1911); J. G. Palfrey, *History of New England*, vol. iv. (1875); and the *Massachusetts Historical Society, Collections*, series 5, vol. vi. (1879).

Joseph Dudley's son, PAUL DUDLEY (1675–1751), graduated at Harvard in 1690, studied law at the Temple in London, and became attorney-general of Massachusetts (1702–18). He was associate justice of the superior court of that province from 1718 to 1745, and chief justice from 1745 until his death. He was a member of the Royal Society (London), to whose Transactions he contributed several valuable papers on the natural history of New England, and was the founder of the Dudleian lectures on religion at Harvard.

DUDLEY, market town, county and parliamentary borough, Worcestershire, England, in a portion of that county enclaved in Staffordshire, 8 mi. N.W. of Birmingham and 121 mi. N.W. of London by the L.M.S. Ry., also served by the G.W. Ry. and on the Birmingham and Stourbridge canals. Pop. (1938) 61,600. Area 6 sq.mi. Dudley stands on a ridge in the Black Country, in which are ironworks and coal mines. The "ten-yard" coal, in the neighbourhood, is the thickest seam worked in England. Limestone, for burning, and dolerite, for road metal, are extensively quarried; while iron and brass foundries and engineering and brickworks are the chief industries. The principal buildings are the churches of the six parishes of the town, the council house (1935), the town hall (1928), county court, free libraries, grammar school, girls' school, technical school, teachers' training college, the Guest hospital (founded by Joseph Guest, 1868) and a dispensary. The town is noted for the excellent Silurian fossils obtained from the limestone quarries of Dudley Castle and Wren's Nest. To the north of the town, on Dudley Castle hill, are extensive remains of an ancient castle, surrounded by beautiful grounds open to the public. The view from the castle is remarkable. The whole district is seen to be set with chimneys, pit-buildings and factories; and at night the glare of furnaces reveals the tireless activity of the Black Country. Dudley and its environs are connected by a bus system.

Brierley Hill, urban district and market town, 2½ mi. S.W. of Dudley, on the G.W. Ry., in Kingswinford parliamentary division, Staffordshire, and on the river Stour and the Stourbridge and Birmingham canals, is an important industrial centre, producing coal, fire clay and glass. Pop. (1938) 46,360. Between here and Dudley are the ironworks of Roundoak and Netherton, a suburb of Dudley. Three miles west of Dudley is Kingswinford (in Brierley Hill urban district), a mining township, with large brickworks, giving name to a parliamentary division of Staffordshire. The parliamentary borough of Dudley returns one member.

In mediaeval times, Dudley (Dudelei) depended on the castle, which is mentioned in the Domesday Survey. Before the Conquest Earl Eadwine held the manor, which in 1086 belonged to William FitzAnsculf, from whom it passed to Fulk Paynel, afterwards to the Somerys, Suttons and Wards, and their descendants, the present earls of Dudley. The first mention of Dudley as a borough occurs in an inquisition taken after the death of Roger de Somery in 1272. In 1865 Dudley was incorporated. Before that time it was governed by a high and low bailiff, appointed every year at the court leet of the manor. Roger de Somery evidently held a market by prescription in Dudley before 1261, in which year he came to terms with the dean of Wolverhampton, who had set up a market in Wolverhampton. According to the terms of the agreement the dean might continue his market on condition that Roger and his tenants should be free from toll there. Two fairs, on Sept. 21 and April 21, were granted in 1684 to Edward Lord Ward, lord of the manor. Dudley was represented in the parliament of 1295, but not again until the Reform Act of 1832. Mines of sea-coal in Dudley are mentioned as early as the reign of Edward I., and by the beginning of the 17th century mining had become an important industry.

DUDO or **DUDON** (*fl. c.* 1000), Norman historian, was dean of St. Quentin, where he was born about 965. Sent in 986 by Albert I. count of Vermandois, on an errand to Richard I., duke of Normandy, he spent some years in that country. During a second stay in Normandy Dudo wrote his history of the Normans, a task which Duke Richard I. had urged him to undertake. Very little else is known about his life, except that he died before 1043. Written between 1015 and 1030, his *Historia Normannorum*, or Libri *III.* de moribus et *actis primorum Normanniae ducum*, was dedicated to Adalberon, bishop of Laon. Dudo appears to have obtained his information from oral tradition, much of it being supplied by Raoul, count of Ivry, a half-brother of Duke Richard I. Consequently the *Historia* partakes of the nature of a romance; nevertheless, J. Lair and J. Steenstrup, while admitting the existence of a legendary element, regard the book as of considerable value for the history of the Normans. The Historia, which is written alternately in prose and in verse of several metres, is divided into four parts, and deals with the history of the Normans from 852 to the death of Duke Richard I. in 996. It was largely used by William of Jumièges, Wace, Robert of Torigni, William of Poitiers and Hugh of Fleury in compiling their chronicles, and was first published by A. Duchesne in his Historiae Normannorum scriptores *antiqui*, at Paris in 1619. Another edition is in the Patrologia Latina, tome cxli. of J. P. Migne (Paris, 1844), but the best is perhaps the one edited by J. Lair (Caen, 1865).

See E. Dummler, "Zur Kritik Dudos von St. Quentin" in the *Forschungen zur deutschen Geschichte*, Bande vi. and ix. (Gottingen, 1866); G. Waitz, "Über die Quellen zur Geschichte der Begrundung der normannischen Nerrschaft in Frankreich," in the *Gottinger gel. Anzeigen* (Gottingen, 1866); J. C. H. R. Steenstrup, *Normannerne*, Band i. (Copenhagen, 1876); J. Lair, *Étude critique et historique* sur *Dudon* (Caen, 1865); G. Kortung, *Über die Quellen des Roman de Rou* (Leipzig, 1867); W. Wattenbach, *Deutschlands Geschichtsquellen*, Band i. (Berlin, 1904); and *A.* Molinier, *Les Sources de l'histoire de France*, tome ii. (Paris, 1902).

DUDWEILER, a town of the Saar district of Germany, on the Sulzbach, 4 mi. by rail N.E. from Saarbriicken. It has extensive coal mines and ironworks and produces fireproof bricks. Pop. (1939) 25,061.

DUEL. A prearranged encounter between two persons, with deadly weapons, in accordance with conventional rules, with the object of voiding a personal quarrel or of deciding a point of honour. The first recorded instance of the word occurs in Coryate's Crudities (1611), but Shakespeare has *duello* in this sense, and uses "duellist" of Tybalt in Romeo and Juliet. In its earlier meaning of a judicial combat we find the word latinized in the Statute of Wales (Edw. I., Act 12), "Placita de terris in *partibus istis non habent* terntinari per *duellum*." The word duel is from Ital. *duello*, Lat. duellum—old form of bellum—from duo, two.

Duels in the modern sense were unknown to the ancient world, and their origin must be sought in the feudal age of Europe. The single combats recorded in Greek and Roman history and legend, of Hector and Achilles, Aeneas and Turnus, the Horatii and Curiatii, were incidents in national wars and have nothing in common with the modern duel. It is, however, noteworthy that in Tacitus (*Germania*, cap. x.) we find the rudiments of the judicial duel (*see* WAGER, for the wager of battle). Domestic differences, he tells us, were settled by a legalized form of combat

between the disputants, and when a war was impending a captive from the hostile tribe was armed and pitted against a national champion, and the issue of the duel was accepted as an omen. The judicial combat was a Teutonic institution, and it was in fact an appeal from human justice to the God of battles, partly a sanction of the current creed that might is right, that the brave not only will win but deserve to win. It was on these grounds that Gundobald justified against the complaints of a bishop, the famous edict passed at Lyons (A.D. 501) which established the wager of battle as a recognized form of trial. It is God, he argued, who directs the issue of national wars, and in private quarrels we may trust His providence to favour the juster cause. Thus, as Gibbon comments, the absurd and cruel practice of judicial duels, which had been peculiar to some tribes of Germany, was propagated and established in all the monarchies of Europe from Sicily to the Baltic. Yet in its defence it may be urged that it abolished a worse evil, the cornpurgation by oath which put a premium on perjury, and the ordeal, or judgment of God, when the cause was decided by blind chance, or more often by priest-craft.

The Judicial Combat. — Those who are curious to observe the formalities and legal rules of a judicial combat will find them described at length in the 28th book of Montesquieu's *Esprit des lois*. On these regulations he well remarks that, as there are an infinity of wise things conducted in a very foolish manner, so there are some foolish things conducted in a very wise manner. For our present purpose it is sufficient to observe the development of the idea of personal honour from which the modern duel directly sprang. In the ancient laws of the Swedes we find that if any man shall say to another, "You are not a man equal to other men," or "You have not the heart of a man," and the other shall reply, "I am a man as good as you," they shall meet on the highway, and then follow the regulations for the combat. What is this but the modern challenge? By the law of the Lombards if one man call another *arga*, the insulted party might defy the other to mortal combat. What is *arga* but the *dummer Junger* of the German student? Beaumanoir thus describes a legal process under Louis le Debonnaire: The appellant begins by a declaration before the judge that the appellee is guilty of a certain crime; if the appellee answers that his accuser lies, the judge then ordains the duel.

From Germany the judicial combat rapidly spread to France, where it flourished greatly from the 10th to the 12th century, the period of customary law. By French kings it was welcomed as a limitation of the judicial powers of their half independent vassals. It was a form of trial open to all freemen and in certain cases, as under Louis VI., the privilege was extended to serfs. Even the Church resorted to it not unfrequently to settle disputes concerning church property. Abbots and priors as territorial lords and high justiciaries had their share in the confiscated goods of the defeated combatant, and Pope Nicholas when applied to in 858 pronounced it "a just and legitimate combat." Yet only three years before the council of Valence had condemned the practice, imposing the severest penance on the victor and refusing the last rites of the church to the vanquished as to a suicide.

Under Louis XII. and Francis I. we find the beginnings of tribunals of honour. The last instance of a duel authorized by the magistrates, and conducted according to the forms of law, was the famous one between Franqois de Vivonne de la Châtaignerie and Guy Chabot de Jarnac. The duel was fought on July 10, 1547, in the courtyard of the château of St. Germain-en-Laye, in the presence of the king and a large assembly of courtiers. It was memorable in two ways. It enriched the French language with a new phrase; a sly and unforeseen blow, such as that by which de Jarnac worsted La Châtaignerie, has since been called a *coup de Jarnac*. And Henry, grieved at the death of his favourite, swore a solemn oath that he would never again permit a duel to be fought. This led to the first of the many royal edicts against duelling. By a decree of the council of Trent (cap. xix.) a ban was laid on "the detestable use of duels, an invention of the devil to compass the destruction of souls together with a bloody death of the body."

Trial by Battle in England. — In England, it is now generally agreed, the wager of battle did not exist before the time of the Norman Conquest. Some previous examples have been adduced, but on examination they will be seen to belong rather to the class of single combats between the champions of two opposing armies. By the laws of William the Conqueror the trial by battle was only compulsory when the opposite parties were both Normans, in other cases it was optional. As the two nations were gradually merged into one, this form of trial spread, and until the reign of Henry II. it was the only mode for determining a suit for the recovery of land. The method of procedure is admirably described by Shakespeare in the opening scene in *Richard II.*, where Henry of Bolingbroke, duke of Hereford, challenges Thomas, duke of Norfolk; in the mock-heroic battle between Horner the Armourer and his man Peter in *Henry VI.;* and by Sir W. Scott in the *Fair Maid of Perth*, where Henry Gow appears before the king as the champion of Magdalen Proudfute.

The judicial duel never took root in England as it did in France. In civil suits it was superseded by the grand assize of Henry II., and in the cases of felony by indictment at the prosecution of the crown. One of the latest instances occurred in the reign of Elizabeth, 1571, when the lists were actually prepared and the justices of the common pleas appeared at Tothill Fields as umpires of the combat. Fortunately the petitioner failed to put in an appearance, and was consequently non-suited (*see* Spelman, *Glossary, s.v.* "Campus"). As late as 1817 Lord Ellenborough, in the case of *Thornton* v. *Ashford,* pronounced that "the general law of the land is that there shall be a trial by battle in cases of appeal unless the party brings himself within some of the exceptions." Thornton was accused of murdering Mary Ashford, and claimed his right to challenge the appellant, the brother of the murdered girl, to wager of battle. His suit was allowed, and, the challenge being refused, the accused escaped. Next year the law was abolished (59 Geo. III., c. 46).

The Duel of Honour. — We are justified, then, in dating the commencement of duelling from the abolition bf the wager of battle. The causes which made it indigenous to France are sufficiently explained by the condition of society and the national character. As Buckle has pointed out, duelling is a special development of chivalry, and chivalry is one of the phases of the protective spirit which was predominant in France up to the time of the Revolution. The third chapter of d'Audiguier's *Ancien usage des duels* is headed, "Pourquoi les seuls Franqais se battent en duel." English literature abounds with allusions to this characteristic of the French nation. Lord Herbert of Cherbury, who was ambassador at the court of Louis XIII., says, "There is scarce a Frenchman worth looking on who has not killed his man in a duel."

Duels were not common before the 16th century. Hallam attributes their prevalence to the barbarous custom of wearing swords as a part of domestic dress, a fashion which was not introduced till the later part of the 15th century. In 1560 the states-general at Orleans supplicated Charles IX. to put a stop to duelling. Hence the famous ordinance of 1566, drawn up by the chancellor de l'Hôpital, which served as the basis of the successive ordinances of the following kings. Under the frivolous and sanguinary reign of Henry III., "who was as eager for excitement as a woman," the rage for duels spread till it became almost an epidemic. In 1602 the combined remonstrances of the church and the magistrates extorted from the king an edict condemning to death whoever should give or accept a challenge or act as second. But public opinion was revolted by such rigour, and the statute was a dead letter. Fontenay-Mareuil says, in his *Mémoires,* that in the eight years between 1601 and 1609, 2,000 men of noble birth fell in duels. In 1609 a more effective measure was taken at the instance of Sully by the establishment of a court of honour. The edict decrees that all aggrieved persons shall address themselves to the king, either directly or through the medium of the constables, marshals, etc.; that the king shall decide, whether, if an accommodation could not be effected, permission to fight should be given; and that anyone who kills

his adversary in an unauthorized duel shall suffer death without burial. Henri Martin has declared this "the wisest decree of the old monarchy on a matter which involves so many delicate and profound questions of morals, politics, and religion touching civil rights" (*Histoire* de *France*, x. 466).

"Who is to Fight To-day?" — In the succeeding reign the mania for duels revived. Rostand's *Cyrano* is a life-like modern portraiture of French bloods in the first half of the 17th century. De Houssaye tells us that in Paris when friends met, the first question was, "Who fought yesterday? who is to fight today?" They fought by night and day, by moonlight and by torch-light, in the public streets and squares. A hasty word, a misconceived gesture, a question about the colour of a riband or an embroidered letter, such were the commonest pretexts for a duel. The slighter and more frivolous the dispute, the less were they inclined to scbmit them to the king for adjudication. Often, like gladiators or prize-fighters, they fought for the pure love of fighting. A misunderstanding is cleared up on the ground. "N'importe," cry the principals, "puisque nous sommes ici, battons-nous." Seconds, as Montaigne tells us, are no longer witnesses, but must take part themselves unless they would be thought wanting in affection or courage; and he goes on to complain that men are no longer contented with a single second, "c'était anciennement des duels, ce sont à cette heure rencontres et batailles." There is no more striking instance of Richelieu's firmness and power as a statesman than his conduct in the matter of duelling. In his *Testament politique* he has assigned his reasons for disapproving it as a statesman and ecclesiastic. But this disapproval was turned to active detestation by a private cause. His elder brother, the head of the house, had fallen in a duel stabbed to the heart by an enemy of the cardinal. Already four edicts had been published under Louis XIII. with little or no effect, when in 1626 there was published a new edict condemning to death any one who had killed his adversary in a duel, or had been found guilty of sending a challenge a second time. Banishment and partial confiscation of goods were awarded for lesser offences. But this edict differed from preceding ones not so much in its severity as in the fact that it was the first which was actually enforced. The cardinal began by imposing the penalties of banishment and fines, but, these proving ineffectual to stay the evil, he determined to make a terrible example. To quote his own words to the king, "Il s'agit de couper la gorge aux duels ou aux édits de votre Majesté." The count de Boutteville, a renommist who had already been engaged in 21 affairs of honour, determined out of pure bravado to fight a 22nd time. The duel took place at midday on the Place Royale. Boutteville was arrested with his second, the count de Chapelles; they were tried by the parlement of Paris, condemned and, in spite of all the influence of the powerful house of Montmorenci, of which de Boutteville was a branch, they were both beheaded on June 21, 1627. For a short time the ardour of duellists was cooled.

Duels Under Louis XIV.—Under the long reign of Louis XIV. many celebrated duels took place, of which the most remarkable were that between the duke of Guise and Count Coligny, the last fought on the Place Royale, and that between the dukes of Beaufort and Nemours, each attended by four friends. Of the ten combatants, Nemours and two others were killed on the spot, and none escaped without some wound. No less than 11 edicts against duelling were issued under le Grand Monarque. That of 1643 established a supreme court of honour composed of the marshals of France; but the most famous was that of 1679, which confirmed the enactments of his predecessors, Henry IV. and Louis XII.

The subsequent history of duelling in France may be more shortly treated. In the preamble to the edict of 1704 Louis XIV. records his satisfaction at seeing under his reign an almost entire cessation of those fatal combats which by the inveterate force of custom had so long prevailed. Addison *(Spectator*, 99) notes it as one of the most glorious exploits of his reign to have banished the false point of honour. Under the regency of Louis XV. there was a brief revival. The last legislative act for the suppression of duels was passed on April 12. 1723. Then came the Revolution, which in abolishing the *ancien régime* fondly trusted that with it would go the duel, one of the privileges and abuses of an aristocratic society. Dupleix, in his ***Military Law*** *concerning the* ***Duel*** (1611), premises that these have no application to lawyers, merchants, financiers or justices. This explains why in the legislation of the National Assembly there is no mention of duels. Camille Desmoulins when challenged shrugged his shoulders and replied to the charge of cowardice that he would prove his courage on other fields than the Bois de Boulogne. The two great Frenchmen whose writings preluded the French Revolution both set their faces against it. Voltaire had indeed, as a young man, in obedience to the dictates of society, once sought satisfaction from a nobleman for a brutal insult, and had reflected on his temerity in the solitude of the Bastille. The story runs that Voltaire met the chevalier Rohan-Chabot at the house of the marquis of Sully. The chevalier, offended by Voltaire's free speech, insolently asked the marquis, "Who is that young man?" "One," replied Voltaire, "who if he does not parade a great name, honours that he bears." The chevalier said nathing at the time, but, seizing his opportunity, inveigled Voltaire into his coach, and had him beaten by six of his footmen. Voltaire set to work to learn fencing, and then sought the chevalier in the theatre, and publicly challenged him. A *bon-mot* at the chevalier's expense was the only satisfaction that the philosopher could obtain. "Monsieur, si quelque affaire d'intérêt ne vous a point fait oublier l'outrage dont j'ai à me plaindre, j'espère que vous m'en rendrez raison." The chevalier was said to employ his capital in petty usury. After this incident and its consequences, Voltaire inveighed against duelling, not only for its absurdity, but also for its aristocratic exclusiveness. Rousseau had said of duelling, "It is not an institution of honour, but a horrible and barbarous custom, which a courageous man despises and a good man abhors." Napoleon was a sworn foe to it. "Bon duelliste mauvais soldat" is one of his best known sayings; and, when the king of Sweden sent him a challenge, he replied that he would order a fencing-master to attend him as plenipotentiary. After the battle of Waterloo duels such as Lever loves to depict were frequent between disbanded French officers and those of the allies in occupation. The restoration of the Bourbons brought with it a fresh crop of duels. Since then duels have been frequent in France — more frequent, however, in novels than in real life — fought mainly between politicians and journalists, and with rare exceptions bloodless affairs. If fought with pistols, the distance and the weapons chosen render a hit improbable; and, if fought with rapiers, honour is generally satisfied with the first blood drawn. Among Frenchmen famous in politics or letters who have "gone out" may be mentioned Armand Carrel, who fell in an encounter with Emile Girardin; Thiers, who thus atoned for a youthful indiscretion; the elder Dumas; Lamartine; Ste. Beuve, who to show at once his sangfroid and his sense of humour, fought under an umbrella; Ledru Rollin; Edmond About; Clément Thomas; Veuillot, the representative of the church militant; Rochefort; and Boulanger, the Bonapartist *fanfaron,* whose discomfiture in a duel with Floquet resulted in a notable loss of popular respect.

Duels in England. — Duelling did not begin in England till some 100 years after it had arisen in France. There is no instance of a private duel fought in England before the 16th century, and they are rare before the reign of James I. A very fair notion of the comparative popularity of duelling, and of the feeling with which it was regarded at various periods, might be gathered by examining the part it plays in the novels and lighter literature of the times. The earliest duels we remember in fiction are that in the *Monastery* between Sir Piercie Shafton and Halbert Glendinning. and that in *Kenilworth* between Tressilian and Varney. (That in *Anne of Geierstein* either is an anachronism or must reckon as a wager of battle.) Under James I. we have the encounter between Nigel and Lord Dalgarno. The greater evil of war, as we observed in French history, expels the lesser, and the literature of the Commonwealth is in this respect a blank. With the Restoration there came a reaction against Puritan morality, and a return to the gallantry and loose manners of French society, which is best represented by the theatre of the day. The drama

of the Restoration abounds in duels. Passing on to the reign of Queen Anne, we find the subject frequently discussed in the *Tatler* and the *Spectator*, and Addison points in his happiest way the moral to a contemporary duel between Thornhill and Sir Cholmeley Dering. "I come not," says Spinomont to King Pharamond, "I come not to implore your pardon, I come to relate my sorrow, a sorrow too great for human life to support. Know that this morning I have killed in a duel the man whom of all men living I love best." No reader of *Esmond* can forget Thackeray's description of the doubly fatal duel between the duke of Hamilton and Lord Mohun, which is historical, or the no less life-like though fictitious duel between Lord Mohun and Lord Castlewood. The duel between the two brothers in Stevenson's *Master of Ballantrae* is one of the best conceived in fiction. Throughout the reigns of the Georges they are frequent. Richardson expresses his opinion on the subject in six voluminous letters to the *Literary Repositor*. Sheridan, like Farquhar in a previous generation, not only dramatized a duel, but fought two himself. Byron thus commemorates the bloodless duel between Tom Moore and Lord Jeffrey:—

> Can none remember that eventful day,
> That ever glorious almost fatal fray,
> When Little's leadless pistols met the eye,
> And Bow Street myrmidons stood laughing by?

There are no duels in Miss Austen's novels, but in those of Miss Edgeworth, her contemporary, there are three or four. As we approach the 19th century they become rarer in fiction. Thackeray's novels, indeed, abound in duels. "His royal highness the late lamented commander-in-chief" had the greatest respect for Maj. Macmurdo, as a man who had conducted scores of affairs for his acquaintance with the greatest prudence and skill; and Rawdon Crawley's duelling pistols, "the same which I shot Captain Marker," have become a household word. Dickens, on the other hand, who depicts contemporary English life, and mostly in the middle classes, in all his numerous works has only three; and George Eliot never once refers to a duel. Tennyson, using a poet's privilege, laid the scene of a duel in the year of the Crimean War, but he echoes the spirit of the times when he stigmatizes "the Christless code that must have life for a blow." Browning, who delights in cases of conscience, has given admirably the double moral aspect of the duel in his two lyrics entitled "Before" and "After."

To pass from fiction to fact we will select the most memorable English duels of the last century and a half. Lord Byron killed Chaworth in 1765; Charles James Fox and Adams fought in 1779; duke of York and Colonel Lennox, 1789; William Pitt and George Tierney, 1796; George Canning and Lord Castlereagh, 1809; Christie killed John Scott, editor of the *London Magazine*, 1821; duke of Wellington and earl of Winchelsea, 1829; Roebuck and Black, editor of *Morning Chronicle*, 1831; Lord Alvanley and a son of Daniel O'Connell in the same year; Earl Cardigan wounded Captain Tuckett, was tried by his peers, and acquitted on a legal quibble, 1840.

The Killing of Captain Boyd.—The year 1808 is memorable in the annals of duelling in England. Major Campbell was sentenced to death and executed for killing Capt. Boyd in a duel. In this case it is true that there was a suspicion of foul play; but in the case of Lieut. Blundell, who was killed in a duel in 1813, though all had been conducted with perfect fairness, the surviving principal and the seconds were all convicted of murder and sentenced to death, and, although the royal pardon was obtained, they were all cashiered. The next important date is the year 1843, when public attention was painfully called to the subject by a duel in which Col. Fawcett was shot by his brother-in-law, Lieut. Monro. The survivor, whose career was thereby blasted, had, it was well known, gone out most reluctantly, in obedience to the then prevailing military code. A full account of the steps taken by the prince consort, and of the correspondence which passed between him and the duke of Wellington, will be found in the *Life of the Prince* by Sir T. Martin. Meanwhile there had been formed in London the association against duelling. It included leading members of both houses of parliament and distinguished officers of both services. The first report, issued in 1844, gives a memorial of the association presented to Queen Victoria through Sir James Graham, and in a debate in the House of Commons (March 11, 1844) Sir H. Hardinge, the secretary of war, announced to the House that her majesty had expressed herself desirous of devising some expedient by which the barbarous practice of duelling should be as much as possible discouraged. In the same debate Turner reckoned the number of duels fought during the reign of George III. at 172, of which 91 had been attended with fatal results; yet in only two of these cases had the punishment of death been inflicted. But though the proposal of the prince consort to establish courts of honour met with no favour, yet it led to an important amendment of the articles of war (April, 1844). The 98th article ordains that "every person who shall fight or promote a duel, or take any steps thereto, or who shall not do his best to prevent duel, shall, if an officer, be cashiered, or suffer such other penalty as a general court-martial may award." These articles, with a few verbal changes, were incorporated in the consolidated Army Act of 1879 (section 38), which is still in force.

Duels in Germany.—Under the late imperial régime, German army duels were authorized by the military code as a last resort in grave cases. A German officer who was involved in a difficulty with another was bound to notify the circumstance to a council of honour at the latest as soon as he had either given or received a challenge. A council of honour consisted of three officers of different ranks and was instructed, if possible, to bring about a reconciliation. If unsuccessful it had to see that the conditions of the duel were not out of proportion to the gravity of the quarrel. Public opinion was greatly aroused by a tragic duel fought by two officers of the reserve in 1896; and the German emperor in a cabinet order of 1897, confirmed in 1901, enforced the regulation of the military court of honour, and gave warning that any infringement would be visited with full penalties of the law. It continued to be the fact that a German officer who was not prepared to accept a challenge and to fight, if the opinion of his regiment demanded it, was compelled to leave the service.

Under the republic, the question is governed (1928) by articles 201 to 210 inclusive of the existing criminal code. It should be noted that the German cabinet have pledged themselves to revise this code. The existing provisions which refer to duelling may be summarized as follows:—

(1) (Article 201.) Any person challenging a second person to a duel or accepting such a challenge is liable to punishment by a term of imprisonment not exceeding six months.

(2) (Article 205.) Persons taking part in a duel are liable to sentences ranging from three months to five years.

(3) (Article 206.) Should anyone kill his opponent in a duel, he will be sentenced to imprisonment for not less than two years. Should it be shown, however, that the duel was entered into with mortal intent, the period of imprisonment shall not be less than three years.

(4) (Article 210.) Should any person intentionally encourage another person to fight a duel, he will, in the event of the duel taking place, be punished by imprisonment for not less than three months.

The German Student Duels.—The celebrated *Mensuren*, or German students' duels, have survived the War changes, and although forbidden by the German criminal code it is probable that the new code will make it plain that they are to be regarded as a sport and therefore legalized. They still form a regular element in German student life. In Berlin alone, there are in 1928 some 12 fighting corps which meet once a week in secret. These meetings continue from 8 o'clock in the morning onwards, and some 20 fights take place on each occasion. The police, as well as the university authorities, naturally know all about them; but are only too willing to close their eyes. These fighting corps or *Verbindungen* exist to-day in every German university.

The entry of a student into one of these clubs is held to be a considerable honour, and is only possible where a student has shown the necessary qualifications to permit of his admission. It moreover carries with it a number of advantages to the ex-

student in after life, and very often helps him to obtain a good position in a profession or industry. The primary qualification would seem to be having fought three "parties" or matches "successfully."

To fight a students' duel, it would seem that a considerable amount of previous practice is necessary. In each fighting *Verbindung*, a *Fechtsaal* forms part of the equipment of the club-house, and daily practice is provided for fighting students under the supervision of the training instructor, who is one of the senior students of the *Verbindung* and named the *Zweiter Chargierter*. There are two categories of fighting students. First, the *Fuchs* or novice; secondly, the *Bursch* (fellow or accepted member); besides these, the "inactive," which means a student who has finished his time in the *Verbindung*, but still retains his membership of the university.

The training practice consists of a number of short bouts fought under rather similar conditions to the actual duel. The student, however, is provided with a steel mask to accustom him to the art of fencing without the possibility of damage. The body and arms are also protected. The sword, moreover, is not sharpened. It is of interest in this connection to note that Roman Catholic members of the German universities are forbidden by their Church to enter fighting *Verbindungen* on penalty of expulsion.

Apparently the only point that is decided for or against a particular fighter is his bearing during the fight. No points are given for skill in attack or defence, and each fighter is judged by the witnessing *Korpsbrüder* of his own fighting *Verbindung* only.

Modern Views of the Duel.—Any formal discussion of the morality of duelling is, in England at least, happily superfluous. No fashionable vice has been so unanimously condemned both by moralists and divines. Some, however, of the problems, moral and social, which it suggests may be noticed briefly. That duelling flourished so long in England the law is, perhaps, as much to blame as society. It was doubtless from the fact that duels were at first a form of legal procedure that English law has refused to take cognizance of private duels. A duel in the eye of the law differs nothing from an ordinary murder. The greatest English legal authorities, from the time of Elizabeth downwards, such as Coke, Bacon and Hale, have all distinctly affirmed this interpretation of the law. But here as elsewhere the severity of the penalty defeated its own object. The public conscience revolted against a Draconian code which made no distinction between wilful murder and a deadly combat wherein each party consented to his own death or submitted to the risk of it. No jury could be found to convict when conviction involved in the same penalty a Fox or a Pitt and a Turpin or a Brownrigg. Such, however, was the conservatism of English publicists that Bentham was the first to point out clearly this defect of the law, and propose a remedy. In his *Introduction to the Principles of Morals and Legislation*, published in 1789, Bentham discusses the subject with his usual boldness and logical precision. In his exposition of the absurdity of duelling considered as a branch of penal justice, and its inefficiency as a punishment, he only restates in a clearer form the arguments of Paley. So far there is nothing novel in his treatment of the subject. But he soon parts company with the Christian moralist, and proceeds to show that duelling does, however rudely and imperfectly, correct and repress a real social evil. "It entirely effaces a blot which an insult imprints upon the honour. Vulgar moralists, by condemning public opinion upon this point, only confirm the fact." He then points out the true remedy for the evil. It is to extend the same legal protection to offences against honour as to offences against the person. The legal satisfactions which he suggests are some of them extremely grotesque. Thus for an insult to a woman, the man is to be dressed in woman's clothes, and the retort to be inflicted by the hand of a woman. But the principle indicated is a sound one, that in offences against honour the punishment must be analogous to the injury. Doubtless, if Bentham were now alive, he would allow that the necessity for such a scheme of legislation had in a great measure passed away. That duels have since become extinct is no doubt principally owing to social changes, but it may be in part ascribed to improvements in legal remedies in the sense which Bentham indicated. A notable instance is Lord Campbell's Act of 1843, by which, in the case of a newspaper libel, a public apology coupled with a pecuniary payment is allowed to bar a plea. In the Indian code there are special enactments concerning duelling, which is punishable not as murder but as homicide.

The duel, which in a barbarous age may be excused as "a sort of wild justice," was condemned by Bacon as "a direct affront of law and tending to the dissolution of magistracy." It survived in more civilized times as a class distinction and as an ultimate court of appeal to punish violations of the social code. In a democratic age and under a settled government it is doomed to extinction. The military duels of the European continent, and the so-called American duel, where the lot decides which of the two parties shall end his life, are singular survivals. For real offences against reputation law will provide a sufficient remedy. The learned professions will have each its own tribunal to which its members are amenable. Social stigma is at once a surer and juster defence against conduct unworthy of a gentleman.

(F. S.; X.)

DUENNA, specifically the chief lady-in-waiting upon the queen of Spain (Span. *dueña*, a married lady or mistress, Lat. *domina*). The word is more widely applied, however, to an elderly lady in Spanish and Portuguese households (holding a position midway between a governess and companion) appointed to take charge of the young girls of the family; and "duenna" is thus used in English as a synonym for chaperon (*q.v.*).

DUEPPEL, a village of Germany, in the Prussian province of Schleswig-Holstein, opposite the town of Sonderburg (on the island of Alsen). (Pop. 600.) The position of Diippel, forming as it does a bridge-head for the defenders of the island of Alsen, played a conspicuous part in the wars between Denmark and the Germans. On May 28, 1848, the German federal troops were there defeated by the Danes under Gen. Hedemann, and a second battle was fought on June 6, 1848. On April 13, 1849, an indecisive battle was fought between the federal troops under Prittwitz and the Danes under Bülow. The most important event in the military history of Diippel was, however, the siege by the Prussians of the Danish positions in 1864. The flanks of the defenders' line rested upon the Alsen sund and the sea, and a second line of trenches was constructed behind the front attacked, and a small réduit opposite Sonderburg to cover the bridges between Alsen and the mainland. The Prussian siege corps was commanded by Prince Frederick Charles and after three weeks' skirmishing a regular siege was begun, the batteries being opened on March 15. The siege was pushed rapidly from the first parallel, completed March 30, and the assault delivered on April 18. The whole line was carried after a brief but severe conflict, and the Prussians had penetrated to and captured the réduit opposite Sonderburg by 2 P.M. The loss of the Danes, half of whose forces were not engaged, included 1,800 killed and wounded and 3,400 prisoners. This operation was followed by the daring passage of the Alsen sund, effected by the Prussians in boats almost under the guns of the Danish warships, and resulting in the capture of the whole island of Alsen (June 29, 1864).

See R. Neumann, *Über den Angriff der Düppeler Schanzen in der Zeit vom 15. März bis 18 April 1864* (1865); and *Der deutschdänische Krieg 1864*, published by the Prussian General Staff (1887).

DUET, a term in music for a composition for two performers, either vocal or instrumental, in which the two parts are of more or less equal importance. Thus a piece for a violin and piano in which the latter provides merely an accompaniment is not properly called a duet. Duo is a term having the same meaning though usually applied to instrumental duets only.

DUFAURE, JULES ARMAND STANISLAS (1798–1881), French statesman, was born at Saujon (Charente-Inférieure) on Dec. 4, 1798. He became an advocate at Bordeaux, and in 1834 was elected deputy. As minister of public works (1839) in the Soult ministry, he freed railway construction in France from the obstacles which till then had hampered it. In 1840 Dufaure became one of the leaders of the Opposition, and on the outbreak of the revolution of 1848 he frankly accepted the Republic. On Oct. 13 he became minister of the interior under G. Cavaignac but retired on the latter's defeat in the presidential election. During the Second Empire Dufaure practised at the Paris bar and was elected *bâtonnier* in 1862. In 1863 he succeeded to Pasquier's seat in the French Academy. In 1871 he became a member of the Assembly, and it was on his motion that Thiers was elected President of the Republic. Dufaure was minister of justice under Thiers and under L. J. Buffet, whom he succeeded (March 9, 1876) as president of the council. He resigned office on Dec. 12 but returned to power on Dec. 24, 1877. Early in 1879 Dufaure took part in compelling the resignation of Marshal MacMahon, but immediately afterwards (Feb. 1), worn out by opposition, he himself retired. He died in Paris on June 28, 1881.

See G. Picot, *M. Dufaure, sa vie et ses discours (1883).*

DUFF, ALEXANDER (1806–1878), Scottish missionary in India, was born at Auchnahyle, Moulin, Perthshire. At St. Andrews university he came under the influence of Dr. Chalmers, and was sent out by the foreign mission committee of the general assembly as their first missionary to India. He was ordained in Aug. 1829, and started at once for India, but was twice shipwrecked before he reached Calcutta in May 1830, and lost all his books and other property. Up to this time Protestant missions in India had been successful only in reaching low-caste and outcaste peoples, particularly in Tinevelly and south Travancore. The Hindu and Mohammedan communities had been practically untouched. Duff therefore devised the policy of an educational mission. He first opened an English school in which the Bible was the centre of the school work, and along with it all kinds of secular knowledge were taught from the rudiments upwards to a university standard. The school soon began to expand into a missionary college, and a Government minute was adopted on March 7, 1835, to the effect that in higher education the object of the British Government should be the promotion of European science and literature among the natives of India.

After six years' furlough in England, Duff returned in 1840 to India. In 1839 the earl of Auckland, governor-general, had yielded to the "Orientalists" who opposed Duff, and adopted a policy which was a compromise between the two. At the Disruption of 1843 Duff sided with the Free Church, gave up the college buildings, with all their effects, and with unabated courage set to work to provide a new institution. He had the support of Sir James Outram and Sir Henry Lawrence, and the encouragement of seeing a new band of converts, including several young men of high caste. In 1844 Viscount Hardinge opened Government appointments to all who had studied in institutions similar to Duff's foundation. In the same year Duff took part in founding the *Calcutta Review*, of which from 1845 to 1849 he was editor. In 1849 he returned home. He was moderator of the Free Church assembly in 1851.

In 1856 Duff returned to India. He gave much thought and time to the University of Calcutta, which owes its examination system and the prominence given to physical sciences to his influence. In 1863 Sir Charles Trevelyan offered him the post of vice-chancellor of the university, but his health compelled him to leave India. He continued his work for foreign missions in different parts of the world, and was the first occupant of the chair of foreign missions at New college, Edinburgh; and at his death, on Feb. 12, 1878, left his personal property to found a lectureship on foreign missions on the model of the Bampton lectures.

See his *Life*, by George Smith (2 vols.).

DUFF, SIR EVELYN MOUNTSTUART GRANT (1863–1926), British diplomatist, second son of the Sir Mountstuart Grant Duff, the administrator and diarist, was born on Oct. 9, 1863. From 1888 he was on Foreign Office service in Rome, Tehrān, St. Petersburg (Leningrad), Stockholm and elsewhere. In 1913 he was made minister at Berne, a post which acquired great importance with the outbreak of war in 1914. Grant Duff had the responsibility of furthering friendly relations between the British and Swiss Governments, and of mitigating the difficulties arising out of the blockade. He was the object of a violent newspaper campaign instigated by the Germans, and was accused of taking observations of Friedrichshaven from the neutral Romanshorn. This propaganda was officially contradicted by the Swiss Government. In 1900 he married Edith Florence, daughter of Sir George Bonham. Lady Grant Duff gave invaluable assistance in organizing the *Bureau de Secours aux prisonniers de Guerre (British Section)*. Sir Evelyn resigned in August 1916. He died at Bath on Sept. 19, 1926.

DUFF, SIR MOUNTSTUART ELPHINSTONE GRANT (1829–1906), British politician and writer, was born at Eden, Scotland. He was educated at Edinburgh and Oxford, and in 1854 was called to the bar. He sat in parliament as the Liberal member for the Elgin Burghs from 1857 to 1881, being undersecretary of state for India from 1868 to 1874 and for the colonies during 1880–81. He was governor of Madras from 1881 to 1886. His writings include *Miscellanies, Political and Literary* (1878); *Studies in European Politics* (1886); *Memoirs of Henry Maine* (1892); *Renan* (1893), and *Notes from a Diary for the years 1851–1901* (14 vols., 1897–1905).

DUFFERIN AND AVA, FREDERICK TEMPLE HAMILTON-TEMPLE-BLACKWOOD, 1ST MARQUESS OF (1826–1902), British diplomatist, son of Price Blackwood, 4th Baron Dufferin, was born at Florence, Italy, on June 21, 1826. The Irish Blackwoods were of old Scottish stock, tracing their descent back to the 14th century. Frederick went to Eton (1839–43) and Christ Church, Oxford (1845–47), where he took a pass school and was president of the Union. His father died in 1841, and the influence of his mother, Helena Selina Sheridan—one of three unusually accomplished sisters, the other two being the duchess of Somerset and Mrs. Norton (*q.v.*)—was very marked on his mental development; she lived till 1867 and is commemorated by the "Helen's Tower" erected by her son in her honour at Clandeboye (the Irish seat of the Blackwoods) in 1861, and adorned with epigraphical verses written by Tennyson, Browning and others. Her son edited her *Poems and Verses* (1894). In 1846–48 Lord Dufferin was active in relieving the distress in Ireland due to the famine. He was a good landlord; in 1855 he already advocated compensation for disturbance and for improvements; but while supporting reasonable reform, he demanded justice for the landowners. When Gladstone adopted Home Rule, Lord Dufferin regarded the new policy as fatal both to Ireland and to the United Kingdom, though, being then an ambassador, he took no public part in opposing it. In 1849 Dufferin was made a lord-in-waiting. In 1855 Lord John Russell took him as attaché on his special mission to the Vienna Conference, and in 1860 sent him as British representative on a joint commission of the powers appointed to inquire into the affairs of the Lebanon (Syria), where the massacres of Christian Maronites by the Mussulman Druses had resulted in the landing of a French force and the possibility of a French occupation. Lord Dufferin was associated with French, Russian, Prussian and Turkish colleagues, and the diplomatic position was delicate. At last it was agreed to place a Christian governor, subordinate to the Porte, over the Lebanon district, and to set up local administrative councils. In May 1861 the French forces departed, and Lord Dufferin was thanked for his services by the government. In 1862 he married Hariot, daughter of Cap-

tain A. Rowan Hamilton, of Killyleagh Castle, Down. He held successively the posts of under-secretary for India (1864–66) and under-secretary for war (1866) in Lord Palmerston's and earl Russell's ministries; and he was chancellor of the duchy of Lancaster, outside the cabinet, under Gladstone (1868–72). In 1871 he was created earl of Dufferin.

In 1872 he was appointed governor-general of Canada. He had already become known as a powerful and graceful orator, and a man of culture and political distinction; and his abilities were brilliantly displayed in dealing with the problems of the newly united provinces of the Canadian Dominion. He admittedly strengthened and consolidated the imperial connection. Lord Dufferin left Canada in 1878, and in 1879 he was appointed by Lord Beaconsfield ambassador to Russia. In 1881 he was transferred to Constantinople, where he was concerned in the negotiations connected with the situation in Egypt caused by Arabi's revolt and the intervention of Great Britain. He was considerably helped by Turkish ineptitude, and by the accomplished fact of British military successes in Egypt, but his own diplomacy contributed to secure freedom of action for Great Britain. From Oct. 1882 to May 1883 he was in Egypt as British commissioner to report on a scheme of reorganization. In 1884 he was appointed viceroy of India, succeeding Lord Ripon. Lord Dufferin though agreeing in the main with Lord Ripon's native policy, gained the confidence of the Anglo-Indian community without producing any undesirable reaction. He initiated stable relations with Afghanistan, and settled the crisis with Russia arising out of the Panjdeh incident (1885), which led to the delimitation of the north-west frontier (1887). The annexation of Burma during his viceroyalty procured for him, on his resignation, the title of marquess of Dufferin and Ava (1888). His viceroyalty was also memorable for Lady Dufferin's work in providing better medical treatment for native women. In 1888 he was made ambassador at Rome, and in 1892 ambassador in Paris. He retired in 1896.

His last years, spent mainly at his Irish home, were clouded by the death of his eldest son, the earl of Ava, at Ladysmith in the Boer War (1900), and by business troubles due to his having accepted the chairmanship of the London and Globe Finance Corporation, of which Whitaker Wright was managing director. He died on Feb. 12, 1902, and was succeeded in the title by his second son Terence (1866–1918). His fourth son Frederick (b. 1875) succeeded in 1918 and was Speaker of the Senate, Northern Ireland, in 1921. Killed in an air smash, July 21, 1930, he was succeeded by his son Basil. Lord Ava (b. 1909).

BIBLIOGRAPHY.—Lord Dufferin's *Letters from High Latitudes*, an account of a voyage to Iceland, was published in 1857 and has been re-issued in the Everyman's Library (1910). His *Speeches and Addresses* have been edited by H. Milton (1882). The official *Life* of Lord Dufferin, by Sir Alfred Lyall, appeared in 1905. There are two Canadian histories of his Canadian administration, one by George Stewart (1878), the other by W. Leggo (1878). **lady** Dufferin wrote *Our Viceregal Life in India* (1889), and *My Canadian Journal* (1891). Sir Spencer Walpole, *Studies in Biography* (1907). Sir Arthur Comyn Lyall, *The Life of the Marquis of Dufferin and Ava*, 2 vols. (1925).

DUFF-GORDON, LUCIE (1821–1869), English woman of letters, daughter of John and Sarah Austin (*q.v.*), was born on June 24, 1821, and died in Egypt on July 14, 1869. Her chief playfellows as a child were her cousin, Henry Reeve, and John Stuart Mill, who lived next door in Queen Square, London. In 1834 the Austins went to Boulogne, and at table d'hôte Lucie found herself next to Heinrich Heine. The poet and the little girl became fast friends, and years afterwards she contributed to Lord Houghton's *Monographs Personal and Social* a touching account of a renewal of their friendship when Heine lay dying in Paris. Her parents went to Malta in 1836, and Lucie Austin was left in England at school. She married in 1840 Sir Alexander Duff-Gordon (1811–72). With her mother's beauty she had inherited her social gifts, and she gathered round her a brilliant circle of friends. George Meredith has analysed and described her extraordinary success as a hostess. and the process by which she reduced too ardent admirers to "happy crust-munching devotees" "In England, in her day," he says, "while health was with her, there was one house where men and women conversed. When that house perforce was closed, a light had gone out in our country." She went in 1860 to the Cape of Good Hope, and later to Egypt, where she died. She had translated among other works *Ancient Grecian Mythology* (1839) from the German of Niebuhr; *Mary Schweidler; The Amber Witch* (1844) from the German of Wilhelm Meinhold; and *Stella and Vanessa* (1850) from the French of A. F. L. de Wailly. Her *Letters from the Cape* (1862–63) appeared in 1865, and were reprinted in 1927; and in 1865 her *Letters from Egypt*, edited by her mother, attracted much attention. *Last Letters from Egypt* (1875) contained a memoir by her daughter, Janet Ross (*q.v.*), Lady Duff-Gordon won the hearts of her Arab dependents and neighbours. She doctored their sick and taught their children.

The *Letters from Egypt* were not originally published in a complete form. A fuller edition with an introduction by George Meredith, was edited in 1902 by Mrs. Janet Ross. *See* also Mrs. Ross's *Three Generations of Englishwomen* (1886).

DUFFTOWN, police burgh, Banffshire, Scotland, on the Fiddich, 64 m. W.N.W. of Aberdeen by the L.N.E.R. Pop. (1931) 1,454. It dates from 1817 and bears the name of its founder, James Duff, 4th earl of Fife. Although planned in the shape of a cross, with a square and tower in the middle, the arms of the cross are not straight, the constructor holding that, in order to prevent little towns from being taken in at a glance, their streets should be crooked. The leading factories are lime-works and distilleries, the water being good for whisky making. The town is a health resort. Dufftown is in the parish of Mortlach. The Stone of Mortlach is traditionally believed to have been erected to commemorate the success of Malcolm II. over the Danes in 1010. There are also three large stones known as "The King's Grave," a hill-fort and cairns. A portion of old Balvenie castle, a ruin, is considered to be of Pictish origin, but most of it is of the Scots Baronial period. Two miles south-east of Dufftown is the ruined castle of Auchindown, on a limestone crag, 200 ft. high, of which three sides are washed by the Fiddich and the fourth was protected by a moat. It dates from the 11th century, and once belonged to the Ogilvies, from whom it passed in 1535 to the Cordons. The Gothic hall with rows of fluted pillars is in fair preservation. About 4 m. to the NW. is Craigellachie, on the confines of Elginshire. It is a growing place, with a large hotel, situated on the Spey amidst fine scenery. The slogan of the Grants is "Stand fast Craigellachie!"

DUFFY, SIR CHARLES GAVAN (1816–1903), Irish and colonial politician, was born in Monaghan, Ireland, on April 12, 1816. He was one of the founders (1842) of the *Nation*, a Dublin weekly remarkable for the fire and spirit of its political poetry. In 1844 Duffy was included in the same indictment with O'Connell, and shared his conviction in Dublin and his acquittal by the House of Lords upon a point of law. His ideas, nevertheless, were too revolutionary for O'Connell; a schism took place in 1846, and Duffy united himself to the "Young Ireland" party. He was tried for treason-felony in 1848, but the jury were unable to agree. Duffy continued to agitate in the press and in parliament, to which he was elected in 1852, but his failure to bring about an alliance between Catholics and Protestants upon the land question determined him in 1856 to emigrate to Victoria. There he became in 1857 minister of public works, and after an active political career, in the course of which he was prime minister from 1871 to 1873, when he was knighted, he was elected speaker of the House of Assembly in 1877, being made K.C.M.G. in the same year. In 1880 he resigned and returned to Europe, residing mostly in the south of France. He published *The Ballad Poetry of Ireland* (1845), several works on Irish history, *Conversations with Carlyle* (1892), *Memoirs* (1898), etc. In 1891 he became first president of the Irish Literary Society. He died on Feb. 9, 1903.

DUFOUR, WILHELM HEINRICH (GUILLAUME HENRI) (1787–1875), Swiss general, was born at Constance, of Genevese parents temporarily in exile, on Sept. 15, 1787. He studied at the Bcole Polytechnique in Paris, served in the French army, and returned to Switzerland after 1815 He became chief instructor at the military school at Thun, where he had Louis Napoleon (Napoleon III.) among his pupils. He carried out the trigonometrical survey of Switzerland, which was thirty-two years in the

making. In *1847* Dufour was made general of the Federal Army, which was employed in reducing the revolted Catholic cantons, a task in which he showed conspicuous skill and moderation. In politics he belonged to the moderate conservative party, and he consequently lost a good deal of his popularity in *1848*. In *1856*, in the conflict with Frederick-William IV. of Prussia over the possession of Neuchâtel, Dufour was put at the head of the republican army and was sent to Paris to obtain the mediation of Napoleon III.; and again in *1859* at the time of the French annexation of Savoy, he was in charge of the negotiations at Paris concerning the neutrality of northern Savoy. *(See* SWITZERLAND: *History.)* In *1864* he presided over the international conference which framed the Geneva Convention as to the treatment of the wounded in time of war, etc. He died on July *14, 1875*.

His works include: *De la fortification permanente* (1850); *Mémoire sur l'artillerie des anciens et sur celle du moyen âge (1840)*; *Manuel de tactique pour les officiers de toutes armes* (1842), and various other works in military science. His memoir, *La Campagne du Sonderbund* (Paris, 1876), is prefaced by a biographical notice.

See Senn-Bardiene, *Das Buch des Generals Dufour* (6th ed., 1897).

DUGDALE, SIR WILLIAM *(1605–1686)*, English antiquary, was born at Shustoke, near Coleshill, Warwickshire, on Sept. *12*, 160*5*. He married at *17*, and lived with his wife's family until his father's death in *1624*, when he went to live at Fillongley, near Shustoke, an estate formerly acquired for him by his father. In *1625* he purchased the manor of Blythe, Shustoke, and removed thither in 1626. In 1635 he met Sir Symon Archer (1581–1662), himself a learned antiquary, who was then employed in collecting materials for a history of Warwickshire, and accompanied him to London. In *1638* Dugdale was created a pursuivant of arms extraordinary by the name of Blanch Lyon, and in *1639* rouge croix pursuivant in ordinary. He now had a lodging in the Heralds' Office, and spent much of his time in London examining the records in the Tower and the Cottonian and other collections of mss. In *1641* Sir Christopher Hatton, foreseeing the war and dreading the ruin and spoliation of the church, commissioned him to make exact drafts of all the monuments in Westminster Abbey and the principal churches in England. In June, *1642*, he was summoned to attend the king at York. When war broke out Charles deputed him to summon to surrender the castles of Banbury and Warwick, and other strongholds which were being rapidly filled with ammunition and rebels. He went with Charles to Oxford, remaining there till its surrender in *1646*. He witnessed the battle of Edgehill, where he made afterwards an exact survey of the field, noting how the armies were drawn up, and where and in what direction the various movements took place, and marking the graves of the slain. In *1646* Dugdale returned to London and compounded for his estates, which had been sequestrated, by a payment of *£168*. He collaborated with Roger Dodsworth (*q.v.*) in his *Monasticon Anglicanum*, which was published successively in single volumes in 1655, *1664* and *1673*. At the Restoration he obtained the office of Norroy king-at-arms, and in *1677* was created garter principal king-at-arms, and was knighted. He died at Blythe Hall on Feb. 10, *1686*.

Dugdale's most important works are *Antiquities of Warwickshire* (1656, 1786); *Monasticon Anglicanum* (1655–73, 1846); *History of St. Paul's Cathedral* (1658), and *Baronage of England* (1675–76). His *Life*, written by himself up to 1678, with his diary and correspondence, and an index to his manuscript collections, was edited by William Hamper, and published in 1827.

DUGGAR, BENJAMIN MINGE *(1872–*), American botanist, was born at Gallion, Ala., on Sept. *1, 1872*. He graduated at Harvard in *1895*, received in *1898* the degree of doctor of philosophy from Cornell university and later studied in various universities in Germany and France, and in Naples. He was cryptogamic botanist in the agricultural experiment station and instructor and assistant professor in plant physiology at Cornell university in 1896–1901. He was physiologist in the bureau of plant industry, U.S. Department of Agriculture. in 1901–02, following which he was professor of botany in the University of Missouri until 1907 and professor of plant physiology in Cornell university until 1913. He then became research professor of plant physiology in the Missouri botanical garden and Washington university, serving until 1927 when he was appointed professor of physiological and economic botany in the University of Wisconsin. He made extensive researches in plant physiology, and was editor for plant physiology of *Botanical Abstracts* from 1917 to *1926* when he became editor of *Biological Abstracts*. Among his published works are *Fungous Diseases of Plants* (1909), *Plant Physiology* (1911), *Mushroom Growing* (1915), and numerous research articles in scientific journals.

DUGONG, one of the two existing genera of the Sirenia, or herbivorous aquatic mammals. Dugongs *(Halicore)* are distinguished from manatee by the presence in the upper jaw of the male of a pair of large tusks. There are never more than five molar teeth on each side of the jaw, and these are flat on the grinding surface. The paddles are unprovided with nails, and the tail is broad and crescent-shaped; the bones are hard and firm. Dugongs frequent the shallow waters of tropical seas where they may be seen basking on the surface of the water, or browsing on submarine pastures of seaweed, for which the thick lips and truncated snout pre-eminently fit them; they are gregarious. The female produces a single young one at a birth, and is remarkable for its great maternal affection. Three species—the Indian dugong (H. *dugong)*, the Red Sea dugong *(H. tabernaculi)* and the Australian dugong *(H. australis)* are recognized. The first abounds in the Indian Ocean, and is captured by the Malays, who esteem its flesh a great delicacy; it is generally taken by spearing. It seldom attains a length of more than 10ft. The Australian dugong is larger, attaining a length of 15ft.; it occurs along the Australian coast from Moreton bay to Cape York, and is highly valued by the natives. Of late years the oil obtained from the blubber of this species has been used in Australia as a substitute for cod-liver oil, A full-grown dugong yields from ten to 12 gallons.

FROM VOGT & SPECHT, "NATURAL HISTORY OF ANIMALS"

DUGONG (HALICORE DUGONG)

DUG-OUT, an underground chamber or passage dug out of a slope or bank or in a trench. The simplest form of dug-out is the small shelter for two or three men, protecting them rather against the elements than against the effects of enemy fire; larger and more elaborate dug-outs will secure their occupants against bullets and splinters of shell; while the deep mined works, constructed by all belligerents on the Western front during the World War, were capable of housing whole units in complete immunity from even the heaviest bombardment, and were in many cases equipped with lighting, sleeping and living facilities. As against this security from shell fire, however, it was found that these large dug-outs often proved traps for the garrisons sheltering in them, who were unable to emerge in time to repel a hostile infantry attack, and during the later years of the war their construction was largely discontinued. The word also designates the Western plain dwellings of North American pioneers. *(See* also CANOE.)

DUGUAY-TROUIN, RENÉ (1673–1736), French sea captain, was born at St. Malo on June 10, *1673*. On the outbreak of the war with England and Holland in *1689* he went to sea in a privateer owned by his family. As a volunteer in a vessel of *28* guns he was present in 1690 at a bloody combat with an English fleet of five merchant vessels. His family then gave him a corsair of 14 guns; and having been cast by a storm on the coast of Ireland, he burned two English ships in the River Limerick. In *1694* his vessel of *40* guns was captured by the English and he was confined in the castle of Plymouth. He escaped and obtained command of a vessel of 48 guns and captured some English vessels on the Irish coast. In *1696* he made a brilliant capture of Dutch vessels and was made *capitaine de frégate* (commander) in the royal navy. In 1704–5 he persistently raided the coasts of England. In 1706 he was raised to the rank of captain of a vessel of the line. In 1707 he captured off the Lizard the greater part of an English convoy of troops and munitions bound for Portugal. His most glorious action was the capture in 1711 of Rio Janeiro, on

which he imposed a heavy contribution. In 1711 he was made *chef d'escadre*, and in 1728 *lieutenant général des armées navales*. He died in Paris on Sept. 27, 1736.

See his own *Mémoires* (1740); and J. Poulain, *Duguay-Trouin* (1882).

DU GUESCLIN, BERTRAND (*c.* 1320–1380), constable of France, the most famous French warrior of his age, was born of an ancient family at the castle of La Motte-Broons (Dinan). The name is spelt in various ways in contemporary records, *e.g.* Claquin, Klesquin, Guescquin, Glayaquin, etc. In his boyhood Bertrand was a dull learner and could never read or write. At the tournament held at Rennes in 1338 to celebrate the marriage of Charles of Blois with Jeanne de Penthièvre he unseated the most famous competitors. In the war which followed between Charles of Blois and John de Montfort for the possession of the duchy of Brittany, he put himself at the head of a band of adventurers, and fought on the side of Charles and of France. He fought a brilliant action at the siege of Vannes in 1342; and after that he disappears from history for some years.

In 1354 he was sent to England with the lords of Brittany to treat for the ransom of Charles of Blois, who had been defeated and captured by the English in 1347. When Rennes and Dinan were attacked by the duke of Lancaster in 1356, Du Guesclin fought continuously against the English, and at this time he engaged in a celebrated duel with Sir Thomas Canterbury. He finally forced his way with provisions and reinforcements into Rennes, which he defended till June 1357, when the siege was raised in pursuance of the truce of Bordeaux. Shortly afterwards he passed into the service of France. In 1359, 1360, 1361 and 1362 he was continually in the field though he was twice a prisoner of the English. In May 1364 he defeated the Navarrese at Cocherel, and took the famous Captal de Buch prisoner. He had previously been made lord of Pontorson (1357), of La Roche-Tesson (1361) and chamberlain (1364); he was now made count of Longueville and lieutenant of Normandy. Shortly afterwards Du Guesclin was taken prisoner by Sir John Chandos at the battle of Auray, in which Charles of Blois was killed. Du Guesclin was ransomed for 100,000 crowns, and was charged to lead the bands of discharged mercenaries, the famous *compagnies*, out of France. He marched with them into Spain, supported Henry of Trastamara against Pedro the Cruel, set the former upon the throne of Castile (1366), and was made constable of Castile and count of Trastamara. In the following year he was defeated and captured by the Black Prince, ally of Pedro, at Navarete, but was soon released for a heavy ransom. Once more he fought for Henry, won the battle of Montiel (1369), reinstated him on the throne, and was created duke of Molinas.

In May 1370, at the command of Charles V., who named him constable of France, he returned to France. For nearly ten years he was engaged in fighting against the English in the south and the west of France, recovering from them the provinces of Poitou, Guienne and Auvergne. In 1373, when the duke of Brittany sought English aid against a threatened invasion by Charles V., Du Guesclin seized the duchy; two years later he frustrated the attempt of the duke with an English army to recover it. In 1380 he was sent into Languedoc to suppress disturbances and brigandage, provoked by the harsh government of the duke of Anjou. His first act was to lay siege to the fortress of Châteauneuf-Randon, but on the eve of its surrender the constable died on July 13, 1380.

See biography by *D.* F. Jamison (Charleston, 1863), which was translated into French (1866) by order of Marshal Count Randon, minister of war; also S. Luce, *Histoire de* B. *du Guesclin* (1876, 3rd ed., 1896).

DUHAMEL, GEORGES (b. 1884–), French poet, novelist and playwright, born in Paris on June 30, 1884. His early life was one of struggle and hardship. He studied medicine, and in the Quartier Latin made the acquaintance of Romains, Vildrac and Arcos, with whom he founded the group of the *Abbaye* (*q.v.*) at Créteil. He obtained his medical degree in 1909, and until the World War he divided his activity between scientific research and literary work. He made his name with a series of volumes of verse: *Selon ma Loi* (1910), and *Compagnons* (1912). Several plays of his were produced about the same time: *La Lumidre* (1911), *Dans l'Ombre des Statues* (1912) and *Le Combat* (1913). It was, however, his two war books, *Vie des Martyrs* (1916) and *Civilisation* (1917) which brought him before the public. Their evidence is at once poignant and unimpeachable. Since the war Duhamel has published a number of essays mainly directed to the creation of a new religious thought independent of any denomination, and to the promotion of a new era of mutual understanding between the peoples of different nationalities. He has also written a series of novels, the three most important of which form a trilogy: *Confession de Minuit* (1920), *Deux Hommes* (1924), *Journal de Salavin* (1927) and *Le Club des Lyonnais* (1929), in which the Russian influence is combined with typically French restraint and interest in everyday things of life.

DUHAMEL DU MONCEAU, HENRI LOUIS (1700–1782), French botanist and engineer, was born in Paris. His discovery of the fungus destroying the saffron plant in Gâtinais gained him admission to the Academy of Sciences in 1728. From then he devoted himself to vegetable physiology, and experimented on the growth and strength of wood, the growth of the mistletoe, on layer planting, on smut in corn, etc. He was probably the first, in 1736, to distinguish clearly between the alkalis, potash and soda. For many years he was inspector-general of marine. He died in Paris on Aug. 13, 1782.

His principal works are: *Traité des arbres et arbustes qui se cultivent en France* (1755); *La Physique des arbres* (1758); *Des Semis et plantations des arbres et de leur culture* (1760); *Éléments d'agriculture* (1762); *De l'exploitation des bois* (1764); *Traité des arbres fruitiers* (1768); *Éléments de l'architecture navale* (1785).

DÜHRING, EUGEN KARL (1833–1921), German philosopher and political economist, was born on Jan. 12, 1833, at Berlin, and died on Sept. 21, 1921. After a legal education he practised at Berlin as a lawyer till 1859. A weakness of the eyes, ending in total blindness, occasioned his taking up the studies with which his name is now connected. In 1864 he became *docent* of the university of Berlin, but, in consequence of a quarrel with the professoriate, was deprived of his licence to teach in 1874. Among his works are *Kapital und Arbeit* (1865); *Der Wert des Lebens* (1865); *Natürliche Dialektik* (1865); *Kritische Geschichte der Philosophie* (1869); *Kritische Geschichte der allgemeinen Principien der Mechanik* (1872)—one of his most successful works; *Kursus d@ National- und Sozialökonomie* (1873); *Der Ersatz der Religion durch Volkommeneres* (1883). He published his autobiography in 1882 under the title *Sache, Leben und Feinde*. Dühring's philosophy claims to be emphatically the philosophy of reality. He is passionate in his denunciation of everything which, like mysticism, tries to veil reality. He is almost Lucretian in his anger against religion which would withdraw the secret of the universe from our direct gaze. His "substitute for religion" is a doctrine in many points akin to Comte and Feuerbach, the former of whom he resembles in his sentimentalism. Dühring's opinions changed considerably after his first appearance as a writer. His earlier work, *Natürliche Dialektik*, in form and matter not the worst of his writings, is entirely in the spirit of the Critical Philosophy. Later, in his movement towards Positivism, he strongly repudiates Kant's separation of phenomenon from noumenon, and affirms that our intellect is capable of grasping the whole reality. In political philosophy Dühring teaches an ethical communism and attacks the Darwinian principle of struggle for existence. In economics he is best known by his vindication of the American writer H. C. Carey, who attracts him both by his theory of value, which suggests an ultimate harmony of the interests of capitalist and labourer, and also by his doctrine of "national" political economy, which advocates protection on the ground that the morals and culture of a people are promoted by having its whole system of industry completed within its own borders. His patriotism is fervent, but narrow and exclusive. He idolized Frederick the Great and denounced Jews, Greeks, and the cosmopolitan Goethe.

See H. Druskowitz, *Eugen Dühring* (Heidelberg, 1888); E. Döll, *Eugen Dühring* (Leipzig, 1892); F. Engels, Eugen *D.'s Umwälzung* der *Wissenschaft* (Eng. trans. by E. Aveling, 1892, reprinted 1925); H. Vaihinger, *Hartmann, Dühring* und *Lange* (1876).

DUIKER or **DUIKERBOK,** a small south African antelope, *Cephalophus grimmi;* the popular name alluding to its habit of diving into and threading its way through thick bush. The genus *Cephalophus,* together with two other African genera, Guaveia and *Sylvicapra,* constitutes the sub-family *Cephalophinae.* Duikers are animals of small or medium size, frequenting thick forest. The horns, usually present in both sexes, are small and straight, situated far back on the forehead; and between them rises a crest-like tuft of hair. The common duiker (C. *grimmi*) is found in bush-country from the Cape to the Zambezi, Nyasaland and Angola. The banded duiker (C. doriae) from West Africa is golden brown with black transverse bands on back and loins. C. *sylvicultor,* of West Africa, is the largest species, and approaches a donkey in size. (See ANTELOPE.)

DUILIUS (or DUELLIUS), **GAIUS,** Roman general during the first Carthaginian War. In 260 B.C., when consul in command of the land forces in Sicily, he was appointed to supersede his colleague Cn. Cornelius Scipio Asina, as commander of the fleet. Recognizing that for the unskilled Romans the only chance of victory lay in fighting under conditions as similar as possible to those of a land engagement, he invented grappling irons (corvi) and boarding bridges, and gained a brilliant victory over the Carthaginian fleet off Mylae on the north coast of Sicily. A memorial column (*columna* rostrata), adorned with the beaks of the captured ships, was set up in honour of his victory.

DUISBURG, a town in the Prussian Government district (*Regierungsbezirk*) of Diisseldorf, Germany. It is situated at the junction of the Rhine and the Ruhr, 15 mi. N. (by rail) of Düsseldorf. Pop. (1885) 47,519; (1939) 431,256. Duisburg was known to the Romans as Castrum Deutonis and under the Frankish kings as Dispargum. In the 12th century it attained the rank of an imperial free town; but in the 17th century it was acquired by Brandenburg. Of the many churches in the town, the fine Gothic Salvatorkirche (15th century) is the most interesting. The town is well provided with educational facilities; of the technical schools, the school of machinery is important. In 1655, the elector Frederick William of Brandenburg founded a Protestant university, which flourished until 1802. The great development of industry on the Rhine made Duisburg into a large industrial town. Its chief industries are connected with metallurgical manufactures; in addition it has important chemical, textile, tobacco, sugar, soap, margarine and plate-glass works, as an entrepôt for the industries of the Ruhr area it exports large quantities of coal. The port—one of the largest inland ports of Europe—covers an area of 632 hectares. The Rhine-Herne canal connects Duisburg with Dortmund and by way of the Dortmund-Ems canal, with German North Sea ports. It is also an important railway centre. It was occupied by the Belgians from 1921 to 1925 as a sanction under the treaty of Versailles and was heavily bombed by the British in World War II.

DUJARDIN, FELIX (1801–1860), French biologist, was born at Tours on April 5, 1801, and died at Rennes on April 8, 1860. He forsook his early training in art and engineering for natural science, from 1843 concentrating on microscopic work in zoology. In 1840 he became dean of Rennes university, but two years later resigned to become a professor. In 1835 he distinguished protoplasm from other viscid substances, designating it "sarcode" and assigning to it all the qualities of life. He made detailed studies of rhizopods which he had discovered in 1834, and of oceanic foraminifera. Besides a manual of microscopic observation, he wrote Natural History of *Infusoria* (1841).

DUKAS, PAUL (1865–1935), French composer, born in Paris Oct. 1, 1865, studied under Matthias, Dubois arid Guiraud. His cantata *Velléda* gained for him a second Grand Prix de Rome. The symphonic poem, *L'Apprenti* Sorcier, produced at the Société Nationale de Musique in 1897, was an immediate success. His next important work was the music which he wrote for Maeterlinck's *Ariane* et *Barbe Bleue,* a lyrical story in 3 acts. This was played at the Opéra Comique in 1907 and subsequently at many of the principal opera-houses in Europe. A "poème dansé," The *Peri,* in which the orchestration is extraordinarily rich, was produced in Paris in 1912 with the Russian dancer Mademoiselle Trouhanova. Dukas is a master of instrumentation, equally effective in bold colour effects and in the delicate passages which he touches in with so sure a hand. His works for piano include a sonata in E flat minor and "Variations, Interlude and Final on a theme of Rameau," while his appreciation of the great harpsichord composers led him to edit a number of the works of Rameau. Couperin and Scarlatti. He was also a critic and a writer on music. held the position of inspector of music at the Beaux-Arts, was on the Conseil Supérieur of the Conservatoire and was an officer of the Légion d'Honneur.

See O. Seré, *Musiciens français d'aujourd'hui* (1911–12); G. Samazeuilh, *Un* musicien *français, Paul Dukas* (1913); V. d'Indy, *Emmanuel* Chabrier *et* Paul Dukas (1920); **A.** Coeuroy, La *musique française moderne* (1922).

DUK-DUK, a secret society of the New Britain Archipelago north-east of New Guinea, in the South Pacific. The society has religious and political as well as social objects.

See "Duk-Duk and other Customs or Forms of Expression of the Melanesian's Intellectual Life," by Graf von Pfeil (*Journ. of Anthrop. Instit.* vol. 27, p. 181); E. **A.** Weber, The *Duk-Duks* (1929).

DUKE, the title of one of the higher orders of the European nobility, and of some minor sovereign princes. The word "duke," which is derived from the Lat. *dux,* a leader, or general, originally signified a leader, and more especially a military chief. In this general sense the word survived in English literature until the 17th century, but is now obsolete.

The origin of modern dukes is twofold. The *dux* first appears in the Roman empire under the emperor Hadrian, and by the time of the Gordians has already a place in the official hierarchy. He was the general appointed to command an expedition and his functions were purely military. In the 4th century, after the separation of the civil and military administrations, there was a duke in command of the troops in each of the frontier provinces of the empire, *e.g.,* the *dux Britanniarum.* The number of dukes increased, and in the 6th and 7th centuries there were *duces* at Rome, Naples, Rimini, Venice and Perugia. They became charged with civil as well as military functions, and even exercised considerable authority in ecclesiastical administration. Under the Byzantine emperors they were the representatives in all causes of the central power. The Roman title of duke was less dignified than that of count (comes, companion) which implied an honourable personal relation to the emperor (see COUNT). Both titles were borrowed by the Merovingian kings for the administrative machinery of the Frank empire, and under them the functions of the duke remained substantially unaltered. He was a great civil and military official, charged to watch, in the interests of the crown, over groups of several *comitatus,* or countships, especially in the border provinces. The sphere of the dukes was never rigidly fixed, and their commission was sometimes permanent, sometimes temporary. Under the Carolingians the functions of the dukes remained substantially the same; but with the decay of the royal power in the 10th century both dukes and counts gained in local authority; the number of dukes became for the time fixed, and finally title and office were made hereditary, the relation to the crown being reduced to that of more or less shadowy vassalage. (See FEUDALISM.)

Side by side with these purely official dukedoms, however, there had continued to exist, or had sprung up, either independently or in more or less of subjection to the Frank rulers, national dukedoms, such as those of the Alemanni, the Aquitanians, and, later, of the Bavarians and Thuringians. These were developed from the early Teutonic custom by which the *herizog* (military chief) was elected by the nation as leader for a particular campaign, as in the case of the *heretogas* who had led the first Saxon invaders into Eritain. Tacitus says of the ancient Germans reges ex *nobilitate,*

duces *ex virtute sumunt, i.e.,* they elected their dukes for their warlike prowess only, and as purely military chiefs, whereas their kings were chosen from a royal family of divine descent. Sometimes the dukes so chosen succeeded in making their power permanent without taking the style of king. To this national category belong, besides the great German dukedoms, the dukes of Normandy, and the Lombard dukes of Spoleto and Benevento, who traced their origin, not to an administrative office, but to the leadership of Teutonic war bands. With the development of the feudal system the distinction between the official and the national dukedoms was more and more obliterated. By the 13th and 14th centuries the title had become purely territorial, and implied no necessary over-lordship over counts and other nobles, who existed side by side with the dukes as tenants-in-chief of the crown. From this time the significance of the ducal title varies widely in different countries.

The abolition of the Holy Roman Empire in 1806 removed the shadow of vassalage from the German reigning dukes, who retained their sovereign status under the new empire. Only one, however, the grand duke of Luxembourg, remained both sovereign and independent. Besides those who were sovereign dukes in Germany there are certain "mediatized" ducal houses, *e.g.,* that of Ratibor, which share with the dispossessed families of the Italian sovereign duchies certain royal privileges, notably that of equality of blood (*Ebenbürtigkeit*). In Italy, where titles of nobility give no precedence at court, that of duke (*duca*) has lost nearly all even of its social significance owing to lavish creations by the popes and minor sovereigns, and to the fact that the title often passes by purchase with a particular estate. Political significance it has none. Some great Italian nobles are dukes, notably the heads of the great Roman ducal families, but not all Italian dukes are great nobles.

In France the title duke at one time implied vast territorial power, as with the dukes of Burgundy, Normandy, Aquitaine and Brittany, who asserted a practical independence against the crown, though it was not till the 12th century that the title duke was definitely regarded as superior to others. At first (in the 10th and 11th centuries) it had no defined significance, and even a baron of the higher nobility called himself in charters duke, count or even marquess, indifferently. In any case the strengthening of the royal power sapped the significance of the title, until on the eve of the Kevolution it implied no more than high rank and probably territorial wealth.

There were, under the *ancien régime,* three classes of dukes in France: (1) dukes who were peers (see PEERAGE) and had a seat in the parlement of Paris; (2) hereditary dukes who were not peers; (3) "brevet" dukes, created for life only. The French duke ranks in Spain with the "grandee" (*q.v.*), and vice versa. In republican France the already existing titles are officially recognized, but they are now no more than the badges of distinguished ancestry. Besides the descendants of the feudal aristocracy there are in France certain ducal families dating from Napoleon I.'s creation of 1806 (*e.g.,* ducs d'Albufera, de Montebello, de Feltre), from Louis Philippe (duc d'Isly, and duc d'Audiffret-Pasquier), and from Napoleon III. (htalakoff, Magenta, Morny).

In England the title of duke was unknown till the 14th century, though in Saxon times the title ealdorman, afterwards exchanged for "earl," was sometimes rendered in Latin as dux, and the English kings till John's time styled themselves dukes of Normandy, and dukes of Aquitaine even later. In 1337 King Edward III. erected the county of Cornwall into a duchy for his son Edward the Black Prince, the first English duke. The second was Henry, earl of Lancaster, Derby, Lincoln and Leicester, created duke of Lancaster in 1351. In Scotland the title of duke was first bestowed in 1398 by Robert III. on his eldest son David, who was made duke of Rothesay, and on his brother, who became duke of Albany.

British dukes rank next to princes and princesses of the blood royal, the two archbishops of Canterbury and York, the lord chancellor, etc., but beyond this precedence they have no privileges which are not shared by peers of lower rank (see PEERAGE). Though their full style as proclaimed by the herald is "most high, potent and noble prince," and they were included in the *Almanach* de *Gotha,* they were not recognized as the equals in blood of the crowned or mediatized dukes of the Continent, and the daughter of a British duke marrying a foreign royal prince could only take his title by courtesy, or where, under the "house. laws" of certain families, a family council sanctioned the match. The eldest son of a British duke takes as a rule by courtesy the second title of his father, and ranks, with or without the title, as a marquess. The other sons and daughters bear the titles "Lord" and "Lady" before their Christian names, also by courtesy. A duke in the British peerage, if not royal, is addressed as "Your Grace" and is styled "the Most Noble." (See ARCHDUKE, GRAND DUKE, and, for the ducal coronet, CROWN AND CORONET.)

(W. A. P.)

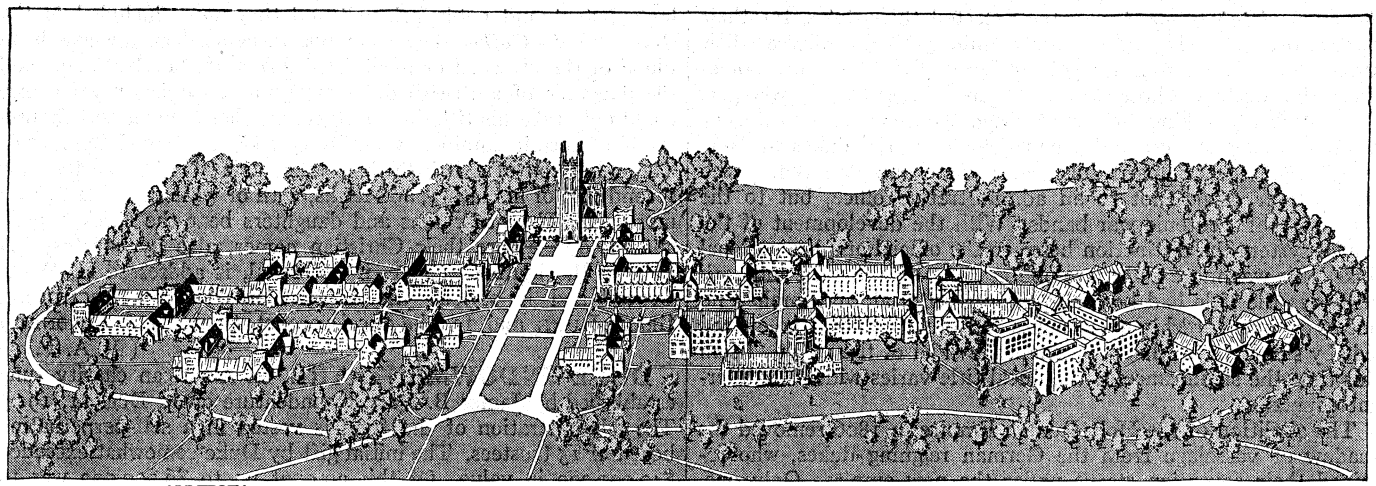
DUKE ENDOWMENT, THE, an American charity fund established by James B. Duke by indenture dated Dec. 11, 1924. The administration of the fund is vested in a self-perpetuating board of 15 trustees. The initial gift by Duke somewhat exceeded $40,000,000 in value. Of this amount up to $6,000,000 was to be used in connection with building and equipping Duke university. Twenty per cent of the net income is to be reinvested until such reinvestments aggregate $40,000,000. The remaining income is distributable as follows: Duke cniversity, 32%; hospitals not operated for private gain in North and South Carolina, 32%; Davidson college, 5%; Furman university, 5%; Johnson C. Smith university, 4%; orphanages in North and South Carolina, 10%; superannuated preachers having served in a North Carolina conference of the Methodist Episcopal Church, South, 2%; building and operating rural churches of the Methodist Episcopal Church, South, in North Carolina, 6% and 4% respectively. By his will Duke added to the fund $10,000,000 together with two-thirds of his residuary estate. Of the $10,000,000, $4,000,000 may be used for providing hospital, medical school and nurses' home facilities at Duke university, the income from the balance of $10,000,000 going to Duke university. He further provided that $7,000,000 out of two-thirds of the residuary estate are to be used for purposes of building and equipping Duke university, 10% of the income going to Duke university and 90% for the benefit of hospitals not operated for private gain in North and South Carolina.

DUKE OF EXETER'S DAUGHTER, a 15th-century instrument of torture resembling the rack. (See TORTURE.)

DUKERIES, THE, a district in the north-west of Nottinghamshire, England, forming part of Sherwood forest (*q.v.*). The name was taken from the existence of several adjacent demesnes of noblemen, and the character of the forest is to some extent preserved here. On the north is the Lincoln, Retford, Worksop, Sheffield branch and on the south, the Lincoln, Ollerton, Chesterfield branch of the L.N.E. railway. The following demesnes are in the district. Worksop Manor formerly belonged to the dukes of Norfolk. Welbeck Abbey, the seat of the dukes of Portland, to whom it came from the Cavendish family (dukes of Newcastle), is mainly classic in style, dating from the early 17th century, but with many subsequent additions; the fifth duke of Portland (d. 1879) built the curious series of subterranean corridors and chambers beneath the grounds. Clumber House, the seat of the dukes of Newcastle, was demolished in 1938. Thoresby Park is the seat of the Pierrepont family (earls Manvers). Part of this demesne is a splendid tract of wild woodland.

DUKES, LEOPOLD (1810–1891), Hungarian critic of Jewish literature. He spent about twenty years in England, and from his researches in the Bodleian library and the British Museum (which contain two of the most valuable Hebrew libraries in the world) Dukes was able to complete the work of Zunz (*q.v.*). The most popular work of Dukes was his Rabbinische Blumenlese (1844), in which he collected the rabbinic proverbs and illustrated them from the gnomic literatures of other peoples. Dukes made many contributions to philology, but his best work was connected with mediaeval Hebrew poets, especially Ibn Gabirol.

DUKE UNIVERSITY at Durham, North Carolina, U.S.A., owes its existence to a trust established by James B. Duke Dec. 11, 1924 (see DUKE ENDOWMENT). The university is



BY COURTESY OF DUKE UNIVERSITY

THE MAIN UNIT OF DUKE UNIVERSITY. WHICH WILL CONSIST OF SOME 40 BUILDINGS ON A 4.000-ACRE WOODLAND CAMPUS. THE MEMORIAL CHAPEL. IN CENTRE, WILL HAVE A SPIRE TOWERING TO 265 FEET. DORMITORY BUILDINGS ARE PLANNED FOR 3,000 STUDENTS

being built around Trinity college, founded 1838. From 1910 to 1925 the college grew in endowment and value of property from $1,221,382 to $6,145,087; in faculty from 32 to 113; and in students from 315 to 1,164.

After spending two years in college, including summer reading. the ablest students may enter the professional schools or continue in the advanced college or university courses.

The woman's college provides for women educational opportunities equal to those provided for men in Trinity college. The graduate school of arts and sciences with the purpose of differentiating more sharply between the college and the graduate school, gives to the work of the latter a more distinctively university character than has heretofore been the rule in the United States. This school aims at developing those especially fitted for teaching, but special emphasis is laid on research, mathematics, chemistry, physics, biology (in close co-operation with the medical school) and on the social sciences including law. The school of medicine runs through four quarters, so that a four-year medical course may be completed in three calendar years. The school of law provides liberal training in law as one of the social sciences closely allied with government, economics and business administration. A university press is maintained, and issues the *South Atlantic Quarterly,* the *Hispanic American Historical Review* and *Studies in American Literature.* In 1928 there were 1,608 students, exclusive of the summer school, and a teaching staff of 170.

Few, *Twenty-five Years of Trinity College* (Trinity College *President's Reports 1917,* and *Trinity Alumni Register,* vol. iii. p. 140–167); E. C. Brooks, *Trinity Alumni Register,* vol. i. p. 4–18, 89–103, 247–257; vol. ii. p. 248–258, 309–321; vol. iii. p. 1–12, 169–185; vol. iv. p. 1–10; W. T. Laprade, *Trinity Alumni Register,* vol. viii. p. 4–18

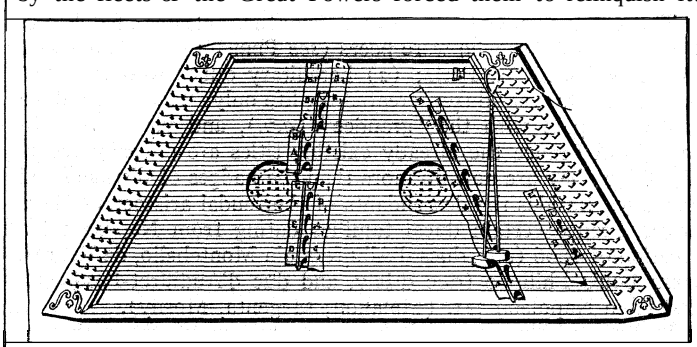
(W. P. F.)

DUKINFIELD, municipal borough, parliamentary division of Stalybridge and Hyde, Cheshire, England, 6 m. east of Manchester. Pop. (1938), 18,700. It lies in a densely populated district and is served by the L.M.S. and L.N.E. railways. The chief industries include coal-mining, cotton manufactures, calico-printing, hat-making, iron-founding, engineering and the manufacture of firebricks and tiles. A portion remains of the old timbered Dukinfield Hall, in the chapel of which Samuel Eaton (d. 1665) taught the first Congregational church in the north of England. The chapel is still used. The borough was incorporated in 1899. Area, 2.69 sq.mi.

DULAC, EDMUND (1882–), illustrator, born at Toulouse in 1882. After having studied in Paris under Jean Paul Laurens he settled in London. His exhibition of watercolours illustrating "Arabian Nights" at the Leicester gallery in 1907 was very much liked and his work was reproduced with a text by Lawrence Housman. Dulac also illustrated Shakespeare's "Tempest," Andersen's *Fairy Tales,* Edgar Allan Poe's *The Bells and other Poems,* and Arthur Quiller-Couch's *Old French Tales.*

DULCIGNO, a seaport of Montenegro, Yugoslavia, on the Adriatic sea. Population 3,748, chiefly Albanians and Turks. Shut in by hills and forests, Dulcigno is the prettiest of Montenegrin towns. The old quarter, built on a promontory, is walled and has a mediaeval castle. There is a Roman Catholic cathedral and an ancient Latin church. Steamers call, and some shipbuilding and fishing are carried on, but the harbour lacks shelter, and is liable to silting. Like the rest of Montenegro, the port in 1941 came under Italian control.

To the Romans, who captured the town in 167 B.C. Dulcigno was known as Ulcinium or Olcinium; in the middle ages it was a noted haunt of pirates; in 1571 it was captured by the Turks from the Venetians. In 1718 it was the scene of a great Venetian defeat; in 1877 the Montenegrins took it from the Turks and in 1878 it was ceded to them by the Treaty of Berlin. The Turks however held it till 1880 when the "Dulcigno demonstration" by the fleets of the Great Powers forced them to relinquish it.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, N.Y.

18TH CENTURY FRENCH DULCIMER AND HAMMERS WITH WHICH IT IS PLAYED

The direct ancestor of the piano, the dulcimer came originally from the East, *being introduced* to Europe probably during the Crusades. It was popular throughout the Middle Ages. In the days of Louis XIV. of France elaborate models were constructed

DULCIMER, the prototype of the pianoforte (*q.v.*), an instrument of great antiquity derived originally from the East, consisting of a horizontal sound-chest over which are stretched a varying number of wire strings set in vibration by strokes of little sticks or hammers. The dulcimer differed from the psalterium or psaltery chiefly in the manner of playing, the latter having the strings plucked by means of fingers or plectrum, a distinction the importance of which was fully recognized when the invention of the pianoforte had become a matter of history. It was then perceived that the psalterium in which the strings

were plucked, and the dulcimer in which they were struck, when provided with keyboards, gave rise to two distinct families of instruments, differing essentially in tone quality, in technique and in capabilities. The evolution of the psalterium stopped at the harpsichord, that of the dulcimer gave us the pianoforte. The dulcimer was very popular all over Europe throughout the middle ages.

The pantaleon, a double dulcimer, named after the inventor, Pantaleon Hebenstreit of Eisleben, a violinist, had two soundboards, 185 strings. one scale of overspun catgut and one of wire. Hebenstreit travelled to Paris with his monster dulcimer in 1705 and played before Louis XIV, who baptized it *Pantaléon.* Quantz and Quirin of Blankenburg both gave descriptions of the instrument.

DÜLKEN, town, Prussian Rhine province, Germany, 11 mi. by rail S.W. from Crefeld. Pop. (1939) 15,952. It has a Gothic parish church. There are manufactures of linen, cotton, silk and velvet, etc., ironworks and foundries.

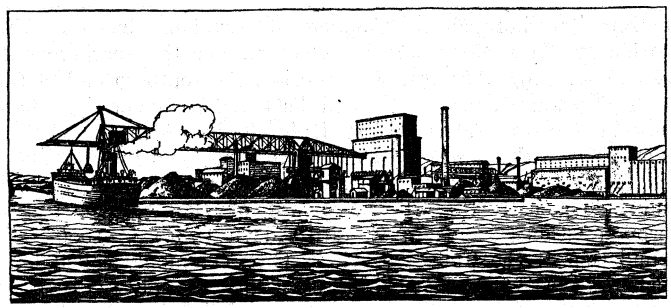
DULONG, PIERRE LOUIS (1785–1838), French chemist and physicist, was born at Rouen on Feb. 12 (or 13), 1785. After acting as assistant to Berthollet, he became successively professor of chemistry at the faculty of sciences and the normal and veterinary schools at Alfort, and then (1820) professor of physics at the École Polytechnique, of which he was appointed director in 1830. He died in Paris on July 18 (or 19), 1838.

His earliest work was chemical in character. In 1811 he discovered nitrogen trichloride; during his experiments serious explosions occurred twice, and he lost an eye, besides sustaining severe injuries to his hand. He also investigated the oxygen compounds of phosphorus and nitrogen, and was one of the first to hold the hydrogen theory of acids.

Dulong's important research work in physics was on heat and was carried out in conjunction with Alexis Thérèse Petit (1791–1820), the professor of physics at the École Polytechnique. In 1815 they made the first accurate comparisons between the mercury and the air thermometer. The first published research (1816) dealt with the dilatation of solids, liquids and gases and with the exact measurement of temperature, and it was followed by one in 1817 in which they showed that Newton's law of cooling was only true for small differences in temperature, and one in 1818 on the measurement of temperature and the transference of heat, which was crowned by the French academy. In another, "On some important points in the theory of heat" (1819), they stated the "law of Dulong and Petit" dealing with atomic heats. Subsequent papers by Dulong were concerned with "New determinations of the proportions of water and the density of certain elastic fluids" (1820, with Berzelius); the property possessed by certain metals of facilitating the combination of gases (1823 with Thénard); the refracting powers of gases (1826); and the specific heats of gases (1829). In 1830 he published a research, undertaken with Arago for the Academy of Sciences, on the elasticity of steam at high temperatures. In his last paper, published posthumously in 1838, Dulong gave an account of experiments made to determine the heat developed in a chemical reaction, together with a description of the calorimeter he employed. He was so badly supplied with apparatus that he spent practically all his wealth in providing what was necessary for his researches.

DULSE, in botany, *Rhodymenia palmata,* one of the red seaweeds, consisting of flat solitary or tufted purplish-red fronds, fan-shaped in general outline and divided into numerous segments, which are often again and again divided in a forked manner. It varies much in size and degree of branching, ranging from 5 to 12 or more inches long. It grows on rocks, shellfish or larger seaweeds, and is used by the poor in Scotland and Ireland as a relish with their food. It is commonly dried and eaten raw, the flavour being brought out by long chewing. In the Mediterranean it is used cooked in ragouts and made dishes.

DULUTH, a city of Minnesota, U.S.A., on the western tip of Lake Superior, at the mouth of the St. Louis river, opposite Superior, Wis.; the county seat of St. Louis county. It is on federal highways 2, 53 and 61; and is served by the Chicago, St. Paul, Minneapolis and Omaha, the Duluth, Missabe and Iron Range, the Duluth, South Shore and Atlantic, the Great Northern, the Northern Pacific. the Soo Line, the Chicago, Milwaukee, St. Paul and Pacific and the Duluth, Winnipeg & Pacific railways, and by an air line and many lake steamers. The population was 101,463 in 1930, of whom 24,929 were foreign-born white and was 101,065 in 1940 by the federal census. The city has a beautiful site (62.3 sq.mi. land area) on slopes rising to 600 ft. above the



BY COURTESY OF THE OFFICE OF THE CHIEF OF ENGINEERS, DULUTH

A VIEW OF DULUTH HARBOUR BASIN SHOWING COAL DOCKS AND ELEVATORS

level of the lake, commanding fine views of harbour, lake, river and surrounding country. A 25-mi. boulevard runs along the top of the bluff back of the city, and there are 3,216 ac. in public parks. The Duluth-Superior harbour, with 49 mi. of water frontage, formed by long narrow strips of land projecting from either shore (Minnesota point and Wisconsin point), is one of the finest in the world, and it ranks second only to New York, among American ports, in the commercial tonnage handled. It is well equipped with modern machinery for transferring cargoes, and had (1941) 21 coal docks, 7 iron ore docks, 46 wharves for general freight, 25 grain elevators and a cement storage elevator with a capacity of 114,000 barrels. Its commerce in 1940 was 54,147,695 tons (valued at $407,484,967), consisting largely of iron ore from the Vermilion, Cuyuna and Mesabi ranges, wheat and other grains from the Red river valley and the plains of Canada, butter and eggs from adjacent territory, automobiles and coal from Lake Erie ports. Among the manufacturing industries, which are increasing in importance, the largest are the great mills of the American Steel and Wire company. established there in 1909. The aggregate factory output in 1937 was valued at $46,020,607. The assessed valuation of property in 1940 was $48,791,248, and bank clearings amounted to $170,548,380. Since 1912 a commission form of government has been in effect. A zoning ordinance was adopted in 1925, and the city's development is under the supervision of a planning commission. The recreation system includes provision for flying, skiing, curling and iceboating, as well as for the more usual sports. The charitable agencies are financed through a joint community chest. There are three daily papers, including one in Finnish. In the city are 43 public and 15 parochial schools, a junior college and the College of St. Scholastica, an extension department of the University of Minnesota and a state teachers' college (established in 1902). The federal government maintains a coast guard station on Minnesota point, a fish hatchery at Lester river and a weather bureau station in the city.

The first visitor on record to the site of Duluth was Daniel Greysolon, Sieur du Lhut (d. 1709), a French trader and explorer, who about 1679 built a stockaded trading post at the mouth of Pigeon river on the north shore of the lake. About 1752 a second trading post, which later became a depot of Astor's American Fur company, was established in the vicinity. Permanent settlement on the site of the city began in 1853. In 1870, when the city was incorporated and the first railway reached it, the population was 3,131, and in 1880 it was only 3,483. Between 1880 and 1890, with the development of railways, of commerce on Lake Superior and of the iron mines of northern Minnesota, the population increased nearly tenfold, to 33,115. The traffic of the port increased from 2,848,672 tons in 1890 to 46,875,416 tons in 1913, fluctuated considerably during the World War and the years immediately following, and reached its maximum (to 1940) in 1929, when the commerce was 60,385,767 tons.

Because of its cool climate and scenic and recreational advantages, Duluth is a popular vacation playground. According to U.S. weather bureau records it is coolest summer city in the U.S., with an average spring and summer temperature of 62 5°. Its freedom from noxious pollen attracts many hay-fever sufferers. Duluth is the gateway to the Superior national forest (largest in the U.S., with more than 3,000,000 ac. within its boundaries).

DULWICH, a county and parliamentary division in the metropolitan borough of Camberwell, London, England, with stations at East, North and West Dulwich on the Southern railway. Pop. (1931) 60,643. It comprises the southern end of the borough from Denmark Hill and Peckham to upper Sydenham and the Crystal Palace. West Dulwich, in which the College is situated, with its wooded lanes descending from the Sydenham hill, still retains much of its rural character. The manor, which had belonged to the Cluniac monks of Bermondsey, passed through various hands to Edward Alleyn (*q.v.*) in 1606. His foundation of the College of God's Gift, commonly called Dulwich College, was opened with great state on Sept. 13, 1619, in the presence of Lord Chancellor Bacon, Inigo Jones and other distinguished men. According to the letters patent the almspeople and scholars were to be chosen from the parishes of St. Giles, St. Botolph without Bishopsgate, and St. Saviour's (Southwark). By a series of statutes signed in 1626, Alleyn ordained that his school should consist of three distinct classes:—(1) twelve poor scholars; (2) children of inhabitants of Dulwich, who were to be taught freely; and (3) "towne or foreign schollers." The almspeople consisted of six "poor brethren" and six "poor sisters," and the head of the teaching and governing staff was to consist of a master and a warden, who were always to be of the founder's surname.

The founder's intention to establish a great public school, with provision for university training, is shown by the statutes; but for more than two centuries the educational benefits were restricted to the twelve poor scholars. In 1857 and 1882, however, the foundation was entirely reconstituted. It now comprises two schools, called respectively Dulwich College and Alleyn's school. The former is one of the important English public schools; the buildings (1866–70) by Charles Barry contain a fine hall. The college possesses one of the leading private picture galleries in the country, the bequest mainly of Sir P. F. Bourgeois, R.A., in 1811, with later additions and a separate endowment. The Dutch and Flemish schools in particular are well represented, together with some fine examples of the Spanish, French and British. Dulwich park (72 ac.) was presented to the public in 1890.

DUMA, an old Russian word meaning thought; in connection with the adjective *Gosudarstvennaya* (of Empire) was the name of the first Russian House of Representatives, granted by Nicholas II. (Oct. 30, 1905), and after the amendment of the electoral law (Dec. 24, 1905), formally sanctioned on March 5, 1906. Electors were distributed in six "curias": large landed proprietors, small landed proprietors, peasants, capitalists, middle class, working men. Direct voting was admitted only in six large cities. The remaining population elected electors who in their turn elected the electors to upper local units, from which the electors were finally sent to provincial assemblies to elect members of the Duma. Thus peasants elected in four stages (village, township, district, province); small landowners in three (preparatory, district, province) as well as working men (factory, district, province); big land-owners, rich citizens and middle class citizens in two (district, province). The number of electors given to various constituencies varied in opposite proportion to the number of population, thus giving enormous preponderance to the upper classes. Landed gentry (about 200,000) had the right to choose 2,594 electors; wealthy citizens (500,000) 788, middle class (8,000,000) 590, working men (12,000,000) 112, peasants (70,000,000) 1,168. The Duma had the power to legislate, to vote the Budget and to control the administration. But its rights were extremely curtailed by the tsar's prerogative, through indiscriminate use of Orders in Council, to thwart regular legislation, by withdrawing from its competence a great part of Budget expenses, by the lack of responsibility of ministers and, last, not least, by an extremely conservative Upper House (the Council of Empire) composed half of old dignitaries nominated by the tsar and half of elected members from gentry, church, commerce, and learned bodies.

The first two Dumas were dissolved after 73 and 103 days of existence. The third Duma, elected after a change of electoral law, lasted for the full five years of its mandate (1907–12), and the fourth (1912–17) was nearing its end when the March revolution hcgan.

See also RUSSIA; *History* and P. *N.* Milyoukov's article on "The Representative System in Russia" in *"Russian Realities and Problenzs,"* ed. *J.* D. Duff (1917). (P. M.)

DUMAGUETE, a municipality (with administrative centre and 23 *barrios* or districts) and capital of the province of Negros Oriental, of the island of Negros, Philippine islands, on Tañon strait, 424 mi. from Manila. Pop. (1939), 22,236, of whom 67 were whites. It is the centre of a fertile agricultural region which supports a flourishing trade. Silliman Institute, a Presbyterian school, founded early in the century, has done excellent work in educating the natives. Of those aged 6 to 19, inclusive, 42.2% were reported in 1939 as attending school and of. those ten years old and over 53·7% were reported as literate. The vernacular is a dialect of Bisayan. There is also a meteorological station. The number of parcels of land declared for taxation in 1938 was 8,172 and the number of owners 6,117.

DUMANJUG, a municipality (with administrative centre and 32 *barrios* or districts), of the province and island of Cebu, Philippine islands, on the west coast, at the mouth of the Dumanjug river, about 40 mi. S.W. of Cebu, the provincial capital. Pop. (1939), 20,973, of whom two were white. Communication with Sibonga, a municipality situated on the opposite shore of the island is accomplished through one of the few passes of the mountains in the interior. Corn and sugar are grown in the neighbouring region and there is an important coastwise trade. There is little industry, aside from agriculture. Cebuano is the vernacular.

DUMAS, ALEXANDRE (ALEXANDRE DAVY DE LA PAILLETERIE) (1802–1870), French novelist and dramatist, was born at Villers-Cotterets (Aisne) on July 24, 1802. His father, General Dumas (Alexandre Davy de la Pailleterie) was born in San Domingo, the natural son of Antoine Alexandre Davy, marquis de la Pailleterie. by a negress, Marie Cessette Dumas, who died in 1772. In 1780 he accompanied the marquis to France, and there the father made a mésalliance which drove the son into enlisting in a dragoon regiment The young Alexandre Dumas was still a private at the outbreak of the revolution, but he rose rapidly and became general of division in 1793. He was general-in-chief of the army of the western Pyrenees, and was transferred later to commands in the Alps and in La Vendée. Among his many exploits was the defeat of the Austrians at the bridge of Clausen on April 22, 1797, where he commanded Joubert's cavalry. He lost Napoleon's favour by plain speaking in the Egyptian campaign, and later returned to France to spend the rest of his days in retirement at Villers-Cotterets, where he had married in 1792 Marie Elisabeth Labouret.

The novelist, who was the offspring of this union, was not four years old when General Dumas died (1806), leaving his family with no further resource than 30 acres of land. Mme. Dumas tried to obtain help from Napoleon, but in vain, and lived with her parents in narrow circumstances. Alexandre received the rudiments of education from a priest, and entered the office of a local solicitor. His chief friend was Adolphe de Leuven, the son of an exiled Swedish nobleman implicated in the assassination of Gustavus III. of Sweden, and the two collaborated in various vaudevilles and other pieces which never saw the footlights. Leuven returned to Paris, and Dumas was sent to the office of a solicitor at Crépy. In 1823 Dumas visited his friend in Paris, and was received by Talma. He then determined to seek his fortune in Paris. An introduction to General Foy procured for him a place as clerk in the service of the duke of Orleans, and he began to collaborate with Leuven in the production of vaudevilles and melodramas. Madame Dumas presently joined her son in Paris, where she died in 1838. Soon after his arrival in Paris Dumas

had entered on a liaison with a dressmaker; Marie Catherine Labay, and their son, the famous Alexandre Dumas *fils (see* below). was born in 1824. Dumas acknowledged his son in 1831, and obtained the custody of him after a lawsuit with the mother.

AS DRAMATIST AND NOVELIST

His Plays.—The first piece by Dumas and Leuven to see the footlights was *La Chasse et l'amour* (Ambigu-Comique, Sept 22, 1825), and in this they had help from other writers. Dumas had a share in another vaudeville, *La Noce et l'enterrement* (Porte Saint-Martin, Nov. 21, 1826). It was under the influence of the Shakespeare plays produced in Paris by Charles Kemble, Harriet Smithson (afterwards Mme. Berlioz) and an English company that the romantic drama of *Christine* was written. The subject was suggested by a bas-relief of the murder of Monaldeschi exhibited at the Salon of 1827. The piece was accepted by the Comédie Française, but its production was deferred Meanwhile Dumas had written, in prose, *Henri III. et sa cour,* which was immediately accepted by the Comédie Française and produced on Feb. 11, 1829. It was the first great triumph of the romantic drama. The brilliant stagecraft of the piece and its admirable historical setting delighted an audience accustomed to the decadent classical tragedy, and brought him the friendship of Hugo and Vigny. His patron, the duke of Orleans, now gave him the librarianship of the Palais Royal. *Christine* was recast as a romantic trilogy in verse in five acts with a prologue and epilogue, with the sub-title of *Stockholm, Fontainebleau, Rome,* and was produced by Harel at the Odéon in March 1830.

The revolution of 1830 temporarily diverted Dumas from letters. The account of his exploits should be read in his *Mémoires,* where the incidents lose nothing in the telling. He finally alienated himself from the Orleans Government by being implicated in the disturbances which attended the funeral of General Lamarque in June 1832, and he received a hint that his absence from France was desirable. A tour in Switzerland undertaken on this account furnished material for the first of a long series of amusing books of travel. Dumas remained, however, on friendly and even affectionate terms with the young duke of Orleans until his death in 1842. Meanwhile he had produced *Napoléon Bonaparte* (Odéon, Jan. 10, 1831), his unwillingness to make a hero of the man who had slighted his father having been overcome by Harel, who put him under lock and key until the piece was finished His next play, *Antony,* hsd a real importance in the history of the romantic theatre It was put in rehearsal by Mlle. Mars, but so unsatisfactorily that Dumas transferred it to Bocage and Mme Dorval, who played it magnificently at the Porte Saint-Martin theatre on May 3, 1831. The Byronic hero Antony was a portrait of himself in his relations with Mélanie Waldor, except of course in the extravagantly melodramatic *dénouement,* when Antony, to save his mistress's honour, kills her and exclaims, "Elle me résistait, je l'ai assassinée." He produced more than 20 more plays alone or in collaboration before 1845, exclusive of dramatizations from his novels. *Richard Darlington* (Porte Saint-Martin, Dec. 10, 1831), the first idea of which was drawn from Sir Walter Scott's *Chronicles of the Canongate,* owed part of its great success to the admirable acting of Frédérick Lemaître. *La Tour de Nesle* (Porte Saint-Martin, May 29, 1832), announced as by MM. × × × and Gaillardet, was the occasion of a duel and a law-suit with the original author, Frédéric Gaillardet, whose ms. had been revised, first by Jules Janin and then by Dumas In rapidity of movement, and in the terror it inspired, the piece surpassed *Henri III.* and *Antony* A lighter drama, *Mademoiselle de Belle-Isle* (Théâtre Français, April 2, 1839), long held the stage.

In 1840 Dumas married Ida Ferrier, an actress whom he had imposed on the theatres that took his pieces. The amiable relations which had subsisted between them for eight years were disturbed by the marriage, which is said to have been undertaken in consequence of a strong hint from the duke of Orleans, and Mme. Dumas lived in Italy separated from her husband

His Novels.—As a novelist Dumas began by writing short stories, but his happy collaboration with Auguste Maquet, which began in 1839, led to the admirable series of historical novels in which he proposed to reconstruct the whole course of French history. In 1844 he produced, with Maquet's help, that most famous of "cloak and sword" romances, *Les Trois Mousquetaires* (8 vols.), the material for which was discovered in the *Me'nzoires de M. d'Artagnan* (Cologne, 1701–02) of Courtils de Sandras. The adventures of d'Artagnan and the three musketeers, the gigantic Porthos, the clever Aramis, and the melancholy Athos, who unite to defend the honour of Anne of Austria against Richelieu and the machinations of "Milady," are brought down to the murder of Buckingham in 1628. Their admirers were gratified by two sequels, *Vingt ans après* (10 vols., 1845) and *Dix ans plus tard, ou le vicomte de Bragelonne* (26 pts., 1848–50), which opens in 1660, showing us a mature d'Artagnan, a respectable captain of musketeers, and contains the magnificent account of the heroic death of Porthos. The three musketeers are as famous in England as in France. Thackeray could read about Athos from sunrise to sunset with the utmost contentment of mind, and R. L. Stevenson and Andrew Lang have paid tribute to the band in *Memories and Portraits* and *Letters to Dead Authors.* Before 1844 was out Dumas had completed a second great romance in 12 volumes, *Le Comte de Monte-Cristo,* in which he had help from Fiorentino as well as from Maquet. The idea of the intrigue was suggested by Peuchet's *Police de'voile'e,* and the stress laid on the earlier incidents, Dantès, Danglars and the Château d'If, is said to have been an afterthought. Almost as famous as these two romances is the set of Valois novels of which Henri IV. is the central figure, beginning with *La Reine Margot* (6 vols., 1845), which contains the history of the struggle between Catherine of Medicis and Henry of Navarre; the history of the reign of Henry III. is told in *La Dame de Monsoreau* (8 vols., 1846), generally known in English as *Chicot the Jester,* from its principal character; and in *Les Quarante-cinq* (10 vols., 1847–@), in which Diane de Monsoreau avenges herself on the duke of Anjou for the death of her former lover, Bussy d'Amboise.

Much has been written about the exact share which Dumas had in the novels which bear his name. The Dumas-Maquet series is undoubtedly the best, but Maquet alone never accomplished anything to approach them in value. The mss. of the novels still exist in Dumas's handwriting, and the best of them bear the unmistakable stamp of his unrivalled skill as a narrator. The chief key to his enormous output is to be found in his untiring industry and amazing fertility of invention, not in the system of wholesale collaboration which was exposed with much exaggeration by Quérard in his *Supercheries littéraires* and by "Eugène de Mirecourt" (C. B. J. Jacquot) in his misleading *Fabrique de romans, maison Alexandre Dumas et c^ie* (1845). His assistants, in fact, supplied him with outlines of romances on plans drawn up by himself, and he then rewrote the whole thing. That this method was never abused it would be impossible to say; *Les Deux Diane,* for instance, a prelude to the Valois novels, is said to have been written entirely by Paul Meurice, although Dumas's name appears on the title-page.

LATER YEARS

The latter part of Dumas's life is a record of excessive toil to meet prodigal expenditure and accumulated debts. His disasters began with the building of a house in the Renaissance style, with a Gothic pavilion and an "English" park, at Saint Germain-en-Laye. This place, called Monte-Cristo, was governed by a crowd of hangers-on of both sexes, who absorbed Dumas's large earnings and left him penniless. Dumas also founded the Théâtre Historique chiefly for the performance of his own works. The enterprise was under the patronage of the duc de Montpensier, and was under the management of Hippolyte Hostein, who had been the secretary of the Comédie Française. The theatre was opened in Feb. 1847 with a dramatic version of *La Reine Margot.* Meanwhile Dumas had been the guest of the duc de Montpensier at Madrid, and made a quasi-official tour to Algeria and Tunis in a Government vessel, which caused much comment in the press. Dumas had never changed his republican opinions. He greeted the revolution of 1848 with delight, and was even a candi-

date for electoral honours in the department of the Yonne. But the change was fatal to his theatrical enterprise, for the failure of which in 1850 he was made financially responsible. His son, Alexandre Dumas, was at that time living with his mother Mlle. Labay, who was eventually reconciled with the elder Dumas. Father and son, though always on affectionate terms when they met, were too different in their ideas to see much of one another. After the *coup d'état* of 1851 Dumas crossed the frontier to Brussels, and two years of rapid production, and the economy of his secretary, Noel Parfait, restored something like order to his affairs. On his return to Paris in the end of *1853* he established a daily paper, *Le Mousquetaire,* for the criticism of art and letters. It was chiefly written by Dumas, whose *Mémoires* first appeared in it, and survived until *1857,* when it was succeeded by a weekly paper, the *Monte-Cristo (1857–60).* In *1858* Dumas travelled through Russia to the Caucasus, and in *1860* he joined Garibaldi in Sicily. After an expedition to Marseilles in search of arms for the insurgents, he returned to Naples, where Caribaldi nominated him keeper of the museums. After four years' residence in Naples he returned to Paris, and after the war of *'66* he visited the battlefields and produced his story of *La Terreur prussienne.* But his powers were beginning to fail, and in spite of the 1,200 volumes which he told Napoleon he had written, he was at the mercy of his creditors, and of the succession of theatrical ladies who tyrannized over him and feared nothing except the occasional visits of Dumas fils. He was finally rescued from these by his daughter, Mme. Petel, who came to live with him in *1868;* and two years later, on Dec. 5, *1870,* he died in his son's house at Puys, near Dieppe.

Auguste Maquet was Dumas's chief collaborator. Others were Paul Lacroix (the bibliophile "P. L. Jacob"), Paul Bocage, J. P. Mallefille and P. A. Fiorentino. The novels of Dumas may be conveniently arranged in a historical sequence. The Valois novels and the musqueteers series brought French history down to *1672.* Contributions to later history are:—La *Dame de volupte' (2* vols., 1864), being the memoirs of Mme. de Luynes, and its sequel *Les Deux Reines (2* vols., *1864);* *La Tulipe noire (3* vols., 1850), giving the history of the brothers de Witt; *Le Chevalier d'Harmental (4* vols., 1853), and *Une Fille du régent (4* vols., 1845), the story of two plots against the regent, the duke of Orleans; two books on Mme. du Deffand, *Mémoires d'une aveugle (8* vols., 1856–57) and *Les Confessions de la marquise (8* vols., 1857), both of doubtful authorship; *Olympe de Clkves* (9 vols., 1852), the story of an actress and a young Jesuit novice in the reign of Louis XV., one of his most popular novels; five books on the beginning of the Revolution down to the execution of Marie Antoinette: the *Me'moires d'un médecin,* including *Joseph Balsamo* (19 pts., 1846–48), in which J. J. Rousseau, Mme. du Barry and the dauphiness Marie Antoinette figure, with its sequels; *Le Collier de la reine* (9 vols., 1849–50), in which Balsamo appears under the alias of Cagliostro; *Ange Pitou (8* vols., 1852), known in English as "The Taking of the Bastille"; *La Comtesse de Charny* (19 vols., 1853–55), describing the attempts to save the monarchy and the flight to Varennes; and *Le Chevalier de maison rouge (6* vols., 1846), which opens in 1793 with the hero's attempt to save the queen. Among the numerous novels dealing with the later revolutionary period are:—*Les Blancs et les bleus (3* vols., *1868)* and *Les Compagnons de Jéhu* (7 vols., *1857). Les Louves de Machecoul* (10 vols., 1859) deals with the rising in *1832* in La Vendée. Other famous stories are:—Les *Frères corses (2* vols., *1845);* *La Femme au collier de velours (2* vols., 1851); *Les Mohicans de Paris* (19 vols., 1854–55), detective stories with which may be classed the series of *Crimes célèbres* (8 vols., 1839–41), which are, however, of doubtful authorship; *La San Félice* (9 vols., 1864–65), in which Lady Hamilton played a prominent part, with its sequels *Emma Lyonna* and *Souvenirs d'une favorite.* Of his numerous historical works other than fiction the most important is his *Louis* XIV. *et son siècle (4* vols., 1845). *Mes Me'moires* (20 vols., 1852–54; Eng. trans. of selections by A. F. Davidson, *2* vols., 1891) is an account of his father and of his own life down to *1832.* There are collective editions of his plays (6 vols., 1834–36, and 15 vols, 1863–74), but of the 91 pieces for which he was wholly or partially responsible, *24* do not appear in these collections.

The complete works of Dumas were issued by Michel Lévy *frères* in 277 vols. (1860–84). The more important novels have been frequently translated into English. There is a long list of writings on his life and his works both in English and French. The more important French authorities are: his own memoirs, already cited; C. Glinel, *Alexandre Dumas et son oeuvre* (Reims, *1884);* H. Parigot, *Dumas père* (Grands écrivains français series, 1902), and *Le Drame d'Alexandre Dumas (1899);* *H.* Blaze de Bury, *Alexandre Dumas* (1885); Philibert Andebrand, *Alexandre Dumas à la maison d'or (1888);* G. Ferry, *Dernières Années d'Alexandre Dumas (1883);* and L. H. Lecomte, *Alexandre Dumas* (1904). Of the English lives of Dumas perhaps the best is that by Arthur F. Davidson, *Alexandre Dumas Père his Life and Works* (1902, bibl.). *See* the lives by P. Fitzgerald (1873) and H. *A.* Spurr (1902), and essays by Andrew Lang *(Letters to Dead Authors)* and *R. L.* Stevenson *(Memories and Portraits). See* also Herbert Gorman, *The Incredible Marquis, Alexandre Dumas (1929).*

DUMAS, ALEXANDRE ("DUMAS **FILS**") (1824–1895), French dramatist and novelist, was born in Paris on July *27,* 1824, the natural son of Alexandre Dumas *(see* above) and the dressmaker Marie Labay. "Happily," writes the son, "my mother was a good woman, and worked hard to bring me up"; while of his father he says, "by a most lucky chance he happened to be well-natured," and "as soon as his first successes as a dramatist" enabled him to do so, "recognized me and gave me his name." Nevertheless, the lad's earlier school-life was made bitter by his illegitimacy. The cruel taunts and malevolence of his companions rankled through life *(see* preface to *La Femme de Claude* and *L'Affaire Clémenceau*), and left indelible marks on his character and thoughts. Nor was his paternity, however distinguished, without peril. Alexandre the younger and elder saw life together very thoroughly, and Paris can have had few mysteries for them. Suddenly the son, who had been led to regard his prodigal father's resources as inexhaustible, was rudely undeceived. Coffers were empty, and he had accumulated debts to the amount of £2,000.

Thereupon he pulled himself together. To a son of Dumas the use of the pen came naturally. Like most clever young writers—and report speaks of him as specially brilliant at that time—he opened with a book of verse, *Péchés de jeunesse (1847).* It was succeeded in *1848* by a novel, *La Dame aux camélias,* a sort of reflection of the world in which he had been living. The book was followed, in fairly quick succession, by *Le Roman d'une femme (1848)* and *Diane de Lys (1851).* All this, however, did not deliver him from the load of debt, which, as he tells us, remained odious. In 1849 he dramatized *La Dame aux came'lias,* but the rigour of the censorship and other circumstances delayed its production until Feb. *2,* 1852, when Napoleon's all-powerful minister, Morny, intervened. The play succeeded then, and has held the stage ever since, less perhaps from inherent superiority to other plays which have foundered than to the great opportunities it affords to any actress of genius.

Thenceforward Dumas's career was that of a brilliant and prosperous dramatist. *Diane de Lys* (1853), *Le Demi-Monde* (1855), *La Question d'argent* (1857), *Le Fils naturel* (1858), *Le Pbre prodigue* (1859) followed rapidly. Debts became a thing of the past, and Dumas a wealthy man. The didactic habit was always strong upon him. "Alexandre loves preaching overmuch," wrote his father; and in most of his plays he assumes the attitude of a rigid and uncompromising moralist commissioned to impart to a heedless world lessons of deep import. The lessons themselves are mostly concerned with the "eternal feminine," by which Dumas was haunted, and differ in ethical value. Thus in *Les Idées de Madame Aubray (1867)* he inculcates the duty of the seducer to marry the woman he has seduced; but in *La Femme de Claude (1873)* he argues the right of the husband to take the law into his own hand and kill the wife who is unfaithful and worthless—a thesis again defended in his novel, *L'Affaire Cle'menceau,* and in his pamphlet, *L'Homme-femme;* while in *Diane de Lys* he had taught that the betrayed husband was entitled to kill—not in a duel, but summarily—the man who had taken his honour; and in *L'Etrangère (1876)* the bad husband is the victim. Nor did he preach only in his plays. He preached in voluminous introductions, and pamphlets not a few And when, in 1870 and *1872,*

France was going through bitter hours of humiliation, he called her to repentance and amendments in a *Nouvelle Lettre de Junius* and two *Lettres sur les choses du jour*.

As a moralist Dumas *fils* took himself very seriously indeed. As a dramatist, didacticism apart, he had great gifts. He knew his business thoroughly, possessed the art of situation, interest, crisis—could create characters that were real and alive. His dialogue also is admirable, the repartee rapier-like, the wit most keen. He was singularly happy, too, in his dramatic interpreters. The cast of *L'Etrangère,* for instance, comprised Sarah Bernhardt, Sophie Croizette, Madeleine Brohan, in the female characters; and Coquelin, Got, Mounet-Sully and Fbbvre in the male characters; and Aimée Desclée, whom he discovered, gave her genius to the creation of the parts of the heroine in *Une Visite* de *noces,* the *Princesse Georges* and *La Femme de Claude*. He possessed wit in abundance, of a singularly trenchant kind. It shows itself less in his novels, which, however do not contain his best work; but in his introductions, whether to his own books or those of his friends, and what may be called his "occasional" writings, there is an admirable brightness. His style is that of the best French traditions. Towards his father Dumas acted a kind of brother's part, and while keeping free from his literary influence, both loved and admired him. The father never belonged to the French Academy. The son was elected on Jan. 30, 1874. He died on Nov. 27, 1895.

Petit de Julleville's *Histoire de la langue et de la littérature française,* viii. pp. 82 *et seq.;* R. Doumic, *Portraits d'écrivains* (1892), Emile Zola, *Documents littéraires, ttudes et portraits* (1881). (F. T. M.)

DUMAS, GUILLAUME MATHIEU, COUNT (1753–1837), French general, was born at Montpellier on Nov. 23, 1753, and entered the army in 1773. He served in America and elsewhere almost continuously up to the outbreak of the Revolution. During the Revolution he acted with the moderate party, and, though he was president of the Legislative Assembly in 1791, spent most of his time abroad until the consulate. Under Napoleon he served at Austerlitz, and then with Joseph Bonaparte in Naples and Spain. He was made a count of the empire in 1810. In 1812 he was intendant-general of the Grande Armée in Russia, but was taken prisoner after the capitulation of Dresden in 1813. At the first restoration he assisted in army administration, but joined Napoleon during the Hundred Days, when he organized the National Guard. He employed his enforced retirement after the second restoration in writing his *Précis des évènements militaires* (19 vols,, 1817–26), the first part of which had appeared anonymously at Hamburg in 1800. The *Précis* embraces the history of the war from 1798 to the peace of 1807. A growing weakness of sight, ending in blindness, prevented him from carrying the work further, but he translated Napier's *Peninsular War* as a sort of continuation to it. In 1818 Dumas was admitted a member of the council of state, from which, however, he was excluded in 1822. After the revolution of 1830, in which he took an active part, Dumas was created a peer of France, and re-entered the council of state. He died in Paris on Oct. 16, 1837.

Besides the *Prtcis des évènements militaires,* which forms a valuable source for the history of the period, Dumas wrote *Souvenirs du lieut.-général Comte Mathieu Dumas* (published posthumously by his son, 1839).

DUMAS, JEAN BAPTISTE ANDRE (1800–1884), French chemist, was born at Alais (Gard) on July 15, 1800. He was apprenticed to an apothecary in his native town. In 1816 he moved to Geneva. There he attended the lectures of Pictet, de la Rive and A. P. de Candolle, and before he was 21 he was engaged with Dr. J. L. Prévost in original work on problems of physiological chemistry, and even of embryology. In 1823 A. von Humboldt induced him to go to Paris, which he made his home for the rest of his life. He became a member of the National Legislative Assembly in 1849; he acted as minister of agriculture and commerce for a few months in 1850–51, and subsequently became a senator, president of the municipal council of Paris and master of the French mint; but his official career came to a sudden end with the fall of the Second Empire. He died at Cannes on April 11, 1884.

Dumas is one of the greatest figures in the chemical history of the middle part of the 19th century. He was one of the first to criticize the electro-chemical doctrines of J. J. Berzelius, which at the time his work began were widely accepted as the true theory of the constitution of compound bodies, and opposed a unitary view to the dualistic conception of the Swedish chemist. In a paper on the atomic theory (1826) he anticipated ideas which are frequently supposed to belong to a later period; and the continuation of these studies led him to the ideas about substitution ("metalepsis") which were developed about 1839 into the theory ("Older Type Theory") that in organic chemistry there are certain types which remain unchanged even when their hydrogen is replaced by an equivalent quantity of a haloid element. Many of his researches were carried out in support of these views, one of the most important being that on the action of chlorine on acetic acid to form trichloracetic acid—a derivative of essentially the same character as the acetic acid itself. 'In the 1836 paper he described his method for ascertaining vapour densities, and the redeterminations which he undertook by its aid of the atomic weights of carbon and oxygen proved the forerunners of a long series which included some 30 of the elements, the results being mostly published in 1858–60. He devised a method of great value in the quantitative analysis of organic substances for the estimation of nitrogen, while the classification of organic compounds into homologous series was advanced as one consequence of his researches into the acids generated by the oxidation of the alcohols.

Dumas was a prolific writer, and his numerous books, essays, memorial addresses, etc., are written in a clear and graceful style. His earliest large work was a treatise (8 vols., 1828–48) on applied chemistry. In the *Essai de statique chimique des êtres organisés* (1841), written jointly with J. B. J. D. Boussingault (1802–87), he treated the chemistry of life, both plant and animal; this book brought him into conflict with Liebig, who conceived that some of his prior work had been appropriated without due acknowledgment. In 1824, in conjunction with J. V. Audouin and A. T. Brongniart, he founded the *Annales des sciences naturelles,* and from 1840 he was one of the editors of the *Annales de chimie et de physique.* As a teacher Dumas was the first French chemist to adopt the practical laboratory teaching instituted at Giessen by Liebig. We used this method at the École Polytechnique and afterwards in his own laboratory. A member of the Académie des Sciences from 1832, he became its perpetual secretary in 1868, and was elected to the French Academy in 1875 to the chair left vacant by the death of Guizot.

DU MAURIER, GEORGE LOUIS PALMELLA BUSSON (1834–1896), British artist and writer, was born in Paris. His father, a naturalized British subject, was the son of *émigrés* who had left France during the Reign of Terror and settled in London. In *Peter Ibbetson,* the first of the three books which won George Du Maurier late in life a reputation as novelist almost as great as he had enjoyed as artist and humorist for more than a generation, the author tells in the form of fiction the story of his singularly happy childhood which was mostly spent at Passy. After some years at a Paris school, he left (in 1851) to study chemistry at University College, London, actually setting up as an analytical chemist afterwards in Bucklersbury. But this was clearly not to be his *métier,* and the year 1856 found him once more in Paris, in the Quartier Latin this time, in the core of that art-world of which in *Trilby,* 40 years later, he was to produce with pen and pencil so idealistic and fascinating a picture. Then (like Barty Josselin in *The Martian,* his third novel) he spent some years in Belgium and the Netherlands, experiencing at Antwerp in 1857, when he was working in the studio of van Lerius, the one great misfortune of his life—the gradual loss of sight in his left eye, accompanied by alarming symptoms in his right. It was a period of tragic anxiety, but the cloud was soon to show its silver lining, for, about Christmas-time 1858, there came to the forlorn invalid a copy of *Punch's Almanac,* and with it the dawn of a new era in his career.

There can be little doubt that the study of this *Almanac,* and especially of Leech's drawings in it, fired him with the ambition

of making his name as a graphic humorist; and it was not long after his return to London in 1860 that he sent in his first contribution (very much in Leech's manner) to *Punch*. Mark Lemon, then editor, appreciated his talent, and on Leech's death in 186j appointed him his successor, counselling him with wise discrimination not to try to be "too funny," but "to undertake the light and graceful business" and be the "romantic tenor" in Mr. Punch's little company, while Keene, as Du Maurier puts it, "with his magnificent highly-trained basso, sang the comic songs." These respective rôles the two artists continued to play until the end, and Du Maurier himself in his book on Social Pictorial Satire has set forth their points both of resemblance and of difference. Besides working for *Punch* he illustrated several books, including his own novels, and from time to time he sent pretty and graceful pictures to the exhibitions of the Royal Society of Painters in Water-Colour, to which he was elected in 1881. In 1885 the first exhibition of his works at the Fine Art Society took place. He died on October 8, 1896, and was buried in the Hampstead parish churchyard. He left a family of two sons—the elder, Major Guy Du Maurier (1865–1915), a soldier who became more widely known in 1909 as author of the military play An Englishman's *Home*, and the second, Gerald (later, Sir), a well-known actor—and three daughters.

See *Thomas Armstrong, C.B.; a Memoir* (1912), and *T.* Martin Wood, *George Du Maurier* (1913). Other volumes containing information about Du Maurier's life and work are: M. H. Spielmann, *The History of Punch;* Felix Moscheles, *In Bohemia with Du Maurier;* *Century Magazine* (1883); *Harper's Magazine* (Sept. 1897, June 1899). *See* also Ruskin, *Art of England*, Lecture 5, Pennell, *Pen Drawing and Pen-Draughtsmen*, and Muther, *Modern Painting.* (F. W. W.)

DUMBARTON, royal, municipal and police burgh, seaport, and county town, Dumbartonshire, Scotland, on the river Leven, near its confluence with the Clyde, 15½ m. W. by N. of Glasgow by the L.N.E.R. and L.M.S.R. Pop. (1931) 21,546. The Alcluith ("hill of the Clyde") of the Britons, and Dumbreatan ("fort of the Britons") of the Celts, it was the capital of the district of Strathclyde. Here the Romans had a naval station called Theodosia. The history of the town, however, practically centres in that of the successive fortresses on the Rock of Dumbarton, a twin-peaked hill, 240 ft. high and a mile in circumference at the base. The Picts seized it in 736, the Northmen in 870, and Thomas Crawford of Jordanhill on March 31, 1571, in the interests of James VI. The castle has been held by Queen Mary's adherents, and gave them free communication with France. William Wallace was in 1305 imprisoned in the castle before he was removed to London. The higher of the two peaks is known as Wallace's seat, a tower being named after him. On the portcullis gateway are rudely carved heads of Wallace and his betrayer. Queen Mary, when a child, resided in the castle for a short time. The rock is basalt, with a tendency to columnar formation.

Dumbarton was of old the capital of the earldom of Lennox, but was given up by Earl Maldwyn to Alexander II., by whom it was made a royal burgh in 1221 and declared to be free from all imposts and burgh taxes. Later sovereigns gave it other privileges, and all were finally confirmed by a charter of James VI. It had the right to levy customs and dues on all vessels on the Clyde between Loch Long and the Kelvin. "Offers dues" on foreign ships entering the Clyde were also exacted. In 1700 these rights were transferred to Glasgow by contract, but were afterwards vested in a special trust created by acts of parliament.

Most of the town lies on the left bank of the Leven, but there is communication with the suburb of Bridgend on the right bank by a five-arched stone bridge. Dumbarton is controlled by provost and council. It unites with Clydebank in returning one member to parliament. The principal industry is shipbuilding. The old staple trade of the making of crown glass, begun in 1777, lapsed some 70 years afterwards when the glass duty was abolished. There are several great engineering works, besides iron foundries, breweries, and rope-yards. There are quays, docks and a harbour at the mouth of the Leven, and a pier for river steamers runs out from the Castle rock, but is now disused. The first steam navigation company was established in Dumbarton in 1815, when the "Duke of Wellington" (built in the town) plied between Dumbarton and Glasgow. But it was not till 1844, consequent on the use of iron for vessels, that shipbuilding became the leading industry.

DUMBARTONSHIRE, western county, Scotland, bounded north by Perthshire, east by Stirlingshire, south-east by Lanarkshire, south by the Clyde and its estuary, and west by Loch Long and Argyllshire. The detached parish of Kirkintilloch and part of that of Cumbernauld are enclosed between the shires of Stirling and Lanark. This formerly formed part of Stirlingshire, but was annexed in the 14th century when the earl of Wigtown, to whom it belonged, became heritable sheriff of Dumbartonshire. Dumbartonshire has an area (excluding water) of 156,927 acres. The north-west and west are mountainous, the highest point exceeding 3,200 feet. This is a district composed of rocks belonging to the metamorphic series of the Highlands, into which, in the north of the county, there is a large plutonic intrusion. In the south of the county are the Kilpatrick Hills (1,300 ft.), a system of lavas, tuffs and agglomerates intercalated in the Calciferous Sandstone series. Sandstones of various ages occupy most of the rest of the county, but the Carboniferous limestone follows them in some parts, and, notably in the detached portion of the county, includes important coal-measures. The boulder clay of the Carboniferous lowland is full of schistose boulders brought by glacial action from areas far to the north-west. The Clyde, the Kelvin and the Leven are the only rivers of importance. The Leven flows out of Loch Lomond at Balloch and joins the Clyde at Dumbarton after a serpentine course of about 7 miles. Most of the other streams are among the mountains, whence they find their way to Loch Lomond, and nearly all afford good fishing. Of the inland lakes by far the largest is Loch Lomond (*q.v.*). The boundary between the shires of Dumbarton and Stirling runs through the lake from the mouth of Endrick Water to a point opposite the Isle of Vow, giving about two-thirds of the loch to the former county. Loch Sloy on the side of Ben Vorlich is a long, narrow lake, 812 ft. above the sea amid wild scenery. From its name the Macfarlanes took their slogan or war-cry. The shores of the Gareloch, a salt-water inlet 6½ m. long and 1 m. wide, are studded with houses of those whose business lies in Glasgow. Garelochhead, and Cove and Kilcreggan at the entrance to Loch Long, are favourite summer resorts. The more important salt-water inlet, Loch Long, is 17 m. in length and varies in width from 2 m. at its mouth to about ½ m. in its upper reach. It is a dumping-place for the dredgers which are constantly at work preserving the tide-way of the Clyde from Dumbarton to Broomielaw. The scenery on both shores is very beautiful. Only a mile separates Garelochhead from Loch Long, and at Arrochar the distance from Tarbet on Loch Lomond is barely 1¾ miles. Nearly all the glens are situated in the Highland part of the shire, the principal being Glen Sloy, Glen Douglas, Glen Luss and Glen Fruin. The last is memorable as the scene of the conflict in 1603 between the Macgregors and the Colquhouns, in which the latter were almost exterminated. It was this encounter that led to the proscription of the Macgregors, including Rob Roy.

History.—Prehistoric peoples have left rude forts and tumuli, and there are several remains of the wall of Antoninus, built from Forth to Clyde, and running along the north of the detached portion of the shire and through the south-eastern corner of the county to Kilpatrick. Other Roman relics have been found at Duntocher, Cumbernauld and elsewhere. The shire forms part of the old Scottish territory of Lennox (*Levenachs*, "fields of the Leven"), which embraced the Vale of the Leven and the basin of Loch Lomond, or all modern Dumbartonshire, most of Stirling and parts of the shires of Renfrew and Perth. It gave the title of the earldom created in 1174 by William the Lion and of the dukedom conferred by Charles II. on his natural son, Charles, duke of Richmond and Lennox. Robert Bruce is said to have mustered his forces at Dullatur prior to the battle of Bannockburn, and died at Cardross Castle in 1329. The Covenanters in their flight from the field of Kilsyth, where in 1645 Montrose had defeated them, made their way through the southern districts. The clans of Macgregor and Macfarlane made their home in the Highland fastness and raided their Lowland neighbours.

Agriculture, Industries and Communications.—The arable

lands extend chiefly along the Clyde and the Leven, and are composed of rich black loam, gravelly soil and clay. The farmers have markets on the Clyde for all kinds of stock and produce, and high farming and dairying prosper. Black-faced sheep and Highland cattle are pastured on the hilly lands and Cheviots and Ayrshires on the low grounds. Oats are the principal cereal, but wheat. potatoes and turnips are also grown.

Turkey-red dyeing has long been a distinctive industry. The water of the Leven being singularly soft and pure, dyers and bleachers have constructed works at many places. Bleaching has been carried on since the early part of the 18th century, and cotton-printing at Levenfield dates from 1768. There are large establishments at Alexandria, Bonhill, Jamestown, Renton and other towns for bleaching, dyeing and printing of cottons, calicoes and other cloths, besides yarns. The engineering works and shipbuilding yards at Clydebank are famous, and at Dumbarton there are others. The Vale of Leven and the riverside towns east of Dumbarton make a busy industrial district. Coal and fireclay are worked, and sandstone and igneous rocks are quarried in the detached portion at Kirkintilloch and Cumbernauld. There is some fishing at Helensburgh and along the Gareloch.

The populous districts of the county are served by the L.N.E.R. From Helensburgh to Inverarnan the West Highland line runs through beautiful scenery. The L.M S.R. has access to Balloch from Glasgow, and traverses the detached portion. Portions of the Forth and Clyde Canal, connecting with the Clyde at Bowling, and opened for traffic in 1775, pass through the shire. There is regular steamer communication between Glasgow and the towns and villages on the coast.

Population and Government. — The population of Dumbartonshire in 1921 was 150,868, and in 1931, 147,751, of whom 1,866 spoke both Gaelic and English. The principal towns, with populations in 1931, are—Bonhill (15,565), Clydebank (46,963), Dumbarton (21,546), Helensburgh (8,893), Kirkintilloch (11,-817), Milngavie (5,056). The county returns one member to parliament, and Dumbarton, the county town and the only royal burgh, one member with Clydebank. Dumbartonshire forms a sheriffdom with the counties of Stirling and Clackmannan, and there is a resident sheriff-substitute at Helensburgh, who sits also at Dumbarton and Kirkintilloch.

DUMB WAITER, originally a small oblong or circular table to hold reserve plates, knives and forks, and other necessaries for a meal. It came into use in England towards the end of the 18th century, and some exceedingly elegant examples were designed by Sheraton and his school. They were usually circular, with three 'diminishing tiers, sometimes surrounded by a continuous or interrupted pierced gallery in wood or brass. The smaller varieties are now much used in England for the display of small silver objects in drawing-rooms.

The term has more recently been extended to mean the small elevator used to convey household commodities from one floor to another in modern apartments. It is a box-like structure, about 2 feet square, built within the walls, and run with a rope and pulley.

DUM-DUM, a town and cantonment in British India, in the district of the Twenty-four Parganas, 4-j m. N.E. of Calcutta. The name is derived from *dam dama,* meaning a raised mound, a battery. Dum-Dum was the headquarters of the Bengal artillery from 1783 to 1853. when they were transferred to Meerut. It contains an army rifle and ammunition factory. The town is divided between two municipalities, North Dum-Dum (pop. 9,885) and South Dum-Dum (pop. **18,471).** It was at Dum-Dum that Siraj-ud-daula signed the treaty of 1757 with Clive.

At the Dum-Dum foundry the hollow-nosed "Dum-Dum" (Mark IV.) bullets were manufactured, the supposed use of which by the British during the Boer War caused considerable comment in 1899. Their peculiarity consisted in their expanding on impact and thus creating an ugly wound, and they had been adopted in Indian frontier fighting owing to the failure of the usual type of bullets to stop the rushes of fanatical tribesmen. They were not, in fact, used during the Boer War. Other and improvised forms of expanding bullet were used in India and the Sudan, the commonest methods of securing expansion being to file down the point until the lead core was exposed and to make longitudinal slits in the nickel envelope. All these forms of bullet have come to be described colloquially, and even in diplomatic correspondence as "dum-dum bullets," and their alleged use by Russian troops in the Russo-Japanese War of 1904–1905 formed the subject of a protest on the part of the Japanese government. An International declaration was made at the second Hague Conference, July 29, 1899, forbidding the use of these bullets. The United States did not participate in this declaration. During the World War actual charges were made by the belligerents of the use of illegal bullets, but there was no evidence forthcoming that such use (if any) was authorized by any power.

DUMESNIL, MARIE FRANÇOISE (1713–1803), French actress, whose real name was Marchand, was born in Paris on Jan. 2, 1713, made her *début* in 1737 at the Comkdie Française as Clytemnestre in *Iphigénie en Tauride.* She played Cléopâtre, Phèdre, Athalie and Hermione with great effect, and when she created Mérope (1743) Voltaire says that she kept the audience in tears for three successive acts. She retired in 1776 and died on Feb. 20, 1803. She authorized the publication of a *Mémoire de Marie Françoise Dumesnil,* in reply to an attack by her rival, Clairon (1800)

DUMFRIES, royal burgh, parish and county town, Dumfriesshire, Scotland (Gaelic, "the fort in the copse"). It lies on the left bank of the Nith, about 8 m. from the Solway Firth and 82 m. S.E. of Glasgow by the L.M.S.R., and is a junction for several lines. Pop. (1931) 22,795. Dumfries is a fine town, beautifully situated. St. Michael's (1746) was the church which Robert Burns attended, and in its churchyard he was buried, his remains being transferred in 1815 to the magnificent mausoleum erected in the south-east corner. The schools include an important academy. In the middle of the market-place stands the old town hall, with red tower and cupola, known from its situation as the Mid Steeple. It was built by Tobias Bachup of Alloa (1708), and is now occupied by shops. The Theatre Royal, reconstructed in 1876, dates from 1787. Burns composed several prologues and epilogues for some of its actors and actresses. The Nith is crossed by three bridges and the railway viaduct. The bridge used for vehicular traffic dates from 1790–1794. Devorguilla's bridge below it, built of stone in 1280, originally consisted of nine arches (now reduced to three), and is reserved in spite of its massive appearance for foot passengers only, as is also the suspension bridge opened in 1875.

Maxwelltown, on the opposite side of the river, is practically part of Dumfries, but is a separate burgh in Kirkcudbrightshire.

The leading industries comprise manufactures of tweeds, hosiery, clogs, aerated water, gloves and various foodstuffs, besides the timber trade, nursery gardening, electrical and motor engineering, and the making of implements. Dumfries markets for horses, cattle and sheep have always ranked with the best, and there is also a market for pork during the five months beginning with November. The Nith is navigable at Dumfries for vessels drawing 8 ft., but the sea-borne trade is small.

Although Dumfries was the site of a camp of the Selgovian Britons, nothing is known of its early history. William the Lion (d. 1214) made it a royal burgh, but the oldest existing charter was granted by Robert II in 1395. The town became embroiled in the struggles that ended in the independence of Scotland. It favoured the claims to the throne, first of John Baliol—whose mother Devorguilla, daughter of Alan, lord of Galloway, had done much to promote its prosperity by building the stone bridge over the Nith—and then of the Red Comyn, as against those of Robert Bruce, who drew his support from Annandale. Until nearly the close of the 16th century the burgh was exposed to frequent raids, both from freebooters on the English side and from partisans of the Douglases, Maxwells and Johnstones. James VI. was royally entertained on Aug 3, 1617, and afterwards presented the seven incorporated trades with a silver gun to encourage craftsmen in the practice of musketry. A competition for this gun, which is now kept in the old town hall, took place annually—with a great festival every seven years—until 1831. John Mayne (1759–1836), a native of Dumfries, commemorated

the gathering in a humorous poem, "The Siller Gun." The Union with England was so unpopular that not only did the provost vote against the measure in the Scottish parliament, but the articles were burned (Nov. 20, 1706) at the Market Cross by a body of Cameronians. In both 1715 and 1745 Dumfries remained apathetic. Burns, the poet, resided here from December 1791 till his death on the 21st of July 1796. The house in which he died is still standing.

The picturesque ruins of Carlaverock Castle, which is claimed to be the "Ellangowan" of Guy *Mannering,* are 8 m. to the south. Part of the present structure is believed to date from 1220 and once sheltered William Wallace. It withstood Edward I.'s siege in 1300 for two days, although garrisoned by only sixty men. Subsequently it often changed hands. In 1570 it fell into disrepair, but was restored, and in 1641 was besieged for the last time by the Covenanters. A mile and a half to the north-west of Dumfries lies Lincluden Abbey, "an old ruin," says Burns, "in a sweet situation at the confluence of the Cluden and the Nith." Originally the abbey was a convent, founded in the 12th century, but converted two centuries later into a collegiate church by Archibald, earl of Douglas. The remains of the choir and south transept disclose rich Decorated work.

DUMFRIESSHIRE, border county, Scotland, bounded south by Solway Firth, south-east by Cumberland, east by Roxburghshire, north by the shires of Lanark, Peebles and Selkirk, and west by Ayrshire and Kirkcudbrightshire. Area (excluding water) 686,302 acres. The county slopes gradually from uplands of 2,700 ft. in the north down to the sea, lofty hills alternating in places with stretches of tableland or rich fertile holms. The greater part belongs to the tableland of Silurian rock in southern Scotland, which is bordered in the north-west and south of the county by old red sandstones, and broken at many points by intensive igneous rocks. Strata of Carboniferous age (among others) occur in hollows of the tableland. and at Sanquhar and Rowanburn include coal-measures, which have been worked but are no longer rich. At various points within a few miles of the Solway are tracts of moss land, like Craigs Moss, Lochar Moss and Longbridge Moor in the west, and Nutberry Moss in the east, all once under water, but now largely reclaimed. The county is cleft from north to south by Nithsdale, Annandale and Eskdale. The Nith (65 m.) enters the shire 16 m. from its source and flows south-east to the Solway. The Annan rises near the Devil's Beef Tub, a remarkable chasm in the far north, and flows south for about 40 m. to the Solway. From the confluence of the White Esk (rising near Ettrick Pen) and the Black Esk (rising near Jock's Shoulder, 1,754 ft.) the Esk flows south-east to the border, and south-west in Cumberland to the Solway. For 1 m. of its course the Esk, and for 7 m. of its course the Sark, form the boundaries between Dumfriesshire and Cumberland. Loch Skene in the north (1,750 ft. above sea), the group of lochs around Lochmaben, and Loch Urr in the west, are the principal lakes. The wild and beautiful passes of Dalveen, Enterkin and Menock, lead up from Nithsdale to the Lowther and other hills. For part of the way Enterkin pass runs between mountains rising sheer from the burn to a height of nearly 2,000 feet. Loch Skene finds an outlet in Tail burn, the water of which at a short distance from the lake leaps from a height of 200 ft. in a fine waterfall, known as the Grey Mare's Tail. A much smaller but picturesque fall of the same name, also known as Crichope linn, occurs on the Crichope, near Thornhill. Mineral waters are found at Moffat, Hartfell Spa, some three miles farther north, and Closeburn on the Solway.

History. — The early populations have left hill forts in the north, stone circles (as in Dunscore and Eskdalemuir), camps (Dryfesdale), tumuli and cairns (Closeburn), and sculptured stones (Dornock). The country around Moffat especially is rich in remains. At Holywood, near Dumfries, there stands the relic of the grove of sacred oaks from which the place derived its name, and a stone circle known locally as the Twelve Apostles. The British inhabitants were called Selgovae by the Romans. In the parish church of Ruthwell (prov. Rivvel: the "rood, or cross, well") is preserved an ancient cross which tells in Runic characters the story of the Crucifixion. There are traces of Roman roads which ran by Dalveen pass into Clydesdale and up the Annan to Tweeddale, and at Birrens is a well preserved Roman camp. Roman altars, pottery and coins have been found in many places. Upon the withdrawal of the Romans, the Selgovae were conquered by Scots from Ireland. The Saxon conquest of Dumfriesshire does not seem to have been thorough, the people of Nithsdale and elsewhere maintaining their Celtic institutions up to the time of David I.

Edward I. besieged Carlaverock castle, and the factions of Bruce (who was lord of Annandale), John Comyn and John Baliol were at constant feud. The Border clans were always at strife until the 18th century. The hill country afforded retreat to persecuted Covenanters, who, at Sanquhar, published in 1680, their declaration against the king, anticipating the principles of the "glorious Revolution" by several years. The Jacobite sentiment made little appeal to the people.

Robert Burns farmed at Ellisland on the Nith for three years, and spent the last five years of his life at Dumfries. Thomas Carlyle was born at Ecclefechan, in a house still standing, and was buried beside his parents in the kirkyard.

Agriculture, Industries and Communications. — Towards the middle of the 18th century farmers began to raise stock for the south, and 100 years later 20,000 head of heavy cattle, formerly Galloways, later mostly shorthorns and Ayrshires, were sent annually to the English markets. Sheep breeding, of later origin, has attained to large dimensions, the walks in the higher hilly country being given over to Cheviots, and the richer pasture of the low-lying farms being reserved for half-bred lambs, a cross of Cheviots and Leicesters or other long-woolled rams. Horse-breeding is pursued on a considerable scale, Oats are the principal crop. Sheep, cattle, pigs, grain, wool, hides and skins are exported. Some lead ore is mined, and limestone and sandstone are quarried. In general, the manufactures are only of local importance, the chief being the woollen and hosiery industries of Dumfries and Langholm. There are distilleries at Langholm and Annan; dyeing and tanning works at Langholm. Nursery gardening and some shipping are carried on at Annan and Dumfries; and the salmon fisheries of the Nith and Annan and the Solway Firth are of value.

Of the two main lines of the L.M.S.R. between Glasgow and Carlisle, one (the former Glasgow and South Western), runs through Nithsdale, practically following the course of the river, and lower Annandale to the Border. The other (the former Caledonian railway) runs through Annandale, throwing off at Beattock a branch to Moffat, at Lockerbie a cross-country line to Dumfries, and at Kirtlebridge a line to Annan. From Dumfries westwards there is communication with Castle Douglas, Kirkcudbright. Newton Stewart, Stranraer and Portpatrick. The L.N.E.R. sends a short line to Langholm from Riddings Junction in Cumberland, giving access to Carlisle and, by the Waverley route, to Edinburgh.

Population and Government. — The population in 1931 was 81.060. The chief towns are Annan (pop. in 1931, 3,959), Dumfries (22,795), Langholm (2,448), Lockerbie (2,574) and Moffat (2,006). The county returns one member to parliament. Dumfries, the county town, Annan, Lochmaben and Sanquhar are royal burghs; Dumfries forms a sheriffdom with the shires of Kirkcudbright and Wigtown, and there is a resident sheriff-substitute at Dumfries. Secondary education has been notably directed by public authorities toward carrying on science and technical classes, embracing agriculture and dairying (at Kilmarnock dairy school). There are academies at Dumfries, Annan, Moffat and other centres.

DÜMICHEN, JOHANNES (1833–1894), German Egyptologist, was born near Grossglogau. He studied philology and theology in Berlin and Breslau, and in 1872 became professor of Egyptology at Strasbourg. In 1875–76 he directed the excavation of the temple at Dendera.

Among his works are *Bauurkunde des Tempels von Dendera* (1865); *Geographische Inschriften altagyptischer Denkmäler* (4 vols., 1865–1885); *Altägyptische Kalenderinschriften* (1866); *Altägypt. Tempelinschriften* (2 vols., 1867); *Historische Inschriften altagypt.,*

Denkmäler (6 vols., 1867–1869); *Baugeschichte und Beschreibung des Denderatempels* (Strassburg, 1877); *Die Oasen der libyschen Wüste* (1878); *Die kalendarischen Opferfestlisten von Medinet-Habu* (1881); *Gesch. des alten Aegypten* (1878–1883); *Der Grabpalast des Patuamenap in der thebanischen Nekropolis* (1884–1894).

DUMKA (pl. Dumky), a Little Russian term signifying a lament and employed frequently by Dvořák in his chamber works to designate movements of a melancholy, mournful character. The English word "dump," signifying a melancholy mood, and also a doleful ditty, is possibly akin. *Cf.* also Ger. *dumpf*, meaning dull, flat, dead.

DÜMMLER, ERNST LUDWIG (1830–1902), German historian, the son of Ferdinand Diimmler (1777–1846), a Berlin bookseller, was born in Berlin, on Jan. 2, 1830. He studied at Bonn under J. W. Löbell (1786–1863), under L. von Ranke and W. Wattenbach. He entered the faculty at Halle in 1855, became professor extraordinary (1858), and full professor (1866). In 1875 he became a member of the revised committee directing the *Monumenta Germaniae historica*, himself undertaking the direction of the section *Antiquitates*, and in 1888 became president of the central board in Berlin. His great work was the *Gesclzichte des ostfränkischen Reiches* (1862–65, in 2 vols.; 2nd ed. 1887–88, in 3 vols.). In conjunction with Wattenbach he completed the *Monumenta Alcuiniana* (1873), which had been begun by Philipp Jaffé, and with R. Köpke he wrote *Kaiser Otto der Grosse* (Leipzig, 1876). He edited the first and second volumes of the *Poetae latini aevi Carolini* for the *Monumenta Germaniae historica* (1881–84). Diimmler died in Berlin on Sept. 11, 1902.

DUMMY, in advertising and printing, a material representation or full-sized complete physical model showing the general appearance of a proposed folder, pamphlet, or other piece of printing. It is used as a guide both in sketching in the details of the various pages and in assisting the printer to follow instructions as to how the work is to appear when finished.

DUMONT, the name of a family of prominent French artists. François Dumont (1688–1726), a sculptor, best known for his figures in the church of Saint Sulpice, Paris, was the brother of the painter Jacques Dumont, known as "le Romain" (1701–1781), whose chief success was gained with a great allegorical composition for the Paris *Hôtel de Ville* in 1761. François' son Edme (1720–1775), the latter's son Jacques Edme (1761–1844), and the son of the last named, Augustin Alexander (1801–1884), were also famous sculptors. A contemporary, Jean Joseph Dumons (1687–1779), sometimes called Dumont, is best known for his designs for the Aubusson tapestries.

See G. Vattier, *Une Famille d'artistes* (1890).

DUMONT, ANDRE HUBERT (1809–1857), Belgian geologist, was born at LiCge on Feb. 1j, 1809. He was professor of mineralogy and geology and afterwards rector in the university of LiCge. He spent 20 years on the preparation of a geological map of Belgium (1849), and then collected materials for a geological map of Europe. The Geological Society of London awarded him the Wollaston medal in 1840, and he died at LiCge on Feb. 28, 1857.

See Memoir by Major-General J. E. Portlock in *Address* to *Geol. Soc.* (1858).

DUMONT, FRANÇOIS (1751–1831), French miniature painter, was born at Lunéville (Meurthe), studied for a time under Jean Girardet, and in 1788 was accepted as an academician and granted an apartment in the Louvre. He married the daughter of Antoine Vestier, the miniature painter, and had two sons, Aristide and Bias, both of whom became painters. He was one of the three greatest miniature painters of France, painting portraits of Louis XVI. and Marie Antoinette, Louis XVIII. and Charles X., and of almost all the important persons of his day. His own portrait was engraved both by Audouin and by Tardieu. He spent the greater part of his life in Paris, and there he died. A younger brother, known as Tony Dumont, was also a miniature painter, a pupil of his brother, a frequent exhibitor and the recipient of a medal from the Academy in 1810. Each artist signed with the surname only, and there is some controversy concerning the attribution to each of his own canvases. Many of Dumont's finest paintings came into the collection of J. Pierpont Morgan, but others are in the Louvre, presented by the heir of Bias Dumont.

See G. C. Williamson, *The History of Portrait Miniatures* (1904); also the privately printed *Catalogue of the Collection of Miniatures of Mr. J. Pierpont Morgan*, vol. iv.

DUMONT, JEAN (d. 1726), French publicist, became historiographer to the emperor, who conferred on him the title of baron de Carlscroon. He died at Vienna in 1726, at an advanced age.

Among his publications are:—*Mémoires politiques pour servir à la parfaite intelligence de l'histoire de la Paix de Ryswick (The* Hague, 1699, 4 vols. 12mo.); *Recherches modcstes des causes de la présente guerre, en ce qui concerne les Provinces Unies* (1713, 12mo); *Recueil de traite's . . . depuis la Paix de Munster* (Amsterdam, 1710, 2 vols. 12mo); *Corps universe1 diplomatique du droit des gens, contenant un recueil des traite's de paix, d'alliance*, etc., *faits en Europe, depuis Charlemagne jusqu'à présent* (Amsterdam, 1626, and following years, 8 vols. fol., continued after Dumont's death by J. Rousset), and *Batailles gagnées par le Prince Eugène de Savoie* (The Hague, 1723). Dumont was also the author of *Lettres historiques conteaant ce qui se passe de plus important en Europe* (12mo). This periodical, which was commenced in 1692, two volumes appearing annually, Dumont conducted till 1710, from which time it was continued by Basnage and others until 1728. The earlier volumes are much prized.

DUMONT, PIERRE ÉTIENNE LOUIS (1759–1829), French political writer, was born at Geneva where his family had been citizens of good repute from the days of Calvin. He was educated for the ministry at the college of Geneva, and in 1781 was chosen one of the pastors of the city. The triumph of the aristocratic party in 1782, however, through the interference of the courts of France and Sardinia, made residence in his native town impossible, though he was not among the number of the proscribed. He therefore went to join his mother and sisters at St. Petersburg (Leningrad). In 1785 Lord Shelburne took him to London as tutor to his sons. There he met Fox, Sheridan, Lord Holland and Sir S. Romilly.

In 1788 Dumont visited Paris with Romilly. During a stay of two months in that city he met Mirabeau with whom he became intimate. On his return from Paris Dumont made the acquaintance of Jeremy Bentham, and set himself to recast and edit the writings of the great English jurist in a form suitable for the ordinary reading public. This literary relationship was, according to Dumont's own account, one of a somewhat peculiar character. All the fundamental ideas and most of the illustrative material were supplied in the manuscripts of Bentham; Dumont's task was chiefly to abridge by striking out repeated matter, to supply *lacunae*, to secure uniformity of style, and to improve the French. The following works of Bentham were published under his editorship: *Traité de législation civile et pénale* (1802), *Théorie des peines et des récompenses* (1811), *Tactique des assemblées législatives* (1815), *Traitd des preuves judiciaires* (1823), and *De l'organization judiciaire et de la codification* (1828).

In the summer of 1789 Dumont went to Paris. He contributed to Mirabeau's journal, the *Courier de Provence*, supplying it with reports as well as original articles, and also furnishing Mirabeau with speeches to be delivered or rather read in the assembly, as related in his posthumous work entitled *Souvenirs sur Mirabeau* (1832).

In 1814 the restoration of Geneva to independence induced Dumont to return to his native place, and he soon became the leader of the supreme council. Many improvements in the judicial and penal systems of his native state are due to him.

See A. P. de Candolle, *Notice sur* la *vie et les kcrits de M. Dumont* (1829).

DUMONT D'URVILLE, JULES SEBASTIEN CÉSAR (1790–1842), French navigator, was born at Condé-sur-Noireau, in Normandy. He went to sea in 1807 as a *novice* on board the "Aquilon." During the next 12 years he gradually rose in the service, and added a knowledge of botany, entomology, English, German, Spanish, Italian and even Hebrew and Greek to the professional branches of his studies. In 1820, while engaged in a hydrographic survey of the Mediterranean, he was fortunate enough to recognize the Venus of Milo (hfelos) in a Greek statue recently unearthed, and to secure its preservation by the report he

presented to the French ambassador at Constantinople. In 1822 he served in the circumnavigating expedition of the "Coquille" under the command of his friend Duperrey; and on its return in 1825 he was promoted *capitaine de frégate,* and given the command of a similar enterprise, with the purpose of discovering traces of the lost explorer, La Pérouse, in which he was successful. The "Astrolabe," as he renamed the "Coquille," left Toulon on April 25, 1826, and returned to Marseille on March 25, 1829, having traversed the south Atlantic, coasted the Australian continent from King George's sound to Port Jackson, charted various parts of New Zealand, and visited the Fiji islands, the Loyalty islands, New Caledonia, New Guinea, Amboyna, Van Diemen's Land, the Caroline islands, Celebes and Mauritius. Promotion to the rank of *capitaine de vaisseau* was bestowed on the commander in Aug. 1829; and in August of the following year he conveyed the exiled king Charles X. to England. On Sept. 7, 1837, he set sail from Toulon with the "Astrolabe" and its convoy "La Zélée" on a voyage of exploration in the South Polar regions. On Jan 1j, 1838, they sighted the Antarctic ice, and soon after their progress southward was blocked by a continuous bank, which they vainly coasted for 300m. to the east. Returning westward they visited the South Orkney islands and part of the New Shetlands, and discovered Joinville island and Louis Philippe Land, but were compelled by scurvy to seek succour at Talcahuano in Chile. Thence they proceeded across the Pacific and through the Asiatic archipelago, visiting among others the Fiji and the Pelew islands, coasting New Guinea, and circumnavigating Borneo. In 1840, leaving their sick at Hobart Town, Tasmania, they returned to the Antarctic region, and subsequently discovered Adélie Land, which D'Urville named after his wife, in 140° E. Nov. 6 found them at Toulon. On May 8, 1842, D'Urville was killed, with his wife and son, in a railway accident near Meudon. An island (also called Kairu) off the north coast of New Guinea and a cape on the same coast bear his name.

His principal works *are:—Enzcnreratio plantarum quas in insulis Archipelagi aut littoribus Ponti Euxini,* etc. **(1822);** *Voyage de la corvette "l'Astrolabe," 1826–1829* (1830–35), and *Voyage au pôle sud et dans l'Océanie, 1837–1840* (1842–54), in each of which his scientific colleagues had a share; *Voyages autour du monde; résumé général des voyages de Magellan,* etc. **(1833** and **1844).**

DUMORTIERITE, a mineral first recorded from pegmatite in gneiss at Chaponost, near Lyons, France, and named after E. Dumortier, a French palaeontologist. It is essentially a basic aluminium borosilicate, most reliable analyses conforming to the formula $8Al_2O_3{\cdot}6SiO_2{\cdot}B_2O_3{\cdot}H_2O$. Crystallizing in the rhombic system, it occurs usually in fibrous or columnar aggregates of blue, lavender or almost black colour. These commonly observed colours are due to the oxides of iron and titanium always present in small amounts. The mineral is strongly pleochroic in blue and violet tints. On heating to 800° C the colour rapidly disappears. At higher temperatures B_2O_3 is volatilized and decomposition occurs with formation of mullite ($3Al_2O_3{\cdot}2SiO_2$), liquid appearing first at a temperature of 1,550°C.

On account of its high alumina content dumortierite possesses considerable advantages as a basis for refractory bodies. Dumortierite occurs as a rare constituent of pegmatites and gneisses. The best known locality is at Clip, Ariz., where it is found as dense fibres embedded in quartz. Among European localities its presence in pegmatite at Ellon (Scotland), in cordierite-gneiss at Tvedestrand (Norway), with corundum in pegmatite at Wolfshan (Silesia) may be mentioned. In company with lazulite and kyanite it occurs in quartzites at Chari (French Central Africa) and Svarina (Madagascar). (C. E. T.)

DUMOULIN, CHARLES (Molinaeus) (1500–1566), French jurist, was born in Paris in 1500. He began practice as an advocate before the parlement of Paris. Dumoulin turned Calvinist, and when the persecution of the Protestants began he went to Germany, where for a long time he taught law at Strasbourg, Besançon and elsewhere. He returned to France in 1557. Dumoulin had, in 1552, written *Commentaire sur l'édit du roi Henri II. sur les petites dates,* which was condemned by the Sorbonne, but his *Conseil sur le fait du concile de Trente* created *a* still greater stir, and aroused against him both the Catholics and the Calvinists. He was imprisoned by order of the parlement until 1564. Dumoulin was regarded by his contemporaries as the "prince of jurisconsults." He had a considerable effect on the subsequent development of French law. He was a bitter enemy of feudalism, which he attacked in his *De feudis* (Paris, 1539). Other important works were his coininentaries on the customs of Paris (Paris, 1539, 1554; Frankfort, 1575; Lausanne, 1576). valuable as the only commentary on those in force in 1510, and the *Extricatio labyrinthi dividui et individui,* a treatise on the law of surety.

A collected edition of Dumoulin's works was published in Paris in 1681, with *a* life by Brodeau. *See* also H. de Pansey, *Eloge de* **C.** *Dumoulin* **(1769);** Hello, *Essai sur la vie et les Ouvrages de C. Dumoulin* **(1839).**

DUMOURIEZ, CHARLES FRANÇOIS DU PÉRIER (1739–1823), French general, born at Cambrai on Jan. 25, 1739, saw his first service as a volunteer in the campaign of Rossbach. He was retired at the peace of 1763, but was subsequently employed in Corsica. Under Choiseul he was in the secret service, and on his patron's fall was imprisoned, being only released on the accession of Louis XVI. in 1774. Dumouriez was commandant of Cherbourg for ten years, and in 1788 became *maréchal de camp.* At the outbreak of the Revolution he went to Paris, where he joined the Jacobin Club. The death of Mirabeau, to whose fortunes he had attached himself, was a great blow to him; but, promoted to the rank of lieut.-general and commandant of Nantes, his opportunity came after the flight to Varennes, when he offered to march to the assistance of the Assembly. He now joined the Girondist party, and on March 15, 1792, was appointed minister of foreign affairs. He was mainly responsible for the declaration of war against Austria (April 20), and the invasion of the Low Countries was planned by him. On the dismissal of Roland, Clavière and Servan (June 13), he took the latter's post of minister of war, but resigned it two days later on account of the king's refusal to come to terms with the Assembly, and went to join the army of Marshal Liickner. After the *émeute* of August 10 and Lafayette's flight he was appointed to the command of the "Army of the Centre," and at the same moment the Coalition assumed the offensive. Dumouriez acted promptly. His subordinate Kellermann repulsed the Prussians at Valmy (Sept. 20, 1792), and he himself severely defeated the Austrians at Jemappes (Nov. 6).

Defeated at Neerwinden in Mar. 1793, he ventured all on a desperate stroke. Arresting the commissaries of the Convention sent to inquire into his conduct, he handed them over to the enemy, and then attempted to persuade his troops to march on Paris and overthrow the revolutionary government. The attempt failed, and Dumouriez with the duc de Chartres (afterwards King Louis Philippe) and his brother the duc de Montpensier, fled into the Austrian camp.

In 1804 he settled in England, where the government conferred on him a pension of £1200 a year. He became a valuable adviser to the War Office in connection with the struggle with Napoleon, though the extent to which this went was only known to the public many years later. He died at Turville Park, near Henley-on-Thames, on March 14, 1823. His memoirs were published at Hamburg in 1794. An enlarged edition, *La Vie et les mémoires du Général Dumouriez,* appeared at Paris in 1823.

See A. von Boguslawski, *Das Leben des Generals Dumouriez* (1878–**79);** *Revue des deux mondes* (July 15, Aug. 1 and 15, **1884);** **H.** Welschinger, *Le Roman de Dumouriez* (1890); A. Chuquet, *La Première Invasion, Valmy, La Retraite de Brunrwick, Jemappes, La Trahison de Dumouriez* (1886–91); A. Sorel, *L'Europe et la Révolution française* (1885–92); *J.* Holland Rose and A. M. Broadley, *Dumouriez and the Defence of England* (1908); *E.* Daudet, *La Conjuration de Pichegru et les complots royalistes du midi et du l'est, 1795–1797* **(1901);** Pouget de Saint-André, in his *Le Général Dumouriez* (1914) contends that Dumouriez has been misjudged.

DUMP. (1) (Of obscure origin), a state of wonder, perplexity or melancholy. The word thus occurs particularly in the plural, in such phrases as "doleful dumps." It was also formerly used for a tune, especially one of a mournful kind. (2) (Connected with "dumpy," but appearing later than that word, and also of obscure origin), something short and thick, and hence used of nrany objects such as a lead counter or medal, of a coin formerly used in

Australia, formed by punching a circular piece out of a Spanish dollar, and of a short, thick bolt used in shipbuilding. (3) (Probably of Norse origin, cf. Nor. *dumpa*, meaning "to fall" suddenly, with a bump), to throw down in a heap, and hence particularly applied to the depositing of any large quantity of material, to the shooting of rubbish, or tilting a load from a cart. It is thus used of the method of disposal of the masses of gravel, etc., disintegrated by water in the hydraulic method of gold mining. A "dump" or "dumping-ground" is thus the place where such waste material is deposited.

Dump was used for an ammunition depot in the World War.

DUMPING, term commonly used to describe the sale of goods for export at prices lower than those charged at the same time and under like circumstances to buyers in the country of manufacture. Anti-dumping legislation exists in the United States, Canada, Australia, New Zealand, the Union of South Africa, and Great Britain. In the United States, Australia and the Union of South Africa dumping is held to exist when the importation of the dumped goods is likely to result in injury to an industry within the territory concerned.

In Great Britain the anti-dumping duty is chargeable subject to the following conditions:

(a) That goods are being imported at a price below the cost of production. Cost of production within the meaning of the act is 95% of the wholesale price charged at the works for consumption in the country of manufacture, subject to the deduction of any excise or similar taxes;

(b) That similar goods can be profitably manufactured in the United Kingdom (not merely in Great Britain);

(c) That by importation under (a) employment in any industry in the United Kingdom is being or is likely to be seriously affected;

(d) That the affected home industry is being carried on with reasonable efficiency and economy;

(e) That the finishing industry which uses the goods in question as material is not too hard hit by a dumping duty (the Act provides that a committee shall make a special report on the subject, to be referred for "consideration" by the board of trade);

(f) That no dumping duty shall be levied which is at variance with any treaty with a foreign State.

According to a memorandum prepared by Prof. Jacob Viner for the economic and financial section of the League of Nations, "Dumping is likely to prevail as a systematic practice only if:

"(a) The exporting industry is trustified or syndicated; or

"(b) The industry, though not organized into a single unit for production or export, is dominated by one or two large concerns, each of which controls a sufficient proportion of the total output to warrant its assumption of a disproportionate part of the burden of accepting export orders at less than the prevailing domestic rates; or

"(c) The product is not standardized as between different producers, so that each producer can individualize his product by trade-mark, brand, pattern, type of container or otherwise, and so escape the full pressure of price competition; or

"(d) An export bounty is granted by some agency external to the industry, such as the State, or another industry supplying the materials which the industry under consideration works up into a more finished product."

Prof. Viner also holds that protective import duties in the exporting country facilitate dumping.

According to the final report of the Committee on Commercial and Industrial Policy After the War (cd. 9035) 1918, the recommendations of which led to the act of 1921, "the view is strongly held that the frequent dumping of any particular class of foreign goods produces a feeling of insecurity in the corresponding industry of this country which diminishes the incentive to development, and that in certain cases the dumping by foreign combinations has been the expression of a persistent policy aiming at the depression of some British industries and the prevention of the establishment of others It is, of course, impossible in every case to prove the truth of this latter suggestion; but we see no reason to doubt that there is at least a *prima facie* ground in support of it." The value of dumping to the dumping industry is held to lie in the fact that it enables it to maintain a high level of output, thus keeping works at or near full production and reducing the incidence of overhead charges. (C. TE.)

DUNAJEC-SAN, BATTLES OF THE. The Dunajec and San rivers, which, rising in the Carpathians, flow northwards across Galicia to join the Vistula on the Polish border, mark the first two stages of the great Austro-German offensive of 1915. The Russian pronunciation of the first of these rivers is Dunaietz.

Austro-German Plans.—By the end of March 191 j the Austrian armies in the Carpathians were on the verge of collapse under pressure of the persistent Russian attacks (see CARPATHIANS, BATTLES IN THE); and it became obvious to Falkenhayn, who directed German strategy, that the available reserves of Germany must be used in the East to bolster up her principal ally—using these reserves to deal Russia a blow which would paralyse her offensive power for a time at least. Reviewing the ineffective Franco-British attacks, he decided that troops could safely be withdrawn for the Russian front. He had also arrived at a just appreciation of the seriousness of Russia's shortage of reinforcements and of munitions. Russia's situation invited attack.

For such an offensive, the choice lay between enveloping operations from the flanks or a break-through attack. The poor railway communications to the Carpathians and the disorganization existing in that region as a consequence of the long winter battle excluded an operation from that flank. An enveloping movement from the northern flank—Ludendorff's favourite projcct—would be too distant to influence immediately the critical situation in the Carpathians. Accepting Conrad von Hotzendorf's suggestion, Falkenhayn determined on a break-through attack east of Cracow between the Carpathians and the upper Vistula. This point of attack appears well chosen. No great obstacle would be met till the line of the San was reached; the Vistula would afford some protection to the left flank of the advance; and a success would immediately influence the Carpathian situation. Moreover, the enemy's line on the selected front of attack was weakly held.

Disposition of Forces.—The Russian III. Army, which in January held from the Vistula-Dunajec junction to about Gorlice in the Carpathian foothills only, had extended its front during the Carpathians battle. It now reached to about Mezo Laborcz, southeast of the Dukla pass, a total front of over 100 miles. It comprised a fighting wing and a defensive wing. The left wing, which had been engaged in the last great offensive of the Carpathians battle, consisted of four corps, all somewhat exhausted. The right, the defensive wing, on which the blow was to fall, had been weakened by the withdrawal of one corps to the Bukowina and by the transfer of another corps to the left, the fighting wing; it now contained two corps only, holding a front of 50 to 60 miles. The right corps, the IX., held the lower Dunajec, from its junction with the Vistula to south of Tarnów; the other, the X., extended between Tuchów and Gorlice. These two corps had been sitting inactive opposite the Austrian IV. Army all winter; and the dispositions they had made were calculated for defence against Austrians, not Germans. Consequently there were neither sufficient rear lines nor alternative gun emplacements. The Army had only a single corps in reserve, the III. Caucasian. The Russian army commander was Radko-Dimitriev. He had some ability and was a gallant fighter, but seems to have distinguished himself more as a corps commander than as an army commander. The German XI. Army, the spear point of the offensive, consisted of eight German divisions from the western Front, two Austrian divisions" and a cavalry division. It was assembled with great secrecy behind the right of the Austrian IV. Army, opposite the Russian X. Corps. Its commander was Mackensen, who had led the Lódz offensive at the end of 1914 (see LÓDZ-CRACOW) and was to win further fame by his victories in Serbia and Rumania. The Austrian IV. Army was placed under him in addition to his own Army. He himself was subordinate to the Austrian High Command.

Mackensen's Attack.—The preliminary bombardment began on May 1 and was continued during the forenoon of the 2nd It was carried out by 1,500 guns of all calibres, and left the Russians

powerless. Mackensen's army swept over the shattered trenches of the X. Corps. meeting with little resistance, and pressed forward in the direction of Rzeszów and Jaroslaw. The Austrian IV. Army forced the Russian IX. Corps from its line on the lower Dunajec. The Austrian II. and III. Armies in the Carpathians also began a forward move. There followed five days of hard fighting, but the Russians were unable to stem the tide. Radko-Dimitriev's reserve corps attacked gallantly but fruitlessly; his left wing had to yield the Dukla pass and the hard-won gains of the April offensive. An attempt to stand on the line of the Wistok river and the Lupków pass failed before renewed Austro-German attacks on May 8. Brusilov's VIII. Army was now also involved in the retreat; and a few days later the left wing of the Russian IV. Army north of the Vistula retired from the line of the Nida.

The Russians now decided to check their foes on the strong line of the river San, with the fortress of PrzemySl to support their left centre, and the Dniester marshes to protect their left flank. Mackensenis army, however, reached Jaroslaw on May 14, stormed the bridge-head next day and established itself east of the San. It extended its gains to Sieniawa on the following days and threatened to jeopardize the whole Russian position on the San. But the impetus of the attack had spent itself for the moment and the Russians were given a breathing space. Strong reinforcements were being hurried up to them, but their losses had been enormous, over 170,000 in prisoners alone.

Further Austro-German Attacks.—The second stage of the fighting began with an attack by Mackensen's forces on May 24, which forced the line of the San at and about Radymno and thrust southeast towards the Przemyśl-Lemberg railway. The Austrians simultaneously attacked Przemyśl from the south, but made little progress. The Russians now made a counter-stroke on Sieniawa, north of Jaroslaw, with the III. Caucasian Corps. This gallant corps stormed the Austrian positions and caused a temporary set-back to Mackensen's plans. At the same time heavy attacks were made on the Austrian IV. Army further north.

But the odds against the Russians were too heavy; they had little or no ammunition for their guns and practically no heavy artillery at all. Before combined attacks of the German XI. and Austrian II. and III. Armies, PrzemySl fell on June 3; and the line here had to be withdrawn to about Gródek. The line of the lower San, north of Sieniawa, was held till June 11, when Mackensen, who had received reinforcements, attacked again and forced the whole of the San line, the Russians retiring to the last line of defence west of Lemberg. *(See* LEMBERG, BATTLES *OF.)*

By the middle of June the Russian losses in Galicia since the beginning of Mackensen's offensive included nearly 400,000 prisoners, over 300 guns and much other material. Their losses in killed and wounded had also been exceedingly heavy, for they had counter-attacked repeatedly with little artillery support. The Russians were in fact paying in flesh and blood for their lack of modern equipment. The dominance of his heavy artillery was the chief factor in Mackensen's success; the Russians had none with which to oppose it. (See WORLD WAR.)

DUNASH, the name of two Jewish scholars of the 10th century.

1. DUNASH BEN LABRAT, grammarian and poet, belonged to the brilliant circle attracted to Cordova by Hasdai, and took a large share in promoting the Jewish "Golden Age" under the Moors in Andalusia. Dunash not only helped in the foundation of a school of scientific philology, but adapted Arabian metres to Hebrew verse, and thereby gave an impulse to the neo-Hebraic poetry, which reached its highest level in Spain.

2. DUNASH IBN TAMIM was, like the preceding, a leader in the critical study of language among Arabic-speaking Jews. Professor Bacher says of him: "In the history of Hebrew philology Ibn Tamim ranks as one of the first representatives of the systematic comparison of Hebrew and Arabic."

DUNBAR, GEORGE (1774–1851), English classical scholar and lexicographer, was born at Coldingham, in Berwickshire. When about 30 years of age, he settled in Edinburgh, where he became tutor in the family of Lord Provost Fettes. In 1807 he succeeded Andrew Dalzel as professor of Greek in the university, and held the post till his death. His Greek-English and English-Greek lexicon (1840), on the compilation of which he spent eight years, was the best work of its kind that had appeared in England.

The little that is known of Dunbar's life will be found in the *Caledonian Mercury* (Dec. 8, 1851).

DUNBAR, PAUL LAURENCE (1872–1906), American author, of negro descent, was born in Dayton (O.), June 27, 1872. In high school he wrote the class poem and was editor-in-chief of the school paper. While earning his living as an elevator boy, assistant in the library of Congress, etc., he continued to write, recite, and publish his work; and after 1898, the year of his marriage, he gave his full time to writing. He died of consumption at his home in Dayton, Feb. 8, 1906. His poetry was brought to the attention of American readers by William Dean Howells, who reviewed *Majors and Minors* (1896) in *Harper's Weekly* and wrote an appreciative introduction to his *Lyrics of Lowly Life* (1896), which was subsequently used in his *Complete Poems* (1913). Dunbar published numerous volumes of verse, novels and short stories. Some of his short stories and sketches, especially those dealing with the American negro, are charming; they are far superior to his novels, which deal with scenes in which the author is not so much at home. His most enduring work, however, is his poetry. Some of this is in literary English, but the best is in the dialect of his people.

See L. K. Wiggins, *Life and Works of Paul Laurence Dunbar* (Naperville (Ill.), 1907). Tributes to him by his wife, Alice Moore Dunbar, also a writer, and by others, were reprinted from the A.M.E. *Church Review* under the title *Paul Laurence Dunbar, Poet Laureate of the Negro Race.*

DUNBAR, WILLIAM (*c.* 1460–*c.* 1520), Scottish poet. He became M.A. at St. Andrews in 1479 and afterwards joined the Order of Observantine Franciscans, at St. Andrews or Edinburgh, proceeding to France as a wandering friar. He spent a few years in Picardy, and was still abroad when, in 1491, Bothwell's mission to secure a bride for the young James IV. reached the French court. About 1500 he returned to Scotland, and became a priest at court, and a royal pensioner. His literary life begins with his attachment to James' household. He is spoken of as the rhymer of Scotland in the accounts of the English Privy Council dealing with the visit of the mission for the hand of Margaret Tudor, rather because he wrote a poem in praise of London than because, as has been stated, he held the post of laureate at the Scottish court. In 1511 he accompanied the queen to Aberdeen and commemorated her visit in verse. Other pieces, such as the *Orisoun* ("Quhen the Gouernour past in France"), apropos of the setting out of the regent Albany, are of historical interest, but they tell us little more than that Dunbar was alive.

One hundred and one poems have been ascribed to Dunbar. Of these at least 90 are generally accepted as his: of the 11 attributed to him it would be hard to say that they should not be considered authentic. Most doubt has clung to his verse tale *The Freiris of Berwik.*

Dunbar's chief allegorical poems are *The Goldyn Targe* and *The Thrissil and the Rois.* The motif of the former is the poet's futile endeavour, in a dream, to ward off the arrows of Dame Beautee by Reason's "scheld of gold." When wounded and made prisoner, he discovers the true beauty of the lady: when she leaves him, he is handed over to Heaviness. The noise of the ship's guns, as the company sails off, wakes the poet to the real pleasures of a May morning. Dunbar works on the same theme in a shorter poem, known as *Beauty and the Prisoner. The Thrissil and the Rois* is a prothalamium in honour of James IV. and Margaret Tudor, in which the heraldic allegory is based on the familiar beast-parliament.

The greater part of Dunbar's work is occasional—personal and

social satire, complaints (in the style familiar in the minor verse of Chaucer's English successors), orisons, and pieces of a humorous character. The last type shows Dunbar at his best, and points the difference between him and Chaucer. The best specimen of this work, of which the outstanding characteristics are sheer whimsicality and topsy-turvy humour, is *The Ballad of Kynd Kittok*. This strain runs throughout many of the occasional poems, and is not wanting in odd passages in Dunbar's contemporaries; and it has the additional interest of showing a direct historical relationship with the work of later Scottish poets, and chiefly with that of Robert Burns. Dunbar's satire is never the gentle funning of Chaucer: more often it becomes invective. Examples of this type are *The Satire on Edinburgh, The General Satire,* the *Epitaph on Donald Owre,* and the powerful vision of *The Dance of the Sevin Deidlie Synnis.* In the *Flyting of Dunbar and Kennedie,* an outstanding specimen of a favourite northern form, analogous to the continental *estrif,* or *tenzone,* he and his rival reach a height of scurrility which is certainly without parallel in English literature. This poem has the additional interest of showing the racial antipathy between the "Inglis"-speaking inhabitants of the Lothians and the "Scots" or Gaelic-speaking folk of the west country.

There is little in Dunbar which may be called lyrical, and little of the dramatic. His *Interlud of the Droichis (Dwarf's) part of the Play,* one of the pieces attributed to him, is supposed to be a fragment of a dramatic composition. It is more interesting as evidence of his turn for whimsicality, already referred to, and may for that reason be safely ascribed to his pen. If further selection be made from the large body of miscellaneous poems, the comic poem on the physician, Andro Kennedy, may stand out as one of the best contributions to mediaeval Goliardic literature; *The Two Mariit Wemen and the Wedo,* as one of the richest and most effective *pastiches* in the older alliterative style, then used by the Scottish Chaucerians for burlesque purposes; *Done is a battell on the Dragon Blak,* for religious feeling expressed in melodious verse; and the well-known *Lament for the Makaris.* The main value of the last is historical, but it, too, shows Dunbar's mastery of form, even when dealing with lists of poetic predecessors.

BIBLIOGRAPHY.—The chief authorities for the text of Dunbar's poems are:—(*a*) the Asloan MS (c. 1515); (*b*) the Chepman and Myllar prints (1508), preserved in the Advocates' library, Edinburgh; (*c*) Bannatyne ms. (1568) in the same; (*d*) the Maitland Folio ms. (*c.* 1570–90) in the Pepysian library, Magdalene college, Cambridge. Some of the poems appear in the Makculloch ms. (before 1500) in the library of the University of Edinburgh; in ms. Cotton Vitellius A. xvi., appendix to royal mss. No. 58, and Arundel 285, in the British Museum; in the Reidpath ms. in the university library of Cambridge; and in the Aberdeen register of Sasines. The first complete edition was published by David Laing (1834) with a supplement (186;). This has been superseded by the Scottish Text Society's edition (ed. John Small, Aeneas J. G. Mackay and Walter Gregor, 1893), and by Dr. Schipper's edition (Kais. Akad. der Wissenschaften, 1894). The editions bv James Paterson (1860) and H. B. Baildon (1907), are of minor value. Selections have been frequently reprinted since Ramsay's *Ever-Green* (1724) and Hailes's *Ancient Scottish Poems* (1817). For critical accounts see Irving's *History of Scottish Poetry,* Henderson's *Vernacular Poetry of Scotland,* Gregorv Smith's *Transition Period,* J. H. Millar's *Literary History of Scotland,* and the *Cambridge History of English Literature,* vol. ii. (1908). Prof. Schipper's *William Dunbar, sein Leben und seine Gedichte* (with German trans. of several of the poems), appeared in 1884.

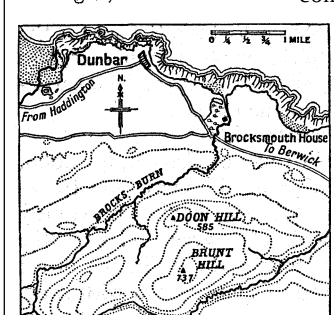
DUNBAR, royal parish and police burgh (Gaelic, "the fort on the point"), and seaport, East Lothian, Scotland. Pop. (1931) 3,751. It is on the southern shore of the entrance to the Firth of Forth, 29¼ m. E. by N. of Edinburgh by the L.N.E.R. Dunbar is said to have the smallest rainfall in Scotland and is a favourite summer resort, with good golf and bathing. The ruins of the castle, and the remains of the Grey Friars' monastery, founded in 1218, at the west end of the town, and Dunbar House in High Street, formerly a mansion of the Lauderdales, but now used as barracks, are of historic interest.

There are two harbours, difficult of access owing to the number of reefs and sunken rocks. On the advent of steam the shipping declined, and even the herring fishery, which fostered a large curing trade, has lost much of its prosperity. Crabs and lobsters are caught. There are few industries, but corn, fish and potatoes are exported.

A castle was built on the cliffs at least as early as 856. In 1070 Malcolm Canmore gave it to Cospatric, earl of Northumberland, ancestor of the earls of Dunbar and March. The fortress was an important bulwark against English invasion, and the town—which was created a royal burgh by David 11.—grew up under its protection. The castle was taken by Edward I., and it afforded shelter to Edward II. after Bannockburn. In 1336 it was besieged by the English under William, Lord Montacute, afterwards 1st earl of Salisbury, but was successfully defended by Black Agnes of Dunbar, countess of March, a member of the Murray family. Joanna Beaufort, widow of James I., chose it for her residence, and in 1479, after his escape from Edinburgh Castle, the duke of Albany concealed himself here before sailing for France, and Mary sheltered here in two crises. The regent Moray dismantled it in 1568, but its ruins are still a picturesque object on the hill above the harbour.

Battle of Dunbar.—This battle was fought on the 3rd (13th) of September 1650 between the English army under Oliver Cromwell and the Scots under David Leslie, afterwards Lord Newark. It took place about 3m S.E. of the centre of the town, where between the hills and the sea coast there is a plain about 1m. wide, through the middle of which the main road from Dunbar to Berwick runs. The plain and the road are crossed at right angles by the course of the Brocks Burn, or Spott Burn, which at first separated the hostile armies. Rising from the right bank of the Brock is Doon Hill (650ft.), which overlooks the lower course of the stream and indeed the whole field. For the events preceding the battle *see* GREAT REBELLION.

Cromwell, after a war of manoeuvre near Edinburgh, had been compelled by want of supplies to withdraw to Dunbar; Leslie pursued and took up a position on Doon Hill, commanding the English line of retreat on Berwick. The situation was more than difficult for Cromwell. Some officers were for withdrawing by sea, but the general chose to hold his ground, though his army was enfeebled by sickness and would have to fight on unfavourable terrain against odds of two to one. Leslie, however, who was himself in difficulties on his post among the bare hills, and was perhaps subjected to pressure from civil authorities, descended from the heights on Sept. 2 and began to edge towards his right, in order first to confront, and afterwards to surround, his opponent. The cavalry of his left wing stood fast, west of Doon Hill, as a pivot of manoeuvre, the northern face of Doon (where the ground rises from the burn at an average slope of fifteen degrees and is even steeper near the summit) he left unoccupied. The centre of infantry stood on the forward slope of the long spur which runs east from Doon, and beyond them, practically on the plain, was the bulk of the Scottish cavalry. But if Leslie had placed himself on Cromwell's line of retreat, he had thereby placed Cromwell on his—to the latter's moral advantage. In the evening Cromwell drew up his army, under 11,000 effective men, along the ravine, and issued orders to attack the Scots at dawn of the 3rd (13th). The left of the Scots was ineffective, as was a part of their centre of foot on the upper part of the hillside, and the English commander proposed to deal with the remainder, Before dawn the English advanced troops crossed the ravine, attacked Doon, and pinned Leslie's left; under cover of this the whole army began its manoeuvre The artillery was posted on the Dunbar side of the burn, directly opposite and north of Doon, the infantry and cavalry crossed where they could, and



BATTLE OF DUNBAR, SEPT. 3, 1650
Oliver Cromwell, with a force of 11,000 men, defeated the Scots under David Leslie in one of the most complete victories of the Great Rebellion. The Scottish commander had been drawn into leaving his stand on Doon Hill for a position on the plains where Brocks Burn divided his army. Cromwell instantly seized this opportunity for a surprise stroke

formed up gradually in a line south of and roughly parallel to the Berwick road, the extreme left of horse and foot, acting as a reserve, crossed at Brocksmouth House on the outer flank. The Scots were surprised in their bivouacs, but quickly formed up, and at first repulsed both the horse and the foot. But ere long Cromwell himself arrived with his reserve, and the whole English line advanced again. The fresh impulse enabled it to break the Scottish cavalry and repulse the foot, and Leslie's line of battle was gradually rolled up from right to left. In the words of an English officer, "The sun appearing upon the sea, I heard Nol say, 'Now let God arise, and let His enemies be scattered,' and following us as we slowly marched I heard him say, 'I profess they run.'" Driven into the broken ground, and penned between Doon Hill and the ravine, the Scots were indeed helpless. "They routed one another after we had done their work on their right wing," says the same officer. Ten thousand men, including almost the whole of the Scottish foot, surrendered, and their killed numbered three thousand. Few of the English were killed. "I do not believe," wrote Cromwell, "that we have lost twenty men."

The account of the battle of Dunbar here followed is that of C. H. Firth, for which *see* his *Cromwell, pp.* 281 ff. and references there given. For other accounts *see* Carlyle, *Cromwell's Letters and Speeches,* letter cxl.; Hoenig, *Cromwell;* Baldock. *Cromwell as a Soldier;* and Gardiner, *Hist. of the Commonwealth and Protectorate,* vol. i.

DUNBLANE, police burgh and parish, Perthshire, Scotland, on the left bank of Allan water, a tributary of the Forth, 3 m. N. by W. of Stirling by the L.M.S.R. Pop. (1931) 2,692. It is a place of great antiquity, with narrow streets and old-fashioned houses. Industry is limited, but a considerable amount of worsted-spinning is carried on; the town is in repute as a watering-place. The cathedral, by the side of the river, was one of the few ecclesiastical edifices that escaped injury at the hands of the Reformers. The first church is alleged to have been erected by Blane, a saint of the 7th century, but the cathedral was founded by David I. in 1141, and almost entirely rebuilt about 1240 by Bishop Clemens. The tower is Early Norman, the rest is Early Pointed style. After the decline of episcopacy the building was neglected for a long period, but the choir, which contains some carved oak stalls of the 16th century, and nave have been restored. From the time of the Reformation the choir only had been used as the parish church, but since its restoration the whole cathedral has been devoted to this purpose. An ancient Celtic cross, 6½ ft. high, stands in the north-western corner of the nave. Of the bishop's palace only a few ruins remain. The Queen Victoria School for the sons of Scottish soldiers and sailors, to the north of Dunblane, was opened in 1908, and the chapel in the grounds in 1910. The battlefield of Sheriffmuir is about 2¾ m. E. of the town.

DUNCAN, the name of two Scottish kings.

DUNCAN I. (d. 1040) was a son of Crinan or Cronan, lay abbot of Dunkeld, and became king of the Scots in succession to his maternal grandfather, Malcolm II., in 1034, having previously as *rex Cumbrorum* ruled in Strathclyde. His accession was "the first example of inheritance of the Scottish throne in the direct line." Duncan is chiefly known through his connection with Macbeth, which has been immortalized by Shakespeare. The only fact which can be ascertained with any certainty about the feud between the two princes is that Duncan was slain by Macbeth in 1040. Two of Duncan's sons, Malcolm III Canmore and Donald V. Bane, were afterwards kings of the Scots.

DUNCAN II. (d. 1094) was a son of Malcolm III. and therefore a grandson of Duncan I. For a time he lived as a hostage in England and became king of the Scots after driving out his uncle. Donald Bane, in 1093, an enterprise in which he was helped by some English and Normans. He was killed in the following year.

See W. F. Skene, *Celtic Scotland* (1876–80), and *A.* Lang, *History of Scotland,* vol. i. (1900).

DUNCAN, ADAM DUNCAN, 1ST VISCOUNT (1731–1804), British naval commander, was born on July 1, 1731, at Lundie, in Forfarshire, Scotland. Entering the navy in 1746, he saw much active service in European and American waters, and in Feb. 1795 he hoisted his flag as commander-in-chief of the North Sea fleet, appointed to harass the Batavian navy. Towards the end of May 1797, though, in consequence of the mutiny in the British fleet, he had been left with only the "Adamant" (50), besides his own ship the "Venerable" (74), Admiral Duncan proceeded to his station off the Texel, where lay at anchor the Dutch squadron of 15 sail of the line, under the command of Vice-admiral de Winter. From time to time he caused signals to be made, as if to the main body of a fleet in the offing, a stratagem which probably secured his freedom from molestation until, in the middle of June, reinforcements arrived. On Oct. 3 the admiral put into Yarmouth roads to refit, but receiving information early on the 9th that the enemy was at sea, he gave chase. On the morning of the 11th de Winter's fleet was sighted lying about 9m. from shore, between the villages of Egmont and Camperdown. The British fleet was slightly superior in force to that of the Dutch. Shortly after mid-day the British ships, without waiting to form in order, broke through the Dutch line, and an engagement commenced which, after heavy loss on both sides, resulted in the taking by the British of 11 of the enemy's vessels. In recognition of this victory, Admiral Duncan was, on Oct. 21, created Viscount Duncan of Camperdown and baron of Lundie, with an annual pension of £3,000 to himself and the two next heirs to his title. The earldom of Camperdown was created for his son Robert (1785–1859) in 1831, and is still in the possession of his descendants. Lord Duncan retired in 1800, and died on Aug. 4, 1804.

See Charnock, *Biog. Nav.* (1794–96); Collins, *Peerage of England,* p. 378 (1812); W. James, *Naval History of Great Britain* (1822); Yonge, *History of the British Navy,* vol. i. (1863); Earl of Camperdown, *Admiral Duncan* (1898), vol. xvi. of the Navy Record Soc. publications, contains the logs of the ships engaged at Camperdown.

DUNCAN, ISADORA (1878–1927), American dancer, was born at San Francisco (Calif.), on May 27, 1878. She began her career as a girl of 17 at Daly's theatre, New York, where she danced the part of a fairy in *A Midsummer Night's Dream.* Her early years were full of poverty and difficulty. With only the sum of $150, the Duncans went to England in a cattle boat; and in London and Paris, before recognition was won, they nearly starved.

Isadora had already conceived the thought of interpretative dancing to awaken the world to the grace and meaning of nature dancing, spiritual expression flowing into the channels of the body. She spent hours studying the Greek vases in the Louvre. Then she danced in Paris, Budapest, Florence and Berlin. Later, amid the ruins of the Theatre of Dionysus in Athens, she meditated on the dances of Hellas. In that atmosphere she further worked out her ideas of the dance evolved directly from nature, through the rhythmic movement of wind and wave and the winged flight of bird and bee. Her ideas were so old that, to an over-civilized world accustomed to the artificiality of the ballet and much-dressed dramatic dancing, they were startlingly new. Even the Russian ballet through Michel Fokine at home and Sergei Diaghilev's Ballets *Russes* abroad was influenced by Isadora Duncan's ideas and technique after she visited St. Petersburg in 1905. In 1904 she established a school for classical dancing near Berlin, where she taught her art to girls who later became known as the Duncan dancers; another in Paris in 1914; and another in Moscow in 1921, which was closed in the spring of 1928. Isadora Duncan and her sister had a school near Tarrytown.

When she returned to her native country in 1908 the United States was puzzled and divided itself into enthusiasts and critics. But later the stage of the Metropolitan opera house itself was hers for her performances. In April 1915, with the dancers from her Paris school she danced for a month at the Century theatre, trying to interest Americans in a project for a school in her own land. One was conducted for a short time near Tarrytown, N.Y., by her sister, Elizabeth, who had much to do with the display of Isadora's genius. Conventionally minded people were estranged, however, by her erratic actions, which became more marked after an automobile tragedy in Paris, 1913, when her two children, Deidre and Patrick, with their nurse were drowned.

She became an ardent advocate of the Soviet revolution in Russia and accepted Lenin's invitation (1921) to open the Moscow school of dancing in the palace of a former nobleman, which was given to her. Her marriage with a Russian, Sergei Essenin, ten years younger than herself, the difficulties at Ellis Island in 1922 on re-entering the United States with him, the episode of the red

scarf waved during a performance on the stage of the Symphony Hall, Boston (Oct. 22, 1922), brought on her such trials that she left America vowing never to return.

The last years of her life were pitiably tragic—in debt and difficulty in Germany and France. Her many friends rallied to establish the Duncan memorial dance school at Neuilly, raising in all 400,000 francs. She was killed in an automobile accident at Nice on Sept. 14, 1927. Her work to a certain extent was carried on by her adopted daughters, Anna and Irma who danced, and by Elizabeth Duncan who had a school near Salzburg.

See her autobiography *My Life* (1927); Shaemas O'Sheel's "Isadora," *New Republic* (Oct. 26, 1927); Jose Clara's "Isadora Duncan," *L'Art decoratif* (1913); *Le Ballet Contemporain, ouvrage edité avec la collaboration de L. Bakst. Traduction francaise de M. D Calvocoressi V. Svetlow,* pseud. of Valerian Yakovlevich Ivchenko; and Charles H. Caffin's "Henry Matisse and Isadora Duncan," *Camera Work* (1909).

DUNCAN, JOHN (1796–1870), Scottish theologian and Hebraist, was born at Aberdeen and studied at Marischall college. In 1836 he was ordained in the Established Church and given charge of Milton church, Glasgow. After three years as a missionary to the Jews in Budapest he was appointed, in 1843, to the chair of Oriental languages in the new Free Church college, Edinburgh. Apart from his 1838 edition of Robinson's Lexicon of the Greek New Testament, Duncan's writings consist largely of sermons and addresses, some of which were edited by J. Steven Sinclaire (1925). He died on Feb. 26, 1870.

See Knight: *Colloquia Peripatetica* (1870) and Brown: *The Late Rev. J. Duncan* (1874).

DUNCAN, ROBERT KENNEDY (1868–1914), American chemist, was born near Brantford, Ont., Canada on Nov. 1, 1868. He graduated at the University of Toronto in 1892; studied at Clark university and later at Columbia university (1897–98). He taught physics and chemistry in New York and Pennsylvania high schools. From 1901 to 1906 he was professor of chemistry at Washington and Jefferson college. During parts of 1903, 1904 and 1907, he made special studies in Europe. In 1906, while attending the International Congress of Applied Chemistry in Rome, he conceived the idea of the industrial fellowship system. His plan was to assist American manufacturers in making their products in a scientific manner and to base their plans for efficient production upon scientific research. In 1907 he became professor of industrial chemistry at the University of Kansas, and the same year arranged for the establishment of the first industrial fellowship. In 1910, his work at Kansas attracted attention in Pittsburgh, and he was made professor of chemistry at the University of Pittsburgh and director of industrial research, which position he held until his death on Feb. 18, 1914. In March 1913, the Mellon Institute of Industrial Research of the University of Pittsburgh was founded by Andrew W. Mellon and Richard B. Mellon of Pittsburgh as a memoriai to their father, Thomas Mellon, and also to Duncan. This placed the industrial fellowship system upon a permanent basis.

Duncan's works are noted for their high scientific accuracy. Among his more important books are: The New *Knowledge* (1905); *The* Chemistry of Commerce (1907), and *Some* Chemical Problems of To-day (1911).

DUNCAN, THOMAS (1807–1845), Scottish portrait and historical painter, was born at Kinclaven, Perthshire, on May 24, 1807, and died at Edinburgh, May 25, 1845. He was a pupil of Sir William Allan. His most famous pictures are: "Prince Charles Edward and the Highlanders entering Edinburgh after the battle of Prestonpans" (1843) and "Charles Edward asleep after Culloden, protected by Flora MacDonald" (1843), which has often been engraved.

DUNCAN, a city of southern Oklahoma, U.S.A.. on Federal highway 81 and the Rock Island railroad; the county seat of Stephens county. The population was 8,363 in 1930 (97% native white), and was 9,207 in 1940 by the federal census. There is a diversified income from agriculture, dairying, produce, livestock and oil production.

Within a few miles of the city of Duncan, there are oil and gas wells, and the city has refineries and casinghead plants and wholesale houses dealing in oil-well supplies, as well as numerous jobbers in other lines. Duncan mas settled about 1890 and incorporated in 1899. It has a well equipped airport.

DUNCE, a stupid person, incapable of learning. "Duns" or "dunsman" was a name applied by their opponents to the Scotists or followers of Duns Scotus, the great schoolman. When, in the 16th century, the Scotists obstinately opposed the "new learning," the term "duns" or "dunce" became, in the mouths of the humanists and reformers, a term of abuse, a synonym for one incapable of scholarship.

DUNCKER, MAXIMILIAN WOLFGANG (1811–1886), German historian and politician, eldest son of the publisher Karl Duncker, was born at Berlin on Oct. 15, 1811. He studied at the universities of Bonn and Berlin till 1834, when he was condemned to six years' imprisonment, afterwards reduced to six months, for belonging to students' societies. In 1842 he became a lecturer at Halle university. Elected to the National Assembly at Frankfort in 1848, he joined the Right Centre party, and was chosen reporter of the projected constitution. He sat in the Erfurt assembly in 1850, and in the second Prussian chamber from 1849 to 1852. In 1859 he was assistant in the ministry of State in the Auerswald cabinet, and in 1867 he became director of the Prussian archives, with which it was his task to incorporate those of Hanover, Hesse and Nassau. He retired on Jan. 1, 1875, and died at Ansbach on July 21, 1886. Duncker's fame rests mainly on his Geschichte des *Alterthums* (1st ed., 1852–57; 5th ed. in 9 vols., 1878–86; Eng. trans. by Evelyn Abbott, 1877–82).

His works include: *Zur Geschichte der deutschen Reichsversammlung in Frankfurt* (1849); the anonymous *Vier Monate auswärtiger Politik* (1851); *Origines Germanicae* (1840); *Die Krisis der Reformation* (1845) and *Feudalitat und Aristokratie* (1858). *See* his *Politischer Briefwechsel* (ed. *W*. Schulze, 1923); and Haym, *Das Leben Max Dunckers* (1891).

DUNCOMBE, SIR CHARLES (c. 1648–1711), English politician, was a London apprentice, who became a goldsmith and a banker, and an alderman of the City of London in 1683. Duncombe was elected M.P. for Hedon in 1685 and afterwards sat for Yarmouth in the Isle of Wight and Downton in Wiltshire. He was made receiver of the customs, and for a short time receiver of the excise, and in this capacity he profited slightly by a transaction over some exchequer bills which had been falsely endorsed. Tried before the court of the king's bench in 1699 he was found "not guilty." He represented Downton a second time from 1702 until his death. In 1709 he served as lord mayor of London. He died at Teddington on April g, 1711.

DUNDALK, a seaport of Co. Louth, Eire, near the mouth of the Castletown river, in Dundalk bay. Pop. of urban district (1936) 14,684. It is an important junction on the G.N. railway, by which it is 54 mi. N. from Dublin. Dundalk was a borough by prescription, and received charters from Edward III. and successive kings. It was stormed in 1315 by Edward Bruce, who here proclaimed himself king. He was defeated and killed by the English in 1318 in the neighbourhood, and was buried at Faughart, near Dundalk. Ruins of a Franciscan priory with a lofty tower may still be seen. There are distilleries, breweries, flax and jute spinning mills, salt works, etc. The town is in large part dependent for its prosperity upon the activity of the Great Northern railway, which maintains large railway shops. There are also shoe factories. Trade is in agricultural produce and livestock. The town is also the centre of sea and salmon fisheries.

DUNDEE, JOHN GRAHAM OF CLAVERHOUSE, VISCOUNT (*c.* 1649–1689), Scottish soldier, was the elder son of Sir William Graham and Lady Madeline Carnegie. Educated at St. Andrews university, he served as a volunteer in France and Holland, returning to England in 1677. In 1678 he became a lieutenant, and soon afterwards captain of a troop, in the regiment commanded by his relative, the marquis of Montrose, and was employed in suppressing the rebellion of the Covenanters.

After the murder of Archbishop Sharp (1679), there were reports of rebels gathering near Glasgow, and Graham went in pursuit. On June 1, the Covenanters being in a well-protected position upon the marshy ground of Drumclog, Graham advanced to the attack. Hindered by the ground, he had to wait till the

impatience of his adversaries induced them to commence an impetuous attack. The charge of the Covenanters routed the royal cavalry, who turned and fled, Graham himself having a narrow escape. This was the only regular engagement he had with the Covenanters. The enthusiasm raised by this victory was the beginning of a serious and open rebellion.

On June 22 Graham was present at the battle of Bothwell Bridge, at the head of his own troop. He was then commissioned to search the south-western shires for the rebels. The wide powers given to him by his commission were most sparingly used, and the gravest accusation made against him in reference to this period is that he was a robber.

His own systematic and calculated terrorism, directed principally against the ringleaders, proved far more efficacious than the irregular and haphazard brutalities of other commanders. During these months he was despatched to London, along with Lord Linlithgow, to influence Charles II. against the indulgent method adopted by Monmouth with the extreme Covenanting party. In April 1680 it appears that his roving commission had been withdrawn; he was not, therefore, responsible for the severe measures which followed the Sanquhar Declaration of June 22, 1680.

In the disorders following the Test Act of 1681 Graham was again commissioned to act in the disaffected districts. At the end of January he was appointed to the sheriffships of Wigtown, Dumfries, Kirkcudbright and Annandale. He retained his commission in the army, and appears to have had powers in life and death in virtue of a commission of justiciary granted to him about the same time. He quartered on the rebels, rifled their houses, and, to use his own words, "endeavoured to destroy them by eating up their provisions." His severities were rewarded with many honours, and with a grant of part of the Maitland lands.

Claverhouse was present at the sittings of the circuit court of justiciary in Stirling, Glasgow, Dumfries and Jedburgh, instituted for the imposition of the test and the punishment of rebels. As a member of the privy council of Scotland he declared—to his honour—against the proposal to let loose the Highland marauders upon the south of Scotland. In June 1684 he was again at his old employment—the inspection of the southern shires; in May 1685 he was ordered with his cavalry to guard the borders, and to scour the south-west in search of rebels. In 1686 he was promoted to the rank of major-general, and had added to his position of constable the dignity of provost of Dundee. In 1688 he was second in command to Gen. Douglas in the army which had been ordered to England to aid the falling dynasty of the Stuarts; he was created Viscount Dundee on Nov. 12, 1688.

After the flight of James II. Dundee returned to Scotland for the meeting of the convention, and sought to confirm the waning resolution of the duke of Gordon with regard to holding Edinburgh Castle for the king. The convention proving hostile he left Edinburgh (March 18) at the head of a company of 50 faithful dragoons. He was not long gone ere the news was brought to the alarmed convention that he had been seen clambering up the castle rock and holding conference with the duke of Gordon. On March 30 he was publicly denoupced as a traitor, and attempts were made to secure him. But the secrecy and speed of his movements outwitted his pursuers, and he retreated to the north.

Gen. Hugh Mackay was now in the field against him, and a Highland chase began. Dundee considered himself at the head of the Stuart interest in Scotland, and to the day of his death expected help to arrive from the exiled king. It mattered little to him that on July 24 a price of £20,000 had been placed upon his head. The clans had begun to reassemble; he was now in command of a considerable force, and in July both sides took the field again. A contest for the castle of Blair forced on the decision. Mackay, in his march towards that place, entered the pass of Killiecrankie, the battle-ground selected by Dundee and his officers. Here, on July 17–27, 1689, was fought the battle of Killiecrankie (*q.v.*) The Highlanders were completely victorious, but their leader was shot beneath the breastplate, and fell dying from his horse. Dundee was conveyed to the castle of Blair, where he died on the night of the battle. His death in battle formed the subject of numerous legends, the best known of which is the long prevalent tradition that he was invulnerable to all bullets and was killed by a silver button from his own coat.

See Mark Napier, *Memorials and Letters of Graham of Claverhouse* (1859–62); Bannatyne Club, *Letters of the Viscount Dundee* (1826); C. S. Terry, *John Graham of Claverhouse, Viscount Dundee;* and authorities quoted in *Dict. Nat. Biogr., s.v.* "Graham of Claverhouse."

DUNDEE, royal, municipal and police burgh, county of a city and seaport of Forfarshire, Scotland. Pop. (1931) 175,583. Broughty Ferry (pop. 11,058) was added to the burgh in 1913, making its acreage 6,548. It lies on the north shore of the Firth of Tay, 59¼ m. N. by E. of Edinburgh by the L.N.E.R. via the Forth and Tay bridges. The L.M.S.R. finds access to the city by way of Perth. The town has a frontage on the water of over 4 m., and rises gradually from the river to Dundee Law and Balgay Hill. The estuary to the E. of Tay bridge is 1½ m. wide, and the docks—accessible from it at all stages of the tide—are within 12 m. of the sea.

The town-hall, built in 1734 from the designs of Robert Adam, stands in High Street. It is surmounted by a steeple 140 ft. high, carrying a good peal of bells, and beneath it is a piazza. A city hall, with a fine classic portico, has been built behind it, largely from a bequest of Sir James Caird (d. 1916). The old Town Cross, a shaft 15 ft. high, bearing a unicorn with the date of 1586, once stood in High Street also, but was re-erected within the enclosure on the south-west of Town Churches (*see* below). The halls used for great public meetings are the Volunteer Drill Hall in Parker Square, and Kinnaird Hall in Bank Street. A central library and sculpture galleries in Ward Street were finished in 1915 and the Albert Institute contains the art-gallery, museum, etc. In Dock Street stands the Royal Arch, erected to commemorate the visit of Queen Victoria in 1844. Dudhope Castle, once the seat of the Scrymgeours, hereditary constables of the burgh—one of whom (Sir Alexander) was a companion-in-arms of Wallace,—was granted by James II. to John Graham of Claverhouse. On his death it reverted to the Crown, and is now used as a technical school. Though Dundee was once a walled town, the only relic of its walls is the East Port, preserved because it was said that George Wishart preached from the top of it during the plague of 1544.

Of the many churches and chapels the most interesting is Town Churches—St. Mary's, St. Paul's and St. Clement's, the three under one roof—surmounted by the noble square tower, 156 ft. high, called the Old Steeple, which was once the belfry of the church erected on this spot by David, earl of Huntingdon, as a thank-offering for his escape from shipwreck on the shoals at the mouth of the Tay (1193). The church perished, but the bell-tower remained and was restored in 1871–1873 by Sir Gilbert Scott. Bishop Forbes (1817–1875) transferred the Anglican see of Brechin to Dundee.

Parks include Dundee Law (18 ac.) on the north, Baxter Park (37 ac.) on the east, Balgay Hill (36 ac.) on the west and, near it, Lochee Park (2½ ac.); in the extreme north is the park of Fair Muir (12 ac.), and, nearer to the heart of the town, Dudhope Park. Near the north end of the Tay bridge is Magdalen Green, an old common of 17 ac., and along the shore of the estuary there runs for a distance of 2¾ m. from Magdalen Point to beyond Craig Pier a promenade called the Esplanade. To the north is Caird Park, opened in 1923 on part of the estate given by Sir James Caird in 1911; it contains the ruins of Claverhouse Castle.

Education.—University college in Nethergate, founded in 1880 by Miss Baxter of Balgavies (d. 1884) and Dr. John Boyd Baxter, was opened in 1883, and finally united to the University of St. Andrews in 1897. The curriculum is especially concerned with medicine and natural and applied science. A technical college and school of art was opened in Bell street in 1910. In connection with the high school, a building in the Doric style, dating from 1833, there is a museum, endowed in 1880 by Mr. William Harris. Morgan hospital, in Scots Baronial style, immediately north of Baxter Park, was founded in 1868 by John Morgan, a native of Dundee, for poor boys, but was acquired by the school board and transformed into a secondary school. A training school for teachers was opened in Park Place is 1920. The Royal Infirmary

is a large institution. The Baldovan asylum for imbeciles, founded in 1854 by Sir John Ogilvy, is said to be the earliest of its kind in Scotland.

Trade and Shipping.— Dundee is noted first for the jute industries. Enormous quantities of the raw material are imported from India. Fabrics in jute range from the roughest sacking to beautiful carpets. Another staple industry is the linen manufacture, which is also one of the oldest, although it was not till the introduction of steam power that headway was made. The chief textile products are canvas (for which the British navy is the largest customer), ropes, sheetings, sackings, carpets, etc. Dundee is also celebrated for its confectionery and preserves, especially marmalade. Other industries are bleaching and dyeing, engineering, shipbuilding, tanning, sawmills, the making of boots and shoes, foundries, breweries, corn and flour mills and the construction of motor-cars. On the front wharves and harbour works extend for 2 m., and the docks cover an area of 3j3 ac., made up thus—Earl Grey Dock, 5¼ ac.; King William IV. Dock, 6¼ ac.; Tidal Harbour, 4¾ ac.; Victoria Dock, 10¾ ac.; Camperdown Dock, 8½ ac. There are, besides, graving docks, the ferry harbour and timber ponds. There is regular communication by steamer with London, Hull, Newcastle, Liverpool, Manchester, Belfast and Leith, besides Rotterdam, Hamburg and other continental ports. Of local excursions the two hours' run to Perth is a favourite summer trip.

Dundee returns two members to parliament. The city council consists of the lord provost, bailies and councillors. The corporation owns the gas, electricity and water supplies (the latter drawn from an artificial loch at Moni Rie to the N.E., and the loch of Lintrathen, 18 m. to the N.W.).

History.— The name of the city is derived most probably from the Gaelic *Dun Taw*, "the fort of the Tay," of which the Latin *Taodunum* is a transliteration— the derivation pointing to the fact of a Pictish settlement on the site. Its earliest authentic mention is in a deed of gift by David, earl of Huntingdon, younger brother of William the Lion, dated about 1200, in which it is designated as "Dunde." Shortly afterwards it was erected into a royal burgh by William the Lion. Edward I. is said to have removed its charter. Robert Bruce and successive kings confirmed its privileges and rights, and Charles I. finally granted it its great charter. Here Wallace finished his education, and here he slew young Selby, son of the English constable, in 1291. In that year the town fell into the hands of the English, and it was whilst engaged in besieging the castle in 1297 that Wallace withdrew to fight the battle of Stirling Bridge. In their incursion into Scotland under John of Gaunt the English captured and partially destroyed the town in 1385, but retreated to meet a counter-invasion of their own country. The English seized it again for a brief space during one of the first earl of Hertford's devastating raids in the reign of Edward VI. Dundee bore such a prominent part in propagating the Reformed doctrines that it was styled "the Scottish Geneva." The marquess of Montrose sacked it in 1645, and then burnt a considerable portion of it. Charles II. spent a few days in the castle after his crowning at Scone (Jan. 1, 1651). In the same year General Monk captured it after an obstinate resistance and put more than one-sixth of the inhabitants and garrison, including its governor Lumsden, to the sword. Sixty vessels were seized and filled with plunder; but the ships, says Gumble in his *Life* of Monk, "were cast away within sight of the town and that great wealth perished." In 1684 John Graham, of Claverhouse— to the north of the town, became constable, and in 1688 provost. In the same year James II. created him Viscount Dundee.

With modern changes, some picturesque but insanitary buildings, narrow winding streets and unsavoury closes disappeared, along with a few structures of more or less historic interest, like the castle, the mint and numerous convents. But the large factory population, together with the number of high tenement buildings, has given rise to slum conditions with which the municipality has endeavoured to cope by means of housing schemes. The wholesale clearances have improved both the public health and the appearance of the city. Queen Victoria granted a charter to Dundee, dated Jan. 25, 1889, raising it to the status of a city, and since 1892 its chief magistrate has been styled lord provost.

Among men more or less eminent who were born or lived in Dundee may be named Hector Boece (1465–1536), Viscount Dundee (1643–89), James Halyburton, the reformer (1518–89), many of the Scrymgeours and Wedderburns, and James Chalmers, the post-office reformer. George Constable of Wallace Craigie, the prototype of Jonathan Oldbuck in Sir Walter Scott's Antiquary, had a residence in the east end of Seagate; and William Thom (1798–1848), the writer of The *Rhymes* of *a Handloom Weaver*, was buried in the Western Cemetery.

Suburbs.—Broughty Ferry lies on the Firth of Tay, 3½ m. E. of Dundee. The name is a corruption of Brugh or Burgh Tay, in allusion to the fortress standing on the rock that juts into the Firth. It is believed that a stronghold has occupied this site since Pictish times. The later castle, built in 1498, fell into the hands of the English in 1547 and was held by them for three years. Gradually growing more or less ruinous it was acquired by the Government in 185j, repaired, strengthened and converted into a Tay defence, mounting several heavy guns. Owing to its healthy and convenient situation, Broughty Ferry has become a favourite residence of Dundee merchants. To the north-west lies Benvie; Camperdown House is in the parish. Fowlis, 5 m. N.W., is remarkable for its 15th century church, with carved ambry and rood-screen (curious representation of the Crucifixion), decorated font, crocketed door canopy and several pictures. The ruined castle adjoining the church ultimately became a dwelling for labourers. Lundie, 3 m. farther out in the same direction, contains several lakelets, and its kirkyard is the burial-place of the earls of Camperdown. Tealing, 4 m. N. of Dundee, was the scene of the ministry of John Glas before he was deposed for heresy. Newport and Wormit, on the opposite bank of the Tay, are connected with Dundee by steam ferry.

DUNDERLANDSDAL, a valley of northern Norway, draining south-westward from the neighbouring glaciers to the Ranenfjord (lat. 66° zo' N.). Valuable deposits of iron ore (magnetite and pyrites), first worked in 1902, occur here. At the mouth of the river is Mo, a considerable trading village. The valley is remarkable for caverns in the limestone, some of the tributary streams flowing for considerable distances underground.

DUNDONALD, THOMAS COCHRANE, 10TH EARL OF (1775–1860), British admiral, was born at Annsfield, Lanarkshire, on Dec. 14, 1775. He was the son of Archibald Cochrane, 9th earl (1749–1831), a most ingenious, but also most unfortunate, scientific speculator and inventor, who was before his time in suggesting and attempting new processes of alkali manufacture, and various other uses of applied science. The family was greatly impoverished owing to his losses over these schemes. Thomas went to sea in his uncle's, Captain Cochrane's ship, the "Hind," in 1793. His promotion was rapid.

In 1800 he was appointed to the command of the "Speedy" brig. His capture of the Spanish frigate "El Gamo" (32) on May 6, 1801, brought him promotion to post rank. He sat in parliament as member for Honiton in 1806 and for Westminster in 1807. In the House of Commons he made his mark as a radical and a denouncer of naval abuses. In April 1809 he was engaged in the attack on the French squadron in the Basque Roads, which was very ill conducted by Lord Gambier. Cochrane's conduct was brilliant, but he made accusations against the admiral which necessitated a court-martial on Gambier. The admiral was acquitted, and Cochrane fell into disfavour with the admiralty. He was not employed again till 1813.

In the interval he speculated on the Stock Exchange. At this moment a notorious fraud was perpetrated on the Stock Exchange by an uncle of his and by other persons with whom he habitually acted. Lord Cochrane was brought to trial with the others before Lord Ellenborough on June 8, 1814, and all were condemned. He was expelled from parliament and deprived of the order of the Bath.

In 1817 he accepted the invitation of the Chileans, who were then in revolt against Spain, to take command of their naval forces, and remained in their service until 1822. His capture of

the Spanish frigate "Esmeralda" (40) in the harbour of Callao, on Nov. j, 1820, was a signal achievement. In 1823 he transferred his services to Brazil, where he helped the emperor Dom Pedro I. to shake off the yoke of Portugal; but by the end of 182 j he had fallen out with the Brazilians, and he returned to Europe. He then entered the Greek service, but he found no opportunity for distinguishing himself, and in 1828 returned home. He succeeded in 1832 in securing reinstatement in the British navy. In 1848 he was appointed to the command of the North American and West India station, which he retained till 1851. At various periods of his life he occupied himself with scientific invention. He took out patents for lamps to burn oil of tar, for the propulsion of ships at sea, for facilitating excavation, mining and sinking, for rotary steam-engines and for other purposes; and in 1843 was an advocate of the employment of steam and the screw propeller in warships. Lord Dundonald died in London on Oct. 30, 1860. and was buried in Westminster Abbey. He was succeeded in the title by his son Thomas as 11th earl (d. 1885), and the latter by his son Douglas as 12th earl (*q.v.*).

See the 10th earl's *Autobiography of a Seaman* (2 vols., 1860–61), which was the main source for his *Life* (1869, *by* his son and heir); his *Notes on the Mineralogy, Government and Condition of the British West India Islands* (1851), and a *Narrative of Services in the Liberation of Chili, Peru and Brazil* (1858); and J. B. Atlay, *The Trial of Lord Cochrane before Lord Ellenborough* (1897).

DUNDONALD, DOUGLAS MACKINNON BAILLIE HAMILTON COCHRANE, 12TH EARL OF (1852–1935), son of the 11th earl of Dundonald and Louisa Mackinnon, was born on Oct. 29, 1852, and succeeded to the earldom in 188 j. On leaving Eton he entered the 2nd Life Guards, in 1870, and served in the Nile expedition of 1884–85, and in the desert march to the relief of Khartoum. In 1899–1900 he commanded the Mounted Brigade in South Natal, and led the 2nd Cavalry Brigade into Ladysmith in 1900. In the same year he was promoted major-general; in 1907 he was made K.C.V.O., and in 1913 K.C.B.

DUNEDIN, a city of New Zealand, capital of the provincial district of Otago, and the seat of a bishop, in Taieri county. Pop. (census of 1926) 85,197. It lies 1 j m. from the open sea, at the head of Otago harbour, a narrow inlet on the south-eastern coast of South island.

The colony of Otago (from a native word meaning ochre, which was found here and highly prized by the Maoris) was founded as the chief town of the Otago settlement by settlers sent out under the auspices of the Free Church of Scotland in 1848. The discovery of large quantities of gold in Otago in 1861 and the following years brought prosperity, a great "rush" of diggers setting in from Australia.

The situation was chosen on the consideration of this harbour alone, for the actual site offered many difficulties, steep forest-clad hills rising close to the sea, and rendering reclamation necessary. The hills give the town a beautiful appearance, as the forest was allowed to remain closely embracing it, being preserved in the public ground named the Town Belt. The principal thoroughfare is comprised in Prince's street and George street, running etraight from south-west to north-east and passing through the Octagon, which is surrounded by several of the principal buildings. From these streets others strike at right angles down to the harbour, while others lead obliquely up towards the Belt, beyond which are extensive suburbs. The town hall, Athenaeum and museum are noteworthy buildings, the last having a fine biological collection. The Otago university at Dunedin is a constituent college of the University of New Zealand with 51 professors and lecturers. The college was founded in 1869. The white Oamaru stone is commonly used in the buildings. Besides the Belt there are several parks and reserves.

Dunedin is connected by rail with Christchurch northward and Invercargill southward, with numerous branches. The depth of the channel to Port Chalmers (9 m. N.E. of Dunedin by rail) is 30 feet, at Dunedin itself the harbour has a depth from 18 to 24 feet and can accommodate vessels up to 22½ ft. draught. The exports include gold (procured by dredging), wool, dairy produce, frozen meat: the imports are coal, timber and manufactured goods.

DUNES or **DUNKIRK DUNES, BATTLE OF,** was fought near Dunkirk on May 24 (June 3), 1658, between the French and English army under the command of Marshal Turenne and the Spanish army under Don Juan of Austria and the prince of Condé. The severest part of the fighting was borne by the English contingents on either side. Six thousand English infantry under Gen. Lockhart were sent by Cromwell to join the army of Turenne, and several Royalist corps under the command of the duke of York (afterwards James II.) served in the Spanish forces. The object of the Spaniards was to relieve Dunkirk, which Turenne was besieging. Don Juan had a strong superiority in cavalry, but left behind his artillery in order not to delay his advance. He took up a position on the dunes with his right on the sea and his left on the Bruges canal, and here Turenne at once attacked him. Condé's cavalry on the left wing charged with great resolution and despite heavy loss gained the upper hand. But their success was nullified by the failure of the Spanish right wing and centre under Turenne's pressure, to which Cromwell's veterans largely contributed. But when all the rest of the Spanish army was in rapid retreat, the one small corps of English Royalists, some 300 strong only, held out stubbornly and only laid down their arms on terms that they were allowed to rejoin their king, Charles II. at Ypres. From this corps, the Royal Regiment of Guards, are descended the present Grenadier Guards. With Turenne's victory, the surrender of Dunkirk speedily followed, and the fortress passed into English hands until sold back by Charles 11.—an ironical last word on this singular footnote to English history.

DUNES, mounds or hills and ridges of sand heaped by wind. They are numerous in (1) deserts, particularly in low-lying areas; (2) on sandy coasts with onshore winds; and (3) near rivers of which the volume varies, leaving sandy beds exposed during the dry season. The areg of the Sahara and Arabian deserts are characterized by vast expanses of dunes, as are the *koums* of the deserts of Persia and Turkistan and the plateaux of Gobi and other Mongolian deserts. Few such desert dunes are found in America or Australia, but the sand hill region of western Nebraska affords a good illustration. The coasts of Brittany, Cornwall, the Landes of France, the shores of the Baltic in Europe; the whole eastern coast of North America from Cape Cod southward, and at places along the Pacific coast; and numerous leeward coasts of Africa, Australia and Asia serve as examples of oceanic coastal dunes. Lacustrine dunes are admirably developed on the east shore of Lake Michigan, the south shores of Lake Superior and Lake Erie, the shores of former Lakes Lahontan and Bonneville in the Great basin of North America, and on the east shores of the Caspian and Aral seas in western Asia. Examples of river bank dunes are found in almost every land, as for instance along the east banks of the Mississippi, Missouri and Rio Grande rivers in the United States.

Dunes migrate constantly unless the sand of which they are composed is prevented from blowing by grass or other vegetation. The rate at which dunes move varies, depending upon the velocity of the wind and the height of the dunes, small dunes migrating the faster. In Denmark the rate is from 3 to 20 ft. a year; in France, on the Bay of Biscay, the sands have advanced at a rate estimated from 1 j to 105 ft. a year, burying in their progress forests, farms, vineyards, churches and whole villages, some of which may in course of time be exhumed as the dunes migrate onward. On the south side of Lake Michigan forests which were buried by sand dunes have been uncovered as the dunes moved on. Hundreds, perhaps thousands of square miles of towns and cities in central Asia are buried under dunes. Moving dunes constantly encroach upon the Suez canal. Nor are dunes merely a contemporary geologic feature. Sand dune deposits are recognizable by the character of their bedding in sandstone rocks of many geologic periods, indicating that aeolian action has been prevalent throughout geologic history. Fossil dunes are widely distributed. See Downs. (W. E. E.)

DUNFERMLINE, JAMES ABERCROMBY, 1ST BARON (1776–1858), speaker of the House of Commons, third son of Gen. Sir Ralph Abercromby, was born on Nov. 7, 1776. He was

called to the bar at Lincoln's Inn in 1801. He sat in parliament for Midhurst (1807) and Calne (1812) in the Whig interest. In 1827 Abercromby was made judge-advocate-general, and chief baron of the exchequer of Scotland in 1830, when he resigned his seat in parliament. He joined the cabinet of Earl Grey in 1834 as master of the mint. In the new parliament of 1835, Abercromby was elected speaker of the House. As speaker he was not very successful in quelling disorder, but he introduced several important reforms in the management of private bills. On his resignation in May 1839 he was created Baron Dunfermline of Dunfermline. He died at Colinton House, Midlothian, on April 17, 1858, and was succeeded in the title by his only son, Ralph.

See Spencer Walpole, *History of England* (London, 1890); *Greville Memoirs*, edited *by* H. Reeve (London, 1896); Lord Cockburn's *Journal* (Edinburgh, 1874).

DUNFERMLINE, a royal burgh and parish, Fifeshire, Scotland (Gaelic, "the fort on the crooked linn"). Pop. (1911) 28.103, (1938) 37,058. The parish was enlarged in 1914, and now includes Rosyth. It is situated on high ground 3 m. from the shore of the Firth of Forth, with two stations on the L.N.E.R.—Lower Dunfermline 16¾ m., and Upper Dunfermline 19¼ m. N.W. of Edinburgh, via the Forth Bridge. The town is intersected from north to south by Pittencrieff Glen, a deep, picturesque ravine, from which the town derives its name and at the bottom of which flows Lyne Burn.

The early Celtic monks known as Culdees had an establishment here; but its fame dates from the marriage of Malcolm Canmore and his queen Margaret, solemnized in the town in 1070. The king then lived in a tower on a mound surrounded on three sides by the glen. A fragment of this castle exists in Pittencrieff Park, a little west of the later palace. Under the influence of Queen Margaret in 1075 the foundations were laid of the Benedictine priory, raised to an abbey by David I. Robert Bruce gave the town its charter in 1322.

The staple industry is the manufacture of table linen. The weaving of damask was introduced in 1718 by James Blake, who had learned the secret of the process in the workshops at Drumsheugh near Edinburgh. Other industries are dyeing and bleaching, brass and iron founding, engineering works, rope-making and the making of soap and fireclay, whilst there are numerous collieries in the immediate vicinity.

Public edifices, besides churches, include the County buildings, the Public, St. Margaret's, Music and Carnegie halls, the last in the Tudor style, Carnegie public baths, high school (founded in 1560), school of science and art and two hospitals. Andrew Carnegie (1835–1919) was a well-known benefactor of Dunfermline. He gave to his birthplace the free library and public baths, and, in 1903, the estate of Pittencrieff park and glen, rich in historical associations as well as natural charm, together with bonds worth £500,000 (increased by £250,000 in 1911) a year, in trust for the maintenance of the park, the support of a theatre for the production of plays of the highest merit, the periodical exhibitions of works of art and science, the promotion of horticulture among the working classes and the encouragement of technical education in the district. A statue of Carnegie has been placed in the park. and Dunfermline is now the headquarters of all the Carnegie trusts. The town is the seat of the sheriff-substitute for Western Fife; it is governed by a provost, bailies and council, and, with Cowdenbeath, Inverkcithing and Lochgelvy (the Dunfermline group) combines in returning a member to parliament.

With the exception of Iona, Dunfermline Abbey has received more of Scotland's royal dead than any other place in the kingdom Within its precincts were buried Queen Margaret and Malcolm Canmore; their sons Edgar and Alexander I., with his queen; David I. and his two queens; Malcolm IV.; Alexander III., with his first wife and their sons David and Alexander; Robert Bruce, with his queen Elizabeth and their daughter Matilda; and Annabella Drummond, wife of Robert III. and mother of James I. Bruce's heart rests in Melrose, but his bones lie in Dunfermline Abbey, where (after the discovery of the skeleton in 1818) they were reinterred below the pulpit of the New church. In 1891 the pulpit was moved back and a monumental brass inserted in the floor to indicate the royal vault. The tomb of St. Margaret and Malcolm, within the ruined walls of the Lady chapel, was restored and enclosed by command of Queen Victoria. During the winter of 1303 the court of Edward I. was held in the abbey, and on his departure next year most of the buildings were burned. When the Reformers attacked the abbey church in March 1560, they spared the nave, which served as the parish church till the 19th century, and now forms the vestibule of the New church (1821), a building in the Perpendicular style. The old building was a fine example of simple and massive Norman, and has a beautiful doorway in its west front. Another rich Norman doorway was exposed in the south wall in 1903. The building is maintained by the commissioners of woods and forests. Of the monastery there still remains the south wall of the refectory, with a fine window. The palace, a favourite residence of many of the kings, occupying a picturesque position near the ravine, was of considerable size, judging from the south-west wall, which is all that is left of it; the last royal tenant was Charles II., who occupied it just before the battle of Pitreavie (July 20, 1650), which took place 3 m. to the south-west, and here also he signed the National League and Covenant.

DUNGANNON, a market town of Co. Tyrone, Ireland, 8 m. W. of the south-western shore of Lough Neagh, 103 m. from Dublin by the G.N. railway, with a branch line thence to Cookstown. Population of urban district 3,762. Its early history is that of the O'Neills, whose chief residence was here, and a large rath or earthwork north of the town was the scene of the inauguration of their chiefs; but of the family castle and abbey there are no remains. In Dungannon the independence of the Irish parliament (to which the town returned two members) was proclaimed in 1782. The town was formerly corporate and was a parliamentary borough until 1885. The royal school, founded in 1614, was moved to new buildings at the end of the 18th century. Linens, muslin, and coarse earthenware are manufactured, tanning is carried on, and there is trade in corn and timber.

DUNGARPUR, an Indian State, in the Rajputana agency, in the extreme south of Rajputana. A large portion is hilly, and inhabited by Bhils. Its area is 1,447 sq m. In 1931 the total population was 227,544. Kherwara is the headquarters of the Mewar Bhil corps.

The chiefs of Dungarpur, who bear the title of maharawal and enjoy a salute of 15 guns, are descended from Mahup, eldest son of Karan Singh, chief of Mewar in the 12th century, and claim the honours of the elder line of Mewar. The town of Dungarpur (pop. 8,560 in 1931), the capital of the state, was founded towards the end of the 14th century and named after Dungaria, an independent Bhil chieftain. After the battle of Khanua in 1527, these territories were divided into the States of Dungarpur and Banswara. Dungarpur fell under the sway of the Moguls and Mahrattas in turn, and was taken under British protection by treaty in 1818.

DUNGARVAN, a market town and seaport of Co. Waterford, Eire, 28½ mi. W.S.W. from Waterford by rail. Pop. of urban district (1936) 5,361. It is situated on the Bay of Dungarvan, at the mouth of the Colligan, which divides the town into two parts. Dungarvan mas incorporated in the 1 jth century. Under John, walls were built, also a castle, of which there are still remains in the town. The eastern suburb is called Abbeyside, where remains of an ancient keep, erected by the M'Graths. still exist, together with portions of an Augustinian friary, founded by the same family in the 14th century and incorporated with a Roman Catholic chapel. Brewing is carried on and there are woollen mills. Trade is in agricultural produce.

DUNGENESS, promontory, south coast of Kent, England. near the town of Lydd. It is a low-lying bank of about 9.4 sq.mi. of shingle, forming the seaward apex of the great Romney marshes. Its seaward accretion by the formation of curved shingle beaches, is about 6 ft. annually. The sea quickly drops into deep water, which is not the case of the other headlands of the south coast. A lighthouse (50° 55′ N., 0° 58′ E.) stands on the ness. There are also here Lloyds' signalling station, a bird sanctuary, and the terminus of a branch of the Southern railway.

The name Dungeness has also been applied elsewhere; thus the point on the north side of the eastern entrance to Magellan strait is so called, and there is a town of Dungeness near a promontory on the coast of Washington, U.S.A. (Strait of Juan de Fuca).

DUNGEON, the prison in a castle. The word is an anglicization of *donjon,* the French for keep (*q.v.*), in whose cellars the prison is usually located. In modern usage, dungeon signifies, especially, the vaulted chambers that formed these prisons, hence any small, vaulted, prison-like room, particularly if dark or partially underground.

DUNKELD, burgh of barony and parish (with Dowally), Perthshire, Scotland, on the left bank of the Tay, 15½ mi. N.W. of Perth by the L M.S.R. The station is at Birnam, on the right bank. Pop. (1931) 946. The river is crossed by a bridge of seven arches designed by Thomas Telford and opened in 1808. The town lies in the midst of luxuriant trees, and the noble sweep of the Tay, the bridge, the grounds of Dunkeld house, and the protecting mountains combine to give it a beautiful site.

As early as 729—some authorities fix the date a hundred and fifty years before—the Culdees possessed a monastery at Dunkeld, converted into a cathedral by David I in 1127. At the Reformation it was unroofed and fell into ruin. The building, given to the nation by the duke of Atholl in 1918, consists of the nave, aisles, choir, chapter house and tower. The Pointed arches rest upon pillars, possibly Norman, and above them, below the Decorated clerestorey windows, is a series of semicircular arches with flamboyant tracery. The choir, founded by Bishop William Sinclair (d. 1337), has been repaired, and serves as the parish church, a blue marble slab in the floor marking the bishop's grave. The chapter house, adjoining the choir, was built by Bishop Thomas Lauder (1395–1481) in 1469, and the vault beneath is the burial place of the Atholl Murrays. Lauder also began the tower, completed in 1501. The most famous of the bishops was Gavin Douglas (1474–1522), translator of the Aeneid. Shortly after the battle of Killiecrankie (1689), the Cameronian regiment which was enrolled in the same year (afterwards the 26th Foot), was despatched to hold Dunkeld prior to another invasion of the Highlands. It was under the command of Colonel William Cleland (b. 1661), a poet of some merit. On Aug. 26 a force of 5,000 Highlanders suddenly appearing, Cleland posted his men in the church and behind the wall of the earl of Atholl's mansion. The Highlanders were forced to withdraw, but while leading a sortie Cleland was killed.

Adjoining the cathedral is Dunkeld house, a seat of the duke of Atholl. The 4th duke planted several square miles of the estate with larches, of which he had made a study. The oak and sycamore in front of Birnam house, a mile south, are believed to be the remnant of the wood of Birnam which Shakespeare immortalized in Macbeth. The Pass of Birnam, where the river narrows, was the path usually taken by Highlanders in their forays.

DUNKIRK, a seaport of northern France (Fr. Dunkerque), capital of an arrondissement in the department of Nord, on the Straits of Dover, 53 mi N.W. of Lille on the Northern railway. Pop. (1936) 31,017. Around a chapel founded by St. Eloi in the 7th century a small village sprang up, and, in the 10th century, was fortified by Baldwin III, count of Flanders. In 1658 Turenne's victory of the Dunes (*q.v.*) gave it into the hands of the French and it was ceded to Cromwell in return for services of the Ironsides. Charles II sold it to Louis XIV, who fortified it. By the terms of the peace of Utrecht (1713) the fortifications were demolished and its harbour filled up, a sacrifice demanded by England owing to damage inflicted by Jean Bart and other corsairs of the port. In 1793 it was besieged by the English under Frederick Augustus, duke of York, who was compelled to retire after the defeat of Hondschoote. It was heavily bombed and damaged in World War I, during which it was, for most of the time, 18 mi. behind the Allied front, and in World War II. Dunkirk is in the low but fertile district of the Wateringues. It lies, amid a network of canals, immediately to the west and south of its port, which disputes with Bordeaux the rank of third in importance in France. The populous suburbs of Rosendael and St. Pol-sur-Mer lie respectively to the east and west of the town; to the north-east is the bathing resort of Malo-les-Bains. The streets of Dunkirk are wide and well paved, the chief of them converging to the square named after Jean Bart (born at Dunkirk in 1651), whose statue by David d'Angers stands at its centre. Close to the Place Jean Bart rises the 16th-century belfry (290 ft. high) which contains a fine peal of bells and also serves as a signalling tower. It was once the western tower of the church of St. Eloi, from which it is now separated by a street. St. Eloi, erected about 1560 in the Gothic style, was deprived of its first two bays in the 18th century; the present façade dates from 1889. The roof was destroyed in World War I. The chapel of Notre Dame des Dunes possesses a small image, which is the object of a well-known pilgrimage. Dunkirk has a communal college, a school of drawing, architecture and music, a library and a rich museum of paintings. Dunkirk forms with Bergues, Bourbourg and Gravelines a group of fortresses enclosed by inundations and canals.

The harbour of Dunkirk (see Docks) is approached by a fine natural roadstead entered on the east and west, and protected on the north by sandbanks. From the roadstead, entrance is by a channel into the outer harbour, which communicates with seven floating basins about 115 acres in area and is accessible to the largest vessels. The port is provided with four dry docks and a gridiron, and its quays exceed 5 mi. in length. Canals bring it into communication with Belgium, the coal basins and industrial towns of Nord and Pas-de-Calais, and the rich agricultural regions of Flanders and Artois. The roadstead is indicated by lightships and the entrance channel to the port by a lighthouse which, at an altitude of 193 ft., is visible at a distance of 19 mi.

Dunkirk annually dispatches a fleet to the Icelandic cod-fisheries, and takes part in the herring and other fisheries. It imports great quantities of wool from the Argentine and Australia. and is in regular communication with New York, London and the chief ports of the United Kingdom, Brazil and the far East. Besides wool, leading imports are jute, cotton, tow, flax, timber, petroleum, coal, iron ore, pig iron, pitch, wine, cereals, oilseeds and oil cake, nitrate of soda and other chemical products, and metals. The principal exports are sugar, coal, cereals, wool, forage, cement, chalk, phosphates, iron and steel, tools and metal goods, thread and vegetables. The industries include the spinning of jute, flax, hemp and cotton, iron founding, and the manufacture of machinery, fishing nets, sailcloth, sacks, casks and soap. There are also saw- and flour-mills, petroleum refineries and oil works. Shipbuilding is carried on and the preparation of fish and cod-liver oil occupies many hands. (X)

Evacuation of Dunkirk, 1940.—The British-French retreat at Dunkirk constitutes one of the most memorable phases of the general battle of France in World War II, and the crucial point of the preceding battle of Flanders. The disaster in that area started with the surrender of the Belgian army (May 28, 1940) which was holding positions to the north of Dunkirk. Thus the Allied forces in Flanders saw themselves cut off from the main French army, in a desperate situation. Only evacuation by sea was left. It was accomplished with skill and heroism, and in spite of uninterrupted, terrific attacks by German dive bombers, some 330,000 French and British troops, with a few Belgian and Dutch forces who refused to surrender, reached England. This amounted to about three-quarters of the Allied effectives trapped in Flanders. The battle-worn troops mere evacuated by all available means of navigation; besides the navy units and merchant ships, yachts and even small private and fishing boats, mostly sent from Great Britain, took an active and gallant part in it, under the protection of the royal air force, which for a certain time held supremacy in the skies. (A. De.)

DUNKIRK, a city of Chautauqua county, New York, on Lake Erie, 40 mi. S.W. of Buffalo. It is a port of entry and is served by the Erie, the New York Central, the Pennsylvania, the Nickel Plate and the Dunkirk, Allegheny Valley railways. The population in 1940 was 17,713. It is a shipping point for great quantities of grapes (the agricultural specialty of the region), and has important manufactures, including stainless steel, shovels, hoes, oil-refining machinery, structural bridges, jellies, lamp globes, radiators, valves, automotive parts, aeroplane parts, sanitary receptacles, silk gloves and underwear. Dunkirk was settled

about 1805, incorporated as a village in 1837, with 700 inhabitants, and chartered as a city in 1880. It owes its name to the similarity of its harbour to that of Dunkirk, France.

DUNLIN or OXBIRD (Tringa alpina), one of the commonest of the sandpipers (*q.v.*). It breeds on elevated moors in Europe. N. Asia and N. America and in winter haunts the mud flats and sand banks in large flocks. A smaller species, *T.* schinzi, occurs in parts of Europe. In the breeding season, the male utters a peculiar whistle. A subspecies of the dunlin, the red-backed sandpiper (*Tringa,* or Pelidna, *alpina* sakhalina), is abundant on both the Atlantic and Pacific coasts of North America.

DUNLOP, JOHN BOYD (1840–1921), Scottish inventor, the pioneer of the pneumatic rubber tire, was born on Feb. 5, 1840, on a farm at Dreghorn, Ayrshire. He settled in 1867 as a veterinary surgeon in Belfast, where he had a large and successful practice. In 1887 he constructed a pneumatic tire for his little boy's tricycle. The invention was tested, and patented on Dec. 7, 1888. Two years later production on a commercial scale began, in conjunction with William Harvey Du Cros, by the Pneumatic Tyre and Booth Cycle agency, Belfast. Dunlop made over the patent to Du Cros for a moderate sum, and took 1,500 shares in the company. Some difficulty arose when it was discovered that the principle of the pneumatic tire had been patented in 1846 by an inventor named Thompson, but the company held various accessory patents which enabled them to establish their position. Dunlop himself did not make a great fortune by the invention, as he took no further part in the great developments which followed the sale of the company in 1896 to E. T. Hooley, who refloated it for £5,000,000. Dunlop died in Dublin, where he had an interest in a drapery firm, on Oct. 23, 1921. See Jean McClintock (his daughter), History of *the* Pneumatic Tyre (1923).

DUNLOP RUBBER COMPANY, LTD. In 1888 J. B. Dunlop invented a pneumatic tire which was really a re-invention, the first pneumatic tire having been patented in 1846. A company was registered in Ireland in 1889 to exploit Dunlop's invention with £15,010 issued capital. Prior to Dunlop's invention cycle tires were made of solid rubber. The first pneumatics were received with derision but quickly established their superiority; cycles were made lighter and propulsion was infinitely easier. The motor car benan to use them. In 1896 the Dunlop Pneumatic Tyre Co. was formed with f 5,000,000 capital.

Up to 1899 the Tyre Co. had no rubber mills, but it then acquired a rubber manufacturing company in Birmingham which had a capital of £20,000. The name of the company so acquired was changed to Dunlop Rubber Co., and in 1912 it acquired all the trading rights of the Tyre Co., thus amalgamating the manufacturing and selling in one company. The share and loan capital held by the public in the Dunlop Rubber Co. and its English subsidiaries amounted in 1939 to over £20,000,000. In addition to tires, the company manufactures wheels and rims for motor vehicles of all kinds, aeroplanes and cycles, footwear, clothing. general rubber goods of every description, tennis rackets, tennis and golf balls, and various other sports requisites. In addition to 11 factories in England it owns through subsidiary companies the largest cotton mills in the world (at Rochdale) and rubber estates in Malay with over 85,024 acres planted. There are Dunlop factories in America, France. Germany, Australia, Canada, India, South Africa, Eire, and Japan. (A. T. F.)

DUNMORE, JOHN MURRAY, EARL OF (1732–1809), English governor of Virginia, succeeded to the peerage in 1756. He sat in the House of Lords from 1761 until he became governor of the colony of New York in 1770. In 1771 he was also appointed governor of Virginia. He made himself unpopular by dissolving the assembly in 1772, 1773 and 1774 because of its expression of revolutionary sentiments. Early in 1775 he removed the powder from the magazine at Williamsburg, Va., and thus occasioned the first armed uprising of Virginia. This led him to remove the seat of government to a man-of-war lying off Vorktown. Further disagreements led the burgesses to contend that he had abdicated. Dunmore returned to England in 1776, and in 1787 was made governor of the Bahamas, a post which he held until 1796. Later critics have felt that the Indian War (see POINT PLEASANT) which bears his name was prompted largely by his greed for western land. He died at Ramsgate in May 1809.

See C. W. Alvord, The Mississippi Valley in British Politics (1917) and *Documentary History* of Dunmore's War, edited by R. G. Thwaites and L. P. Kellogg (Madison, Wis., 1905).

DUNMORE, a borough of Lackawanna county, Pa., U.S.A., adjoining Scranton on the north-east. It is served by the Erie, the Lackawanna, and the Lackawanna and Wyoming Valley (electric) railways. The population was 20,250 in 1920 (22% foreign-born white), and it was 23,086 in 1940 by the federal census. Anthracite mining and work on the railroads are the principal occupations. There are also car shops, silk mills, and stove works. The Pennsylvania Oral school is here. Dunmore was settled in 1783 and was incorporated as a borough in 1862.

DUNMOW or GREAT DUNMOW, a market town of Essex. England, on the river Chelmer, 40 mi. N.N.E. from London on a branch from Bishop's Stortford of the L.N.E. railway. Pop. of civil parish (1931) 2,882. The church of St. Mary is Decorated and Perpendicular. The town was corporate from 1556 until 1886. Roman remains have been discovered. The manufacture of baize was introduced there in the 17th century but became extinct. Two miles east is the village of LITTLE DUNMOW. The old church of St. Mary, Little Dunmow, contains some interesting early monuments. Here was buried Robert Fitzwalter, "Marshal of the Army of God and Holy Church," who was leader of the barons who negotiated Magna Carta. It was formerly the seat of an Augustinian priory, remarkable for the custom of presenting a flitch of bacon to any couple who could give proof that they had spent the first year of married life in unbroken harmony. Later in place of the monastic judicature, a jury of six bachelors and six maidens appears in the 16th century. A rhyming oath, quoted by Fuller, was taken. This institution, which had its parallel at Whichanoure (or Wichnor) in Staffordshire, at St. Moleine in Brittany, and apparently also at Vienna, appears to be of very ancient origin. The first recorded instance of its award is in the reign of Henry VI. But there are references which point to it in Piers *Plowman* and Chaucer. The manorial documents relating to it are kept in the church. The custom was revived in 1855 by Harrison Ainsworth, author of the novel The Flitch of Bacon, but the scene of the ceremony was transferred to the old town hall of Great Dunmow. (For details see Chambers' Book of Days, ii. 748–751; and W. Andrews, History of *the Dunmow* Flitch of Bacon *Cus*-tovns, 1877.)

DUNNE, FINLEY PETER (1867–1936), American journalist and humorist of Irish descent, was born in Chicago, Illinois, July 10, 1867, and educated in the public schools. In 1885 he became a newspaper reporter. Later he was a member of the editorial staff of the Chicago *Evening* Post, and of the Chicago *Times-Herald* (1892–97), and editor of the Chicago Journal (1897–1900).

For several years he contributed humorous sketches in Irish brogue to the daily papers, but he did not come into prominence until he wrote for the Chicago *Journal* a series of satirical observations and reflections on social and political topics of the day, attributed to an honest Irish-American, Martin Dooley, the shrewd philosopher of Archey road. They were widely copied by the press of America and England.

The first published collection, *Mr.* Dooley *in* Peace and in War (1898), was followed by several others, similar in subject matter and in method, including Mr. Doaley's Philosophy (1900), Observations by Mr. Dooley (1902), and Mr. Dooley *Says* (1910). These books made their author famous as the creator of a delightfully original character and as a humorist of shrewd insight.

DUNNOCK, a name for the European hedge-sparrow (*Prunella modularis*). (*See* SPARROW.)

DUNOIS, JEAN, COUNT OF (1403–1468), commonly called the "Bastard of Orleans," a celebrated French commander, was the natural son of the duke of Orleans (brother of Charles VI) and Mariette d'Enghien, Madame de Canry. His earliest feat of arms was the surprise and rout in 1427 of the English, who were besieging Montargis—the first successful blow against the English power in France following a long series of French defeats. In 1428 he

defended Orleans with the greatest spirit, and enabled the place to hold out until the arrival of Joan of Arc, when he shared with her the honour of defeating the enemy there in 1429. He then accompanied Joan to Reims and shared in the victory of Patay. After her death he raised the siege of Chartres and of Lagny (1432) and engaged in a series of successful campaigns which ended in his triumphal entry into Paris (April 13, 1436). He gradually drove the English northward; in 1450 he reconquered northern France, and in 1451 attacked the English in Guienne, taking among other towns Bordeaux and Bayonne. In 1465 he joined the league of revolted princes, but, assuming the function of negotiator, he was after a time reinstated in his offices. He died on Nov. 24, 1468.

DUNOON, police burgh and parish (with Kilmun), Argyllshire, Scotland, on the west shore of the Firth of Clyde, opposite to Gourock. Pop. (1931) 8,780. (These figures are increased in the holiday season.) Including Kirn and Hunter's Quay, it presents a practically continuous front of seaside villas, with an esplanade two miles long. The mildness of its climate and the beauty of its situation have made it one of the most prosperous watering-places on the west coast. On a conical hill above the pier stand the remains of Dunoon Castle, the hereditary keepership of which was conferred by Robert Bruce on the family of Sir Colin Campbell of Loch Awe, an ancestor of the duke of Argyll. It was visited by Queen Mary in 1563, and in 1643 was the scene of the massacre of the Lamonts by the Campbells. The grounds have been laid out as a recreation garden. The town itself is modern, having been a mere fishing village at the beginning of the 19th century. There is frequent communication daily by steamer with Glasgow. Hunter's Quay is the yachting headquarters, the Royal Clyde Yacht club's house adjoining the pier. Kilmun, on the northern shore of Holy loch, a portion of the parish of Dunoon and Kilmun, contains the ruins of a Collegiate chapel founded in 1442 by Sir Duncan Campbell of Loch Awe and used as the burial-ground of the Argyll family.

DUNS, burgh of barony, parish and county town, Berwickshire, Scotland. Pop. (1931) 1,788. It is situated 44 m. E.S.E. of Edinburgh by road, with a station on the branch line of the L.N.E.R. from Reston to St. Boswells. Trade in grain and flour is carried on, and stock sales are held. On Duns Law (joo ft.) the Covenanters, under Alexander Leslie, were encamped in 1639, and the Covenanters' Stone on the top of the hill has been enclosed. Duns castle, adjoining the town on the W., includes the tower erected by Thomas Randolph, earl of Moray (d. 1332).

DUNSANY, EDWARD JOHN MORETON DRAX PLUNKETT, 18TH BARON (1878–), Irish dramatist, was born in London on July 24, 1878. He was educated at Eton and Sandhurst, and succeeded his father as 18th Baron Dunsany in 1899. Entering the Coldstream Guards, he served in the Boer War, and, in the Royal Inniskilling Fusiliers, in the World War. As a playwright, he first attracted attention with *The Glittering Gate,* produced in Dublin, 1909. His plays are expressed in richly coloured language. They include: *The Gods of the Mountain* (1911), *A Night at an Inn* (1916), *If* (1921) and *Alexander and other Plays* (192j). He has also written numerous tales in similar style, to be found in, among other volumes: *The Gods of Pegana* (1905); *The .Sword of Welleran* (1908); *Tales of Wonder* (1916); the *Chronicles of Rodriguez* (1922); *Evil Kettle* (1926); *Old King's Tale* (1926).

DUNSINANE, a peak of the Sidlaw hills, in the parish of Collace, Perthshire, Scotland, 8 m. north-east of Perth. It is 1,012 ft. high, and commands a fine view of the Carse of Gowrie and the valley of the Tay. Its chief claim to mention, however, is due to its association with Birnam Wood (about 12 m. N.W.) in two well-known passages in Shakespeare's *Macbeth.* An old fort on the summit, of which faint traces are still discernible, is traditionally called Macbeth's castle.

DUNS SCOTUS, JOHN (*c.* 1265–1308), the famous *doctor subtilis* and the greatest British mediaeval philosopher, was born in the village of Duns, Scotland. He became a Franciscan and studied at Oxford, where shortly after 1290 he lectured on the *Sentences.* He then spent some four years in Paris, and after returning to Oxford, was again, by 1302, lecturer in Paris. There he received the master's licence. He was transferred to Cologne, where he died on Nov. 8, 1308.

Broadly speaking, Scotus, like Bonaventure and Pecham, seeks to defend the traditional Scholastic doctrines against Thomistic innovations (the same desire had already led Bishop Tempier of Paris to condemn in 1277 a number of Thomistic theories), and in so doing, incidentally manifests the scientific bent of the Oxford Franciscan school by his hesitation in accepting what others regard as proof. He is commonly represented only as a destructive critic of St. Thomas, which is to say, as a Franciscan antagonistic to a Dominican, but, in reality, the critical position involved in many of his famous speculations, *e.g.,* his doctrine of the Trinity, his formal distinction in God, the univocacy of being in God and creatures, and the importance of the *species intelligibiles,* applies to the system of Henry of Ghent, while his voluntaristic leanings are a protest against Godfrey of Fontaine's stress on the passivity of the will. His is the legitimate aim of contributing to philosophical speculation by evaluating the theories of others. Again, certain superficial readers have absurdly accused Scotus, whom Thomas Cromwell in the 16th century attacked as the great defender of Scholasticism, of pantheism, scepticism. Pelagianism, indeterminism, excessive realism, subjectivism and a host of other imaginable iniquities. These accusations are due either to the assumption of the genuineness of the *De Rerum Principio,* now rejected by all first-rate scholars, or to a lack of patience in coping with the subtle and extensive writings of Scotus.

Bearing in mind the common doctrines of the Schoolmen (*see* SCHOLASTICISM), the chief points of interest in the metaphysics of Scotus are his rejection of the Augustinian theory of *rationes seminales* in matter, a theory which he regards as uselessly multiplying entities and as destroying the true nature of becoming; his contention that matter is not pure passive potency but has some positive entity of its own and, therefore, by the absolute power of God, could exist apart from form; his denial of the numerical unity of matter in all things; his belief that the form is educed successively from the potency of matter, that the resulting composite has in itself both a universal and an individual nature, the latter, which for Scotus means repugnance to division into subjective parts, being due to none of the factors usually suggested, *e.g.,* negation, existence, accidents, matter and quantity, but to a positive entity *(haecceitas),* an *ultima realitas entis,* which is a unity of *this* matter with *this* form in *this* composite.

In cosmology his two most important doctrines are those which maintain that elements must remain at least virtually in compounds, since they can be regained from them, and that the Ptolemaic system of eccentric and epicycles is necessary to account for the phenomena observable in the movements of the celestial bodies.

In psychology, Scotus naturally upholds the theory of the plurality of forms in man, since he is interested in proclaiming the separability and independence of the rational soul and the body. The soul is created by God and is immortal, though its immortality for Scotus, contrary to the general Scholastic opinion, cannot be positively proved but only supported by possible persuasions. As regards the hylomorphic composition of the soul, a doctrine which had been proclaimed by all his Franciscan predecessors, Scotus neither accepts nor rejects it in his genuine works. The faculties of intellect, will and memory through which the soul acts, are for him, neither really distinct from the soul's essence, for that would imply their separability, nor only logically distinct, for then they would exist *potenfialiter* rather than *actualiter;* they are formally distinct, which is to say, they are inseparably founded in the essence *ex natura rei* and yet cannot be included in the same definition.

His view of cognition is very much the common Scholastic doctrine of moderate realism, except that he stresses the activity of the intellect, including the passive as well as the active intellect, and the importance of induction, that he rejects the Augustinian doctrine of Divine illumination, and that he maintains we have a direct though imperfect intuitive knowledge of singulars. In discussing our knowledge of spiritual beings, he denies that we have

an immediate knowledge of the self and that we can have any other than *a posteriori* proofs for the existence of God. His assertion that the concept of being which we apply to God is univocal with that applied to creatures, is meant to avoid agnosticism by proclaiming that our concept gives us some positive knowledge of the quiddity of being in God. He does not countenance pantheism by supposing that the actual realization of being in God is univocal with created being. All activities of the human intellect are closely related to those of the will, and hence, attention is a *sine qua non* for knowledge, just as much as a known object is essential for an act of will. Nevertheless, if the will requires such direction, it is not determined by the intellect. It is still able to deliberate and it alone must accept or reject. It is just this emphasis on the will which has led to Scotus being called an extreme voluntarist, but, in reality, the necessity of interaction between intellect and will is fully recognized by the subtle doctor, the primacy of the will being more pronounced only in the supernatural life.

In angelology, the chief contributions of Scotus are his indecision as to their hylomorphic composition, his denial that each angel is a complete species, his opinion that, if the angelic beings are capable of development, they must receive *species intelligibles* from externals and must also possess a passive as well as an active intellect, and his assertion that the angelic will has a dependency of activity as regards the intellect but a primacy of nature.

Finally in theodicy, the most important contributions of Scotus are his formal distinction between the Divine attributes and the Divine essence, which means that the attributes can be more than conceptual without imperilling the Divine simplicity; his rejection of Henry of Ghent's *esse essentiae simpliciter* for the existence of things in the mind of God before creation; his support of the Divine knowledge of singulars and of the necessity of interaction between the Divine intellect and will, the latter being limited only according to the distinction between God's absolute power and his ordained power; and lastly his discussion of the unsatisfactory objections both to the theory of the possibility of eternal creation and to that of the necessity of a temporal creation. The teaching of Scotus on the relation between reason and faith is practically that of St. Thomas.

BIBLIOGRAPHY.—The uncritical edition of the works of Scotus by Wadding, 13 vols. (Lyons, 1639) was reprinted at Paris, 26 vols. (1891–95). Of these, as E. Longpré, *La Philosophie du B. Duns Scot* (Paris, 1924), has shown, only the *Opus. Oxon.*, the *Rep. Paris, Quodl. De Primo Principio* and the *Quaestiones* on the *Metaphysics* can be unquestionably accepted as genuine.

As regards the life of Scotus, all that can be said with certainty has been summarized by A. G. Little, "The Franciscan School at Oxford" in *Arch. Fran. Hist.* (1926, p. 869 *sq.*). The most trustworthy accounts of the philosophy of Scotus are to be found in Longpré *(see* above); J. Klein, *Der Gottesbegriff des D. Scotus* (Paderborn, 1913); H. Klug, "Die Lehre des Scotus über Materie und Form" in *Philos. Jahrb.* (1917); P. Minpes, *Ist Duns Scotus Zndeterminirt* (Miinster, 1905) and *Der angeblich exzessive Realismus des Duns Scotus* (Miinster, 1908); R. Seeberg, *Die Theologie des Duns Scotus* (1900); *K.* Werner, *Die Psych. u. Erkenntnislehre des Scotus* (Vienna, 1877) and *Die Scholastik des spateren Mittelalters*, vol. i. (Vienna, 1881). B. Landry, *Duns Scot* (Paris, 1922) is most uncritical, and C. R. S. Harris, *Duns Scotus*, 2 vols. (Oxford, 1927) is largely based on the spurious *De Rerum Principio.* (D. E. SH.)

DUNSTABLE, a municipal borough and market town in the Luton parliamentary division of Bedfordshire, England, 34 mi. N.W. of London, served by the L.N.E. and L.M.S. railways. Pop. (1938) 13,760. Area 2,03j ac. It lies at an elevation of about 500 ft. on the northward slope of the Chiltern hills. The church of St. Peter embodies a fine fragment of the church of the Augustinian priory founded by Henry I including the west front and part of the nave, with rich Early English and Norman details. Foundations of a palace of Henry I are traceable near the church. The main part of the town extends for a mile along the Roman Watling street, while the high road from Luton to Tring, which crosses it in the centre of the town, represents the ancient Icknield way. The straw hat industry which formerly flourished here removed to Luton; but there is an extensive printing works, and brewing, foundry and chain works, besides a manufactory of spark plugs. The borough is under a mayor. 6 aldermen and 12 councillors, and has a separate commission of the peace.

It appears probable that there was a Romano-British village on this site corresponding to the *Forum Dianae* of the Romans. Many interesting fragments have been found, also a walled camp of *c.* A.D. 9, called "Maiden Bower." Dunstable *(Dunestaple, Donestaple)* appears as a royal borough in the reign of Henry I, who in 1331 founded and endowed a priory with the lordship of the manor and borough, which it retained till its dissolution in 1536–37. The *Dunstable Annals* deal exhaustively with the history of the monastery and town in the 13th century. At Dunstable Cranmer held the court which, in 1533, declared Catherine of Aragon's marriage invalid. At the Dissolution a plan was formed for the creation of a new bishopric to include Dunstable as cathedral city. The scheme was never realized, though plans for the cathedral were actually drawn up.

Dunstable has always been an agricultural town. The *Annals* abound with references to the prices and comparative abundance or scarcity of the two staple products, wool and corn. Henry I granted a market and fair, to which John added a second fair. A statute fair and the weekly market are still held. Dunstable had also a gild merchant and was affiliated to London. In 1864 the town was made a municipal borough. It was extended in 1933. Whipsnade, the country branch of the London zoo, was opened in 1931, occupying 500 ac. 33 mi. by road from Dunstable.

DUNSTAN, SAINT (909–988), English archbishop and son of a West Saxon noble, was born near Glsstonbury, where he was educated by the Irish pilgrims. He entered the household of King Aethelstan, but his love of books and of song and his mechanical skill soon excited the dislike of his kinsfolk at the court. Accused of practising the black arts, he took refuge with his kinsman, Alphege, bishop of Winchester, whose persuasion, seconded by a serious illness, induced him to become a monk. Dunstan then lived as a hermit near the old church of St. Mary until Aethelstan's successor, Edmund, recalled him as one of his counsellors. His enemies again procured his expulsion, but Edmund soon revoked the sentence, and about 943 made Dunstan abbot of Glastonbury. Under him the abbey became a famous school, monastic life was revived and St. Peter's re-erected. Edred, the successor of Edmund, left the administration of the realm largely in the control of Dunstan, who sought to establish royal authority, to conciliate the Danish section, to uproot heathenism and to reform the secular clergy and the laity. On the accession of Edwig, however, in 955, Dunstan's fortunes underwent a temporary eclipse. Having given offence to the influential and unprincipled Aelfgifu, he was outlawed and driven to Flanders. But in 957 the Mercians and Northumbrians revolted and chose Edgar as their king. The new king at once recalled Dunstan, who was appointed to the see of Worcester as soon as it fell vacant. In 959 he also received the bishopric of London. In the same year Edwig died and Edgar became sole king. Dunstan now became archbishop of Canterbury. On Edgar's death in 975 the archbishop secured the crown for his elder son, Edward. who was murdered three years later. On the accession of Aethelred Dunstan's public career came to an end; he retired to Canterbury. where he died on May 19, 988.

Dunstan was one of the chief English saints until his glory was overshadowed by Thomas à Becket. He sought to reform monasticism according to the strict observance of the Benedictine rule, which he had seen at the abbey of Blandinium, near Ghent, during his exile under Edwig, and by the re-building of churches and the promotion of education, he endeavoured to uplift his people. In political matters his policy was, as we have said, one of unification and of respect for law.

See *Memorials of St. Dunstan,* edit. *W.* Stubbs in the *Rolls Series* (1874); *Anglo-Saxon Chronicle,* edit. C. Plummer (Oxford, 1892–99); the *Bosworth Pralter,* edit. Bishop and Gasguet (1908); Freeman, *The Norman Conquest,* vol. i. (Oxford, 1870) and J. A. Robinson, *The Times of St. Dunstan* (Oxford, 1923).

DUNSTAN, SIR WYNDHAM ROWLAND (1861–), C.M.G. (1913), K.C.M.G. (1924), English scientist, was born at Chester on May 24, 1861. He was director of the Imperial Institute, London, from 1903 to 1924. Dunstan wrote many chemical papers, notably on the pharmacology of the alkaloids, and on the aconite alkaloids in particular. He was concerned in the identi-

fication of the new mineral, thorianite, which he isolated during an examination of the minerals of Ceylon. An account of the properties, composition and uses of this mineral are given by Dunstan in his parliamentary paper, *Mineral Survey in Ceylon 1903–04* (1905). During his term of office as director of the Imperial Institute, Dunstan visited Cyprus, Asia Minor, India and Newfoundland at the request of the Colonial Office. Reports on agricultural and mineral resources were presented to parliament. Dunstan, a distinguished member of many learned societies connected with science, geography and agriculture, has acted also as a member of a number of Government committees on mineral resources, agriculture, etc.

His works include *British Cotton Cultivation* (1904 and 1908), *Agricultural Resources of Cyprus* (1906), *Agricultural Resources in* Asia *Minor* (1908) and *Cotton Cultivation of the World* (1910)

DUNSTER, a town in the Bridgwater parliamentary division of Somersetshire, England, 1½ mi. from the shore of the Bristol channel, on the Minehead branch of the G.W. railway. Pop. of civil parish (1931) 839. Its streets, sloping sharply, contain many old houses. On an eminence stands the ancient castle, with its two massive gateways of the 13th and 15th centuries and other early portions, though it has been restored and modernized as a residence. The church of St. George, with its fine tower, is mainly Perpendicular, but has Norman and Early English portions. Near the church are traces of the Benedictine house to which it was attached. The Yarn market, a picturesque octagonal building with deep sloping roof, in the main street, dates from *c.* 1600. There were British, Roman and Saxon settlements at Dunster (*Torre Dunestorre, Dunester*), fortified against the piracies of the Irish Northmen. The Saxon fort of Alaric was replaced by a Norman castle, dating from the Domesday Survey, built by William de Mohun, first lord of Dunster, who founded the priory of St. George. Before 1183, Dunster had become a mesne borough, owned by the de Mohuns until the 14th century when it was sold to the Luttrells, the present owners. Reginald de Mohun granted the first charter between 1245 and 1247. John de Mohun granted other charters in 1301 and 1307. Dunster was represented in parliament in conjunction with Minehead, one of its tithings being part of that borough. Representation began in 1562, and was lost in 1832. During this time the port had a considerable wool, corn and cattle trade with Ireland. In the middle ages the Friday market and fair in Whit week, granted by the first charter, were centres for the sale of yarn and cloth called "Dunsters," made in the town. With the silting up of the harbour, its importance as a port disappeared. An 18th century tower on Conegar hill forms a well-known landmark.

See Sir *H. C.* Maxwell Lyte, *Dunster and its Lords* (1882); *Victoria County History, Somerset,* vol. ii.

DUNTOCHER (Gaelic, "The Fort of ill hap"), a small town on Dalmuir Burn, Dumbartonshire, Scotland, 9 m. from Glasgow. The district contains coal, limestone and ironstone, but there is not much mining. There are considerable Roman remains in the neighbourhood. Antoninus' Wall passed immediately to the south; the burn is crossed by a bridge doubtfully alleged to be of Roman origin; subterranean remains indicate a Roman structure; a Roman camp has been traced, and the vicinity has yielded a number of altars, urns, vases, coins and tablets, which are now in the custody of Glasgow university.

DÜNTZER, JOHANN HEINRICH JOSEPH (1813–1901), German philologist and historian of literature, was born at Cologne on July 12, 1813. Educated at Bonn and Berlin he settled in 1837 at Bonn as *Privatdocent* for classical literature. He had already, in his *Goethes Faust in seiner Einheit und Ganzheit* (1836) and *Goethe als Dramatiker* (1837), advocated a new critical method in interpreting the German classics, which he wished to see treated like the ancient classics. In 1846 he became librarian at the Roman Catholic gymnasium in Cologne, where he died on Dec. 16, 1901.

Of his works on the German classical poets, especially on Goethe, Schiller and Herder. may be mentioned *Aus Herders Nachlass* (3 vols., 1856–57); *Schiller und Goethe; Übersicht und Erläuterung zum Briefwechsel zwischen Schiller und Goethe* (1859); *Goethes Leben* (1880; 2nd ed. 1883; Eng. trans, 1884); *Schillers Leben* (1881); *Abhandlungen zu Goethes Leben und Werken* (a vols. 1885).

DUNWICH, a village in the Eye parliamentary division of East Suffolk, England, on the coast, 5 mi. S.S.W. of Southwold. Pop. of civil parish (1931) 174. This was in Anglo-Saxon days the most important commercial centre and part of East Anglia. It was probably a Romano-British site. Early in the 7th century, when Sigebert became king of East Anglia, Dunwich was chosen his capital and became the nursery of Christianity in eastern Britain. A bishopric was founded (according to Bede in 630, while the Anglo-Saxon chronicle gives 635), the name of the first bishop being Felix. Sigebert's reign was notable for his foundation of a school modelled on those he had seen in France; it was probably at Dunwich, but formed the nucleus of what afterwards became the University of Cambridge. By the middle of the 11th century Dunwich had already suffered from an evil which later caused its total ruin, namely the inroads of the sea upon the coast. At the Norman Conquest the manor was granted to Robert Malet. In 1173 the sight of its strength caused Robert earl of Leicester to despair of besieging Dunwich. The town received a charter from King John. In the reign of Edward I it is recorded to have possessed 36 ships and "barks," trading to the North seas, Iceland and elsewhere, with 24 fishing boats, besides maintaining 11 ships of war. The Benedictines, Franciscans and Dominicans all maintained establishments here. In 1347 more than 400 houses were washed away. In 1570, after a terrible storm, appeal was made to Elizabeth. But the old wealthy port was gradually engulfed and inroads of the sea still continue, the ruined tower of the old church having gone over the cliff during World War I. Many relics have been discovered by excavation, and even from beneath the waves. Until 1832 Dunwich returned two members to parliament. The corporation was abolished in 1886, and part of the civil parish was transferred to Southwold in 1934. In the same year a bishopric suffragan to St. Edmundsbury was constituted, receiving the name Dunwich.

DUPANLOUP, FÉLIX ANTOINE PHILIBERT (1802–1878), French ecclesiastic, was born at St. Félix in Savoy on Jan. 3, 1802, and educated at the seminaries of St. Nicolas de Chardonnet and of St. Sulpice, Paris. In 1825 he was ordained priest, and was appointed vicar of the Madeleine at Paris, being for a time tutor to the Orleans princes. He became the founder of the celebrated academy at St. Hyacinthe, and received a letter from Gregory XVI. eulogizing his work there, and calling him *Apostolus juventutis.* He became a canon of Notre-Dame in 1845. When made bishop of Orleans in 1849, he pronounced a fervid panegyric on Joan of Arc, which attracted attention in England as well as France. Before this he had been sent by Archbishop Affre to Rome, and had been appointed Roman prelate and protonotary apostolic. He was a distinguished educationalist who fought for the retention of the Latin classics in the schools and instituted the celebrated catechetical method of St. Sulpice. Among his publications are *De l'éducation* (1850), *De la haute éducation intellectuelle* (3 vols., 1866), *Oeuvres choisies* (1861, 4 vols.); *Histoire de Jésus* (1872), a counterblast to Renan's *Vie de Jésus.* He died on Oct. 11, 1878.

See F. Lagrange, *Life* (Eng. tr. *by* Lady Herbert, 1885) and E. Faguet, *Mgr. Dupanloup* (1914).

DUPERRON, JACQUES DAVY (1556–1618), French cardinal, was born at St. Lô, in Normandy, on Nov. 15, 1556, the son of a Protestant minister, who settled at Berne, Switzerland, where Jacques Davy received his education. Returning to Normandy he abjured Protestantism and took orders. On the death of Henry III., after having supported for some time the cardinal de Bourbon, the head of the league against the king, Duperron became a faithful servant of Henry IV., and in 1591 was created by him bishop of Evreux. He instructed Henry in the Catholic religion; and in 1594 was sent to Rome, where with Cardinal d'Ossat (1536–1604) he obtained Henry's absolution. At the conference at Fontainebleau in 1600 he argued with much eloquence and ingenuity against Du Plessis Mornay (1549–1623). In 1604 he was sent to Rome as *chargé d'affaires.* While still at Rome he was made a cardinal, and in 1606 became archbishop of Sens. In the states-general of 1614 he vigorously upheld the

ultramontane doctrines against the Third Estate. He died in Paris on Sept. 6, 1618.

See *Les Diverses Oeuvres de l'illustrissime Cardinal Duperron* (1622); Pierre Féret, *Le Cardinal Duperron* (1877).

DUPIN, ANDRE MARIE JEAN JACQUES (1783–1865), commonly called Dupin the elder, French advocate, president of the chamber of deputies and of the Legislative assembly, was born at Varzy, in Nièvre, on Feb. 1, 1783. Entering the chamber of deputies in 1815, he joined the Liberal opposition. At the election after the second restoration Dupin was not re-elected. He defended with great intrepidity the principal political victims of the reaction, among others, in conjunction with Nicolas Berryer, Marshal Ney; and in October 1815 published a tractate entitled *Libre Défense des accusés.* In 1827 he was again elected a member of the chamber of deputies and in 1830 actively supported the revolution. At the end of 1832 he became president of the chamber, which office he held successively for eight years. On Louis Philippe's abdication in 1848 Dupin introduced the young count of Paris into the chamber, and proposed him, in vain, as king, with the duchess of Orleans as regent. In 1849 he was president of the committee of the Assembly on legislation. After the *coup d'ktat* of Dec. 2, 1851, he retained his office of *procureur-général,* until effect was given to the decrees confiscating the property of the house of Orleans. In 1857 he was offered his old office by the emperor, and accepted it, explaining his acceptance by the words: "I have always," he said, "belonged to France and never to parties." He died on Nov. 8, 1865. Among Dupin's works, which are numerous, may be mentioned *Principia Juris Civilis,* 3 vols. (1806), *Mkmoires et plaidoyers de 1806 au Ier janvier 1830,* in 20 vols., and *Mkmoires ou souvenirs du barreau,* in 4 vols. (1855–57). But his greatest work was his share in the codification of the laws of the empire, of which he had sole charge after the interruption of the work of the commission after 1815.

His brother, FRANÇOIS PIERRE CHARLES DUPIN (1784–1873), wrote several geometrical works, treating of descriptive geometry after the manner of Monge, and of the theory of curves.

DUPIN, LOUIS ELLIES (1657–1719), French ecclesiastical historian, was born at Paris on June 17, 1657, and educated at the college of Harcourt and the Sorbonne, receiving his B.D. (1680) and D.D. (1684). The first volume of his *Bibliothèque universelle de tous les auteurs ecclésiastiques* appeared in 1686, but the liberty with which he treated the doctrines of the Fathers aroused the prejudice of ecclesiastics, including Bossuet, and, although he consented to a retractation, the book was suppressed in 1696. He was subsequently exiled to Châtellerault as a Jansenist, but the sentence of banishment was repealed on a new retractation. His correspondence with William Wake, archbishop of Canterbury, with a view to a union of the English and Gallican Churches, threw further suspicion upon him. The same zeal for union induced him, during the residence of Peter the Great in France, and at that monarch's request, to draw up a plan for uniting the Greek and Roman Churches. He died at Paris on June 6, 1719. Besides his great work, Dupin wrote a *Bibliothèque universelle des historiens* (2 vols., 1707); *L'Histoire de l'église en abrégé* (1712); and *L'Histoire profane depuis le commencement du monde jusqu'à présent* (4 vols., 1712).

DUPLEIX, JOSEPH FRANÇOIS (1697–1763), governor-general of the French establishment in India, the great rival of Clive (*q.v.*), was born at Landrecies, France, on Jan. 1, 1697. His father, François Dupleix, a wealthy farmer-general, sent him on a voyage to India in 1715 on one of the French East India Company's vessels. He made several voyages to America and India, and in 1720 was named a member of the superior council at Pondicherry. There, in addition to his official duties, he made large ventures on his own account and acquired a fortune. In 1730 he was made superintendent of French affairs in Chandernagore, which he administered with great success, and in 1742 he was appointed governor-general of all French establishments in India. He determined to acquire for France vast territories in India. The British took the alarm; but the danger to their settlements and power was partly averted by the bitter mutual jealousy between Dupleix and La Bourdonnais, French governor of the isle of Bourbon. When Madras capitulated to the French in 1746 Dupleix opposed the restoration of the town to the British thus violating the treaty signed by La Bourdonnais. He then sent an expedition against Fort St. David (1747), which was defeated on its march by the nawab of Arcot, the ally of the British. Dupleix succeeded in gaining over the nawab and again attempted the capture of Fort St. David, but unsuccessfully. A midnight attack on Cuddalore was repulsed with great loss. In 1748 Pondicherry was besieged by the British; but in the course of the operations news arrived of the peace of Aix-la-Chapelle. Dupleix next entered into negotiations which had for their object the subjugation of southern India, and he sent a large body of troops to the aid of two claimants of the sovereignty of the Carnatic and the Deccan. The British were engaged on the side of their rivals. After temporary successes the scheme failed. Though Dupleix was a great organizer, he did not possess Clive's genius for war. The conflicts between the French and the British in India continued till 1754, when the French government, anxious to make peace, sent out to India a special commissioner, Godeheu, a director of the *Compagnie des Indes,* with orders to supersede Dupleix and, if necessary, to arrest him. Dupleix's work was ruined at a blow, and he himself was compelled to embark for France on Oct. 12, 1754. He had spent his private fortune in the prosecution of his public policy; the company refused to acknowledge the obligation; and the government would do nothing for a man whom they persisted in regarding as an ambitious and greedy adventurer, The greatest of French colonial governors died in obscurity and want on Nov. 10, 1763. In 1741 he had married Jeanne Albert (d. 1756), widow of one of the councillors of the company, a woman of strong character and intellect, known to the Hindus as Joanna Begum, who proved of great use to her husband in his negotiations with the native princes. Dupleix defended his case against the company in a Mémoire—*Contre la Compagnie des Indes avec les pièces justicatives* (1751), to which Godeheu replied in his *Lettre à M. Dupleix* (1760).

Malleson, *Dupleix* (1890) and *History of the French in India* (1894); P. Cultru, *Dupleix, ses plans politiques; sa disgrace* (1901); E. Guérin, *Dupleix* (1908); A. A. Martineau, *Dupleix et l'Inde française, 1722–1754,* 3 vols. (Paris, 1920–27).

DUPLICATING MACHINES: *see* OFFICE APPLIANCES.

DUPONT, PIERRE (1821–1870), French song-writer, the son of a blacksmith, was born at Lyons on April 23, 1821. He was brought up in the country by his godfather, a village priest, and apprenticed to a notary at Lyons. In 1839 he found his way to Paris, and some of his poems were inserted in the *Gazette de France* and the *Quotidienne.* Two years later he was saved from the conscription and enabled to publish his first volume, *Les Deux Anges,* through the exertions of a kinsman and of Pierre Lebrun. Gounod's appreciation of his peasant song, "J'ai deux grands boeufs dans mon étable" (1846), settled his vocation as a song-writer. He had to engage Ernest Reyer to write down his airs. He sang his own songs, as they were composed, at the workmen's concerts in the Salle de la Fraternité du Faubourg Saint-Denis; the public performance of his famous *Le Pakz* was forbidden; *Le Chant des ouvriers* was even more popular; and in 1851 he was condemned to seven years' exile. The sentence was cancelled, and for a time Dupont renounced politics. He died at Lyons on July 24, 1870. His songs have appeared in various forms, *Chants et chansons* (3 vols., with music, 1852–1854), *Chants et poésies* (7th ed., 1862), etc. Among the best-known are "Le Braconnier," "Le Tisserand," "La Vache blanche," and "La Chanson du blé."

See Sainte-Beuve, *Causeries du lundi,* iv.; Ch. Baudelaire, *Notice sur P. Dupont* (1849); Déchaut, *Biographie de Pierre Dupont* (1871); Ch. Lenient, *Poesie patriotique en France* (1889), ii. 352 *et seq.*

DU PONT, THOMAS COLEMAN (1863–1930), American manufacturer and statesman, was born at Louisville, Ky., Dec. 11, 1863. He was educated at the Massachusetts Institute of Technology, and entered the Kentucky coal and iron mining industries in 1883. In 1900 he removed to Wilmington, Del.,

being president, 1902–15, of the E. I. du Pont de Nemours Powder company. Appointed senator in July 1321, in place of Josiah O. Wolcott, who had resigned, he failed to secure election on the Republican ticket in 1922, but was successful in 1924. He built a concrete motor highway at a cost of $4,000,000 in the State of Delaware, and made a gift of it to the State.

His cousin, PIERRE SAMUEL DU PONT (1870–), having graduated from the Massachusetts Institute of Technology in 1890, engaged in manufacturing at Wilmington. He became chairman of the board of the E. I, du Pont de Nemours Powder company, and also chairman of the General Motors Corporation. The E. I. du Pont company, which originally confined its activities to the making of explosives, under his guidance engaged in the manufacture of artificial silk, motion-picture films, paints and varnishes.

DUPONT, an anthracite-mining borough of Luzerne county, Pa., U.S.A., half way between Scranton and Wilkes-Barre, on the Lackawanna and Wyoming Valley railroad. The population in 1920 was 4,576 (33% foreign born), and 5,278 in 1940.

DUPONT DE L'ÉTANG, PIERRE ANTOINE, COUNT (1765–1840), French general, born at Chabanais on July 4, 1765, first saw active service as a member of Maillebois' legion in Holland, and in 1791 was on the staff of the Army of the North under Dillon. He rose rapidly, and in the campaign of 1800 he was chief of the staff to Berthier. After the battle of Marengo he defeated the Austrians at Pozzolo. In the campaign on the Danube in 1805, as the leader of one of Ney's divisions, he prevented the escape of the Austrians from Ulm, and so contributed to the subsequent capture of Mack and his whole army (see NAPOLEONIC CAMPAIGNS). At Friedland he won further fame. He entered Spain in 1808 at the head of a corps. After the occupation of Madrid, Dupont, newly created count by Napoleon, was sent to subdue Andalusia, but had to retire on the passes of the Sierra Morena. Pursued and cut off by the Spanish army under Castaños, his corps was defeated and capitulated (Baylen, July 19–23; see PENINSULA WAR). His troops were for the most part raw levies, and ill-luck contributed materially to the catastrophe, but Dupont was deprived of his rank and title, and imprisoned from 1812 to 1814. On April 3, 1814, his nomination as minister of war was confirmed by Louis XVIII., but his portfolio was removed from him on Dec. 3, owing to his incompetence. Appointed commander of the 22nd military division, he lost his post at the return of Napoleon, hut after Waterloo recovered it. After the Second Restoration he was a member of the *conseil privé* of Louis XVIII. From 1815 to 1830 he was deputy for the Charente. He lived in retirement from 1832 till his death in Paris on March 8, 1840.

Amongst the writings Dupont left are some poems, including *L'Art* de la *guerre* (1838), and verse translations from Horace (1836), and some military works.

See Lieut.-Col. Titeux, *Le Général Dupont: une erreur historique* (1903).

DUPONT DE L'ÉURE, JACQUES CHARLES (1767–1855), French lawyer and statesman, was born at Neubourg, Eure, in Normandy, on Feb. 27, 1767. In 1789 he was an advocate at the parlement of Normandy. In 1798 he was a member of the Council of Five Hundred, and in 1813 he became a member of the Corps Législatif. During the Hundred Days he was vice-president of the chamber of deputies, and when the allied armies entered Paris he was one of the commissioners to negotiate with the allied sovereigns. From 1817 till 1849 he was uninterruptedly a member of the chamber of deputies, acting consistently with the liberal opposition. For a few months in 1830 he held office as minister of justice, but resigned before the close of the year and resumed his place in the opposition. At the revolution of 1848 Dupont de l'Eure was made president of the provisional assembly as being its oldest member. He died at Rouge-Peniers, Eure, on Mar. 2, 1855. His fidelity to the cause of constitutional Liberalism won for him the name of the Aristides of the French tribune.

DU PONT DE NEMOURS, PIERRE SAMUEL (1739–1817), French economist and statesman, one of the founders of the school of "Physiocrats," was born at Paris on Sept. 14, 1739. He became intimate with François Quesnay, Turgot and other leaders of the school known as the "economists," and advocated their doctrine of free trade in his Exportation et importation *des* grains (1764). The Physiocratic School (*q.v.*) took its name from Du Pont's treatise, Physiocratie, ou constitution *naturelle du* gouvernement *le* plus *avantageux* au geare *humain* (1768). An admirably clear expression of the doctrine is given in his De *l'origine et* des *progrès d'une* science nouvelle (1767). Du Pont aided Turgot during his brief period of office (1774–76). He was recalled from retirement by Vergennes in 1782 to negotiate with the English commissioner, Dr. James Hutton, for recognition of the independence of the United States (1782), and to prepare a treaty of commerce with Great Britain (1786). Under Calonne he became councillor of State, and was appointed commissary-general of commerce.

Du Pont was a member of the states-general, and then of the Constituent Assembly, of which he was elected president on Oct. 16, 1790. But after Aug. 10, 1792, when he took the side of the king, he was driven into hiding. He was eventually arrested and imprisoned in La Force (1794). The death of Robespierre saved him from the guillotine. As a member of the Council of Five Hundred, Du Pont was a leader of the reaction. After the republican triumph on the 18th Fructidor (Sept. 4), 1797 his house was sacked by the mob, and in 1799 he emigrated to the United States. Jefferson requested him to prepare a scheme of national education, which was published in 1800 under the title *Sur l'éducation* notionale *dans les Etats-Unis d'Amérique.* Though the scheme was not carried out in the United States, several of its features have been adopted in the existing French code. On his return to France in 1802 he was elected to the *Institut.* In 1814 he was secretary to the provisional Government, and on the restoration he was made a councillor of State. In 1815 he returned to America, and died at Eleutherian Mills near Wilmington, Delaware, on hug. 6, 1817.

The powder-mills founded by his son Eleuthère at Wilmington, brought the family considerable wealth. Du Pont's grandson, Admiral Samuel Francis Du Pont (1803–65), played a conspicuous part as a U.S. naval officer in the American Civil War.

See Schelle, *Du Pont de Nemours et l'école physiocratique (1888).*

DU PONT DE NEMOURS AND COMPANY, E. I., organized in 1802 as a gunpowder company, has developed into a world-known chemical manufacturing corporation with 80 factories in 2; States and with connections in many foreign countries. Among the products of the company are explosives, acids and chemicals, synthetic ammonia, industrial alcohols, dyes, lacquers, paints, pigments, coated fabrics, rayon, cellulose film, photographic film and plastics. Its explosives have helped to build canals. railroads, highways and tunnels, and to extract coal, oil and minerals. Its dyes, nitrogen products, camphor, neoprene chemical rubber and nylon have contributed importantly to the nation's self-sufficiency. It has been the chief source of military explosives in all wars of the United States since 1802, and in the World War of 1914–18 it supplied 40% of the explosives used by the Allies. Since then, however, less than 2% of its income has been derived from military sales. It has had eight presidents, all members of the du Pont family. Headquarters are at Wilmington, Del., the site of the original powder plant, long since abandoned, built by Eleuthère Irénée du Pont de Nemours, its founder. nho had learned to manufacture powder in the French Government factory. (L. DU P.)

DU PONT HIGHWAY: see COLEMAN DU PONT ROAD.

DUPORT, JAMES (1606–1679), English classical scholar, was born in Cambridge. In 1639 he was appointed regius professor of Greek there, in 1664 dean of Pcterborough, and in 1668 master of Magdalen college. Throughout the Civil War, in spite of the loss of his clerical offices and eventually of his professorship, Duport continued his lectures. He is best known by his Homeri *gnomologia* (1660), a collection of the aphorisms in the Iliad and Odyssey, illustrated by quotations from the Bible and classical Literature. His other published works chiefly consist of translations (from the Bible and Prayer Book into Greek) and short original poems (Norae *subsecivae* or *Stromata* and *Sylvae*;

Duport did much to keep alive the study of classical literature in his day.

The chief authority for the life of Duport is J. H. Monk's "Memoir" (1825); *see* also Sandys, *Hist. Class. Schol.* (1908), ii. 349.

DUPPLIN MOOR, scene of the battle of Dupplin, Aug. 9, 1332. This battle is of importance not only as the turning point in the Scottish Wars but as the birthplace of the tactics which gained the English victories later against France in the Hundred Years War (*q.v.*). The series of defeats suffered by Edward II. in Scotland, and the initial failure of Edward III., had led to the Peace of Northampton. As a consequence, the Scottish supporters of the Plantagenets were disinherited. but, headed by Edward Baliol and Henry de Beaumont, they organized an expedition to regain their fiefs. Edward III., bound by the treaty, not merely refused help but prohibited them from crossing the border. Not to be baulked, they collected a small force of English archers and men-at-arms, hired ships, and, sailing from Ravenspur, landed at Kinghorn in Fife. Thence they marched on Perth but were met at the river Earn by a large Scottish army under the earl of Mar. Trying to discount their inferiority by the use of surprise, the "disinherited" crossed the river under cover of darkness and made an audacious night onslaught on the rear of the Scottish camp. But this only affected part of the enemy's bivouac, and at day-break the main force moved out in battle order to swamp their puny adversary. The "disinherited" fell back to the slopes of Dupplin muir, and there the knights and men-at-arms dismounted to form a phalanx of spears, while the archers spread out in a dispersed line amid the heather on either flank. Only 40 men-at-arms were kept mounted as a reserve. The Scottish, all dismounted according to their custom, charged direct at the opposing men-at-arms, disregarding the archers. Once spears were locked the charge lost impetus and the archers, closing in from either side, poured a hail of arrows into the press, which grew ever denser until the close-locked mass became helpless to use their weapons. Held in front and galled on both flanks, those who could, broke away and fled, pursued by the "disinherited" horse, and those in the centre fell easy victims.

See J. E. Morris, *Eng. Historical Review* (1897); Oman, *History of the Art of War in the Middle Ages* (1924).

DU PRAT, ANTOINE (1463–1535), chancellor of France and cardinal, was born at Issoire on Jan. 17, 1463. He began life as a lawyer, and rose rapidly in the legal hierarchy owing to the influence of his cousin Antoine Bohier, cardinal archbishop of Bourges. In 1507 he became first president of the parlement of Paris. Louise of Savoy had employed him as her adviser in her affairs, and had made him tutor to her son. When Francis I. ascended the throne he made Du Prat chancellor of France. During the regency of Louise of Savoy he, together with Florimond Robertet, was at the head of affairs. After the death of his wife in 1507 Du Prat had taken orders; he received the bishoprics of Valence, Die, Meaux and Albi, and the archbishopric of Sens (1525); in 1527 he became cardinal, and in 1530 papal legate. He was a determined adversary of the Reformation. He died at Nantouillet on July 9, 1535.

See the marquis Du Prat, *Vie d'Antoine* Du *Prat* (1857).

DUPRE, GIOVANNI (1817–1882), Italian sculptor, born in Siena on March 1, 1817. After having learned the craft of his father, a carver in wood, he worked in Siena, Pistoia, Pisa, Livorno and in Florence, where he associated with the sculptor Cambi. By drawing and modelling in his spare time he succeeded in winning the prize-competition of the academy in 1840 without having attended the academy schools. His first work of importance was "Abel" (1842, Pitti, Florence). It attracted much notice. He was befriended by L. Bartolini, a distinguished sculptor; the grand-duchess Maria of Russia commissioned him with a statue of "Cain" (1844, Pitti); the grandduchess of Tuscany with "Giotto" (1845, Arcades of the Uffizi, Florence). The mourning Sappho (1857) is his most famous work of this period. His success was due to his lifelike and original interpretation of form at a time when Italian sculpture was deteriorating into a mannered imitation of Canova. A visit in 1856 to Naples and Rome, where he admired Canova's monument to Pius VI., influenced him towards a more ideal conception of form, contrasting with the naturalism of his early period. Among his later work we may mention a "Pieta" in the cemetery of Siena, executed for the Bichi-Ruspoii family and the monument of Cavour in Turin. His realistic treatment of form here seems to conflict with the allegorical elements of the composition. Dupre also executed many portrait busts. He died in Florence on Jan. 10, 1882.

His autobiography *Pensieri sull' Arte e Ricordi Autobiographici* (1882) was translated into English by Peruzzi.

DUPRÉ, JULES (1811–1889), French painter, and one of the chief members of the Barbizon group of romantic landscape painters, was born at Nantes, and died at L'Isle Adam, Oct. 6, 1889. If Corot stands for the lyric and Rousseau for the epic aspect of the poetry of nature, Dupré is the exponent of her tragic and dramatic aspects. He was the son of a porcelain manufacturer and started his career in his father's works, whence he went to his uncle's china factory at Sèvres. Dupré exhibited first at the Salon in 1831, and three years later was awarded a second-class medal. In the same year he came to England, where he was deeply impressed by the genius of Constable. From him he learnt how to express movement in nature; and the district of Southampton and Plymouth, with its wide, unbroken expanses of water, sky and ground, gave him good opportunities for his special gifts. Late in life he changed his style, and gained appreciably in largeness of handling and arrived at greater simplicity in his colour harmonies. Among his best known works are the "Morning" and "Evening" at the Louvre, the early "Crossing the Bridge" in the Wallace collection, and the "River Scene" now in the Tate Gallery, London.

See Jules Claretie, *Peintres et sculpteurs contemporains* (2nd series, 1884).

DUPUIS, CHARLES FRANÇOIS (1742–1809), French author and politician, was born of poor parents at Trye-Château, near Gisors. He represented Seine-et-Oise in the Convention, was secretary to the Assembly in An III. and a member of the Council of Five Hundred in An IV. After the 18th Brumaire he was a member of the Legislative Body, eventually becoming its president. In 1781 he had published a memoir on the origin of the signs of the zodiac, which he placed in Upper Egypt, and on the connection with the whole fabric of the mythology of the ancients His chief work, *Origine de tous les cultes* (3 vols., 1795), developing his theories, aroused a bitter controversy, and was one of the factors which led Napoleon to send a scientific expedition to Upper Egypt. The *Origine* passed through many editions (modern ed. 1876), and the author himself published an abridged edition in 1798. Dupuis died on Sept. 29, 1809.

DUPUY, CHARLES ALEXANDRE (1851–1923), French statesman, born at Le Puy (Haute Loire) on Nov. 5, 1851. In 1885 he was elected to the chamber as an Opportunist Republican, and became minister of public instruction in Ribot's cabinet, in 1892. In April 1893 he formed a ministry himself, but resigned at the end of November, and on Dec. 5 was elected president of the chamber. During his first week of office the anarchist Vaillant, who had gained admission to the chamber, threw a bomb at the president, and M. Dupuy's collected bearing, and his historic words: "Messieurs, la séance continue," gained him much credit. In May 1894 he again became premier and minister of the interior; and he was by President Carnot's side when the latter was assassinated at Lyons in June. His cabinet remained in office till January 1895; it was under it that Captain Dreyfus (*q.v.*) was arrested and condemned (Dec. 23, 1894). In November 1898, after Brisson had at last remitted the case to the judgment of the court of cassation, Dupuy formed a cabinet of Republican concentration. It was no sooner discovered that the judges were likely to decide in favour of Dreyfus than Dupuy proposed a law in the chamber transferring the decision to a full court of all the divisions of the court of cassation. This arbitrary act, though adopted by the chamber, was at once construed as a fresh attempt to maintain the judgment of the first court-martial; but the whole court of cassation decided that there must be a new court-martial, and Dupuy at once resigned (June 1899). In June 1900 he was elected senator for the Haute-Saône. He died in 1923.

DUPUY, PIERRE (1582–1651), French scholar, otherwise known as PUTEANUS, was born at Agen (Lot-et-Garonne). In 1615 he was commissioned by Mathieu Molé, first president of the parlement of Paris, to catalogue the "Trésor des chartes." His ms. inventory is preserved in the original and in copy in the Bibliothèque Nationale, and transcriptions are in the national archives in Paris, at the record office in London, and elsewhere. Dupuy and his brother then bought from Rigault the post of keeper of the king's library, and drew up a catalogue of the library. He was author of some important books, written from the Gallican standpoint, on the history of the relations of Church and State in the middle ages. Dupuy died in Paris on Dec. 14, 1651.

DUPUY DE LOME, STANISLAS CHARLES HENRI LAURENT (1816–1885), French naval architect, the son of a retired naval officer, was born at Ploemeur, near Lorient, on Oct. 15, 1816. He entered the École Polytechnique in 1835, and in 1842 was sent to England to study and report on iron shipbuilding. Acting on his report, which was published in 1844, the Government built their first iron vessels under his supervision. He planned and built the steam line-of-battle ship "Napoléon" (1848–1852), and devised the method of altering sailing ships, of the line into steamers, which was afterwards extensively practised in both France and England. He also showed the practicability of armouring the sides of a ship, and the frigate "Gloire" gave a very clear demonstration of his views. It was the beginning of a great change in the construction of ships. At the beginning of the Franco-German War Dupuy sat on the committee of defence, and during the siege of Paris planned a steerable balloon, for carrying out which he was given a credit of 40,000 fr ; but the balloon was not ready till a few days before the capitulation. In 1877 he was elected a senator for life. He died in Paris on Feb. 1, 1885.

DUQUE DE ESTRADA, DIEGO (1589–1647), Spanish memoir writer, soldier and adventurer, was born at Toledo. He left a book of amazingly vivid memoirs, entitled *Comentarios* de el *Desengañado* de *si* Mismo, *prueba* de todos estados, y *elección del* Mejor de ellos—"The Commentaries of one who knew his own little worth, the touchstone of all the states of man, and the choice of the best."

The memoirs have been reprinted by Don Pascual de Gayangos in the Memorial histdrico *español,* vol. xii. (1860).

DUQUESNE, ABRAHAM, MARQUIS (1610–1688), French naval officer, was born at Dieppe in 1610. He spent his youth in the merchant service, and captured the island of Lerins from the Spaniards in May 1637. About the same time his father was killed in an engagement with the Spaniards, and the news raised his hatred of the national enemy to the pitch of a personal and bitter animosity. He distinguished himself in the engagement at Guetaria (1638), the expedition to Corunna (1639) and in battles at Tarragona (1641), Barcelona (1643) and the Cabo de Gata. Serving as a volunteer in the Swedish service in 1643, he defeated the Danish fleet near Gothenburg and thus raised the siege of the city. The Danes returned to the struggle with increased forces under the command of King Christian in person, but they were again defeated—their admiral being killed and his ship taken. On the conclusion of peace between Sweden and Denmark in 1645, Duquesne returned to France. The revolt at Bordeaux, supported as it was by material aid from Spain, gave him the opportunity of at once serving his country and gratifying his long-cherished hatred of the Spaniards. In 1650 he fitted out at his own expense a squadron with which he blockaded the mouth of the Gironde, and compelled the city to surrender. Peace with Spain was concluded in 1659, and Duquesne was then occupied in suppressing piracy in the Mediterranean. On the revolt of Messina from Spain, he was sent to support the insurgents, and encountered the united fleets of Spain and Holland under the command of de Ruyter. After several battles, in which the advantage was generally on the side of the French, a decisive engagement took place near Catania (April 20, 1676), when the Dutch fleet was totally routed and de Ruyter mortally wounded. The greater part of the defeated fleet was afterwards burned in the harbour of Palermo, where it had taken refuge, and the French thus secured the undisputed command of the Mediterranean. For this service Duquesne received a letter of thanks from Louis XIV., together with the title of marquis and the estate of Bouchet. His last achievements were the bombardment of Algiers (1682–83), to effect the deliverance of the Christian captives, and the bombardment of Genoa in 1684. He retired from service in 1684, on the ground of age and ill-health. It is probable also that he foresaw the revocation of the Edict of Nantes, which took place in the following year. He died in Paris on Feb. 2, 1688.

See Jal, Abraham Duquesne, et la marine de son temps (1873).

DUQUESNE, a city of Allegheny county, Pa., U.S.A., on the Monongahela river, 12m. S.E. of Pittsburgh; served by the Pennsylvania railroad. The population was 19,011 in 1920, of whom 5,790 were foreign-born white (largely from central and eastern Europe), and was 20,693 in 1940 by the federal census. It is an important steel-manufacturing centre, with a total production in 1940 of about 1,200,000 gross tons of pig iron, 1,500,000 tons of ingots and 950,000 tons of merchant bars. Duquesne was settled in 1885, incorporated as a borough in 1891 and chartered as a city in 1917.

DU QUOIN, a city of Perry county, Ill., U.S.A., in the fertile agricultural and coal-mining region southeast of St. Louis; on federal highway 51 and state highways 153 and 154 and the Illinois Central railroad. The population was 7.285 in 1920 (86% native white) and was 7,515 in 1940 by the federal census. It is a shipping point for coal, grain, livestock, fruit and the home of the Du Quoin state fair. Its manufacturing industries include machine shops, a dairy and bottling and a meat-packing plant. The largest strip coal mines in the country are there. The city was settled about 1845 and incorporated in 1860.

DURALUMIN. An aluminium alloy discovered by A. Wilm and originally made at Diiren in Germany. It possesses the valuable property of being greatly strengthened by heat treatment, as steel is hardened by quenching and tempering. In addition to 94% aluminium, 4% of copper and 1% of manganese, duralumin contains 1% of magnesium and owes its special qualities to the association of the last-named component with the silicon always present in aluminium as an impurity. (For a brief explanation see ALUMINIUM ALLOYS.) The original composition has been varied, manganese being sometimes eliminated and sometimes replaced by iron, nickel or chromium, but magnesium and silicon remain as essential constituents, while copper, which itself confers somewhat similar properties on aluminium (see ALUMINIUM ALLOYS), is also generally retained. Special trade names have been applied to some of these later alloys and the whole class is now frequently known as the "Strong Aluminium Alloys."

In the normal state these alloys are soft and ductile and may be rolled into sheets and bars or drawn into tubes, angles, etc. Such work hardens them, as all metals, but leaves them like many aluminium alloys, unduly subject to corrosion. Annealing at about 400°C. removes this "work hardness," but if the alloys be heated to temperatures which vary with the alloy and its intended use from 450°C.–550°C. and are then plunged into water, although at first softened and, therefore, still capable of being worked, hardening soon commences and continues for several days. By reheating at about 200°C. the hardening process can be hastened.

Heat treated duralumin is comparatively resistant to corrosion. It is ductile (elongation 8–15%), will bear a load of 30,000lb. per square inch without permanent distortion and breaks under a load of 55,000–62,000 lb. per square inch.

As the alloys are light (sp.gr.=2.8j) their strength per unit of weight (specific tenacity) is high (9·3) compared with nickel steel (5.9) and nickel chrome steel (7.2). These properties make them particularly suitable for aircraft construction, for which they have been used to a very great extent. It may be said that the development of the rigid airship would have been impossible without duralumin, which is used throughout for the framework of these gigantic craft (see illustration in article AIRSHIP), whilst all-metal heavier-than-air machines also depend on these alloys. Connecting rods forged from duralumin find favour for internal combus-

tion engines, whilst an alloy in which nickel replaces manganese (Y alloy) is used for the pistons of the large Diesel engines of submarines, for which it is particularly suited, because it can be cast to shape and retains its strength at comparatively high temperatures.

Like aluminium and its other alloys duralumin cannot be effectively soldered since joints so made corrode rapidly, nor can it be welded without losing the special properties to which it owes its utility.

To all ordinary fabricating processes as spinning, pressing, riveting, machining, etc., duralumin lends itself perfectly.

For a full account of these alloys see R. J. Anderson, *The* Metallurgy of *Aluminium and Aluminium Alloys,* where an extensive bibliography will be found. (R. S.)

DURAN, a Jewish Provencal family of rabbis and scholars. of whom the following are the most important: —

1. PROFIAT DURAN, called also EPHODI.

He was in 1391 compelled to profess Christianity, but remained devoted to Judaism. His chief works were grammatical and philosophical In the former realm his most important contribution was the *Ma'aseh 'Ephod* (completed in 1403); in the latter, his commentary to the Guide of the Perplexed by Maimonides (*q.v.*).

2. SIMON BEN ZEMAH DURAN (1361–1441), rabbi of Algiers. He was one of the first of the mediaeval rabbis to be a salaried official of the synagogue. Before the 14th century the rabbinical post had been almost invariably honorary, and filled by men who derived their income from a profession, especially medicine. Duran wrote a systematic work on theology, *Magen 'Aboth,* but is chiefly famous for his numerous Responsa (known as Tashbaz), published in 1738–39, which gives valuable information as to social and religious conditions of his day. (I. A.)

DURÁN, AGUSTIN (1789–1862), Spanish scholar, was born in 1789 at Madrid, where his father was court physician. He was sent to the seminary at Vergara. He studied philosophy and law at the University of Seville, and was admitted to the bar at Valladolid. He held a post in the education department at Madrid (1821–23), but was suspended on account of his political opinions. In 1834 he became secretary of the board for the censorship of the press, and shortly afterwards obtained a post in the national library at Madrid. The revolution of 1840 led to his dismissal; but he was reinstated in 1843, and in 1854 was appointed chief librarian; he retired, however, in the following year. In 1828 he published anonymously his *Discurso sobre* el *influjo* que *ha* tenido la *crítica* moderna en la decadencia det teatro *antiguo,* which greatly influenced the younger dramatists of the day. He next endeavoured to interest his fellow-countrymen in their ancient, neglected ballads, and in the forgotten dramas of the 17th century. His Romancero general was published in 5 volumes (1828–32; later ed. 2 vols., 1849–51); Talia *española* (1834) is a reprint of old Spanish comedies. Durán's Romancero *general* is the fullest collection of the kind.

DURANCE (anc. Druentia), one of the principal rivers draining the French slope of the Alps towards the Mediterranean. Its total length from its source in the High Alps of Dauphin6 to its junction with the Rhône, a little below Avignon, is 217½ miles It is commonly said to take its origin in some small lakes a little south of the Mont Genèvre pass, but has two other head streams of much greater length and volume. These are the Clairée, flowing in from the north, through the smiling Névache glen, at the head of which, not far from the foot of the Mont Thabor (10,440 ft.) it rises in some small lakes, on the east side of the Col des Rochilles; and the Guisane (flowing in from the north-west and rising near the Col du Lautaret, 6,808 ft.). Between its junction with the Cerveyrette and the Gyronde the Durance passes throcgh fine deeply-cut gorges. It then runs through a stony plain, where it frequently overflows and causes great damage, this being indeed the main characteristic of the Durance throughout its course. At the foot of the fortress of Mont Dauphin and some distance above the town of Embrun, it receives (left) the Guil, which flows through the Queyras valley from near the foot of Monte Viso. It becomes the boundary for a while between the departments of the Hautes-Alpes and of the Basses-Alpes, and receives the considerable Ubaye river, flowing from near the foot of Monte Viso past Barcelonnette (left).

Flowing through the Basses-Alpes it is joined above Sisteron (right) by the wild torrent of the Buech, flowing from the desolate region of the Dévoluy, the Bléone (left) (on which Digne, the capital of the department, is situated) and the Asse (left). The Verdon, flowing past the town of Castellane, joins it from the lower summits of the Maritime Alps. After passing through some narrow gorges near Sisteron the bed of the river becomes wide and liable to flood, the frequent overflows being kept within bounds by numerous dykes and embankments. These features are especially marked when the river, after leaving the Basses-Alpes, bends north-west and, always serving as the boundary between the departments of Vaucluse (north) and of the Bouches-du-Rhône (south), passes Cavaillon above its junction with the Rhône. The drainage area of the Durance is about 5,166 sq.m., while the height it descends is 6,550 ft., if reckoned from the lakes on the Mont Genèvre, or 7,850 ft. if we take those at the head of the Névache valley as the true source of the river.

DURAND, ASHER BROWN (1796–1886), American painter and engraver, was born at South Orange (N.J.), on Aug. 21, 1796. He worked with his father, a watchmaker; was apprenticed, in 1812, to an engraver named Peter Maverick; and his first work, the head of an old beggar after Waldo. attracted the attention of the artist Trumbull. Durand established his reputation by his engraving of Trumbull's "Declaration of Independence." After 1835, however, he devoted himself chiefly to portrait painting. He painted several of the presidents of the United States and many other men of political and social prominence.

In 1840 he visited Europe, where he studied the work of the old masters; after his return he devoted himself almost entirely to landscape. He died at South Orange on Sept. 17, 1886. He was one of the founders of the National Academy of Design in 1826, and was its president in 1845–61. Durand may be called the father of the Hudson River school. Although there was something hard and unsympathetic about his landscapes and unnecessary details and trivialities were over-prominent, he was a well-trained craftsman, and his work is marked by sincerity.

DURAND, GUILLAUME (DURANTI or DURANTIS) (*c.* 1230–1296), French canonist and liturgical writer, and bishop of Mende, was born at Puimisson, near Beziers. He studied law at Bologna, and about 1264 was teaching canon law at Modena. Clement IV. called him to the pontifical court as a chaplain and auditor of the palace, and in 1274 he accompanied Gregory X. to the Council of Lyons, the constitutions of which he helped to draw up. Martin IV. made him vicar spiritual in 1281, then governor of Romagna and of the March of Ancona (1283). In the midst of the struggles between Guelphs and Ghibellines, Durand successfully defended the papal territories, both by diplomacy and by arms. Honorius IV. retained him in his offices, and although elected bishop of Mende in 1286, he remained in Italy until 1291. In 1295 he refused the archbishopric of Ravenna, and in 1296 retired to Rome, where he died on Nov. 1.

Durand's principal work is the *Speculum* judiciale, which was drawn up in 1271, and revised in 1286 and 1291 (best ed. Turin, 1578). It is a general explanation of civil, criminal and canonical procedure, and also includes a survey of the subject of contracts. It is a remarkable synthesis of Roman and ecclesiastical law, distinguished by its clarity, its method, and especially its practical sense, in a field in which it was pioneer, and its repute was as lasting in the courts as in the schools. His Rationale *divinorum officiorum,* on the origin and symbolic sense of the Christian ritual, written before 1286, is one of the authorities on the Western liturgy (latest ed. Naples, 1866). The other important works of Durand comprise a *Repertorium juris canonici* (*Breviarium* aur*eum*), a collection of citations from canonists on questions of controversy, a *Commentarius in* sacrosancturn Lugdunense *concilium* (ed. 1569), of especial value owing to the share of Durand in the elaboration of the constitutions of this council (1274), and inserted by Boniface VIII. in the *Sextus.*

Durand's nephew, also named GUILLAUME DURAND (d. 1330),

and also a canonist, was rector of the university of Toulouse and succeeded his uncle as bishop of Mende. He wrote in 1311, in connection with the Council of Vienne, *De modo celebrandi concilii et corruptelis in Ecclesia reformandis.*

On the elder Durand *see* V. Leclerc in *Histoire littéraire de la France*, vol. xx. pp. 411–497 (1842); Schulte, *Geschichte der Quellen des canonischen Rechts* (1877); E. Male, *L'Art religieux au XIIIe siècle* en *France* (1898). On the nephew *see* B. Hauréau, in *Journal des savants* (1892).

DURAND, GUILLAUME (Durandus of St. Pourqain) (d. 1332), French scholastic theologian, known as *Doctor Resolutissimus,* was born at St. Pourqain, Auvergne. He entered the Dominican order at Clermont, and in 1313 was made a doctor in Paris, where he taught till Pope John XXII. called him to Avignon as master of the sacred palace, *i.e.,* theological adviser and preacher. He subsequently became bishop of Limoux (1317), of Le Puy (1318) and of Meaux (1326). He composed a commentary on the Sentences of Peter Lombard (Paris, 1508, etc.), in which, breaking with the moderate realism of Aquinas, he anticipated the *terminism* of William of Occam. Singularity alone exists in things, and is known immediately by the intellect. From this it follows that the active intellect, which is supposed to abstract universals, is superfluous and the problem of individuation absurd. Durand also denied a distinction between essence and existence, and opposed the realms of reason and faith. In the question of the beatific vision, arising out of opinions promulgated by John XXII. (*q.v.*), he sided with Thomas Walleis, Armand de Bellovisu and the doctors of Paris against the pope, and composed his *De statu animarum sanctarum.* Mention should also be made of his *De jurisdictione ecclesiastica et de legibus* (Paris, 1506).

See B. Hauréau, *Histoire de la philosophie scolastique* (1880); C Werner, *Die Scholastik des spateren Mittelalters,* vol. ii. (1883); J. Koch, *Durandus de S. Porciano,* O.P. (Miinster, 1927).

DURAWDO, GIACOMO (1807–1894), Italian general and statesman, was born at Mondovi in Piedmont. He was implicated in the revolutionary movements of 1831 and 1832. In 1848 he was one of those who asked King Charles Albert for the constitution. On the outbreak of the war with Austria he commanded the Lombard volunteers, and in the campaign of 1849 he was aide-de-camp to the king. He was elected member of the first Piedmontese parliament and was a strenuous supporter of Cavour; during the Crimean campaign he took General La Marmora's place as war minister. In 1855 he was nominated senator, lieutenant-general in 1856, ambassador at Constantinople in 1859, and minister for foreign affairs in the Rattazzi cabinet two years later. He was president of the senate from 1884 to 1887, after which year he retired from the army.

His brother, GIOVANNI DURANDO (1804–1869), also spent his early life abroad. Returning to Italy on the outbreak of the revolution of 1848, he was appointed commander of a division of the pontifical forces, and fought against the Austrians in Venetia until the fall of Vicenza, when he returned to Piedmont as major-general. In the campaign of 1849 he commanded the first Piedmontese division; he subsequently served in the Crimea, in the war of 1859, and in that of 1866 as commander of the I. Army Corps.

DURANGO, a city of south-western Colorado, U.S.A., 6,525ft. above sea-level; the county seat of La Plata county. It is on federal highways 160 and 550, and is served by the Denver and Rio Grande Western and the Rio Grande Southern railways. The population was 5,400 in 1930, and u-as 5,887 in 1940 by the federal census. Durango is the trading centre of a wide area, rich in coal, oils, metals and timber. Its manufacturing industries include a smelter and ironworks. The Durango national forest (3,000,000 ac.) is 11 mi. N.; and 60 mi. W. is the Mesa Verde national park, containing the most notable prehistoric cliff dwellings in the United States. At Hesperus (8 mi. W.) is the Fort Lewis School of Agriculture, a branch of the state agricultural college. The city was incorporated in 1880, four years after Colorado was admitted to statehood.

DURANGO, a state of northern Mexico, bounded north by Chihuahua, east and southeast by Coahuila, south by Zacatecas and the state of Nayarit, and west by Sinaloa. Pop. (1895) 292,549; (1937) 467,360. Area 47,692 sq. miles. Durango is a continuation southward of the high, semi-arid plateau of Chihuahua, with the Sierra Madre extending along its western side. The rainfall is very light in the eastern part of the State, a succession of years sometimes passing without any precipitation whatever, but in the west it is sufficient to produce good pasturage and considerable areas of forest. There are no rivers of any magnitude in the State. The largest are the Rio Nazas, and the Mezquital. The climate is generally dry and healthy. Cotton is produced to a limited extent, especially where irrigation is employed, and wheat, Indian corn, tobacco, sugar-cane and grapes are also grown. In the elevated valleys of the sierras stock-raising is successful. The principal industry of Durango, however, is mining, and some of the richest and best known mines of Mexico are found in the State. Besides silver, which has been extensively mined since the first arrival of the Spanish under Francisco de Ibarra (1554–62), gold, copper, iron, cinnabar, tin, coal and rubies are found. The famous Cerro del Mercado, 2m. from the city of Durango, is a hill composed in great part of remarkably pure iron ore, and is estimated to contain 300,000,000 tons of that metal. Near it are iron and steel works. In the district of San Dimas is the celebrated Candelaria mine, where the ores (largely argentite) assay between $70 and $140 a ton, the aggregate output being estimated as over $100,000,000 before the close of the 19th century. With the exception of silver, the mineral resources of the State have been but slightly developed because of difficult and expensive transportation. The Mexican Central railway crosses the eastern side of the State, and the Mexican International crosses north-east to south-west through the State capital on its way to the port of Mazatlán. The history of Durango is similar to that of Chihuahua, the State originally forming part of the province of Nueva Viscaya. The capital is Durango, and among the principal towns are Guanacevi (pop. [1900] 6,859) ([1930] 5,675), El Oro (12,015 in 1930), Nombre de Dios (the first Spanish settlement in the State), San Juan de Guadalupe, San Dimas and Villa Lerdo. These are comparatively small mining towns. Mapimí lies 130m. N.N.E. of Durango and gives its name to the great arid depression situated still farther north.

DURANGO, sometimes called CIUDAD DE VICTORIA, a city of Mexico, capital of the State of Durango, 574 m. N.W. of the Federal capital, in lat. 24° 25′ N., long. 105° 55′ W. Pop. (1930) 58,160. Durango is served by the Mexican International railway. The city stands in the picturesque Guadiana valley formed by easterly spurs of the Sierra Madre, about 6,200 ft. above the sea. It has a mild, healthy climate, and is surrounded by a district of considerable fertility. Durango is an important mining and commercial centre, and was for a time one of the most influential towns of northern Mexico. It contains a mint erected in 1811, and is famous for the great mountain of iron that lies north-west of the city. The city is provided with an abundant water-supply, and there are thermal springs in its vicinity. Its manufacturing establishments include reduction works, cotton and woollen mills, glass works, iron foundries, tanneries, flour mills, sugar refineries and tobacco factories. Durango was founded in 1563 by Alonso Pacheco under the direction of Gov. Francisco de Ibarra, who named it after a city of his native province in Spain. It was known, however, as Guadiana for a century thereafter, and its first bishops were given that title. It was the capital of Ibarra's new province of Nueva Viscaya, which included Durango and Chihuahua, and continued as such until their separation in 1823.

DURANI or **DURRANI,** the dominant race of Afghans, to which the ruling family at Kabul belongs. *See* AFGHANISTAN.

DURANT, a city of southeastern Oklahoma, U.S A., 15 mi. from the Red river, where a $50,000,000 hydroelectric dam is (1941) under construction; the county seat of Bryan county. It is on federal highways 69, 70 and 75, and is served by the Frisco, the Kansas, Oklahoma and Gulf and the Missouri-Kansas-Texas railways. The population was 7.463 in 1930; 10,027 in 1940. The county farms and raises livestock; has cotton gins and cotton oil mills; also a nursery and a fish hatchery. On its northern boundary is the Southeastern state teachers college (established 1909).

DURANTE, FRANCESCO (1684–1755), Italian composer, was born at Frattamaggiore, in the kingdom of Naples, on March 15, 1684. At an early age he entered the Conservatorio dei poveri di Gesù Cristo, at Naples, where he received lessons from Gaetano Greco; later he became a pupil of Alessandro Scarlatti at the Conservatorio di Sant' Onofrio. He is also supposed to have studied under Pasquini and Pitoni in Rome, but no documentary proof of this statement can be given. He is said to have succeeded Scarlatti in 1725 at Sant' Onofrio, and to have remained there until 1742, when he succeeded Porpora as head of the Conservatorio di Santa Maria di Loreto, also at Naples. This post he held for 13 years, till his death on Aug. 13, 1755, at Naples. His fame as a teacher was all but unrivalled, and Jommelli, Paesiello, Pergolesi, Piccini and Vinci were among his pupils. A complete collection of Durante's works, consisting all but exclusively of sacred compositions, was presented by Selvaggi, a Neapolitan lover of art, to the Paris library. The imperial library of Vienna also preserves a valuable collection of Durante's manuscripts. Two requiems, several masses (one of which, a most original work, is the *Pastoral Mass* for four voices) and the *Lamentations* of the prophet Jeremiah are among his most important settings.

DURAO, JOSE DE SANTA RITA (*c.* 1737–1784), Brazilian poet, was born in the parish of Cata Preta, near the boundary of Minas Geraes, Brazil, probably in 1737, though some authorities place his birth within the years 1718–22. He received his early education at the Jesuit college in Rio de Janeiro, and in 1756 obtained the degree of doctor of theology from the historic University of Coimbra, Portugal. Two years later he entered the Gratian convent of the order of St. Augustine. Famous already as a preacher, he offended his superiors by his liberality of thought, and particularly by his openly expressed regard for the proscribed Jesuits. In consequence he was forced to leave the country. He was detained in Spain as a spy in 1762, but was released in the following year, and then went to Rome, where he became acquainted with Alfieri, Pindemonte, Casti and other literary men of the time. In 1778 he returned to Portugal to accept the chair of theology at the University of Coimbra, and at the opening of the university for the year delivered an address in Latin, *De sapientia,* which marked him as one of the foremost intellectuals of his day. He soon retired, however, to the Gratian convent, and became its prior. In 1781 he published in Lisbon his great epic *Caramkru: poema épico do descubrimento da Bahia,* a poetic treatment in ten cantos of the discovery of Bahia (southern Brazil), by Diego Alvarez. This is one of the masterpieces of Brazilian literature, and is remarkable especially for the beauty of its descriptions of South American scenery and Indian life. Failure of the poem to command instant recognition embittered its author, and led him to burn nearly all his other works. A French translation of the *Caramkru* appeared in Paris in 1829. He died in Lisbon on Jan. 24, 1784.

DURATION AND TIME are commonly used as synonymous terms. In recent philosophy, however, great stress has been laid on the need of differentiating between them in order to avoid certain confusions. The difference has been expressed most clearly by Bergson, who, however, has only revived and elaborated the distinction drawn already by Spinoza (*see* Letter XII in *A.* Wolf, *The Correspondence* of *Spinoza, p.* 119). Time is commonly conceived abstractly and is thought of as composed of discrete instants or moments which follow one another in a uniform manner. For the purposes of science such an abstraction is often necessary. But *real* time, time as it actually passes, as it is actually experienced and lived in the world of changing events is not composed of such instants which replace one another. It is duration, that is a continuous change in which "the past gnaws into the future and swells as it advances" (H. Bergson, *Creative Evolution,* p. 5). When time is conceived as a succession of discrete parts it is incomprehensible how any period of time, say an hour, can ever elapse, seeing that it involves the sequence of an infinity of parts. Hence Zeno's paradox of Achilles and the tortoise. But real time is only apprehended in intuition, and is continuous duration. The abstract concept of time, as commonly used in science, is the result of an attempt to assimilate it to space, or at least to measure it by means of certain correlated positions in space. Such is the view of Bergson, whose views may be summarized as follows. When science speaks of time it really refers to the motion of a body M on its trajectory. This motion is taken to represent time, and, by definition, is assumed to be uniform. Let $M_1, M_2, M_3 \ldots$ be points which divide the path of the moving body, M, into equal parts from its starting-point Mo onwards. Then it will be said that 1, 2, 3, . . . units of time have elapsed when M is at $M_1, M_2, M_3 \ldots$ Hence to consider the state of the universe at a certain time, say t, is simply to consider its state when M will be at the position Mt. No attention is paid to the actual *flow* of time, much less to its effect, on consciousness. For only points or positions are taken into account. And all that is considered in connection with all other parts of the universe is their positions on their several paths. With each *virtual position* of M ($M_1, M_2, M_3, \ldots$) there is correlated a *virtual position* of all other moving bodies. But these correspondences in position are *simultaneities* which take no account of the *flow* of time, the continuous transitions from position to position in unbroken sequence. If real time could be measured by *feeling,* independently of physical events, then the sequence of physical events would continue to be expressed by the same equations, however much their actual *tempo* might be varied as judged independently by our duration-feeling, Science, as a matter of fact, has no symbols to express real succession or duration. *See* H. Bergson, *Time and Freewill* (1910); *see* also the article SPACE-TIME. (A. Wo.)

DURAZZO (DURRËS), a seaport of Albania. Pop. (1930) 8,739, of whom 70% were Mohammedans, 25% Orthodox, and 5% Roman Catholics. Most of the merchant class are of Vlach origin. Durazzo is the seat of a Roman Catholic archbishop and a Greek metropolitan. It is built on the slope of Mt. Durazzo and stretches down into a picturesque valley, but is surrounded by marshes, dotted with lakes, and the water supply, from wells, is far from satisfactory. The old crenellated walls are dilapidated; plane trees grow on the gigantic ruins of the old Byzantine citadel, and the harbour, commodious and safe when used by the Venetian galleys, is gradually becoming silted up, sandbanks rendering the approach difficult. The only features worthy of notice are the quay with its rows of cannon, and the viaduct, 750 ft. long, which crosses the marsh to the road to Tirana. The chief exports are olive oil, wheat, oats, barley, skins, tobacco, sumach and sheep. Salt is obtained by evaporation, and there are brick kilns in the district, while the making of the national costumes is an important industry.

Epidamnus, the ancient name of Durazzo, was founded by a joint colony of Corcyreans and Corinthians towards the close of the 7th century B.C., and from its admirable position and the fertility of the surrounding country, soon rose into considerable importance, and played a part in bringing about the Peloponnesian War (431–404 B.C.). In 312 B.C. the city was seized by the Illyrian king Glaucias, and shortly after it passed to the Romans, who changed its name to Dyrrachium, and it again rose to importance. It was a favourite point of debarkation for the Roman armies; the great military road known as the Via Egnatia led from Dyrrachium to Thessalonica (Salonica); and another highway passed southwards to Buthrotum and Ambracia. Broad swamps rendered the city almost impregnable, and in 48 B.C. Pompey made his last successful resistance to Caesar here. After the battle of Actium in 31 B.C. Augustus made over Dyrrachium to a colony of his veterans; it became a *civitas libera,* and reached the summit of its prosperity at the end of the 4th century when it was made the capital of Epirus Nova.

Its bishopric, created about A.D. 58, was raised to an archbishopric in 449. In 481 the city was besieged by Theodoric the

Goth, and during the 10th and 11th centuries was frequently attacked by the Bulgarians. In 1081 it was stormed by Robert Guiscard, the Norman, and in 1185 it fell into the hands of King William of Sicily; was surrendered to Venice in 1202, and in 1268 came into the possession of Charles of Anjou. In 1273 it was destroyed by an earthquake, but soon recovered from the disaster, and became an independent duchy under John of Anjou (1294–1304), and afterwards under Philip of Otranto. In 1333 it was annexed to Achaea, in 1336 to Serbia, and in 1394 to Venice. The Turks captured it in 1501, and held it till 1913. In that year Essad Pasha set up a government of his own in Durazzo, but in 1914 Prince William of Wied landed there as King of Albania, and Essad fled to Italy. His partisans, however, attacked the town, and three months later Prince William abandoned the country. At Kavaja, near Durazzo, an Albanian American school of agriculture was founded in 1925 for the promotion of better methods of cultivation and cattle raising.

Durazzo was a main point of disembarkation for the Italian troops invading Albania in 1939. During the Greek-Italian war of 1940–41 it was subjected to heavy air raids by the British. British warships also shelled the port from the Adriatic, disrupting Italian supplies to its armies facing the Greeks.

D'URBAN, SIR BENJAMIN (1777–1849), British general and colonial administrator, entered the British army in 1793. In 1794 he took part in operations in Holland and Westphalia. In 1795 he served under Sir Ralph Abercromby in San Domingo. He spent the years 1800–05 at the Royal Military college, and then served in Hanover under Lord Cathcart. In Nov. 1807 he went to Dublin as assistant-quartermaster-general, being transferred successively to Limerick and the Curragh. He joined the army in the Peninsula in 1808 and acted as quartermaster general to General (afterwards Viscount) Beresford in the reorganization of the Portuguese army. He served throughout the Peninsular War, being present at Busaco, Albuera, Badajoz, Salamanca, Vitoria, the Pyrenees, the Nivelle, the Nive and Toulouse. He was made a K.C.B. in 1815. He remained in Portugal until 1816. In 1819 he became major general and in 1837 lieutenant general. From 1829 he was colonel of the 51st Foot.

Sir Benjamin began his career as colonial administrator in 1820 as governor of Antigua. In 1824 he was transferred to Demerara and Essequibo, then in a disturbed condition owing to a rising among the slaves consequent on the emancipation movement in Great Britain. In 1831 he carried out the amalgamation of Berbice with the other counties, the whole forming the colony of British Guiana, of which D'Urban was first governor. The four years of his governorship in Cape Colony (1834–38) were of great importance in the history of South Africa. They witnessed the abolition of slavery, the establishment of a legislative council and municipal councils in Cape Colony, the first great Kafir war and the beginning of the Great Trek. The firmness and justice of his administration won the cordial support of the British and Dutch colonists. The greater part of 1835 was occupied in repelling an unprovoked invasion of the eastern borders of the colony by Xosa Kafirs. To protect the inhabitants of the eastern province Sir Benjamin extended the boundary of the colony to the Kei river and erected military posts in the district, allowing the Xosa to remain under British supervision. But Lord Glenelg, secretary for the colonies in the second Melbourne administration, adopted the view that the Kafirs had been the victims of systematic injustice. In a despatch dated Dec. 26, 1835, he instructed D'Urban to give up the newly annexed territory. At the same time Sir Andries Stockenstrom, Bart. (1792–1864), was appointed lieutenant governor for the eastern provinces of the colony to carry out the policy of the home Government, in which the Kafir chiefs were treated as being on terms of full equality with Europeans. One result of the new policy was to recreate a state of insecurity, bordering on anarchy, in the eastern province, and this condition was one of the causes of the Great Trek of the Dutch farmers which began in 1836. In various despatches D'Urban justified his position, characterizing the trek as due to "insecurity of life and property occasioned by the recent measures, inadequate compensation for the loss of the slaves, and despair of obtaining recompense for the ruinous losses by the Kafir invasion." (See **SOUTH** AFRICA, **UNION** OF, and CAPE COLONY.) D'Urban was relieved of his office (May 1, 1837), but remained governor until the arrival of his successor, Sir George Napier, in Jan. 1838.

During his governorship Sir Benjamin helped the British settlers at Port Natal, who in 1835 named their town D'Urban (now written Durban) in his honour, but his suggestion that the district should be occupied as a British possession was vetoed by Lord Glenelg. D'Urban remained in South Africa until April 1846. In 1840 he was made a G.C.B., and in 1842 declined a high military appointment in India offered him by Sir Robert Peel. In Jan. 1847 he took up command of the troops in Canada, and held it at the time of his death at Montreal on May 25, 1849.

DURBAN, a seaport on the coast of Natal, Union of South Africa, situated in 29° 52' S., 31° 1' E., just south of the Umgeni river. It is 6,992 nautical miles from London by the West Coast route, and 7,785 via Suez. Owing to its low latitude and proximity to the Mozambique current, its climate is humid and sub-tropical. The mean annual temperature is about 70°, and the temperature ranges, both daily and annual, are comparatively small. The monthly means for July and January are 64·6° and 76·6°, the mean minimum for July being 52·3° and the mean maximum for January 84.5'. Rains mostly fall in the summer months, October to March inclusive; the annual rainfall is just over 40 inches. The dry season, however, is not so marked here as it is further inland, the six winter months receiving 29% of the total rainfall. The average number of rainy days is between 110 and 118. The relative humidity is high, making the climate rather enervating, a fact that is probably reflected by the large number of jinrickshas, drawn by Zulus, which ply for hire in the streets. The health of the town is good, though malaria is liable to occur in the summer, and in 1926–27 there was a serious epidemic of dengue fever.

Durban is the largest urban centre in Natal, and is exceeded in the Union only by Johannesburg and Cape Town. In 1936 the European population was 95,033; total pop. 259,606. In 1921 the population consisted of 57,095 Europeans, 37,530 natives, 47,811 Asiatics and 3,874 Negroes, making a total of 146,310. The town is built near the shores of what was originally a shallow lagoon, 8 sq.m. in extent, cut off from the sea by a line of ancient partially consolidated sand dunes. The northern end of this barrier, known as the Bluff, 195 ft. high, overlooks the narrow entrance to the lagoon. On the northern side of the entrance is a low sandy spit, called the Point. The main business part of the city is laid out on a low-lying sandy tract on the north, and northwestern side of the bay (*i.e.,* the lagoon). In West street are most of the principal shops, the theatre, and, at the western end, a large technical college, near which is a colossal statue of the late Louis Botha in the dress of a Boer general, erected by citizens of Durban. About the middle of West street is a rectangular area occupied by gardens and a large war memorial. Along the West street side of this open space is the general post office, while on the opposite, southern side, is a hotel and an imposing block of insurance offices. The western flank is occupied by shops, and on the eastern side is a block of buildings containing the town hall, municipal offices, public library and art gallery. The town hall has an assembly room, which is capable of accommodating 3,000 people, and which is fitted with a fine organ. The art gallery has some good pictures by modern British painters. The border of the lagoon is laid out as an esplanade, and is known as the Victoria embankment. It forms a picturesque walk, lined with palms. About the middle is an equestrian statue of Dick King, commemorating his famous nine days ride to Grahamstown (600 m.) to obtain relief when Durban was besieged by the Dutch in 1840.

The Harbour.— The area about the Point is occupied by harbour works, loading sheds, etc. Here also is a memorial to Vasco da Gama. Owing to the presence of sandbanks it was originally difficult for any but smaller craft to enter the lagoon. The entrance has, however, been greatly improved. A wall has been constructed from the end of the Bluff for about 2,000 ft. out to sea. Nearly parallel with this the North pier was carried out to the same distance from the Point. The narrow entrance thus formed is kept

free from sand by the tidal scour and by dredging. The depth at L.W.O.S.T. is about 35 ft., and the average rise of a spring tide is 4 ft. 11 inches.

Along the lagoon side of the Point are the sheds and wharves, of which there are about 3 miles. The depth alongside ranges from 23 to 34 ft. For coaling purposes electrically-driven belt and bucket transporter appliances have been installed at the Bluff, capable of coaling five ships simultaneously. Oil depôts exist near by.

For repairs there is a floating dock capable of lifting 8,500 tons, and a patent slip capable of lifting craft up to 150 tons. At the south-western end of the bay, near Congella, is a graving dock, 1,150 ft. long and 110 ft. broad. The depth of the entrance channel is 32 feet.

Not far away is the largest grain elevator in South Africa, with a storage capacity of 42,000 tons.

Passengers landing at Durban and wishing to travel inland by railway have to reach the railway station in the centre of the town by car, tram or jinricksha.

Homes and Recreation. — Behind the business section rises a sharp ridge, the Berea, which runs in a more or less northerly direction until it meets the Umgeni river, where the Dwyka conglomerate, of which it is formed, is quarried for road metalling and harbour works. The Berea is the favourite residential quarter, and building sites are, therefore, dear. Most of the houses stand in their own grounds, surrounded by trees and shrubs, flowers and lawns.

The streets are lined with the beautiful flamboyant tree, which is sharply restricted to the coastal strip of Natal. The general appearance of this quarter, and the views out to sea are very pleasing.

A bridge was constructed across the mouth of the Umgeni.

On most of its other sides the town is hemmed in by a zone of Indian settlements, with squalid huts, untidy surroundings and sanitary conditions which could not be regarded as being satisfactory. On the sea front, north of the harbour, and stretching in the direction of the Umgeni, is a large esplanade, with its accompaniment of hotels, bathing conveniences, bandstands, etc. Near its northern end is a capacious concert hall, built in 1924. Between this and the river is an area of open beach and sand dunes. A part of the latter is occupied by the Country club and its golf links and tennis courts. Durban is one of the most important seaside holiday resorts in South Africa. Many people from the high country inland come down during the winter for relaxation, and to escape the severe frosts. During July important race meetings are held here.

Public Services. — The town is well supplied with public services. It has a good water supply, obtained from a large reservoir on the Umlaas river, a water borne sewage, electric light and a good tram service. The Botanical gardens on the lower slopes of the Berea contain a fine collection of plants, more tropical in character than those in most other parts of South Africa. There are several other open spaces, such as Albert park, between West street and the bay, Mitchell park, Bulwer park, etc. Opportunities for sport are provided by a race-course, near the centre of the town, polo and football grounds and golf links. Near the Point is a hospital capable of accommodating 135 patients. In addition to the usual primary and secondary schools, there is a large technical college, and in 1931, the Howard college, which houses the faculty of engineering of the Natal University college (University of South Africa), was built on a jo-ac. site.

Industry. — The first settlers on the site of Durban were a few British elephant hunters, who arrived in 1824. In 1835 a township was laid out, and named after Sir Benjamin d'Urban, the then governor of the Cape. Since that date the town has experienced many alternations of prosperity and depression. It derived much benefit from the increase of trade due to the discovery of diamonds and gold in South Africa, and to the Zulu and Boer Wars. It owes its importance largely to the fact that it is the only reasonable port between East London and Delagoa bay, and that there is a comparatively easy way leading inland. Much of its trade is with the Transvaal and Orange Free State. It also deals with practically all the overseas trade of Natal. Among its chief exports are maize from the high veld, coal, for bunking and export, from the Natal coalfields, wattle bark from the midlands of Natal, and wool. It is also the chief focus of the sugar industry, which occupies most of the coastal belt of Natal. Durban is second only to Cape Town as a shipping centre in the Union. In 1939, 1,699 vessels entered the harbour, with a total tonnage of 6,730,390, and in 1938–39, 63,566 passengers landed or embarked at Durban. Durban is also the centre of the whaling activities on this coast. The season lasts from May to November, and a whaling station has been established on the seaward side of the Bluff. The oil is used by local soap factories. The establishment of industries in the town is favoured by the plentiful supplies of coal, water, electricity and coloured labour that are available, and by the facilities for importing and exporting raw material and finished products. Land is being reclaimed at the south-western end of the bay, and is quickly taken up for industrial development. Among the industries already established are those dealing with the production of soap, matches, jams and preserves, biscuits, furniture, etc.

See G. Russell, *History of* Old *Durban (to 1860)* (Durban, 1899); *Fifty Years of* Municipal *History,* compiled for the Corporation by the town clerk, 1904; *South* Africa *Year Book.* (R. U.S.)

DURBAR, a term in India for a court or levee, from the Persian *darbar. A* durbar may be either a council for administering affairs of state, or a purely ceremonial gathering. In the former sense the native rulers of India in the past received visitors and conducted business in durbar. A durbar is the executive council of a native state. In the latter sense the word has come to be applied to great ceremonial gatherings like Lord Lytton's durbar for the proclamation of the queen empress in India in 1877, or the Delhi durbar of 1911.

DUREN, a town in Rhenish Prussia. Germany, on the right bank of the Roer, 19 mi. E. from Aix-la-Chapelle on the main line of railway to Cologne. Pop. (1939) 45,441. The Gothic St. Annakirche is said to contain a portion of the head of the saint, to the shrine of which frequent pilgrimages are made. There are several high-grade schools, and, in the town hall, a collection of antiquities. It is the seat of considerable manufactures, notably cloth, paper, flax-spinning, carpet, artificial wool, sugar, beer and spirits, iron wares, needles, machinery, glass.

Diiren derives its name from the *Dura* or *Duria,* assemblies held by the Carolingians in the 8th century. It received civic rights early in the 13th century. Hypothecated by the emperor Frederick II. to Count William of Jülich, it became incorporated with the duchy of that name, and with it passed to Prussia in 1816.

DURENE (1·2·4·5 tetramethylbenzene) $C_6H_2(CH_3)_4$, a hydrocarbon occurring in the light oils of coal-tar and prepared by the action of methyl iodide on brompseudocumene or 4.6 dibrom metaxylene, in presence of sodium; or by the action of methyl chloride on toluene, in presence of anhydrous aluminium chloride. It crystallizes in plates, having a camphor-like smell, melting at 79–80°C. and boiling at 189–191°C.

DURER, ALBRECHT (1471–1528), German painter, draughtsman and engraver, was born at Nuremberg on May 21, 1471. Albrecht Diirer the elder, born at Gyula, Hungary, in 1427, was a goldsmith by trade, and settled soon after the middle of the 15th century in Nuremberg. He served as assistant under a master-goldsmith of the city, Hieronymus Holper, and in 1468 married his master's daughter Barbara, the bridegroom being 40 and the bride 15 years of age. They had 18 children, of whom Albrecht was the second. Diirer painted the portrait of his father (who died in 1502) twice, in 1490 and again in 1497. The former of these is in the Uffizi at Florence; of the latter, four versions exist, that in the National Gallery, London (formerly in the Ashburton-Northampton collection) having the best claim to originality.

The young Albrecht was his father's favourite son, and was apprenticed at the age of fifteen and a half to the principal painter of the town, Michael Wolgemut. Wolgemut furnishes a complete type of the German painter of that age. There were

produced in the workshop of Wolgemut a great number of woodcuts for book illustration. We cannot with certainty identify any of these as being by the prentice hand of the young Durer. Authentic drawings done by him in boyhood, however, exist, including one in silver-point of his own likeness at the age of 13 in the Albertina at Vienna, and others of two or three years later in the print room at Berlin, at the British Museum and at Bremen.

At the end of his apprenticeship in 1490 he entered upon the usual course of travels — the Wanderjahre — of a German youth. It had at one time been his father's intention to apprentice him to Martin Schongauer of Colmar. But after travelling two years in various parts of Germany, the young Durer arrived at Colmar in 1492, only to find that Schongauer had died the previous year. He was received kindly by three brothers of the deceased master established there, and afterwards, still in 1492, by a fourth brother at Basle. Under them he evidently had some practice both in metal-engraving and in furnishing designs for the woodcutter. There is in the museum at Basle a wood-block of St. Jerome executed by him and elaborately signed on the back with his name. This was used in an edition of Jerome's letters printed in the same city in 1492. In the early part of 1494 he was working at Strasbourg, and returned to his home at Nuremberg immediately after Whitsuntide in that year. Of works certainly executed by him during his years of travel there are extant, besides the Basle wood-block, only a much-injured portrait of himself, dated 1493 and originally painted on vellum but since transferred to canvas (this is the portrait of the Felix Goldschmid collection); a miniature painting on vellum at Vienna (a small figure of the Child-Christ); and some half-a-dozen drawings, of which the most important are the characteristic pen portrait of himself at Erlangen, with a Holy Family on the reverse much in the manner of Schongauer; another Holy Family in nearly the same style at Berlin; a study from the female nude in the Bonnat collection; a man and woman on horseback in Berlin; a man on horseback, and an executioner about to behead a young man, at the British Museum, etc. These drawings all show Durer intent above all things on the sternly accurate delineation of ungeneralized individual forms by means of strongly accented outline and shadings curved, somewhat like the shadings of Martin Schongauer's engravings, so as to follow their modellings and roundness.

Within a few weeks of his return (July 7, 1494) Durer was married, according to an arrangement apparently made between the parents during his absence, to Agnes Frey, the daughter of a well-to-do merchant of the city. By the autumn of the same year he must have made an excursion of some months to Italy. The evidences of this travel consist of: (1) some fine drawings, three of them dated 1494 and others undated, but plainly of the same time, in which Durer has copied, or rather boldly translated into his own Gothic and German style, two famous engravings by Mantegna, a number of the "Tarocchi" prints of single figures which pass erroneously under that master's name, and one by yet another minor master of the North-Italian school; with another drawing dated 1495 and plainly copied from a lost original by Antonio Pollaiuolo, and yet another of an infant Christ copied in 1495 from Lorenzo di Credi; (2) several landscape drawings done in the passes of Tirol and the Trentino; (3) two or three drawings of the costumes of Venetian courtesans, one of which is used in his great woodcut Apocalypse series of 1498; (4) a general preoccupation from this date with the problems of the female nude, treated in a manner for which Italy only could have set him the example; and (5) the clear implication contained in a letter written from Venice in 1506 that he had been there already 11 years before. Some time in 1495 Durer must have returned from this first Italian journey to his home in Nuremberg, where he seems to have lived for the next ten years.

The hour when Durer, the typical artist of the German nation, attained maturity was one of the most pregnant in the history of his race. It was the crisis, in northern Europe, of the transition between the middle ages and our own. The art of printing had been invented in good time to help and hasten the new movement of men's minds Nor was it by the diffusion of written ideas only that the new art supplied the means of popular enlightenment. Along with word-printing, or indeed in advance of it, there had sprung into use another kind of printing, picture-printing, or what is commonly called engraving. Just as books were the means of multiplying, cheapening and disseminating ideas, so engravings on copper or wood were the means of multiplying, cheapening and disseminating images which gave vividness to the ideas, or served, for those ignorant of letters, in their stead. The genius of Albrecht Durer cannot be rightly estimated without taking into account the position which the arts of engraving on metal and on wood thus held in the culture of this time. He was indeed professionally and in the first place a painter; but throughout his career a great, and on the whole the most successful, part of his industry was devoted to drawing on the block for the woodcutter or engraving with his own hand on copper. Nuremberg was a favourable home for the growth and exercise of his powers. Of the free imperial cities of central Germany, none had a greater historic fame or a more settled and patriotic government. Nuremberg had imported before the close of the 15th century a fair share of the new learning of Italy, and numbered among her citizens distinguished humanists like Hartmann Schedel, Sebald Schreier, Willibald Pirkheimer and Conrad Celtes. From associates like these Durer could imbibe the spirit of Renaissance culture and research; but the external aspects and artistic traditions which surrounded him were purely Gothic, and he had to work out for himself the style and form-language fit to express what was in him. During the first seven or eight years of his settled life in his native city from 1495, he betrays a conflict of artistic tendencies as well as no small sense of spiritual strain and strife. His finest work in this period was that which he provided for the woodcutter. After some half-dozen miscellaneous single prints — "Samson and the Lion," the "Annunciation," the "Ten Thousand Martyrs," the "Knight and Men-at-arms," the "Men's Bath," etc. — he undertook, and by 1498 completed, his famous series of 15 great designs for the Apocalypse. Founding himself to some extent on traditional motives, Durer conceived and carried out a set of designs in which the qualities of the German late Gothic style, its rugged strength and restless vehemence, its love of gnarled forms, writhing actions and agitated lines, are fused by the fire of the young master's spirit into vital combination with something of the majestic power and classic severity which he had seen and admired in the works of Mantegna. Of a little later date, and of almost as fine a quality, were the first seven of a large series of woodcuts known as the "Great Passion"; and a little later again (probably after 1500), a series of 11 subjects of the Holy Family and of saints singly or in groups: then, towards 1504–05, came the first 17 of a set illustrating the life of the Virgin: neither these nor the "Great Passion" were published till several years later.

In copper-engraving Durer was at the same time diligently training himself to develop the methods practised by Martin Schongauer and earlier masters into one suitable for his own self-expression. He contented himself for the most part with Madonnas, single figures of scripture or of the saints, some nude mythologies founded upon the impressions received in Italy, and groups, sometimes bordering on the satirical, of humble folk and peasants. In the earliest of the Madonnas, the "Virgin with the Dragon-fly" (1495–96), Durer has thrown something of his own rugged energy into a design of the traditional Schongauer type. In examples of a few years later, like the "Virgin with the Monkey," the design of Mother and Child clearly betrays the influence of Italy and specifically of Lorenzo di Credi. On the other hand, he treats the subjects of the "Prodigal Son" and "St. Jerome in the Wilderness" in an almost purely northern spirit. In the nudes of the next four or five years, which included a "St. Sebastian," the so-called "Four Witches" (1497), the "Dream" or "Temptation," the "Rape of Amymome," and the "Jealousy" or "Great Hercules," Venetian, Paduan and Florentine memories are found, in the treatment of the human form. In these early engravings the highly wrought landscape backgrounds, whenever they occur, are generally the most satisfying feature, This feature reaches a climax of beauty and

elaboration in the large print of "St. Eustace and the Stag," while the figures and animals remain still somewhat cramped and immature. In the first three or four years of the 16th century we find Durer in his graver work still contending with the problems of the nude, but now with added power, though by varying methods. Thus the "Nemesis," belonging probably to 1503, is a marvellously wrought piece of quite unflinching realism in the rendering of a common type of mature, muscular, unshapely German womanhood. The conception and attributes of the figure are taken, as has lately been recognized, from a description in the "Manto" of Politian: the goddess, to whose shoulders are appended a pair of ,huge wings, stands like Fortune on a revolving ball, holding the emblems of the cup and bridle, and below her feet is spread a rich landscape of hill and valley. In the "Adam and Eve" of 1504 we find Diirer treating the human form in an entirely opposite manner; constructing it, that is, on principles of abstract geometrical proportion. The Venetian painter-etcher, Jacopo de Barbari, whom Durer had already, it would seem, met in Venice in 1494–95, and by the example of whose engravings he had already been much influenced, came to settle for a while in Nuremberg in 1500. He was conversant to some extent with the new sciences of perspective, anatomy and proportion, which had been making their way for years past in Italy, and from him it is likely that Durer received the impulse to similar studies and speculations. At any rate a whole series of extant drawings enables us to trace the German gradually working out his own ideas of a canon of human proportion in the composition of his famous engraving of "Adam and Eve" (1504), which at first, as a drawing in the British Museum proves, had been intended to be an Apollo and Diana conceived on lines somewhat similar to one of Barbari's. Two or three other technical masterpieces of the engraver's art, the "Coat-of-Arms with the Skull," the "Nativity," with its exquisite background of ruined buildings, the "Little Horse" and the "Great Horse," belong to 1505.

The pictures of this earlier Nuremberg period are not many in number and not very admirable. Among the earliest seem to be two examples of a method practised in Italy especially by the school of Mantegna, but almost without precedent in Germany, that of tempera-painting on linen. One of these is the portrait of Frederick the Wise of Saxony, formerly in the Hamilton collection and now at Berlin; the second, much disfigured by restoration, is the Dresden altar-piece with a Madonna and Child in the middle and St. Anthony and St. Sebastian in the wings. A mythology reminiscent of Italy is the "Hercules and the Stymphalian Birds" in the Germanic museum at Nuremberg, founded directly upon the "Hercules and Centaur Nessus" of Pollaiuolo, now at New Haven, Conn., U.S.A. Of portraits, besides that of his father already mentioned as done in 1497, there is his own of 1498 at Madrid. Two totally dissimilar portraits of young women, both existing in duplicate examples, for each of which has been claimed the name Furlegerin, that is, a member of the Fürleger family at Nuremberg, belong to nearly the same time. Other panel portraits of the period are three small ones of members of the Tucher family at Weimar and Cassel, and the striking, restlessly elaborated half-length of Oswald Krel at Munich. In some devotional pictures of the time Durer seems to have been much helped by pupils, as in the two different compositions of the Maries weeping over the body of Christ preserved respectively at Munich and Nuremberg. Two examples of high value are the Paumgartner altar-piece at Munich, with its romantically attractive composition of the Nativity with angels and donors in the central panel and the fine armed figures of St. George and St. Eustace on the wings; and the "Adoration of the Magi" in the Uffizi at Florence.

In the autumn of 1505 Durer journeyed for a second time to Venice, and stayed there until the spring of 1507. One of the motives for this journey was the prospect of a commission for an important picture from the German community settled at Venice, who had caused an exchange and warehouse—the Fondaco de' *Tedeschi*—to be built on the Grand canal, and who were then desirous of dedicating a picture in the church of St. Bartholomew. The picture painted by Durer on this commission was the "Adoration of the Virgin," better known as the "Feast of Rose Garlands"; it was subsequently acquired by the emperor Rudolf II., and carried as a thing beyond price upon men's shoulders to Vienna; it now exists in a greatly injured state in the monastery of Strahow at Prague. Of all Durer's works, it is the one in which he most deliberately rivalled the combined splendour and playfulness of certain phases of Italian art. A similar festal intention in design and colouring, with similar mastery in passages and even less sense of harmonious relations in the whole, is apparent in a second important picture painted by Durer at Venice, "The Virgin and Child with the Goldfinch," formerly in the collection of Lord Lothian and now at Berlin. A "Christ disputing with the Doctors" of the same period, in the Barberini gallery at Rome, is recorded to have cost the painter only five days' labour. The most satisfying of Durer's paintings done in Venice are the admirable portrait of a young man at Hampton Court (the same sitter reappears in the "Feast of Rose Garlands"), and two small pieces, one the head of a brown Italian girl modelled and painted with real breadth and simplicity, formerly in the collection of Mr. Reginald Cholmondeley and now at Berlin, and the small and very striking little "Christ Crucified" with the figure relieved against the night sky, which is preserved in the Dresden gallery and has served as model and inspiration to numberless later treatments of the theme. An interesting, rather fantastic, portrait of a blonde girl wearing a wide cap, now in the Berlin museum, is dated 1507 and may have been done in the early months of that year at Venice. A portrait of a Venetian woman, discovered in 1924 at Vienna, belongs to this period, and possibly also the famous portrait of himself at Munich bearing a false signature and date, 1500. In the latter the artist modified his own lineaments according to a preconceived scheme of facial proportion, so that it must be taken as an ideal rather than a literal presentment of him.

From the spring of 1507 until the summer of 1520, Durer was again a settled resident in his native town. Except the brilliant existences of Raphael at Rome and of Rubens at Antwerp and Madrid, the annals of art present the spectacle of few more honoured or more fortunate careers. His reputation had spread all over Europe. He was on terms of friendship or friendly communication with all the first masters of the age, and Raphael held himself honoured in exchanging drawings with Durer. 'In his own country, all orders of men, from the emperor Maximilian down, delighted to honour him; and he was the familiar companion of chosen spirits among the statesmen, humanists and reformers of the new age. His temper and life seem to have been remarkably free from all that was jarring, jealous and fretful; unless, indeed, we are to accept as true the account of his wife's character which represents her as an incorrigible shrew and skinflint. The name of Agnes Diirer was for centuries used to point a moral, and among the unworthy wives of great men the wife of Durer became almost as notorious as the wife of Socrates. It is to be noted that neither in Durer's early correspondence with his intimate friend, Willibald Pirkheimer, nor anywhere in his journals, does he use any expression of tenderness or affection for his wife, only speaking of her as his housemate and of her help in the sale of his prints, etc. But it is fair to remember in her defence that Pirkheimer, when he denounced her in the letter which forms the basis of these imputations, was old, gouty and peevish, and that the immediate occasion of his outbreak against his friend's widow was a fit of anger because she had not let him have a pair of antlers out of the property left by Diirer. After her husband's death Agnes Durer behaved with generosity to his brothers.

The 13 or 14 years of Durer's life between his return from Venice and his journey to the Netherlands (spring 1507–midsummer 1520) may be divided according to the classes of work with which he was principally occupied. The first five years, 1507–11, are pre-eminently the painting years of his life. In them he produced what have been accountrd his four capital works in painting, besides several others of minor importance The first is the "Adam and Eve" dated 1507, two version: sf

which exist, one in Florence at the Pitti palace, the other, which is generally allowed to be the original, at Madrid. To 1508 belongs the life-sized "Virgin with the Iris," a piece remarkable for the fine romantic invention of its background, but plainly showing the hand of an assistant, perhaps Hans Baldung, in its execution: the best version is in the Cook collection at Richmond, an inferior one in the Rudolphinum at Prague. In 1508 Durer returned to a subject which he had already treated in an early woodcut, the "Massacre of the Ten Thousand Martyrs of Nicomedia." The picture, painted for the elector Frederick of Saxony, is now in the Imperial gallery at Vienna. In 1509 followed the "Assumption of the Virgin" with the Apostles gathered about her tomb, a rich altar-piece with figures of saints and portraits of the donor and his wife in the folding wings, executed for Jacob Heller, a merchant of Frankfurt, in 1509. This altar-piece was afterwards replaced at Frankfurt (all except the portraits of the donors, which remained behind) by a copy, while the original was transported to Munich, where it perished by fire in 1674. In 1511 was completed another famous painting, multitudinous in the number of its figures though of very moderate dimensions, the "Adoration of the Trinity by all the Saints," now at Vienna.

In the meantime Durer had added a few to the number of his line-engravings and had completed the two woodcut series of the "Great Passion," begun about 1498–99, and the "Life of the Virgin." In 1511 these two works were brought out for the first time, and the Apocalypse series in a second edition; and for the next three years, 1511–14, engraving both on wood and copper, but especially the latter, took the first place among Durer's activities. Besides such fine single woodcuts as the "Mass of St. Gregory," the "St. Christopher," the "St. Jerome," and two Holy Families of 1511, Durer published in the same year the most numerous and popularly conceived of all his woodcut series, that known from the dimensions of its 37 subjects as the "Little Passion" on wood; and in the next year, 1512, a set of 15 small copper-engravings on the same theme, the "Little Passion" on copper. Both of these must represent the labour of several preceding years: one or two of the '(Little Passion" plates, dating back as far as 1507, prove that this series at least had been as long as five years in his mind. In thus repeating over and over on wood and copper nearly the same incidents of the Passion, or again in rehandling them in yet another medium, as in the highly finished series of drawings known as the "Green Passion" in the Albertina at Vienna, Durer shows an inexhaustible variety of dramatic and graphic invention, and is never betrayed into repeating an identical action or motive.

In 1513 and 1514 appeared the three most famous of Durer's works in copper-engraving, "The Knight and Death" (or simply "The Knight," as he himself calls it, 1513), the "Melancolia" and the "St. Jerome in his Study" (both 1514). These are the masterpieces of the greatest mind which ever expressed itself in this form of art. The idea at the bottom of the "Knight and Death" seems to be a combination of the Christian knight of Erasmus's *Enchiridion militis Christiani* with the type, traditional in mediaeval imagery, of the pilgrim on his way through the world. The "Melancolia," numbered "I" as though intended to be the first of a series, with its brooding winged genius sitting dejectedly amidst a litter of scientific instruments and symbols, is hard to interpret in detail, but impossible not to recognize in general terms as an embodiment of the spirit of intellectual research (the student's "temperament" was supposed to be one with the melancholic), resting sadly from its labours in a mood of lassitude and defeat. Comparatively cheerful beside these two is the remaining subject of the student saint reading in his chamber, with his dog and domestic lion resting near him, and a marvellous play of varied surface and chequered light on the floor and ceiling of his apartment and on all the objects which it contains. Besides these three masterpieces of line-engraving, the same years, 1512–15, found Durer occupied with his most important experiments in etching, both in dry-point ("The Holy Family and Saints" and the "St. Jerome in the Wilderness") and with the acid bath. At the same time he was more taken up than ever, as is proved by the contents of a sketch-book at Dresden, with mathematical and anatomical studies on the proportions and structure of the human frame. A quite different kind of study, that of the postures of wrestlers in action, is illustrated by a little-known series of drawings, still of the same period, at Vienna. Almost the only well-authenticated painting of the time is a "Virgin and Child" in the Imperial museum at Vienna. The portraits of the emperors Charles the Great and Sigismund (1512), in their present state at any rate, can hardly be recognized as being by the master's hand. An interval of five years separates the Vienna "Madonna" from the two fine heads of the apostles Philip and James in the Uffizi at Florence, the pair of boys' heads painted in tempera on linen in the Bibliothèque Nationale at Paris, the "Madonna with the Pink" at Augsburg, and the portrait of Wolgemut at Munich, all of 1516. Among engravings of the same time are three Madonnas, the apostles Thomas and Paul, a bagpiper and two peasants dancing, and three or four experiments in etching on plates of iron and zinc. In wood-engraving his energies were almost entirely given to his share in the great decorative schemes commanded by the emperor Max in his own honour: namely, the Triumphal Gate and the Triumphal March or Procession. A third and smaller commemorative design, the Triumphal Car, originally designed to form part of the second but in the end issued separately, was entirely Diirer's own work. A far more successful effort of his genius is to be found in the marginal decorations done by him in pen for the emperor's prayer-book. This unequalled treasure of German art and invention has been broken up, the part executed by Durer being preserved at Munich, the later sheets, which were decorated by other hands, having been transported to Besançon. Durer's designs, drawn with the pen in pale lilac, pink and green, show an inexhaustible richness of invention and an airy freedom and playfulness of hand beyond what could be surmised from the sternness of those studies which he made direct from life and nature.

All these undertakings for his imperial friend and patron ceased with the emperor's death in 1519. A portrait-drawing by the master done at Augsburg a few months previously, one of his finest works, served him as the basis both of a commemorative picture and a woodcut. In line engravings we have four more Madonnas, two St. Christophers, one or two more peasant subjects, the well-known St. Anthony with the view of Nuremberg in the background, and the smaller of the two portraits of the cardinal-elector of Mainz; and in wood-engraving several fine heraldic pieces, including the arms of Nuremberg.

In the summer of 1520 he set out for the Netherlands, together with his wife and her maid, in order to be present at the coronation of the young emperor Charles V., and if possible to conciliate the good graces of the all-powerful regent Margaret. He journeyed by the Rhine, Cologne, and thence by road to Antwerp, where he was handsomely received, and lived in whatever society was most distinguished, including that of Erasmus of Rotterdam. Besides his written notes, interesting traces of his travels exist in the shape of the scattered leaves of a sketch-book filled with delicate drawings in silver-point, chiefly views of places and studies of portrait and costume. Several of his finest portrait-drawings in chalk or charcoal, including those of his brother artists Lucas Van Leyden and Bernard Van Orley, as well as one of two fine portrait paintings of men, belong to the period of this journey. So does a magnificent drawing of a head of a nonagenarian with a flowing beard who sat to him at Antwerp, together with a picture from the same head in the character of St. Jerome; the drawing is now at Vienna, the picture at Lisbon. Besides going to Aachen for the coronation, he made excursions down the Rhine from Cologne to Nimwegen, and back overland by Hertogenbosch; to Brussels; to Bruges and Ghent; and to Zealand with the object of seeing a natural curiosity, a whale reported ashore. The diary contains a passionate outburst of sympathetic indignation at the supposed kidnapping of Luther by foul play on his return from the diet of Worms. Without being, properly speaking, a reformer, Durer in his art and his thoughts was the incarnation of those qualities

of the German character and conscience which resulted in the Reformation; and, personally, with the fathers of the Reformation he lived in the warmest sympathy.

On July 12, 1521, Durer reached home again. Drawings of this and the immediately following years prove that on his return his mind was full of schemes for religious pictures. There exist fine drawings for a "Lamentation over the body of Christ," an "Adoration of the Kings," and a "March to Calvary"; of the last-named composition, besides the beautiful and elaborate pen-and-ink drawing at Florence, three still more highly wrought versions in green monochrome exist; whether any of them are certainly by the artist's own hand is matter of debate. But no religious paintings on the grand scale, corresponding to these drawings of 1521–24, were ever carried out. The artist allowed much of his time and thoughts to be absorbed in the preparation of his theoretical works on geometry and perspective, proportion and fortification. Like Leonardo, but with much less than Leonardo's genius for scientific speculation and divination, Durer was a confirmed reasoner and theorist on the laws of nature and natural appearances. The consequence was that in the last and ripest years of his life he produced as an artist comparatively little. In painting there is the famous portrait of Hieronymus Holtzschuher at Berlin. This and the Antwerp head of Jerome are perhaps the most striking examples of Durer's power of forcing into subordination to a general impression such a multiplicity of insistent detail as would have smothered any weaker conception than his. To the same period belong a "Madonna and Child" at Florence, and finally, still in the year 1526, the two famous panels at Munich embodying the only one of the great religious conceptions of the master's later years which he lived to finish. These are the two pairs of saints, St. John with St. Peter in front and St. Paul with St. Mark in the background. The John and Paul are conceived and executed really in the great style, with a commanding nobility and force alike in the character of the heads, the attitudes, and the sweep of draperies; they represent the highest achievement of early German art in painting. In copper-engraving Diirer's work during the same years was confined entirely to portraits, those of the cardinal-elector of Mainz ("The Great Cardinal"), Frederick the Wise, elector of Saxony, Willibald Pirkheimer, Melanchthon and Erasmus. To the tale of his woodcuts, besides a few illustrations to his book on measurements (that is, geometry and perspective), and on fortification, he added only one Holy Family and one portrait, that of his friend Eoban Hesse. Of his theoretical books he succeeded in getting only two finished and produced during his lifetime, that on geometry and perspective or measurements—to use his own title—which was published at Nuremburg in 1525, and that on fortification, published in 1527; the work on human proportions was brought out shortly after his death in 1528. His labours, whether artistic or theoretic, had for some time been carried on in the face of failing health. In the canals of the Low Countries he had caught a fever, of which he never shook off the effects. We have the evidence of this in his own written words, as well as in a sketch which he drew to indicate the seat of his suffering to some physician, and again in a portrait engraved on wood just after his death, from a drawing made no doubt not long before: in this portrait we see his shoulders already bent, the features somewhat gaunt, the old pride of the abundant locks shorn away. The end came suddenly on the night of April 6, 1528. An appropriate *Requiescat* is contained in the words of Luther, in a letter written to their common friend Eoban Hesse:—"As for Durer, assuredly affection bids us mourn for one who was the best of men, yet you may well hold him happy that he has made so good an end, and that Christ has taken him from the midst of this time of trouble and from greater troubles in store, lest he, that deserved to behold nothing but the best, should be compelled to behold the worst. Therefore may he rest in peace with his fathers: Amen."

The principal extant paintings of Durer, with the places where they are to be found, have been mentioned above. Of his drawings, which for students are the most vitally interesting part of his works, the richest collections are in the Albertina at Vienna, the Berlin museum and the British Museum. The Louvre also possesses some good examples, and many others are dispersed in various public collections, as in the Musée Bonnat at Bayonne, at Munich, Hamburg, Bremen, Frankfurt, Dresden, Basle, Milan, Florence and Oxford, as well as in private hands.

The principal editions of Diirer's theoretical writings are:

Geometry and Perspective.—*Underweysung* der Messung mit dem Zirckel und Richtscheyt, in *Linien,* Ebnen und *ganzen* Corporen (Nuremberg, 1525, 1533, 1538). A Latin translation of the same, with a long title (Paris, Weichel, 1532) and another ed. in 1535. Again in Latin, with the title *Institutionum* geometricarum libri quatuor (Arnheim, 1605).

Fortification.—*Etliche* Underricht *zu* Befestigung der Stett, Schloss und *Flecken* (Nuremberg, 1527), and other editions in 1530, 1538 and 1603 (Arnheim). A Latin translation with the title De urbibus, arcibus, castellisque muniendis ac condendis (Paris, Weichel, 1535).

Human Proportion.—*Hierinnen sind* begriffen vier *Bücher* von menschlicher Proportion (Nuremberg, 1582, and Arnheim, 1603). Latin translation: De symetria partium in rectis *formis* humanorum corporum libri in *latinum* conversi, de varietate *figurarum,* etc., libri ii. (Nuremberg, 1528, 1532 and 1534); (Paris, 1535, 1537, 1557). French translation (Paris, 1557, Arnheim, 1613, 1614). Italian translation (Venice, 1591, 1594); Portuguese translation (1599); Dutch translation (Arnheim, 1622, 1662).

The private literary remains of Diirer, his diary, letters, etc., were published most completely in Lange and Fuhse's Durers schriftlicker *Nachlass* (Halle, 1903); W. M. Conway's Literary Remains of A. Durer (London, 1889) contains extensive transcripts from the mss. in the British Museum.

The principal remaining literature on the subject will be found in the following books and treatises: F. Lippmann, *Zeichnungen* von A. *Dürer* in Nachbildungen (1883–1905); A. Springer, Albrecht Durer (1892); D. Burckhardt, Diirers Aufenthalt in *Basel, 1492–94* (Munich, 1892); G. von Terey, A. Diirers venezianischer Aufenthalt, *1494–95* (Strasbourg, 1892); S. R. Koehler, A Chronological Catalogue of the Engravings, Dry Points and Etchings of A. *Dürer* (New York, 1894); L. Cust, A. Durer, a Study of his Life and Works (1897). Durer Society's Publications (1898–1907), edited by C. Dodgson and S. M. Peartree; M. Thausing, Diirer, die Geschichte seines Lebens (2nd ed. 1884; English translation 1882); B. Haendcke, Die Chronologie der Landschaften *A.* Durers (Strasbourg, 1899); H. Wolfflin, Die Kunst A. Diirers (Munich, 1905; 2nd ed. 1908); V. Scherer, *A. Dürer* (Klassiker der Kunst, iv.), (3rd ed. 1908); Max Friedländer, A. Diirer (1921); Pierre de Colombier, Albert Diirer (1927).

See also the *Jahrbücher* of the Berlin and Vienna museums, *Repertorium* fur Kunstwissenschaft, Zeitschrift *für* bildende Kunst, etc.; Prof. H. W. Singer's Versuch einer *Dürer-Bibliographie* (Strasbourg, 1903); A. Jellinek's Internationale *Bibliographie* der Kunstwissenschaft (Berlin); an *édition* de luxe of Dr. Willi Kurth's Complete Woodcuts of Albrecht Diirer (intro. by Campbell Dodgson) was published in 1927. (S. C.; X.)

DURESS, in law, constraint or compulsion. Duress may be of two kinds. It may consist of personal restraint or actual violence or imprisonment; or it may be by threats (per minus), as where a person is compelled to an act by threats of immediate death or grievous bodily harm. (See COERCION; CONTRACT.)

D'URFEY, THOMAS (1653–1723), better known as Tom d'Urfey, English song-writer and dramatist, belonged to a Huguenot family settled at Exeter. Honoré d'Urfé, the author of *Astrée,* was his uncle. His first play, The Siege of Memphis, or the *Ambitious* Queen, a bombastic rhymed tragedy, was produced at the Theatre Royal in 1676. He was much more successful with his comedies, which had brisk, complicated plots carried out in lively dialogue. He had a light touch for fitting words on current topics to popular airs; moreover, many of his songs were set to music by his friends Dr. John Blow, Henry Purcell and Thomas Farmer. Many of these songs were introduced into his plays. Addison in the Guardian (No. 67) relates that he remembered to have seen Charles II. leaning on Tom d'Urfey's shoulder and humming a song with him. Even William III. liked to hear him sing his songs, and as a strong Tory he was sure of the favour of Princess Anne, who is said to have given Tom fifty guineas for a song on the Electress Sophia, the next heir in succession to the crown. "The crown's far too weighty, for shoulders of eighty," said d'Urfey, with an indirect compliment to the princess, "So Providence kept her away,—poor old Dowager Sophy." He was poor in his old age; but his gaiety and invincible good humour had made him friends in the craft, and by the influence of Addison his Fond Husband, or The Plotting Sisters was revived for d'Urfey's benefit at Drury Lane on June 15, 1713. He died on Feb. 26, 1723.

Collections of his songs with the music appeared during his lifetime, the most complete being the 1719–20 edition (6 vols.) of *Wit and Mirth; or Pills to Purge Melancholy*. The best known of the twenty-nine pieces of his which actually found their way to the stage were *Love for Money; or The Boarding School* (Theatre Royal, 1691), *The Marriage-Hater Match'd* (1692), and *The Comical History of Don Quixote*, in three parts (1694, 1694 and 1696), which earned the especial censure of Jeremy Collier. In his burlesque opera, *Wonders in the Sun; or the Kingdom of the Birds* (1706, music by G. B. Draghi), the actors were dressed as parrots, crows, etc.

DURFORT, a family distinguished in French and English history and taking its name from a feudal lordship situated at the village of Durfort. in south-western France. formerlv in the province of Guienne, now in the department of Tarn-et-Garonne, 18 m. north-west of Montauban. The pedigree of the family is only clearly traceable to Arnaud de Durfort (*fl.* 1305), who acquired the fief of Duras by his marriage with a niece of Pope Clement V. His descendant, Gaillard de Durfort, having embraced the side of the king of England, went to London in 1453, and was made governor of Calais and a knight of the Garter.

The greatness of the family dates from the 17th century. Guy Aldonce (1605–65), marquis de Duras and comte de Rozan, had, by his wife Elizabeth de la Tour d'Auvergne, sister of Marshal Turenne, six sons, three of whom played a distinguished part. The eldest, Jacques Henri (1625–1704) was governor of Franche Comté in 1674 and a marshal of France. The second, Guy Aldonce (1630–1702), comte de Lorges and duc de Quintin (known as the duc de Lorges), became a marshal of France in 1676, commanded the army in Germany from 1690 to 1695, and captured Heidelberg in 1693. The sixth son, Louis (1640?–1 jog), marquis de Blanquefort, came to England in the suite of James, duke of York, in 1663, and was naturalized in the same year. On Jan. 19, 1672–73, he was raised to the English peerage as Baron Duras of Holdenby, his title being derived from an estate in Northamptonshire bought from the duke of York. In 1676 he married Mary, daughter and elder co-heiress of Sir George Sondes, created in that year Baron Throwley, Viscount Sondes and earl of Feversham. On the death of his father-in-law (April 16, 1677), Duras succeeded to his titles under a special remainder. He was appointed by Charles II. successively to the command of the third and second troops of Horse Guards, was sent abroad on several important diplomatic missions, and became master of the horse (1679) and lord chamberlain to the queen (1680). In 1682 he was appointed a lord of the bed-chamber, and was present at the king's deathbed reconciliation with the Roman Church. Under James II. Feversham became a member of the privy council, and in 1685 was given the chief command against the rebels under Monmouth, in which he mainly distinguished himself by his cruelty to the vanquished. He was rewarded with a knighthood of the Garter and the colonelcy of the first troop of Life Guards, and in 1686 he was appointed to the command of the army assembled by King James on Blackheath to overawe the people. On James's flight, Feversham succeeded in making his peace with William, on the intercession of the queen dowager, at whose instance he received the mastership of the Royal Hospital of St. Catherine near the Tower (1698). He died without issue on April 8, 1709. (See G. E. C[ockayne], Complete Peerage, and art. in D.N.B.)

Jean Baptiste (1684–1770), duc de Duras, son of Jacques Henri, was also a marshal of France. His son Emmanuel Félicité (1715–89), duc de Duras, took part in all the wars of Louis XV. and was made a marshal of France in 1775. His grandson, Amédée Bretagne Malo (1771–1838), duc de Duras, is mainly known as the husband of Claire Louise Rose Bonne de Coetnempren de Kersaint (1778–1828), daughter of Armand Guy Simon de Coetnempren Kersaint (*q.v.*), who, as duchesse de Duras, presided over a celebrated salon and wrote several novels once widely read.

The family of Durfort is represented in France now by the branch of Durfort-Civrac, dating from the 16th century.

DURGA, one of the many cult-titles of Devi, "the Goddess," in Hindu mythology. Durga first appears in the Epics, as a name of Umā, wife of Siva (*q.v.*), and she may have been originally worshipped by savage aborigines. She is also a manifestation of Kālī (*q.v.*), and the hook-swinging rite of self-devotion is done in her honour. One of her principal festivals, as a war-goddess, is the Durga-puja (see DASEHRA). Durga is pictured, in spite of her fierce nature, with a gentle face.

DURHAM, JOHN GEORGE LAMBTON, 1ST EARL OF (1792–1840), English statesman, son of William Henry Lambton of Lambton Castle, Durham, was born in London on April 12, 1792. His mother was Anne Barbara Villiers, daughter of the 4th earl of Jersey. Lambton succeeded to large estates when he was five years old. In 1805 he went to Eton, and in 1809 obtained a commission in the 10th Hussars. In 1812, while still a minor, he made a runaway match with Henrietta, natural daughter of Lord Cholmondeley, whom he married at Gretna Green; she died in 1815. In 1813 he was elected to the House of Commons as member for the county of Durham in the Whig interests.

In 1816 he married Louisa Elizabeth, eldest daughter of Lord Grey, and as early as 1818 he was taken into the political confidence of his father-in-law and other Whig leaders. But Lambton belonged to the avowedly Radical wing of the party, with whose aims Grey had little sympathy; and when he gave notice of a resolution in 1819 in favour of shortening the duration of parliaments, and of a wide extension of the franchise, he found himself discountenanced. He warmly espoused the cause of Queen Caroline. In April he made his first great speech in the House of Commons on parliamentary reform, when he proposed a scheme for the extension of the suffrage to all holders of property, the division of the country into electoral districts and the disfranchisement of rotten boroughs. He was now one of the recognized leaders of the advanced Liberals, forming a connecting link between the aristocratic Whig leaders and the Liberals of the great towns. His opposition to any compromise on the question of Catholic emancipation led (1825) to his first conflict with Brougham, with whom he had been on terms of close friendship. While supporting the candidature of his brother-in-law, Lord Howick, for Northumberland in the elections of 1826, Lambton fought a duel with T. W. Beaumont, the Tory candidate, but without bloodshed on either side. Lambton supported the ministry of Canning, and after Canning's death that of Lord Goderich, on whose advice he was raised to the peerage in 1828 with the title of Baron Durham. Lord Durham was on terms of friendship with Prince Leopold of Saxe-Coburg, who, after he became king of the Belgians as Leopold I., continued to correspond with Durham as a trusted confidant; the same confidential relations also existed between Durham and Leopold's sister, the duchess of Kent, and her daughter, afterwards Queen Victoria.

In November 1830 Durham entered the Grey cabinet as lord privy seal. To ardent reformers in the country the presence in the cabinet of "Radical Jack" was a pledge that thorough-going reform would not be shirked by the Whigs, now in office for the first time for 20 years. Lord Grey gave him the task of preparing a scheme to serve as the basis of the proposed legislation. He was chairman of the famous committee of four, which met at his house in Cleveland Row and drew up the scheme submitted by the government to parliament. It was Durham who selected Lord John Russell, not then in the cabinet, to introduce the bill in the House of Commons. When the deadlock between the two Houses occurred over the second Reform Bill (1832), he pressed on the prime minister the necessity for a creation of peers to overcome the resistance of the House of Lords.

After the passing of the Reform Act, Durham was sent on a difficult diplomatic mission to Russia. On his return he resigned office in March 1833, ostensibly for reasons of health, but in reality owing to his disagreement with the government's Irish policy as conducted by Lord Stanley; in the same month he was created earl of Durham and Viscount Lambton. His advanced opinions gradually alienated the more moderate of his late colleagues, such as Melbourne and Palmerston, and even Lord Grey often found his son-in-law intractable and self-assertive; but the growing hostility of Brougham was mainly due to Durham's undoubted popularity in the country, where he was regarded by many, including J. S. Mill, as Grey's probable successor in the leadership of the Liberal party. At the great banquet given to

Lord Grey at Edinburgh in Sept. 1834 Brougham made a venomous attack on Durham, repeated shortly afterwards at Salisbury, and anonymously in the *Edinburgh Review*. But the strength of Durham's position in the country was shown when a concourse of more than a hundred thousand persons assembled to hear him speak at Glasgow Green in October. Durham however found no place in the Melbourne administration, partly because of his difficult temper, and partly on account of his radicalism.

In 1837 Durham accepted the post of governor-general and lord high commissioner in Canada, with the almost dictatorial powers conferred on him by an act passed in Feb. 1838, by which the constitution of Lower Canada was suspended for two years. Having secured the services of Charles Buller (*q.v.*) as first secretary, and having appointed Thomas Turton and Edward Gibbon Wakefield (*q.v.*) to be his unofficial assistants, Durham arrived at Quebec on May 28, 1838. Papineau's rebellion had been quelled, but the French Canadians were sullen, the attitude of the United States equivocal, and the general situation dangerous, especially in the Lower Province where government was practically in abeyance. Durham at once issued a conciliatory proclamation. He dismissed his predecessor's executive council and created a new and unprejudiced one. On June 28, the day of Queen Victoria's coronation, he issued a proclamation of amnesty, from which eight persons only were excepted; these were to be transferred from Montreal to Bermuda, where they were to be imprisoned without trial. Papineau and 15 other fugitives were forbidden on pain of death to return to Canada.

These proceedings were violently attacked in England by Brougham. Of the ministers Lord John Russell alone defended the public servant to whom they had promised "the most unflinching support"; and the prime minister and the colonial secretary, who had signified their "entire approval," now disallowed the ordinance, and carried an Act of Indemnity the terms of which were insulting to Durham. The latter immediately resigned; but before returning to England he put himself in the wrong by attempting a public justification of his actions. He laid his memorable "Report on the Affairs of British North America," before parliament on Jan. 31, 1839. This report, one of the greatest state papers in the English language, laid down the principles, then unrecognized, which have guided British colonial policy ever since. It was not written or composed by Charles Buller, as Brougham was the first to suggest, and the credit for the statesmanship it exhibits is Lord Durham's alone, though he warmly acknowledged the assistance he had derived from Buller, Wakefield and others in preparing the materials on which it was based. With regard to the future government of British North America, Durham had at first inclined towards a federation of all the colonies on that continent; but as a more immediately practical policy he advised the legislative union of Upper and Lower Canada. He further urged the creation of an executive council responsible to the colonial legislature; he advised state-aided emigration on the broadest possible scale, and the formation of an intercolonial railway for the development of the whole country. Meantime Durham, who almost alone among the statesmen of his time saw the importance of imperial expansion, interested himself in the emigration schemes of Gibbon Wakefield (*q.v.*); he became chairman of the New Zealand Company, and was thus concerned in the enterprise which forestalled France in asserting sovereignty over the islands of New Zealand in Sept. 1839. He died at Cowes on July 28, 1840, just five days after the royal assent had been given to the bill giving effect to his project for uniting Upper and Lower Canada.

Lord Durham filled a larger place in the eyes of his contemporaries than many statesmen who have been better remembered. He was in his lifetime regarded as a great popular leader; and his accession to supreme political power was for some years considered probable by many; his opinions were, however, too extreme to command the confidence of any considerable party in parliament before 1840. That Brougham hated him and Melbourne feared him, is a tribute to his abilities; and in the first Reform Act, of which he was the chief author, and in the famous *Report* on the principles of colonial policy, he left an indelible mark on English history. His personal defects of character did much to mar the success of a career, which, it must be remembered, terminated at the age of 48. He was impatient, hot-tempered, hypersensitive to criticism, vain and prone to take offence at fancied slights; but he was also generous and unvindictive, and while personally ambitious his care for the public interest was genuine and untiring.

By his first wife Durham had three daughters; by his second, who was a lady of the bedchamber to Queen Victoria but resigned on her husband's return from Canada, he had two sons and three daughters, the eldest son, Charles William, the "Master Lambton" of Sir Thomas Lawrence's celebrated picture, died in 1831; the second, George Frederick d'Arcy (1828–1879), succeeded his father as 2nd earl of Durham. The latter's son, John George Lambton (1855–1928), became 3rd earl in 1879.

DURHAM, a county of England bounded north by Northumberland, east by the North sea, south by Yorkshire, and west by Westmorland and Cumberland. Area 1,014.7 sq.mi. The Derwent, a tributary of the Tyne, forms part of the northern boundary with Northumberland, while the Tees in the south forms almost the whole of the boundary with Westmorland and Yorkshire. The county is divided into a highland west and a lowland east. No clearly marked contour separates these regions but geologically the Permian scarp, forming the right bank of the middle Wear and continuing north-north-eastwards to just south of Tynemouth is a suitable dividing line. West of this the Carboniferous limestone series prevails, a succession of thick beds of limestone with intervening sandstones and shales. This series forms the high ground of the north Pennines which are the backbone of the western section of the county. It is, however, broken by intrusive dykes and sills of basalt, especially in the Tees valley above Middleton; one of these, the Great Whin Sill, extends 120 miles. The Cockfield dyke and Little Whin Sill are similar intrusions of basalt. Millstone Grit caps many of the higher points in the west as at Muggleswick and Walsingham commons. On these plateaux, Bolts Law reaches 1,778 ft. and Fatherly hill 1,504 feet. The outcrop of the Millstone Grit broadens eastward until it is covered by the Durham coalfield which occupies the centre of the county from Newcastle and South Shields to Barnard Castle. There are some small Silurian outcrops near Cronkley on the Tees, once famous for its slate pencils. South and east of the Permian Scarp the newer rocks are exposed and dip eastwards or south-eastwards. The Permian magnesian limestone reaches from the Tees to South Shields in a broad tract and occupies the coast between that town and Hartlepool. The south-eastern corner of the county is low-lying with Triassic and Jurassic material — red marls and sandstones with beds of gypsum and rock salt.

The drainage system as represented by the major streams, the Wear, Derwent and Tees, bears a curious relation to the geology. When flowing over the older rock of the west they follow a general north-west to south-east line, well marked in the Upper Wear and Tees, but, once they enter the newer rocks, the general direction of the drainage runs almost at right angles south-west to north-east. Of additional interest is the final section of the Wear from Chester-le-Street to the sea. In pre-glacial times the south-west to north section of the middle course continued and the Wear was a tributary of the Tyne entering it just to the west of Gateshead. The blocking of its former lower course by glacial débris caused it to turn at Chester-le-Street to the eastward and it cut through the low Permian scarp and found the sea at its present mouth at Sunderland. Between the Wear and lower Tees is the strange valley of the Skerne. This river flows on Permian rock in an

opposite direction to the general trend of the larger rivers and enters the Tees just as it changes its course (near Darlington) from the upper north-west to south-east section on the older rocks (where it takes advantage of important fault lines) to its lower course on newer rocks in a broad open valley with wide stretches of sand near the coast.

Glacial deposits containing derived material from the Cheviots and Pennines obscure the older rocks. There are evidences from sunk meanders in the middle courses of the Wear and Tees, raised beaches, and submerged forests off the coast at West Hartlepool and other points of post-glacial earth movements. Except in the western moorlands only a few scraps of the county have been left in their natural state. The ballast-hills at Shields, Jarrow and Hartlepool, have many foreign plants elsewhere unknown in England. Stockton was almost the last retreat in England of the native black rat. Peatbog remains testify to the former abundance of deer, wild ox and boar, which appear to have existed in the reign of Henry VIII.; records of red deer are found in the 18th century.

Early Settlement. — Evidence of early man is scarce. It would seem that the area was but sparsely populated at least until Saxon times. Copt hill, Houghton-le-Spring, has a barrow which shows a series of burials, the earliest of which may be of neolithic date. Finds of the Bronze age are more numerous, yet from their characteristic distribution along the river valleys, especially those of the Tyne and Wear, it may be taken that the Bronze age invaders were more "birds of passage" than settlers. The Bronze hoard at Heathery Burn Cave has yielded important finds. Evidence of the Iron age is very scanty—a fine late Iron age sword, at Barnston, near Sadberge being its only representative.

History. — In Roman and Romano-British times, county Durham was an outpost and the main concern of the Romans was for the safely of communication to the frontier walls. Through the county ran the great north road, from outside York via Cataractonium to Vinduia at the bend of the Wear and thence northward to the Tyne at Corstopitum. Chester-le-Street and South Shields were Roman stations. The post-Roman centuries saw the county overrun by northern raiders until the Saxon settlement and the establishment of the kingdom of Northumbria. The church sites at Monk Wearmouth (Sunderland), Jarrow, Escomb, near Bishop Auckland, and numerous sculptured crosses (as those at Aycliffe) are of the Anglo-Saxon period.

In the 6th century Northumbria was divided into Bernica and Deira, separated by the Tees, the latter including the district afterwards known as Durham. The post-Norman palatinate grew around a grant of land originally made by Egfrith to St. Cuthbert on his election to the see of Lindisfarne in 685. On the transference of the see to Chester-le-Street in the 9th century, Guthred the Dane endowed it with the whole district between the Tyne and the Wear, stretching west as far as Watling street, a grant confirmed by Alfred; the endowment was again enriched at the establishment of the see at Durham in 995. The ravages of the Danes caused much disruption in this area in the 9th century when the Tees formed the northern boundary of the Danelaw. Durham continued, however, to form part of the earldom of Northumbria, and it was not until after the purchase of the earldom by Bishop Walcher in 1075 that the bishops began to exercise regal rights in their territory. The term palatinus is applied to the bishop in 1293. At the time of the Conquest the bishop's possessions included nearly all the district between the Tees and the Tyne, except Sadberge, and also the outlying districts of Bedlingtonshire, Norhamshire, Islandshire and Crayke, together with Hexhamshire, the city of Carlisle, and part of Teviotdale. Henry I. deprived the bishopric of the last three but made over to it three vills of the earldom of Northumberland. The wapentake of Sadberge was purchased by Bishop Pudsey in 1189, but continued independent in administration. The division into the four wards of Chester-le-Street, Darlington, Easington and Stockton existed in the 13th century. The diocese was divided into the archdeaconries of Durham and Northumberland.

The palatinate was administered by a steward with a sheriff. coroners, chamberlain and chancellor. The palatine assembly represented the whole county and dealt chiefly with fiscal questions. The bishop's council, consisting of the clergy, the sheriff and the barons, regulated judicial affairs. The prior of Durham had his own court. The repeated efforts of the crown to check the powers of the palatinate bishops culminated in 1536 in the Act of Resumption, which deprived the bishop of much of his judicial power. In 1596 further restrictions were imposed and in 1646 the palatinate was abolished. It was revived, however, after the Restoration, and continued with much the same power until the Act of 1836, which finally vested the palatine jurisdiction in the crown. The most important palatinate barons of the 12th century were the Hiltons, the Bulmers, the Conyers, the Hansards and the Lumleys. The Nevilles owned large estates in the county, which they ruled from Raby castle. Owing to its isolated position the palatinate took little part in the great rebellions of the Norman and Plantagenet period. On the outbreak of the Civil War Durham inclined to support the cause of parliament, and in 1640 harboured the Scottish army. In 1642 the earl of Newcastle organized the western counties for the king, but in 1644 the palatinate was again overrun by the Scottish army, and after Marston Moor fell entirely into the hands of the parliament.

Agriculture. — Agriculture centres in the river valleys. East of the line from Barnard Castle to Consett the hills are covered with a dry loam, whose fertility varies with its depth. West of the line the bills are in great part waste moorland. About 58½% of the total area of 645,739 ac. was under cultivation in 1939 and of this two-thirds was in permanent pasture, including 132,482 ac. of rough pasture. Oats, with 33,854 ac., were the main crop, with wheat (20,652 ac.) and barley (5,797 ac.) coming next. Potatoes and turnips and swedes, with 24,156 ac. almost equally divided, were prominent among the green crops. Cattle are imported. The sheep are esteemed, particularly the Teesdale and Weardale breeds. The National Trust owned only 18½ ac. in Durham in 1942.

Industrial Activities. — The coal-field has two sections, that west of Durham on the Pennine plateau where early mining occurred, and that east of the Wear. In the former region the coal measures outcrop on the valley sides and the mines are shallow. In the latter the coal is beneath the Permian rocks and the mines deep but productive. Little mining is done now west of Durham as the mines are shallow and the habitations consequently scattered, hut east of the Wear large quantities of coal are raised, which can easily be transported to the coast for exportation. Here the big industrial towns are gathered. The Frosterley marble has been quarried for many centuries near Stanhope, and excellent slate is quarried at several places. Fireclay is obtained in various parts of Durham, and exported in considerable quantity. The industrial districts may be taken to lie almost wholly east of a line from Darlington through Bishop Auckland to Consett. The manufacture of machines, appliances, locomotives, trams and tools is important, and the ship-building yards on the Tyne are second only to those on the Clyde; building is carried on also at Sunderland, the Hartlcpools and Stockton-on-Tees. The use of the waste gases from the iron foundries gives an impetus to the manufacture of chemicals, glass and bottles and earthenware. The heavy chemical industry has developed on Tees-side. Local iron ore was formerly used, but now vast quantities are imported. The Tyne and the Tees mouth are the main areas. Much timber is imported from Scandinavia. There is a large production of salt gypsum and artificial manures on the Tees mouth. The sea fisheries of Sunderland and Hartlepool are valuable.

The decline in shipping and the contraction of foreign markets (especially for coal), combined with the cessation of intensive wartime activity, led to widespread unemployment and poverty in the industrial section of Durham and Tyneside in the decades between World Wars I and II. Unemployment in June 1933 reached a peak of about 34% of the insured population, and relief from public funds was annually more than double the amount per capita expended in the country as a whole. Complete recovery from this condition was almost impossible and was made the more difficult by the deteriorated financial position of the local industries and the water-logged condition of many mines in the southwest of the county. When, therefore, under the act of 1934 almost all Durham became a "special area," the commissioner's attention was primarily directed toward the attraction of new industries to the area. A development board for the northeast as a whole was formed, along with local development councils. Derelict sites were cleared, public works were undertaken by the local authorities with the aid of government grants and a trading estate of 700 ac. was established in 1936 at Gatesbead, within two mi. of Newcastle, for light industries, while facilities were created to provide capital to potentially successful small businesses. In addition. land settlement schemes were promoted. The success of these measures led to an expansion of the commissioner's powers undrr the 1937 act, so that further sites were cleared and new factories set up outside trading estate areas.

The L.N.E R. main line runs northward through Darlington, Dur-

ham and Gateshead, and there are branches through the mining and industrial districts. The company also owns some docks. From Stockton to Darlington ran the railway engineered by George Stephenson and opened in 1825. Its main object was to transport coal to the coast for exportation.

Administration and Population. — The area of the administrative county is 973.7 sq.mi., with a population (est. 1938) of 1,440,000. Wartime movements, caused mainly by evacuation, led to a decline of 6% in the county population between Sept. 1939 and Feb. 1941. The county boroughs are Darlington, Gateshead, South Shields, Sunderland and West Hartlepool. Municipal boroughs are the city of Durham, Hartlepool, Jarrow and Stockton-on-Tees. There are 21 urban districts. Durham is in the northeastern circuit, and assizes are held at Durham. There are two courts of quarter sessions and the county is divided into 25 petty sessional divisions. It is in the diocese of Durham, excepting part of one parish in that of York, and contains 168 civil parishes. The bishop strongly opposed in 1614 a bill for securing representation to the county and city of Durham and the borough of Barnard Castle. The county mas first summoned to return members to parliament in 1654. After 1918 it returned one member for each of 11 divisions. The five county boroughs and Stockton-on-Tees also return one member each, except Sunderland, which returns two.

DURHAM, a city, and county town of Durham, England, in the Durham parliamentary division, 256 mi. N.W. from London, on the L.N.E.R. Pop. (est. 1938) 19,370. Area 6.3 sq.mi. The nucleus of the site is a narrow, rocky peninsula formed by a sharp bend of the river Wear, on which stands the cathedral and castle Though the mediaeval city grew around this site there are indications of earlier settlement, particularly on Maiden hill, where there is a Romano-British encampment. On the projecting rock rising some 70 ft. above the river the monks of Lindisfarne found, in 995, a resting place for the body of St. Cuthbert, which they had removed from its tomb in fear of Viking raids. The naturally strong position selected was possibly artificially fortified also, thereby laying the foundations of one of the few examples in Britain of a mediaeval fortress city. In 1928 it was reported that Durham castle was in danger of collapse from moving foundations. A national appeal for £150,000 "to save the castle from falling into the river" was made, and the restoration was successfully completed.

On the peninsula, which was called Dunholm (softened in Norman times to Duresme, whence Durham), a church was built by Bishop Ealdhun and the see was removed hither from Chester-le-Street in 995. In 1093 Ealdhun's church was rebuilt by Bishop Saint Calais, who changed the early establishment into a Benedictine abbey. The grand Norman building in which his designs were carried out remains, with numerous additions. The cathedral library, formerly the dormitory and refectories of the abbey, contains a number of printed books and mss. and the relics found in St. Cuthbert's grave.

In 1072 Earl Waltheof erected the castle to the north of the cathedral, but Ranulph Flambard was the designer of the Norman fortifications as they can be traced today. Of this there remains a beautiful crypt chapel. Other interesting portions are the Norman gallery, with its fine arcade, Bishop Hatfield's Hall of *c.* 1350, a reconstruction of the previous Norman one by Bishop Pudsey, and the Black Staircase of fine woodwork of the 17th century.

The church of St. Mary le Bow in the North Bailey is a 17th century building on a very ancient site, while that of St. Mary the Less possesses slight traces of Norman work. Of other churches in Durham, the site of St. Oswald is apparently pre-Norman, and the building contains Norman work of Bishop Pudsey, also some fine early 1 jth century woodwork. St. Margaret's and St. Giles's churches show work of the same period, while the latter has earlier portions.

The remarkable meander of the Wear served as a natural defense and replaced, in parts, the usual mediaeval town wall. Three of the present bridges across the river are old, that of Elvet having been built 1153–95. Framwellgate was rebuilt in the early 15th century. Outside the city on the Wear is the priory of Finchale (1196), of which there are considerable remains of Early English and later styles, but in the main Decorated. The earliest charter, dated 1179 or 1180, is a grant of exemption from toll merchet and heriot. Before that time, however, the monks had a little borough at Elvet, which is divided from Durham by the Wear and afterward became part of the city. In 1183 the city mas at farm and rendered 60 marks. The bishop of Durham. among other privileges, claimed a mint in the city, which according to Boldon Book rendered ten marks yearly until its value was reduced by that established by Henry II at Newcastle, and it was temporarily abolished by the same king.

The palatinate of Durham in the middle ages was a great border ecclesiastic state occupying the extent of the present county, with many outlying portions, and the cathedral functioned as "half church of God, half castle against the Scots." In the neighbourhood of the city is Neville's Cross. of which little remains. A battle was fought there in 1346 resulting in the defeat of the Scots. With the Reformation came the rise of other city buildings. A grammar school was founded by Henry VIII in place of the monastic school. The town hall, a 16th century building, was reconstructed in 1851. The city possesses a gild hall and shire hall, together with other county buildings. Four miles west of the city is the great Roman Catholic college of St. Cuthbert, Ushaw, the representative of the old college at Douai.

Durham was at first governed by a bailiff appointed by the bishop, but in 1j6j Bishop Pilkington ordained that the government should consist, in addition to the bailiff, of one alderman and twelve assistants, the latter to continue in office for life and the former to be chosen every year from among their number. This form of government was replaced in 1602, under the charter of Bishop Matthew, by that of a mayor, 12 aldermen and 24 burgesses, the aldermen and burgesses forming a common council and electing a mayor every year from among the aldermen. This was confirmed by James I, but in 1684 the corporation were obliged to resign their charters to Bishop Crew, who granted them a new one, probably reserving to himself a right of veto on the election of the mayor and aldermen. At the time of the Revolution, however, Bishop Matthew's charter was revived and continued to be the governing charter of the city until 1770, when. owing to dissensions as to the election of the common council, the number of aldermen was reduced to four and the charter became void. No mayor or aldermen were elected for 10 years, but in 1780 Bishop Egerton, on the petition of the burgesses, granted them a new charter, which was practically a confirmation of that of 1602 and remained in force until the Municipal Reform act of 183 j. Being within the county palatine, the city of Durham sent no members to parliament, until, after several attempts beginning in 1614, it was enabled by an act of 1673 to return two members, which it did until 1885, when the number was reduced to one. It was disfranchised in 1918.

The University. — Prior Richard de Hoton (1290–1308) erected a hall in Oxford for students from Durham. In 1380 Bishop Hatfield refounded this hall as Durham college, which became Trinity college (see OXFORD) on a new foundation (1 jjj). Henry VIII had the unfulfilled intention of founding a college in Durham, and a similar attempt failed during the Commonwealth. In 1831 the scheme for a college was projected by the chapter; an act of 1832 specified the foundation as a university, which was opened in 1833. In 1837 the university received its charter from William IV. Instruction in civil engineering and mining was established as early as 1837. In 1871 the university and the North of England Institute of Mining and Mechanical Engineers co-operated to found a college at Newcastle-upon-Tyne, which was incorporated with the university in 1874. The College of Medicine at Newcastle has been connected with Dur-

ham university since 1852. In 1895 women were admitted to degrees. In 1889 music degrees were instituted, and a professorship was founded in 1897.

In 1908 the university was reconstituted to consist of the Durham and the Newcastle divisions. The latter had the College of Medicine and Armstrong college, while the Durham colleges, University college, Hatfield college, St. Chad's college, St. John's college, St. Mary's college (women) and three residential colleges are controlled by the former. The university was later reorganized along lines suggested by a royal commission appointed in 1934, so that, although it still consisted of two divisions known as Durham colleges and King's college, Newcastle, the senate received greatly increased powers over the university as a whole.

Industries.—The corporation of Durham claim their fair and market rights under Bishop Pudsey's charter of 1179, confirmed in 1565, as a weekly market and three yearly fairs. There is also a fourth fair. In 1610 the bishop recovered the markets and fairs, which he afterward leased to the corporation for a rent of £20 yearly until they were purchased from the Ecclesiastical commissioners in 1860. Durham has never been noted for any particular trade; and the attempts to introduce the manufacture of cloth and wool in the 17th and 18th centuries were failures. The manufacture of carpets was begun in 1814.

The uplands have many collieries, and iron working and smelting is important. Durham is no longer one of the great cities of the north, but has become a small market town for the industrial population.

DURHAM, a city of North Carolina, U.S.A., 25 m. W. of Raleigh; the county seat of Durham county. It is on Federal highways 15, 70, 264 and 501, and is served by the Durham and Southern, the Norfolk and Western, the Norfolk Southern, the Seaboard Air Line and the Southern railways. The population was 21,719 in 1920 (35% Negroes), and was 60,195 in 1940 by the Federal census. It is the seat of Duke university (*q.v.*), and is one of the leading tobacco markets and tobacco-manufacturing centres of the country.

In the city of Durham there are large cotton mills, hosiery mills and various other manufacturing industries. The factory output within the city limits in 1933 was valued at $160,336,002. The assessed valuation of property in 1940 was $86,168,000 and bank debits amounted to $411,878,666. The North Carolina college for Negroes, Lincoln hospital (one of the finest in the country for Negroes), and the largest Negro life insurance company in the country are situated here. The tobacco industry of Durham was founded soon after the Civil War by W. T. Blackwell (1839–1904) and Washington Duke (1820–1910). The city was incorporated in 1869; became the county seat of the newly constituted county in 1881; and in 1921 adopted a council-manager form of government. In the Bennett house, near the city, Gen. J. E. Johnston on April 26, 1865, surrendered to Gen. Sherman.

DURIAN, the fruit of *Durio zibethinus,* a tree of the family Bombacaceae, which attains a height of 70 or Soft., has oblong, tapering leaves, rounded at the base, and yellowish-green flowers, and bears a general resemblance to the elm. The durian is cultivated in Sumatra, Java, Celebes and the Moluccas, and northwards as far as Mindanao in the Philippines; also in the Malay Peninsula, in Tenasserim, on the Bay of Bengal, to 14° N. lat., and in Siam to the 13th and 14th parallels. The fruit is spherical, and 6 to 8in. in diameter, approaching the size of a large coco-nut; it has a hard external husk or shell, and is completely armed with strong pyramidal tubercles, meeting one another at the base, and terminating in sharp, thorny points. On dividing the fruit at the joints of the carpels, where the spines arch a little, it is found to contain five oval compartments, each filled with a cream-coloured, glutinous pulp, in which are embedded from one to five seeds about the size of chestnuts. The pulp and the seeds, which latter are eaten roasted, are the edible parts of the fruit. With regard to the taste of the pulp, A. R. Wallace (The Malay Archipelago, 1872) remarks, "A rich butter-like custard, highly flavoured with almonds, gives the best idea of it, but intermingled with it come wafts of flavour that call to mind cream-cheese, onion-sauce, brown sherry and other incongruities; . . . it is neither acid, nor sweet, nor juicy, yet one feels the want of none of these qualities, for it is perfect as it is." The fruit, especially when not fresh from the tree, has an exceedingly offensive smell, which has been compared to that of rotten onions or of putrid animal matter.

DURIS, of Samos, Greek historian, according to his own account a descendant of Alcibiades, was born about 340 B.C. He must have passed his early years in exile, since from 352 to 324 Samos was occupied by Athenian cleruchs, who had expelled the original inhabitants. He was a pupil of Theophrastus of Eresus, whom he met at Athens. When quite young he won a prize at the Olympic games; a statue by Hippias was set up to commemorate his victory (Pausanias vi. 13, 5). He was for some time despot of Samos. Duris was the author of a history (*Historiae*) from the battle of Leuctra (371) down to the death of Lysimachus (281), and a life of Agathocles of Syracuse (both used by Diodorus), the annals (*ὧροι*) of Samos, arranged according to the lists of the priests of Hera, and treatises on literary and artistic subjects. Plutarch (Pericles, 28) expresses doubt as to his trustworthiness, Dionysius of Halicarnassus (De *compos. verborum,* 4) criticises his style, and Photius (cod. 176) the arrangement of his work. Cicero (ad Att. vi. 1) accords him qualified praise as an industrious writer.

Fragments in C. W. Müller, Frag. *Hist. Graec.* ii. 446, where the passage of Pausanias referred to above and the date of Duris's victory at Olympia are discussed.

DURKHEIM, EMILE (1858–1917), French philosopher, was born on April 15, 1858, at Les Vosges, and studied at the École Normale Supérieure under Boontroux. After travelling in Germany, he accepted the chair of sociology founded for him at Bordeaux in 1887, and five years later became professor in Paris. Contending that progress is a mechanical fact, Durkheim maintained that social investigations should be scientifically carried out and special attention given to facts capable of exact determination. The mentality of the group, he thought, is not simply that of the individual, but has its own specific reality. Because the mental life of the individual comes principally from his social environment, education is a "filling-up" process as well as a "drawing-out" one.

Durkheim's chief publications are De la division *du* travail social (1893); Les *règles* de la me'thode sociologique (1894); Le Suicide (1897); Les formes *élémentaires* de la vie religieuse, *le système* tote'mique en Australie (1912; Eng. trans., 1915); and Sociologie et *philosophie* (1924). In 1898 he founded *L'Année* Sociologique, which he edited annually.

See C. E. Gehlke, Durkheim's Contributions to Sociological Theory (1915); and R. Lacombe, La *Méthode* Sociologique de Durkheim (1926).

DÜRKHEIM, a town in the Bavarian Palatinate, Germany, near the foot of the Hardt mountains, and at the entrance of the valley of the Isenach, 15 mi. N.W. of Spires on the railway Monsheim-Neustadt. Population 7,770. The town hall occupies the site of the castle of the princes of Leiningen-Hartenburg. It is well known as a health resort, for the grape cure and for the baths of the brine springs of Philippshalle which produce marketable salt. There is a brisk trade in wine. As a dependency of the Benedictine abbey of Limburg, built and endowed by Conrad II., Diirkheim or Thurnigheim came under the counts of Leiningen, who in the 14th century made it the seat of a fortress. It was often damaged in wars but was rebuilt after the French invasion of 1689. The ruins of the Benedictine abbey of Limburg lie about 1 m. S.W. of the town; and in the neighbourhood rises the Kastanienberg, with ancient fortification of the Heidenmauer or Heathen's Wall.

DURLACH, a town in the *Land* of Baden, Germany, 2½m. by rail from Karlsruhe, with which it is connected by canal, on the left bank of the Pfinz, at the foot of the vineyard-covered Thurmberg. Pop. (1933) 18,658. It possesses a castle (1565) now a barracks, and an ancient town hall. It has manufactures of brushes, chemicals, machinery, gloves, leather, tobacco, beer, vinegar and chicory; and considerable trade in market produce.

Durlach was bestowed by the emperor Frederick II. on the margrave Hermann V. of Zahringen as an allodial possession, but afterwards came into the hands of Rudolph of Habsburg. It was chosen as his residence by the margrave Charles II. in 1565, and retained this distinction till the foundation of Karlsruhe in 1715, though it was almost totally destroyed by the French in 1688.

DUROC, GÉRAUD CHRISTOPHE MICHEL, DUC DE FRIULI (1772–ISIS), French general, was born at Pont à Mousson (Meurthe et Moselle) on Oct. 25, 1772. He was gazetted second lieutenant (artillery) in the 4th regiment in 1793, and advanced steadily in the service. Captain Duroc became aide-de-camp to Napoleon in 1796, and distinguished himself at Isonzo, Brenta and Gradisca in the Italian campaigns of 1796–97. He served in Egypt, and was seriously wounded at Aboukir. His devotion to Napoleon was rewarded by complete confidence. He became first aide-de-camp (1798), general of brigade (1800) and governor of the Tuileries. After the battle of Marengo he was sent on missions to Vienna, St. Petersburg, Stockholm and Copenhagen. As grand marshal of the Tuileries he was responsible for the measures taken to secure Napoleon's personal safety whether in France or on his campaigns, and he directed the minutest details of the imperial household. After Austerlitz, where he commanded the grenadiers in the absence of General Oudinot, he was employed in negotiations with Frederick William of Prussia, with the elector of Saxony (December 1806), in the incorporation of certain states in the Confederation of the Rhine, and in the conclusion of the armistice of Znaim (July 1808). In 1808 he was created duke of Friuli, and after the Russian campaign he became senator (1813). He was in attendance on Napoleon at the battle of Bautzen (May 20–21, 1813) in Saxony, when he was mortally wounded, and died in a farmhouse near the battlefield on May 23.

The chief source for Duroc's biography is the *Moniteur* (May 31, 1797, Oct. 24, 1798, May 30, 1813, etc.).

DURRA: *see* KAFIR.

DURUY, JEAN VICTOR (1811–1894), French historian and statesman, was born in Paris. He studied under Michelet at the École Normale Supérieure, and taught at the Collège Henri IV. at Paris for over a quarter of a century. Already known as a historian by his *Histoire des Romains et des peuples soumis à leur domination* (2 vols., 1843–44), he was appointed minister of education in 1863.

Among his measures may be cited his organization of higher education ("enseignement spécial"), his foundation of the "conférences publiques," which later became universal throughout France, and of a course of secondary education for girls by lay teachers, and his introduction of modern history and modern languages into the curriculum both of the *lycées* and of the colleges. He greatly improved the state of primary education in France and proposed to make it compulsory and gratuitous, but was not supported in this project by the emperor. In 1884 he was elected to the Academy. He died on Nov. 25, 1894.

Duruy's fame rests mainly on the revised edition of his Roman history, which appeared in a greatly enlarged form in 7 vol. under the title of *Histoire des Romains depuis les temps les plus reculés jusqu'à la mort de The'odose* (1879–85), Eng. trans. by W. J. Clarke, 6 vol., 1883–86. He also wrote *Histozre des Grecs* (3 vol., 1886–91; Eng. trans., 4 vol., 1892); *Histoire de France de 1453 à 1815* (1856; new enlarged ed. 1891); and other works on French history.

A memoir by Ernest Lavisse appeared in 1895 under the title of *Un Ministre: Victor Duruy*. *See* also the notice by Jules Simon (1895) and S. Monod, *Portraits et souvenirs* (1897).

DURYEA, an anthracite mining borough of Luzerne county, Pa., U.S.A., on the Susquehanna river and the Lackawanna railroad, 8 mi. S.W. of Scranton. The population in 1920 was 7,776 (28% foreign-born white) and 8,275 in 1940.

The borough, originally called Babel because the first inhabitants came from so many different countries and spoke so many different languages, was called Duryea after Abram Duryea, who began working coal mines in that region in the middle of the 19th century.

DU RYER, PIERRE (1606–1658), French dramatist, was born in Paris in 1606. His masterpiece, *Sckvole*, probably dates from 1644 (the date generally given is 1646). *Alcionke* (1638) was so popular that the abbé d'Aubignac knew it by heart, and Queen Christina is said to have had it read to her three times in one day. Among du Ryer's other works may be mentioned *Saül* (printed 1642) and a comedy, *Les Vendanges de Suresnes* (1635 or 1636). He died in Paris on Nov. 6, 1658.

DUSART (DU SART) **CORNELIS,** the younger (1660–1704), Dutch painter and engraver. He was born at Haarlem on April 24, 1660, and became one of the most distinguished pupils of Adriaen van Ostade, following his master closely both as regards style and subject matter. His engravings are much sought after. He died at Haarlem on Oct. 1, 1704.

DUSE, ELEONORA (1859–1924), Italian actress, belonged to a family of actors from Chioggia, near Venice. Her grandfather, Luigi Duse, a celebrated actor of Goldoni plays, created the 18th century Venetian masque of Giacometto, round which a whole dialect repertory turned. Born on a tour in Lombardy on Oct. 3, 1859, Eleonora Duse was carried to her christening at Vigevano in a gilt theatrical property-box; some Austrian soldiers presented arms, thinking it was a reliquary. She acted the part of Cosette in *Les Misérables* at the age of four in a booth at Chioggia. At Verona she played Juliet when just 14, and drew public attention by her love of flowers and the use she made of them in her art. The incident is always referred to as "the device of the roses" *(la trovata delle rose)*.

About this time her mother, to whom she was passionately attached, died, and thrown on her own resources, often in dire poverty, she passed from one travelling company to another, eventually reaching fame through sheer hard work, no less than by genius and the exceptional beauty of her speaking voice. She acted in *Alcibiades* of Felice Cavallotti, in *Orfeo* of Alfieri, and took the part of Shakespeare's Ophelia with success. She gained wider recognition in 1878 when, one night at Naples, she was called upon suddenly to take the leading part in *Les Fourchambault* by Augier. In the following year, after securing a real triumph in the part of Zola's *Thérèse Raquin,* Cesare Rossi engaged her for his famous company as *prima diva* and she added *La Princesse de Bagdad* to her repertory. A memorable year was 1882: she saw Sarah Bernhardt act at Turin in *La Dame aux Camélias* of Dumas fils, and felt inspired to give her own interpretation of Marguerite Gautier—"fille galante, extrêmement distinguée," a character which both actresses idealized, The Frenchwoman, less realistic and temperamental, possessed a more subtle style; but, in certain scenes, the passionate, almost volcanic, powers of the Duse admitted of no rival. The greatest triumph, perhaps, in her career was gained in this part, and she was induced to act it in Paris in 1897, when the Parisians were taken by storm, Sarah Bernhardt leading the applause. She also acted in *Frou Frou* and *La Femme de Claude.* Her *Magda,* in the opinion of Sudermann the author, was never surpassed. In the character of Mirandolina *(La Locandiera* of Goldoni) she also showed a remarkable gift for light comedy. She created the character of Santuzza in *La Cavalleria Rusticana,* given for the first time in 1884, and such was her success that Verga said the play belonged as much to her as to him. Her acting during all this period was characterized by realism devoid of any excess; hers was the highest kind of romantic realism which had passed through the flame of intense feeling. Coquelin the elder said of her: "No one draws from humanity as she does; she is passionately beautiful and great." Her own words still further help to explain her vivid and varied personality: "How I have loved life!" she wrote to a friend, and again: "There are a thousand women within me, and each one makes me suffer in turn."

Eleonora Duse was a woman of wide culture; her intellectual life had been greatly influenced early in life through a close friendship with Arrigo Boito, the composer, whose sound criticism proved of considerable value to her art. The books she steeped herself in included the writings of Pascal, Keats, and Thomas à Kempis; *The Letters of St. Catherine of Siena, The Confessions of St. Augustine* and *L'Action by* Maurice Blondel.

Essentially religious by nature, she was untouched by organized religion. She travelled a great deal both for her profession and for pleasure: Matilde Serao called her "the impassioned pilgrim." She had no fixed home; the nearest approach to one was her summer house at Asolo. She lived simply but spent large sums on producing plays and in financing her company of actors whom she would sometimes keep idle for long spells on account of health. She made her first appearance in Paris in 1884; went to London and New York in 1893, and to Moscow in 1892 and 1897, and to Egypt. She always particularly liked acting in Vienna.

Her restless, soaring spirit eventually grew weary of Dumas and Augier, finding in La Dame aux *Camélias* alone "a thread of gold to hold together the string of false pearls"; and, towards middle age, the Duse turned definitely to poetry and "les oeuvres de pensée." In 1896 she commissioned Panzacchi to translate *L'Abbesse* de Houarre, which she acted in Rome with so much success that Renan wrote her a letter full of praise and gratitude. At this time she passed under the spell of the later works of Ibsen, to be closely followed by the aestheticism of D'Annunzio. In the Scandinavian dramatist she saw the poet more vividly than the scourger of society. Ellida, The Lady from the Sea, with whom she felt some affinity, was her favourite heroine. Ibsen was not altogether satisfied with her interpretation of Hedda Gabler; he is reported to have said as he left the theatre: "She believes Hedda to be a neurotic, but she is absolutely wrong."

Her life-consuming friendship with D'Annunzio began in 1897; they parted in 1902, only to meet 18 years later at a patriotic gathering in Milan. D'Annunzio immortalized their friendship in Fuoco, the novel of the lagoons, incorporating many of her letters and sayings. La *Città morta* he had dedicated to Sarah Bernhardt; La Gioconda he wrote for "Eleonora Duse of the beautiful hands," and wrote many other plays under her enthusiastic inspiration. She took up the cause of D'Annunzio as a dramatist with almost mystic exaltation, and threw all her energies into trying to found a theatre which was to be a D'Annunzio Bayreuth for the glory of a pure art. A site was offered to her on the shores of Lake Albano, near the Baths of Diana, but to her grief the scheme fell through, chiefly because the public did not recognize the real Duse in the drama of D'Annunzio. La Gloria was hissed at Naples in 1898 and no better success attended Sogno *di* un *mattino* di *primavera,* but she won some applause for Francesca da *Rimini* in 1902. Undaunted, the Duse insisted upon acting only the plays of D'Annunzio when she went to America in 1902–3 with Ermete Zacconi, and, in spite of financial losses, she refused to revive old favourites. Some people think that D'Annunzio had an enervating effect upon her art, and that her recitation tended towards monotony; while, in the opinion of others, her style lost rough edges and gained in classical grandeur, and her general culture was enriched.

At the height of her fame in 1909, Eleonora Duse definitely left the stage, mainly on account of health. For twelve years she retired into private life. But, owing to pecuniary losses arising out of the World War, she had to face the necessity of returning to the stage. After much anxious thought she accepted collaboration once more with Ermete Zacconi, appearing at Turin in 1921 in The Lady from the Sea. "I only want to act the part of mothers," she said, "women without age, creatures of eternity, like Ellida and so many heroines of the great Ibsen. . . . No wigs, they must accept me with my white hair." They did, and Eleonora Duse found that she had conquered the world a second time. A desire to do something for Italy acted as an incentive to work at this time. Animated by a passionate desire to participate in the joys and sorrows of her fellow creatures, she strove to teach "the good and beauty of life" to a world devastated by a spirit of violence, which was abhorrent to her nature. For the purpose of this spiritual crusade, and also for the benefit of young authors, she tried to found an Italian theatre—Teatro dei Giovani. She complained that her scheme was not supported by the Government, but her ideas were vague and perhaps, too, time was not ripe for the venture.

This, the last period in her career, was marked by a wonderful revival of her youthful genius, rather than by any new creations or change of style. She continued to play Ibsen, D'Annunzio and La Porta *Chiusa* of Marco Praga. After touring Italy she made her last appearance in London in June 1923 when she acted to far fuller houses than in the heyday of her glory. She courageously accepted a tour in America the following spring, where she also received a triumphal reception. But her health was broken, and often she had to be revived with oxygen after a performance, though her vitality never gave out during the play. She died from the results of a chill at Pittsburgh on April 21, 1924, at the age of 64. She was pitifully anxious not to die far away from Italy, and gave feverish orders, almost with her last breath, to pack up quickly so as to catch the boat home. Italian emigrants knelt on the quay as her coffin was lowered on to the battleship "Duilio" at New York, and national mourning was proclaimed in Italy. Her countrymen desired to see her laid at rest with other illustrious Italians in Santa Croce at Florence, but they respected her wishes to be quietly buried at Asolo.

DUSSEK, JAN LADISLAV (1761–1812), Bohemian pianist and composer, was born at Caslar, Bohemia, on Feb. 9, 1761, the son of the cathedral organist. He played in public at the age of 6, became a choir boy, and then studied theology at Prague. He found a pattern in Count Manner, whom he accompanied to Malines, Belgium. He was organist there for some time, then at Bergen-op-Zoom. He then spent some time at Amsterdam and the Hague, and attained a great reputation as a pianist. He had already written a large number of sonatas for the pianoforte with string accompaniments, when he went to Hamburg about 1783 to study under Karl Philipp Emanuel Bach. Dussek found a patron in Prince Radziwill and in Paris in Marie Antoinette. He spent twelve years in London from 1792 onwards, marrying in that year a singer, the daughter of Domenico Corri. Later he entered into partnership with Corri in a music shop, which failed. He left England in 1800 for Hamburg. His later patrons were Prince Louis Ferdinand of Prussia, the prince of Ysenburg and finally Talleyrand. In Talleyrand's household, where he lived from 1809 until his death at St. Germain-en-Laye (Nov. 20, 1812) he was a great and honoured figure. A complete list of Dussek's works will be found in Grove's Dictionary of Music and Musicians. It includes a large number of pianoforte works and a considerable amount of chamber music. His sonatas for the pianoforte represent him at his best.

See L. Schiffer, J. L. Dussek (1915).

DÜSSELDORF, a government district (Regierungsbezirk) of Rhenish Prussia, Germany. Area 2,121 sq.mi. Pop. (1939) 4,153,691. (2) A town, the capital of the district. Pop. (1939) 539,905. It is situated on the right bank of the Rhine 24 mi. northwest (by rail) from Cologne. It was long a place of small importance until, in 1288, it was raised to the rank of a town by Count Adolf of Berg. It suffered severely in the Thirty Years' War and the War of the Spanish Succession, but recovered its prosperity under the patronage of the elector John William of the Palatinate who dwelt in the castle many years until his death in 1716. In 1795 the town after a violent bombardment was surrendered to the French; and after the peace of Lunéville it was deprived of its fortifications. In 1805 it became the capital of the Napoleonic duchy of Berg; and in 1815 it passed with the duchy into Prussian possession. After 1870, it developed into an important industrial and commercial town. It is the commercial and manufacturing centre of the Wupper and Ruhr areas and is a great centre of the metallurgical, engineering, machinery, glass and chemical industries; other important industries are paper, enamel, weaving, spinning, silk. dyes, furniture and brewing. It is an important railway junction. The extensive quays provide accommodation for large steamers ordinarily sailing to England

Northern Europe and certain Mediterranean ports. The famous Academy of Painting founded by the elector Charles Theodore in 1767 was reorganized by King Frederick William III in 1822 Among the celebrities of the town are Johann Georg and Frederick Henrich Jacobi; Heinrich Heine and Peter von Cornelius; and Louise Dumont, who founded a theatre. Large international industrial exhibitions were held at Dusseldorf in 1880, 1902 and 1937. In order to facilitate better city-planning in regard to streets, traffic and parks, several adjacent towns and suburbs (Benrath, Garath, Urdenbach. Kaiserwerth, Lohausen and Ludenberg) were incorporated into Dusseldorf on Aug. 1. 1929. During World War II the city suffered severely from frequent British bombing attacks.

See H Ferber, *Historische Wanderung durch die alte Stadt Düsseldorf (Diisseldcrf,* 1889–90); Wilden, *Grundlagen und Triebkrafte der Wirtschaft in Dusseldorf* (1923); H. Stolz, *Düsseldorf* (1925).

DUST. Dust is earth or other solid matter in a fine state of subdivision, so that the particles are light enough to be easily raised and carried as a cloud by the wind. The presence of dust in the atmosphere is obvious on the most casual inspection. Particles of dust, varying from the motes in the sunbeam to big flakes of soot, are readily visible to the naked eye. The origin of the dust is varied in character. Smoke from domestic and factory chimneys contains particles of carbon (soot), as well as small particles of ashes and drops of liquid tar. These particles are carried by the wind, and even spread upward through considerable heights by the turbulent or eddy motion of air *(see* METEOROLOGY: *Turbulence)*

Over the deserts coarse dust is raised from the ground by windstorms, and can be carried for thousands of miles by the wind. The "red rain" which has been observed in Europe from time to time is due to the washing down of desert dust which has originated in tropical deserts. A notable example of "red rain" occurring on Feb. 21 and 22, 1903, is described in the *Quarterly Journal Roy. Met. Soc.,* xxx., 1904 p. 57, where it is shown that the dust must have travelled from north-west Africa round the western edge of an anticyclone over southern Europe. The amount of dust which fell in England during the two days in question was estimated at about ten million tons. The *harmattan,* a dry easterly wind which blows off the west coast of Africa between Cape Verde and Cape Lopez, carries with it quantities of dust, causing thick haze for a distance up to 1 j m. from the shore. Enormous quantities of volcanic dust are poured into the atmosphere by the eruption of volcanoes. The eruption of Krakatoa near Java in 1883 produced, among many effects, a vast cloud of small particles which is said to have taken two years to settle down completely. The dust from Krakatoa produced the most extraordinary colours in the sky. Even in the British Isles sunsets of unusually gorgeous colours were observed Meteoric matter disintegrating in the air is another source of atmospheric dust. A phenomenal dust storm visited the United States in May 1934. Rising from the parched soil of the Western plains, where drifts as deep as six inches often covered the highways, a vast cloud of dust moved slowly eastward, hung for a time in yellow haze over the cities along the coast and finally was precipitated in the Atlantic Ocean.

The particles of dust or soot, from whatever source they originate, are distributed over a wide area by the wind. Granted a sufficient wind velocity, the smoke from the largest city will be distributed over such a wide area, and through so great a volume of air, that it cannot acquire a sufficient density to be troublesome. But when the wind falls below a certain limit, it ceases to be an effective distributor. Another factor of importance in connection with the concentration of smoke is the turbulence in the atmosphere, which scatters the smoke through a greater range of height than it would otherwise attain. When there is an increase of temperature with height (*i.e.,* an inversion) instead of the normal decrease, turbulence is suppressed; since inversions of temperature at the ground are usually associated with light winds, they generally give smoke fogs in large towns.

The rate of settlement of spherical particles of dust through a still atmosphere is given approximately by the formula,

$$V = \text{density} \times R^2 \times 12 \times 10^5$$

where V is the velocity in centimetres per second and R is the radius of the particle in centimetres. Thus a particle of unit density and of diameter 1 micron will fall through still air at a rate of about 0.003 centimetres per second, which is equivalent to a fall of 30 metres (100 ft.) in 278 hours, during which time a wind of 10 m p.h. would carry it 2,780 miles. It is thus readily seen that smoke particles can travel over immense distances under favourable conditions. A drop of water of diameter 10 microns would fall with a velocity of ·3 cm/sec. or roughly 10 metres in one hour.

The first investigations of the amount of dust in the atmosphere were those of John Aitken in 1880. Aitken succeeded in showing that water drops will not form, even in supersaturated air, in the complete absence of solid nuclei upon which the molecules of water can collect. It was but a step further, to utilize this idea to count the number of condensation nuclei in a given volume of air. Aitken's method consisted in placing the air under examination in an airtight receiver and saturating it with water vapour. It was then caused to expand adiabatically until condensation was produced, the drops being collected on a reticule and counted by the aid of a short focussed lens. Certain precautions were necessary in carrying out this procedure. It was found that if more than 500 nuclei were present in each cubic centimetre of air, they would not all form water drops. In such cases it was necessary first to dilute the air with air which had been carefully filtered, subsequently allowing for the dilution in computing the number of particles per second. Aitken's method was applied in thousands of tests in different parts of the world, and in no case was the air found to be completely free of nuclei. The numbers of particles per c.c. in cities such as London and Paris were often found to exceed 100,000. Fridlander used Aitken's dust counter on a voyage across the Atlantic and never found values below 2.000 per c.c. but in crossing the Pacific and Indian oceans he found values as low as about 250 per c.c. But we can safely conclude that air, no matter where it is sampled, contains an ample supply of particles capable of acting as condensation nuclei. The instrument which Aitken devised for counting the particles suspended in air was called a "dust-counter," but subsequent research has shown that the particles which Aitken counted were not dust in the ordinary sense of the word, but what are known as hygroscopic nuclei.

The only effective nuclei are particles of certain hygroscopic salts, in particular the chlorides of sodium and magnesium derived from salt spray, and sulphates. Ordinary dust, except such particles as may be hygroscopic, will not act as nuclei for condensation, and particles of soot, being of a tarry nature, tend to repel water rather than to attract it. The hygroscopic nuclei are so small as to be in general invisible in the field of a high-power microscope, but on account of their hygroscopic properties they are capable of producing water drops in air whose humidity falls short of saturation. Thus particles of common salt will produce condensation when the relative humidity is only 75%, and are thus capable of producing fogs at times when the conditions do not otherwise seem favourable for their formation.

It was first suggested by Wigand (A. Wigand, *Meteor. Zeitschrift.* 30 p. 10 Jan. 1913) that the particles counted by Aitken's dust counter were not dust in the ordinary sense of the word. Wigand compared the figures obtained by Aitken's method in air which was artificially made dusty and found that the number of condensation nuclei per c.c. was not dependent on the amount of dust introduced into the atmosphere. This is confirmed by Owen's observations. A recent investigation by Boylan *(Proc. Roy. Irish Acad.* vol. 37A. N.O. 6, 1926) shows very definitely that the dust and nuclei are different, and that ordinary dust particles will not act as nuclei for condensation.

The horizontal visibility of objects on the earth's surface depends upon the degree of pollution of the atmosphere. Poor visibility is due to the obscuration of the atmosphere by water-drops or by solid particles. The condition known as haze is due to the presence in the atmosphere of small solid particles, whose diameter is about ·5 micron (·0005 mm.), together with varying quantities

of water-drops. In a series of observations of haze by Owens it was found that in some cases no water-drops were present, while in other cases large numbers of water-drops were found. The distinction is largely a question of relative humidity, since haze is probably always a mixture of insoluble particles and hygroscopic nuclei. If the relative humidity is low, the haze effect is almost entirely due to small solid particles of dust whose diameter is of the order of $\frac{1}{2}$ micron; but if the humidity increases sufficiently, condensation takes place on the hygroscopic nuclei, and the haze changes into a true mist. Similarly fog may be divided into two classes—smoke fogs and water fogs. The diameter of the solid particles in a smoke fog vary from $\frac{1}{2}$ micron up to several micron, while the diameter of water drops in a water fog vary from 5 to 20 microns. The fine smoke particles which produce the dust horizon frequently seen in the British isles have diameters of about ·8 micron, while the Indian dust horizon consists of blown sand of similar size.

The most troublesome aspect of atmospheric dust is provided by the smoke produced in great cities. The problem of pollution produced by smoke has been the study of a special Advisory Committee on Atmospheric Pollution. The work of this committee has been summarized by Sir Napier Shaw and Dr. J. S. Owens in *The Smoke Problem of Great Cities*. Smoke as it issues from the chimney consists of particles of soot of varying sizes as well as acid products of combustion, small particles of ash, and small drops of tar. The larger aggregations of soot fall in the near neighbourhood of their source, while the smaller particles of diameter rather less than one micron are carried to considerable distances. Shaw and Owens describe a variety of methods for the detection and measurement of the quantities of different forms of pollution in the atmosphere, and the reader is referred to their treatise for fuller details of these methods. Of particular interest, however, is the jet dust counter devised by Dr. J. S. Owens, depending upon the principle that when air containing dust and a sufficient quantity of water vapour has its pressure suddenly reduced, there is a fall of temperature and a condensation of moisture into water drops.

It is not clear how the ordinary dust particles become attached to their share of water, but it appears probable that the particles which are hygroscopic become nuclei of condensation and that the condensed water captures the dust. When the dust-bearing water drops are brought into contact with a glass surface they adhere to it. In the Owens dust-counter the dusty air is drawn through a slit as a fine ribbon-shaped jet, and impinges on a coverglass placed at a millimetre from the slit. The air is first passed through a damping chamber in which it acquires sufficient moisture to produce condensation. The lowering of pressure by which the air is drawn through the jet is sufficient to produce condensation in the air striking the coverglass. As the velocity falls off, the pressure and temperature rise, and the waterdrops evaporate from the coverglass, leaving the dust deposited. By a careful adjustment of the amount of air drawn through the jet, a record is obtained on which the dust particles can be examined and counted by means of a microscope with $\frac{1}{12}$ inch oil-irnmersion objective.

The results derived by the use of the Owens dust-counter show a wide variation in the number and nature of the particles in the atmosphere. For example, in a dense fog on Jan. 22, 1922, there were 21,710 particles per cubic centimetre. The average diameter of the particles was 0·85 microns, but a large proportion had diameters twice as great as the average. Somewhat similar results were obtained from a fog on Oct 26, 1921, but in this case there were numerous small spherical particles of diameters up to 0·85 microns. A slight haze in dry sunny weather yielded 100 to 200 particles per cubic centimetre, of sizes from 0·3 microns up to 1·7 microns. Further, it was found that when the damping chamber of the Owens dust-counter was slightly warmed, and a large quantity of air drawn through the jet, the condensed water flowed out sideways in streams, and on evaporation left the soluble matter crystallized in the dried-up stream beds. The crystals could then be examined microscopically and micro-chemically. The deposit on the coverglass frequently showed needle-shaped and rhomboid crystals, sometimes with a tarry deposit. Most of the records obtained showed a number of transparent spherical particles, occasionally accounting for as much as 50% of the total number of particles counted. When very small these particles appear opaque, but when the diameter exceeds about 0·75 micron they show a bright centre. The spherical particles are insoluble in water, xylol, and cedarwood oil.

Perhaps the most remarkable fact brought out by the observations mentioned above is the remarkable uniformity as to the size of the particles. Shaw and Owens in the book referred to (p. 185) give a comparison between numbers of particles counted by the jet dust-counter, and the total impurity present in the atmosphere, showing a remarkably close proportionality. The number of particles counted should therefore give a measure of the degree of obscurity of the atmosphere. These numbers bear no relationship to the numbers of particles obtained in the Aitken dust-counter, since the latter may give extremely high values in apparently clear air.

The fact that the particles measured by the Owens dust-counter differ from those observed by Aitken is also confirmed by the observations made by Owens while crossing the Atlantic. No dust was to be recognized in any of the records, though some showed numbers of crystals, some of which were not hygroscopic and were only sparingly soluble in water. Aitken, on the other hand, never found less than about 2,000 particles in one cubic centimetre of air over the Atlantic.

Optical Effects.—The scattering of light by small obstacles was exhaustively studied by the late Lord Rayleigh, who showed that true scattering only takes place when the diameter of the obscuring particles is smaller than the wave length of the incident light. Rayleigh showed also that the coefficient of scattering was inversely proportional to the fourth power of the wave length. so that light in the blue end of the spectrum is scattered more than light in the red end of the spectrum. Thus a cloud of tobacco smoke (consisting of small liquid particles of about ·2 microns in diameter) or a smoke haze in the atmosphere will appear blue by scattered light, while the sun appears red when viewed through a thick smoke fog, but white when viewed through a country fog consisting of water drops. Water drops are too large to produce true scattering, their effect being of the nature of diffraction and reflection which is almost equally effective for all wave lengths. Hence water drops appear white, whether viewed by scattered or direct solar radiation.

During the first two or three years after the eruption of Krakatoa a reddish brown corona was often observed around the sun. It had an angular radius of 22° to 23°, and was 10° to 12° wide. Pernter explained this phenomenon, which was known as Bishop's ring, as a result of diffraction of sunlight by small dust particles, and assuming the particles to be spherical he found their diameter to be 1·85 microns. It is of interest to combine this figure with Stokes's formula for the rate of fall of particles. We find their rate of fall should be 0·02 cm/sec. or 10 km. in a time between one or two years.

Another aspect of the optical effects of dust in the atmosphere upon sunlight relates to the loss of ultra-violet rays which is directly produced by dust and smoke pollution. In the *Times* of Dec. 22, 1924, Professor Leonard Hill gave a comparison of the relative amounts of ultra-violet light at different places in the British isles, showing the lowest values in the centre of London. In view of the importance of ultra-violet rays to human health, the results are highly suggestive.

It has been frequently suggested that a smoke fog such as a London fog might be penetrated by the longer infra-red rays. On theoretical grounds we should expect that infra-red rays of wave length large by comparison with the mean diameter of the smoke particles (0·8 micron), should show some degree of penetration. In Wood's *Physical Optics* (3rd Edition p. 416), there is a statement that a film of smoke which was absolutely opaque to light was transparent to infra-red rays of wave length 100 microns. This result in itself is not suggestive of any practical solution of penetration, since there still remain the problems of finding not only suitable sources for such radiation but also a means of rendering visible the rays which have penetrated the fog.

The problem is a long way from solution, and no definite observations of the penetration of fogs by infra-red rays of different wavelength appear to have been published.

Country fogs, composed of drops of water whose diameter is of the order of 10 microns, show no appreciable selective effect in the transmission of light, and there is no obvious reason for supposing that infra-red rays would penetrate such fogs.

F. Entwistle (Jour. Ry. Aer. *Soc.* vol. xxxii., p. 374, 1928) reproduces two interesting photographs by C. J. P. Cave, of a landscape—the one photograph taken in the usual way without a screen, and the second with a red screen, which cuts out all the blue light. The first shows a light fog, while in the second only slight traces of the fog are visible.

Vulcanism.—In Physics of the Air, W. J. Humphreys has discussed in considerable detail the effect of clouds of volcanic dust on solar and terrestrial radiation. He finds that these clouds have an inverse green-house effect, in that they would obstruct the inward passage of solar radiation more than the outward passage of terrestrial radiation. For since solar radiation at its point of maximum intensity has a wave length of a little less than half a micron, it would be reflected rather than scattered by the dust particles whose diameter is of the order of 2 microns. Terrestrial radiation, on the other hand, has a wave length of about 12 microns at the point of maximum intensity, and should therefore be scattered by the dust particles in accordance with Rayleigh's law. On this basis Humphreys evaluates the coefficients of attenuation of solar and terrestrial radiation by volcanic dust, and concludes that a shell of volcanic dust is some thirty times more effective in shutting out solar radiation than it is in keeping in terrestrial radiation. Humphreys' computation is admittedly a rough approximation only. It assumes that all the dust is uniformly of the size of the particles which give Bishop's ring by diffraction. This we know to be incorrect. The wonderfully coloured sunsets produced by Krakatoa dust indicated a scattering of solar rays by dust particles of a diameter considerably less than 2 microns. Such dust would scatter both direct solar and terrestrial radiation, in proportion to the inverse fourth power of their wavelengths. This would increase the ratio of 30:1, given above.

Humphreys develops in considerable detail the theory that the emission of large quantities of volcanic dust into the atmosphere can produce large variations of climate, of a sufficient magnitude to account for ice-ages. It is clearly established that after the eruption of Krakatoa in 1883 there were marked changes in the pyrheliometric measurements of solar radiation (Arctowski, *Annals* New York Acad. Sci. 26, 1915, p. 149, and Kimball, Monthly Weather Review, 46, 1918, p. 355). The theory, known as the vulcanism theory, has by no means met with general acceptance, though there is some evidence, especially in eastern Australia, of the association of glaciation with volcanic activity, which appears to bear out the theory. In any case, volcanic dust may well have been a deciding factor in starting glaciation when other factors were also favourable. For further details the reader is referred to Humphreys' Physics of the Air, and to works on climatology.

DUST STORMS: See DUST.

DUTCH AUCTION. A form of auction in which the property for sale is put up at a certain figure, and if not bid for at that price, offered successively at lower prices until a bid is obtained. The starting price is assumed to be higher than the seller hopes to get. (See AUCTIONS AND AUCTIONEERS.)

DUTCH EAST INDIA COMPANY, THE (*Oostindische Vereenigde Maatschappij*), a body founded by a charter from the Netherlands states-general on March 20, 1602. It had a double purpose: first to regulate and protect the already considerable trade carried on by the Dutch in the Indian ocean, and then to help in prosecuting the long war of independence against Spain and Portugal. Before the union between Portugal and Spain in 1580–81, the Dutch had been the chief carriers of eastern produce from Lisbon to northern Europe. When they were shut out from the Portuguese trade by the Spanish king they were driven to sail to the East in order to make good their loss. Unsuccessful attempts were made to find a route to the East by the north of Europe and Asia, which would have been free from interference from the Spaniards and Portuguese. It was only when these failed that the Dutch decided to intrude on the already well-known route by the Cape of Good Hope, and to fight their way to the Spice islands of the Malay archipelago. A first expedition, commanded by Cornelius Houtman, a merchant long resident at Lisbon, sailed on April 2, 1595. It was provided with an itinerary or book of sailing instructions drawn up by Jan Huyghen van Linschoten,[1] a Dutchman who had visited Goa. The voyage was marked by many disasters and losses, but the survivors, who reached the Texel on their return on Aug. 20, 1597, brought back some valuable cargo and a treaty made with the sultan of Bantam in Java.

These results were sufficient to encourage a great outburst of commercial adventure. Companies described as "Van Ferne"—that is, of the distant seas—were formed, and by 1602 from 60 to 70 Dutch vessels had sailed to Hindustan and the Indian archipelago. On those distant seas the traders could neither be controlled nor protected by their native government. They fought among themselves as well as with the natives and the Portuguese, and their competition sent up prices in the eastern markets and brought them down at home. Largely at the suggestion of Jan van Oldenbarneveldt, and in full accordance with the economic principles of the time, the states-general decided to combine the existing separate companies into one united Dutch East India Company, which could discharge the functions of a government in those remote seas, prosecute the war with Spain and Portugal, and regulate the trade. A capital estimated variously at a little above and a little under 6,500,000 florins, was raised by national subscription in shares of 3,000 florins. The independence of the states which constituted the United Netherlands was recognized by the creation of local boards at Amsterdam, in Zealand, at Delft and Rotterdam, Hoorn and Enkhuizen. The boards directed the trade of their own districts, and were responsible to one another, but not for one another as towards the public. A general directorate of 60 members was chosen by the local boards. Amsterdam was represented by 20 directors, Zealand by 12, Delft and Rotterdam by 14, and Hoorn and Enkhuizen also by 14. The real governing authority was the "Collegium," or board of control of 17 members, of whom 16 were chosen from the general directorate in proportion to the share which each local branch had contributed to the capital or joint stock. Amsterdam, which subscribed a half, had eight representatives; Zealand, which found a quarter, had four; Delft and Rotterdam, Hoorn and Enkhuizen had two respectively, since each of the pairs had subscribed an eighth. The 17th member was nominated in succession by the other members of the United Netherlands. A committee of ten was established at The Hague to transact the business of the company with the states-general. The "collegium" of 17 nominated the governors-general who were appointed after 1608. The charter, which was granted for 21 years, conferred great powers on the company. It was endowed with a monopoly of the trade with the East Indies, was allowed to import free from all custom dues, though required to pay 3% on exports, and charged with a rent to the states. It was authorized to maintain armed forces by sea and land, to erect forts and plant colonies, to make war or peace, to arrange treaties in the name of the stadtholder, and to coin money. It had full administrative, judicial and legislative authority over the whole of the sphere of operations, which extended from the west of the Straits of Magellan westward to the Cape of Good Hope. Its headquarters were early fixed at Batavia in Java. Only the main

[1] Linschoten was born at Haarlem in or about 1563. He started his travels at the age of 16 and, after some years in Spain, went with the Portuguese East India fleet to Goa, returning in 1589. In 1594 and 1595 he took part in the Dutch Arctic voyages, and in 1598 settled at Enkhuizen where he died on Feb. 8, 1611. His *Navigatio ac itinerarium* (1595–96) is a compilation based partly on his own experiences, partly on those of other travellers with whom he came in contact. It was translated into English and German in 1598; two Latin versions appeared in 1599 and a French translation in 1610. The English version was reprinted for the Hakluyt Society in 1885. Large selections, with an Introduction are published in C. Raymond Beazley's *Voyages and Travels*, vol. ii. *(English Garner,* 1903).

dates of its progress can be mentioned here. By 1619 it had founded its capital in Batavia in Java on the ruins of the native town of Jacatra. It expelled the Portuguese from Ceylon between 1638 and 1658, and from Malacca in 1641. Its establishment at the Cape of Good Hope, which was its only colony in the strict sense, began in 1652. A treaty with the native princes established its power in Sumatra in 1667. The flourishing age of the company dates from 1605 and lasted till the closing years of the century. When at the summit of its prosperity in 1669 it possessed 150 trading ships, 40 ships of war, 10,000 soldiers, and paid a dividend of 40%. In the last years of the 17th century its fortunes began to decline. Its decadence was due to a variety of causes. The rigid monopoly it enforced wherever it had the power provoked the anger of rivals. When Pieter Both, the first governor-general, was sent out in 1608, his instructions from the Board of Control were to see that Holland had the entire monopoly of the trade with the East Indies, and that no other nation had any share whatever. The pursuit of this policy led the company into violent hostility with the English, who were also opening a trade with the East. Between 1613 and 1632 the Dutch drove the English from the Spice islands and the Malay archipelago almost entirely. The English were reduced to a precarious footing at Bantam in Java. One incident of this conflict, the torture and judicial murder of the English factors at Amboyna in 1623, caused bitter hostility in England. The success of the company in the Malay archipelago was counterbalanced by losses elsewhere. It had in all eight governments: Amboyna, Banda, Ternate, Macassar, Malacca, Ceylon, Cape of Good Hope and Java. Commissioners were placed in charge of its factories or trading posts in Bengal, on the Coromandel coast, at Surat, and at Gambroon (or Bunder Abbas) in the Persian Gulf, and in Siam. Its trade was divided into the "grand trade" between Europe and the East, which was conducted in convoys sailing from and returning to Amsterdam; and the "Indies to Indies" or coasting trade between its possessions and native ports.

The rivalry and the hostilities of French and English gradually drove the Dutch from the mainland of Asia and from Ceylon. The company suffered severely in the War of American Independence. But it extended and strengthened its hold on the great islands of the Malay Archipelago. The increase of its political and military burdens destroyed its profits. In the early 18th century it was already embarrassed, and was bankrupt when it was dissolved in 1798, though its credit remained unshaken, largely, if its enemies are to be believed, because it concealed the truth and published false accounts. In the later stages of its history its revenue was no longer derived from trade, but from forced contributions levied on its subjects. The immediate causes of its destruction were the conquest of Holland by the French revolutionary armies, the fall of the government of the stadtholder, and the establishment of the Batavian Republic in 1798.

BIBLIOGRAPHY.—The great original work on the history of the Dutch East India Company is the monumental *Beschryving van oud en niew oost Indien* (Dordrecht and Amsterdam, 1724), by François Valentyn, in 8 vols., folio, profusely illustrated. Two modern works of the highest value are: J. K. J. de Jonge, *De Opkomst van het Nederlandsch Gezag in oost Indien* (The Hague and Amsterdam, 1862–88), in 13 vols.; J. J. Meinsma, *Geschiedenis van de Nederlandsche oost-Indische Bezittingen* (3 vols. Delft and The Hague, 1872–75). *See* also John Crawford, *History of the Indian Archipelago,* (Edinburgh, 1820); Clive Day, *The Dutch in Java* (New York, 1904); Sir W. W. Hunter, *A History of British India* (1899); and Pierre Bonnassieux, *Les Grandes Compagnies de commerce* (1892).

DUTCH LANGUAGE AND LITERATURE. Dutch is spoken in Europe by about 10,000,000 people spread over the present kingdom of the Netherlands, the northern half of Belgium and the northern part of the French Département du Nord. Outside Europe it is spoken in the Dutch Indies, Dutch Guiana and the Dutch Antilles.

Cape Dutch (Afrikaans), spoken in South Africa, has developed into an independent language; its resemblance to Dutch, however, is very great for although its grammar has been considerably simplified, its vocabulary has for the greater part remained the same as that of "High" Dutch.

In the United States of America, there are about 250,000 people whose mother-tongue is Dutch, and in Canada the number is estimated at 125,000. In Ceylon, where Dutch was used in the 18th century as a Church and Government language, it is almost extinct; only a few Dutch words now remain. The Negro-Dutch with its strong Creole admixtures, spoken at the former Danish Antilles, is doomed.

At an early date the language of the Netherlands occupied an independent position among the Low German dialects spoken along the coasts of the North Sea and Baltic from Dunkirk to Poland. At first it was chiefly the language of western Flanders (with the world-market Bruges), which was dominant, but in the course of the 15th century, Brabant came more to the fore. Antwerp at the height of its prosperity was a metropolis of about 100,000 inhabitants. In the course of the 16th century, the centre of Dutch culture moved to the northern Netherlands, especially to Holland. During the Eighty Years' War (1568–1648) the province of Holland formed the centre of the resistance against Spanish rule. The northern provinces rallied round Holland, and when free from the Spanish yoke, rose to great prosperity in the 17th century. The southern provinces remained in Spanish possession and fell into decay. French threatened to supersede the original language. The development of the language in the north was aided by the exodus to Holland of refugees from the provinces occupied by the Spanish. In the language of Holland this southern Dutch influence is distinctly noticeable. In the 16th century the inhabitants of Holland pronounced the words *bijten* (to bite), *vijf* (five), *huis* (house), *muis* (mouse), etc., still monophthongal. From the middle of the 16th century the southern Dutch diphthongization spread more and more and has now become general in the educated language of north and south, though the monophthongs still survive in numerous dialects. There still exists considerable difference between the colloquial and the written language of Holland. The more dignified, formal, official terms are originally southern Dutch, whereas colloquial speech has preserved the original linguistic forms. It is also owing to this old southern influence that the written language of the north differs comparatively little from that of the south and the authorized version of the Bible, the *Statenbijbel* (executed at Dordrecht 1626–35) was written in a language coloured by certain southern characteristics.

The history of the Netherlands is distinctly reflected in the spread of the Dutch language and its dialects. The original language of the Belgian provinces West-Flanders, East-Flanders, Antwerp, Brabant and Limburg and of French-Flanders is still characterized by a wealth of dialects as in the middle ages. The dialects of all these districts are generally grouped together under the name *Flemish.* In these Flemish districts the dialect is spoken by preference, although the written language is taught in the schools. By the side of it French has taken a prominent place from the time of the middle ages. In Brussels the language of the greater part of educated people is at present chiefly French. As a protest against this increasing Frenchification the Flemish language-conflict has arisen. Before the law French and Flemish now have equal legal recognition.

The state of affairs in Holland is less complex. The name "Holland", which originally only referred to the present provinces of north and south Holland, is now also used at home and abroad to designate the whole kingdom of the Netherlands. As a consequence of the expansion of the province of Holland in the 16th and 17th centuries, the language of this province was gradually adopted as the language of daily intercourse by all the provinces grouped round Holland. Provincial dialects are still spoken, a peculiar position being occupied by Frisian in the province of Friesland, which is separated from the Dutch dialects proper by a sharp linguistic boundary-line. The other dialects cannot be sharply differentiated. If we move eastward from the centre of culture, Amsterdam, an increasing "eastern" colour can be remarked in the dialects, as they merge imperceptibly into those of the Low German group, where, in the adjoining German districts, numerous Dutch influences are found.

BIBLIOGRAPHY.—The *Middelnederlandsch Woordenboek* bij *E.* Verwijs and J. Verdam (The Hague, 188; *seq.*) embraces almost all the material of Middle Dutch, which has been handed down since the

middle of the 13th century, and is one of the best dictionaries of mediaeval languages existing; this standard work is complete except for part ix. Excellent is also the great *Woordenboek der Nederlandsche Taal* (The Hague, 1882, *seq.*) of which 15 parts have been completed. Jac. van Ginneken, *Handboek der Nederlandsche Taal* i.–ii. (Nijmwegen, 1913, *seq.*) pays special attention to the dialects; J. Verdam, *Uit de Geschiedenis der Nederlandsche Taal*, 4th ed. by F. A. Stoett (Zutphen, 1923) is adapted to the requirements of the general public; M. Schonfeld, *Historiese Grammatika van het Nederlands* 2nd ed. (Zutphen, 1924) is useful as an introduction to historical grammar and has a good bibliography. Of the *Historische Grammatik der niederlandischen Sprache* bij M. J. van der Meer (Heidelberg, 1927), the first part *(Einleitung und Lautlehre)* has been completed; the numerous bibliographical references have been brought up to 1927. For some years the geographical method has been employed in an increasing degree in dialect investigation. In his work *De Hollandsche Expansie in de 16de en 17de eeuw en haar weerspiegeling in de hedendaagsche Nederlandsche dialecten* (The Hague, 1927), G. G. Kloeke shows with the aid of a map of the Dutch speaking territory how the language spoken in the cultural centre spreads over the surrounding dialect districts. For the practical study of the Dutch language the following work may be recommended: E. Kruisinga, *A grammar of modern Dutch* (1924). The best English-Dutch and Dutch-English Dictionary is: K. ten Bruggencate's *Engelsch Woordenboek*, 10th ed. bij A. Broers (Groningen). (G. G. K.)

LITERATURE

The oldest literary writings to be found to-day in Netherlandish or Dutch are the works of Heynrik van Veldeken, who lived near Maastricht in Limburg at the end of the 12th century. He wrote a Life of St. Servatius, the patron saint of the town, after a Latin original, and an *Eneide* (Aeneid) after the French *Roman d'Enéas*. He also wrote love songs which, like his *Eneide*, were translated into German and exercised a very considerable influence upon German poetry. But his influence on Middle Dutch literature was less considerable, although it is probable that the mystical poets of the Netherlands, and in particular the poetess Hadewych, borrowed from him.

The Influence of France. — The great efflorescence of Dutch literature occurred in the middle of the 13th century in Flanders and Brabant. Most of the works written there were translations from the French. This applies in particular to the romances of chivalry. The French originals of these romances came into existence at different periods, but their translations into Dutch belong more or less to one period. Among others, there exist in Middle Dutch fragments of a translation of the *Chanson de Roland*, of a *Willem van Oringen*, a *Renout van Montalbaen*, *De Lorreinen*, *Aiol*, etc. All these are "Frankish" romances. To this section also belongs *carel end Elegast*. It is almost certain that there was a French original of this remarkable work, but so far it has not been discovered.

In the section of Celtic romances, there exists one, or rather a double romance, by Jacob van Maerlant, about whom more will be said in connection with the didactic poems of the *bourgeoisie*. This romance is the *Historie van den Grale* (History of the Grail) and *Merlijns Boeck*. It is a translation and, as regards the beginning, a rather abbreviated and free adaptation of the *Joseph d'Arimathie* and the *Merlin* of Robert de Borron. These adaptations date from approximately 1261. In 1326 Lodewijc van Velthem added to this the translation of a much more extensive work called *Koning Artur's Boek* after *Le Livre du Roi Artus*. Maerlant also adapted a romance of Torec, while books about the adventures of Lancelot, Percival and the death of Arthur have also come down to us. Under the name *Roman van Lancelot* we possess a vast work of compilation, in which a number of British stories have been put together, and which also contains the original Dutch romance of *Moriaen*. And there is the *Ferguut*, which tells how a peasant lad was turned by love into a perfect knight.

The most important of the eastern romances is the adaptation of *Floris ende Blancefloer* by Diederic van Assenede. It is the story of the love of two children who are brought up together, one a heathen prince, the other the daughter of a Christian count. Another eastern romance is that of *Partenopeus en Melior*, which describes the love of a young man for a mysterious beauty who proves to be the daughter of the emperor of Constantinople. Of the classical romances we may mention the *Alexander* of Maerlant, after a Latin model. and his *Historie van Troyen* after Benoît de St. More's *Roman de Troie*.

Religious Literature. — Religious poetry occupies a prominent place in Middle Dutch literature. There exists among other poems a *Leven ons Heren* (Life of our Lord), compiled from various sources, written between 1260 and 1270. Various lives of saints were also narrated in verse. We have a life of St. Lutgarde by Willem van Afflighem, and fragments of several other lives of saints. Maerlant, whom we have already mentioned when speaking of the romances of chivalry, wrote a life in verse of St. Francis of Assisi, after St. Bonaventura.

The ecstatic mystical songs of the nun Hadewych, who also wrote visions and letters, are the most important, from the aesthetic point of view, of the 13th century religious poems. The 14th century saw the decay of the romance of chivalry, while, on the other hand, religious literature acquired still greater importance. From that period also date a few lives of saints which, however, have no great literary value. Most of them are translations from the Latin, and are written in a rather clumsy style. More importance must be ascribed to the poem about Theophilus and to the beautiful legend of *Beatrijs*, which are poetic version? of "Exempelen" (models or examples) displaying the favours which the Virgin Mary is able to obtain for those who serve her. The really significant religious literature of the period is the mystic prose, notably that of Jan van Leeuwen, "the good cook of Groenendaal," and, even more important, that of Jan van Ruusbroec, prior of the monastery at Groenendaal, near Brussels (1294–1381). His principal work was *Die Chierheit der geesteleker Brulocht*. Some of his other works are *Spieghel der ewigher Salicheit*, *Vingherlinc of vanden blinckenden Steen*, *Van den Gheestelijken Tabernacule*, *Van den Twaalf Beghinen*. In all these works the relations between God and the soul which loves Him are described, and the ways in which one can turn to Him.

Maerlant's Significance. — There further exists an interesting and original literature of the third estate in the middle ages. Jacob van Maerlant is its first and principal representative. We have seen that he also produced romances of chivalry and religious poetry. He was a Fleming by birth, went to live first at Maerlant in the isle of Oost-Voorne, where he was a sacristan, and finally at Damme in Flanders. His special significance lies in the fact that he satisfied the craving of the new *bourgeoisie* for useful reading. So he wrote the *Rijmbijbel*, which is an adaptation of the *Historia Scolastica* of Petrus Comestor. With this work and with his *Sente Franciscus' Leven* he had entered a new field. Five lyrical poems, which were partly translated but also very probably original in parts, belong to this section of his work. He wrote didactic poetry in the same very skilful strophic arrangement. There are two dialogues between Jacob (who represents Maerlant himself) and Martijn, about society and the church, about the relations between social classes, love, God, sin and similar subjects. But there are also works on a larger scale and of more scientific content, written to instruct the *bourgeoisie*. His *Heimelijkheid der Heimelijkheden* (Secret of Secrets) is a guide for princes. *Der Naturen Bloeme* (The Flower of Nature) is a moralizing handbook of natural history. These works are adaptations of Latin models. His last creations were again two strophic lyrical songs, the first a complaint about bad priests, the second preaching a new crusade after the fall of St. Jean d'Acre. For us Maerlant is principally a source of information about his time, rather than an artist. Nevertheless he proved himself a real poet. His original contributions in the sphere of didactic poetry found many imitators during the 14th century, among whom Boendale deserves special notice.

We may further mention among mediaeval poets the "Sprookspreker" (*i.e.*, a poet who also recites poems, which are usually of a moralizing character) Willem van Hildegaersberch (d. shortly after 1308); and Dirc Potter van der Loo (d. 1428), who put into inartistic rhymes a vast collection of love stories with a moralizing aim. The title of the work is *Der Minnen Loop*.

The mediaeval bestiary is represented by *Esopet*, a volume of fables after a Latin original (*Romulus*). But of much greater importance is *Van den Vos Reinaerde*, one of the masterpieces of Dutch literature. It was a free translation from the French branch

of the Reynard romance *Le Plaid,* by one Aernout, made about 1250, while a certain Willem, who tells us that he also had written a Madoc story, completed this adaptation with a piece about equal in length, which described how Reynard succeeded in escaping the gallows by a series of extremely clever, though false accusations. made at the court of King Nobel. The whole Dutch Reynard is a beautiful work, full of the most delicate popular humour and psychology. At a later period a further addition was made and this eventually became the so-called *Reinaert II.* The poem is much less plastic, life among the animals is less vividly imagined, and there is more moralizing.

Mediaeval Drama. — Among what remains of the drama of the middle ages, there are a number of religious plays, and a quantity of very interesting secular plays, from which the religious element however is usually not lacking. The "Abele Spelen," *i.e.,* serious secular plays, which have come down to us, are *Esmoreit, Gloriant,* and *Lanseloet van Denemarken.* Each "Abel Spel" was followed by a farce ("Sotternie"). Six "Sotternien" are still known, dating from the 13th century. They are pleasant pictures of daily life. Of a later period is the similar *Nu noch.*

The mystery plays date from the 15th century. Seven such plays had been written about the seven joys of the Virgin, one of them being performed in each of seven successive years. There are still extant *Die Erste Bliscap van Maria,* and *Die Sevenste Bliscap van Maria.* There also exists *Tspel van de Vroede ende van de Dwase Maegden,* in which the wise and foolish virgins bear the names of different virtues and sins. This takes us far upon the way to allegory. Other plays, dating probably from a later period in the 15th century, are the two miracle plays *Van den Heylighen Sacramente van der Nyeuwervaert* by Smeken, and *Mariken van Nieumeghen.* The second, like the *Reinaert* and a few of the mystical songs of the nun Hadewych and of Sister Bertke, a hermit of Utrecht, is one of the jewels of mediaeval Dutch literature. The later middle ages produced a considerable number of popular songs, many of which are very beautiful.

Chambers of Rhetoric. — The 16th century was, in the provinces of the Netherlands, the century of the "Rederijkers," a name which is a popular rendering of rhetoricians, or members of the Chambers of Rhetoric. These Chambers were of much more ancient date, and their curious literature goes back to about 1400. They were societies of burghers who wished to practise literature by recitations, theatrical performances, and even by poetic composition. In this domain also the southern Netherlands gave the lead. In the north, the oldest Chamber, "Het Bloemken Jesse" of Middelburg, dates from 1430. A highly placed person usually acted as patron. The real leader of the activities was the "factor," who often wrote the plays himself and produced them. These Chambers really had a great significance in social history. If they diffused notions about poetry and its technique among the masses, they were also instrumental in spreading new ideas of every kind. They did not, however, produce anything of real artistic value. In 1548 Matthijs de Casteleyn published his *Const van Rhetoriken.* It was an *ars poetica* for rhetoricians, and placed the emphasis on the technique of poetry. The importance attached by the Chambers of Rhetoric to difficult forms and complicated rhyme arrangements gradually increased. Still real sentiment is expressed in three volumes of *Refereynen* by the Antwerp schoolmistress, Anna Bijns, who proved herself a very militant servant of the old church in the fight against the "damnable Lutheran doctrines." Most of the extant works by rhetoricians are allegorical plays, so-called moralities or "Spelen van Sinnen." The morality *Elckerlyc,* written at the end of the 15th century, is unmistakably related to the English *Everyman.* It has not been decisively established which of the two is of earlier date. The mediaeval farce also persisted: by the rhetoricians it was usually called "Esbattement." There is a collection of 16th century plays which form the archives of the former Chamber of Rhetoric of Haarlem called *Trou moet blijcken.* This collection contains several such "Esbattements." The principal poet of this genre is Cornelius Everaert of Bruges (1485–1556). To "Esbattement" as well as to allegory he made important and fine contributions

The great moments in the life of the rhetoricians were the "landjuweelen," or poetic and dramatic competitions between different Chambers. The name of "land-jewels" comes from the prizes that were given.

The Early Renaissance. — The effect of the Renaissance was noticeable. In this connection it is unnecessary to say much about the world-famous Desiderius Erasmus, of Rotterdam, because he wrote exclusively in Latin. A few quite interesting writers who belonged to the early Renaissance used the national language: the Brabander Jan van der Noot, and Carel van Mander, who also wrote an important book on painting *(Het Schilderboeck).* There was also Jan van Hout, secretary to the town of Leyden. These men differ altogether from the rhetoricians who adorned their style with mythological names. They have communed with the pure spirit of the Renaissance through the poets of the French Pléiade.

Greater, however, was the effect of the Reformation, a movement which touched and agitated the whole of the population. We have mentioned already a poetess who opposed the movement— Anna Bijns. The other side is amply represented in the political and religious struggle against Spain by the so-called "Geuzenliedjes," which tried to spur people on to action. Marnix van St. Aldegonde (1538–98) wrote the *Biencorf der Heiligher Roomscher Kercke,* perhaps the bitterest satire ever written against the Catholic Church, which called forth a number of replies. The poet D. V. Coornhert (1522–90) occupied a peculiar neutral position between the warring factions, which duly persecuted him each in its turn. His principal work is the *Zedenkunst, dat is Wellevenskunst.*

Meanwhile in Amsterdam the Chamber of Rhetoric "De Eglantier" was flourishing as a centre of literary culture. Its motto was "In liefde bloeyende" (*i.e.,* flourishing in love). During the later part of the 16th century and the beginning of the 17th one of the principal members of this Chamber was the humanist Hendrik Laurenszoon Spieghel (1549–1612), whose principal work was the *Hertspieghel,* a rather elaborately composed poem, which expounded a doctrine not unlike that of Coornhert's. Another important member was Roemer Visscher, who wrote familiar and comical little rhymes (Brabbeling), and also wrote little mottoes in prose to accompany printed pictures ("Sinnepoppen").

The Golden Century. — The Chamber "De Eglantier" also made great efforts to refine the national language, to polish it, and to free it from French bastard-words. In 1584 it published a *Tweespraack van de Nederduytsche letterkunst,* a Renaissance grammar with an important preface by Coornhert. A factor of the greatest significance in relation to the civilization and culture of the Netherlands was the emigration of Calvinists from the southern Netherlands.

The principal poets and prose writers of the Golden Century are Jacob Cats (1577–1660); Pieter Corneliszoon Hooft (1581–1647); Gerbrand Adriaanszoon Bredero (1585–1618); Joost van den Vondel (1587–1679) and Constantijn Huygens (1596–1687).

Jacob Cats, born at Brouwershaven, studied at Leyden and at Orleans. He became "advocate" of the town of Middelburg (1603), made a fortune by reclaiming land from the sea, successively occupied the position of pensionary of Middelburg (1621) and of Dordrecht (1623). From 1636 to 16jo he was pensionary of Holland, after which he retired to his country house "Zorgh-vlied" near The Hague. His work is wordy but easy to understand, and during the whole of the 17th and 18th centuries it was read by the people and had its place beside the Bible It is a treasurehouse of moral precepts and practical worldly wisdom. His principal works are: *Houwelijck* (1625); *Spieghel van den ouden ende nieuwen Tijdt* (1632); *Trou-Ringh* (1637); and *Ouderdom, Buytenleven en Hofgedachten op Zorgh-vliet* (1656). This work, the title of which means "Old Age, Country Life and Courtly Thoughts at Zorgh-vlied" (the poet's country house), is autobiographical. Cats was only a'mediocre poet, but culturally his significance has been immense. He is the representative of the ideas of the Calvinist masses.

Constantijn Huygens was born at The Hague. In 1616 and 1617 he studied law at Leyden, and travelled several times as secretary of embassy (he made three journeys to England). In 1625 he became secretary to the Stadholder Frederic Henry, after-

wards to Prince William II., and finally to Prince William III. He considered his professional work to be the principal part of his existence, and his poems were "flowers in his cornfield." He has little fantasy and in his work mainly depicted himself and his surroundings. His principal works in Dutch—for he also wrote in Latin—are *Voorhout* (1621), a description of the well-known promenade at The Hague; *Costelick Mal* (1622), a satire on eccentric fashions; *Dagwerck* (1639), a description of the manner in which he spends his day; *Oogentroost,* a poem in which he tried to console his blind friend Lucretia van Trello by explaining how nearly all people go through life blinded by their passions; *Hofwijck* (1653), a description of his little country home; *Zeestraat* (1666), which describes the road made after his plan between The Hague and Scheveningen. There is also a play called *Trijntje Cornelis Dochter,* and an autobiography of his later years, *Cluyswerck* (1680), which was only published in the 19th century.

The Influence of **Amsterdam.**—We now pass to Amsterdam. There, at the beginning of the 17th century, two Chambers of Rhetoric were flourishing, "De Eglantier" already mentioned and "'t Wit Lavendel," which was the "Braband" Chamber, where refugees from the southern Netherlands came together. Differences of opinion made themselves felt in the "Eglantier." Many of the best members, in whose view the practice of "rhetoric" did not mainly consist in pleasant gatherings, seceded in 1617. Among their number were Hooft and Bredero. Under the direction of Dr. Samuel Coster, a medical man who also wrote, they founded the "Duytsche Academie," which aimed at giving instruction; after some time, however, the activities of the new chamber limited themselves to the production of plays. In 1635 the old "Eglantier" amalgamated with the seceders and the result was the foundation of the "Amsterdamsche Schouwburg" (Amsterdam theatre) in 1637.

One of the more talented writers in this circle was G. A. Bredero, who was an exception among the great authors of his day, in that he had received no classical education. His voluminous lyrical poetry has been collected in his *Boertigh, Amoureus en Aendachtigh Groot Liedboeck.* The first part of the book contains comical poems, little sketches of popular life, representing in the sphere of literature those things which in painting characterized the work of Jan Steen, Brouwer and Ostade. The amorous poems of the volume are in the vein fashionable at the time. As a dramatic author Bredero wrote in the first place romantic plays, the subject matter of which came from Spanish romances of chivalry. The comical interludes in these plays, full of popular realism, showed a talent for comedy which reached its full height in his farces *Klucht van de Koe* (1612); *Klucht van Symen ender Soelighyd* (1612–13); *Klucht van den Molenaer* (1613); and also in his two comedies: *Het Moortje* (1616) and *De Spaansche Brabander* (1617). The first was based on the *Eunuch* of Terence, the second was after Lazarillo de Tormez. The local colour in both plays was entirely derived from Amsterdam.

Another lyric poet and playwright whose gifts were more modest, but who was decidedly related to Bredero, was Jan Starter (1594–1628), born in England, who was a member of the "Eglantier" at the same time as Bredero. Afterwards he became a bookseller and founded a Chamber of Rhetorique at Leeuwarden. His poetry has been collected in the volume *De Friesche Lusthoj* (1621).

Pieter Hooft is the most typical representative of the Renaissance in the literature of the Netherlands. His art is personal and refined. He came from an Amsterdam merchant family, was destined for commerce, and was sent on a commercial journey to Italy (1598–1601). The love poems which he wrote after his return, and the pastoral play *Granida* (1605) show the influence of the Italian Renaissance. In 1606 he was allowed to study law at Leyden. When his studies were finished he was appointed *drost* of Muiden. In this function he lived in the famous *Muiderslot* or castle of Muiden. Inspired by the place in which he was living and also strongly influenced by the tragedies of Seneca, he wrote in 1613 *Geeraerd van Velsen* and in 1626 *Baeto.* In both plays he has expressed his political ideas in a very anachronistic manner. We also adapted Plautus's *Aulularia* into a comedy of Amsterdam called *Warenar* (1617). Particularly after 1627 his home became the centre of artistic and intellectual life, formed by the "Muiderkring" (circle of Muiden). During the last 20 years of his life, he devoted himself almost exclusively to historical prose. In 1626 he wrote *Henrik de Grote;* in 1628–47, *Nederlandsclze Historien,* which he left unfinished. The artistic prose of these writings, strongly influenced by Latin, exercised a great influence on the literary prose style of the 17th century

The Genius of **Vondel.**—Joost van den Vondel is the greatest poet of the Golden Century in Holland. He was born in Cologne of parents who came from Antwerp, whence they had fled as Anabaptist refugees. When Joost was still very young his parents migrated to Amsterdam. There he had a hose shop in the Warmoesstraat, but his wife Maaiken de Wolf entirely managed the business and allowed her husband to give all his time to study and to art. He was a real product of the Renaissance, full of veneration for the ancients whom he tried to imitate, particularly in his tragedies.

Vondel's work is voluminous. There are in the first place the satirical poems occasioned by the religious and political struggles between Arminians and Gomarists: *Geuzenvesper,* which was written against the doctrine of predestination; *Rommelpot van 't Hanekot; Otter in 't Bolwerk.* His tragedy *Palamedes* (1635) represents the struggle between Prince Maurice and Oldenbarnevelt in an allegorical form and belongs to his satirical work. There are further *Roskam,* which criticizes the abuses of the government of the Regents, and *Harpoen,* which compares the good and the bad minister. We may mention, among his songs celebrating the national greatness of the Dutch republic, the glory of the House of Orange, and of Amsterdam, *Lof der Zeevaert* (1622); *Geboortklock van Willem van Nassau* (1625); *Inwijding van izet Stadhuis* (1655). He showed the interest which he took in important events abroad in *Maeghdeburghs Lijckoffer* (1631), *Olijftack van Gustaaf Adolf* (1632). After he had become a Catholic he wrote three long poems in defence of his faith: *Altaergeheimenissen* (1645); *Bespiegelingen van Godt en Godsdierzst* (1662); *Heerlijckheit der kercke* (1663). But the principal work of Vondel consisted of 24 original dramas. The first was *Pascha of de Uyttocht der Kinderen Israels uit Egypte.* Among his other dramas are *Gysbreght van Aemstel* (1637); *Maeghden* (1639), *a* dramatic version of an episode of the life of St. Ursula; *Joseph in Dothan* (1640); *Maria Stuart* (1646); *Leeuwendalers* (1647), a play written on the occasion of the Peace of Munster. His masterpiece was *Lucifer* (1654), describing the revolt of the angels against God. *Jephtha* (1659) and *Adam in Ballingschap* (1664) are other plays of his.

Three religious poets from the great period of the 17th century deserve separate notice. The first is Johannes Stalpaert van der Wielen, parish priest at Delft (1579–1630), whose *Life of St. Agnes* and *Geestelijcke Lofsangen,* imbued with *a* true mediaeval spirit, are his best known works. Jacobus Reefsen of Revius (1586–1658), was a Protestant minister of Deventer (*Over-Yselsche Sangen en Dichten,* 1630), and D. R. Camphuysen (1586–1627) wrote *Stichtelijcke Rijmen.*

The Late **17th** Century.—Later in the 17th century comes Jan Vos whose rhetorical pieces *Aran en Titus* (1641) and *Medea* (1666), were produced with elaborate stage machinery, which made quite a sensation. Geraert Brandt (1626–85) was a prose author who wrote *Historie der Reformatie, Leven van Adr. de Ruyter, Leven van P. C. Hooft, Leven van Vondel.* Heiman Dullaert (1636–84) was a painter, pupil of Rembrandt, who wrote a few poems full of true sentiment which were among the best of his time.

The last generation of the 17th century is represented by the following writers: Johannes Antonides van der Goes (1647–84) was an imitator of Vondel. His principal work was *De Ystroom.* His language has something of the ease and grace of Vondel's but rather lacks simplicity. Jan Luiken (1649–1712), a world famous etcher and engraver, ranks as a poet near to Hooft and Vondel. The work of his youth was *De Duitse Lier,* a volume of love and nature poems. When he was 26 he became converted to a mystic and ascetic conception of life. Henceforth he only wrote pious

verses, of which the best is the first, *Jesus en de Ziel.* Thomas Asselyn and Pieter Bernagie wrote comedies. The first is known mainly for his play *Jan Klaesz of de gewaende Dienstmaegd,* in which he makes fun of the Quakers.

The decadence which had already set in by the end of the 17th century became accentuated in the 18th. The so-called "Pruikentijd" or period of wigs was a time of great wealth, when people were seized with a mania for collecting, and the art of poetry was practised in an amateurish way. Written in a form that was bound by the strictest rules, it was nothing but servile imitation of French models. The best known among the societies where that kind of poetry was practised, the "Nil volentibus arduum," was established at Amsterdam in 1669. One of its leading members was Andries Pels, who published in 1677 an *ars poetica.*

Gallican Dramatists. — The three principal authors of the first half of the 18th century are Pieter Langendijk (1683–1756), known to our own day as an author of comedies which are still performed, the moralist Justus van Effen (1684–1735), and the peasant poet Huibert Poot. The principal works of Langendijk were: *Het Wederzijds Huwelijks Bedrog* (1712–14); *Krelis Louwen of Alexander de Groote op het Poeetemaal* (1715), and *De Wiskenstenaars of 't Gevluchte Juffertje* (1715). He is an imitator of Molière, and in the polish of his smooth alexandrines shows himself a real man of the 18th century. His comedy of manners *De Spiegel der Vaderlandsche Kooplieden,* in which he opposes old fashioned solidity to new-fangled lightheartedness, remained unfinished. Justus van Effen was mainly the author of moralizing works written in French. He followed the example of the English reviews, *The Tatler* and *The Spectator,* and applied their methods also when later in life (1731–35) he published *De Hollandsche Spectator.* Between 1741 and 1800 at least 30 weekly papers of the same kind appeared. The, best known are *De Denker* and *De Grijzaard.* These *Spectatoriale vertoogen* had a great influence on the Dutch "Verlichting." Poot was a peasant with much poetical talent, but was unhappily too much under the influence of a dead classicism.

Some further typical representatives of the period are: Hoogvliet, author of *Abraham de Aartsvader;* Feitama, translator of the *Télémaque* of Fénelon and of the *Henriade* of Voltaire; Huydecoper, a philologist and author of tragedies in the style of the French classics. The two Friesian noblemen, Willem and Onno Zwier van Haren, have a certain imaginative originality, and are remarkable for the choice of more national subjects for their poetry.

English Influence on the **Novel.**—In the last quarter of the 18th century started the movement of "Verlichting." Classicism, which had gradually become a rigid and soulless form, was the special butt of the critics. The "enlightened" Betje Wolff-Bekker (1738–1804) and her friend Aagje Deken (1741–1804), who started by being more piously inclined, joined forces after they had for some time been publishing independently. Their collaboration produced some novels in letter form. Of these the first two *Sara Burgerhart* (1782) and *Willem Leevend* (1784–85), are the more important. In construction and in form they belong entirely to the school of Richardson. They are remarkable for their easy style and facility of expression. Rhijnvis Feith (1753–1824) is an entirely different type, a sentimentalist strongly influenced by Young, d'Arnaud, and Klopstock. He wrote a few sentimental novels, *Julia* (1783) and *Ferdinand en Constantia* (1785). Later in life he wrote didactic poems (e.g., *De Ouderdom* 1803) and many songs which are still used as church hymns. He also had a certain significance as a writer on aesthetics, but in that sphere he was less important than Hieronymus van Alphen (1746–1803), who translated Riedel's *Theory of Fine Arts* and provided it with an important introduction. He is now better known as the author of children's poems. Another poet, also very patriotic, was Jacobus Bellamy (1757–86). His style was rather bombastic.

Bilderdijk.—Willem Bilderdijk (1756–1831) is a great figure, who exercised considerable influence upon the spiritual life of Holland. He was an Orangist, an opponent of the party of the Patriots. In 1795 he refused to take the oath of allegiance to the Government of the Batavian republic which had been established by the French, and received the unusually severe penalty of exile. He roamed about Hamburg and London, where he fell in love with Katerina Wilhelmina Schwerckhardt, who later became his second wife. When Louis Napoleon became king of Holland, Bilderdijk was recalled to Holland and treated with much consideration. After the restoration, King William I. gave him a pension. He was not appointed a professor at Leyden as he had hoped to be, but established himself in that town as a private tutor (1817–27) and had a number of very able students who attended his courses in national history, venerated him as a prophet, and adopted a considerable part of his political and religious views. The movement which aimed at propagating these religious ideas was called the "Réveil."

Bilderdijk wrote ballads and longer narrative poems such as *Elius* and *Urzijn en Valentijn.* The epic *De Ondergang der Eerste Wereld* (1810), which he left unfinished, contains beautiful passages. The immense bulk of his lyric poetry contains some expressive poems, especially among his love songs, and others full of very deeply felt religious emotion, such as *Gebed* (1796) and *Boetzang* (1826). Among the longer poems the *Ode Van Napoleon* (1806) and *Afscheid* (1810) are celebrated. His *Geschiedenis des Vaderlands* contains part of an autobiography.

Johannes Kinker (1764–1845) was also a critic, a philosopher and a philologist. He criticized the insignificance of his conventional and sentimental contemporaries. Among the numerous but insignificant writers of the French period mention may be made of Adriaan Loosjes, whose *Maurits Lijnslager* is a forerunner of the historical novel, and Frederik Helmers (1767–1813) who published his bombastic but deeply patriotic poem *De Hollandsch Natie* in 1812 during the French domination.

The 19th Century. — The first part of the 19th century was less distinguished even than the revolutionary period. It was a time of rhetorical self-complacency. The orator Van der Palm (1763–1841), whose *Geschied-en-Redekunstig Gedenkschrift van Nederlands Herstelling* (1816) is the best known work, re-established formalism after the laxity of the revolutionary period. The typical representative in Holland of familiar fireside poetry was Hendrik Tollens (1780–1856). During that period we may notice Bilderdijk's ardent admirer and disciple Isaak da Costa (1798–1860). Da Costa's main work, directed against Liberalism, was *Bezwaren tegen den Geest der Eeuw* (1823). Among his poetic works the best known are his *Tijdzangen,* which Da Costa himself called his political poetry. His biblical poem *Hagar* (1848) had a symbolical meaning: Islam will one day bend the knee before Christ. In 1859 he wrote a historical poem *De Slag bij Nieuwpoort.*

Antoni Christiaan Winand Staring (1747–1840), an excellent poet who stood almost entirely by himself, was a gentleman farmer of Gelderland. Apart from many lyric poems and some epigrams ("sneldichten"), he wrote a few fine storks in verse: *De Twee Bultenaars,* the cycle of *Jaromir, Marco, De Hoofdige Boer, De Leerling van Pankrates, De Verjongingskuur.*

Jacob Geel (1789–1862), excellent prose writer, became librarian of Leyden university in 1822, and afterwards a professor. His main work consists of a series of treatises and essays, of which the eight principal ones have been brought together in one volume, *Onderzoek en Phantasie.* One of them, *Gesprek op den Drachenfels* (1835), attempts a just appreciation of romanticism, which had made its way into Holland about that period. Jacob van Lennep (1802–68) and Jan Frederik Oltmans (1806–54) are gifted followers of Scott, but their subject matter was national. Van Lennep wrote poetic stories, a few plays, but mainly historical novels and short stories which gave him considerable popularity. He started with mediaeval stories: *De Pleegzoon, De Roos van Dekama, Onze Voorouders.* His later novels *Ferdinand Huyck* and *Elizabeth Musch,* written under the influence of *De Gids* (about which more presently) describe the period of the Dutch republic. Van Lennep is easy and entertaining, but superficial. Under the influence of French naturalism, he also wrote a contemporary novel called *Klaasje Zevenster.* Under the pseudonym J. van den Hage, Oltmans wrote two novels: *Het Slot Loevestein* and *De Schaapherder.*

National Consciousness. — Typical of the romantic movement in Holland was the periodical De Gids. The critic and author Aernout Drost, who died young, started a review in 1836, called De *Muzen,* which had only a short existence. Everardus Johannes Potgieter followed him in 1837 with De Gids, in which he tried to strengthen the national consciousness of his compatriots. He was haunted by the ideal of national strength, represented by the grandeur of the 17th century. From 1837 to 1865 he directed De Gids, contributing to it a number of important criticisms and many sketches, the most characteristic of which is *Jan, Jannetje,* en hun jongste *Kind* (1842), where he contrasts the past and present of Holland. In Het *Rijksmuseum* (1844) he extolled the Holland of the 17th century. Potgieter's style is difficult and full of learned allusions. This also applies to his poetry, especially to his Zangen des Tijds and to his *Nalatenschap* van den *Landjonker.* Before he died Potgieter had come to despair of the success of his enterprise, and among the younger men he could discover no one whom he judged able to take over his task. The learned historian (later archivist) Reinier Bakhuizen van den Brink (1810–65), mainly known through his studies of the 17th century, published in De Gids, was a kindred spirit.

In the Dutch literature of that period a very peculiar place is occupied by Nicolaas Beets (1814–1903). During his student days he was an enthusiastic admirer of the English and French romantics. Under the influence more particularly of Byron, he wrote four stories in verse. But he owes his fame entirely to Camera *Obscura,* a book which has become a classic. It consists of a number of sketches which give a delicately humorous picture of the middle-class society of his day. Beets also wrote many poems, most of which are in the manner of Tollens.

Pieter Hasebroeck (1812–96) was, like Beets, a Protestant minister. His volume Waarheid en Droomen, published under the pseudonym of Jonathan, somewhat resembles the Camera *Obscura.* A similar resemblance appears in the sketches of student life by Johannes Kneppelhout, who wrote under the pseudonym Klikspaan (1814–85). Another important figure in the romantic movement is Anna Louise Geertruida Bosboom-Toussaint (1812–86), who, like Beets. began to write under the influence of the English romantics (*Almagro,* De Graaf van Devonshire). The criticism of De Gids made her choose national subjects. She wrote in praise of the heroes of Protestantism during the 80 years war against Spain. Her best known works are: Het *Huis Lauernesse* (1840), the cycle about Leicester in ten volumes (1845–55), and De Delftsche *Wonderdokter.* Like Van Lennep she deserted the historical novel during her later period and wrote a novel in the form of a diary entitled Majoor *Frans* (1874).

There is also a Catholic romantic, Josephus Albertus Alberdingk Thym (1820–89). Like Potgieter he loved the Amsterdam of the 17th century, but his description of that period is mainly restricted to Catholic circles. The modernist Protestant minister Petrus Augustus de Genestet (1829–61) was a popular poet and also wrote a series of Leekedichtjes (lay poems) about the religious struggle between the orthodox and the modernists.

Conrad Busken Huët (1826–86), of French descent, was mainly important as a critic, and adopted the method of Sainte-Beuve. From 1862 to 1865 he contributed a regular series of critical articles called *Kroniek* en Kritiek to De Gids. He worked as a journalist in the Dutch East Indies, and spent the last part of his life in Paris.

Eduard Douwes Dekker (1820–87) was a forerunner of the movement of 1880. Under the pseudonym of Multatuli, he wrote his Max *Havelaar,* a glowing protest against the treatment of the Javanese by the Dutch authorities. Dekker had been an official in India. The book created an immense sensation. In 1861 there followed the Minnebrieven (love letters). This book is extremely loose in form. Between 1862 and 1877 he published seven volumes of *Ideeën,* which contain his unfinished ncvel *Woutertje* Pieterse. Douwes Dekker was a neurotic who lacked equilibrium, but he had real flashes of genius.

In the southern Netherlands, where in the course of the several successive foreign dominations popular education had been stagnant, a new movement arose after 1830, the Flemish movement, of which the novelist Hendrik Conscience (1812–83) was for some time the best known literary representative. Conscience celebrated the grandeur of the past of Flanders. His best known novels are: De Leeuw van Vlaanderen, Jacob van Artevelde, De Loteling. Among the poets of the movement the foremost is Guido Gezelle (1830–99), one of the very greatest poets in the Dutch language.

The Renaissance of the '80s.—In the northern Netherlands an important renaissance of literature took place about 1885. It is usually considered to have started in Oct. 1885 with the publication of the first number of the review *De* Nieuwe Gids. The forerunners of this movement were Dekker, the novelist and poet Marcellus Emants and the delicate lyric poet Jacques Perk (1859–81). The Nieuwe Gids differs from De Gids in that it pursues an exclusively aesthetic ideal. The leaders of the movement were the poets Willem Kloos (1859–1938), Albert Verwey (1865–1937) and Lodewijk van Deyssel, the pseudonym of Karel Alberdingk Thym (b. 1864). Kloos sings the beauty that pleases the senses. Verwey passed from impressionist to symbolical verse. He also did good work in literary history (among other works he wrote a book about Potgieter). Van Deyssel is the violent and lyrical critic of the movement. Frederik van Eeden (1860–1932), dramatist, poet and prose writer, occupied a special place in the movement. His best work in prose is De Kleine *Johannes,* the story of the soul of a child. His Van de koele Meren des Doods is an important pathological novel. Van Eeden also took part in an experiment at communistic life which proved a failure. His plays are largely the expression of his social feelings and opinions. The poetess, Hélène Swarth (b. 1859) stands very near to the movement with her lyrical works written in particularly delicate language full of resonance. Herman Gorter (1864–1927) has acquired a foremost position in Dutch poetry by his poem Mei.

Among the men of the '80s (De Tachtiger) we must also place Jacobus van Looy (1855–1930), a writer of beautiful prose (*Proza,* Gekken, *Feesten,* Jaapje, Jaap, the last two of which are autobiographical). The great novelist Louis Couperus (1863–1923) describes the life of The Hague (*Eline* Vere, De Boeken der Kleine Zielen) and makes splendid imaginative reconstructions of antiquity (De Berg van Licht, Antiek *Toerisme, Herakles,* De *Komedianten,* Zskander). The movement of the '80s was mainly individualistic. Immediately afterwards came a group of authors whose feelings were more social. The dramatist and writer of sketches, Herman Heyermans (1864–1924), wrote social dramas which are among the greater triumphs of the Dutch stage (Ghetto, Het Zevende Gebod, *Op* Hoop van Zegen, Ora et labora, *Allerzielen,* De Opgaande Zon, *Schakels,* etc.). The novelist Israel Querido (1872–1932) mas one of the greatest Dutch naturalists (Levensgang, Menscherzwee and the cycle De *Jordaen* in four volumes). Herman Robbers wrote among other novels De *Bruidstijd* van Annie de *Boogh* and De *Roman* van een *Gezin.* To the same movement also belong Henriette Roland Holst (b. 1869), an emotional poet who professes extreme revolutionary doctrines, and the popular poet Adam van Scheltema, a Socialist.

Recent Writers. — This generation has again been followed by an entirely new one, poets and prose writers, whose mottoes and tendencies differ considerably from one another. They are too near us to be grouped and classified, and it must suffice to mention a few names of those whose work is generally recognized as excellent. Peter Cornelis Boutens first wrote in an obscure fashion but gradually obtained a mastery of his poetic form and became able to express himself in strongly rhythmic verse. Jan Hendrik Leopold (1865–1925) wrote sensitive poems, Carel and Margo Scharten-Antink are novelists (Een *Huis* vol *Menschen,* De Vreemde *Heerschers, 't* Geluk Hangt als een Druiventros). Other women novelists are: Augusta de Wit (*Orpheus* in de Dessa), Ina Boudier Bakker, Top Naeff, Carry van Bruggen and Jo van Ammers-Kuller. There is a young poetic school about which it is still difficult to pronounce a definite opinion. Martinus Nyhoff and van Schagen are talented representatives of this school. Contemporary Flanders represents a strong element of feeling and also a striking power in modern Dutch literature. There are the prose writers Stijn Streuvels (pseudonym of Frank Lateur) and Felix Timmer-

mans, and the classicist and imaginative poet, Karel van den Woestijne. (J. WAL.)

DUTCHMAN'S BREECHES *(Dicentra Cucullaria)*, a North American plant of the fumitory family (Fumariaceae), known also by various local names, as butterfly-banner, boys-and-girls, ear-drops and soldier's-cap, native to woods from Nova Scotia to South Dakota and southward to North Carolina and Kansas. It is a smooth, delicate plant, rising from a granulated bulb, with the slender-stalked, finely dissected leaves, appearing to spring from the surface of the ground. In shape the irregular flowers, about ¾ in. broad, resemble a pair of baggy trousers, whence the popular name. The flowers are white or pinkish, tipped with yellow, and hang tremulously from a slender stalk, 5 in. to 10 in. long. This plant, which blossoms abundantly in early spring, is one of the most dainty of North American wild flowers. (See DICENTRA.)

DUTCHMAN'S BREECHES. AN EARLY SPRING FLOWER IN NORTHERN AND EASTERN UNITED STATES

DUTCH METAL. A variety of brass, in which the proportion of zinc is high, giving the alloy a yellow colour, simulating gold. The proportions of copper and zinc in dutch metal range from 88:12 to 85:15, the colour becoming paler with the higher zinc content. Dutch metal is used in bronzing, and in the preparation of imitation gold-leaf, its great ductility lending itself to the purpose. Gilding with dutch metal costs less than one-third the price of real gilding, but the work rapidly tarnishes unless coated with a lacquer. (See BRASS.)

DUTCH OVEN. This utensil was in general use in American colonial days for baking before the open fire, which was the only means of cooking except the brick oven (*q.v.*). It was round, square or oblong, with the front open. The round variety was often fitted with a spit, turned by a handle on the outside, for roasting meat. Otherwise, the oven was used for baking only. The open side was set close to the fire, to receive the full heat of flames or coals. Usually of tin, it was often called "tin kitchen" or "Dutch kitchen." The bake kettle—a covered receptacle on high legs to set over the fire-wag sometimes called a Dutch oven.

DUTCH WARS, a general title for the three naval wars fought between England and the United Provinces (1652–74); but also for the almost continuous series of land campaigns fought by the Dutch against Louis XIV. (1667–78).

NAVAL OPERATIONS

First Dutch War (1652–54).—The immediate causes of the war were the continuous diplomatic rebuffs given by the Dutch to the English Commonwealth government. The real and underlying cause, however, was the commercial rivalry of the two nations, especially in the North Sea and Spitzbergen fisheries and in the East Indian trade, while in addition the English disputed the Dutch claim to make their neutral flag cover goods consigned to France, with whom England was already unofficially at war. (See HOLLAND: History; ENGLISH HISTORY; SHIPPING; and NAVIGATION LAWS, etc.)

Despite the great maritime strength of the Dutch, which had developed unchecked for nearly fifty years, England began the war with three overwhelming advantages. Geographically, she dominated the Dutch trade route passing through the Straits of Dover; her navy was directed by a single and united body, the Council of State, whereas the Dutch relied on the sporadic co-operation of five different provincial admiralties; finally, the Commonwealth government was prepared to lavish huge capital sums on the war, seized from the Royalists, while the Dutch were compelled to finance the war from an income largely derived from their threatened carrying trade and fisheries.

In the spring of 1652 Admiral Martin Tromp (*q.v.*) took a strong Dutch fleet into the Channel to protect the returning trade. Neither country was anxious to appear as the aggressor; but a collision occurred with Admiral Robert Blake's squadron on May 19 off Dover on Blake making the claim to the salute, some Dutch ships having been attacked further down the Channel for the same cause. Admiral Bourne came up later with a squadron from the Downs to assist Blake, and Tromp was eventually driven over to the French coast with the loss of two ships.

Blake was now ordered north to destroy the Dutch herring fisheries, which he succeeded in doing; also if possible to intercept the Dutch East Indiamen, said to be returning by the north of Scotland, and to harry their Baltic trade. Meanwhile Tromp and later on de Ruyter (*q.v.*) had matters their own way in the Channel against Sir George Ayscue who had only 14 ships, the remainder being with Blake. As soon as the Dutch understood this, Tromp was ordered north to engage Blake. He sighted his adversary; but a storm scattered his fleet off the Shetlands, and in returning home he was superseded by Cornelius de Witt (*q.v.*) as a result of the outcry caused by the loss of the herrings. In September de Witt concentrated his force, as did Blake, each having over 60 sail, and an action was fought on Sept. 28, when the English admiral cleverly neutralized de Witt's attempt to exploit the leeward side of the Kentish Knock as a defended anchorage. The Dutch were severely handled, while many of their captains refused action towards the close, being jealous of de Witt on personal and political grounds.

Tromp was now reinstated in command by the States General with over 80 ships, and ordered to force the outgoing convoy through the Channel; but the English Council of State, thinking that the season for active operations was passed, reduced the fleet considerably, and when Tromp appeared off the Goodwins on Nov. 29 Blake had only 40 ships ready in the Downs, many of them being only hired merchantmen. However, he determined to attack, and on Nov. 30 both fleets were clear of the Goodwins on parallel courses. Off Dungeness a general action was fought in the late winter afternoon, in which Tromp was successful, his convoy passing down mid-channel without loss.

An immediate naval reorganization followed this set-back. The Council of State ordered several captains to be tried for unsatisfactory conduct and issued articles of war by which all captains of merchant ships engaged on government service were in future to be entirely under government discipline. The seamen's pay was increased, the victualling improved, and the command was strengthened by the addition of the generals George Monk (*q.v.*) and Richard Deane for service at sea.

Early in Feb. 1653 Blake took his fleet of about 70 sail down channel to intercept Tromp, who was known to be attempting to conduct the home-bound Dutch convoy of merchantmen through the Channel. Thick fog made reconnaissance difficult, and the English fleet was somewhat scattered when Tromp suddenly appeared off Portland on Feb. 18 with about 80 sail, the wind being north-west. Blake's squadron having become separated had to withstand the whole of the Dutch fleet alone for some hours, till at last help arrived, when Tromp drew off to rejoin his convoy which had meanwhile slipped by unmolested. Next day, Blake pressed the Dutch vigorously and a running fight took place past the Isle of Wight, Tromp forming his fleet in a crescent to protect his convoy which sailed ahead. On Feb. 20, both fleets were off Beachy Head, and Blake again attacked; the English frigates

pressed through to the convoy, which became seriously disorganized, so that night alone saved them from disaster. It seemed impossible for the Dutch to round Cape Gris Nez, but Tromp managed to get the remainder of his fleet and convoy clear away before next morning, after a total loss of 17 men-of-war and over 50 merchantmen.

Both countries were now feeling the strain of the war, and for some time administrative and financial difficulties incapacitated their fleets, though Tromp was active in protecting convoys coming round the north of Scotland. Blake had been wounded off Portland, and upon Deane and Monk at last getting to sea in force, Tromp at once sought action, and on June 2 and 3 there was heavy fighting, beginning off the Gabbard and ending near the Dutch coast. For the first time the English fleet showed a decided superiority, recent fighting instructions having strictly enjoined them to maintain a line ahead formation and so develop their broadside fire to the utmost. Deane was killed, but Blake joined in with reinforcements on the second day and the Dutch fleet was routed, losing over 20 ships. Blake and Monk at once blockaded the Dutch coast, without returning to harbour. This imposed a great strain on the English resources, but it was amply justified by the disorganization of Dutch trade which quickly followed; Tromp with the main fleet being confined to the Weilings while a small force under de Witt lay in the Texel. Early in July the English fleet had to withdraw to land the sick (among them Blake) and to reprovision, but it was back in position in three weeks, during which time Tromp was unable to make any move owing to lack of men, ammunition and stores. At last on July 25 Tromp put to sea and, heading north, succeeded in drawing Monk south from the Texel in a running fight, after which he slipped north during the night of July 29 and effected a junction with de Witt. The action which followed on July 31 (O.S.) was the fiercest of the whole war. Tromp, who throughout the operations had shown marked superiority in seamanship, obtained the wind and attacked with over 100 sail. The fight lasted nearly 12 hours, by which time the Dutch were completely beaten and had lost 30 ships, while many deserted earlier in the action, and Tromp himself was killed. No other operations of any importance followed, and by the Treaty of Westminster, concluded in April 1654, the Dutch conceded all trade questions under dispute, acquiesced in the Navigation Act, and paid a heavy indemnity. In the Far East their commercial expansion was checked, though in the Mediterranean they remained supreme.

Second Dutch War (1664–67).—Charles II.'s government pursued a vigorous commercial policy, and was soon embroiled with the Dutch over the West African slave trade, and the interpretation of the Navigation Act. In Oct. 1663, therefore, Captain Robert Holmes was sent to raid the Dutch West African trading posts, and in 1664 he crossed the Atlantic and captured the Dutch colony of New Amsterdam (New York). The Dutch at once sent out Admiral de Ruyter, who recaptured the African ports and attacked Barbados. He was on his way home when, in May 1665, official operations of war began, and a Dutch fleet of over 100 sail under the lord of Opdam captured some English ships which were bringing naval stores from Hamburg. The English fleet, of equal strength, was at once hurried to sea under James, duke of York, then lord high admiral. He was assisted by Prince Rupert, Lord Sandwich and Sir William Penn, and encountered the Dutch off Lowestoft on June 3 (O.S.). The action lasted all day and resulted in the decisive defeat of the Dutch, after a total loss of over 30 ships, Opdam being blown up in his flagship and Cornelius Van Tromp, the son of Admiral Martin Tromp, covering the Dutch retreat with great skill. Great dissatisfaction was shown at the duke of York's failure to pursue the enemy, and he was quickly replaced by Sandwich who, after a short time, was himself replaced by Monk (now duke of Albemarle), together with Prince Rupert.

The Plague, meanwhile, had so disorganized English administration that no further operations could be undertaken till May 1666, when Monk and Rupert were ready in the Downs with 80 sail. Here they received orders from Charles II. to detach one of their three squadrons, to meet a French squadron said to be approaching up channel from the Mediterranean, whence all English warships had recently been withdrawn. The French had declared war, but their squadron never came north of Lisbon, and the east wind, which took Rupert to Portsmouth with 25 sail, brought de Ruyter out with 85 ships against Albemarle's weakened force. Nevertheless, when the wind changed to south-west on June 1 (O.S.), he attacked the Dutch brilliantly, trying to concentrate the whole of his force against their van In this he was partially successful; the Dutch vice-admiral Evertzen was killed during the action, which lasted all day. On June 2 the Dutch were reinforced, and continued the fight. Their van was disorganized owing to Evertzen's death, and Albemarle concentrated all his force against the rear under Tromp, who was at last relieved by de Ruyter, when Albemarle retired. On June 3 Albemarle continued his retirement, protecting his injured ships with great skill, though Sir George Ayscue surrendered the "Royal Prince" after running on the Galloper shoal. In the evening Rupert and his squadon returned, and on June 4 Albemarle again offered battle and a great *mêlée* ensued, the English finally retiring into the Thames after a total loss of nearly 20 ships. De Ruyter now blockaded the Thames, based on the Essex shore, but Albemarle and Rupert quickly refitted and, working their way through the shoals, eventually forced him into action on St. James's day, July 25, off the North Foreland, where he was completely defeated with a loss of 20 ships. Albemarle now crossed to the Dutch coast and on Aug. 8–9 a special force under Sir Robert Holmes burnt 160 merchantmen anchored in the Vlie Channel and a million pounds' worth of goods in storehouses on shore.

Peace negotiations now began; but the English, exhausted by the war, the Plague and the Great Fire, laid up their line of battle ships for the winter; and the Dutch, pretending to do the same, resolved on a desperate raid in order to obtain better terms. Early in June 1667 de Ruyter suddenly appeared in the Thames and, forcing an entrance into the Medway Channel, despite the forts and boom protecting it, did immense damage to the shipping lying there, burning three first-raters, capturing another, and causing a panic in London. By the Peace of Breda (July 1667) the Dutch ceded New York, and the Navigation Act was amended in their favour.

Third Dutch War (1672–74).—Unlike the two previous wars, which were entirely commercial, this war was part of a great European political struggle. Louis XIV. who was intent on seizing the Spanish Netherlands, had recently been checked by the Triple Alliance of England, Sweden and the United Provinces; but in 1670 by the "Secret Treaty of Dover" he had persuaded Charles II. to abandon his former allies and co-operate with the French. The English and French fleets were to be combined under an English admiral; Charles was to establish Roman Catholicism in England, and was to receive large money subsidies. The Dutch, anxious to avoid a simultaneous war by land and sea, made every possible concession demanded of them and finally no better way of provoking them could be found than to order Sir Robert Holmes to attack their Smyrna convoy in the Channel (March 13, 1672).

De Ruyter with about 80 sail was at once ordered to sea, but administrative difficulties made him too late to prevent the junction of the French fleet of 35 sail under d'Estrees with the English fleet of 55 sail under James, duke of York, assisted by Lord Sandwich, Sir John Harman and Sir Edward Spragge. The allies, however, were also suffering from hasty preparation, and went to Solebay on the Suffolk coast to complete their complements and stores. Early in the morning of May 28, 1672, they were surprised by de Ruyter while still at anchor. Sandwich with the Blue squadron at once stood to the north and engaged the Dutch, and though his flagship was burnt and he himself drowned, his squadron routed the one opposed to it under Van Ghent, who was also killed. Meanwhile, the French turned south and held off from the battle, and de Ruyter, merely detaching a small force to watch them, concentrated his attack on the English centre. Here the duke of York was very hard pressed and had to shift his flag twice, and only the arrival of the ships of the Blue

squadron prevented complete disaster; after which de Ruyter drew off.

The Test Act now forced the retirement of the duke of York and many other Catholic officers, and no further operations were attempted till 1673, when the allied fleet was commanded by Prince Rupert, and it was planned to land troops on the Dutch coast. The Dutch, who were also attacked by Louis XIV. on land, passed through an internal revolution which brought William, prince of Orange, to the chief naval and military command. He at once ordered de Ruyter to sea, but there was hardly enough ammunition for both army and fleet. De Ruyter occupied a well-chosen anchorage in the Schoonveldt channel from where he could command his own coast. On May 28, 1673, the allied fleet attacked him with fireships and frigates, but were severely handled and driven back on their main fleet, de Ruyter counter-attacking with great skill and the fight lasting till night, when the Dutch again retired to their own coast.

On June 4 de Ruyter himself made a sortie and caught the allies somewhat dispersed, and after a running fight again retired to his shoals, the allies returning to the Thames to refit. De Ruyter now attempted to blockade them, but was driven back by plague in his ships, and at the end of July the allies returned in force to blockade the Dutch ports, and threatened an invasion from the east coast. William of Orange ordered de Ruyter to break the blockade and relieve the Dutch trade at all costs. De Ruyter found the allies off the Texel and, through the deliberate slowness of the French, easily out-manoeuvred them and obtained the weather gauge. On Aug. 11, 1673, he again had the wind, and attacked them running south. The French, who were leading, attempted to surround his van and, having failed, withdrew from the action. Spragge in the rear fought a magnificent but detached action with Cornelius Tromp, regardless of the general tactics of the battle. The French having disappeared, de Ruyter was again able to concentrate superior numbers against the English centre, which was very hard pressed. The centre and rears now became confused in a general *mêlée* and Spragge was drowned while crossing in a boat to his third ship. Great efforts were made to capture his first ship, the "Royal Prince," but she was splendidly defended, and towards evening the French returned and the Dutch withdrew. The unpopularity of the war in England compelled the English government to make peace with the Dutch in the following year.

Meanwhile, a revolt in Sicily led the insurgents to seek help from the French against their Spanish rulers, and a French army occupied Messina. The Spaniards appealed to the Dutch for help, and de Ruyter took out a squadron and fought an indecisive action on Jan. 8, 1676, with Duquesne who was bringing French reinforcements to Sicily. Later, a combined Hispano-Dutch attack on Messina failed, and de Ruyter was mortally wounded off Augusta on April 22. Charles II. now made a treaty of alliance with the Dutch, despatched troops to help them in Flanders, and sent Sir John Narbrough to the Mediterranean, on which the French evacuated Sicily and, in 1678, made the peace of Nijmwegen.

OPERATIONS ON LAND

The contemporary military history of Europe included, first, the war between France and Spain, 1654–59, usually called the Spanish Fronde (see FRONDE, THE), of which the most notable incident was the great battle of the Dunes (*q.v.*). About the same time a war was fought in northern Europe (1655–60), celebrated chiefly for the three days' battle of Warsaw (July 28–30, 1656), and the successful invasion of Denmark by the Swedes, carried out from island to island over the frozen sea (Feb. 1658), and culminating in a long siege of Copenhagen (1658–59). Between the second and third wars of England and the United Provinces came the short War of Devolution (1667–68)—a war of sieges in the Low Countries in which the French were commanded chiefly by Turenne. In 1668 the French under Condé made a rapid conquest of Franche-Comté. This was, however, given up at the peace, The war of 1672–78, the first of the three great wars of Louis XIV., was fought on a grander scale.

Invasion of Holland, 1672.—The diplomacy of Louis had, before the outbreak of war, deprived Holland of her allies—England (Treaty of Dover, 1670), Sweden (Treaty of Stockholm, 1672) and the emperor, and when he declared war on the United Provinces in March 1672, it seemed that the Dutch could offer little resistance. The French army under Louis in person started from Charleroi and marched down the Meuse unopposed. The powerful Dutch fortress of Maastricht was masked, and the French then moved towards Dusseldorf. In the electorate of Cologne they were in friendly country, and the main army soon moved down the Rhine from Dusseldorf, the corps of Turenne on the left bank, that of Condé on the right. At the same time a corps under Marshal Luxemburg, composed of Louis' German allies (Cologne and Miinster) moved from Westphalia towards Over-Yssel and Groningen. The Rhine fortresses offered but little resistance to the advance of Turenne and Condé. William of Orange with a weak field army tried to defend the Yssel-Rhine line, but the French rapidly forced the passage of the Rhine at Tolhuis (June 12) and passed into the Betuwe (between the Lek and the Waal). Condé now advised a cavalry raid on Amsterdam, but Louis, acting on the suggestion of the war minister, Louvois, preferred to reduce Nijmwegen, Gorinchem and other places, before entering Utrecht province. Condé's plan was, however, partially carried out by Count Rochefort, who with 1,800 troopers captured successively Amersfoort and Naarden. His further progress was checked at Muyden, which the Dutch garrisoned in the nick of time, and he returned to the main army, taking Utrecht en route. Louis now moved on Amsterdam, brushing aside the feeble opposition which was offered, and it seemed that the French must achieve their object in one short campaign. But the Dutch people were roused. The month before, the citizens of Utrecht had refused to raze their suburban villas, and defence of the fortifications had consequently been impossible. Now, the dikes were cut and the sluices opened, and Amsterdam was covered by a wide inundation, against which the invader was powerless. At the same time the men of Zeeland repulsed a French raid from Ath on Aadenburg, and this infraction of the neutrality of the Spanish Netherlands served but to raise up another enemy for Louis. Luxemburg too, at first successful, was repulsed before Groningen. A revolution placed William of Orange at the head of the Government. The alliance of Brandenburg and the Mainz electorate had already been secured, and Spain, justly fearing for the safety of her Flemish possessions, soon joined them. The emperor followed, and Louis was now opposed, not by one State, but by a formidable coalition.

War Against the Coalition.— In the autumn the war spread to the Rhine. No attempt could be made on Amsterdam until the ice should cover the floods. Turenne was therefore despatched to Westphalia and Condé to Alsace, while a corps of observation was formed on the Meuse to watch the Spanish Netherlands. But the coalition had not yet developed its full strength, and Turenne's skill checked the advance of the Imperialists under Montecucculi and of the Brandenburgers under the Great Elector. A war of manoeuvre on the middle Rhine ended in favour of the French, and the allies then turned against the territories of Cologne and Miinster, while William, disappointed in his hopes of joining forces with his friends, made a bold, but in the end unsuccessful, raid on Charleroi (Sept.–Dec. 1672). The allies in Germany were now not merely checked, but driven from point to point by Turenne, who displayed a degree of energy rare in the military history of the period. After a severe winter campaign, the elector, defeated in combat and manoeuvre, was forced back to the Weser, and being but weakly supported by the Imperialists, found himself compelled to make a separate peace (June 6, 1673). Turenne then turned his attention to the Imperialists who were assembling in Bohemia, and made ready to meet them at Wetzlar. Meanwhile the other French armies were

fully employed. During the winter, Luxemburg made a bold attempt to capture Leyden and The Hague by marching a corps from Utrecht across the frozen inundations. But a sudden thaw imperilled his force and he had to make a painful retreat along the dikes to Utrecht. And Condé, who then returned to the command of the army in Holland, failed to make headway against the defence of Amsterdam. Louis' own army, originally collected for the relief of Charleroi in Dscember (advanced on Maastricht, and after a brief siege, in which Vauban directed the besiegers, captured this most important fortress (June 29, 1673). Louis, after the capture of Maastricht, led his army southwards into Lorraine and overran the electorate of Trier. But nothing of importance was gained, and Turenne's summer campaign was wholly unsuccessful.

Capture of Bonn.—From Wetzlar he moved to Aschaffenburg. Soon the Imperialists advanced in earnest, greatly superior in numbers. Marching via Eger and Nuremberg (Sept. 3) on the Main, Montecucculi drew Turenne to the valley of the Tauber; then, having persuaded the bishop of Wiirzburg to surrender the bridge of that place, he passed to the right bank of the Main before Turenne could intervene. The Imperialists soon arrived at Frankfurt, and the French position was turned. Montecucculi thus achieved one of the greatest objects of the 17th century strategist, the wearing down of the enemy in repeated and useless marches. The French retreat to the Rhine was painful and costly, and Montecucculi then passed that river at Mainz and made for Trier. Turenne followed, unable to do more than conform to his opponent's movements, and took post to defend Trier and Alsace. Thereupon Montecucculi turned northward to meet William of Orange, who evaded Condé's weak army and marched rapidly via Venló (Oct. 22) on Coblenz. The elector of Trier, who had not forgotten the depredations of Louis' army in the spring, followed the example of the bishcp of Würzburg and gave a free passage at Coblenz. William and Montecucculi joined forces in the electorate and promptly besieged Bonn. This fortress fell on Nov. 12, and the troops of the coalition gained possession of an unbroken line from Amsterdam to the Breisgau, while Louis' German allies (Cologne and Münster), now isolated, had to make peace at once. Louis' allies were leaving him one by one. The German princes and the empire itself rallied to the emperor, Denmark joined the coalition (Jan. 1674), the Great Elector reentered the war, and soon afterwards England made peace.

Operations of 1674.—In 1674 therefore Louis reluctantly evacuated those of the United Provinces occupied by his army. He had derived a considerable revenue from the enemy's country, and he had moreover quartered his troops without expense. The resources of the French Government were almost intact for the coming campaign; the corps of observation in Roussillon, under Marshal Schomberg, made a successful campaign against the Spaniards, and the war was carried even into Sicily. Condé, in the Spanish Low Countries, opposed with inferior forces the united army of Spaniards, Dutch and Austrians under William, and held the Meuse from Grave to Charleroi on the Sambre. The war in this quarter was memorable for Condé's last, and William's first, battle, the desperate and indecisive engagement of Seneffe (Aug. 11), in which the two armies lost one-seventh of their strength in killed alone. The king's part in the campaign was, as usual, a war of sieges; an army under his personal command overran Franche-Comté in six weeks, and Louis, aided by the genius of Vauban, reduced Besançon in nine days. Turenne's Rhine campaign began with an invasion of Germany, undertaken to prevent interference with Louis in Franche-Comté. Bournonville, the imperial commander who now replaced Montecucculi, lay in the Cologne and Trier electorates. An army of South Germans, in the Breisgau, under the duke of Lorraine and Count Caprara, moved northward to the Neckar valley to unite with Bournonville. Turenne determined to attack the southern army before the junction could be effected. He crossed the Rhine at Philipsburg early in June, and on the 16th fell upon the inferior forces of Caprara in their entrenched position of Sinsheim. The result of the battle was a complete victory for the French, who followed up their success by driving a portion of Bournonville's army (on which the duke of Lorraine had rallied his forces) from the Neckar (action of Ladenburg near Heidelberg, July 7). Turenne then laid waste the Palatinate, in order that it should no longer support an army, and fell back over the Rhine, ignoring the reproaches of the elector palatine, who vainly challenged him to a duel. This devastation has usually been considered as a grave stain on the character of the commander who ordered it, but Turenne's conception of duty did not differ in this respect from that of Cromwell, Marlborough, Wellington and the generals of the American Civil War. It was held to be necessary and expedient, and it was accordingly carried out. Bournonville's army near Frankfurt was still to be dealt with, and the Great Elector and his Brandenburgers were rapidly approaching the Main valley. After a slight attempt to invade Lorraine, which Turenne easily stopped, the Imperialists suddenly recrossed the Rhine and marched rapidly into the neighbourhood of the Strasbourg bridge.

Turenne's Winter Campaign in Alsace.—The magistrates of this city were not less amenable than had been the bishop of Würzburg in 1673. Bournonville obtained a free passage, and Turenne was too late to oppose him. The French general, however, determined to fight, as he had done at Sinsheim, to prevent the junction of the two hostile armies. The Great Elector was still in the Neckar valley when the battle of Enzheim (8m. from Strasbourg) was fought on Oct. 4. This time it was indecisive, and Bournonville's superior forces, soon augmented by the arrival of the elector, spread into Alsace. Turenne steadily retired to his camp of Dettweiler, unable for the moment to do more, and the Germans took up winter quarters in all the towns from Belfort to Strasbourg (Oct.–Nov. 1674). But Turenne was preparing for another winter campaign, the most brilliant in the great commander's career.

First he placed the fortresses of middle Alsace in a state of defence, to deceive the enemy. Then he withdrew the whole of the field army quietly into Lorraine. Picking up on his way such reinforcements as were available, he marched southward with all speed behind the Vosges, and in the last stages of the movement he even split up his forces into many small bodies, that the enemy's spies might be misled. After a severe march through hilly country and in the midst of snowstorms, the French reunited near Belfort, and without a moment's delay poured into Alsace from the south. The scattered Imperialists were driven towards Strasbourg, every corps which tried to resist being cut off. Bournonville stood to fight at Mulhausen with such forces as he could collect (Dec. 29, 1674), but Turenne's men carried all before them. The advance continued to Colmar, where the elector, who was now in command of the Germans, stood on the defensive with forces equal to Turenne's own. The battle of Tiirkheim (*q.v.*) (Jan. 5, 1675) nevertheless resulted in another and this time a decisive victory for the French; a few days after the battle Turenne could report that there was not a soldier of the enemy left in Alsace. His army now went into winter quarters about Strasbourg, and drew supplies from the German bank of the Rhine and even from the Neckar valley (Jan. 1675).

Operations of 1675.—This opening of the campaign promised well, and Louis as usual took the field as early as possible. In the course of the spring (May–June) the king's army recaptured some of the lost fortresses of the Meuse and took in addition Liège and Limburg, The expeditionary corps in Sicily also gained some successes in this campaign, and Schomberg invaded Catalonia. On the Rhine was fought the last campaign of Turenne and Montecucculi. The elector having withdrawn his forces to Brandenburg *(see* SWEDEN: *History),* Montecucculi resumed command, and between Philipsburg and Strasbourg the two great commanders manoeuvred for an advantage, each seeking to cover his own country and to live upon that of the enemy. At last Turenne prevailed and had the Imperialists at a disadvantage on the Sasbach, where, in opening the action, he was killed by a cannon-shot (July 27). The sequel showed how dependent was even the best organized army of the time upon the personality of its commander.

All the advantages won were hastily surrendered, and Montecucculi, sharply following up the retreat of the French, drove

them over the Rhine and almost to the Vosges. At the same time the duke of Lorraine defeated Marshal Créqui (Aug. 11) at Conzer Briicke on the Moselle, and recaptured Trier (Sept. 6), which, as a set-off against Bonn, Turenne had taken in the autumn of 1673. The situation was more than alarming for the French, but Condé was destined to achieve a last success—for once a success of careful strategy and prudent manoeuvre. Luxemburg was left in charge in Flanders, and Condé took command of the remnant of Turenne's old army and of the fugitives of Créqui's. Montecucculi's skill failed completely to shake his position, and in the end Condé compelled him to retire over the Rhine. Both retired from their commands at the close of the year, Turenne was dead, and a younger generation of commanders henceforward carried on the war.

Operations of 1676.—In 1676 the naval successes of France in the Mediterranean enabled the corps under Marshal Vivonne in Sicily to make considerable progress, and he won an important victory at Messina on March 25. Vivonne was made viceroy of Sicily. Louis himself, with his marshals and Vauban, conducted the campaign in the north. The town of Condé fell on April 26, and the king then manoeuvred against the prince of Orange in the neighbourhood of Valenciennes. An attempt made by the latter in the summer to besiege Maastricht was frustrated by Marshal Schomberg with a detachment of the king's army (August). Rochefort meanwhile covered the Meuse country and Luxemburg. Créqui, who had now returned from captivity (he had been taken after the battle of Conzer Briicke) opposed the Imperialists in Lorraine, but he was unable to prevent the fall of Philipsburg, which occurred on Sept. 17. The French now laid waste the land between the Meuse and Moselle for the same reason which brought about the devastation of the Palatinate in 1674, and the year closed with a war of manoeuvre on the upper Rhine between the Imperialists under the duke of Lorraine and the French under Luxemburg.

Operations of 1677 **and 1678.**—The chief event of the campaign of 1677 in the Netherlands was the siege of Valenciennes, which fortress was invested by Louis in the first weeks of the campaigning season. Five marshals of France served under the king in this enterprise, but their advice was of less value than that of Vauban, whose plans the king followed implicitly, even so far as to order an assault de vive force against the unanimous opinion of the marshals. This succeeded beyond Vauban's own expectation; the picked troops entrusted with the attack of an outwork forced their way into the town itself (March 17). The success was followed by the siege of St. Omer and the defeat of William's relieving army by the duke of Orleans (battle of Mont Cassel, April 11, 1677). The summer campaign was a contest of skill between Luxemburg and William, which resulted in favour of the French.

In Germany the credit of the French successes was due to Créqui, who was no longer the defeated general of Conzer Brucke, but the most successful of Turenne's pupils. He began by driving back the duke of Lorraine to the Rhine. Another attempt by the Lorraine family to reconquer their duchy was thus foiled, and at the same time a second imperial army, which had crossed the Rhine by Philipsburg, was shut up in an island of the Rhine and forced to make terms with the French. A large reinforcement sent by the duke of Lorraine to its assistance was completely defeated by Créqui in the battle of Kochersberg near Strasbourg (Oct. 7) and the marshal followed up his successes by the capture of Freiburg on Nov. 14. During the year there was a brisk war in the West Indies, and also in Catalonia, where the French maintained the ground won by Schomberg in the previous campaign.

In 1678 Louis took the field in February. The skilful manoeuvres of the French, whether due to Louis' own generalship or that of his advisers, resulted in the speedy capture of Ghent and Ypres (March), and the retention of the prizes in the usual war of posts which followed. The last battle of the war was fought at St. Denis (outside Mons) between William and Luxemburg on Aug. 14, three days after the peace of Nijmwegen had been concluded. William sustained another defeat, but the battle was one of the most fiercely contested of the whole war. On the Rhine, Créqui began by winning the battle of Rheinfelden (July 6), after which he inflicted upon the Imperialists another defeat at Gengenbach (July 23) and took Kehl. In the short campaign of 1679, before France and the empire had concluded peace, he was equally successful.

In Spain the French army under Marshal de Navailles had also made steady progress, and thus the last campaign was wholly in favour of the French. The peace of Nijmwegen gave Louis many of the Netherlands frontier fortresses, and little else. He was threatened by the intervention of England on the side of the coalition, and would have made peace earlier but for his reluctance to abandon his ally Sweden. The French army had, however, well established its reputation. Vauban was unique amongst the officers of his time, and Créqui and Luxemburg were not unworthy successors of Turenne and Condé. The two marshals added to their reputation in the "Reunion War" of 1680–84. Créqui died in 1687, Luxemburg's greatest triumph was won seven years later (see GRAND ALLIANCE, WAR OF THE). Vauban retired from active service as a marshal 25 years after the peace of Nijmwegen. But the interest of the war does not reside wholly in the personalities of the leaders. There were great commanders before Turenne and Condé. It is as the début of a new method of military organization and training—the first real test of the standing army as created by Louvois—that the Dutch War of 1672–79 is above all instructive. (C. F. A.)

DUTCH WEST INDIA COMPANY, THE (De Westindische *Compagnie*), a company founded by letters-patent from the Netherlands states-general dated June 3, 1621. The purpose for which the company was formed was to regulate and protect the contraband trade already carried on by the Dutch in the American and African possessions of Spain and Portugal, and to establish colonies on both continents and their islands. By the terms of the charter the company was to be composed of five boards or branches, established in Amsterdam, Zeeland, the Meuse (Rotterdam), the North Department (Friesland and Hoorn), and Groningen. Each was to be represented on the general governing board according to the importance of the capital contributed by it. Thus Amsterdam, which contributed four-ninths of the capital, had eight directors on the board. Zealand, which subscribed two-ninths, had four. Rotterdam was represented by two directors. The northern district and Groningen appointed one director each.

The company was granted the monopoly of the trade with America and Africa and between them, from the Arctic regions to the Straits of Magellan, and from the Tropic of Cancer to the Cape of Good Hope. The policy the company proposed to follow was to use its monopoly on the coast of Africa in order to secure the cheap and regular supply of negro slaves for the possessions it hoped to acquire in America. The trade was thrown open by the voluntary action of the company in 1638. The general board was endowed with ample power to negotiate treaties, and make war and peace with native princes; to appoint its officials, generals and governors; and to legislate in its possessions subject to the laws of the Netherlands. The states-general undertook to secure the trading rights of the company, and to support it by a subvention of one million guilders (about £100,000). In case of war the states-general undertook to contribute sixteen vessels of 300 tons and upwards for the defence of the company, which however, was to bear the expense of maintaining them. In return for these aids the states-general claimed a share in the profits, stipulated that the company must maintain sixteen large vessels (300 tons and upwards) and fourteen "yachts" (small craft of 50 to 100 tons or so); required that all the company's officials should take an oath of allegiance to the Netherlands as well as to the board of directors; and that all despatches should be sent in duplicate to the government and to the board.

The history of the Dutch West India Company is one of less prosperity than that of the Dutch East India Company. In early days the trade was not sufficient to meet the heavy expense of the armaments raised against Spain and Portugal. The company was never able to secure the control of the supply of slaves from Africa. Its settlement of New Netherland was lost to England.

In the West Indies it gained a valuable footing among the islands. It occupied St. Eustatius in 1634, Curaçao with Bonaire and Aruba in 1634 and 1635, Saba in 1640 and St. Martin in 1648. But its greatest conquests and its greatest losses were alike met on the continent of South America. After a first unsuccessful occupation in 1623 of Bahia, which was immediately retaken by a combined Spanish and Portuguese armament, the company obtained a firm footing in Pernambuco. The story of the wars which arose out of this invasion belongs to the history of Brazil. The company had been largely guided in its policy of assailing the Portuguese possessions by the advice of the Jews, who were numerous in Brazil, and who found means to communicate with their fellows in religion, the refugees in Amsterdam. The most prosperous period of the company was during the tolerant and liberal administration of Count John Maurice of Nassau-Siegen (1636–44).

The monopolist tendency of all Dutch colonization, the religious hostility of the Roman Catholic Portuguese, and the support given by France and England to Portugal after her revolt from Spain combined at last to make the position of the company in Brazil untenable. It resigned all claim on the country by the treaty of 1661. But though deprived of its establishment in Brazil, the. company found a compensation in Surinam and Essequibo (Dutch Guiana), where there was no Spanish or Portuguese population to resist it, and where the resources of the country offered great profits. The advantages of the settlement in Guiana were not, however, reaped by the company founded in 1621. In 1674 it had become so embarrassed that it was dissolved, and reconstructed in 1675. The newly formed company continued to exploit the Dutch possessions in America till 1794, when they were all swept into the general reorganization consequent on the French invasion of Holland. The West India Company founded after the Napoleonic epoch in 1828 was only meant to develop trade, and was not successful

DUTT, MICHAEL MADHU SUDAN (1824–1873), the greatest native poet of India in the 19th century, was born at Sagandari, in the district of Jessore in Bengal, on Jan. 25, 1824. His father was a pleader in Calcutta, and young Madhu Sudan received his education in the Hindu college of Calcutta. In 1843 he ran away to avoid a marriage into which his father wished to force him, and embraced the Christian religion. Continuing his studies now in the Bishop's college, Madhu Sudan learnt Greek and Latin and some modern European languages, and in 1848 went to Madras. There he wrote English verses, and married the daughter of a European indigo-planter, but was soon separated from her. He then married an English lady. with whom he returned to Calcutta in 1856, and soon discovered that the true way to win literary distinction was by writing in his own language, not by composing verses in English. His three classical dramas—*Ratnavali* (1858; Eng. trans, 1904), *Sarmishtha* (1859; Eng. trans. 1859, 1914) and *Krishna* Kumari—appeared between 1858 and 1861, and were recognized as works of merit. But his great ambition was to introduce blank verse into Bengali. His knowledge of Sanskrit poetry, his appreciation of the Greek and Latin epics, and his admiration of Dante and of Milton, impelled him to break through the fetters of the Bengali rhyme, and to attempt a spirited and elevated style in blank verse. His first poem in blank verse, the *Tilotfama,* was only a partial success; but his great epic which followed in 1861, the *Meghanad-Badha,* took the Indian world by surprise, and at once established his reputation as the greatest poet of his age and country. He took his story from the old Sanskrit epic, the *Ramayana,* but the beauty of the poem is all his own. and he imparted to it the pathos and sweetness of Eastern ideas combined with the vigour and loftiness of Western thought. In 1862 Madhu Sudan left for Europe. He lived in England for some years, and was called to the bar; and in 1867 returned to his country to practise as a barrister in Calcutta. He still wrote much, but nothing of enduring merit. He died in a Calcutta hospital on June 29, 1873.

DUTT, TORU (1856–1877), Indian poetess, was born in Calcutta on March 4, 1856, and died there of tuberculosis on Aug. 30, 1877. She was the youngest child of Govin Chunder Dutt, member of a distinguished Christian family in Bengal who were noted for their poetical gifts. Toru visited Europe with her parents in 1869 and spent some time in Nice and at Paris. Toru Dutt became an enthusiastic lover of France and French literature, James Darmesteter, in his *Essais de Littérature Anglaise,* states that "French became her favourite language and France the country of her election." Early in 1870 the family arrived in London, removing in 1871 to Cambridge. On their return to India in 1873 Toru contributed to the *Bengal Magazine* translations into English from the Romantic school of French poetry, which were afterwards published, with other pieces, in a volume entitled *A Sheaf Gleaned in French Fields* which won the praise of André Theuriet and Sir Edmund Gosse. Her translations of speeches delivered by Victor Hugo and Thiers in the French Legislative Assembly were also published in the *Bengal Magazine* for June and July, 1875. Her most remarkable work was a French novel, *Le Journal de Mlle. D'Arvers,* dedicated to Lord Lytton, and published post-humously by Didier (Paris, 1879), with a preface by the Orientalist, Mlle. Clarisse Bader. This book was highly praised by Madame de Saffray, and James Darmesteter has included an appreciation of it in his *Essais. Ancient Ballads and Legends of Hindustan* (London, 1882) constitute Toru Dutt's best work in English. In this book she made available, for the appreciation of English readers, some of the great stories of Indian classical literature and also some beautiful miscellaneous poems. Of these, *Our Casuarina Tree* is rich in imagery and musical cadences.

See H. Das, *Life and Letters of Toru Dutt* (1921). (*H.* DA.)

DUTY, a term loosely applied to any action or course of action which is regarded as morally incumbent, apart from personal likes and dislikes or any external compulsion. Such action must be viewed in relation to a principle, which may be abstract in the highest sense (*e.g.,* obedience to the dictates of conscience) or based on local and personal relations. That a father and his children have mutual duties implies that there are moral laws regulating their relationship; that it is the duty of a servant to obey his master within certain limits is part of a definite contract, whereby he becomes a servant engaging to do certain things for a specified wage. Thus it is held that it is not the duty of a servant to infringe a moral law even though his master should command it. For the nature of duty in the abstract, and the various criteria on which it has been based, *see* ETHICS.

From the root idea of obligation to serve or give something in return, involved in the conception of duty, have sprung various derivative uses of the word; thus it is used of the services performed by a minister of a church, by a soldier, or by any employee or servant. A special application is to a tax, a payment due to the revenue of a state, levied by force of law. Properly a "duty" differs from a "tax" in being levied on specific commodities, transactions, estates, etc., and not on individuals; thus it is right to talk of import-duties, excise-duties, death- or succession-duties, etc., but of income-tax as being levied on a person in proportion to his income.

DUUMVIRI or **DUOVIRI,** in ancient Rome, the official style of two joint magistrates. Such pairs of magistrates were appointed in Rome itself and in the colonies and municipia. (1) *Duumviri iuri* (*iure*) *dicundo,* municipal magistrates, whose duties were concerned with the administration of justice. (2) *Duumviri quinquennales,* municipal officers, who were elected every fifth year for one year to exercise the function of the censorship. (3) *Duumviri sacrorum,* officers who originally had charge of the Sibylline books *(see* DECEMVIRI). (4) *Duumviri aedi locandae,* originally officers specially appointed to supervise the erection of a temple. (5) *Duumviri navales,* officers appointed for the equipment of a fleet. Originally chosen by consuls or dictator, they were elected by the people after 311 B.C. (6) *Duumviri perduellionis,* the earliest criminal court for trying offences against the State *(see* TREASON: *Roman Law).* (7) *Duumviri viis extra urbem purgandis,* subordinate officers under

the aediles, whose duty it was to look after those streets which were outside the city walls. By 12 B.C. their duties were transferred to the *Curatores viarum.*

DU VAIR, GUILLAUME (1556–1621), French author and lawyer, was born in Paris. Du Vair was in orders, and, though during the greater part of his life he exercised only legal functions, he was, from 1617 till his death, bishop of Lisieux. His reputation, however, is that of a lawyer, a statesman and a man of letters. He became in 1584 counsellor of the parlement of Paris, and as deputy for Paris to the Estates of the League he pronounced his most famous politico-legal discourse, an argument nominally for the Salic law, but in reality directed against the alienation of the crown of France to the Spanish infanta. In 1595 appeared his treatise *De l'éloquence française.* He was sent to England in 1596 with the marshal de Bouillon to negotiate a league against Spain; he became (1599) first president of the parlement of Provence (Aix), and in 1616 keeper of the seals. He died at Tonneins (Lot-et-Garonne) on Aug. 3, 1621. The most celebrated of his treatises are *La Philosophie morale des Stoïques,* translated into English (1664) by Charles Cotton; *De la constance et consolation ès calamités publiques,* composed during the siege of Paris in 1589, and translated into English as *A Buckler against Adversitie* (1622), and *La Sainte Philosophie,* in which religion and philosophy are intimately connected. Pierre Charron drew freely on these and other works of Du Vair, who had a great indirect influence on the development of style in French, for Malherbe was an admirer of his writings. The reformer of French poetry learned much from the treatise *De l'éloquence française,* to which the counsels of his friend were no doubt added.

Du Vair's works were published at Paris in 1641. *See* Nicéron, *Mémoires,* vol. xliii.; and monographs by C. A. Sapey (1847 and 1858).

DUVAL, ALEXANDRE VINCENT PINEUX (1767–1842), French dramatist, was born at Rennes on April 6, 1767. He was in turn sailor, architect, actor, theatrical manager and dramatist. Of his 60 or more plays *Les Projets de ménage* (1790), *Les Tuteurs vengés* (1794) and *Les Héritiers* (1796) have been revived on the modern French stage. In 1812 he was elected to the Academy. He died on Sept. 1, 1842.

DUVAL, CLAUDE (1643–1670), a famous highwayman, was born at Domfront, Normandy, in 1643. Having entered domestic service in Paris, he came to England at the time of the Restoration in attendance on the duke of Richmond, and soon became a highwayman notorious for the daring of his robberies and his gallantry to ladies. In the end he was captured in London, and hanged at Tyburn on Jan. 21, 1670. His body was buried in the centre aisle of Covent Garden church, under a stone with the following epitaph:—

"Here lies Du Vall: Reader if male thou art,
Look to thy purse: if female to thy heart."

A full account of his adventures, ascribed to William Pope, was reprinted in the *Harleian Miscellany,* and Samuel Butler published a satirical ode *To the Happy Memory of the Most Renowned Du Val.*

DUVENECK, FRANK (1848–1919), American figure and portrait painter, was born at Covington, Ky., Oct. 9, 1848. He was a pupil of Diez in the Royal Academy of Munich, and a prominent member of the group of Americans who in the '70s overturned the traditions of the Hudson river school and started a new art movement. His work shown in Boston and elsewhere about 1875 attracted great attention, and many pupils flocked to him in Germany and Italy, where he made long visits. After returning from Italy to America, he gave some attention to sculpture, and modelled a fine monument to his wife, now in the English cemetery in Florence. In 1915 he presented to the Cincinnati (O.) Museum a large collection of his own works. He died in Cincinnati, Jan. 3, 1919.

DU VERGIER DE HAURANNE, JEAN (1581–1643), abbot of St. Cyran, father of the Jansenist revival in France, was born of wealthy parents at Bayonne and studied theology at Louvain. After taking holy orders he settled in Paris, where he became known as a mine of miscellaneous erudition. His friendship with Cornelius Jansen, a young champion of Augustinianism, led him to oppose the Louvain Jesuits who stood for Scholasticism. The two divines retired to Du Vergier's home at Bayonne, where he became a canon of the cathedral, and Jansen a tutor in the bishop's seminary. Here they remained some years, intently studying the fathers. Eventually, Jansen went back to Louvain, while Du Vergier became confidential secretary to the bishop of Poitiers, and was presently made sinecure abbot of St. Cyran. Thereafter he was generally called M. de St. Cyran. At Poitiers he met Richelieu—as yet simply the zealous young bishop of the neighbouring diocese of Luçon. Western Touraine being the headquarters of French Protestantism, the two prelates turned St. Cyran's learning against the Huguenots. He began to dream of reforming Catholicism on Augustinian lines, and thus defeating the Protestants by their own weapons. They appealed to primitive antiquity; he answered that his Church understood antiquity better than theirs. They appealed to the spirit of St. Paul; he answered that Augustine had saved that spirit from etherealizing away, by coupling it with a high sacramental theory of the Church. They flung practical abuses in the teeth of Rome: he entered on a bold campaign to bring those abuses to an end. Before long, his reforming zeal necessitated his removal to Paris where his attempt to gain the support of influential people led to his friendship with the Arnauld family. Jansen was now attacking Jesuit dialectics, which he thought had corrupted theology, by writing a book on Augustine, the great master of theological method.

St. Cyran attacked their hand-to-mouth utilitarianism which had played havoc with traditional church institutions, and their defiance of episcopal authority by his *Petrus Aurelius* (1633).

This work so annoyed Richelieu, now the powerful and extremely Erastian prime minister, that St. Cyran was imprisoned until Richelieu's death in 1642. St. Cyran himself died of a stroke of apoplexy in Oct. 1643.

St. Cyran's character has been always something of a puzzle. Many excellent contemporary judges were profoundly impressed; others, as one of them said, went away bewildered by this strange abbe, who leapt from one point to another in incoherent phrases. Grace of expression he had none; perhaps no man of equal spiritual insight ever found it so hard to make his meaning clear. On the other hand, Jansenism, considered as a practical religious revival, is altogether his work.

He dragged the Augustinian mysticism out of the Louvain classrooms, and made it a spiritual force in France. Without him there would have been no Pascal—no Provincial Letters, and no *Pensées.*

See C. Lancelot, *Memoires de M. de S. Cyran* (Cologne, 1738); Sainte-Beuve, *Port-Royal,* 5 ed. (1888). J. Laporte, *La doctrine de Port-Royal,* vol. 1 (1923) contains a list of the printed and ms. works of St. Cyran.

DUVEYRIER, HENRI (1840–1892), French explorer of the Sahara, was born in Paris, and at the age of 19, having already learnt Arabic, began a journey in the northern parts of the Sahara which lasted nearly three years. In 1864 he published *Exploration du Sahara: les Touareg du nord.* After 1870 he made several other journeys in the Sahara. He also examined the Algerian and Tunisian *shats* and explored the interior of western Tripoli.

Duveyrier devoted special attention to the customs and speech of the Tuareg, and to the organization of the Senussi. In 1881 he published *La Tunisie,* and in 1884 *La Confrérie musselmane de Sidi Mohammed Ben Alî-Es-Senôusi et son domaine géographique.*

See C. Maunoir and H. Schivmer, *Sahara, Algérien et Tunisien,* with a Biography of Duveyrier by C. Maunoir (1905).

DUX, BOHEMIA: *see* DUCHCOV.

DUX (Lat., leader), in music, an old name for the opening statement of the subject in a fugue, so called because, coming first, it is the "leader"; the second statement, or answer, being

called, in the same fanciful spirit, the *comes* or companion. *(See* FUGUE and CONTRAPUNTAL FORMS.)

DUXBURY, a town of Plymouth county, Massachusetts, on Plymouth bay, 36 mi. S.S.E. of Boston. The population in 1930 was 1,696, and in 1940 it was 2,359 by the federal census. Duxbury was settled in 1631 by Miles Standish, William Brewster, John Alden and a few others, and it was named- after the Lancashire seat of the Standish family. A church was organized in 1632 and the town was incorporated in 1637 The house built in 1666 by Alexander Standish, son of Miles, is still standing. The cod, mackerel and clam fisheries were formerly important, and in the 18th century and the first half of the 19th there were large shipyards here.

DVINA, the name of two rivers of European Russia.

1. The Northern Dvina, or *Dvina Syevernaya,* belongs to the basin of the White sea, and is formed by the junction of the Sukhona and the Yug, which meet in the neighbourhood of Velikiy-Ustyug, at a height of 300 ft. above the sea, in 61°20′ N. and 46°20′ E. The conjoint stream then flows north-west to the Gulf of Archangel, which it reaches 50 m. below the city of Archangel. From its mouth to the confluence of the co-tributary streams the distance is about 470 m., and to the source of the Sukhona 780 m. The drainage area is estimated at 141,000 sq.m. Except at the rapids the current of the Dvina is comparatively slow, as the average fall per mile is only 9 in. Till its union with the Vychegda, a river which exceeds it in volume, it flows for the most part in a single, well-defined and permanent channel; but below that point it often splits into several branches, and not infrequently alters its course. Near Archangel it divides into three distinct arms, which form a regular delta, but of these that of Berezov alone is navigable for sea-going vessels, and even it is impeded by a bar at the mouth, with not more than $14\frac{1}{2}$ or $15\frac{1}{2}$ ft. of water at full tide. Just above the point where the delta begins the river is joined by a large tributary, the Pinega, from the right. Above the confluence of the Vychegda the breadth is about 1,750 ft.; below that point it widens out to 3,500 ft.; and near Archangel it attains more than three times that measure. The channel is free from ice for about 174 days in the year. By means of the Duke Alexander of Wiirttemberg Canal, the river is connected with the Neva and the Volga.

2. The Southern Dvina, or *Dvina Zapadnaya* (western Dvina) belongs to the Baltic basin, and takes its rise in a small lake about 800 ft. above the level of the sea, not far from the sources of the Volga and the Dnieper. It flows south-west through the province of Pskov, and through the White Russian S.S.R. But some distance west of Vitebsk it turns north-west, forming part of the boundary between White Russia and Poland, and then flows through Latvia where it enters the southern end of the Gulf of Riga. Its length is 640 m. and it drains an area of 32,960 sq.m. From Daugavpils (Dvinsk) to Riga, a distance of 135 m., there is altogether a fall of 295 ft., of which 105 ft. are in the 40 m. from Jakobstadt to Friedrichstadt. In the lower part of its course the river attains an ordinary depth of 30 ft. and an average breadth of 1,400 ft.; but during the spring flood it sometimes rises 14 ft. above its usual level, and its waters spread out to a mile in width. Near the mouth the river is usually free from ice for 245 days in the year, and in White Russia 229. It is navigable from the confluence of the Mezha (*i.e.,* from Vitebsk) downwards, but the number of rapids and shallows greatly diminishes its value. Navigation can also be carried on by the following tributaries: the Usvyat, Mezha, Kasplya, Ulla, Disna and Bolder-aa. Salmon and lampreys abound in its waters. The river was formerly called the Khezin or Turunt, and is known to the White Russians as the Polot and to the Latvians as the Daugava. It is the natural outlet for timber from the west of Russia, and timber rafts, usually in charge of gypsies living in grass huts on them, are still floated down it. Its strategic importance has always been great and Riga and Daugavpils (*q.v.*) have witnessed many struggles for power. The construction of a hydro-electric station on the Daugava to provide power equivalent to that from 3,000,000 tons of coal, are now under consideration by the Latvian Government.

DVINSK: *see* DAUGAVPILS.

DVORAK, ANTON (dvor'zhahk) (1841–1904), Bohemian musical composer born at Nelahozeves (otherwise Miihlhausen) in Bohemia on Sept. 8, 1841, was the son of Frantisek Dvořák, a small publican and village butcher. At the door of his father's inn Dvořák first appeared as a practical musician, taking his place among the fiddlers who scraped out their "furiants" and other wild dances for the benefit of the holiday-making local beaux and belles. At the village school he learnt from Josef Spitz both to sing and to play the violin, with so much effect that soon he was able to assist in the parish church services. At 12 years old he was sent by his father to Zlonic, near Schlan, to an uncle, with whom he lived while passing through the higher-grade classes at school. Here, too, he was fortunate enough to find a valuable friend in **A.** Liehmann, organist and chief musician of the little town, a competent musician, who instructed the boy in elementary theory, organ and pianoforte playing. The theory studies, however, could not long be continued, since Liehmann soon acknowledged in his own dialect that the boy was extraordinarily full of promise ("Aus Tonda, dem Sappermentsbuben 'mal 'was werden konnte"), at the same time realizing that he could not do much to assist. But Dvofdk soon left Zlonic for Bohmisch-Kamnitz, where he learnt German and advanced his musical studies under Hancke. A year later he was summoned to return to Zlonic to assist his father, who had set up in business there. But his craving for a musical career was not to be checked, and after considerable trouble, his father's consent was obtained to his settling in Prague to devote himself entirely to the study of music.

In Oct. 1857 Dvořák ent'ered the organ-school of the *Gesellschaft der Kirchenmusik,* where he worked for three years. The small financial aid his father was at first able to lend soon ceased, and after being in Prague but a very few months Dvofdk found himself practically thrown on his own resources. By playing the viola in a private orchestra and in various inns of the town he succeeded in obtaining a precarious livelihood. On the opening in 1862 of the Bohemian Interimstheater, Dvořák, with part of this band, formed the nucleus of the theatrical orchestra, and remained connected with it for 11 years, when he became organist of the church of St. Adalbert. At this time his small stipend was augmented slightly by the fees of a few pupils, though the privations suffered by him and his wife (for he had recently married) must have been great. But in spite of financial worry and of the amount of time he had to devote to his professional duties and private pupils, Dvořák found leisure not only for his own studies of the classics, but also to compose. His work, like his daily life, was beset with difficulties, for he had not the means to prbvide himself with sufficient music-paper, much less to hire a pianoforte; and it is possible that several of his important early works would never have been written had it not been for the generosity of Karel Bendl, the composer, who helped him in many ways.

Dvořák himself said afterwards that he retained no recollection of much that he then composed. In and about 1864 two symphonies, a host of songs, some chamber-music, and an entire opera, *Alfred,* lay unheard in his desk. The libretto of this opera was made up from materials found in an old almanac. Most of these works were burnt long ago. In 1873 he made his first bid for popularity by his patriotic hymn *Die Erben des weissen Berges* (published many years later as op. 30). Its reception was enthusiastic, and Dvořák's subsequent works were eagerly awaited and warmly received on production. In 1874 his opera *König und Köhler* resulted in a fiasco at Prague, owing to its mixture of styles. Nothing daunted, Dvořák recomposed the whole work in three months. In 1875, on the recommendation of Brahms and Hanslick, he obtained a stipend from the Kultus-Ministerium at Vienna, which freed him from care and enabled him to indulge in composition to his heart's content. Following on this success came a commission in 1877 for a series of Slavonic dances, which took the public by storm. Immediately compositions, old and new, began to pour from the publisher. English sympathy was entirely won by the *Stabat Mater* in 1883, and increased by the symphonies which succeeded it, and the cantata *The Spectre's Bride,* based on K. J. Erben's elaboration of

the Bohemian version of the saga treated in Biirger's *Leonore*. The favoarable impression produced by these works was somewhat lessened by the oratorio *St. Ludmila*, a comparatively feeble work written "to suit English taste" for the Leeds Festival of 1886. Of the three overtures, op. 91, 92, 93, only the *Carneval* holds its place; but the New World symphony has become one of the most popular works in the modern repertory, and much of the chamber-music, of which there is abundance, may also be regarded as having permanently established itself, and with good reason, too, for it teems with beauties of every kind. So, too, his *Requiem* (op. 89), written for the Leeds Festival of 1890, will certainly be rediscovered, though it will never be regarded as religious music. In 1892, after having frequently visited England, Dvořák became head of the National Conservatory of Music of America in New York. There he remained till 1895, when he returned to Prague, where he died on May 1, 1904.

Dvořák's talent for composition was of the highest order, but success came to him after a long experience of uneducative hardships. The world then informed him in a loud instructive voice that his music had the charm of bucolic naïveté; and he thereupon extensively wrote himself down in affectations of his own simplicity. His first three symphonies, the Scherzo Capriccioso and the Symphonic Variations will be recognized as great music as soon as criticism ceases to worry about forms, fashions and derivations and proceeds to attend to permanent values. Brahms, assuredly no friend to diffuse form, was so delighted with Dvořák's violoncello concerto (op. 104, one of his most diffuse yet most inventive works) that he said to Hausmann, "Why did nobody tell me that one could write a 'cello concerto like this?"

See W. H. Hadow, *Studies in Modern Music* (second series, 1908). (X.; D. F. T.)

DVŮR KRÁLOVÉ or KÖNIGINHOF, a town of north-east Bohemia, on the left bank of the Elbe. It is a very old city founded by King Wenceslas II. of Bohemia in the 13th century and given by him to his wife, thus deriving its name (the court of the queen). During the Hussite and Austro-Prussian Wars, owing to its important strategic site, it suffered severely. The fertile basin around produces cereals, the basis of its brewing and flour-milling industries, and the town also shares in the cotton-weaving of the neighbouring highland valleys. Population, 16,588. The town became widely known as a result of the supposed discovery by the notorious Václav Hanka in 1817 of a 13th century ms. containing epic and lyric poems in Czech. Critics. headed by Gebauer and Masaryk, proved conclusively that the ms. is a forgery.

DWARF, the term generally used to describe an extraordinarily under-sized individual of a race of normal stature *(see* PYGMY). In Scandinavian mythology the word connoted smallness and deformity, and was used of the elfins and goblins who were supposed to live on the mountains or in the bowels of the earth, and to be kings of metals and mines.

Deficiency in stature is sometimes associated with infantilism, in other cases with injury or deficiency of the pituitary gland, or general endocrine deficiency, with failure of cerebral development. There are two classes, those who are normal in proportions and the disproportionate.

From the earliest historic times there was much competition on the part of kings and the wealthy to obtain dwarfs as attendants. Members of the Akka race of equatorial Africa figured at the courts of the Pharaohs of the early dynasties. Philetas of Cos. poet and grammarian (c. 330 B.C.), tutor of Ptolemy Philadelphus, was alleged to be so tiny that he had to wear leaden shoes lest he should be blown away. The Romans practised artificial dwarfing, and the Latin *nanus* or *pumilo* were terms alternatively used to describe the natural and unnatural dwarf. Julia, the niece of Augustus, had a dwarf named Coropas aft. 4in. high, and a freed-maid, Andromeda, who measured the same.

In later days there have been many dwarf-favourites at European courts. British tradition of dwarfs begins in the old ballad "In Arthur's court Tom Thumb did live." The first authentic English dwarf appears to be John Jarvis (2ft. high), who was page to Queen Mary I. Her brother, Edward VI., had his dwarf Xit. Jeffery Hudson (1619–82), the son of normal parents, at nine years measured scarcely 18in., though gracefully proportioned. At a dinner given by the duke to Charles I. and his queen he was brought in to table in a pie out of which he stepped, and was at once adopted by Henrietta Maria. He followed the fortunes of the court in the Civil War, and was a captain of horse, earning the nickname of "strenuous Jeffery" for his activity. He fought two duels—one with a turkey-cock, and a second with Crofts, who came to the meeting with a squirt, but who in the more serious encounter which ensued was shot dead by Hudson, who fired from horseback, the saddle putting him on a level with his antagonist. Twice was Jeffery made prisoner—by the Dunkirkers as he was returning from France, and by Turkish pirates. His sufferings during this latter captivity made him grow, and he steadily increased until he was 3ft. gin. At the Restoration he returned to England, where he lived on a pension granted him by the duke of Buckingham. He was later accused of participation in the "Popish Plot," and was imprisoned in the Gate House. He was released and shortly after died in the 63rd year of his age.

Henrietta Maria had two other dwarfs, Richard Gibson and his wife Anne. They were married by the queen's wish; and the two together measured only 2in. over 7ft. They had nine children, five of whom, who lived, were of ordinary stature. Edmund Waller celebrated the nuptials, Evelyn called the husband as the "compendium of a man," and Lely painted them hand in hand. Gibson was miniature painter to Charles I., and drawing-master to the daughters of James II., Queens Mary and Anne, when they were children. He began his career as a page, first in a "gentle," next in the royal family, died in 1690, in his 75th year, and is buried in St. Paul's Covent Garden. The last court dwarf in England was Coppernin, a lively little imp in the service of the princess (Augusta) of Wales, the mother of George III. The last dwarf retainer in a gentleman's family was kept by Beckford, the author of *Vathek* and builder of Fonthill.

Of European court dwarfs the most famous were those of Philip IV. of Spain, the hunchbacks whose features have been immortalized by Velazquez. Stanislaus, king of Poland, owned Nicholas Ferry (Bébé), who measured 2ft. gin. He died in his 23rd year (1764). Richebourg, who died in Paris in 1858, at the age of go, was only 23in. high. He began life as a servant in the Orleans family. In later years he was their pensioner. In the Revolution—he passed in and out of Paris as an infant in a nurse's arms, but with despatches, dangerous to carry, in his baby-wrappings!

The Pole, Borulwaski (1739–1837), at six measured 17in., and in his 30th year reached 39 inches. He had a sister shorter than himself by the head and shoulders. Borulwaski was a handsome man, a wit, and something of a scholar. He travelled over all Europe; and—born in the reign of George 11.—died in retirement near Durham, in the reign of Victoria, where he is buried at Durham by the side of the Falstaffian Stephen Kemble.

In 1837 Charles Stratton, better known as "General Tom Thumb," was born. When 25 he was 31in. high. In 1844 he appeared in England, where he had an extraordinary success. After extensive travel in both hemispheres, Stratton again visited England in 1857, but the man, despite many personal and intellectual qualities, was less attractive than the boy. In 1863, the "General" married the very minute American lady, Lavinia Warren (born in 1842). He died on July 15, 1883.

Other modern dwarfs include Mary Jane Youngman (Australia), who at 1j was 35in. high. She was called the "dwarf-giantess" because she was 3ft. 6in. round the shoulders, 4ft. gin. round the waist, and 2ft. round the leg. The so-called Aztec dwarfs were exhibited in London in 1853. In 1867 the pair were married. Che-mah, a Chinese, 42 years old and 25in. high, appeared in London in 1880. George Prout (1774–1851), who was less than 3ft. high was well known in London in the early Victorian period, as a messenger at the Houses of Parliament.

See E. J. Wood, *Giants* and *Dwarfs* **(1860)**; C. Dieckhoff, *The Position of the Iberians and the Dwarfish Races in the Ethnology of the British Isles* (Inverness, 1918–25).

DWARF TREE: see BON-SAI.

DWARKA or **JIGAT,** town, British India, in Baroda State, near the extremity of the peninsula of Kathiawar, Bombay. Pop. (1931) 7,632. As birthplace and residence of Krishna, it is one of the most sacred spots in this part of India, and attracts many thousands of pilgrims. The port of Ruphan, 1 m. N., is a point of call on the Bombay-Karachi route. Steamers lie offshore.

DWARS, a tract of country in north-east India. It consists of two divisions, the Western Dwars and the Eastern Dwars, both of which belonged to Bhutan prior to the Bhutan War of 1864–65, as a result of which they passed into possession of the British, when the Eastern Dwars were assigned to Assam and the Western to Bengal. Since 1905 both divisions have been in the province of Eastern Bengal and Assam. (See BENGAL.) The Western Dwars are an important centre of the tea-planting industry. (See ASSAM.)

DWELLING: *see* HOUSE.

DWELLINGS, PRIMITIVE. Climate imposes the need of shelter, and man can build only with what nature gives him. Even in the civilized 20th century the building materials are mainly local, and in primitive dwellings a closer dependence is shown in the Eskimo *iglu,* the Blackfoot *tipi,* the Australian *wurly* or the Andaman hut, of snow, skins, birch bark and turf or palm leaves. Where nature provides caves or rock shelters man builds no houses at all, and these homes are used by the Vedda of Ceylon, the Bushmen of South Africa, the cave dwellers of Kenya or Tanganyika, China, or the Pueblo region of Arizona, as in Europe in Palaeolithic times. (See CAVE.)

In Neolithic settlements pit dwellings or beehive huts formed the family habitations, and wattle and daub houses characteristic of the bronze age continued into the iron age. For pit dwellings, the earth was scooped out and piled in a circular bank, on which a wall of stone was built. The bank, with a drain outside, kept out the wet, and the hollowing of the floor gave more head room under the low roof. This was made of converging stones in the beehive dwellings, or perhaps of skins stretched across or of brushwood or turf where easily procurable. Prehistoric beehive dwellings of loose stones can be seen in outlying parts of the British Isles, and the Scottish shieling or the Norwegian saeter, shelters for girls tending cattle in their summer pastures, are of the same type. With skins stretched across the large bones of whale or walrus, similar huts are found among tundra and polar peoples from Lapland to Kamchatka, and from Alaska to Labrador. There is a long entrance tunnel, and the hut may also be entered through the roof, a hole in which acts as door, window and chimney in one. Links may be found to connect these pit or bee-hive dwellings with the earth lodges of Missouri and the *kiva* of Arizona. Wattle and daub huts, such as those of the Swiss lake dwellings or of the lake village of Glastonbury, are very easily built. Stakes are driven into the ground, and withes or branches wattled in and out for walls, the hollows in the wattling being filled in and plastered over with mud; the thatched roof has overhanging eaves to protect the mud walls. Such houses were used in Scotland down to the end of the 18th century. They are found across Africa from east to west, north and south of the forest region, and are specially characteristic of the central and Lake Chad areas, in which rainless districts walls and roof may be made in one. They occur rarely in America, except in Mexico and Peru, and in the south-east of the United States, east of the Mississippi.

Pygmy **Huts.**—In a mixed ethnic region, huts are often a truer test of race than language. The most backward peoples show the simplest types. Just as gypsies or travelling tinkers, or boy scouts drive sticks in the ground and hang a piece of sacking or a blanket across to act as a windscreen, so the Negrito of the Philippines, the Andaman islander or the Semang of the Malay peninsula, who rarely stay two nights in the same place, fix up a plaited mat or a row of boughs and sleep to leeward. If the Semang need more shelter, the boughs may be plaited in a circle and joined overhead, or two screens may be tilted against each other, as in building a house of cards. In their camps the Andamanese raise their mat screens to form a roof propped up on four posts, 2ft. to 4ft. high at the back, and 5ft. to 7ft. in front, and better houses are made of two of these mats, forming a saddle roof, with two extra posts to support it, but no walls. These huts are placed in a rough circle round the cleared dancing ground. The Bushmen of the Kalahari desert scoop out hollows in which to curl up, as in a nest, sheltered if possible by natural bushes or by brushwood covered with a skin. The leaf-roofed huts or booths of the Negrilloes of Central Africa are much alike from the Cameroons to Semliki valley. Sticks are bent over with both ends in the ground and roughly thatched with leaves. They are very low, with entrances barely 3ft. high, and are scarcely distinguishable in the gloom and thick foliage of the equatorial forest.

VILLAGE SCENE IN THE FIJI ISLANDS, SHOWING THE STRAW THATCHED DWELLINGS OF THE NATIVES

In Australia, when men are camping for a night or two, the windscreen of brushwood is sufficient; in bad weather the boughs are interlaced overhead to form a horseshoe hut; for longer residence in favoured districts where the search for food does not require constant moves, a regular framework of branches is set up, covered with sheets of bark, leaves or grass, skins, sods of earth or a plastering of clay. An Australian folk-tale (collected before 1850) describes a hut built of the bones of the emu and the kangaroo, covered with skins. To this home the hero brings the admiring heroine (or heroines) and "it was the most beautiful camp ever made" (W. Dunlop, J.A.Z. 1899, p. 32). In South America the natives of British Guiana, when on hunting expeditions, put up temporary shelters or benabs, which may be a few palm leaves laid flat one over the other with their stalks bound together and stuck into the ground, so that the natural curve of the leaf affords sufficient roof. A more pretentious *benab* is made by sticking three posts in a triangle and laying a bunch of palm leaves over the top. The Arawak and Carib tribes living in dense forests, sheltered by surrounding trees, build wall-less houses; the Macusi, living in the open savannah, add walls, filling in the sides and daubing them thickly with clay to keep out the cold winds blowing from the mountains.

Eskimo Snow House.—Without the snow *iglu* life in winter would be impossible for the Eskimo. The original construction was a ring of stones filled in with earth, the roof of sods being supported on branches, as is still the custom to the east and west of the Eskimo territory where wood is obtainable; but from the mouth of the Mackenzie eastward, where the supply of driftwood dwindles, snow houses are the common residence in winter and skin tents in summer. Even where there are stone and wooden houses (and wooden houses spread with Christianity), the snow *iglu* is put up for special occasions or on journeys, as it is quickly built and is impervious to weather. A man cuts a trench some 5ft. long and 20in. deep in a newly made snowdrift, where he means to place his house. From the face of the trench he cuts blocks with his bone knife. These are slightly concave so that they lean inward when set up on edge. A circle of blocks is laid and then shaved down so that the succeeding blocks form an ascending and narrowing spiral, the builder cutting the material from the inside of his house as he works. A key-stone with edges wider above than below is dropped into the space at the top, and

all cracks and crevices are filled in with soft snow. A small house can be built in a couple of hours, but for longer residence more care and time are taken, and on special occasions houses of a large size can be built on the same plan. One erected to welcome the Stefansson-Anderson expedition to Akuliakattagmiut, near Coronation gulf, was 9ft. in height and accommodated 40 people standing up, with a circular space of about 5ft. left in the centre for the

CHARACTERISTIC DALA HOUSE OF THE FIJI ISLANDS

dancers; and festival halls 16ft. high and 70ft. across are reported from Labrador. If it is wanted for more than temporary residence, an alley-way 10ft. to 20ft. long is built outside the house as a shelter for the dogs and gear, with recesses where food can be stored out of the dogs' reach. When the house has been built with the snow platforms for beds inside — this is the man's work — the housewife takes possession. She lights her blubber lamp, feeds it generously so that it burns with all possible heat, closes the door with a block of ice and makes all air-tight. The snow soon begins to melt and, owing to the curve of the domed roof, it does not drip, but soaks gradually into the blocks so that they are nearly wet through. When they are sufficiently sodden the woman puts out her lamp and opens the door. In rushes the intensely cold air, and in a few minutes the house is transformed from a fragile structure of snow that would crumble if touched carelessly, to a vaulted dome of ice so strong that a polar bear might crawl over the roof (as often happens) without the danger of breaking it in.

When the long winter is nearing its end and the temperature rises, the snow houses, however solidly built, begin to melt. The roof is the first to go, and if this caves in, an old skin can be stretched across, but the inhabitants lead an uncomfortable life until they can camp in the open in the skin tents which are their common summer dwellings. These may be merely little bits of three-cornered shelters where skins are spread over the sides of a tripod leaving the lee side open, or large affairs, 6ft. by 14ft., with a ridge-pole supported on a tripod at each end, and a door in the middle of one of the long walls. This, like so many of the snow houses, may contain two families, one to the right and one to the left of the door.

NORTH AMERICA, OCEANIA, AFRICA

Of the three Eskimo types of dwelling, the semi-underground earth house occurs down the west coast as far as San Francisco bay and is met with again in the "earth lodge" of the Missouri region; while the tent, made of skins in the bison area, of birch bark where birches abound, and sometimes of mats among the Ojibway (Chippewa), was the universal shelter across the centre of the continent to the barrier of the Rocky mountains. On the west coast were the timber-built houses, such as those of the Haida and Tlingit or the Coast Salish. These were built entirely of massive posts of red "cedar" (*thuja* gigantea), and planks split with elk horn or maple wood wedges, tied to the uprights. These houses, with almost flat roofs, often 40ft. deep and some hundreds of feet in length, stretched along the shores of river or sea. Inside they were divided by grass mats into separate family compartments, and again into "hearths" or "fireplaces." In front were the totem poles carved and painted with the emblems of the occupants. Further south are the brush shelters of California, or shelters of branches, covered with grass, but nothing of substantial structure is found until the Pueblo region of Arizona and New Mexico is reached. In the Rio Grande (which is also the area of the cliff-dwellers) the houses are built of adobe (sun-dried bricks), wattle and daub, or stone. The Pueblo stone buildings are linked on to the earlier Nahua or Maya culture, for in Mexico and Peru alone was architecture developed in masonry, though neither had attained to the knowledge of the arch. The buildings were massive, and height was gained by platforms of natural or artificial mounds. Inca influence did not spread far in South America. A shelter for the hammock was sufficient in the Amazon region, though large communal thatched houses are not unknown; a skin tent is characteristic of the guanaco area, and this, in the extreme south, dwindles to little more than a lean-to.

In Oceania, although the huts of the indolent are poor and mean, especially in Melanesia, the abundance of timber and various palms, reeds and grasses, the universal agriculture and fishing, with fairly easy life, have raised the general standard of house-building to a high level. Round houses are associated with earlier culture, but for the most part houses are oblong, built either on the ground or on piles. Some of the chiefs' houses are of enormous size. One at Pare (Tahiti) was 397ft. long, and held two or three thousand people. This was rectangular with rounded ends, built by men specially trained to the craft.

African houses are easily made, whether by nomadic hunters, pastors or agriculturalists, and as easily deserted. To the south of the Sahara, uninhabited save for the sun-dried brick houses of the oases and the goats' hair cloth tents of the nomads, round beehive or conical huts with low entrances and thick grass thatches are typical of the plains and open country and of Bantu culture in general. In hotter, drier regions the walls are often plastered with mud. Across the centre of Africa, west of the great lakes (Wa Nyamwezi, Manyema and some of the Ba Rotse), to the west coast stretches a belt of rectangular huts, in striking contrast to the circular shapes north and south of it. This is the forest region, and the contrast has been variously attributed to *(a)* influence of street formation rather than kraal formation, (*b*) derivation from the lean-to shelter, rather than the circular tent, or (c) recent or Arab contact.

Tree-houses and Pile-dwellings. — The need for defence against enemies led to the construction of tree-houses, pile-dwellings, crannogs and floating islands in many dilferent parts of the world. The need of portable shelters by wandering hunters or nomadic pastors developed the Bedouin tent, the Dakota *tipi*, the Mongol gher and the Khirgiz *yurt*. Similar or contrasted social conditions produced the communal houses in Africa, the East Indies, Melanesia and North and South America.

Houses built in trees are for temporary use, either as look-out places or for refuge in case of attack. A platform is often built in a tall tree from which the incursions of enemies are discovered, or crops watched and guarded. More substantial structures are made as refuges in case of an enemy raid. In the inland unsettled parts of New Guinea small strongly built houses are erected in trees. They are reached by ladders, which can be pulled up when the refuge has been gained. It is by no means an easy or rapid matter to cut down a large tree with stone axes, especially when overhead foes are hurling down stones and spears. Houses are also built for defence on piles standing out of the water. A platform is laid on the piles, and huts are built on the platform., Dwellings of this type were built on the edges of lakes in prehistoric Europe, and occur on shallow shores of the sea, lakes or rivers in North and South America, Africa, the East Indian archipelago and Me-

TYPES OF PRIMITIVE DWELLINGS

1. Ceylon. Vedda rock shelter. Caves and overhanging rocks provide shelter for jungle dwellers
2. A Blackfoot camp or *tipi* on Two Medicine Lake, Glacier National Park, Montana. A tripod of poles against which other poles are propped, is covered over with stitched skins pegged down all around at the bottom. Occasionally birch bark is used instead of skins. A skin flap covers the entrance, which usually faces the east. A hole at the top allows smoke to escape
3. Hebridean *shieling* made of stones and turf. The floors of these dwellings are scooped out to make more head room under the low roofs
4. An Andaman hut. A roof of mat screens is propped up on four posts from 2 to 4 ft. high at the back, and from 5 to 7 ft. in front. Better huts are made by using two mats to form a saddle-roof
5. Pile dwellings in New Guinea. Hard-wood poles, sometimes 30 ft. long, are sunk at ebb-tide, and are then covered with a platform of planks upon which the huts are built
6. Mount Ruwenzori, Africa, Ba-Kongo hut. Bamboo sticks are bent over with both ends to the ground, to be thatched later with leaves or grass
7. Ba-Kongo hut completed, with banana leaf thatch. Note the low entrance, barely 3 ft. high

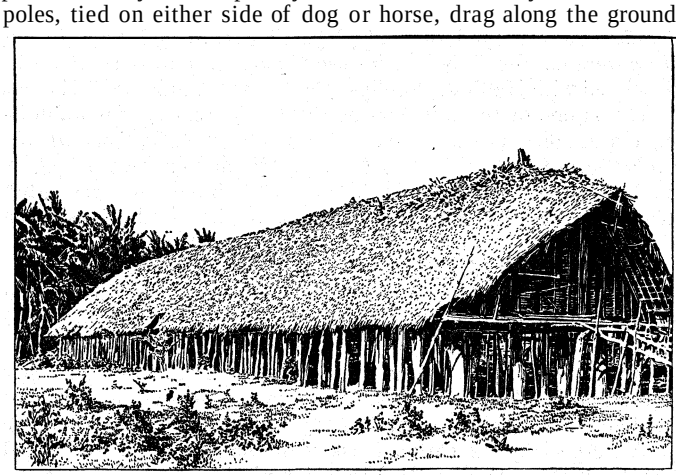
lanesia. Pile-houses may be built on land, forming wet season houses in districts which are liable to be inundated. In the pile village of Bulaa in the Rigo district of British New Guinea, the piles are often 30 ft. in height, of very hard wood, with one end roughly pointed. This end is dropped into a hole at low tide by the help of several men and ropes, and the pole is swayed backwards and forwards, until by its own weight it worms its way into the ground. Heavy planks are laid on the piles to form a platform and on this the houses are built.

Crannogs are built on natural or artificial islands formed of brushwood, logs, stones and clay. They were common in prehistoric times in Ireland, and used down to the reign of Elizabeth.

The lake village of Glastonbury was made of brushwood on layers of tree trunks, pegged down with small piles. Above was a platform of logs laid side by side, and on this was plastered clay several feet thick. The round wattle and daub huts were erected on this foundation. In the African lakes floating islands of papyrus are artificially strengthened and huts built on the top.

PORTABLE DWELLINGS

Tents.—People who are constantly shifting camp, whether wandering hunters in pursuit of game or nomadic herdsmen moving their flocks to pasture, have invented portable dwellings, varying from the flimsy skin tent of the Eskimo, or the equally skimpy tent of the guanaco area of South America, to the luxurious and spacious yurt of the rich steppe lands of Asia. The Eskimo tent, the common summer residence from Alaska to Labrador, is found also in Siberia, and is perhaps linked on to the cloth-covered tent of the reindeer Lapps in Scandinavia. South of the Eskimo area the typical *tipi* (its Dakota name) is found from northern New England throughout the Cree and Ojibway (Chippewa) country and across the bison area to north-west Canada. The nucleus is a tripod of poles against which other poles are propped, and over this is stretched a cone-shaped cover of stitched skins, pegged out all round. A skin curtain hangs across the entrance, which faces the rising sun, and poles on the outside regulate smoke flaps on either side of the hole at the top. In wooded areas where birches grow, sheets of bark are used as coverings, but skins are more suitable for transport. This is the ideal dwelling of nomadic peoples; it is easy to set up, easy to take down and easy to shift. The poles, tied on either side of dog or horse, drag along the ground,



BY COURTESY OF DR. G. LANDTMAN

MOTU COMMUNAL HOUSE OF NEW GUINEA

the cover wraps the scanty household gear in a bundle and lies across their trailing ends. The Ostiak *choom* in the lower Obi district is made of 20 or 30 thin poles fixed in a circle and fastened together at the top, covered with sheets of birch bark boiled to make them pliant, and cut with convex curves to fit over the cone shape of the framework. Extra skins may be added outside with an opening to leeward. The most luxurious tents in all Asia are those of the rich steppe lands of the centre, from the Khalka in eastern Mongolia to the Khirgiz nearing the Urals in the west. In this mainly treeless area long tent poles are not easily found, and the foundation is made of latticework hurdles (usually willow) lashed to posts firmly fixed in the ground. From these, smaller poles radiate towards the centre. Over this framework are stretched the covers of skins or felt, threefold in winter to mitigate the intense cold. There is a hole in the centre of the roof, through which the smoke from the fire of argol or cattle dung can escape, though it is usually kept closed by a piece of felt drawn across by a string. A felt curtain, often beautifully embroidered, falls over the entrance facing south, and curtains fastened to the sides of the tent can be let down to form separate compartments. This form of tent is heavy and cumbersome, but camels, horses and cattle provide abundant beasts of burden, and the setting up and taking down of the tent is always woman's work.

A far simpler tent suffices for the hardy desert herdsmen of western Asia and north Africa. The typical Bedouin tent is of sticks, sometimes forked with a ridge-pole, which irregularly supports a cover made of woven goats' hair strips sewn together, usually black from use if not by nature. The cover may be pegged down at the back or banked up with stones and sand, but it is an awning rather than a tent.

Long Houses.—A great stimulus is given to house building in those primitive societies in which the house belongs not to the individual but to the clan; or where there are secret societies or men's club-houses; or where it is the custom for the unmarried men or the warrior class to sleep in a separate house. These customs lead to the building of houses such as the long houses of British Columbia; the circular houses on the Putumayo, 70ft. in diameter, holding 70 families under one roof; the long houses built of piles along the river banks in Borneo, containing 40 to 50 families; the Kiwai houses, on piles, off the New Guinea coast, two or three hundred feet in length, holding 180 people; and the men's club-houses that are a conspicuous feature of Melanesian villages generally. The best of the long houses in Borneo are built by the Kayan. The piles are massive posts of iron-wood, 25ft. to 30ft. high, supporting a ridge-pole roof. The floor is laid on piles 7ft. or 8ft. high, with cross beams mortised to these and large planks laid across, running the length of the house. The side furthest from the river is walled in, forming separate rooms, but on the river side is a long gallery, protected by the overhanging roof. This is the sleeping place for bachelors and male visitors and the place for receiving guests and carrying on the daily work, such as *padi* husking, etc. The floors of the inner rooms are of split bamboo, placed a little way apart like latticework, so that all rubbish falls to the ground underneath. The pigs live under the house, and this also serves as a place for storing boats. Entrance to the house is by a notched pole at one end of the verandah.

DWIGHT, JOHN (d. 1703), the first distinguished English potter. The date of his birth has been variously given from 1637 to 1640, and he died at Fulham in 1703. He took the degree of B.C.L. of Christ Church, Oxford, in 1661, and was appointed in that year registrar and scribe to the diocese of Chester. **At** Chester he was secretary to four successive bishops. He seems also to have resided at Wigan where three of his children were baptized between 1667 and 1671. He was granted in 1671 his first patent for the "Mistery of transparent earthenware, commonly known by the names of porcelain or china, and of stoneware, vulgarly called Cologne ware." He probably moved to Fulham about that time. His name appears on the rate books for a house in Bear street in 1674. It has been claimed, though without proof, that Dwight made the first porcelain in England. It has, however, been proved that he preceded John and David Elers in the manufacture of that fine red stoneware which these foreign potters were supposed to have first made in Great Britain. The British and Victoria and Albert Museums contain a number of his pieces, of which the finest is the bust of Prince Rupert.

See Sir *A. H.* Church, *The Family of John Dwight, B.C.L., Potter* (reprinted from *The Genealogist*, 1910).

DWIGHT, THEODORE WILLIAM (1822–1892), American jurist and educator, cousin of Theodore Dwight Woolsey and of Timothy Dwight, was born July 18, 1822, in Catskill, New York. He graduated at Hamilton college in 1840 and studied law for one year at Yale. After tutoring at Hamilton and teaching law privately he was made Maynard professor of law, history, civil polity, and political economy in 1846; and in 1858 accepted an invitation to Columbia to teach law upon his own condition that he should found a law school. For many years he himself was the school and did not retire from it until about a year before his death, in Clinton (N.Y.), on June 28, 1892.

A man of broad culture, he used the Socratic method of teaching. For several years he was a non-resident professor of law at Cornell and at Amherst. An able jurist, he frequently acted as referee in difficult questions and engaged in other legal and judicial work. He was a prominent figure in political and social (notably prison) reforms. He published in 1867 a *Report on the Prisons and Reformatories of the United States and Canada* (with *E.* C. Wines); favoured indeterminate sentences; drew up the bill for the establishment of the Elmira Reformatory, and organized the State Charities Aid Association. He edited Sir Henry Maine's *Ancient Law* (1864); was associate editor of the *Anzerican Law Register* and legal editor of *Johnson's Cyclopaedia,* and published *Ckaritable Uses: Argument in the Rose Will Case* (1863).

DWIGHT, TIMOTHY (1752–1817), American divine, writer, and educationalist, was born at Northampton (Mass.), May 14, 1752. His father, Timothy Dwight, a merchant, was a graduate of Yale; his mother, Mary, was the third daughter of Jonathan Edwards. After his graduation from Yale in 1769 he taught in a grammar school at New Haven, and he was a tutor in Yale college from 1771 to 1777; then, having been licensed to preach, he was a chaplain for a year in a revolutionary regiment. He inspired the troops by his sermons and by several war songs, the most famous of which is "Columbia." From 1778 until 1783 he lived at Northampton, studying, farming, preaching and dabbling in politics. From 1783 until 1795 he was pastor of the Congregational church at Greenfield (Conn.), where he opened an academy which at once acquired a high reputation. From 1795 until his death at Philadelphia (Penn.), Jan. 11, 1817, he was president of Yale college, and by his judicious management, by his remarkable ability as a teacher, and by his force of character he won great influence and did much to raise the standard of the college. President Dwight was also well known as an author. In verse he wrote an ambitious epic in 11 books, the *Conquest of Canaan,* virtually finished in 1774 but not published until 1785; a somewhat ponderous and solemn satire, *The Triumph of Infidelity* (1788), directed against Hume, Voltaire and others; *Greenfield Hill* (1794); and a number of minor poems and hymns. Many of his sermons were published posthumously in *Theology Explained and Defended* (5 vol., 1818–19), to which a memoir of the author by his two sons, W. T. and Sereno E. Dwight, is prefixed, and in *Sermons by Timothy Dwight* (2 vols., 1828), which had a large circulation. Probably his most important work, however, is his *Travels in New England and New York* (4 vols., 1821–22), which contains much material of value concerning social and economic New England and New York during the period 1796–1817.

His fifth son, SERENO EDWARDS DWIGHT (1786–1850), born in Greenfield (Conn.), graduated at Yale in 1803, was a tutor there, a lawyer, a preacher and president of Hamilton college, Clinton, New York. His publications include *Life and Works of Jonathan Edwards* (10 vol., 1830); *The Hebrew Wife* (1836); and *Select Discourses* (1851), to which was prefixed a biographical sketch by his brother, William Dwight (1795–1865), who was also successively a lawyer and a Congregational preacher.

President Dwight's grandson, TIMOTHY DWIGHT (1828–1916), preacher and educationalist, was born at Norwich (Conn.), Nov. 16, 1828. Educated at Yale, Bonn and Berlin, he was professor in the Yale Divinity school from 1858 to 1886, was licensed to preach in 1861, and from 1886 to 1899 was president of Yale, which during his administration greatly prospered. Dr. Dwight was also a member in 1872–85 of the American committee for the revision of the English Bible, was an editor from 1866 to 1874 of the *New Englander,* which corresponded to the *Yale Review;* and in addition to his translating and editorial work he published numerous magazine articles and a collection of sermons, *Thoughts of and for the Inner Life* (1899).

For the elder Timothy Dwight, *see* W. B. Sprague's "Life of Timothy Dwight" in vol. iv, and series, of Jared Sparks's *Library of Anzerican Biography;* also, *"A* Great College President and What He Wrote" in M. C. Tyler's *Three Men of Letters* (1895). For the younger Timothy Dwight, see *Timothy Dwight: Memorial Addresses,* issued *by* Yale university; also, for a full record of his scholastic life, *see* his *Memories of Yale Life and Men, 1845–1899* (1903).

DYAKS or DAYAKS, the name given to the wild tribes found in Borneo by the Malays on their first settlement there. The principal groups are: (1) The sea Dyaks or Ibans, (2) Kayans, (3) Kenyahs, (4) Klemantans, (5) Muruts, (6) Punans. *(See* BORNEO: *Ethnology.)*

DYCE, ALEXANDER (1798–1869), British dramatic editor and literary historian, was born in Edinburgh on June 30, 1798. He was educated at Edinburgh high school and Exeter college, Oxford. He took holy orders, and became a curate at Lantegloss, in Cornwall, and subsequently at Nayland, in Suffolk. In 1827 he settled in London. His first books were *Select Translations from Quintus Smyrnaeus* (1821), an edition of Collins (1827), and *Specimens of British Poefesses* (1825). He issued annotated editions of George Peele, Robert Greene, John Webster, Thomas Middleton, Marlowe, and Beaumont and Fletcher, with lives of the authors and much illustrative matter. He completed, in 1833, an edition of James Shirley left unfinished by William Gifford, and contributed biographies of Shakespeare, Pope, Akenside and Beattie to Pickering's Aldine Poets. He also edited (1836–38) Richard Bentley's works, and *Specimens* of *British Sonnets* (1833). His carefully revised edition of John Skelton, which appeared in 1843, did much to revive interest in that trenchant satirist. In 1857 his edition of Shakespeare was published by Moxon; and the second edition, much improved, was issued by Chapman and Hall in 1866. He also published *Remarks on Collier's and Knight's Editions of Shakespeare* (1844); *A Few Notes on Shakespeare* (1853); and *Strictures on Collier's new Edition of Shakespeare* (1859), a contribution to the Collier controversy *(see* COLLIER, JOHN PAYNE), which ended a long friendship. He undertook the publication of Kempe's *Nine Days' Wonder* for the Camden Society; and the old plays of *Timon* and *Sir Thomas More* were published by him for the Shakespeare Society. He was associated with Halliwell-Phillips, John Payne Collier and Thomas Wright as one of the founders of the Percy Society, for publishing old English poetry. Dyce also wrote *Recollections of the Table Talk of Samuel Rogers* (1856). He died on May 15, 1869. He bequeathed his valuable library, containing amongst other treasures many rare Elizabethan books, to the South Kensington Museum.

DYCE, WILLIAM (1806–1864), Scottish painter, was born Sept. 19, 1806, in Aberdeen, where his father, a fellow of the Royal Society, was a physician of some repute. He attended Marischal college, Aberdeen, took the degree of M.A. at 16 years of age, and studied in the school of the Royal Scottish academy in Edinburgh, then as a probationer in the Royal Academy of London. In 1825, and again in 1827, he went to Italy, where he studied especially the earlier masters of the Florentine and allied schools. In 1829 Dyce settled in Edinburgh and in Feb., 1837, he was appointed master of the school of design of the Board of Manufactures, Edinburgh, whence he was transferred to London as superintendent of the then recently established school of design at Somerset house. In 1844 he was appointed professor of fine art in King's college, London, and became an associate, and in 1848 a full member, of the Royal Academy. He died at Streatham on Feb. 14, 1864.

Dyce's finest productions are the frescoes in the robing-room in the Houses of Parliament, begun in 1848. They depict scenes from the legend of King Arthur, but he died before the series was completed.

See Redgrave's *Dictionary of Artists* (1878), and *Dictionary of National Biography.*

DYEING. The art of colouring textile and other materials in such a way that the colour appears to be a property of the dyed material and not a superficial effect such as that produced by painting. The result of a dyeing operation may be regarded as satisfactory and the substance can be truly termed dyed when the colour is not removed by rubbing or washing or by the action of light. Comparatively few colours pass all tests to these influences; other types of fastness such as resistance to perspiration, street mud, bleaching and finishing are frequently required, and dyeings are approved if they meet some specific demand. A coloured effect, which is comparatively slight considering the amount of colour required to produce it, is regarded by the dyer as a worthless stain. Such stains are produced by dipping fabrics in the aqueous extracts of many fruits and flowers. It is natural to suppose that a desire to transfer the beautiful colours of these substances to textile fabrics may have been the origin of dyeing, but the art is such an ancient one that this is mere conjecture.

Fabrics found in the tombs of Egypt prove that those who dyed them must have been expert in the application of substances which do not immediately reveal their colouring power, but must be associated with other products in a manner which admits of variation only within well defined limits. The dyeing of red with madder or some allied product and of blue with indigo are processes which appear to have been familiar to the people of India, China, Persia and Egypt several thousand years before the Christian era. Some information regarding the dyeing processes used was evidently communicated to Europeans by Phoenicians and Alexandrian merchants, but possibly owing to the state of barbarism which followed the civilizations of Greece and Rome records of the methods practised by these people are very scarce. Pliny gives a description of the dyeing of Tyrian purple and some other colours. In the early period of its development dyeing was probably a home industry carried on mainly by women.

In the 13th century there was a notable revival in the art, for a Florentine named Federigo discovered how to prepare and use certain lichens found in Asia Minor for the dyeing of purple. For this he was awarded great honour and the privilege of adopting the family name *Rucellia.* (The lichen he used was *Roccella tinctoria.*) In 1429 the first European book on dyeing was published at Venice, *Mariegola dell'arte de tentori.* After that time knowledge of the subject spread to Germany, France and Flanders, from which latter country the English king Edward III. procured dyestuffs for England and a Dyers' Company was incorporated in 1472 in London.

The discovery of America in 1492 and the opening up of the Cape route to the East Indies resulted in new products (dyewoods) and new methods of dyeing being used in Europe. In 1518 the Spaniards imported cochineal from Mexico where they had observed the natives employing the insects for dyeing. It is of interest to note that the Incas were skilled in the art of dyeing, but how they acquired the knowledge is unknown. In 1630 a Dutchman named Drebbel discovered how to obtain a brilliant scarlet on wool with tin and cochineal. The process was communicated to other dyers, and the new scarlet was dyed as a specialty at the Gobelin works in Paris, and, in 1643, at a dyeworks at Bow, near London.

On the initiative of the Royal Society, the first English book on dyeing entitled *An apparatus to the history of the common practices* of *dyeing* was published in 1662. In France much attention was given to the promotion of the art by the various ministers of State. Colbert, published a code of instructions to wool dyers and manufacturers, but the greatest service was rendered by a number of eminent chemists who investigated the processes in vogue and attempted to explain and improve them. In different ways Dufay, Hellot, Macquer, Berthollet, Roard and Chevreul in France, and Henry, Home and Bancroft in England did much to improve the methods of dyeing and to establish the industry on a more systematic basis. During this period (1700–1825) a number of important chemical product3 were introduced and prejudice against the use of dyewoods was overcome. it was not until the middle of the 19th century that dyers began to consider the possibility of using coal-tar products for their work. In 1856 the first colour made from coal tar dyed wool and silk directly but could not be applied to cotton until Perkin and Pullar devised the method of tanning and fixing the tannic acid with tartar emetic, before immersing the cotton in the colour solution.

As early as 1834 Runge had conceived the idea of producing colour on the fibre by the oxidation of aniline, but it was the Accrington chemist Lightfoot who, in 1859, discovered the catalytic action of copper, in using sodium chlorate to oxidize aniline on cotton fabric, and produced a black by this method. The method of dyeing cotton with a solution of colour in sodium sulphide was introduced with the colour cachou de Laval in 1873 by Croissant and Bretonniere.

The substitution of naturally occurring substances used in indigo dyeing commenced about the middle of the 18th century with the introduction of ferrous sulphate (copperas) and lime In 1845 the zinc-lime vat was first used, and for many years it was the most important vat for dyeing cotton. It reduced the loss of indigo from 20 to 10%; and the time occupied in waiting for the sediment formed in the copperas vat to settle was saved, the zinc vat clearing quickly. A product of outstanding importance is sodium hydrosulphite discovered in 1868 by Schutzenberger and Lalande. Its use was suggested by these chemists in 1872, but it was some time before any extensive use was made of the discovery. Some dyers prepared calcium hydrosulphite in solution for themselves, with sodium bisulphite, zinc dust and lime, but in 1897 the Badische Anilin und Soda Fabrik offered to dyers a commercial product which produced a clear solution of icdigo white in the presence of alkali without sediment. This was improved by the solid white anhydrous sodium hydrosulphite, which was put on the market in 1903. Hydrosulphite, as the product is generally called, is extensively employed in the dyeing of vat colours. It might be dispensed with, if colours of the indigosol (1922) and soledon jade green type were less expensive.

One of the most interesting and valuable dyeing processes was discovered in 1880 by R. Holliday. This was the formation of para-nitraniline red on cotton, a process which soon achieved great importance and formed a basis for the production of a range of allied colours on cotton (insoluble azo colours). Dyeing by this method has been greatly assisted by the introduction of the intermediate products such as Naphthol A.S. (1912), which yields faster colours. The rapid fast colours are admixtures of this with stabilized diazo compounds. These can be applied directly to cotton and produce the colour on the fibre by steeping in hot dilute acetic acid.

It is to Mercer and Greenwood that we owe the discovery of the effect of sulphuric acid on oils in producing more satisfactory results in turkey-red dyeing than could be obtained with the oil emulsions. Turkey-red oil, sulphated oil and allied products have found extended application in dyeing since the introduction of acetate silk. The study of their influence on the fastness of dyed colours is important. J. R. Hannay and F. W. A. Ermen have contributed to this knowledge concerning sulphur and vat colours respectively.

General Principles. — The art of dyeing is a branch of applied chemistry in which the dyer is continually making use of chemical and physical principles in order to bring about a permanent union between the material to be dyed and the colouring matter applied. If cotton or wool is boiled in water containing finely powdered charcoal, or other insoluble colourgd powder, the material is not dyed, but merely soiled or stained. This staining is entirely due to the entanglement of the coloured powder by the rough surface of the fibre, and a vigorous washing and rubbing suffices to remove all but mere traces of the colour.

There must always be some marked physical or chemical affinity existing between fibre and colouring matter, and this depends upon the physical and chemical properties of both. It is well known that the typical fibres, wool, silk and cotton, behave very differently towards the solution of any given colouring matter, arid that the method of dyeing employed varies with each fibre. As a general rule wool has the greatest attraction for

colouring matters and dyes most readily; cotton has much less attraction, while silk occupies in this respect an intermediate position. These differences may be to some extent due to differences of physical structure in the fibres, but they are mainly due to their different chemical composition. Many processes and treatments to which textile fibres are subjected yield materials which show very different dyeing properties from the original substance.

Dyeing processes may be classified under the following headings:—

I. Direct dyeing, using
  (1) Basic colours for animal fibres and acetate silk.
  (2) Acid colours for wool.
  (3) Direct cotton colours for both vegetable and animal fibres.

II. Dyeing with reduced colour solutions in
  (1) Sulphur colours.
  (2) Vat colours.

III. Mordanting and dyeing, using
  (1) Basic colours for cotton.
  (2) Mordanting with metallic compounds and dyeing.

IV. Producing colours on the fibre. Mainly used for vegetable fibres.
  (1) Aniline black.
  (2) Insoluble azo colours.
  (3) Mineral colours.

Direct Dyeing.— This is the simplest of all dyeing operations. It is most successful in the case of animal fibres, wool showing such a decided affinity for both acidic and basic organic compounds which possess colouring power that a very numerous selection of colouring matters is possible.

(1) Wool is dyed with basic colours directly from a neutral aqueous solution (without additions) the wool combining with the colour base to form a coloured salt or lake on the fibre. Although a neutral dyebath may be employed, an addition of 2% soap gives a brighter colour, and in some cases acid is added to the bath. Silk is dyed in a bath containing boiled off liquor; 2 to 3% on the weight of material is usually necessary.

Acetate silk has such a remarkable affinity for organic compounds of a basic character that it is capable of combining with these under a variety of circumstances. The basic colours act as direct dyes for acetate silk and some (brilliant green, for example) show better fastness on this than they do on tanned cotton. Amino azo and insoluble basic dyes converted into their carboxylic acids dye acetate silk. The compounds of insoluble organic bases with the omega sulphonic acid group ($CH_2{\cdot}OH{\cdot}SO_3H$) are soluble colours, ionamines, which dye acetate silk in the presence of formic or sulphuric acid. Some can be diazotized and developed on the fibre.

Insoluble basic compounds in a dispersed or colloidal condition with sulpho-ricinoleic acid (soluble oils) dye acetate silk direct at 80°C. (S.R.A. colours). Other colours employed in this way are amino anthraquinone derivatives (duranol, celatene and dispersol colours).

(2) The acid colours are applied to wool in this way because it is necessary to modify the composition of the fibre to render it capable of uniting with the colour acid of the dyestuff. Wool boiled with dilute sulphuric acid and then thoroughly washed with boiling water until free from acid acquires the property of dyeing with acid colours even in neutral solution. The amount of colour used is from $\frac{1}{2}$ to 6% on the weight of the wool with 2 to 5% sulphuric acid (1·84 sp. gr.) and 10% sodium sulphate (Glauber's salt). The last addition is made to produce level dyeing for it exerts a restraining action. This is also effected by the use of old dye liquors, a diminished amount of acid, the employment of weaker acids, acetic or formic acid or ammonium acetate and entering the material at a low temperature.

The woollen material is introduced and continually handled or moved about in the solution, while the temperature of the latter is gradually raised to the boiling point in the course of $\frac{3}{4}$ to 1 hour; after boiling for $\frac{1}{4}$ to $\frac{1}{2}$ hour longer, the operation is complete, and the material is washed and dried.

In the application of alkali blue the process of dyeing in an acid bath is impossible, owing to the insolubility of the colour-acid in an acid solution. Wool and silk, however, possess an affinity for the alkali salt of the colouring matter in neutral or alkaline solution, hence these fibres are dyed with the addition of about 5% borax; the material acquires only a pale colour, that of the alkali salt, in this dyebath, but by passing the washed material into a cold or tepid dilute solution of sulphuric acid a full bright blue colour is developed, due to the liberation of the colour-acid within the fibre. In the case of other acid colours, *e.g.*, chromotrope, chrome brown, chromogen, alizarin yellow, etc. the dyeing in an acid bath is followed by a treatment with a boiling solution of bichromate of potash, alum or chromium fluoride, whereby the colouring matter on the fibre is changed into insoluble oxidation products or colour lakes. This operation of developing or fixing the colour is effected either in the same bath at the completion of the dyeing operation, or in a separate bath.

When dyeing with certain acid colours, *e.g.*, eosine, phloxine and other allied bright pink colouring matters derived from resorcin, the use of sulphuric acid as an assistant must be avoided, since the colours would thereby be rendered paler and duller, and only acetic acid must be employed.

The properties of the dyes obtained with the acid colours are extremely varied. Many are fugitive to light; on the other hand, many are satisfactorily fast, some even being very fast in this respect. As a rule, they do not withstand the operations of milling and scouring very well, hence acid colours are generally unsuitable for tweed yarns or for loose wool. They are largely employed, however, in dyeing other varieties of woollen yarn, silk yarn, union fabrics, dress materials, leather, etc. Previous to the discovery of the coal-tar colours very few acid colours were known, the most important one being indigo extract. Prussian blue as applied to wool may also be regarded as belonging to this class, also the purple natural dyestuff, orchil or cudbear. Xylidine scarlet, discovered in 1879, was the first synthetic colouring matter of this class, which comprises such members as picric acid, tartrazine, orange II, fast acid violet, lissamine fast yellow and orange, alphanol, cyanol, lanacyl, kiton and neolan colours. The last compounds contain copper and chromium and are therefore mordant colours which can be dyed direct on wool from an acid bath. They are fast to milling.

(3) Direct cotton colours may be regarded as a particular type of acid colours because wool and silk dye in the presence of acetic acid, but they are characterized by the fact that cotton shows a decided affinity for them. At the same time cotton does not show that complete absorption of colour which is characteristic of wool and merely absorbs a portion of the colour from the bath, in amount depending very much upon the concentration of the dye liquor. The first colouring matter of the class was the so-called congo red, discovered in 1884. Since that time a very great number have been introduced which yield almost every variety of colour. The method of dyeing cotton consists in merely boiling the material in a solution of the dyestuff, when the cotton absorbs and retains the colouring matter by reason of a special natural affinity. The concentration of the dyebath is of the greatest importance, since the amount of colour taken up by the fibre is in an inverse ratio to the amount of dye liquor present in the bath. The addition of 1 to 3 oz. sodium sulphate and $\frac{1}{12}$ to $\frac{1}{3}$ oz. carbonate of soda per gallon gives deeper colours, since it diminishes the solubility of the colouring matter in the water and increases the affinity of the cotton for the colouring matter. An excess of sodium sulphate is to be avoided, otherwise precipitation of the colouring matter and imperfect dyeing result. With many dyestuffs, it is preferable to use $\frac{1}{6}$ to $\frac{1}{3}$ oz. soap instead of soda. On cotton the dyed colours are usually not very fast to light, and some are sensitive to alkali or to acid, but their most serious defect is that they are not fast to washing, the colour tending to run and stain neighbouring fibres. Wool and silk are dyed with the direct colours either neutral or with the addition of a little acetic acid to the dyebath. On these fibres the dyed colours are usually faster than on cotton to washing, milling and light; some are fast even to light, *e.g.*, diamine fast red, chrysophenine, hessian

yellow, etc. Many of the direct colours are very useful for dyeing plain shades on union fabrics composed of wool and cotton, silk and cotton, or wool and silk. Owing to the facility of their application, they are also very suitable for use as household dyes, especially for cotton goods. Colours of this type are benzo purpurine, benzo fast violet, chlorazol and dianoi colours. The fastness may be improved by after treatment, (a) diazotizing and developing, (b) formaldehyde treatment and (c) after treatment with metallic salts. (a) Applies to colours such as primuline which contain a free amido group and can be passed through a bath of sodium nitrite and hydrochloric acid and afterwards through a solution of an amino compound or phenol. Primuline yellow is converted into a red by this treatment. In some cases the colour change is not so marked, but the colours are distinctly improved in fastness to washing. (b) The treatment with formaldehyde applies to the benzoform colours and it improves the fastness to washing. It is carried out at about 70°C. with an aqueous solution. Treatment with boiling copper sulphate (0·5%) increases the light fastness.

Different batches of viscose silk show considerable variation in affinity for the direct cotton colours. In some cases colours appear distinctly light in shade on one batch and dark on another batch of viscose, so that defects may appear in manufactured articles which happen to contain the two types of viscose. Whittaker has shown that this trouble may be overcome by the careful selection of colours which show low capillarity, or in the case of shades composed of mixtures of colours by making these up from colours of nearly the same capillary properties. The icyl colours do not show conspicuous differences when dyed on different batches of viscose silk.

So many colours have been introduced for the direct dyeing of acetate silk that methods of treating the fibre in order to impart to it an affinity (which it does not show in the ordinary condition) for direct cotton colours have comparatively little interest. The hydrolyzing, or saponifying, action of alkali, if cautiously applied to the silk, does not reduce its lustre but may result in loss of weight and strength. This treatment and the action of ammonium thiocyanate impart to acetate silk some affinity for direct cotton colours.

Immunized cotton, that is cotton first converted into alkali cellulose and then treated with toluol sulphonic chloride or allied compounds, shows no affinity for direct colours. The process of immunizing may be applied to yarn or piece goods either wholly or locally. Esterified cotton has somewhat similar properties.

Dyeing **with** Reduced Colour Solutions. — Many insoluble coloured substances form soluble reduction products which show a definite affinity for fibres. Characteristic in this respect are (1) sulphur colours which dissolve in sodium sulphide and (2) vat colours which react with sodium hydrosulphite and other reducing agents in a somewhat similar way. These colours are most easily applied to vegetable fibres because the solution is invariably alkaline and special devices have to be employed in the case of wool. As a rule it is generally found preferable to use direct dyeing acid and mordant colours for wool, but a number of preparations have been put on the market to protect wool from the injurious action of alkali in dyeing sulphur and vat colours.

(1) Sulphur colours. The material is heated for about one hour in a solution of the colour (10 to 15%), with the addition of sodium carbonate (1 to 10%), common salt (10 to 20%) and sodium sulphide (5 to 30%); it is then washed in water and may be developed by heating in a bath containing 2 to 5% of bichromate of soda, and 3 to 6% acetic acid. A final washing with water containing a little soda to remove acidity is advisable. The sulphide colours are remarkable for their fastness to light, alkalis, acids and washing, but unless proper care is exercised the cotton is apt to be tendered on being stored for some time. This is particularly noticeable in the case of blacks and to some extent with yellow sulphur colours. The cause of tendering has been the subject of much research. Zanker (1914) considers it to be due to the oxidation of sulphur in chemical combination with the dyestuff. Most workers agree that the tendering is due to the formation of acid. Holden's method of overcoming the tendering is probably the most efficient. It consists in impregnating the cotton with tannic acid, and then passing through lime water before dyeing in the sulphur colour. The tannate of lime so formed provides an insoluble and powerful base present on the fibre and combined only with the tannic acid. Sulphur colours are suitable for dyeing goods which are intended for rubber-proofing.

Some kinds of finishing materials affect the fastness of sulphur colours very materially. Hannay (1912) has shown that castor oil preparations (soluble oil, monopol soap) very materially reduced the light-fastness of sulphur colours.

(2) Vat dyeing is one of the oldest dyeing processes, naturally occurring substances being used for the production of fermentation vats for the dyeing of indigo blue. In the early days of dyeing in England and as soon as dyers were by law permitted to use indigo in place of woad, vats were prepared from woad, bran, madder and wood ashes. These substances were used for wool dyeing long after chemical reagents had been suggested and introduced for cotton dyeing. Practically any substance or mixture of substances capable of producing hydrogen in an alkaline medium will reduce indigo. The reduction product, leuco indigo or indigo white, dissolves in the alkali with a yellow colour. In the fermentation vat, butyric acid fermentation is induced in the bran and madder by the ferment contained in woad and hydrogen is formed. Wood ashes or lime provide the alkali necessary for the solution of the indigo white. Other vats which have found application in dyeing are the copperas and lime, zinc-lime, bisulphite-zinc-lime, and the sodium hydrosulphite vats. The last is the most important; it produces a vat free from sediment and little loss of indigo. It is usual to prepare a stock vat and then to add some of this to a large volume of water (1,000 gals.) from which the dissolved oxygen has been removed by adding a little sodium hydrosulphite (9½ ozs.) and caustic soda (⅛ pint 76°Tw.). The stock vat may be made suitable for cotton by mixing 100 lb. indigo (20% paste) with 10 gals. warm water and 5½ gals. caustic soda 76°Tw., heating to 40–50°C. and adding about 20 lb. sodium hydrosulphite. Dyeing is carried out by dipping cotton in the cold vat for a few minutes, and darker shades are obtained by repeated dipping alternated with exposure to air. Washing with cold water assists the oxidation of the leuco compound. In dyeing wool, the amount of alkali in the vat must be strictly limited. Substances such as protectol or the sulphite pulp waste liquor from paper manufacture and glue are recommended for use in wool dyeing with vat colours to protect the fibre from the injurious action of alkali. In wool dyeing a temperature not lower than 70°C. is required for the dyeing of other vat colours and in all cases the time of dyeing for wool is longer than for cotton. Wool requires ½ to 2 hours for the dyeing of indigo. It is now difficult to buy suiting dyed with indigo, for the shade is generally imitated with acid chrome colours and with other acid (wool) colours.

The leuco compounds of the anthraquinone colours are usually less soluble than those of the indigoid colours and require more caustic soda to produce a vat. The amount of alkali has frequently to be double the quantity used for indigo, so they are difficult to apply to wool. Indanthrene blue is a colour of remarkable fastness, but unfortunately this cannot be said of all members of the series of colours of which this is the type. Cibanone yellow fades on exposure to light and at the same time the fibre is considerably tendered. In connection with colours of this type it has been noticed by F. Scholefield that if light is allowed to fall on the fabric during the development of colour after dyeing in the vat, the shades appear brighter than if developed in the dark but the fabric becomes tender in a few minutes and other colours that may be dyed in the same vat are destroyed.

The production of a vat is always accompanied by chemical change, which is shown by the formation of solution and frequently by colour change; but this is not so in the case of indanthrene which merely forms a vat of different shade of blue to that of the decoction of colour and water. Indanthrene yellow produces a blue vat, thio-indigo red gives a yellow vat.

The indigosols and corresponding anthraquinone products (soledon colours) are vat colours presented to the dyer in an already reduced condition. They are applied like acid dyes to wool and silk and are mixed with a solution of sodium nitrite and padded on cotton. Various acid oxidizing agents may be used for developing the colours on wool and treatment with acid to react with the sodium nitrite in the case of cotton. They may be developed in other ways, one of the most interesting being that of steaming cotton padded with chlorate of soda, vanadium chloride, neutral ammonium oxalate and indigosol O which resembles a process of producing aniline black. This renders possible the production of different colours side by side and is most valuable from the point of view of calico printing. Colours include durantherene, algol, ciba, besides those already mentioned.

Mordanting and Dyeing.— (I) Basic colours applied to cotton. Unlike the animal fibres cotton has little affinity for the basic colours. It is usual to deposit tannic acid on the fibre in the form of an insoluble tannate. For this purpose pieces are steeped in a solution containing 2 to 6 oz. per gallon tannic acid and after being evenly squeezed are passed through a warm solution of tartar emetic or other salt of antimony or tin. The tannic acid has the power of combining with the base of the colouring matter in the subsequent dyeing operation, which is generally carried out with ½–2% colour on the weight of cotton to be dyed and sufficient water, in the cold or if the temperature is raised at all it is best not higher than 70°C. The basic colours are moderately fast to soap, but most of them are very loose to light. Methylene blue is one of the best in this respect. The first coal-tar colour mauve belonged to this dyeing class, which is especially remarkable for brilliance and high colouring power. One natural colour which has long been known to dye in this way is the barberry, which contains the alkaloid berberine; but in 1918 Everest showed that the flower colours (antho-cyanines) could be dyed on tanned cotton. They are fast to light but loose to soap, and in respect to these properties are therefore quite different from the synthetic colours dyed in this way. In the dyeing of basic colours, tannic acid may be substituted by katanol (a phenolic compound containing sulphur) which can be applied in alkaline solution and in presence of salt. It does not require fixing but appears to have some affinity for cotton which is rather like that of direct colours. Direct cotton, sulphur and vat colours will act as mordants for basic colours forming lakes on the fibre.

Some important basic colours are rhodamine, brilliant green, auramine and methyl violet. A dyestuff astrafloxine has been offered as a substitute for rhodamine.

(2) Mordanting with metallic compounds and dyeing. The deposition and fixation of metallic oxides or basic salts of certain metals on vegetable and animal fibres is a necessary feature of the production of colour in the case of certain organic compounds such as alizarine and haematine which may be termed colour principles. Colour principles are the essential constituents as far as dyeing is concerned of many woods and other natural products which have found considerable application, consequently mordanting operations have been of great interest to dyers. The method provides some dyeings of great fastness. The animal fibres are very easily mordanted. For example, wool boiled for 1 to 1½ hours with 2–3% potassium bichromate absorbs chromic acid and reduces it to chromium chromate tinting the fibre a pale olive yellow. On subsequent dyeing the chromium chromate is reduced to chromium hydrate by a portion of the dyestuff and this result can with advantage be obtained previous to dyeing by the use of assistants such as sulphuric acid, cream of tartar, tartaric acid, lactic acid, etc. For special purposes chromium fluoride, chrome alum, etc., are employed. Alum or aluminium sulphate (8%), along with acid potassium tartrate (cream of tartar) (7%), is used for brighter colours—*e.g.*, reds, yellows, etc. The object of the tartar is to retard the mordanting process and ensure the penetration of the wool by the mordant, by preventing superficial precipitation through the action of ammonia liberated from the wool; it ensures the ultimate production of clear, bright, full colours. For still brighter colours, notably yellow and red, stannous chloride was at one time largely employed, but it is used less frequently; and the same may be said of copper and ferrous sulphate, which were used for dark colours. Silk may be often mordanted in the same manner as wool, but as a rule it is treated like cotton. The silk is steeped for several hours in cold neutral or basic solutions of chromium chloride, alum, ferric sulphate, etc., then rinsed in water slightly, and passed into a cold dilute solution of silicate of soda, in order to fix the mordants on the fibre as insoluble silicates. Cotton does not, like wool and silk, possess the property of decomposing metallic salts, hence the methods of mordanting this fibre are more complex and vary according to the metallic salts and colouring matters employed, as well as the particular effects to be obtained. One method is to impregnate the cotton with a solution of so-called sulphated oil or turkey-red oil; the oil-prepared material is then dried and passed into a cold solution of some metallic salt—*e.g.*, aluminium acetate, basic chromium chloride, etc. The mordant is thus fixed on the fibre as a metallic oleate, and after a passing through water containing a little chalk or silicate of soda to remove acidity, and a final rinsing, the cotton is ready for dyeing. Another method of mordanting cotton is to fix the metallic salt on the fibre as a tannate instead of an oleate. This is effected by first steeping the cotton in a cold solution of tannic acid or in a cold decoction of some tannin matter, *e.g.*, sumach, in which operation the cotton attracts a considerable amount of tannic acid; after squeezing, the material is steeped for an hour or more in a solution of the metallic salt, and finally washed. The mordants employed in this case are various—*e.g.*, basic aluminium or ferric sulphate, basic chromium chloride, stannic chloride (cotton spirits), etc. There are other methods of mordanting cotton besides those mentioned, but the main object in all cases is to fix an insoluble metallic compound on the fibre. It is interesting to note that whether the metallic oxide is united with the substance of the fibre, as in the case of wool and silk, or precipitated as a tannate, oleate, silicate, etc., as in the case of cotton or silk, it still has the power of combining with the colouring matter in the dyebath to form the coloured lake or dye on the material.

The dyeing operation consists in working the mordanted material in a decoction of the necessary colouring matter, the dyebath being gradually raised to the boiling point. With many colouring matters, *e.g.*, with alizarin, it is necessary to add a small percentage of calcium acetate to the dyebath, and also acetic acid if wool is being dyed. In wool-dyeing, also, the mordanting operation may follow that of dyeing instead of preceding it, in which case the boiling of the wool with dyestuff is termed "stuffing," and the subsequent developing of the colour by applying the mordant is termed "saddening," since this method in the past has usually been carried out with iron and copper mordants, which give dull or sad colours. The method of "stuffing and saddening" may, however, be carried out with other mordants, even for the production of bright colours, and it is now frequently employed with certain alizarin dyestuffs for the production of pale shades which require to be very even and regular in colour. There is still another method of applying mordant colours in wool-dyeing, in which the dyestuff and the mordant are applied simultaneously from the beginning; it is called the single-bath method. This process has become of greater interest; copper and chromium (chromium oxalate or "chromosul") being used in conjunction with acid azo colours. Some colouring matters which contain copper or chromium in combination are soluble in water and are applied like acid colours (Neolan colours).

Deposition of tannate of iron on and in the fibre is the method used for the dyeing of logwood on cotton. Logwood still finds use for the production of black both on cotton and wool. In the case of wool it is dyed on chrome mordant. Acetate silk may be dyed black (Bedford's patent) by treating first with logwood extract (haematine) and afterwards adding borax and nitrate of iron.

For dyeing turkey-red, cotton is boiled but not bleached. After boiling, mordanting with red liquor (4° Tw.) and ageing, fixing with phosphate or silicate or arsenate of soda (0·5% solution) follows. Dyeing is carried out at the boil with 10% alizarine paste and the goods are afterwards soaped and cleared (using a little

stannous chloride). Steaming improves the colour.

Interest in mordant dyeing on cotton is diminishing considerably with the introduction of colours which are more readily applied and can compete well with the fastest mordant colour alizarine or turkey-red in point of fastness.

Cutch is a natural colour which is still very largely used in dyeing. Sailors believe that this colour protects the fabric of fish-

ing nets from the action of light and air. It is dyed with copper sulphate in the bath but contains in addition to the mordant colour principle (catechin), a kind of tannic acid (catechu tannic acid), consequently this colour can be topped with basic colours.

Colours Produced on the Fibre. — (I) Aniline black is produced in situ upon the fibre by the oxidation of aniline. It is chiefly used for cotton, also for silk and cotton (silk union) fabrics, but seldom or not at all for wool. Properly applied, this colour is one of the most permanent to light and other influences with which we are acquainted. One method of dyeing cotton is to work the material for about two hours in a cold solution containing aniline (10 parts), hydrochloric acid (20 parts), bichromate of potash (20 parts), sulphuric acid (20 parts), and ferrous sulphate (10 parts). The ferrous sulphate here employed is oxidized by the chromic acid to a ferric salt, which serves as a carrier of oxygen to the aniline. This method of dyeing is easily carried out, and it gives a good black; but since much of the colouring matter is precipitated on the fibre superficially as well as in the bath itself, the colour has the defect of rubbing off. Another method is to impregnate the cotton with a solution containing aniline hydrochloride (35 parts), neutralized with addition of a little aniline oil, copper sulphate (1·6 part), sodium chlorate (10 parts), ammonium chloride (1 part). Another mixture is 1·8 part aniline salt, 12 parts potassium ferrocyanide, 200 parts water, 3·5 parts of potassium chlorate dissolved in water. After squeezing, the material is passed through a special oxidation chamber, the air of which is heated to about 50°C. and also supplied with moisture. This oxidizing or ageing is continuous, the material passing into the chamber at one end in a colourless condition, after about 20 minutes passing out again with the black fully developed. A final treatment with hot potassium bichromate and soaping is necessary to complete the process. In this method probably chlorate of copper is formed and this being a very unstable compound, readily decomposes and the aniline is oxidized by the liberated chlor-oxygen compounds. The presence in the mixture of a metallic salt is very important in aiding the development of the black (Lightfoot's observation). Salts of vanadium and cerium may be substituted for copper. In the after-chroming process, chromium is fixed on the fibre and in all methods some mineral substance is fixed; chromium in the dyed black and iron in the prussiate black. The organic compound on the fibre is produced by oxidation which proceeds in four stages to nigraniline and the condensation of this substance with aniline. At the end of the ageing process there should be some unchanged aniline to condense and produce an ungreenable black in the chroming process. On the fibre, chromate of nigraniline may be formed. There is still much material for further investigation especially concerning the prussiate black. One of the serious disadvantages of aniline black is the liability to tender the cotton. It is by no means certain whether this is due to oxidation of the cellulose or to the action of acid upon it during ageing. The latter is probable, for substances which prevent drying during ageing also prevent tendering.

(2) The insoluble azo colours are produced as insoluble coloured precipitates by adding a solution of a diazo compound to an alkaline solution of a phenol, or to an acid solution of an amido compound. The necessary diazo compound is prepared by allowing a solution containing nitrous acid to act upon a solution of a primary aromatic amine. It is usually desirable to keep the solutions cool with ice, owing to the unstable nature of the diazo compounds produced. (Products can be obtained which are stable and only decompose on acidifying.) The colour obtained varies according to the particular diazo compound, as well as the amine or phenol employed, 0-naphthol being the most useful among the latter. The same coloured precipitates are produced upon the cotton fibre if the material is first impregnated with an alkaline solution of the phenol, then dried and passed into a cold solution of the diazo compound. The most important of these colours is para-nitraniline red, which is dyed in enormous quantities on cotton pieces. The pieces are first prepared by running them on a padding machine through a solution made up of 30 grms. 8-naphthol, 20 grms. caustic soda, 50 grms. turkey-red oil, and 5 grms. tartar emetic in 1,000 grms. (1 litre) water. They are then dried on the drying machine, and are passed, after being allowed to cool, into the diazo solution, which is prepared as follows: 15 grms. para-nitraniline are dissolved in 53 c.c. hydrochloric acid (34°Tw.) and a sufficiency of water. To the cold mixture a solution of 10½ grms. sodium nitrite is added while stirring. The whole is then made up to 1,200 c.c. and just before use 60 grms. sodium acetate are added. The colour is developed almost immediately, but it is well to allow the cotton to remain in contact with the solution for a few minutes. The dyed cotton is squeezed, washed, soaped slightly, and finally rinsed in water and dried. A brilliant red is then obtained which is fast to soap but not to light. If the para-nitraniline used in the foregoing process is replaced by meta-nitraniline, a yellowish-orange colour is obtained; with a naphthylamine, a claret red; with amido-azo-toluene, a brownish red; with benzidine, a dark chocolate; with dianisidine, a dark blue; and so on. The dyed colours are fast to washing and are much used in practice, particularly the para-

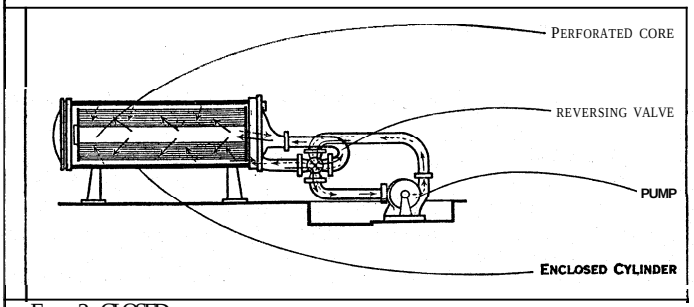

FIG. 2—CLOSED BEAM DYEING MACHINE, IN WHICH THE DYE SOLUTION IS DRAWN THROUGH THE CORE AND BEAM IN THE DIRECTION INDICATED BY THE ARROWS

nitraniline red, which has served as a substitute for turkey-red, although it is not so fast to light as the latter. Superior results can be obtained by substituting Naphthol A.S. (the anilide of -oxynaphthoic acid) and other related products for β-naphthol. The combinations of these compounds with various diazotized amines result in shades which sometimes differ from those with β-naphthol, generally giving improved appearance and almost always colours of superior fastness. Some will stand the full bleaching process. A further advantage is that the cotton shows decided direct affinity for Naphthol AS. products and there is no necessity to dry the material after padding. E. Higgins (1927) has given valuable information regarding the behaviour of insoluble azo colours.

(3) Mineral colours. These include chrome yellow, iron buff,

prussian blue, manganese brown and khaki.

Chrome yellow is only useful in cotton dyeing as a self-colour, or for conversion into chrome orange, or, formerly in conjunction with indigo, for the production of fast green colours. The cotton is first impregnated with a solution of lead acetate or nitrate, squeezed, and then passed through a solution of sodium sulphate or lime water to fix the lead on the fibre as sulphate or oxide

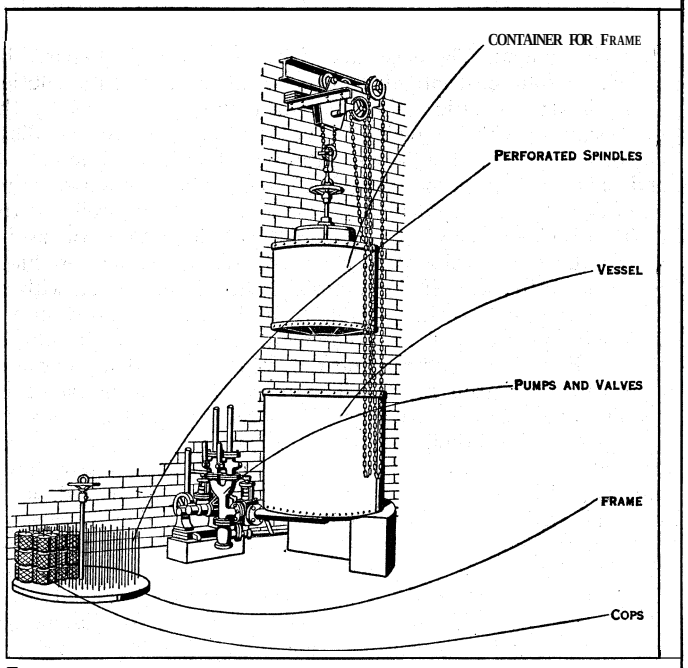

FIG. 3.— DYEING BY THE SPINDLE SYSTEM (IMPROVED FORM), IN WHICH THE CONTAINER FOR THE FRAME HOLDS THE COPS ON PERFORATED SPINDLES. IN THIS YESSEL THE CONTAINER WITH ITS CHARGE OF COPS IS CONNECTED WITH THE CIRCULATING SYSTEM FOR DYE LIQUOR

of lead. The material is then passed through a solution of bichromate of potash. The colour is changed to a rich orange by a short, rapid passage through boiling milk of lime, and at once washing with water, a basic chromate of lead being thus produced. The colour is fast to light, but has the defect of being blackened by sulphuretted hydrogen.

Iron buff is produced by impregnating the cotton with a solution of ferrous sulphate, squeezing, passing into sodium hydrate or carbonate solution, and finally exposing to air, or passing through a dilute solution of bleaching powder. The colour obtained, which is virtually oxide of iron, or iron-rust, is fast to light and washing.

Prussian blue is applicable to wool, cotton and silk, but since the introduction of coal-tar blues its employment has been very much restricted. The colour is obtained on cotton by first dyeing an iron buff, according to the method just described, and then passing the dyed cotton into an acidified solution of potassium ferrocyanide, when the blue is at once developed. A similar method is employed for silk. Wool is dyed by heating it in a solution containing potassium ferricyanide and sulphuric acid. The colour is developed gradually as the temperature rises; it may be rendered brighter by the addition of stannous chloride. On wool and silk prussian blue is very fast to light, but alkalis turn it brown (ferric oxide).

Manganese brown or bronze can be applied in wool, silk and cotton dyeing. The animal fibres are readily dyed by boiling with a solution of potassium permanganate, which, being at first absorbed by the fibre, is readily reduced to insoluble brown manganic hydrate. Since caustic potash is generated from the permanganate and is liable to act detrimentally on the fibre, it is advisable to add some magnesium sulphate to the permanganate bath in order to counteract this effect. Imitation furs are dyed in this manner on wool-plush, the tips or other parts of the fibres being bleached by the application of sulphurous acid. Cotton is dyed by first impregnating it with a solution of manganous chloride, then dyeing and passing into a hot solution of caustic soda. There is thus precipitated on the fibre manganous hydrate, which by a short passage into a cold dilute solution of bleaching powder is oxidized and converted into the brown manganic hydrate. This manganese bronze or brown colour is very susceptible to, and readily bleached by, reducing agents; hence when exposed to the action of an atmosphere in which gas is freely burnt, the colour is liable to be discharged, especially where the fabric is most exposed. In other respects manganese bronze is a very fast colour.

Khaki is a mixture of iron buff and chromium oxide. The green shades of khaki are as a rule most sought after and on this account it is necessary to secure the deposition of much chromium on the fibre. This may be done by tanning and then destroying the tannic acid with sodium bichromate; otherwise this would destroy the cotton.

Dyeing on a Large Scale.—Textile fibres may be dyed in all forms in which they appear during the course of manufacture from loose fibres to fabrics. Dyestuffs are usually applied in solution or decoction with water and this is frequently heated, while the material is immersed in it. During the process the material to be dyed or the dye liquor or both must be almost continuously moved about in order to effect uniform or even dyeing. Numerous machines are used to effect this movement for particular kinds of material and also to secure uniform heating of the vessel; devices are fitted for preventing the material from coming into contact with the steam pipes. Loose material is liable to become matted together so machines have been arranged with hooks or fingers to prevent this. It is best dealt with by circulating the liquor through the material (fig. 1). Loose dyed wool is especially useful in producing fancy fabrics with fibres dyed in different colours.

Yarn Dyeing.—Yarn is dyed in the form of hanks, warps, cops and cheeses. The hank form involves the most simple devices for obtaining even results by turning the material. Machines made to imitate the effect of turning the yarn by hand over wooden pegs, take the form of a series of reels each holding about 2 lb. of yarn which are arranged so that large batches can be lifted in and out of the liquid automatically. In other machines the yarn is arranged on rods or carriers which revolve on a central axis into half cylindrical dye vats and, during the revolution, the rods are turned so that the yarn moves to another position. Machines have been introduced for dyeing warps on the beam, the dye liquor being

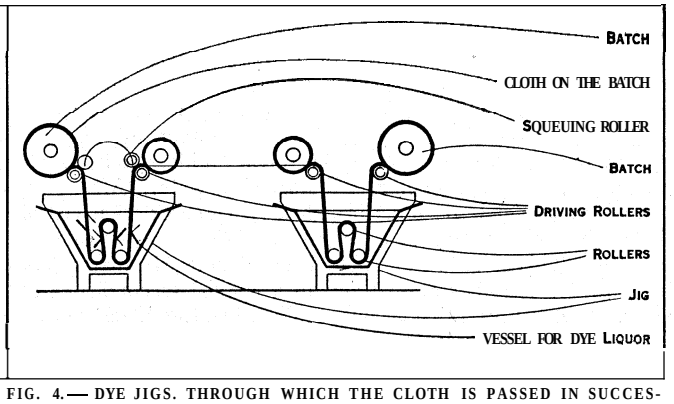

FIG. 4.— DYE JIGS. THROUGH WHICH THE CLOTH IS PASSED IN SUCCESSION OR THE JIGS CAN BE USED SEPARATELY, AFTER THE CLOTH ON THE BATCH HAS BEEN PASSED BY DRIVING ROLLERS THROUGH THE DYE LIQUOR OVER THE GUIDE ROLLERS. AND THE SQUEEZING ROLLER APPLIED

caused to circulate through the material, and the system meets with considerable success.

Large quantities of yarn, especially cotton, are dyed in the cop, for weft. The main advantage of this method is at once apparent, inasmuch as the labour, time and waste of material incurred by reeling into hanks and then winding back into compact form, so as to fit into the shuttle are avoided. A thin tapering perforated metallic tube is inserted in the hollow of each cop. The cops are then attached to a perforated disc (which constitutes the lid of a chamber or box) by inserting the protruding ends of the tubes into the perforations. The chamber is now immersed in the dye-bath

and the hot liquor is drawn through the cops by means of a centrifugal pump and returned continuously to the dye-bath. This principle is known as the skewer or spindle system.

In the so-called "compact" system of cop dyeing the cops are packed as closely as possible in a box, the top and bottom (or the two opposite sides) of which are perforated, the interstices between the cops being filled up with loose cotton, ground cork or

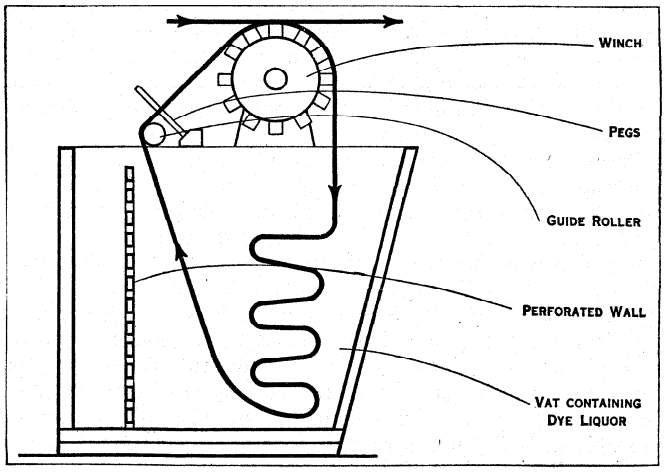

FIG 5.—THE WINCH, WHICH DRAWS THE PIECES IN ROPE FORM INTO THE VAT CONTAINING DYE LIQUOR, OVER A GUIDE ROLLER, BETWEEN PEGS Without pegs the cloth can be treated at open width, protected from the heating coil by the perforated wall

sand: The dye liquor is then drawn by suction or forced by pressure through the box, thus permeating and dyeing the cops.

Dyeing **of** Pieces.—Plain shades are usually dyed in the piece, this being the most economical and at the same time the most expeditious means of obtaining the desired effect. In the dye-jigger (fig. 4) the goods are passed backwards and forwards over guide rollers between two batching rollers. The arrangement admits of treating a large quantity of material with comparatively little dye liquor. Another machine is that shown in fig. 5. This is suitable for heavy fabrics. The pieces are stitched end to end in a band which passes over a winch. Washing off may be done on the same machine.

Except for the dyeing of light shades only the preliminary operations of bleaching (washing and scouring) are carried out before dyeing.

Theory **of** Dyeing.—The peculiar property characteristic of dye-stuffs, as distinguished from mere colouring matters, namely, that of being readily attracted by the textile fibres, notably the animal fibres, appears to be due to their more or less marked acid or basic character. Intimately connected with this is the fact that these fibres also exhibit partly basic and partly acid characters due to the presence of carboxyl and amido groups. The behaviour of magenta is typical of the basic colours. Rosaniline, the base of magenta, is colourless, and only becomes coloured by its union with an acid, and yet wool and silk can be as readily dyed with the colourless rosaniline (base) as with the magenta (salt). The explanation is that the base rosaniline has united with the fibre, which here plays the part of an acid, to form a coloured salt. It has also been proved that in dyeing the animal fibres with magenta (rosaniline hydrochloride), the fibre unites with rosaniline only, and liberates the hydrochloric acid. Further, magenta will not dye cotton unless the fibre is previously prepared, *e.g.*, with the mordant tannic acid, with which the base rosaniline unites to form an insoluble salt. In dyeing wool it is the fibre itself which acts as the mordant. In the case of the acid colours the explanation is similar. In many of these the free colour-acid has quite a different colour from that of the alkali-salt, and yet, on dyeing wool or silk with the free colour-acid, the fibre exhibits the colour of the alkali-salt and not of the colour-acid. In this case the fibre evidently plays the part of a base. Another fact in favour of the view that the union between fibre and colouring matter is of a chemical nature is that by altering the chemical constitution of the fibre its dyeing properties are also altered; oxycellulose, nitrocellulose and acetate silk for example, have a greater attraction for basic colours than cellulose. Such facts and considerations as these have helped to establish the view that in the case of dyeing animal fibres with many colouring matters the operation is a chemical process, and not merely a mechanical absorption of the dyestuff. A similar explanation does not suffice, however, in the case of dyeing cotton with the direct colours. These are attracted by cotton from their solutions as alkali salts, apparently without decomposition, the affinity existing between the fibre and colouring matter is distinctly feeble in comparison with wool. This fibre is capable of taking up as much as 20% of acid colour without appearing bronzey. Cotton absorbs under favourable conditions about 2% of actual direct colour.

The dyeing of cotton is most probably of a physical character but there are different opinions as to the nature of this. Some favour colloidal, some purely mechanical (solid solution) and some electrical theories. The latter explains phenomena which occur during dyeing and in some instances supports the chemical as well as the mechanical theory. In the case of colours which are dyed on mordants the question is merely transferred to the nature of the attraction which exists between the fibre and the mordant. G. T. Morgan finds that the co-ordination theory of valency explains and correlates known facts with regard to mordant dyeing.

The trend of advance in the industry in America, in Great Britain and on the Continent is shown by a real endeavour to meet the demands for fast dyeings and a greater value and utilization of scientific methods in the investigation of processes and the effects produced by them. Colour measuring and matching instruments have been greatly improved and may prove of value in giving a more definite expression to fastness. Products produced by the action of light on vat colours have been isolated, the first of these being the oxidation product, isatin, from indigo dyed cotton (1927). In Great Britain the Society of Dyers and Colourists has appointed a committee with F. Scholefield as chairman to consider the whole question of fastness and already contributions have been made towards elucidating some of the problems. Many of these can only be solved by steady co-operation of workers. In December 1925 the dyeing industry suffered a severe loss by the death of Edmund Knecht, who had enriched tinctorial and analytical chemistry by important researches, many of which are recorded in the pages of the *Journal* of the Society of Dyers and Colourists. "A Manual of Dyeing" by E. Knecht, C. Rawson and R. Loewenthal is a work of reference of international fame. (E. HI.)

DYER, SIR EDWARD (d. 1607), English courtier and poet, son of Sir Thomas Dyer, Kt., was born at Sharpham Park, Somersetshire. He was educated, according to Anthony à Wood, either at Balliol college or at Broadgates hall, Oxford. He left the university without taking a degree, and after some time spent abroad appeared at Queen Elizabeth's Court. His first patron was the earl of Leicester, and he is mentioned by Gabriel Harvey with Sidney as one of the ornaments of the Court. Sidney in his will desired that his books should be divided between Fulke Greville (Lord Brooke) and Dyer. He was employed by Elizabeth on a mission (1584) to the Low Countries, and in 1589 was sent to Denmark. He was knighted and made chancellor of the order of the Garter in 1596. Wood says that many esteemed him to be a Rosicrucian, and that he was a firm believer in alchemy. He had a great reputation as a poet among his contemporaries, but very little of his work has survived. Puttenham in the *Arte of English Poesie* speaks of "Maister Edward Dyar, for Elegie most sweete, solempne, and of high conceit." One of the poems universally accepted as his is "My Mynde to me a kingdome is."

See the collection of his works by *A.* B. Grosart, *Fuller Worthies Library* (vol. iv., 1876).

DYER, JOHN (c. 1700–1758), British poet, the son of a solicitor, was born in 1699 or 1700 at Aberglasney, in Carmarthenshire, and died at Coningsby on Dec. 15, 1758. In 1726 his first poem, *Grongar Hill*, appeared in a miscellany published by Richard Savage, the poet. It was an irregular ode in the so-called Pindaric style, but Dyer entirely rewrote it and printed it separately in 1727. *Grongar Hill*, as it now stands, is a short poem

of only 150 lines, describing in language of much freshness and picturesque charm the view from a hill overlooking the poet's native vale of Towy. A visit to Italy bore fruit in *The Ruins of Rome* (1740), a descriptive piece in about 600 lines of Miltonic blank verse. He was ordained priest in 1741, and held successively various Lincolnshire parishes. In 1757 he published his longest work, the didactic blank verse epic of *The Fleece*, in four books, discoursing of the tending of sheep, of the shearing and preparation of the wool, of weaving, and of trade in woollen manufactures.

His poems were collected by Dodsley in 1770 and by Mr. Edward Thomas in 1903, for the Welsh Library, vol. iv.

DYER, REGINALD EDWARD HARRY (1864–1927), British general, was born at Simla, India, Oct. 9, 1864, and educated at Middleton College, Co. Cork. He entered the army in 1885, took part in 1886–87 in the Burma campaign, in 1888 in the Hazara Expedition, in 1895 in the relief of Chitral, in 1901–2 in the Waziristan blockade and in 1908 in the operations in the Zakka Kiel country. In the World War he commanded the 45th Infantry Brigade. He was awarded the C.B. in 1916 for his success against the Sarhad raiders while in charge of the Eastern Persian cordon, and published an account of his experiences, *The Raiders of the Sarhad* (1921). In April 1919, while Dyer was Brigade Commander at Jullundur, he was called to quell a rising at Amritsar. He used military force, opening fire, without warning, on an unarmed crowd, and causing over three hundred deaths and 1,200 other casualties. His action was called in question by commission of enquiry set up under Lord Hunter. At the enquiry Dyer admitted that, although he believed that the mob could have been dispersed without firing, his attack would have been even more violent if he had not been restricted by space. He said that his avowed purpose was "to strike terror into the whole of the Punjab," and to this end he even refused succour to the wounded. In 1919 he was given command of his brigade to organize the relief of Thal from the Afghan Army, but was subsequently asked to resign by the Commander-in-Chief in India, with the approval of the Army Council. This incident roused a great deal of hostile feeling in India, and the Indian National Council bought the Jallianwala Bagh, the site of the massacre, as a "martyrs' memorial" to be used as a place of pilgrimage. The Duke of Connaught, at the inauguration of the new Indian legislature on February 2, 1921, said, "The shadow of Amritsar has lengthened over the fair face of India." In 1924 interest in the affair was again revived, by the libel action brought by Sir Michael O'Dwyer, Lieutenant General of the Punjab, against Sir Sankaran Nair. In this case Mr. Justice McCardie said in his summing-up, "General Dyer, in the grave and exceptional circumstances, acted rightly . . . and was wrongly punished by the Secretary of State for India." The Labour Government then in office protested against this statement in a letter to the Viceroy, and upheld the action of the previous government in censuring General Dyer. During the remainder of his life General Dyer devoted his time to scientific study and invented a range-finder for sighting aircraft. He died on July 23, 1927, at Long Ashton, Bristol.

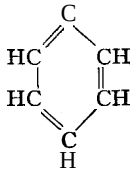
DYERSBURG, a city of north-western Tennessee, U.S.A., 15m. from the Mississippi river; the county seat of Dyer county. It is on the Jefferson Davis highway, and is served by the Gulf, Mobile and Ohio and the Illinois Central railways. The population was 8,733 in 1930 (37% negroes) and was 10,034 in 1940 by the federal census. Large crops of cotton (40,676 bales in 1940), corn. peonies and small fruits are grown in the county; dairy farming is growing in importance; and there are abundant timber resources. The city has flour and saw-mills, spoke and stave factories, a cheese factory, cotton gins and compresses, cotton-seed-oil mills and textile mills employing 1,200. Dyersburg was founded about 1826.

DYES, NATURAL. The utilization of plant products for dyeing is of ancient origin, and without doubt at the first consisted in the staining of material with the coloured juices of fruits, flowers and the like. It would be observed that certain of these effects resisted the washing process, a true fixation of the colour having occurred, and such discoveries would in course of time be extended; but on the other hand few substantive dyestuffs exist in nature, the variety of shade they yield is limited, and their effects in the main are not permanent in sunlight. Again, the observation that the leaf juice of the indigo plant develops a blue colour on keeping, and that the sea-snail, *Murex,* when crushed and exposed to light acquires a purple tint, would prepare the way for the subsequent application to fabrics of both the indigo and the purple of the ancients. The process of isolating indigo from the plant was no doubt preceded by a practice of developing this colouring matter in the leaf itself and the employment of the latter as such in the dyeing process, a method which is still adopted in remote parts of China and Africa.

The antiquity of the use of indigo is evident from the discovery at Thebes of a garment dyed therewith, of date about 3000 B.C., whilst the words "blue" and "purple" occurring in Exodus, xxv. 4, and xxxv. 25, can hardly refer to colours other than indigo and the Murex purple. The latter, also known as "Tyrian" or "royal" purple, was of much importance, and the city of Tyre where, according to legend, it was discovered, became famous for its production. The Scriptural quotation "clothed in purple and fine linen" refers not only to this dyestuff but also to its expensive character. It was only as the result of the discovery of the art of mordanting, however, which occurred (probably in India) not later than 2000 B.C., that the practice of dyeing really advanced, for as a result many natural colouring matters otherwise useless could be applied to fabrics. Thus the Biblical scarlet without doubt refers to the colour given by kermes on alum-mordanted material, whereas both madder and the lac dye of India, which have been in use from time immemorial for red dyeing, only give this colour to fabrics which have been similarly treated. Very ancient too is the use of "archil," a colour resulting from the action of ammonia as stale urine on certain lichens, and referred to by Pliny as of service in reinforcing the shade of the Tyrian purple. Early references to mordant yellow dyestuffs are meagre, though according to the same author, "cotinus" (evidently the shrub *Rhus cotinus,* that is, young fustic and weld, which was the more valuable of the two) was in use for this purpose. Again, saffron was known to both Egyptians and Greeks, and there is evidence of Egyptian use of the yellow colouring matter of safflower as a dye or stain for mummy cloths.

As a result of the discovery of Mexico and South America by the Spaniards at the end of the 11th century, many important dyes indigenous to those countries, as for instance, logwood, old fustic and the like, became available in Europe and provided the dyer with a range of effects formerly inaccessible. Kermes was soon replaced by the richer cochineal, and the employment of weld, young fustic and certain of the minor natural dyestuffs greatly decreased or was restricted to the production of special effects. (A. G. P.)

DYES, SYNTHETIC. Synthetic or artificial dye-stuffs, also known as coal-tar dye-stuffs, artificial colouring matters, aniline dyes, like those of natural origin, are complex compounds of carbon in association with other elements, more especially with hydrogen, nitrogen, oxygen or sulphur. They belong to the class of organic substances included in the aromatic division *(see* CHEMISTRY: *Organic*). Like "aromatic" compounds in general, dyes have their constituent carbon atoms arranged in the form of closed chains. They may be regarded as derived from "closed chain" or "benzenoid" hydro-carbons by the replacement of certain of the hydrogen atoms by atomic groups of other elements. Thus the hydro-carbon benzene or benzol, C_6H_6, has the structure:—

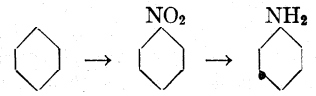


which, for the sake of simplicity, is usually abbreviated to a plain hexagon. The replacement of certain of the hydrogen atoms in this colourless benzene by suitable atomic groups gives rise to dye-stuffs; and these dye-stuffs may contain a single benzene nucleus, or more frequently are constituted of two or more such benzene nuclei united by certain of the atomic groups introduced. Furthermore, the hydro-carbon nuclei which are thus bound together to form a more complex molecule, may be those of the same or of different hydro-carbons. In other words, we may regard the dye-stuff molecule as consisting of one or more chains of carbon atoms, which form the skeleton of the system, and to which are attached various other groups of atoms. Upon the structure and position of the latter groups the character and properties of the dye-stuff (colour, fastness, etc.) mainly depend.

Raw **Materials.**—Nearly all the synthetic dyes are derived from one or other of the five hydrocarbons, benzene, toluene, xylene, naphthalene and anthracene. The most convenient source of these hydrocarbons is coal-tar, obtained in the high temperature carbonization of coal for the manufacture of illuminating gas or of metallurgical coke. The more volatile hydrocarbons, benzene and toluene, are contained also in considerable quantities in the gas produced in these operations and can be extracted therefrom by washing or "scrubbing" the gas with high-boiling solvents. In addition to the hydrocarbons mentioned above, cqal-tar contains a large number of other substances, bases, phenols, and more complex hydrocarbons, most of which find no application in dye-stuff manufacture.

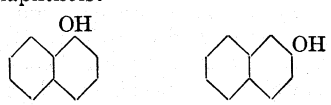
The separation of the useful hydrocarbons from the other compounds present in coal-tar and from each other, is effected by making use of the differences in their boiling-points and other physical and chemical properties. Upon submitting coal-tar to distillation, which is carried out in very large wrought-iron stills containing many tons, the first portion of the distillate contains benzene and methyl-benzenes. This is followed by a fraction rich in the hydrocarbon naphthalene, and finally a high-boiling oil containing anthracene passes over. The two latter substances being solids crystallize out from the oils upon cooling and are separated by filtration. The raw hydrocarbons thus obtained are purified by submitting them to distillation or recrystallization, and also to chemical washing with acids and alkalis. When finally purified benzene, toluene, and xylene are colourless volatile liquids whilst naphthalene and anthracene are colourless solids.

Intermediates.—With these hydrocarbons as starting materials the various dyestuffs are built up in successive stages. In the first place the hydrocarbons are converted into so-called "intermediate products." which are obtained by replacing one or more atoms of hydrogen attached to the carbon nucleus by simple atomic groups such as the amido group NH_2, the dimethylamido group $N(CH_3)_2$, the hydroxy group OH, the sulphonic group HSO_3, etc. Only a few illustrations can be given. Thus from benzene there is prepared by treatment with nitric acid, nitrobenzene, and from this by reduction (hydrogenation) aniline:—



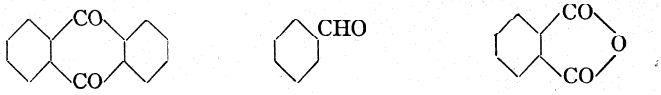
Benzene Nitrobenzene Aniline

From naphthalene there is prepared by the action of sulphuric acid the α and β-sulphonic acids, which upon fusion with caustic soda give α and β-naphthols:—



α-Naphthol β-Naphthol

By the action of nitric acid upon naphthalene, nitronaphthalene is obtained, which upon reduction gives α-naphthylamine. On the other hand β naphthylamine is obtained by heating β-naphthol with ammonia and sodium bisulphite under pressure. Again, from the hydrocarbon anthracene there is obtained by oxidation. anthraquinone. a very important intermediate for fast dyestuffs; whilst by oxidation of toluene there is produced benzaldehyde. and of naphthalene, phthalic anhydride:—



Xnthraquinone Benzaldehyde Phthalic anhydride

Rfethyl- and ethyl-anilines are obtained by heating aniline with methyl or ethyl alcohol and an acid under pressure. Diphenylamine derivatives are prepared by causing chloro compounds to react with amido compounds. The base benzidine (*q.v.*), which is an important intermediate for direct dyeing cotton colouring-matters, is obtained by a molecular transposition from hydrazobenzene under the influence of acids, this substance itself being prepared by alkaline hydrogenation of nitrobenzene:—

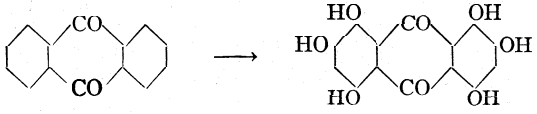
Hydrazobenzene Benzidine

By applying these and similar chemical treatments, and thus introducing two or more of such atomic groups, either of the same or of different kinds, into the hydrocarbon nucleus, there are obtained a great variety of intermediate compounds,—diamines, dihydroxy compounds, amidophenols, naphthol sulphonic acids, naphthylamine sulphonic acids, amidonaphthols, amidonaphthol sulphonic acids, etc. In these compounds isomerism plays an important rôle, since the position occupied by the respective groups in reference to the carbon skeleton is a factor of great importance in determining the properties of the colouring-matter finally resulting.

The commercial importance of some of these intermediates is illustrated by the following production figures for the year 1927 published by the Tariff Commission of the United States (the only country for which statistics are at present available):—

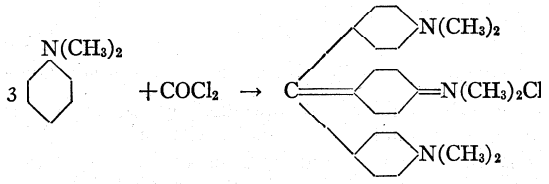
	tons
Aniline	13,542
Dimethylaniline	1,502
Ortho-toluidine	1,145
Para-toluidine	418
Meta-phenylene diamine	331
Meta-tolylene diamine	402
Dinitrochlorobenzene	4,018
Paranitraniline	800
Benzidine	306
Phthalic anhydride	2,275
Sulphanilic acid	656
Metanilic acid	270
β-naphthylamine	298
β-naphthol	2,700
β-naphtholdisulphonic 'acid' R	302
a-naphthylaminesulphonicacid	438
Amidonaphtholsulphonic acid Y	175
Amidonaphtholsulphonic acid J	84
Amidonaphthol disulphonic acid H	202

Dye Synthesis.—The above intermediate products are for the most part colourless bodies like the hydro-carbons from which they are derived. They are convertible into dye-stuffs when, by further chemical treatment, a greater complexity of molecular structure is obtained. This may be effected, (1) by the introduction of further substituent groups, or *(2)* by the linking together of the molecules of two or more intermediate compounds into a larger molecule. An example of the first kind is the formation of the yellow dye-stuff picric acid *(2*:4:6-trinitro-phenol) by the nitration of colourless phenol *(see* CARBOLIC ACID). Another case in point is the conversion of the nearly colourless anthraquinone into the dark blue hexahydroxyanthraquinone (alizarine hexacyanine) by the introduction of six hydroxyl groups:—



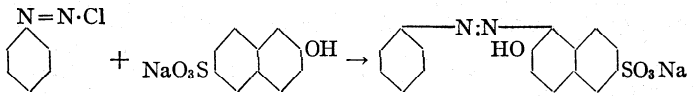
The synthesis of dye-stuffs by the linking together (chemically termed "condensation") of simpler molecules is employed in a great number of cases. Thus crystal violet is obtained by the con-

densation of three molecules of dimethyl-aniline by means of a molecule of phosgene gas:—

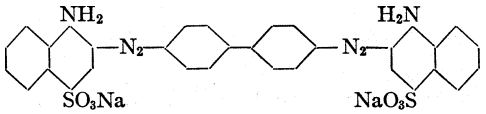


water and hydrochloric acid being also formed in the reaction. This crystal violet is a hexamethyl derivative of pararosaniline. The pentamethyl derivative comprising the chief constituent of methyl violet is made from dimethylaniline, phenol and salt in presence of cupric chloride by the oxidizing action of air.

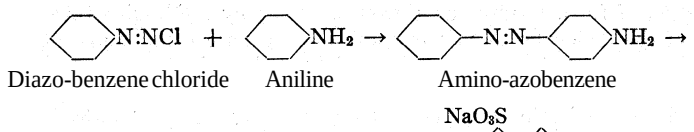
The Diazo-reaction.—The most largely used of all methods of dye-stuff synthesis is the diazo-reaction (P. Griess, 1864), by which the very large class of compounds known as azo-dyes are obtained. The procedure depends upon the fact that almost all primary amino-derivatives of aromatic hydro-carbons, when treated in acid aqueous solution with nitrous acid are converted into diazonium salts. These latter are for the most part colourless compounds of great instability and extremely reactive. When brought in contact with hydroxy or amino-derivatives of aromatic hydro-carbons they "couple" with the latter giving rise to compounds in which the two hydro-carbon residues are united by a double nitrogen group (azo group). For example, when benzene-diazonium chloride or diazo-benzene chloride, derived from aniline hydrochloride, is mixed with an alkaline solution containing, *e.g.*, the sodium salt of Schaeffer's acid (2-naphthol-6-sulphonic acid), a bright orange dye-stuff (crocein orange) is at once produced:—



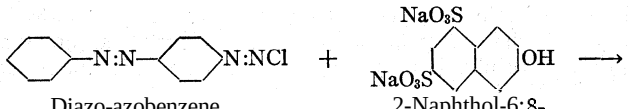
This method of dye-stuff synthesis has proved capable of wide application and is very suitable for technical employment, since it can be effected in cold aqueous solution, gives almost theoretical yields and allows of any required substituent being introduced in prearranged position into the final dye-stuff. When applied to diamino-compounds such as benzidine, it gives rise to dyes containing three hydro-carbon residues (disazo-dyes), such as Congo red:—



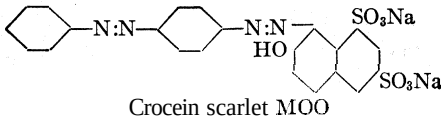
Disazo-dye-stuffs of another type are obtained by coupling diazo-compounds with primary monoamino-derivatives, again diazotizing the free amino-groups in these products and recoupling the diazo-compounds with suitable hydroxy or amino-derivatives. For example:—



Diazo-benzene chloride — Aniline — Amino-azobenzene



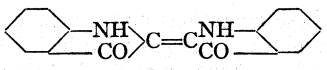
Diazo-azobenzene chloride — 2-Naphthol-6:8-disulphonic acid



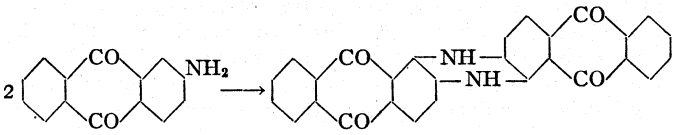
Crocein scarlet MOO

By applying a similar process to diamines, and also by making use of the fact that certain phenols and aminophenols are capable of coupling with more than one molecule of a diazo-compound, azo-dyes can be built up containing three, four or more azo-groups, and a correspondingly increased number of hydro-carbon residues. With growing molecular complexity, the colour of the dye-stuff obtained increases in depth, especially when naphthalene residues are introduced into the reaction. The diazo-reaction can be applied not only for producing dye-stuffs in substance but also for their synthesis within or upon textile fibres, whereby colours can be obtained. Thus when cotton which has been impregnated with an alkaline solution of β-naphthol is passed through a cold solution of diazotized p-nitroaniline, the bright scarlet "para red" is immediately produced and remains fixed on the cotton.

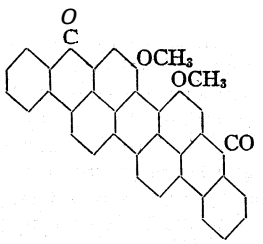
Among the many other methods of dye-stuff synthesis, dependent upon the linking together of hydro-carbon nuclei into more complex molecules, may be mentioned the production of synthetic indigo. The raw materials in this case are aniline and chloro-acetic acid, which upon condensation give phenylglycine. This, upon fusion with caustic alkali, produces indoxyl and by air oxidation indigo:—



The most complex molecular structures are those possessed by the vat dyes of the anthraquinone class. These are obtained by the linking together of two or more anthraquinone residues or by the fusion of these residues with other groups in such a way as to produce new carbon rings. The very fast indanthrene blue RS or duranthrene blue is obtained by heating β-aminoanthraquinone with caustic alkalis and subsequent oxidation by air. The change is thus represented:—



A still more complex example is the dye-stuff caledon jade green which has the structure:—



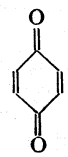
It is obtained from anthraquinone, by first condensing with glycerine, then fusing with caustic soda, oxidizing the product (dibenzanthrone), and finally introducing methyl groups in place of two hydrogen atoms. While initially all the alizarine or anthraquinone dyes were synthesized from anthracene, recently with the cheapening of phthalic anhydride, these dyes are also made by condensation of phthalic anhydride with benzene or its derivatives.

In the United States of America practically all of the anthraquinone dyes are made from phthalic anhydride, and not from anthracene. It will be seen from the examples given that it is possible for the colour chemist to build up dye-stuff molecules having almost any required structure and containing the particular atomic groupings which are known to produce the desired properties. Details of manufacture are given in the books in the bibliography appended.

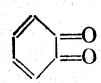
Colour and Chemical Constitution.—The cause of colour in organic compounds is still not fully explained. Most deeply coloured compounds, whether organic or inorganic, exhibit a condition which may be described as *unsaturation; i.e.*, a tendency to take up hydrogen or to pass from a higher to a lower stage of oxidation, accompanied by a disappearance of the

colour. In the compounds of carbon, colour is only present in those having a chain of atoms which are not fully saturated. In the simpler hydro-carbons of the aromatic series, in which this condition exists, colour is not apparent to the eye. Nevertheless, these substances exert a large degree of selective absorption of light in non-visible regions of the spectrum (the ultra-violet). To bring this absorption within the visible portion of the spectrum requires the introduction into the molecule of other atomic groups or the production of greater complexity of structure. It was at one time believed that hydro-carbons were invariably colourless and that only their substituted derivatives containing nitrogen or oxygen were coloured, but a number of complex hydro-carbons are now known which exhibit this property to a high degree.

Quinonoid Structure.—The manifestation of strong colour and dyeing properties amongst aromatic compounds is very frequently found associated with a quinonoid structure; *i.e.*, with a peculiar unsaturated condition of the hydro-carbon ring similar to that occurring in the quinones. Some chemists, in fact, have gone so far as to assert that all dye-stuffs have a quinonoid structure, or are capable of existence in a quinonoid state. The two quinones derived from benzene have the structure:—

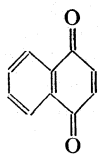


Para-benzoquinone

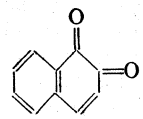


Ortho-benzoquinone

while those derived from naphthalene have the structure:—



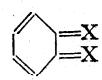
α-Naphthoquinone



β-Naphthoquinone

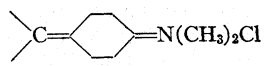
Dye-stuffs having a quinonoid structure may be represented therefore upon the general types:—

and



Para-quinonoid Ortho-quinonoid

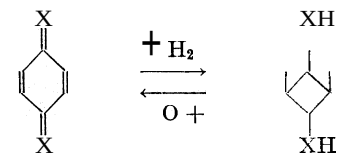
or by similar formulae derived from naphthoquinone or anthraquinone. In these formulae the symbol X may stand for various simple or complex atomic groups. Thus in the formula of crystal violet, already mentioned, the central benzene nucleus,



is quinonoid, and this, or a similar group, is regarded as the source of colour in all the dye-stuffs of the carbonium or triphenylmethane class. It may therefore be termed the chromophor (colour-giver) of this class of dye-stuffs.

Some dye-stuffs are capable of existence both in a quinonoid and a benzenoid (non-quinonoid) form, and may change from one to the other with alteration of conditions (acidity, alkalinity, temperature, solvent, etc.). This transformation is accompanied by a loss or gain of colour. A familiar example is the change of the colourless phenolphthalein (*q.v.*) to its deep red alkaline salts, and the loss of colour of the latter when rendered acid. Such changes probably have an important bearing upon the want of fastness of certain dye-stuffs to light, soap and other agencies, especially in the carbonium class.

Leuco-compounds.—It is a common property of all dye-stuffs, which is obviously associated with their colour, that they readily take up hydrogen with the production of (generally) colourless compounds. While in the case of nitro, nitroso and azo dyes, amino-compounds are thereby produced, from which the original dyes cannot be reconstituted, all other classes of colouring-matters are converted with greater or lesser ease into so-called leuco-compounds. These leuco-compounds contain two atoms of hydrogen more than the original dye from which they are formed, and are reconvertible into the latter upon oxidation. The above facts receive a ready explanation from the quinonoid hypothesis and may be represented by the general expression:—



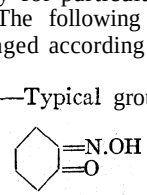
In other words, the reduction (hydrogenation) of dye-stuffs, as of their prototypes the quinones, gives rise to more saturated benzenoid compounds. In the case of the dyes of the indigo and anthraquinone groups alone, are the leuco-compounds coloured, these exceptions being probably referable to the presence in the dye of two chromophoric groups, only one of which is hydrogenated so that the leuco-compound is still quinonoid.

The facility with which the leuco-compounds derived from dye-stuffs of various classes are reoxidized to the original dye-stuffs varies with the structure, and is probably dependent upon whether the dye-stuff has an ortho-quinonoid or a para-quinonoid configuration. The leuco-compounds of indigo dyes, which must have an orthoquinonoid constitution, are readily oxidized by air, while those of the triphenylmethane, indophenol and indamine classes, to which only a paraquinonoid structure can be ascribed, are fairly stable to atmospheric oxidation and require the application of a stronger oxidizing agent, such as chromic, persulphuric, or permanganic acid, to restore their colour.

Classification of Dyes.—While the hydro-carbon framework of the dye-stuff molecule may be regarded as primarily responsible for the existence of colour, the specific properties of the dye, such as shade, affinity for particular fibres, fastness, or behaviour to reagents, depend largely upon the particular atomic groups with which this framework is clothed. These atomic groups are of two kinds, namely (a) chromophoric groups, nitro, azo, carbonium, etc., and (b) salt-forming groups, such as basic, acidic, hydroxylic, sulphide groups. While the atomic groupings of the first kind determine the chemical class to which a particular dye-stuff belongs and its behaviour when submitted to hydrogenation and reoxidation, those of the second kind are largely responsible for its dyeing properties and the resistance of the dyed material towards soap, alkalis, acids, milling, light, etc. A dye-stuff molecule of almost any class may be given basic, acidic, or mordant-fixing properties by the introduction of amino [NH_2 or $N(CH_3)_2$], sulphonic (HSO_3), or hydroxyl (OH), groups respectively in suitable positions. Dye-stuffs are therefore classified in two ways, that is *(a)* in *chemical* classes dependent on the specific chromophor present, and (b) in dyeing classes according to dyeing properties and affinity for particular fibres.

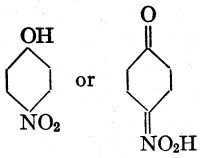
Chemical Classes.—The following are the most important classes of dye-stuffs arranged according to their constituent chromophoric groupings:

I. *Nitroso-compounds.*—Typical grouping:—

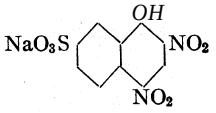


This is a very small class, obtained by the action of nitrous acid upon phenols or phenol-sulphonic acids, and mainly represented by naphthol green and fast green O. They are employed as iron lakes, the nitroso-group having the property of forming stable compounds with heavy metallic oxides.

II. Nitro-compounds.—Typical grouping:—

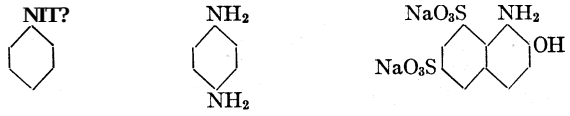


This is also a small class, consisting of yellow acidic dyes, such as martius vellow and naphthol yellow S. The latter has the constitution:—



and is obtained by the action of nitric acid upon nitroso-I-naphthol-2:7-disulphonic acid. Picric acid, no longer used as a dye but as an explosive, also belongs to this class.

III. Aso-compounds.—Typical grouping:— $R-N:N-R$, in which R stands for hydro-carbon residues of the benzene or naphthalene series. This is a very large class of dye-stuffs with over 500 members in general use. The annual production in the United States (for which country alone statistics are available) is approximately 13,500 tons, valued at over $15,000,000 (£3,000,000). The azo-compounds comprise members of nearly every shade and exhibit a great variety of properties according to structure and the auxiliary atomic groupings present. The azo (N_2) group may be present in the molecule once, twice, three or more times, the number of hydro-carbon nuclei thus linked increasing with the number of azo-groups. The simpler azo-dyes are usually yellow to red, those of more complex structure, especially when containing naphthalene nuclei, violet, blue or black. Lake formation also leads to a deepening of the colour; thus the red chromotropes, containing only one azo-group, become dark blue upon conversion into chromium lakes. Under the action of reducing agents such as sodium hydrosulphite, stannous chloride or zinc dust, the azo-dyes are split up into two or more colourless amino-compounds, each N_2 group being severed between the two nitrogen atoms. Thus crocein scarlet, MOO, the structure of which has already been given, yields upon boiling with zinc dust and ammonia the following three products:—

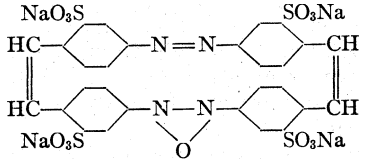


Aniline — p-phenylenediamine — 1:Amino-a-naphthol-6:8-disulphonic acid

By separating and identifying the products of reduction, the structure of the azo-dye may be inferred, and this procedure has become a valuable method of examination and analysis. When the constitution of the dye-stuff is known, the determination of the amount of hydrogen consumed during its reduction, best ascertained by titration with a standard solution of titanious chloride, serves as a convenient and accurate method for the quantitative estimation of the dye either in substance or upon textile fibres.

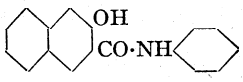
The property possessed by azo-dyestuffs of being resolved by hydrogenating agents into colourless components is also of value to the calico printer. In the production of so-called "discharge" or "foulard" styles, cotton or silk materials which have been dyed dark blue or other shades with appropriate azo-dyes, are printed with thickened reducing agents. Upon steaming the material the azo-colour is discharged leaving a white pattern upon a coloured ground. Certain azo-dyestuffs contain, in addition to the N_2 group, a second chromophore. Upon reduction, such dyes give the parent amino-compound, for example indoin blue gives safranine, while primuline red gives the yellow primuline. Oxidizing agents also effect a splitting of azo-dyes into two or more products, but in this case the division does not occur between the two nitrogen atoms, for the azo-group is left intact as a diazonium group attached to one of the hydro-carbon residues. By the action of strong nitric acid upon para red, nitro-diazobenzene nitrate and nitro-@-naphtholare obtained.

A special class of dye-stuffs containing the azo-group but obtained without the employment of the diazo-reaction, by the intra-molecular rearrangement of p-nitro-toluene-o-sulphonic acid, is the stilbene series. When p-nitro-toluene-o-sulphonic acid is submitted to the action of aqueous caustic soda, a yellow dye-stuff, direct yellow *R*, is formed, having the constitution:—



This yellow compound is the most important member of this series, over 200 tons valued at $200,000 (£40,000) being sold annually in the United States alone. Upon alkaline reduction it gives rise to other members of this group. The dye-stuffs of the stilbene series dye cotton directly and exhibit a greater fastness to light than other azo-dyes. They also behave differently with reducing agents, for instead of being at once split into colourless components they give at first hydrazo-compounds which are readily reoxidized to the stilbene dye-stuff.

Azo-dyes which do not contain a salt-forming group, acidic or basic, are insoluble in water and therefore cannot be used in ordinary dyeing operations. They are employed as pigment colours (ground with mineral materials), and for colouring oils: waxes and varnishes. Certain of them also find a large and increasing application as colours produced on, or within, the fibre itself, and which on account of their insolubility are very resistant to washing, bleaching and light. The typical example of this class is para red, to which reference has already been made. This method of dyeing has been greatly extended by the introduction of the so-called *azoic* series, in which the cotton is impregnated with an anilide of β-oxynaphthoic acid (known commercially as a "naphthol AS" compound), such as



and subsequently passed through a bath containing the diazo-compound of a nitroaniline, nitrotoluidine, nitrochloroaniline, naphthylamine, etc. Certain of the reds obtained in this manner exhibit a very high degree of fastness, even resisting the process of cotton bleaching known as "bowking."

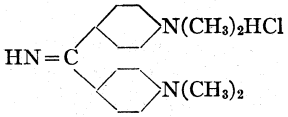
The group of azo-dyes may be divided according to their dyeing properties into the following subdivisions: (a) Neutral or pigment colours; (b) basic dyes: a small group represented by chrysoidine, Bismark brown, and a few other products; (c) acidic dyes: a large group to which the ordinary wool yellows, oranges, scarlets and blacks belong; (d) mordant dyes or chrome dyes: used in dyeing fast colours on wool or in cotton printing; (e) direct substantive or salt dyes: a large group of colouring-matters which have an affinity for cotton and other cellulose fibres; (f) acetate silk dyes (ionamines, S.R.A. colours, etc.): a class of recent introduction, dyeing acetyl-cellulose ("Celanese," etc.), but having no affinity for cotton, linen, or viscose silk; (g) spirit soluble dyes: employed in the colouring of stains, varnishes, waxes and gasolene (petrol).

IV. *Carbonium* or *Triphenylmethane* Compounds.—Characteristic grouping:—

in which R' and R'' may both represent benzene nuclei or R' may be a benzene nucleus and R'' a naphthalene nucleus. Crystal and methyl violet, the constitutions of which have been given already, are typical members of this class. In the United States in 1926 over 1,000 tons of the carbonium dyes were sold for over $3,000,000 (£600,000).

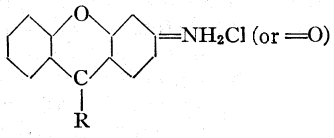
The carbonium dye-stuffs are characterized by very brilliant and intense shades of red, violet, blue and green. They have basic, acidic, or mordant fixing properties, according to the auxiliary grouping they contain. As a class they are rather deficient in fastness to light, and frequently also in fastness to washing and alkalis, by which they are partially decolourized. This loss of colour, especially noticeable in the case of the alkali and soluble blues, is attributed to a change of type from a quinonoid to a carbinol structure. It is diminished by the introduction of a chlorine atom or a sulphonic or other group into one of the benzene nuclei in a contiguous (ortho) position to the central carbon atom. Setoglaucine, patent blues, erioglaucines, xylene blues and some of the acid violets possess such a structure and exhibit a degree of fastness to washing superior to that of the other members of the class. The basic dyes of the carbonium series are represented by magenta, methyl violet, crystal violet, malachite green, brilliant green, setoglaucine, setocyanine, and the Victoria blues. The acidic members comprise acid magenta, alkali and soluble blues, acid greens, acid violets, patent blues, erioglaucines, xylene blues, etc. The mordant-fixing members are known as eriochrome azurols and eriochrome cyanines. their mordant-fixing property being due to the presence of a carboxyl group in the molecule.

The bright yellow basic dye, auramine, which has the constitution:

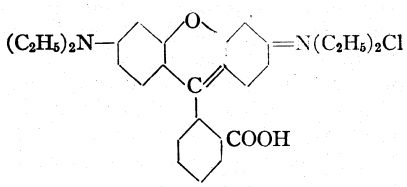


should also be classed as a carbonium compound, though it has but two benzene nuclei. The basic carbonium dyes have powerful toxic and antiseptic properties; thus auramine is employed in surgery, especially in operations upon the eye. It appears probable that derivatives of these dyes containing "labile-acidic" groups such as the sulphato-group $C_2H_4{\cdot}OSO_3H$, which can be split off in the organism, may find application in internal medicine. It has also been observed that the leuco-derivatives of the carbonium dyes, which are far less toxic than the dye-stuffs themselves, exert a powerful neutralizing effect upon certain disease toxins such as those of diphtheria and tetanus.

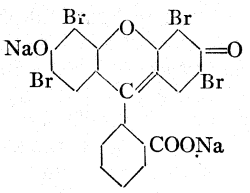
V. Xanthene, Pyrone or *Phthalein* Class. — Characteristic grouping:—



This class, consisting partly of basic and partly of acidic and a few mordant-fixing members, comprises some of the most brilliant dye-stuffs available to the colour user. In the United States the consumption during 1926 was over 250 tons valued at over $700,000. They are closely related to the carbonium class, from which they differ by the presence of an oxygen atom linking two of the benzene nuclei, and are less liable than the latter class to undergo conversion into colourless carbinol forms, and hence are faster to alkalis, soap and milling. The basic members of this class are known as rhodamines. the B brand of which has the structure:



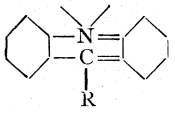
and is obtained by condensing phthalic anhydride with *m*-diethylamino-phenol. The acid rhodamines and fast acid violets are sulphonic acids of the basic dyes. The eosines are weakly acidic and have a phenolic structure, for example eosine A:—



The eosines are capable of forming unstable metallic lakes and their lead salts are employed for the preparation of bright red pigments ("vermillionettes") used in poster printing. The unbrominated compound, fluorescein (*q.v.*), has a yellow colour and in alkaline solution an intense green fluor scence, which is apparent at extreme dilutions and has led to the dye-stuff being employed for tracing the course of underground streams and the contamination of water supplies by drainage.

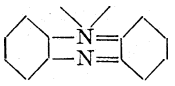
In their behaviour towards reducing agents, the xanthene colours are distinguished from the carbonium class by a greater resistance to decolourization, and a somewhat greater oxidizability of their leuco-derivatives. In this respect they occupy an intermediate position between the para- and the ortho-quinonoid classes of dye-stuffs. The eosines and rhodamines, when not containing sulphonic acid groups, are taken up from aqueous solution by ether, the former from an acid medium, the latter from an alkaline or neutral medium. The sulphonated (acidic) members of both classes are entirely insoluble in ether. The eosines, being brominated or iodinated compounds, are further characterized by the liberation of the respective halogen when heated with sulphuric acid and manganese dioxide.

VI. *Acridine* Class. — Characteristic grouping: —



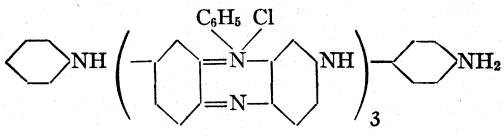
This is a small class of yellow and orange dyes containing basic members only, which find their main application in leather dyeing, calico printing and medicine. The chief representatives are phosphine, acridine yellow, acridine orange, benzoflavine and rheonine. Acriflavine (see ACRIDINE) has obtained considerable importance in surgery as a local antiseptic, but is not employed in dyeing. The Acridine dye-stuffs are somewhat resistant to reduction and are therefore not easily decolourized by hydrosulphite.

VII. *Azine* Class, — Characteristic grouping: —



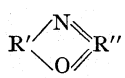
This class contains both basic and acidic dye-stuffs, ranging in shade from red to blue. While the basic members are represented by the red safranines and by the blue to black spirit-soluble indulines and spirit-soluble nigrosines, the acidic members comprise the rosindulines, water-soluble nigrosines, water-soluble indulines, indocyanines, acid cyanines, etc. Closely related to safranine is Perkin's mauve, the earliest coal-tar dye-stuff. The indulines and nigrosines find their chief application in the colouring of leathers, oils and waxes (boot polishes, printing inks and lacquers), and more than 800 tons are sold annually in the United States alone.

Aniline black is an insoluble dye, which is produced on the cotton fibre by impregnation of the latter with salts of aniline and subsequent oxidation with chlorates, dichromates, etc. It is largely employed in the dyeing of cotton cloth and in calico printing. The colouring-matter is a very complex azine containing eleven benzene nuclei and probably represented by the following formula:—.

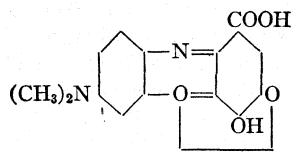


The fastness of aniline black to light and atmospheric influences depends on the completeness with which this complex structure is formed in the dyeing process. The quantity of aniline black present upon dyed cotton can be estimated by first removing all finishing materials and other dye-stuffs and then determining the nitrogen present by the Kjeldahl method, using about 5 g. of cloth. The percentage of nitrogen found, subtracting 0·1% for that normally present in the cotton fibre, gives when multiplied by the factor 6·6 the percentage of aniline black.

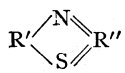
VIII. *Oxazine* Class.—Characteristic grouping:—



in which R' is a benzene nucleus and R'' a benzene or naphthalene nucleus. This class comprises the basic dyes, Meldola's blue, nile blue, capri blue, and cresyl blue; also the basic-mordant dyes, gallocyanines, gallamine blue, celestine blue, prune, delphine blue, modern violets, modern cyanines, anthracyanines, chromazurines, etc. The dyes of the latter category possess both "basic" and "mordant-fixing" properties and are employed in calico printing. Gallocyanine has the following structure:—

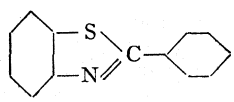


IX. *Thiazine* Class.—Characteristic grouping:—

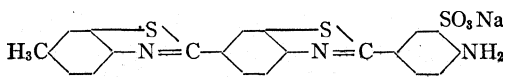


To this class belongs the important basic dye-stuff, methylene blue together with the acidic dye-stuff thiocarmine, the mordant-fixing dyes, brilliant alizarine blues and indochromine. The thiazine chromophore is probably present also in the blue and black dye-stuffs of the "sulphide" class. The leuco-compounds of this and the two preceding classes are very oxidizable, being readily reoxidized by air into the original dye-stuffs.

X. *Thiazole* Class.—Characteristic grouping:—

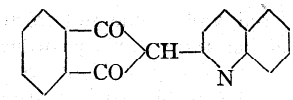


The most important dye-stuff of this class is the diazotizable dye-stuff, primuline, in which the typical thiazole group is present twice:—



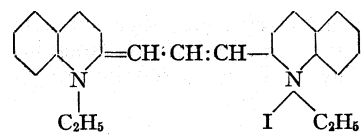
This colouring-matter dyes cotton directly in primrose-yellow shades, which, owing to the presence of an amino-group, can be diazotized and coupled on the fibre. Thus the largely used primuline red is produced by passing cotton dyed with primuline through an acidified solution of sodium nitrite and afterwards through an alkaline bath of β-naphthol. The colours thus obtained are very fast to washing. Other members of the thiazole class which dye cotton directly, though they are not diazotizable, are chlorophenine yellow, Clayton yellow and thioflavine S. Thioflavine T has basic properties and is used in calico printing, giving very pure greenish-yellow shades. In the thiazole class also belong the direct-dyeing reds, erika, geranines, titan pink and diamine rose, which contain an azo-group in addition to the thiazole chromophore. The thiazole chromophore is difficult to reduce and those dyes containing this group only are but little affected by reducing agents. When, however, as is the case with developed colours from primuline, an azo-group is also present, the latter suffers disruption and the parent thiazole remains.

XI. *Quinoline* Class.—Typical representative, quinoline yellow spirit-soluble:—



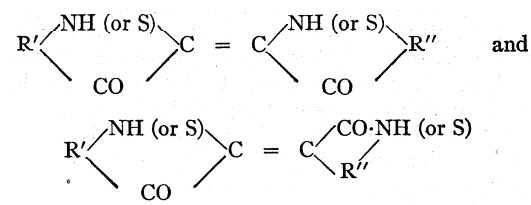
This compound is obtained from 2-methyl-quinoline and phthalic anhydride. It is insoluble in water and is only used for colouring varnishes and oils, but its disulphonic acid, quinoline yellow water-soluble, is an acidic dye-stuff giving bright greenish-yellow fast-to-light shades upon wool and silk.

Certain derivatives of the quinoline series, although too fugitive to be used for dyeing, find a very important application in photography as "sensitizers" in the manufacture of panchromatic or autochrome plates. These dyes are obtained by the action of alkalis on quaternary ammonium derivatives of quinolines and methyl-quinolines, either alone (isocyanines) or in presence of formaldehyde (carbocyanines). Examples of these products are ethyl red, pinaverdole, pinachrome, pinacyanol, kryptocyanine and dicyanine **A.** Pinacyanol, for example, has the constitution:



and is prepared by adding formaldehyde and caustic potash to a boiling solution of 2-methyl-quinoline ethyl iodide. Photographic plates treated with these dye-stuffs become exceedingly sensitive to red light, and in some cases (*e.g.*, dicyanine **A**) even to infra-red rays.

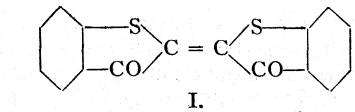
XII. *Indigoid* Class.—Characteristic groupings:—



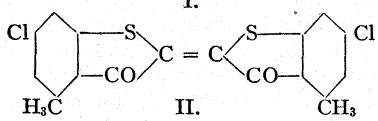
Until 1905, this class of dye-stuffs was represented only by indigo itself, its isomeride indorubin and its sulphonic acid indigo carmine. As a result of the intensive research promoted by the successful synthesis and manufacture of indigo from benzene derivatives, a large new class of analogous dye-stuffs has become known (thioindigo series, ciba series, helindone series, etc.). These possess in general the same dyeing properties as indigo itself, *i.e.*, they are insoluble in water and when reduced to their leuco-compounds they dissolve in alkalis, and from such solutions are absorbed by animal and vegetable fibres; *i.e.*, they are "vat" dyes. Originally obtained by fermentation of the expressed sap of the Indigofera *tinctoria* and other similar plants growing in India, Java, etc., indigo is now produced almost entirely artificially by chemical means. This synthesis, which has already been mentioned, ranks with that of alizarine as one of the greatest chemical achievements of the 19th century. The manufacture was commenced about 1900 and synthetic indigo has now almost entirely replaced the natural product, the production greatly exceeding that of any other individual dye-stuff and amounting for the world to about 10,000 tons of 100% product per annum with an approximate value of over £4,000,000. In the United States alone in 1926 there were sold 14,219 tons of the 20% paste (2,843 tons of 100% product) at an average price of 12·8 cents per pound, which was below the pre-war price of 1913, when all the indigo consumed there was imported from Germany and Switzerland.

Many members of the indigo class contain chlorine or bromine atoms in substitution for hydrogen in the two benzene nuclei: thus ciba blue 2B is a tetrabromo-derivative of indigo and dyes clearer and brighter shades of blue than the parent dye-stuff.

Thioindigo red has the structure **I.**, while helindone pink is represented in **II.**



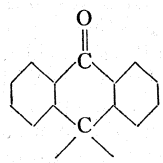
I.



II.

Indigo itself and many of its analogues exhibit the unusual property of being volatile at high temperatures and thus of giving coloured vapours on heating. Being more or less neutral in properties, the indigoid dyes can be extracted from the animal or vegetable fibre by organic solvents such as pyridine or cresol, and extraction by these solvents forms the basis of a convenient method for estimating indigo on wool or cotton materials in the presence of other dye-stuffs. Upon reduction, indigoid dyes give rise to leuco-compounds which have a yellow colour and are readily reoxidized by air to the original dye.

XIII. Anthraquinone Class.—Representative grouping:—



This important class contains acidic, mordant-fixing and vat-dyeing members, all of which are remarkable for a high degree of fastness to light. The older members, comprising the alizarines, purpurines, alizarine cyanines and alizarine blues, mostly hydroxy-derivatives of anthraquinone, are mordant-fixing colouring-matters. With aluminium, chromium, or iron hydroxides, they produce fast colours, the shades of which vary with the metallic hydroxide employed. Thus the typical dye-stuff, alizarine, yields with aluminium, a red; with chromium, a maroon; and with iron, a purple. When fixed upon a compound mordant of aluminium, calcium and a fatty acid, the celebrated Turkey red is produced. This colour was originally dyed by means of madder, the ground root of the Rubia *tinctorum,* which contains alizarine, and which up to about 1875 was grown in large quantities for this purpose. The synthesis of alizarine from the hydro-carbon anthracene by Graebe and Liebermann in 1868 laid the foundation for the artificial manufacture of this dye-stuff, and also for the great developments in anthraquinone chemistry which have followed since. In a few years the natural colouring-matter was entirely replaced by the synthetic, the manufacture of which is effected by oxidizing anthracene to anthraquinone, converting this into a sulphonic acid and fusing the latter with caustic soda.

The acidic members of the anthraquinone class are represented by alizarine red WS, alizarine acid blues, acid alizarine green, alizarine saphirol, alizarine astrol, alizarine irisol, alizarine cyaninol, alizarine rubinol, alizarine direct blue, alizarine cyanine green, cyananthrols, etc. Many of these dye wool directly from an acid bath without a mordant while others give shades which are faster to washing when a mordant is used (acid-mordant dyes). The vat dye-stuffs of the anthraquinone series are the fastest dye-stuffs known. They comprise the indanthrene (duranthrene) series, the caledon series, algol colours, cibanone colours, ponsol colours, etc., the first representative of which, indanthrene blue RS, was discovered in 1901 (vide supra). Many of these dyes have an extremely complex constitution, containing two or more anthraquinone residues united together by other groups or fused in such a way as to produce new ring structures. In these structures at least one of the two carbonyl (CO) groups of each anthraquinone residue remains intact, and it is to this group that the property of vat dyeing is to be attributed.

All the anthraquinone dye-stuffs, to whichever dyeing class they belong, exhibit the property of giving upon reduction deeply coloured leuco-compounds which usually reoxidize readily. The colour of these often differs remarkably from that of the original dye-stuff: for example, the lenco-compound of flavanthrene is blue, reoxidizing in air to yellow. The application of stronger reducing agents frequently converts the first leuco-compound into a more stable second leuco-compound from which the dye-stuff is not easily regenerated.

Dye Classes.—In the previous section the synthetic dyes were regarded from the standpoint of their chemical or chromophoric structure. It is now proposed to consider their dyeing properties and the dependence of the latter upon specific constitution or the presence in the molecular structure of particular atomic groupings. In the different categories there will frequently be found representatives of several chromophoric classes (see DYEING).

I. Basic Dyes.—The basic dyes are salts. usually hydrochlorides of coloured bases containing amino or substituted amino-groups, such as NH_2, $N(CH_3)_2$, $N(C_2H_5)_2$, etc. They dye animal materials—wool, silk, leather, feathers, etc.—directly from a neutral bath, but possess for vegetable fibres, jute excepted, only a small affinity. They are applied to cotton and linen by mordanting these fibres with tannin and a metallic salt, such as a salt of antimony, which produce insoluble compounds with the dye base. In calico printing, for which dye-stuffs of the basic class find their chief application, a thickened mixture of the dye-stuff with acetic acid and tannin is printed upon the cotton. This is then steamed to drive off acetic acid, leaving the insoluble dye tannate, the fixation of which is completed by passing through a bath of antimony potassium tartrate. The basic dyes can be applied to jute, hemp and cocoanut fibre without a mordant and are frequently used for dyeing these materials. Some are used for lake pigments for wall-paper printing, while the salts of certain dye bases with the higher fatty acids, oleic, linoleic, stearic or resin acids, are used for colouring oils, varnishes, etc.

The basic dye-stuffs appear to owe their affinity for animal fibres to a chemical combination (salt-formation) occurring between the amino or substituted amino-groups of the dye and the carboxylic acid groups (CO_2H) of the wool or silk protein. The maximum affinity for these fibres is exerted in a neutral or slightly alkaline bath, and conversely the dye-stuff can be partially removed from the dyed fibre if the latter is boiled with a dilute acid. Loss of colour on boiling with a 5% solution of acetic acid therefore forms a suitable test for distinguishing dye-stuffs of this class when dyed upon animal fibres. Before testing vegetable fibres (cotton or linen) it is necessary to remove the tannin mordant by boiling with dilute caustic soda saturated with common salt, which leaves the released dye base on the fibre, from which it can then be removed by dilute acid. The addition of caustic soda to a solution of a basic dye-stuff usually precipitates the dye base, though in a few cases (*e.g.*, safranine) the base remains in solution. The best test for distinguishing basic dye-stuffs from other classes of dyes is the production of an insoluble precipitate on the addition of a solution of tannin and sodium acetate. The most important basic dyes belong to the triphenylmethane and xanthene classes. These are magenta, methyl violet, malachite green, brilliant green, setocyanine, rhodamines, etc. They are remarkable for extreme brilliancy and tinctorial power, but unfortunately their resistance to light leaves much to be desired. Basic members of the azine, oxazine and thiazine classes are safranine, rhoduline reds, spirit-soluble induline, spirit-soluble nigrosine, Meldola's blue, nile blue, capri blue, etc. The azo-class is mainly represented by chrysoidine and Bismarck brown.

II. Acid *Dye-stuffs.*—These are salts, usually sodium salts, of coloured compounds containing acidic groups, especially the sulphonic group, SO_3H. They dye animal fibres (silk and wool) directly from an acidified solution. Certain of them (notably acid violets, wool blues and quinoline yellow) will also dye wool from a neutral bath. For cotton and other vegetable fibres they have little or no affinity, but are used to some extent in the dyeing of jute and book-binding cloths which are not required to be washed. They find their chief application in the dyeing and printing of wool and silk. In the production of lake-pigments many of the acid dye-stuffs are extensively employed (*e.g.*, naphthol yellow, azo scarlets, azo oranges, eosines, etc.), for which purpose they are precipitated as insoluble salts upon a mineral substratum by addition of barium chloride, etc. Certain acid dye-stuffs

(lithol reds, lake reds, pigment yellows, monolite reds and yellows, etc.) are manufactured especially for this purpose.

The acid dyes owe their affinity towards animal fibres to the sulphonic or other acid groups they contain, which doubtless enter into combination (salt-formation) with the amino-groups of the protein molecules. As such combinations have little stability, the dyes of this class are generally deficient in fastness to alkalis and soap, which by neutralizing the dye acid loosen its attachment to the fibre. Loss of colour upon boiling the dyed material with a 1% solution of ammonia serves as a convenient test for recognizing this class of dye-stuff. It is to be noted however that certain acid dye-stuffs (sulphone cyanines, sulphone azurines, milling reds, etc.) have a higher degree of fastness to alkalis than the normal, which is probably to be referred to the possession by these compounds of a supplementary affinity for the fibre similar to the substantive properties possessed to a greater degree by the direct dyes (see IV. below).

Acid dyes which contain carboxyl (CO_2H) groups or hydroxy (OH) groups in suitable positions frequently exhibit an affinity for metallic mordants, by the presence of which their attachment to the fibre can be increased. Such colouring-matters, which occupy an intermediate position between acid dyes and mordant-fixing dyes proper, are termed acid-mordant or chrome dyes (see III. below). A special class of the latter is supplied to the consumer in the form of already prepared copper or chromium compounds, which when dyed from an acid bath give very fast colours (fast acid red RH, fast acid purple, neolans, palatine fast colours, etc.). Naphthol green B is similarly an acid-dyeing iron compound of the nitroso-class. Most of the acid dyes are azo-compounds, *e.g.,* fast yellow, metanil yellow, orange II., acid scarlets, fast reds, carmoisine, lissamine red, naphthalene blacks, etc. The acid dyes of the carbonium class comprise acid magenta, soluble and alkali blues, patent blues, acid violets, acid greens, etc. The eosines, acid rhodamines and fast acid violets belong to the xanthene class, the water soluble nigrosines, water soluble indulines, wool fast blues, wool fast violets and indocyanines to the azine class. The acid dyes fastest to light are those of the anthraquinone class, namely alizarine saphirol, alizarine irisol, alizarine emeraldol, alizarine cyanine green, alizarine direct blues, etc.

III. Mordant and *Chrome* Dyes.—These are coloured compounds containing particular groups, usually OH or CO_2H groups, capable of forming stable coloured lakes (co-ordinative compounds) with metallic hydroxides, particularly with those of chromium, aluminium, iron and copper. The mordant dye-stuffs proper comprise many of the older natural colouring-matters, much as logwood, fustic, cutch, cochineal, Persian berries and brazilwood, but only a few synthetic dyes, which belong chiefly to the anthraquinone class (alizarine, purpurines, alizarine blue, alizarine cyanines, anthragallol, etc.). Most of the mordant-dyeing colouring-matters of synthetic origin contain acid groups (SO_3H or CO_2H, or both) and may therefore be classified as acid-mordant colours. These are mainly used on a chromium mordant and are therefore generally termed chrome colours. In wool dyeing the chromium mordant (sodium bichromate, chromium acetate or chromium fluoride) is applied to the wool either before or after dyeing, or even more frequently (metachrome or solochrome colours) both dye stuff and mordant (chromate) are added together to the dye-bath. The shades dyed with mordant and acid-mordant dye-stuffs are generally much faster to alkalis and therefore to washing and milling than those obtained with ordinary acidic dyes, whilst the resistance to light, more particularly of those belonging to the anthraquinone group, is very good. Mordant dyes are also employed in calico printing, in which case the solution of the dye-stuff suitably thickened is mixed with chromium acetate and acetic acid, printed upon the cotton cloth and steamed.

Whilst many mordant dye-stuffs are not greatly altered in shade by combination with the mordant, in some cases a complete change of colour is produced. Thus the yellow alizarine gives a red with aluminium and a purple with an iron mordant; the red chromotropes are changed to dark blue or black by chromium salts or chromic acid; and with the same mordant the red eriochrome azurol becomes blue. A special category of the mordant dye-stuffs are those which also contain basic groups. These may be termed basic-mordant dyes and belong chiefly to the oxazine class (gallocyanines, etc.). They are distinguished from acid-mordant dyes by giving a precipitate with tannin and sodium acetate. The only general method for distinguishing mordant dye stuffs on the fibre from other alkali-fast dyes, consists in seeking the metallic hydroxide. In the case of chromium this is readily accomplished by burning the dyed fibre and testing the ash. The mordant or chrome dyes of the azo-class comprise the alizarine yellows, milling yellows, palatine chrome red, diamond blacks, eriochrome blacks, solochrome browns, reds and blacks, and many others. The carbonium class is represented by the eriochrome azurols and eriochrome cyanines; the xanthene class by gallein, coeruline and ultraviridine; the thiazine class by the brilliant alizarine blues; and the anthraquinone class by alizarine, purpurine, alizarine cyanines and anthracene blues.

IV. Direct, *Substantive* or *Salt* Dyes.—These are colouring matters which dye cotton or other vegetable fibres from a neutral or alkaline solution without the application of a mordant or fixing agent. They dye animal fibres in a similar manner and also from an acid bath. They are therefore said to have a substantive affinity for these fibres. Like the acid dye-stuffs they are sodium salts of sulphonic acids, but while with the acid dyes it is the free colour acid which is taken up and combined with the fibre, in the case of the direct dyes the compound is absorbed as a whole (hence the term salt dyes). The cause of this direct affinity or substantivity is not precisely known, but it appears to be associated with long-chain structures in the dye-stuff and the presence of hydroxy-groups in the fibre itself. Acetate silk, in which the hydroxy-groups of cellulose are etherified, displays no affinity for these dye-stuffs. The direct dye-stuffs are mainly used in cotton dyeing and printing and in the dyeing of those types of artificial silk which consist of pure cellulose (viscose silk). For the latter purpose a special class of these dye-stuffs (icyl colours) has been introduced, giving more level shades than the ordinary direct cotton dyes, the affinity of which is frequently too great. Certain direct dyes are also employed in wool dyeing giving faster colours than ordinary acid dye-stuffs (diamine fast red, milling scarlet, etc.). A few contain mordant-fixing groups and can be dyed upon wool with a chrome mordant or fixed upon cotton by after treatment with a metallic salt (chromium or copper). Certain of these (sirius colours) are supplied as ready-prepared copper compounds for dyeing cotton directly in shades fast to light.

The direct dyes are a very numerous group, the principal categories of which are the following: (a) Diamine colours, consisting of azo-compounds derived from diamino-bases, such as benzidine. These include amongst others congo red, benzopurpurine, rosophenine, chrysophenine, diamine blues, diamine greens, diamine blacks and chlorazol colours. (b) J-acid colours, consisting of dye-stuffs obtained by coupling diazo-compounds with benzoyl or carbonyl derivatives of 2-amino-5-naphthol-7-sulphonic acid. They comprise the benzo fast scarlets, diamine azo scarlets, rosanthrenes and diazo brilliant scarlets. (*c*) Stilbene dyes, consisting of azo-compounds containing the group $C_6H_5{\cdot}CH{:}CH{\cdot}C_6H_5$, and comprising direct yellow, stilbene yellows and mikado oranges. (d) Thiazole dyes, comprising primuline yellow, clayton yellow, chlorophenine, erika, diamine pink, geranine and rosophenine 10B.

V. Developed *Colours.*—Many of the preceding class of dyes when containing a free amino-group, are capable of being converted on the fibre into colours of greater fastness or intensity by the process of "development." The dyed material is treated with an acidified solution of sodium nitrite, followed after washing by an alkaline bath of β-naphthol or other intermediate product. A complex azo-dye is thus built up within the fibre from a simpler one. The process, first applied in 1887 to the dye-stuff primuline, which is changed thereby from yellow to red, has since been extended to a variety of "direct-dyeing" azo colouring-matters (diazo blacks, diamine blacks, chlorazol blacks, oxamine blues, diaminogens, diazo scarlets, rosanthrenes, etc.).

In most cases the shade only becomes deeper or darker and the chief object of the process is to increase the fastness to washing.

Another method of development is termed the "coupling" process, in which the dyed material is passed through a solution containing a diazo-compound (see Diazo-reactions above), usually diazotized *p*-nitroaniline. The diazonium salt combines with the dye on the fibre, to yield a more complex compound, having a deeper shade and increased fastness to washing. This process is applicable to the benzonitrol browns, toluylene browns and diamine nitrazol colours.

VI. Sulphide Dyes.—These colouring-matters, belonging to various chromophoric classes, possess in common the property of dyeing cotton from a bath of sodium sulphide. They are produced by heating various intermediate compounds, mostly of the aminophenol class, with sodium polysulphides. The dye-stuffs themselves are insoluble in water but dissolve, probably as leuco-compounds, in an aqueous solution of sodium sulphide, from which solution vegetable fibres are dyed in shades of remarkable fastness to washing. Although their structure is not as yet fully ascertained, it seems certain that they owe their dyeing properties, which are akin to that of the "vat" dyes, to the presence in the molecule of a chain of sulphur atoms, –S–S– or –S–S–S–S, which upon reduction in an alkaline medium yields a soluble sulphydrate –SNa or –S–SNa. This is taken up by the fibre and by aerial oxidation regenerates the insoluble dye.

The sulphide dyes belong to several chemical classes: the blue and black members contain the thiazine grouping; the purple and maroon members the azine grouping; the yellow, orange and brown members, the thiazole grouping. The most important are the sulphide or sulphur blacks, which are very largely used and compete with aniline black in cotton dyeing. The blue members (thianol blues, immedial blues, pyrogene blues, etc.) are used as substitutes for indigo, while the yellows and browns (thianol yellows and browns, etc.) are employed for dyeing khaki and cutch shades. The chain of sulphur atoms to which the sulphide dyes owe their dyeing properties is somewhat unstable, and under the influence of acid reducing agents, such as stannous chloride and hydrochloric acid, a part of the sulphur is split off as hydrogen sulphide, readily detectable by lead acetate paper thus giving a convenient test for dyes of this class. Though tolerably fast to light, the sulphide dyes are readily attacked by hypochlorites (used in bleaching) even in weak solution.

VII. Vat Dyes.—This term is applied to dye-stuffs which, being insoluble in water, are applied to the fibre in the form of their alkali-soluble leuco-compounds, followed by reoxidation by air. Indigo is the typical representative and was formerly the only example of this class. During the present century, however, many new dye-stuffs have been discovered having similar dyeing properties and exhibiting a great variety of shades. These colours meet modern demands for a high degree of fastness, not only towards alkalis and washing but also for the most part to light, bleaching and other agencies. Owing to the insolubility in water of the dye-stuffs themselves, these products are usually sold in the form of pastes generally containing 20% of dry dye-stuff.

The property of dyeing "in the vat," *i.e.*, in a similar manner to indigo, may be referred to the capacity of forming leuco-compounds of weakly acid properties which possess an attraction for the fibre and are readily reoxidized by air. In the case of the vat dyes of the indigoid and anthraquinone classes this property is attributable to the presence in the molecule of $\rangle C{:}O$ groups, which by alkaline reducing agents are converted into $\rangle C\langle^{H}_{OH}$ groups and their soluble alkali salts. In the sulphide-vat colours it is doubtless due to chains of sulphur atoms, similar to those present in ordinary sulphide dyes but not so easily reducible. Attempts have recently been made to simplify the dyeing operations for vat colours by preparing soluble stable derivatives of their leuco-compounds containing "labile-acidic" groups, which derivatives can be appiied to the fibre and afterwards treated with an oxidizing agent such as ferric chloride or nitrous acid, when the labile-acidic group is eliminated and the insoluble dye becomes fixed on the fibre (indigosols and solindone colours).

The vat dye-stuffs may be subdivided into the following categories: (a) Indigoid vat colours, comprising indigo and thioindigos, ciba colours, durindones, helindone colours, etc. They are applicable to both animal and vegetable fibres. Reduction is usually effected by means of sodium hydrosulphite, though in the case of indigo itself, other reducing agents are sometimes used (fermentation vat, etc.). (b) Anthraquinone vat colours, comprizing the indanthrenes, duranthrenes, algol, cibanone, ponsol, carbanthrene and caledon series. They are employed in dyeing and printing cotton and linen, upon which materials they produce the fastest colours known. They have not yet found general application in wool and silk dyeing owing to the fact that the reduction by sodium hydrosulphite requires the presence of strong alkalis. (c) Benzoquinone and naphthoquinone vat dyes are at present only a small class comprizing certain vat browns and yellows employed in wool dyeing (helindone series). (d) Sulphide vat colours, mainly represented by the hydrone blues, derived from carbazole, probably contain the thiazine chromophor. They are closely related to the ordinary sulphide dyes, from which they only differ in their method of dyeing and greater fastness. They are employed for vegetable fibres only, upon which they are applied from an alkaline bath of sodium hydrosulphite. The hydrone blues dye cotton in indigo blue shades of great fastness, superior in some respects to indigo. They give upon reduction nearly colourless leuco-compounds, which readily reoxidize upon exposure to air. They are not sublimable upon heating and cannot be extracted from the fibre by pyridine (distinction from indigo).

VIII. Pigment *Colours.*—Under this heading may be classed synthetic colouring-matters which are insoluble in water and are not applicable for textile dyeing in the usual way. Certain azo-dyes when generated upon or within the fibre produce very fast shades (such as para red, dianisidine blue and the azoic colours). Prepared in substance certain of them are used for colouring oils, waxes, varnishes, etc. (sudans and oil colours); while other members of the class which are insoluble in oils are used for oil-colour and lithographic printing (hansa yellows, pigment red, monolite fast scarlet, typophor colours, etc.). Insoluble dye-stuffs of the indigoid and anthraquinone classes, especially prepared in a finely divided condition, may also be similarly employed.

The insolubility in water of these pigment dyes is due to the absence of strong salt-forming groups, either acid or basic. Certain soluble dye-stuffs can also be converted into insoluble compounds by precipitation as barium or aluminium salts (presence of SO_3H, CO_2H or OH groups), or as tannates, phosphates, silicates, phosphomolybdates (presence of $N(CH_3)_2$ or other basic groups). The insoluble compounds thus formed are termed lakes or lake pigments, and are also largely used in the paint, wall-paper and printing-ink industries, the dye-stuffs particularly suited for these uses being the lithol yellows and reds, monolite yellows and reds, lake scarlets and many of the ordinary acid and basic colouring-matters.

IX. Acetate Silk Dyes.—The particular kind of artificial silk which consists of acetylcellulose and is known as "Celanese," is only dyed by a few acidic dye-stuffs and by some of the basic dyes. For the majority of the acidic dyes and for the entire class of the direct dyes this fibre exerts no affinity whatever. To overcome the difficulties encountered in dyeing this material, special colouring-matters have been introduced. The first of these new classes were the ionamines, in which insoluble compounds of azo or anthraquinone series are converted into temporarily soluble derivatives by the introduction of methyl—ω—sulphonic groups, $CH_2{\cdot}SO_3Na$. These groups are split off during dyeing and the insoluble dye-stuff formed is absorbed by the fibre. Another class, the S.R.A. colours, consists of insoluble azo-dyes maintained in colloidal suspension by means of sulphonated castor oil; while in the duranol series the same principle is applied to insoluble dyes of the anthraquinone class. In addition to dyeing fast shades upon acetate silk, all these dyes have the further advantage, that they exert no affinity for cotton, linen or viscose silk, and can there-

fore be employed together with direct dyes for producing two-colour effects upon fabrics woven from these fibres together with acetate silk.

X. *Food* Dyes.—This class of dye application has been developed particularly in the United States where the Government officially "certifies" as to purity of even individual factory lots of a dozen selected dyes, in which case the lots in question can be sold as certified dyes. The selected dyes are mainly naphthol yellow S, yellow OB, poncean 3R, orange I, amaranth, tartrazine, guinea green B, erythrosine and indigo disulphonic acid. They are chosen for their harmlessness when properly made, and for their food (candy, iced drinks, confectionery) colouring ability. The amount sold in the United States in 1926 was 141 tons valued at $1,115,000 (£228,000).

INDUSTRIAL PRODUCTION

The genesis of the synthetic dyestuff industry is found in the discovery of aniline purple, or mauve, in 1856 by W. H. Perkin, in the course of an attempt to prepare quinine from aniline. Manufacture was commenced in the following year by Perkin and Sons, at Greenford Green, near Harrow, England, and in Dec. 1857 this colour was in commercial use for the dyeing of silk. Two years later Verguin in France, also experimenting with aniline, obtained Magenta, which was followed by Violet Imperial and Bleu de Lyon (Girard and de Laire), and in 1862 by Nicholson's Blue, the first soluble acid dye for wool, whilst in 1863 aniline yellow, the first representative of the vast group of azo colours, was introduced by Messrs. Simpson, Maule and Nicholson. At this period the manufacture of dyestuffs was mainly confined to England and France.

The possibilities of the new industry, however, were attracting attention in other countries, and it was in Germany that the most fertile soil for its development was found. In 1868 Graebe and Liebermann made the important discovery that Alizarine (madder) could be prepared from anthracene, a constituent of coal tar, and the synthesis of the first natural colouring matter was effected. Manufacturing processes were patented simultaneously by Perkin in England, and in Germany by Caro, Graebe and Liebermann, and in 1869 production commenced. The rapidity with which the natural product was driven from the market is shown by the decline of the British imports of madder from 15,300 tons, value £690,000, in 1868, to 1,650 tons in 1878, the total value of the world's madder trade in the former year being £2,000,000. Perkin and Sons produced 40 tons of Alizarine in 1870, and 435 tons in 1873. The Badische Aniline Company in Germany commenced production in 1871 with 150 tons, which during 1873 had risen to 1,000 tons.

Large profits were now being made both in Great Britain and elsewhere, and in 1874 Perkin retired from the business, which was taken over by Messrs. Brooke, Simpson and Spiller. Further important discoveries were announced from Germany with, in 1874, the Eosines, in 1876 Methylene Blue, the first basic blue soluble in water, and in 1877 Malachite Green, the first green of real dyeing value; and the supremacy of the German manufacturers was hy now definitely established. The value of the production of dyestuffs in 1878 is given at £3,150,000, participated in as follows:—

	£		£
Germany	2,000,000	France	350,000
Great Britain	450,000	Switzerland	350,000

Later landmarks in the development of the industry were the introduction (1880) by Read Holliday and Company of Para Red, the first dyestuff to be produced on the fibre, and the discovery in Germany in 1884 of Tartrazine as well as of Congo Red, the first colour having direct affinity for cotton. In 1885 only 20% of the synthetic dyestuffs consumed in Great Britain were of home manufacture.

In 1880 Von Bayer succeeded in preparing indigo by synthetic means. In 1897 after an expenditure of £900,000 had been incurred by the development work, synthetic indigo was marketed. At this time the annual value of the world's growth of indigo was about £4,000,000; in India alone 1,400,000 acres of land were devoted to this crop, but a continuous decline set in and by 1912 the Indian area had fallen to 214,000 acres. The German production of the synthetic product, which in 1900 was about 2,500 tons, had increased to 39,000 tons in 1913. Cultivated indigo thus met the fate which 40 years earlier had befallen the madder root.

The Pre-War Output.—The position of the dyestuff industry in 1913 is shown by the following statistics of production and consumption:—

Production of Dyestuffs in ~ 03r

Country	Indigo Tons	Alizarine red Tons	Other colours Tons	Total Tons	Value £	Value %
Germany	34,000	8,200	92,800	135,000	14,000,000	80·8
Switzerland	2,000	..	8,000	10,000	1,300,000	7·5
France	1,600	..	5,400	7,000	900,000	5·2
U.K.	1,400	1,800	1,800	5,000	350,000	2·0
U.S.A.	..	..	3,000	3,000	495,000	2·9
Other countries	..	..	2,000	2,000	270,000	1·6
	39,000	10,000	113,000	162,000	17,315,000	100·0

Consumption of Dyestuffs in 1913

Country	Indigo Tons	Xlizarine red Tons	Other colours Tons	Total Tons
Great Britain	2,600	3,000	17,400	23,000
Germany	1,400	1,700	16,900	20,000
France	1,650	350	7,000	9,000
Russia, Austria, Italy and Switzerland	3,150	650	21,200	25,000
U.S.A.	3,700	500	21,800	26,000
India	300	3,000	4,700	8,000
China	21,740	..	6,260	28,000
	34,540	9,200	95,260	139,000

The predominance of Germany at this time was even more pronounced than the above figures indicate, since a considerable proportion of the output shown for Switzerland, Great Britain and other countries was manufactured from "intermediates" which were of German origin. In Germany the organic chemical industry, of which dyestuffs manufacture was the mainstay, was developed on the broadest lines, supported by the banks, and directed by University trained scientists. By 1880 two German works were employing sixty scientific chemists. In 1900 six firms employed 500 chemists, 350 engineers and technologists and 18,000 workpeople. In Great Britain at the latter date the corresponding figures were 30 to 40 chemists and 1,000 workpeople. Whereas between 1886 and 1900 German firms obtained 948 patents for the manufacture of dyes, British firms took out only 86, the ratio of the number of patents closely corresponding to that of the number of chemists employed.

Modern Developments.—Such was the position in 1914 at the outbreak of War. Britain was then importing annually, at a cost of £2,000,000, dyes essential to industries producing goods valued at £200,000,000, upon which 1,500,000 workers were dependent. The United States consumed annually 26,000 tons of dyes of which 3,000 tons only were home manufacture, the total consumption being valued at £4,000,000. In all countries from

which supplies of German dyes and drugs were cut off a serious shortage rapidly supervened. Industrialists realized that although dyes were in respect of cost a minor item amongst their raw materials, they were an essential commodity to make the products saleable.

In Great Britain and the United States steps were quickly taken to stimulate production, and Government assistance was invoked. In the former country enemy patents were revoked, and the chief existing producers, Messrs. Levinstein Ltd. and Read Holliday and Co., rapidly expanded their output. The latter firm was bought out in 1915 by British Dyes Ltd., a company promoted with financial assistance by the Government and largely subscribed to by the dyestuff consumers. Processes required to be worked out, buildings and plants constructed, chemists trained. Government requirements for the war were paramount, these consisting not only of khaki and blue dyes for the army and navy, but of explosives. By 1917 the essential requirements of the country were being fully met. Alizarin had been produced in quantity for many years by the British Alizarine Co., a company formed by the Turkey Red Dyers Association in response to a German threat to increase largely the price. The British production of dyes in 1918 amounted to 13,600 tons. In 1918 an amalgamation of British Dyes Ltd. and Levinstein Ltd. was effected under the style of British Dyestuffs Corporation, Ltd. A new company, Scottish Dyes Ltd., concentrated on the production of the important fast to light vat dyes produced from anthracene. France, Japan and Italy, each formerly dependent upon German and Swiss supplies, similarly developed the industry, and by 1919 all the above countries were capable of supplying, in bulk, 80% to over 90% of their home requirements, as well as of exporting considerable quantities to the Chinese and Indian markets.

The world's annual capacity to produce dyestuffs was now at 300,000 tons, almost twice the capacity in 1914. Over production and severe competition were everywhere experienced with the return of the German colours to the market, and each of the producing countries adopted measures for protecting their hdme trade. The United States, Italy and France, created high import duties. Japan subsidized the industry and instituted a licence system of import control. Great Britain by a Proclamation in 1919 prohibited imports except under licence from the Board of Trade. A test case, however, resulted in a judgment that this procedure was illegal, and throughout 1920 there was no restriction, dyes to the value of £7,500,000 being imported. This severe blow dealt to the British industry was followed shortly by a world-wide slump in trade. The Dyestuff (Import Regulations) Act was passed, becoming operative in Jan. 1921, whereby for a period of ten years importation of dyestuffs and intermediates was only permitted under licence. Licences are granted if the corresponding product is not offered by the home producer, and also on price grounds. Initially the British manufacturer was required to supply at a price not exceeding three and a half times the established pre-war price, this factor having been since successively reduced to 3 times, $2\frac{1}{2}$ times and in 1927 to twice the pre-war figure.

In 1923 the French occupation of the Ruhr, which resulted in the shutting down of the principal German factories and the seizure and export of large stocks of dyes, was a disturbing factor in the international dyestuff situation, and the first normal years subsequent to the war were those of 1924 and 1925. The statistics for the year 1937 are given below; these represent the latest available figures of international dyestuff production.

Dyestuffs in 1937

	Production tons	Exports tons	Value of exports
Germany	63,000	42,400	£12,345,225
United States	61,122	8,350	£1,290,376
Great Britain	31,633	5,728	£1,365,544
Japan	11,769	6,683	£368,320
France	11,400	4,728	
Switzerland	7,700	7,113	£3,938,189
Other Countries	17,868		
	204,492		

The total production in bulk is 26% higher than 1913, the German production having fallen from 83% to 31%. While Germany still holds first place as an exporting country, however, dyestuff production in Great Britain and the United States increased tremendously and the range of dyes manufactured is sufficiently diversified to make these countries independent of outside sources of supply. Italy also made considerable progress in the dyestuff field producing 13,800 tons in 1937. The high value of the German exports in comparison with those of other countries excepting Switzerland is due to concentrations on the more expensive types of dye, in particular, of the vat colours, in the manufacture of which the newer producing countries were then less able to compete. (M. BA.; *X.*)

UNITED STATES

In the United States prior to 1914 about 104 dyes were manufactured almost wholly from imported intermediates, and dependence was largely upon Germany. The famine of coal-tar products which followed the outbreak of the war led to the establishment of the manufacture of intermediates and dyes on a large scale, so that by 1919, 250 and by 1925, 350 types of synthetic dyes were being manufactured. The indanthrene or vat dyes were the last to be offered by American manufacturers, the output in 1924 of such vat dyes other than indigo being 1,821,319 pounds. This increased by 43% to 2,608,361 lb. in 1925. In 1923 production had reached so satisfactory a state that 96% of domestic consumption was met in the country and there was in addition an exportable surplus of 18,000,000 lb. of dyestuffs. Since 1917, the annual progress of this branch of the chemical industry has been published in detail in the annual census issued by the United States Tariff Commission. In 1937, 43 firms were engaged in the manufacture of dyestuffs, producing more than 1.000 distinct types having a sales value of $64,613,000. Of this total vat dyes other than indigo accounted for $13,110,000 or about 20 per cent.

Early in the war it became evident that many enemy-owned American patents were being used to interfere with production incident to the successful prosecution of the war. These patents, some 4,000 in number, were taken by the alien property custodian and later sold to the Chemical Foundation, Inc., formed for the purpose of administering these patents for the public good. Any profits above 6% earned on a comparatively small capital stock are devoted to scientific research and educational activities. The Chemical Foundation, Inc., was later sued by the Government for the return of these patents, the case going to the Supreme Court, and the Chemical Foundation being sustained in the district, the appellate, and the supreme courts.

While the sales value of dyestuffs is not large when compared with many other American industries, its importance lies in the fact that others having great values are dependent upon it. It is for this reason a key industry. Textiles and textile products, paper and allied products, leather, ink, and carbon paper are among the industries dependent upon an unfailing source of dyestuff supply, for their practical existence and their products are valued at several billions of dollars annually. Furthermore, the dyestuffs group is the foundation of the entire organic chemical industry, From it has grown a large business in such products as medicinals, flavours, and perfume materials, rubber chemicals, resins, and miscellaneous coal-tar chemicals amounting in 1937 to an additional $64,123,000. The manufacture and sale of synthetic organic chemicals not of coal-tar origin in 1937 produced items to the value of $119,420,000.

At an early date the manufacturers of dyestuffs placed dependence upon scientific research, established extensive laboratories for the purpose, and encouraged the training of suitable personnel through the establishment of numerous fellowships in educational institutions. In 1934, 129 separately organized research laboratories were in operation, employing about 1,350 technically trainedpersons. Net cost of research for that year was about $8,000,000 or 4% of the sales value of all synthetic organic chemicals.

Under the "Trading with the Enemy Act" of Oct. 1917, the President of the United States on Feb. 14, 1918, issued a proclamation which excluded certain articles from import from specified

countries except by license. Dyes and chemicals were included in this proclamation. The industry rapidly developed under this embargo, which remained in force until the passage of the Tariff Act, Sept. 21, 1922. Under this act coal-tar chemicals received special protection for two years. While the industry has been required to meet severe competition under this act with its decreased protection after the first two years, it has nevertheless made great strides, offering an increased number of dyes of all classes, entirely satisfactory in quality and at prices which have been steadily lowered.

The dyestuffs industry has been well served by various bureaus and departments of the United States Government, which have furnished statistics as to imports by classes of dyes and by origin and which have published the census of dyestuffs at stated intervals to guide those developing the domestic dyestuffs industry. In 1921 the Synthetic Organic Chemical Manufacturers Association of the United States was formed for the purpose of furthering the interests of the organic chemical industry and presenting through the association the united efforts of many manufacturers. The achievements of the industry since 1917 have had a far-reaching effect. The products and processes developed have enabled manufacturers of consumer goods to make great improvements, to evolve new products, and to produce them at lower cost. In addition to so largely satisfying domestic demands, the American dyestuffs manufacturers have given a good account of themselves in foreign markets, where they have had to win a share of the business on the quality of the products offered in the face of long-established preferences and prejudices. (H. E. H.)

DYETSKOYE SELO (Detskoe Selo), a town in north Russia, formerly Tsarskoye Selo, 1 j m. south of Leningrad in lat. 59° 43' N., long 30° 24′ E., on the Duderhof Hills. Pop. (1926) 19,284. When Peter the Great took the mouth of the Neva river, a Finnish village, Saarimois, stood on the site now occupied by the town and its Russified name, Sarskaya, was changed into Tsarskoye Selo (The Tsar's Village) when Peter presented it to his wife, Catherine. It was later arranged as a summer abode by the Tsaritsas Elizabeth and Catherine II. and was subsequently used as such by the Imperial family. As a court residence, the town was the earliest Russian town to be supplied with the conveniences of modern civilization. The first Russian railway, built in 1837–8, connected it with Leningrad, and in 1887, it was lighted by electricity, the first town on the European continent to be so lighted. It also has the best system of water supply and sanitation in Russia, and on account of its cleanness, its good sanitation and dry climate, it is a health resort. In 1917 the Tsar Nicholas II. and his family were imprisoned here from March to August, when they were transferred to Tobolsk. Under the Soviet government the former palaces and villas have been turned into museums, schools, hospitals and sanatoria for children. Its present name means Children's Village and has been given to it because in summer it is practically a children's colony. The cathedral of St. Catherine, built by Thon in 1840, is a miniature copy of that at Constantinople. The former imperial park, now the Dyetskoye Selo park, covers 1,680 acres. In it is the "old palace," built in 1724 by Rastrelli, and gorgeously decorated with mother-of-pearl, marble, amber, lapis lazuli, silver and gold, the gallery of Cameron, adorned with fine statues and entrance gates, numerous pavilions and kiosks, and a bronze statue of the poet Pushkin, who was a scholar at the Lyceum. A second palace, the Alexander, was built by Catherine II. 1792–96, and designed by Guarenghi. The Chinese village, bridge and theatre were designed as a result of the interest in China taken by Catherine II. Behind the north wall of the park is the Federovsky Gorodok (Fedor town), built for the Tsar's family 1914–17 by the architect Prestchinsky in old Russian style, and now controlled by the Institute of Agronomy. The Fedor Cathedral was built by Pokrovsky in 1912 in the Pskov-Novgorod style. For a full description of the town, see "Guide to the Soviet Union" (Moscow, 1925; in *English*). The town is now named Pushkin.

DYEWORKS AND CHEMICAL INDUSTRIES, AMALGAMATION OF. The company known as I. G. Farbenindustrie Aktiengesellschaft, founded Dec. 2, 1925, embodies the amalgamation of the German tar dye factories (Badische Anilin- & Soda-Fabrik, Ludwigshafen, Farbenfabriken vorm. Friedr. Bayer & Co., Leverkusen, Farbwerke vormals Meister Lucius & Briining, Hoechst, Aktiengesellschaft für Anilinfabrikation Berlin, Chemische Fabrik Griesheim-Elektron, Frankfort-on-Main, and Chemische Fabriken vorm. Weilerter Meer, Uerdingen Rhine). It is the largest German chemical industry undertaking and has absorbed other concerns. The company's object is the production and sale of dye-stuffs, pharmaceutical and photographic articles, artificial silks, rich materials, metals, nitrogen compounds, benzine and products from the liquefaction of coal and chemical products of all kinds, also the working of other industrial undertakings. It is qualified to establish branches at home and abroad, to participate in other companies and undertakings and to take over wholly or partly their working. A working together in the United States of America was agreed to with the Standard Oil Company of New Jersey with regard to the negotiation of the mutual patents and processes in the territory of the refining of crude oil. The company works with the Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Oslo in the manufacture of nitrogen. At the end of 1927 a regulation of production and sale of dyes in accordance with standardised viewpoints was agreed with the French dye industry. In 1928 the company was amalgamated with the Ansco Photoproducts Inc., New York. The share capital of the I. G. Farbenindustrie Aktiengesellschaft amounts to 1,100 million Marks. Furthermore it has issued convertible Bonds up to an amount of 250 million Marks. (W. J.)

DYKE: *see* DIKE.

DYMOKE, the name of an English family holding the office of king's champion. The functions of the champion were to ride into Westminster Hall at the coronation banquet, and challenge all comers to impugn the king's title. (See CHAMPION.) The earliest record of the ceremony at the coronation of an English king dates from the accession of Richard II. On this occasion the champion was Sir John Dymoke (d. 1381), who held the manor of Scrivelsby, Lincolnshire, in right of his wife Margaret, granddaughter of Joan Ludlow, who was the daughter and co-heiress of Philip Marmion, last Baron Marmion. The Marmions claimed descent from the lords of Fontenay, hereditary champions of the dukes of Normandy, and held the castle of Tamworth, Leicestershire, and the manor of Scrivelsby, Lincolnshire. The right to the championship was disputed with the Dymoke family by Sir Baldwin de Freville, lord of Tamworth, who was descended from an elder daughter of Philip Marmion. The court of claims eventually decided in favour of the owners of Scrivelsby on the ground that Scrivelsby was held in grand serjeanty.

Sir Thomas Dymoke (1428?–1471) joined a Lancastrian rising in 1469, and, with his brother-in-law Richard, Lord Willoughby and Welles, was beheaded in 1471 by order of Edward IV. after he had been induced to leave sanctuary on a promise of personal safety. The estates were restored to his son Sir Robert Dymoke (d. 1546), champion at the coronations of Richard III., Henry VII. and Henry VIII., who distinguished himself at the siege of Tournai and became treasurer of the kingdom. His descendants acted as champions at successive coronations. Lewis Dymoke (d. 1820) put in an unsuccessful claim before the House of Lords for the barony of Marmion. His nephew, Henry (1801–65) was champion at the coronation of George IV. He was accompanied on that occasion by the duke of Wellington and Lord Howard of Effingham. Henry Dymoke was created a baronet; he was succeeded by his brother John, rector of Scrivelsby (1804–73), whose son, Henry Lionel, died without issue in 1875, when the baronetcy became extinct, the estate passing to a collateral branch of the family. After the coronation of George IV. the ceremony was allowed to lapse, but at the coronation of King Edward VII. H. S. Dymoke bore the standard of England in Westminster Abbey.

DYNAMICS, a branch of mechanics. The term is usually applied (as here) to the study of the motion of matter, but sometimes it includes statics, which is concerned with matter at rest.

The Fundamental Equation. — If we were to consider a material system isolated in space it would theoretically be

possible (though perhaps not practicable) to describe the motion merely as related to the configuration. We more frequently consider, however, some arbitrary and not necessarily isolated portion of matter — a "dynamical system." The motion of such a system depends not merely on its configuration but also upon matter external to the system. The effect of this external matter is most simply comprehended in the notion of force. And although we could perhaps study the behaviour of a self-contained system without the aid of this notion, yet when once it has been introduced there is no good reason for restricting its use.

The measurement of mass and of force, Newton's "Laws of Motion," the idea of work, and the theory of the simplest systems — such as a single particle or rigid body under given forces, or two particles mutually attracting — are dealt with in the article MECHANICS. One particular case of two particles subject only to their mutual attraction is of special interest and importance, namely, when the attraction varies inversely as the square of the distance between the particles. This is the famous "problem of two bodies." The methods developed in the study of this particular problem have had a profound effect on the history of the whole subject.

In the present article we consider the general theory of systems of particles and rigid bodies. A rigid body is conceived of, for our present purpose, as an aggregate of particles, finite in number, set in a rigid imponderable frame. (It is hardly necessary to remind the reader that this conception, adequate for the purpose of dynamics, is totally inadequate in other connections.) Thus the whole system consists of a number (perhaps large, but essentially finite) of particles, each subject to forces, including the reactions of other particles of the system; and these reactions must so adjust themselves that the necessary geometrical relations imposed by the constitution of the system are fulfilled. It is easy to see of what form these relations are. For if we denote by $\xi_1, \xi_2, \ldots, \xi_{3N}$ the $3N$ co-ordinates of the N particles of the system referred to fixed rectangular axes, then we shall have m relations of the type

$$\sum_{s=1}^{3N} a_{rs}\,d\xi_s + a_r dt = 0, \qquad r = 1, 2, \cdots, m \tag{1}$$

where $m < 3N$. The coefficients a_{rs}, a_r depend upon the configuration and the time. Thus for a single particle constrained to move without friction on a variable surface $f(x, y, z, t) = 0$ we have

$$\frac{\partial f}{\partial x}dx + \frac{\partial f}{\partial y}dy + \frac{\partial f}{\partial z}dz + \frac{\partial f}{\partial t}dt = 0.$$

In the systems usually considered we have often an important simplification, namely, that in the equations (1) there are no terms in dt, and the coefficients a_{rs} are independent of t.

The motion of a typical particle of the system is controlled by the equations

$$\begin{aligned} m\ddot{x} &= X + X', \\ m\ddot{y} &= Y + Y', \\ m\ddot{z} &= Z + Z', \end{aligned} \tag{2}$$

where m denotes the mass of the particle, x, y, z, its co-ordinates with respect to fixed rectangular axes, and $X+X'$, $Y+Y'$, $Z+Z'$ the components parallel to these axes of the resultant force acting on the particle. The notation implies the division of the forces into two groups, and the division is to be effected thus: The "internal" forces X', Y', Z' are such that altogether they do no work in any infinitesimal displacement of the system compatible with the constraints as they exist at the instant considered. We will call such displacements "admissible." It is important to observe that if the constraints are variable the admissible displacements are those appropriate to the system as constituted at the given instant. Thus in the case of the particle constrained to move on the variable surface $f(x, y, z, t) = 0$ the admissible displacements are in the tangent plane to the surface as it is at the given instant. Explicitly the increments $\delta x, \delta y, \delta z$ must satisfy the single condition

$$\frac{\partial f}{\partial x}\delta x + \frac{\partial f}{\partial y}\delta y + \frac{\partial f}{\partial z}\delta z = 0.$$

And generally the admissible displacements are subject to the equations obtained from (1) by writing $\delta\xi_s$ for $d\xi_s$ and omitting the terms in dt.

We have then

$$S(X'\delta x + Y'\delta y + Z'\delta z) = 0, \tag{3}$$

where S denotes here, and throughout the present article, a summation over the particles of the system, and the equation holds for all sets of values of $\delta x, \delta y, \delta z$ corresponding to admissible displacements. The forces which fall into this category are familiar from the theory of virtual work in statics. The most important are (i.) the mutual reactions between pairs of particles whose distance apart is invariable, (ii.) the reactions between perfectly smooth surfaces, and (iii.) the reactions between perfectly rough surfaces; in the last case the admissible displacements include only a relative motion of pure rolling. From (2) and (3) we derive at once

$$S\{(X - m\ddot{x})\delta x + (Y - m\ddot{y})\delta y + (Z - m\ddot{z})\delta z\} = 0. \tag{4}$$

This is the fundamental equation of dynamics. It expresses the fact that the work of the "kineta" (mx, my, mz) for any admissible displacement is equal to the work of the "external" forces, X, Y, Z. It is the immediate analogue for a dynamical system of d'Alembert's principle for a single rigid body.

First Deductions from the Fundamental Equation. — It may happen that among the admissible displacements is included the displacement that the system actually suffers in a small time succeeding the instant considered. This will be the case, for example, if a particle is constrained to move on a *fixed* smooth surface, but not if the particle moves on a variable surface as in the example considered above. Suppose that this does hold, and consequently that we may write $\dot{x}, \dot{y}, \dot{z}$ for $\delta x, \delta y, \delta z$ in the equation (4). We have then

$$S(X\dot{x} + Y\dot{y} + Z\dot{z}) = \frac{dT}{dt},$$

where $T = \frac{1}{2}Sm(\dot{x}^2 + \dot{y}^2 + \dot{z}^2)$, the "kinetic energy." The rate of working of the external forces is equal to the rate of increase of the kinetic energy. This is the famous "equation of energy."

Again, it may happen that among the admissible displacements is included a displacement of the whole system without distortion as if rigid, in the direction of x. Then we may write $\delta x = \text{constant}$, $\delta y, \delta z = 0$ in the equation (4), whence

$$SX = Sm\ddot{x}.$$

In particular if $SX = 0$ we have

$$Sm\ddot{x} = 0, \qquad Sm\dot{x} = \text{constant}.$$

This is the equation of the "conservation of linear momentum." And in the same way, if a rotation without distortion of the system about the axis of x is admissible, and if further

$$S(yZ - zY) = 0,$$

then

$$Sm(y\dot{z} - z\dot{y}) = \text{constant},$$

the "conservation of angular momentum."

Transformation of the Fundamental Equation. — The equation (4) is the starting point for a number of lines of development. Thus (a) for systems of a suitably restricted type we can derive from it a new variational equation (see equation [8] below), the variables whose differentials appear being new generalized co-ordinates and their derivatives. The compact and elegant form of such variational equations — equivalent, of course, to a set of differential equations — is of peculiar value in dynamics. Or (b) we can exhibit the equation as the condition that some function is to be stationary under given conditions. In Gauss's principle we have to minimize an algebraic function of the accelerations (the co-ordinates and velocities, which appear in the function, being treated as mere constants while the equa-

tions are being formed). In Hamilton's principle and in the "Principle of Least Action" of Maupertuis it is an integral that has to be minimized by the usual methods of the calculus of variations. Or (c) we can transform to differential equations—equations associated with the names of Appell, Lagrange, Hamilton, Routh. The various lines of development are of course intimately connected. Thus the minimizing equations for Gauss' function are Appell's equations, and the minimizing equations obtained from Hamilton's principle are Lagrange's equations.

The methods just enumerated are not applicable over identical ranges. Thus Appell's equations of motion have the advantage that they may be applied at once to systems containing rolling surfaces, *e.g.*, a rough sphere, to which given forces are applied, rolling on a fixed or moving surface. Lagrange's equations may not be applied directly to such problems—though it is easy to modify them (by the introduction of multipliers associated with the reaction at the point of rolling contact) to include problems of this type. Again, Hamilton's principle has a wide range of applicability. It may be applied, by a natural extension, even to continuous systems, such as a vibrating string or membrane; though in practice the differential equations can usually be obtained more simply in other ways—either by considering the motion of a small element treated as a particle, or directly from a suitably modified form of the fundamental equation.

In a short article it is of course impossible to consider all these methods in detail. We shall therefore restrict our further enquiry to systems of a particular type—the type with which we are in fact most often concerned—leaving the reader to consult the books mentioned at the end of this article for information as to systems of more general types. To begin with, we suppose that the co-ordinates x, y, z, of every particle of the system can be expressed as functions, not involving t, of n generalized co-ordinates $q_1, q_2, \ldots, q_n$ capable of continuous variation in a certain domain; and that the admissible displacements of the system are represented by arbitrary infinitesimal increments $\delta q_1, \delta q_2, \ldots, \delta q_n$. This is a very sweeping simplification. The class of admissible displacements is identical with the class of possible displacements (there are no dt terms in the equations [1]), and these displacements are represented in a particularly simple way—by arbitrary increments in the q's. The restriction excludes the possibility of a motion inexorably imposed on the system from without. It also excludes the possibility of rolling surfaces; for although in this case all possible displacements may be admissible, it is not possible, in general, to represent the displacements by arbitrary increments of a set of parameters. Thus, as a simple concrete example, for a rough sphere rolling on a plane we can express the co-ordinates of any particle as functions of five parameters; but the increments of these parameters representing the displacements are subject to two non-integrable relations.

We suppose further that the external forces are "conservative," *i.e.*, that the sum $S(X\delta x+Y\delta y+Z\delta z)$ is the perfect differential of a function, $-V$, of the q's. The outstanding example of conservative forces is the mutual attraction F between a pair of particles, when F depends only on the distance r: for these forces $V=\int F\,dr$.

With these limitations the equation (4) takes a very simple form. Consider separately the term $\ddot{x}\delta x$ appropriate to one particular particle. We have

$$\frac{\partial \dot{x}}{\partial \dot{q}_r}=\frac{\partial x}{\partial q_r}, \qquad \frac{\partial \dot{x}}{\partial q_r}=\frac{d}{dt}\left(\frac{\partial x}{\partial q_r}\right),$$

so that

$$\begin{aligned}\ddot{x}\delta x &= \ddot{x}\frac{\partial x}{\partial q_r}\delta q_r \\ &= \left\{\frac{d}{dt}\left(\dot{x}\frac{\partial x}{\partial q_r}\right)-\dot{x}\frac{d}{dt}\left(\frac{\partial x}{\partial q_r}\right)\right\}\delta q_r \\ &= \left\{\frac{d}{dt}\left(\dot{x}\frac{\partial \dot{x}}{\partial \dot{q}_r}\right)-\dot{x}\frac{\partial \dot{x}}{\partial q_r}\right\}\delta q_r, \qquad (5)\end{aligned}$$

where repeated suffixes imply summation (this convention is to be understood throughout), and the three similar terms for each particle can be transformed in the same way. The kinetic energy T is now a quadratic form in the $\dot{q}$'s with coefficients depending on the q's. We write

$$L=T-V, \qquad (6)$$

$$p_r=\frac{\partial L}{\partial \dot{q}_r}, \qquad (7)$$

so that $$p_r=\frac{\partial T}{\partial \dot{q}_r}=Sm\left(\dot{x}\frac{\partial \dot{x}}{\partial \dot{q}_r}+\dot{y}\frac{\partial \dot{y}}{\partial \dot{q}_r}+\dot{z}\frac{\partial \dot{z}}{\partial \dot{q}_r}\right).$$

From (4) and (5) we have

$$\left(\dot{p}_r-\frac{\partial L}{\partial q_r}\right)\delta q_r=0,$$

or

$$\dot{p}_r\delta q_r+p_r\delta\dot{q}_r=\delta L, \qquad (8)$$

where

$$\delta L=\frac{\partial L}{\partial q_r}\delta q_r+\frac{\partial L}{\partial \dot{q}_r}\delta\dot{q}_r.$$

If we write $\frac{d}{dt}\delta q_r=\delta\dot{q}_r$ the equation (8) may be written compactly in the form

$$\frac{d}{dt}(p_r\delta q_r)=\delta L, \qquad (9)$$

where 6 denotes a contemporaneous variation, and δq_r, $\delta\dot{q}_r$ are arbitrary.

Equations of Motion.—If L be expressed in its natural form as a function of q's and $\dot{q}$'s we have from (8) or (9)

$$p_r=\frac{\partial L}{\partial \dot{q}_r}, \qquad \dot{p}_r=\frac{\partial L}{\partial q_r}. \qquad (10)$$

If we eliminate p_r between these equations we get at once

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}_r}\right)=\frac{\partial L}{\partial q_r}. \qquad (11)$$

This is the form of the equations of motion given by Joseph Louis Lagrange, the author of the great *Mécanique Analytique* (1788). It is usually the most convenient form to apply to concrete problems.

As a simple example, consider a particle moving in a plane under given conservative forces, the position of the particle at any time being given by polar co-ordinates (r, θ). Here

$$T=\tfrac{1}{2}m(\dot{r}^2+r^2\dot{\theta}^2), \qquad (12)$$

and Lagrange's equations are

$$m(\ddot{r}-r\dot{\theta}^2)=-\frac{\partial V}{\partial r}, \qquad (13)$$

$$m(r\ddot{\theta}+2\dot{r}\dot{\theta})=-\frac{1}{r}\frac{\partial V}{\partial \theta} \qquad (14)$$

In particular for a central attraction for which V is a function only of r we have from (14)

$$r\ddot{\theta}+2\dot{r}\dot{\theta}=0,$$

whence

$$r^2\dot{\theta}=\text{constant}. \qquad (15)$$

This is the equation of angular momentum already mentioned.

Next we introduce the function

$$H=p_r\dot{q}_r-L=T+V, \qquad (16)$$

and express H as a function of q's and p's, suppressing the $\dot{q}$'s in favour of the p's by means of the equations (7). Then (9) may be written

$$\dot{p}_r\delta q_r-\dot{q}_r\delta p_r=-\delta H,$$

the δq_r, δp_r being arbitrary variations; so that

$$\dot{q}_r = \frac{\partial H}{\partial p_r}, \quad \dot{p}_r = -\frac{\partial H}{\partial q_r}. \tag{17}$$

These are the equations of motion given by Sir William Ronan Hamilton in 1834. We have here $2n$ equations of the first order as contrasted with the n equations of the second order of Lagrange. Hamilton's equations, though usually less convenient than Lagrange's for concrete problems, are of great importance in theoretical work.

In connection with Lagrange's equations we can picture the motion of the system as the motion of a representative point $(q_1, q_2, \ldots, q_n)$ in an n-dimensional manifold, the q-space. The co-ordinates and velocities of the representative point at a given instant suffice to determine the motion. In the same way, in connection with Hamilton's equations, we can consider the motion of a representative point $(q_1, q_2, \ldots, q_n, p_1, p_2, \ldots, p_n)$ in a an-dimensional manifold, the (q, p) space. The co-ordinates alone of the representative point at a given instant suffice to determine the motion. The path of the representative point, either in the q-space or the (q, p) space, is called an "orbit" of the system.

In the q-space, but not in the (q, p) space, any path is geometrically possible. When, as in Hamilton's principle, we consider variations to neighbouring paths which are not necessarily natural orbits of the system, we think in terms of the q-space. But when we consider variations to neighbouring natural orbits, *i.e.*, orbits satisfying the equations of motion, we may use either representation.

It is possible to produce a function which plays the part of a Lagrangian function for some freedoms, and of a Hamiltonian function for the rest. For the equation (9) may be written

$$\sum_1^m (\dot{p}_r \delta q_r - \dot{q}_r \delta p_r) + \sum_{m+1}^n (p_r \delta \dot{q}_r + \dot{p}_r \delta q_r) = \delta(L - \sum_1^m p_r \dot{q}_r);$$

if therefore we express

$$R = L - \sum^m p_r \dot{q}_r$$

in terms of $p_1, p_2, \ldots, p_n, \dot{q}_{m+1}, \dot{q}_{m+2}, \ldots, \dot{q}_n$ and the q's we have as the equations of motion

$$\begin{aligned} \dot{q}_r &= -\frac{\partial R}{\partial p_r}, \quad \dot{p}_r = \frac{\partial R}{\partial q_r} \qquad r = 1, 2, \cdots, m \\ p_r &= \frac{\partial R}{\partial \dot{q}_r}, \quad \dot{p}_r = \frac{\partial R}{\partial q_r} \qquad r = m+1, m+2, \cdots, n. \end{aligned} \tag{18}$$

Thus the equations corresponding to the first m co-ordinates are of the form (17), and the rest of the form (10). The method was devised by Edward John Routh (1876) for the special case in which $q_1, q_2, \ldots, q_m$ do not appear in L, nor, consequently, in R; so that $p_1, p_2, \ldots, p_m$ remain constant during the motion. Such co-ordinates appear conspicuously in the study of gyroscopes, and Routh's method is commonly applied to such problems.

Hamilton's Principle.—So far we have supposed the equation (9) to refer to a given instant. It will, however, remain true for all time if we consider variations to contemporaneous points on a neighbouring orbit in the q-space, and this will still hold whether the neighbouring orbit is one of the natural orbits of the system—satisfying the equations of motion—or not. Suppose first that we do not restrict the neighbouring orbit to be a natural orbit of the system. Let the original orbit start from (q_{r0}) at the zero of time, and reach (q_r) at time t: and let the neighbouring orbit pass through $(q_{r0} + \delta q_{r0})$, $(q_r + \delta q_r)$ at these same times. Then we derive at once from (9)

$$p_r \delta q_r - p_{r0} \delta q_{r0} = \delta \int_0^t L dt \tag{19}$$

where 6 denotes, as before, a contemporaneous variation. In particular if $\delta q_r, \delta q_{r0} = 0$ we have $\delta \int_0^t L dt = 0$. The integral $\int L dt$ is stationary along a *natural* orbit as compared with *any* neighbouring orbit having the same termini and the same times of departure and arrival. This is Hamilton's principle.

As we have already hinted above the principle holds under less restricted conditions than those imposed in the proof just given. But in some cases (*e.g.*, that of the rolling sphere) there is a new feature which must be carefully borne in mind. The variation to the contemporaneous point on the neighbouring orbit must always be an admissible variation; but the neighbouring orbit itself may be, not only not a natural orbit, but not even an orbit which is geometrically possible. (In the case of the sphere rolling on a rough plane the motion in the varied orbit would, in general, involve sliding as well as rolling on the plane.)

The Equation of Energy.—Consider now variations to contemporaneous points on a neighbouring orbit which is a natural orbit for the system. And suppose first that the neighbouring orbit is the same as the original orbit, but not quite synchronized with it; so that the system passes through the same sequence of configurations, but reaches any configuration a small time τ earlier than it did in the original orbit. Then

$$\delta q_r = \dot{q}_r \tau, \qquad \delta L = \frac{dL}{dt} \tau,$$

and the equation (9) leads to

$$\tau \frac{d}{dt}(p_r \dot{q}_r) = \tau \frac{dL}{dt}.$$

Hence

$$p_r \dot{q}_r - L = H = \text{constant}. \tag{20}$$

This is the equation of energy already established otherwise, in a different form and under less restricted conditions, above.

As an example of the use of this equation, consider again the problem of a particle moving in a plane under a central attraction derived from a potential function $V = V(r)$. The equation of energy is

$$\tfrac{1}{2}m(\dot{r}^2 + r^2\dot{\theta}^2) + V = \text{constant} = E, \text{ say}. \tag{21}$$

We have also the equation (15) of angular momentum

$$mr^2\dot{\theta} = A. \tag{22}$$

From (21) and (22) we have at once

$$m\dot{r} = \sqrt{[2m(E - V) - A^2/r^2]} = \sqrt{\rho}, \text{ say}, \tag{23}$$

where the positive value of the radical is to be taken so long as r increases with t. If r lies originally between two consecutive real positive zeros r_1, r_2, of ρ, then r lies always in the range (r_1, r_2). From (23) we have

$$t - t_0 = \int_{r_1}^{r} \frac{m dr}{\sqrt{\rho}} \tag{24}$$

Also from (22) and (23) we have

$$\frac{d\theta}{dr} = \frac{A/r^2}{\sqrt{\rho}}, \qquad \theta - \theta_0 = \int_{r_1}^{r} \frac{A/r^2}{\sqrt{\rho}} dr. \tag{25}$$

This completes the solution; $t = t_0$ and $\theta = \theta_0$ when $r = r_1$. (25) is the equation of the orbit, and (24) gives the position of the particle in its orbit at any time.

If the attraction at distance r is $\gamma Mm/r^2$ we have $V = -\gamma Mm/r$. For $E < 0$ the orbit (23) is an ellipse having the centre of attraction in one focus.

The Integral-invariant $\oint p_r \delta q_r$.—Returning to the equation (9), consider now variations to contemporaneous points on any neighbouring natural orbit. Consider the orbits starting at $t = 0$ from points on a closed curve in the (q, p) space. Denote by $\oint$ an integral round the curve traced out in the (q, p) space by the contemporaneous points on these orbits at any time. From the equation (9) we have

$$\frac{d}{dt} \oint p_r \delta q_r = \oint \delta L, \tag{26}$$

which vanishes for a closed curve. Hence the integral $\oint p_r \delta q_r$ is constant for all time; the integral is a relative integral-invariant of the Hamiltonian equations.

Transformation Theory.—Consider again variations to any neighbouring natural orbit, and denote by S the integral $\int L dt$ taken along a natural orbit, and expressed in terms of (q_r, q_{r0}, t). We have then, as before,

$$p_r \delta q_r - p_{r0} \delta q_{r0} = \delta S, \tag{27}$$

so that

$$\frac{\partial S}{\partial q_r} = p_r, \qquad \frac{\partial S}{\partial q_{r0}} = -p_{r0}. \tag{28}$$

We have further

$$L = \frac{dS}{dt} = \frac{\partial S}{\partial t} + \frac{\partial S}{\partial q_r} \dot{q}_r = \frac{\partial S}{\partial t} + p_r \dot{q}_r,$$

whence

$$\frac{\partial S}{\partial t} = -(p_r \dot{q}_r - L) = -H. \tag{29}$$

Thus, denoting by d a completely general variation, we have

$$d\delta = p_r dq_r - p_{r0} dq_{r0} - H dt. \tag{30}$$

The equation (30) retains the same form if we replace the constants (q_{r0}, p_{r0}) defining the orbit by new constants (A_r, μ_r), provided

$$p_{r0} dq_{r0} = \lambda_r d\mu_r + dM, \tag{31}$$

where dM is a perfect differential; then

$$p_r dq_r = \mu_r d\lambda_r + H dt + dN. \tag{32}$$

This equation (32) is precisely equivalent to the equations of motion. We have derived it from the equation (9), and it can be shown that the equations of motion (17) are equally implied in it.

A transformation from (q_r, p_r) to (a_r, β_r), where (a_r, β_r) are functions of $(q_1, q_2, \ldots, q_n, p_1, p_2, \ldots, p_n, t)$ is called a contact transformation if

$$\beta_r d\alpha_r = p_r dq_r + R dt + dW, \tag{33}$$

where R, W can be expressed at will in various forms—for example, as functions of the q's and p's and t, or as functions of the a's and β's and t. In particular the equation (32) is of the form (33); the solution of a dynamical problem—the transformation from (A_r, μ_r) to (q_r, p_r)—is a contact transformation.

Suppose now we have a dynamical problem for which the variables are (q_r, p_r)—satisfying the equation (32)—and we transform to new variables (a_r, β_r) by means of a contact transformation satisfying (33). We have then

$$\beta_r d\alpha_r = \mu_r d\lambda_r + (H+R) dt + d(N+W), \tag{34}$$

so that (a_r, β_r) *satisfy* new *Hamiltonian* equations, the new *Hamiltonian function* being $(H+R)$. This important theorem is due in substance to Carl Gustav Jacob Jacobi (1837).

The Hamilton-Jacobi Theorem.—In particular if $R = -H$ the solution of the dynamical problem is given by

$$\alpha_r = \text{constant}, \qquad \beta_r = \text{constant}. \tag{35}$$

To find such a transformation we proceed as follows:

Consider the equation

$$\frac{\partial S}{\partial t} + H\left(q_r, \frac{\partial S}{\partial q_r}\right) = 0, \tag{36}$$

where the second term in the first member is obtained from H by substituting $\frac{\partial S}{\partial q_r}$ for p_r. This (the Hamilton-Jacobi equation) is a partial differential equation of the first order with $(n+1)$ independent variables $q_1, q_2, \ldots, q_n, t$. Let

$$S = S(q_1, q_2 \ldots, q_n, \alpha_1, \alpha_2, \ldots, \alpha_n, t)$$

be a complete integral of the equation, the a's being arbitrary constants, none of which is merely additive. Write the equations

$$p_r = \frac{\partial S}{\partial q_r}, \tag{37}$$

$$\beta_r = -\frac{\partial S}{\partial \alpha_r}, \tag{38}$$

and let these equations be solved to express the a's and β's in terms of the q's and p's and t. Then the transformation from (q_r, p_r) to (a_r, β_r) is a contact transformation having the property we require. For we have

$$\begin{aligned} \beta_r d\alpha_r &= -\frac{\partial S}{\partial \alpha_r} da, \\ &= \frac{\partial S}{\partial q_r} dq_r + \frac{\partial S}{\partial t} dt - dS \\ &= p_r dq_r - H dt - dS, \end{aligned} \tag{39}$$

which is of the required form. For this transformation, appropriate to the particular system characterized by H, the *integrals of the new equations of motion* are the *equations* (35). This is the Hamilton-Jacobi theorem, one of the most famous and beautiful theorems of mathematical physics. It was discovered independently by Hamilton (1834) and Jacobi (1837).

As a simple example of the use of this theorem consider again the problem of a particle moving in a plane under a central attraction derived from a potential function $V = V(r)$. The equation (36) is

$$\frac{\partial S}{\partial t} + \tfrac{1}{2} m \left\{ \left(\frac{\partial S}{\partial r}\right)^2 + \frac{1}{r^2} \left(\frac{\partial S}{\partial \theta}\right)^2 \right\} + V = 0, \tag{40}$$

and a complete integral is

$$S = -\alpha_1 t + \alpha_2 \theta + \int_{r_1}^{r} \sqrt{\rho}\, dr \tag{41}$$

where

$$\rho = 2m(\alpha_1 - V) - \alpha_2^2 / r^2,$$

and r_1 is a zero of ρ. The equations (38) are

$$t - \beta_1 = \int_{r_1}^{r} \frac{m dr}{\sqrt{\rho}}, \tag{42}$$

$$\theta + \beta_2 = \int_{r_1}^{r} \frac{\alpha_2 / r^2}{\sqrt{\rho}}\, dr. \tag{43}$$

These are the integrals of the equations of motion, obtained previously by another method. The compactness of the present method is very striking.

Perturbations.—Returning to the general theory, consider the problem modified by the substitution of a new function $(H+K)$ for H. We may call the new term K a "perturbation function." Let us apply to the new problem the contact transformation defined by the equations (37) and (38), appropriate to the original system. In virtue of the theorem proved above we see, from the equation (39), that the new variables (a_r, β_r) satisfy the equations

$$\dot{\alpha}_r = \frac{\partial K}{\partial \beta_r}, \qquad \dot{p}_r = -\frac{\partial K}{\partial \alpha_r}. \tag{44}$$

If K is zero, then the a's and β's remain constant during the motion; but if K is not zero, then they vary in accordance with the equations (44). This exhibits the perturbed orbit as the gradual modification of an orbit within the group of orbits appropriate to the unperturbed system. This form of solution is particularly important when K is small in comparison with H.

DYNAMISM (Gr. *δύναμις*, power), is the name coined by **A.** Van Gennep for that attitude of the primitive mind towards the sacred or occult which involves a prevailing sense of its peculiar power or *mana.* He is careful not to impute to the savage a theology in which any clear distinction is drawn between the impersonal and the personal aspects of the divine—as contrasted with advanced religion, which, as may be seen in Buddhism and Christianity respectively, may emphasize the one aspect almost to the exclusion of the other—but suggests dynamism as a term that may be used for classifying any phase of primitive religion in which *mana,* rather than soul or moral personality, receives emphasis as the leading attribute of that which is worshipped.

BIBLIOGRAPHY.—A. Van Gennep, ***Les*** *Rites de Passage* (1909); Rev. E. W. Smith and Capt. *A.* M. Dale, *The Zla-speaking Peoples of Northern Rhodesia* (1920). *(See* also MANA; ANIMATISM; ANIMISM.)
(R. R. M.)

DYNAMITE, a high explosive consisting essentially of nitroglycerine absorbed in an inert solid material in order to'reduce its sensitivity to shock. The most frequently used absorbent is kieselguhr (an infusorial earth), and an average composition is nitroglycerine 75%, kieselguhr 25%. Gelatine dynamite consists of nitroglycerine 75%, nitro-cellulose 6%, potassium nitrate 16%, and small quantities of wood-meal and chalk. (See EXPLOSIVES.)

DYNAMO-ELECTRIC MACHINES: see ELECTRIC GENERATOR, MOTOR, ELECTRIC, and ELECTRICAL ARTICLES.

DYNAMOMETER, an instrument for measuring force exerted by men, animals and machines. (Gr. *δύναμις*, strength, and *μέτρον*, a measure). The name has been applied generally to all kinds of instruments used in the measurement of a force, as for example electric dynamometers, but the term specially denotes apparatus used in connection with the measurement of work, or in the measurement of the horse-power of engines and motors. If P represent the average value of the component of a force in the direction of the displacement, s, of its point of application, the product Ps measures the work done during the displacement. When the force acts on a body free to turn about a fixed axis only, it is convenient to express the work done by the transformed product $T\theta$, where T is the average turning moment or torque acting to produce the displacement θ radians. The apparatus used to measure P or T is the dynamometer. The factors s or θ are observed independently. Apparatus is added to some dynamometers by means of which a curve showing the variations of P on a distance base is drawn automatically, the area of the diagram representing the work done; with others, integrating apparatus is combined, from which the work done during a given interval may be read off directly. It is convenient to distinguish between absorption and transmission dynamometers. In the first kind the work done is converted into heat; in the second it is transmitted, after measurement, for use.

Absorption Dynamometers.— Baron Prony's dynamometer *(Ann. Chim. Phys.* 1821, vol. 19), which has been modified in various ways, consists in its original form of two symmetrically shaped timber beams clamped to the engine-shaft. When these are held from turning, their frictional resistance may be adjusted by means of nuts on the screwed bolts which hold them together until the shaft revolves at a given speed. To promote smoothness of action, the rubbing surfaces are lubricated. A weight is moved along the arm of one of the beams until it just keeps the brake steady midway between the stops which must be provided to hold it when the weight fails to do so. The general theory of this kind of brake is as follows:—Let F be the whole frictional resistance, r the common radius of the rubbing surfaces, W the force which holds the brake from turning and whose line of action is at a perpendicular distance R from the axis of the shaft, N the revolutions of the shaft per minute, ω its angular velocity in radians per second; then, assuming that the adjustments are made so that the engine runs steadily at a uniform speed, and that the brake is held still, clear of the stops and without oscillation, by W, the torque T exerted by the engine is equal to the frictional torque Fr acting at the brake surfaces, and this is measured by the statical moment of the weight W about the axis of revolution; that is—

$$T=Fr=WR. \qquad (1)$$

Hence WR measures the torque T.

If more than one force be applied to hold the brake from turning, Fr. and therefore T, are measured by the algebraical sum of their individual moments with respect to the axis. If the brake is not balanced, its moment about the axis must be included. Therefore, quite generally,

$$T=\Sigma WR. \qquad (2)$$

The factor θ of the product $T\theta$ is found by means of a revolution counter. The power of a motor is measured by the rate at which it works, and this is expressed by $T\omega=\frac{T2\pi N}{60}$ in foot-pounds per second, or $\frac{T2\pi N}{33{,}000}$ in horse-power units. The latter is commonly referred to as the "brake horse-power." The maintenance of the conditions of steadiness implied in equation (1) depends upon the constancy of F, and therefore of the coefficient of friction μ between the rubbing surfaces. The heating at the surfaces, the variations in their smoothness, and the variations of the lubrication make μ continuously variable, and necessitate frequent adjustment of W or of the nuts. J. V. Poncelet (1788–1867) invented a form of Prony brake which automatically adjusted its grip as μ changed, thereby maintaining F constant.

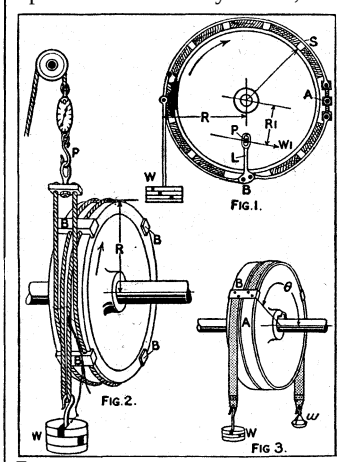

FIG. 1.—APPOLD COMPENSATING BRAKE
FIG. 2.—KELVIN ROPE BRAKE
FIG. 3.—THOMSON SELF-ADJUSTING BRAKE

The principle of the compensating brake devised by J. G. Appold (1800–1865) is shown in fig. 1. **A** flexible steel band, lined with wood blocks, is gripped on the motor fly-wheel or pulley by a screw **A,** which, together with W, is adjusted to hold the brake steady. Compensation is effected by the lever L inserted at B. This has a slotted end, engaged by a pin P fixed to the framing, and it will be seen that its action is to slacken the band if the load tends to rise and to tighten it in the contrary case. The external forces holding the brake from turning are W, distant R from the axis, and the reaction, W_1, say, of the lever against the fixed pin P, distant R from the axis. The moment of W_1 may be positive or negative. The torque T at any instant of steady running is therefore $\{WR \pm W_1R_1\}$.

Lord Kelvin patented a brake in 1858 (fig. 2) consisting of a rope or cord wrapped round the circumference of a rotating wheel, to one end of which is applied a regulated force, the other end being fixed to a spring balance. The ropes are spaced laterally by the blocks B, B, B, B, which also serve to prevent them from slipping sideways. When the wheel is turning in the direction indicated, the forces holding the band still are TY, and P, the observed pull on the spring balance. Both these forces usually act at the same radius R, the distance from the axis to the centre line of the rope, in which case the torque T is $(W-P)R$, and consequently the brake horse-power is $\frac{(W-P)R\times 2\pi N}{33{,}000}$ When μ changes the weight W rises or falls against the action of the spring balance until a stable condition of running is obtained. The ratio $\frac{W}{P}$ is given by $e^{\mu\theta}$, where $e=2{\cdot}718$; μ is the coefficient of friction and θ the angle, measured in radians, subtended by the arc of contact between the rope and the wheel. In fig. 2 $P,\theta=2\pi$. The ratio W/P increases very rapidly as θ is increased, and therefore, by making θ sufficiently large, P may conveniently be made a small fraction of W, thereby rendering errors of observation

of the spring balance negligible. Thus this kind of brake, though cheap to make, is, when θ is large enough, an exceedingly accurate measuring instrument, readily applied and easily controlled.

It is sometimes necessary to use water to keep the brake wheel cool. Engines specially designed for testing are usually provided nith a brake wheel having a trough-shaped rim. Water trickles continuously into the trough, and the centrifugal action holds it as an inside lining against the rim, where it slowly evaporates.

Fig. 3 shows a band-brake invented by Professor James Thomson, suitable for testing motors exerting a constant torque (see *Engineering*, 22nd October 1880). To maintain $e^{\mu\theta}$ constant, compensation for variation of μ is made by inversely varying θ. A and *B* are fast and loose pulleys, and the brake band is placed partly over the one and partly over the other. Weights W and w are adjusted to the torque. The band turns with the fast pulley if μ increasc, thereby slightly turning the loose pulley, otherwise at rest, until θ is adjusted to the new value of μ. This form of brake was also invented independently by J. A. M. L. Carpentier, and the principle has been used in the Raffard brake. A self-compensating brake of another kind, by Marcel Deprez, was described with Carpentier's in 1880 (*Bulletin de la société d'encouragement*, Paris). W. E. Ayrton and J. Perry used a band or rope brake in which compensation is effected by the pulley drawing in or letting out a part of the band or rope which has been roughened or in which a knot has been tied.

In an effective water-brake invented by W. Froude (see Proc. *Inst.* M. E. 1877), two similar castings, A and B, each consisting of a boss and circumferential annular channel, are placed face to face on a shaft, to which B is keyed, A being free (fig. 4). A ring tube of elliptical section is thus formed. Each channel is divided into a series of pockets by equally spaced vanes inclined at 45°. When A is held still, and B rotated, centrifugal action sets up vortex currents in the water in the pockets; thus a continuous circulation is caused between B and **A,** and the consequent changes *of* momentum give rise to oblique reactions. The moments of the components of these actions and reactions in a plane to which the axis of rotation is at right angles are the two aspects of the torque acting, and therefore the torque acting on B through the shaft is measured by the torque required to hold A still. Froude constructed a brake to take up 2,000 H.P. at go revs. per min. by duplicating this apparatus. This replaced the propeller of the ship whose engines were to be tested, and the outer casing was held from turning by a suitable arrangement of levers carried to weighing apparatus conveniently disposed on the wharf. The torque

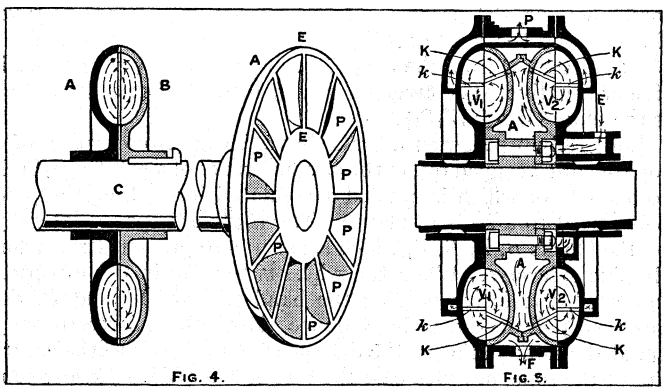

FIG. 4. FIG. 5.

FIG. 4.— DIAGRAMMATIC ILLUSTRATION OF THE HYDRAULIC BRAKE
FIG. 5.— FROUDE-REYNOLDSHYDRAULIC BRAKE

corresponding to 2,000 H P. at go revs. per min. is 116,772 foot-pounds, and a brake 5 ft. in diameter gave this resistance. Thin metal sluices were arranged to slide between the wheel and casing, and by their means the range of action could be varied from 300 H P. at 120 revs. per min. to the maximum. The form of the Froude Brake developed by Messrs. Heenan and Froude is widely used. It is specially convenient for measuring the torque of high speed engines.

Professor Osborne Reynolds in 1887 patented a water-brake (see Proc, *Inst C* E 99, p 167), using Froude's turbine to obtain the highly resisting spiral vortices, and arranging passages in the casing for the entry of water at the hub of the wheel and its exit at the circumference. Water enters at E (fig. 5), and finds its way into the interior of the wheel, **A,** driving the air in front of it through the air-passages K, K. Then following into the pocketed chambers V_1, V_2, it is caught into the vortex, and finally escapes at the circumference, flowing away at F. The air-ways k, k, in the fixed vanes establish communication between the cores of the vortices and the atmosphere. From $\frac{1}{5}$ to 30 H.P. may be measured at 100 revs. per min. by a brake-wheel of this kind 18 in. in diameter. For other speeds the power varies as the cube of the speed. The casing is held from turning by weights hanging on an attached arm. The cocks regulating the water are connected to the casing, so that any tilting automatically regulates the flow, and therefore the thickness of the film in the vortex. In this way the brake may be arranged to maintain a constant torque, notwithstanding variation of the speed. In G. I. Alden's brake (see Trans. Amer. *Soc. Eng.* vol. xi.) the resistance is obtained by turning a cast iron disk against the frictional resistance of two thin copper plates, which are held in a casing free to turn upon the shaft, and are so arranged that the pressure between the rubbing surfaces is controlled, and the heat developed by friction carried away, by the regulated flow of water through the casing. The torque required to hold the casing still against the action of the disk measures the torque exerted by the shaft to which the disk is keyed.

Transmission Dynamometers.—The essential part of many transmission dynamometers is a spring whose deformation indirectly measures the magnitude of the force transmitted through it. For many kinds of spring the change of form is practically proportional to the force, but the relation should always be determined experimentally. General A. J. Morin (see *Notice sur divers appareils dynamométriques*, Paris, 1841), in his classical experiments on traction, arranged his apparatus so that the change in form of the spring was continuously recorded on a sheet of paper drawn under a style. For longer experiments he used a "Compteur" or mechanical integrator, suggested by J. V. Poncelet, from which the work done during a given displacement could be read off directly. This device consists of a roller of radius r, pressed into contact with a disk. The two are carried on a common frame, so arranged that a change in form of the spring causes a relative displacement of the disk and roller, the point of contact moving radially from or towards the centre of the disk. The radial distance x is at any instant proportional to the force acting through the spring. The angular displacement, θ, of the disk is made proportioaal to the displacement, s, of the point of application of the force by suitable driving gear. If $d\phi$ is the angular displacement of the roller corresponding to displacements, $d\theta$ of the disk, and ds of the point of application of P, a, and C constants, then $d\phi = \frac{x\,d\theta}{\gamma} = \frac{a}{\gamma}\,\mathrm{P}ds = C \cdot Pds$, and therefore $\phi = C\int_{s_1}^{s_2} Pds$; that is, the angular displacement of the roller measures the work done during the displacement from s_1 to s_2. The shaft carrying the roller is connected to a counter so that ϕ may be observed. The angular velocity of the shaft is proportional to the rate of working. Morin's dynamometer is shown in fig. 6. The transmitting spring is made up of two flat bars linked at their ends. Their centres s_1, s_2, are held respectively by the pieces A, B, which together form a sliding pair. The block A carries the disk D, B carries the roller R and counting gear. The pulley E is driven from an axle of the carriage. The dynamometer car used by railway engineers to measure the tractive resistance of trains is essentially a development of the Morin apparatus. The pull exerted by the engine on the train passes through a spring. The deflection of the spring is carried through a mechanism to a pencil working on a drum driven continuously from the axle of the car itself. The curve drawn by the pencil then shows the tractive force in terms of the distance. A second pencil electrically connected to a clock traces a time line on the diagram with a kick at definite intervals of time. A third pencil traces an observation line in which a kick can be made at will by pressing any one of the electrical pushes

placed about the car, and a fourth draws a datum line. Other lines are also traced recording events of interest. The spring of the dynamometer car is usually made up of flat plates, spaced by distance pieces nibbed into the plates at the centre and by rollers at the ends. The draw-bar is connected to the buckle, which is carried on rollers, the ends of the spring resting on plates fixed to the under-frame. The gear operating the paper roll is driven from the axle of an independent wheel which is let down into contact with the rail when required. This wheel serves also to measure the distance travelled. A Morin disk and roller integrator is usually connected with the apparatus, so that the work done during a journey may be read off. A detailed account of a railway dynamometer car will be found in the "Railway Engineer," Dec. 1923.

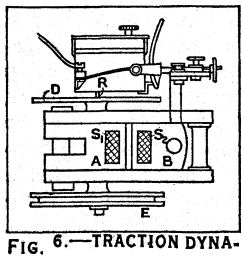

FIG. 6.—TRACTION DYNAMOMETER

In spring dynamometers designed to measure a transmitted torque, the mechanical problem of ascertaining the change of form of the spring is complicated by the fact that the spring and the whole apparatus are rotating together. In the Ayrton and Perry transmission dynamometer or spring coupling of this type, the relative angular displacement is proportional to the radius of the circle described by the end of a light lever operated by mechanism between the spring-connected parts. By a device used by W. E. Dalby (Proc. *Inst.* C.E. 1897–1898, p. 132) the change in form of the spring is shown on a fixed indicator, which may be placed in any convenient position. Two equal sprocket wheels, Q_1,Q_2, are fastened, the one to the spring pulley, the other to the shaft. An endless band is placed over them to form two loops, which during rotation remain at the same distance apart, unless relative angular displacement occurs between Q_1 and Q_2 (fig. 7) due to a change in form of the spring. The change in the distance d is proportional to the change in the torque transmitted from the shaft to the pulley. To measure this, guide pulleys are placed in the loops guided by a geometric slide, the one pulley carrying a scale, and the other an index. A recording drum or integrating apparatus may be arranged on the pulley frames.

Every part of a machine transmitting force suffers elastic deformation, and the force may be measured indirectly by measuring the deformation. The relation between the two should in all cases be found experimentally. G. A. Hirn (see Les *Pandynamomètres,* Paris, 1876) employed this principle to measure the torque transmitted by a shaft. Signor Rosio used a telephonic method to effect the same end, and mechanical, optical and telephonic devices have been utilized by the Rev. F. J. Jervis-Smith. (See Phil, Mag. February 1898.) H. Frahm (Zeitschrift des *Vereins* deutscher, *Ingenieure,* 31st May 1902), during an important investigation on the torsional vibration of propeller shafts, measured the relative angular displacement of two flanges on a propeller shaft, selected as far apart as possible, by means of an electrical device (Engineering, 6th of February 1903). These measurements were utilized in combination with appropriate elastic coefficients of the material to find the horse-power transmitted from the engines along the shaft to the propeller. In this way the effective horse-power and also the mechanical efficiency of a number of large marine engines, each of several thousand horse-power, have been determined.

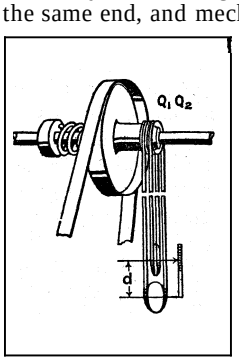

FIG. 7.—DALBY TRANSMISSION DYNAMOMETER

The method of deducing the power transmitted from observations based on the elastic deformation of the parts is specially useful in turbine driven engines because the steam engine indicator from which the indicated horse power is calculated cannot be used with a turbine.

In the Thring-Hopkinson Torsion Meter, the twist between points on a short length of the propeller is observed. A cylindrical sleeve is gripped to the shaft at one end and is free from the shaft at the other end so that there is relative motion of twist between the free end of the sleeve and the shaft. This relative motion is utilized to give angular displacement to a mirror which reflects light from a fixed source to a fixed scale and flashes an image to the scale once per revolution. At moderate speeds the intermittent images appear continuous to the eye and so a continuous indication is given on the scale of the relative twist of the ends of a length of shaft equal in length to the sleeve. As the torque increases the twist increases and the angular displacement of the mirror increases and the indication on the scale shows the instantaneous amount of twist. From the twist the torque on the shaft can be calculated.

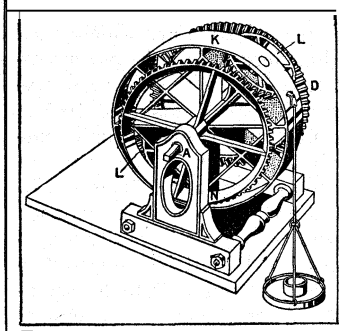

FIG. 8.— TRANSMISSION DYNAMOMETER

In the Moullin Torsion meter the relative twist of a defined length of the shaft is made to alter the self induction of a coil mounted upon and rotating with the shaft. An alternating current is supplied to the coil through brushes and slip-rings, and the variation of this current depends upon the variation of the self induction of the coil so that current variation is thereby related to twist of shaft. Meters placed in series with the coil are calibrated to read torque directly. A description of this instrument will be found in the first Report of the Marine Oil Engine Trials Committee together with some records taken on the shaft of the "Sycamore" when under trial.

In the Ford Torsion meter the relative twist of a definite length of shaft alters the air gap on a transformer mounted on the shaft, with the result that there is a variation of the e.m.f. of the secondary circuit. This variation is related to the twist and therefore to the torque on the shaft.

The difference in the tensions in the driving and slack sides of a driving belt has been made the basis of transmission dynamometers. For examples, reference may be made to the W. Froude belt-dynamometer (Proc. *Inst. M.E.* 1858) and to the Hefner-Alteneck dynamometer (see Electrotechnischen *Zeitschrift,* 1881, 7).

When a shaft is driven by means of gearing the driving torque is measured by the product of the resultant pressure P acting between the wheel teeth and the radius of the pitch circle of the wheel fixed to the shaft. Fig. 8, which has been reproduced from

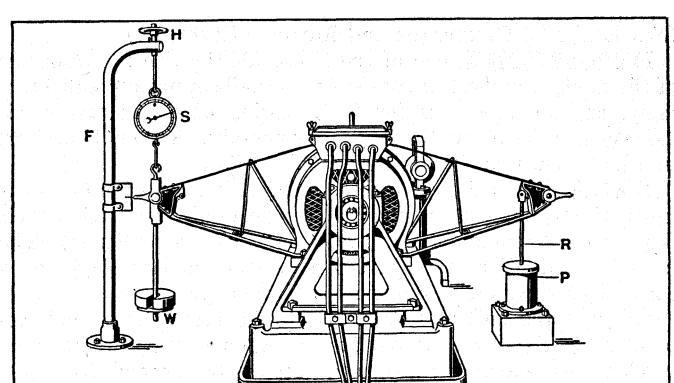

FIG. 9.—ELECTRIC CRADLE DYNAMOMETER

J. White's *A New Century* of Inventions (Manchester, 1822), illustrates possibly the earliest application of this principle to dynamometry. The wheel D, keyed to the shaft overcoming the resistance to be measured, is driven from wheel N by two bevel wheels L, L, carried in a loose pulley K. The two shafts, though in a line, are independent. A torque applied to the shaft A can be transmitted to D, neglecting friction, without change only if the central pulley K is held from turning; the torque required to do this is twice the torque transmitted.

The torque acting on the armature of an electric motor is neces-

sarily accompanied by an equal and opposite torque acting on the frame. If, therefore, the motor frame is mounted so that it is free to turn, and it is prevented from turning by the application of a torque, this applied torque T, measures the armature torque. The rate at which the motor is transmitting work is then $\frac{T2\pi n}{550}$ H.P., where n is the revolutions per second of the armature.

Electric dynamometers based on this principle are widely used to measure the power of high speed engines. Fig. 9 is an illustration of the electric dynamometer coupled to the Ricardo Experimental Petrol Engine. The engine shaft is coupled to the armature of the dynamo. The dynamo frame is held in ball bearings only and is thus free to turn about the axis of the armature shaft. Attached to the dynamo frame are light arms. The arm to the left carries a scale pan W and is hooked to a spring balance suspended from a fixed support F and adjustable in position vertically by the handwheel H. The arm to the left is connected to the piston of a dash pot P by the vertical rod R. Small oscillations are controlled by the dash pot. When the engine is running under load, weights are added to W and the hand wheel H is adjusted to keep the pointed end of the arm at the centre of the scale on the fixed support. The load, derived from W and the spring balance reading multiplied by the perpendicular distance of its line of action from the axis of revolution, measures the reaction T against which the armature is turned. A machine designed by F. W. Lanchester to test the efficiency of worm gears may be classed as a dynamometer since frictional loss in a worm and wheel is measured directly by weighing the reaction the friction produces. A description of this interesting machine, set up in the National Physical Laboratory will be found in Appendix Q of a paper entitled "Worm Gear," read before the Institution of Automobile Engineers, Proceedings Session 1912–13.

Hyde, "Mechanical Testing" (Chapman & Hall, London, 1922); G. W. Watson, "Recording Dynamometer for Tractors" (Engineering, June 30, 1922); "A New Fan Brake Dynamometer" (Automobile Engineer, April 1923). (W. E. D.)

DYNAMOTOR, an electrical machine which when set in motion by mechanical means generates electricity, and which, without any alteration, is capable of doing mechanical work when supplied with an electric current. Its action is thus reversible. (See ELECTRIC GENERATOR and MOTORS, ELECTRIC.)

DYNAPHONE, one of the latest additions to the resources of the modern orchestral composer. Described, not too enlighteningly, as "an apparatus for the emission of sound waves," it has been utilized by the French composer, Arthur Honegger, in a ballet entitled "Roses en métal."

DYNASTY, a family or line of rulers, a succession of sovereigns of a country belonging to a single family or tracing their descent to a common ancestor (Gr. δυναδεία, sovereignty). The term is particularly used in the history of ancient Egypt as a convenient means of arranging the chronology.

DYNE, the unit of force in the centimetre-gram-second system. It is the force which, acting on one gram, produces an acceleration of one centimetre per second per second: It is $1/g$ the gravitational unit of force which is the weight of one gram, g being the acceleration due to gravity. (See MECHANICS and PHYSICAL UNITS.)

DYRRACHIUM, CAMPAIGN OF (48 B.C.). Having destroyed Pompey's power in Spain, Julius Caesar returned to Italy, and on Nov. 28, 49 B.C., set sail from Brundisium with seven legions for Palaeste on the Epirotic coast. Landing on the 29th, on Dec. 2 he headed for Dyrrachium, which, however, he failed to capture. Though numerically weaker than Pompey he succeeded in cutting him off from this city, and then to safeguard his convoys he drew a circle of trenches some 16 miles in length round Pompey's army. Two deserters from Caesar's camp informed Pompey of the weak position in his defences, and acting on this information Pompey determined to attack his enemy's left flank, which rested on the coast.

Caesar had built round Pompey's right flank a line of contravallation and one of circumvallation, between which was posted the IX. legion. Pompey's attack was made at dawn. He landed a number of archers and slingers in rear of Caesar's men, and whilst these broke into the unfinished works he attacked them in front with 60 cohorts. The IX. legion, taken in front, flank and rear, broke in confusion and spread panic amongst the reinforcements which had been sent out by Marcellinus, near whose camp Antony checked the Pompeians by a bold counter-attack. Caesar, hearing of the disaster, moved rapidly with such cohorts as he could collect towards the scene of action, only to find that Pompey had established a new camp on his own original left flank. Nothing daunted, Caesar entrenched his men opposite to Pompey, and attempted to turn Pompey's left flank, but his forces, taking panic fell back, and the attack failed. In this battle Caesar suffered a severe defeat, and not only were his losses considerable, but his loss of prestige almost disastrous to his cause. Caesar's operations throughout this campaign, though daring in the extreme, were essentially faulty. By attempting to enclose a numerically superior adversary he was strong nowhere, and had Pompey known how to win victory as well as fight a battle Caesar must have been decisively defeated. (See PHARSALUS.)

DYSART, royal burgh and seaport, Fifeshire, Scotland, on the shore of the Firth of Forth, 2 m. N.E. of Kirkcaldy by the L.N.E.R. Pop. (1921) 4,598. Many ancient houses in High street bear inscriptions and dates. Scarcely anything is left of the old chapel dedicated to St. Dennis, which for a time was used as a smithy; and of the chapel of St. Serf, the patron saint of the burgh, only the tower remains. The chief industries are the manufacture of bed and table linen, towelling and woollen cloth, flax-spinning; there are power-loom factories and coal is exported. In smuggling days the "canty carles" of Dysart were professed "free traders." In the 15th and 16th centuries the town was a seat of the salt industry, but the salt-pans have been abandoned. During the time of the alliance between Scotland and Holland, which was closer in Fifeshire than in other counties, Dysart became known as Little Holland. To the west of the town is Dysart House, the residence of the earl of Rosslyn. With Burntisland, Kinghorn, Buckhaven, Methil and Inverleven Dysart forms one of the Kirkcaldy district group of parliamentary burghs. The town is mentioned as early as 874 in connection with a Danish invasion. Its name is said to be a corruption of the Latin *desertum,* "a desert," which was applied to a cave on the seashore occupied by St. Serf. From James V. the town received the rights of a royal burgh. In 1559 it was the headquarters of the Lords of the Congregation, and in 1607 the scene of the meetings of the synod of Fife known as the Three Synods of Dysart. Ravenscraig Castle, on the shore to the west of the town, is the Ravensheugh of Sir Walter Scott's ballad of "Rosabelle." William Murray, a native of the place, was made earl of Dysart in 1643. This borough was added to Kirkcaldy in 1930.

DYSENTERY. A disease which in man is characterized by the passage of blood and mucus, the bloody flux of former times. It results from the superficial and deep ulcerative action of certain protozoal and bacterial micro-organisms, primarily upon the large bowel and particularly its lower part. As dysentery may be due to diverse micro-organisms, the causal one or its family or generic name is employed to specify the type of infection, thus—amoebic, bacillary, spirochaetic, ciliar and helminthic dysentery, the first two being the most prevalent and of world-wide incidence.

Pseudo-dysentery. — The term has been given to passage of blood and mucus arising from ulceration of the lower bowel in diseases in which the activity of the causal micro-organism is not specifically selective for the lower bowel, but may occur in other parts, as in tubercle, syphilis, typhoid or paratyphoid. Again, passage of blood and mucus may be associated with a pathological state of the kidney, heart or liver or with carcinoma of the bowel, the impaction of a foreign body or mechanical irritation.

Clinical Dysentery. — The term clinical dysentery is applied

to a mild form of dysentery of short duration, seen especially in natives in the tropics, the aetiology of which is not yet known. In all forms of dysentery frequently there is abdominal pain and tenesmus, but one or both may be absent, for they depend on the site or extent of the ulceration.

Casual **Organisms.**—The casual micro-organisms have been grouped. Protozoa and bacteria found in the intestine of man have been classified into pathogenic and non-pathogenic, and the varieties of form certain protozoal organisms undergo in their life histories in the intestines, or when, as some helminths do, they pass through a phase of existence in an invertebrate host, have been studied and made known.

The findings of Walker and Sellards in Manila from experiments on condemned prisoners show that of the five amoebae found in man only one, *Entamoeba histolytica,* is pathogenic to him. Later Darling, James and others at Panama, differentiated it from the non-pathogenic E-coli. Recently Cutler, Boeek and Dr. Bohlar have cultivated E. *histolytica* in artificial media. In the Philippine Islands Vedder studied the specific action on amoebae of emetine, an alkaloid from ipecacuanha, and its application with beneficial results to man was first made by Sir Leonard Rogers in India. **A** new species of bacillus dysenteriae, B. dys. *Schmitz,* was first found in Rumania in 1916.

Improvements in Technique.—Mechanical aids have been improved to obtain more precise clinical knowledge. The sigmoidoscope, by which one can see 20cm. up the bowel, is now employed to look for any ulceration and its character in this region and, if present, specimens for laboratory examination can be taken direct therefrom. Skiagrams taken after a barium mixture, given by mouth or injected per anum, indicate the movements and the nature of the bowel condition, and presence of any ulceration, filling defects, strictures or diverticula in its wall in subacute or chronic cases *(see* X-RAY).

In England and France the existence of bacteriophage has been determined. Regarding dysentery d'Hérelle found that if a few drops of the filtrate from a broth culture of the faeces of a convalescent case of B. *dys. Shiga* be placed in a broth culture of this bacillus, the micro-organisms are dissolved *(see* BACTERIA AND DISEASE).

AMOEBIC DYSENTERY

This is also called amoebiasis, loeschiasis or tropical dysentery, the latter because of its early endemicity and greater incidence in the tropical areas.

The causal organism *E. histolytica* (Loesch 1871) affects man alone in nature, though the dog, cat, guinea-pig and rat have been infected experimentally. The *E. histolytica* in its life-cycle in man passes through three stages—a large vegetative stage when living within the tissues, giving rise to ulceration and passage of blood and mucus; a pre-cystic stage found in convalescents and carriers, when the amoebae are much smaller and live on the mucous membrane within the bowel, from which they may pass into the membrane and assume the larger vegetative form; and a cystic stage. The amoebae increase in numbers by division of the parent into two. In the pre-cystic stage they contract into smaller, rounded or ovoid forms, develop a firm outer wall and become transformed into cysts with one to four characteristic nuclei and chromatoid rods which possibly act as food stores. It is by swallowing these cysts that man is infected. They do not resist drying, but retain their vitality for two weeks if kept moist in the faeces or in water. They can therefore be transmitted by direct contamination with faeces, through handling soiled linen, by flies carrying them to food, by soil or by drinking contaminated water; and prophylaxis must be directed accordingly. The cysts pass through the stomach unchanged; in the small intestines they germinate, and amoebulae are set free. These grow, divide and penetrate into the submucous layer of the large bowel where they continue to proliferate and destroy the tissue, thus leading to haemorrhage and outpouring of mucus. Locally, a flask-shaped ulcer is formed, with roughened undermined edges at the orifice, and such ulcers are frequently joined by submucous tunnels.

Symptoms.—Clinically the disease is characterized by its chronicity and tendency to recrudescence. The onset is insidious, the sufferer first noticing debility and lassitude with an increase of stools, soft and mixed with blood and mucus. These may clear up after a few days and be the only signs noticed, or may recur months later. Most often the initial stage is followed by an acute exacerbation of symptoms, dependent in their degree upon the extent of the ulceration in the large bowel, the most markedly affected sites being the entire colon, the caecum, flexures and appendix, sigmoid and rectum. Stools become still more frequent, even up to 40 or 50 in 24 hours, and the ulceration gives rise to abdominal pain and, if at the rectum, to severe tenesmus. In uncomplicated cases there is but slight rise of temperature or other symptoms of toxaemia as the entamoeba produces no toxin. Diagnosis is quickly made by microscopical examination of the stools.

Occasionally infection with other bowel organisms supervenes, and gangrene may follow, or the amoebae may perforate the large bowel, giving rise to peritonitis, or, penetrating a blood-vessel and being conveyed by the blood stream they may cause an abscess in the liver, or, most exceptionally, in the brain or lung. Healing is brought about by the development of fibrous tissue at the sites of the ulcers.

Treatment.- he specific treatment is ipecacuanha, or its alkaloid, emetine. Combined hypodermic injections of emetine hydrochloride with oral administration of ipecacuanha (Brazilian), or of bismuth subnitrate in large doses, to attack the amoebae from within and without have given striking results. The toxic action of emetine on the heart must be watched. Added to the specific treatment in acute cases there is the general and symptomatic, which may include an early free flushing of the bowel by a dose of castor oil with tinct. opii. added; later followed by magnesium (or sodium) sulphate in hourly or two-hourly half or drachm doses for 12 or **24** hours. Morphia may be necessary to relieve the abdominal pain and straining. The diet must be light and easily assimilated, and raw food should be withheld.

The symptoms subside in one to three weeks, the patient regains his general health after suitable convalescence and no further trouble may follow. However, not infrequently the scar tissue formed in healing leads to thickening of the bowel wall, partial loss of peristalsis or constriction producing chronic constipation; or again the entamoeba may persist in the lumen of the bowel, ready to enter its wall and renew symptoms when conditions so favour.

Therapy Notes.—Treatment to eliminate the entamoeba in its pre-cystic form from within the lumen of the bowel of the carrier is not yet on an equally satisfactory basis. Emetine hydrochloride injections have no effect upon it. An important measure to avoid recrudescence is to maintain the general health and avoid indiscretions in diet. Intravenous injections and colonic lavage with neosalvarsan have been much used to supplement oral treatment by the French. Amoebic hepatitis and small abscess of the liver respond well to injections of emetine hydrochloride, but a large abscess needs surgical intervention. **A** carrier should, if possible, live in the temperate zone.

BACILLARY DYSENTERY

While sharing with the amoebic the clinical dysenteric syndrome above described, it differs therefrom by the shortness of the incubation period, generally **24** to 72 hours, its acute onset with fever that may persist several days or more, and other symptoms of toxaemia; extreme contagiousness; seasonal prevalence (midsummer and autumn); epidemic character and incidence in temperate regions, where the amoebic type is practically limited to sporadic cases; higher death-rate. It also differs in the complications that may follow infection more especially with B. *dys. Shiga,* namely: arthritis, fibrositis, conjunctivitis, muscular paralysis and myocarditis. Clinically it may vary from mild to severe, and occasionally be hypertoxic, typhoidal or ulcero-gangrenous. Outbreaks of dysentery in asylums, prisons, concentration camps and ships are generally bacillary in type.

The bacillary dysentery group comprises:—

1. B. *dys. Shiga,* containing endotoxins pathogenic to man and experimental animals.

2. *B. dys. Schmitz,* containing endotoxins acting severely on rabbits but much less pathogenic to man. Its incidence is rare.

3. *B. dys. Flexner-Hiss,* heterogeneous group fermenting mannite and producing indol from peptone. It contains many species recently distinguished by agglutination and absorption reactions.

4. A further group rarely found and having specific agglutination and absorption properties and power to ferment certain sugars; *e.g., Bacillus* of *Strong, Castellani, Gay, d'Hérelle* and others, each capable of producing a mild, clinically dysenteric syndrome in man.

Symptoms. — Clinical symptoms vary, as do the degree of the intestinal lesions and the toxicity of the causal bacillus. Infections with B. *dys. Shiga* are the most severe. The ulcerative lesions are not confined to the large bowel but extend one to two feet up into the small intestine. The bacilli pass through the stomach, multiply in the small intestine and produce at least two toxins which are absorbed into the blood, one acting on the nervous system and the other excreted into the large bowel, causing inflammation with coagulation of lymph, thrombosis of vessels and necrosis of the submucous layer and superimposed mucous membrane. The bacilli proliferate on the bowel wall, diphtheritic-like membrane, forms and separates off, leaving superficial ulcers with raised, red, oedematous edges. These may deepen by continued microbic action and even perforate, leading to peritonitis, or gangrene may set up in the damaged necrosed tissue, and in either case death follows unless surgical intervention is early. Repair proceeds along the same lines as in amoebic cases, but, the ulcers being generally more superficial, the permanent damage is not so great.

The stools have a characteristic microscopic appearance, as numerous pus and epithelia1 cells and large, macrophage cells are present in the mucus. Microscopically the stool most often consists of mucus, like cloudy-grey jelly streaked or stained by bright red blood, or the mucus may be bile-stained in a diarrhoea-like stool, or, in very severe cases, there are shreds of necrosed mucosa.

Treatment. — In bacillary dysentery the patient is much more ill than in amoebic, and treatment is directed to neutralizing the toxins which act strongly on the heart and other vital organs, and elimination of the micro-organism from the intestines. Infections with *B. dys. Shiga* are outstandingly the most severe, and it is the anti-Shiga serum which is the most efficacious. It has also been used in severe cases due to B. *dys. Flexner-Hiss* with some success. A serum prepared by inoculating strains of both these groups of micro-organisms has been extensively used in cases of either infection. The injections should be given as early in the disease as possible and in large doses, *e.g.,* 60c.c., 40c.c., 20c.c., on successive days in a severe case; saline aperients until the stools become faecal should be given frequently. Heart stimulants may be needed. Diet as above. Thereby amelioration is rapid, sequelae rare, the bacillus early eliminated and convalescent carriers much more rare than after amoebic dysentery, and the bowel wall is not so often permanently damaged. After an attack careful dieting is needed.

Prophylaxis. — The general prophylactic measures are the same as those against infections with E. *histolytica.* Dependent on several factors, bacillary is more contagious than amoebic dysentery. Inoculations with a vaccine of *B. dys. Shiga* were made in epidemic areas in the World War. Its contained toxins give rise to acute local reactions unless modified prior to inoculation by special methods. These series of inoculations made by various workers gave encouraging results. Vaccine-therapy employed to rid the convalescent carrier of *B. dys. Shiga* has not been successful. In striking contrast with B. *dys. Shiga* the killed and untreated emulsions of the *B. dys. Flexner-Hiss* group give rise to no reaction, even in high doses.

Spirochaetic Dysentery. — This is due to *Spirochaeta eurygyrata* (Le Dantec 1900, Werner 1910). Evidence is increasing that this spirochaeta is capable of giving rise to an acute condition with passage of blood and mucus or, more frequently, of maintaining a chronic or intermittent mild form of dysentery. It is never found free in faecal matter but only in mucous shreds excreted, in the detached crypts and occasionally within the lining epithelial cells of the mucous membrane. Many observers consider that it proliferates and gains a footing on a bowel damaged by the entamoeba. It is a rare form of dysentery but has a wide endemic distribution in tropical and subtropical countries. Treatment of the very rare acute condition is by frequent saline aperients. In its chronic form best results have followed enemata containing oil of eucalyptus, or by calomel followed by a saline aperient or by Slovarsol.

Helminthic Dysentery. — The chief helminths which give rise to dysentery are the bilharzia worms, *Schistosoma mansoni,* in Africa, South America, West Indies and *Schistosoma japonicum* in the Far East. Another trematode which may cause dysenteric symptoms is *Fasciolopsis buski,* found in China, Assam and India. Thymol or beta-naphthol are used in treatment of this latter.

Infections with hookworm *(see* HOOKWORM), *Ankylostoma duodenale,* are widely distributed in tropical lands and extend to subtropical regions. In such infections blood and mucus are sometimes passed in large quantities and these cases may be mistaken for true dysentery.

Ciliar dysentery due to *Balantidium coli* is a form of dysentery that has been found in Europe, Japan and the Philippine Is., but rarely elsewhere. An investigation of a number of habitants of Utuado, Porto Rico, led to the detection of many carriers without symptoms. The ciliar form of dysentery is rarely seen outside endemic regions.

Carriers. — A certain number of cases of dysentery become convalescent carriers, harbouring the parasite in the intestine with or without obvious activities on the host. The contact or healthy carrier may have no signs past or present. Neither type of carrier is common in the bacillary form, but both are not very uncommon in amoebic dysentery.

GENERAL CONCLUSION

Epidemiology. — Dysentery is markedly more frequent in hotter countries and tends to arise in subjects of lowered body resistance. The disease appears in its most devastating epidemic form in armies, fugitives, refugees and pioneers, and vanishes before the comfort and prosperity of a well-fed and settled people, especially when living under favoured climatic and sanitary conditions. During the World War, its incidence was great in all armies, especially those fighting in tropical countries where the conditions favoured it, and in parts of eastern Europe where sanitary control was not scrupulously exercised. On the Gallipoli Peninsula, nearly every soldier who landed suffered from dysentery or diarrhoea, and few escaped the former disease. Severity of the climatic conditions, difficulties of obtaining adequate food and sterilized water, fly pests, fatigue, hastily improvised resting places and sanitary arrangements, prolonged periods in trenches, were the important factors conducive to infection. The comparatively small death roll was due to the knowledge that dysentery may be due to diverse organisms, each having a specific line of treatment. Most deaths were due to *B. dys. Shiga* infections.

Incidence. — In most temperate zones the incidence of dysentery is practically limited to occasional small outbreaks of the bacillary form, to sporadic cases of this or of the amoebic form due to infection from a patient or carrier, and to cases that have been infected in tropical or subtropical lands or under war and such like conditions of life; but in hot climates these forms of dysentery normally claim a very high incidence and death rate, approximating to that of malaria.

To show the benefit arising from applied research it suffices to mention that amoebic dysentery, once so prevalent in the Panama Canal Zone, is now uncommon there, while in the Malay States, where bacillary dysentery is the more frequent form, there has been an increasing fall in the number of cases and death rate.

DYSON, SIR FRANK WATSON (1868–1939), British astronomer, was born at Ashby-de-la-Zouch, Leicestershire, on Jan. 8, 1868, and was educated at Bradford Grammar School and Trinity College, Cambridge, where he was second wrangler and Smith's Prizeman. In 1894 he became chief assistant at the Royal Observatory, Greenwich, and in 1905 was made astronomer royal of Scotland, a position which he held until his return to Greenwich as astronomer royal of England (1910–33). From 1899 to 1905 he was secretary of the Royal Astronomical Society. He was elected F.R.S. in 1901, subsequently serving on the council, and was in 1921 awarded the royal medal for his numerous contributions to astronomy, and especially for his important investigations of the distribution and movements of stars and the bearing of these upon the structure of the stellar universe. His observations of the spectrum of the corona and chromosphere during eclipses of the sun were published in Determination of Wave Length from Spectra Obtained at the Total Solar Eclipses of *1900, 1901 and 1905* (1906). Knighted in 1915, he was created R.B.E. in 1926. He also wrote Astronomy, *a* handy *manual* for *students* and others (1912), and many valuable contributions to the *Quarterly Journal* of Mathematics, etc.

DYSPEPSIA or **INDIGESTION,** a term vaguely given to a group of pathological symptoms. Dyspepsia may occur in almost any organic disease of moment, particularly if it involves the alimentary canal, but here the term is used to describe derangement of the natural process of digestion, without obvious change in the organs concerned in the act.

The condition may depend on (a) the food, and (b) the organism. In respect of food common causes are indigestible articles of diet, over-eating, irregular and over-hasty meals, insufficient mastication especially of smoked or salted meat, whether from haste or poor dentition. Drinks are a common source of dyspepsia, particularly new beer, vinegar, acid wines and tea. Even too much water at mealtimes may cause indigestion, since the food in the mouth is softened by water instead of saliva, and, the gastric juice being diluted, digestion in the stomach is too slow and prolonged. Mention must also be made of chronic alcoholism and excessive tobacco smoking.

Of the causes which concern the organism, nervous influences come first. Crises in the money market are a fertile source of dyspepsia among financiers. Bad news, worry or mental trouble may take away all power of digestion and even provoke vomiting. General weakness and atony affect the stomach also, and, if the muscles of the abdominal wall be much wasted, they fail to support the abdominal viscera. Hence results a general tendency for these organs to fall (visceroptosis), when an obstinate dyspepsia is a very marked feature. Again, dyspepsia is often one of the early symptoms of renal disease, or, in young people, of pulmonary tuberculosis. In fact, any condition which lessens the general well-being of the organism as a whole, apart from its producing a permanent morbid condition in the stomach, may yet interfere with the normal digestive processes and so give rise to dyspepsia.

Symptoms.—A furred tongue, foul breath, disturbance of appetite, nausea and vomiting, oppression in the chest, pain, flatulence and distension, acidity, pyrosis and constipation or diarrhoea are the commonest symptoms.

When the attack is acute, *e.g.*, a few hours after a heavy meal following severe exertion, there is often pain with sickness and vomiting, after which the patient soon regains his former healthy state. In chronic cases the symptoms are somewhat different. A sensation of discomfort comes on shortly after a meal, and is more of the nature of weight and distension in the stomach than of actual pain, although this too may be present. These feelings may follow each meal, or only certain meals, and they may arise irrespective of the kind of food taken, or only after certain articles of diet. The stomach is dilated and lactic acid fermentation of the contained food leads to accumulation of gases which causes flatulence and eructations of an acid or foul character. Occasionally quantities of hot, sour, tasteless or bitter fluid—pyrosis—or mouthfuls of half-digested food, regurgitate from the stomach. Temporary relief may be obtained when another meal is taken, but soon the discomfort returns as before. The appetite may be craving or deficient, or desirous of abnormal kinds of food. Constipation is more common in the chronic forms of dyspepsia, diarrhoea in the acute.

Symptoms in other parts are often more distressing than the merely gastric symptoms. Pains in the chest, shortness of breathing, palpitation, headache, giddiness, affections of vision, coldness of the extremities, and general languor are common accompaniments of dyspepsia; the nervous phenomena include sleeplessness, irritability, despondency and hypochondriasis.

Treatment.—Experience has shown that no particular kind of food or avoidance of food is absolutely to be relied on; in general the best diet is one of a mixed animal and vegetable kind, simply but well cooked. Highly-seasoned or salted meats, raw vegetables, newly-baked bread, pastry and confectionery are all well-known common causes of dyspepsia, and should be avoided. When even a simple diet is found to disagree it may be necessary to change it temporarily for a milk diet, and that even in very moderate quantity. Alcohol in small doses is usually beneficial in atonic dyspepsia of the aged, but in the young, and particularly in acute gastric conditions, it is injurious.

The medicinal treatment of dyspepsia can only be undertaken by a physician, but the following is a very brief résumé of the drugs he depends on. Bicarbonate of soda with some bitter, as quassia, gentian or columba, is much in vogue as a direct gastric stimulant. In irritable dyspepsia some form of bismuth in solution or powder; and, to assist digestion through the nervous system, nux vomica and strychnine can be relied on. Hydrochloric acid, pepsin and rennet are prescribed in many forms, but where there is much vomiting ingluvin is more efficacious than pepsin. When starchy food is badly borne, diastase is helpful, given either before or with the meal. To prevent fermentation, phenol, creosote and sulpho-carbolate of soda are all extremely useful in skilled hands; and for intestinal decomposition and flatulent distension, bismuth salicylate with salol or β-naphthol is much used.

DYSPROSIUM is a metallic element belonging to the rare-earth group. In 1886 de Boisbaudran deposited a sealed paper with the Académie des Sciences; this was opened at a later date and read at the writer's request. It contained the statement that a new element possessing a characteristic absorption spectrum had been separated from crude holmia. The oxide was obtained pure for the first time in 1906 by G. Urbain. This element occurs along with erbium, holmium, etc., in the minerals gadolinite, euxenite, xenotime, etc. Its symbol is Dy, atomic number 66, and atomic weight 162.5. It is best obtained free from its congeners by the fractional crystallization of the bromates. The white oxide dissolves in many acids forming yellowish-green solutions which show a strong absorption spectrum. The salts of this metal possess the highest magnetic susceptibility of all salts. See RARE EARTHS. (C. J.)

DYSTELEOLOGY, a modern word invented by Haeckel (*Evolution* of Man) for the doctrine of purposelessness, as opposed to the philosophical doctrine of design (Teleology).

DYVEKE: see *s.v.* CHRISTIAN II., KING OF DENMARK.

DZERZHINSKY, FELIX EDMUNDOVICH (1877–1926), Russian politician of Polish descent, was born at Vilna. He joined the Social Democratic Party of Lithuania in 1895, and two years later was arrested and banished to Siberia for political agitation. In 1899 he escaped, was rearrested in the following year and in 1902 again escaped. After he had taken part in the revolution of 1905 there followed further years of banishment until 1912, when he returned to Warsaw, was arrested again and sentenced to nine years hard labour. After the revolution of March 1917, he was released and became a member of the military revolutionary committee which organized the Bolshevik revolution. In Dec. 1917 he organized and became chairman of the Cheka, or secret police, afterwards the Ogpu. He was appointed commissar of the home department in 1919. The organization of the Cheka was found to be so complete that it was possible to dispense with Dzerzhinsky's supervision and in 1921 he was transferred to the commissariat of transport, where

he carried out an exhaustive reform of the railways. In 1924, after the party dispute on policy at the time of Lenin's death, Dzerzhinsky was placed at the head of the supreme economic council. He died in July, 1926.

DZUNGARIA, DSONGARIA or JUNGARIA, a former Mongolian kingdom of central Asia, raised to its highest pitch by Kaldan or Bushtu Khan in the latter half of the 17th century, but completely destroyed by Chinese invasion about 1757–59. It derived its name from the Dsongars, or Songars, who were so called because they formed the left wing (dson, left; gar, hand) of the Mongolian army. Its widest limit included Kashgar, Yarkand. Khotan, the whole region of the T'ien Shan (or Tian-shan) mountains, and the greater proportion of that part of central Asia which extends from 35° to 50°N. and from 72° to 97°E. The name, however, is more properly applied only to the later Chinese province of T'ien-Shan-pei-lu and the country watered by the Ili. As a political or geographical term it has practically disappeared from the map.

E the fifth letter of the alphabet, answers to Semitic 𐤄, Greek Ε or Ε, Latin E. Forms in use at Corinth were Ε or Β. The Lydian form was 𐤄 and there was an alternative form 𐤄 in use in the Faliscan and Latin alphabets. The uncial form was from the 4th century A.D. rounded Ε and the cursive form was also round, ℯ. From these developed the Carolingian e from which the modern minuscule *e* is derived.

The sound represented by the letter was a low front vowel corresponding, though inexactly, to the sound of English *a* in *take*. The latter is a diphthong, whereas *e* represented an unmixed vowel sound, such as that heard in French *tête* or *été*. In Greek

THE DEVELOPMENT OF THE LETTER "E" FROM THE PHOENICIAN THROUGH CLASSICAL LATIN TO THE PRESENT FORM

ε stood for a short, close vowel as opposed to η whose sound was long and open, although in all local alphabets, especially in early times, this distinction was not exactly observed. In Attic Greek the long, close sound was expressed by EI. In the Latin alphabet the letter E did duty for all shades of the sound, long or short, close or open.

In English an extensive change has taken place in the sound of the long vowel during and since the later Middle English period (probably between the 11th and 17th centuries). Just as the sound represented by *a* moved forward till it now covers the ground of that formerly represented by *e*, so the latter moved upward, encroaching upon and occupying the territory of the sound of *i*, which became a diphthong. The sound of English long e is now a close high palatal vowel, as in *be*, that of short *e* a more open and less high front vowel, as in *bed*, that has not to any great extent shifted from what may be called its original position (cf. the sounds of French *été* and English *bed*). When followed by *r* the sound is modified and is less high, as in *here*. In the word *there* the vowel has the same sound as that of a in *hare*. In many English words a mute final *e* is employed as a device to mark the fact that the preceding vowel is long, e.g., *take*, *wine*, *stone*. This occurs only when the final *e* is separated from the long vowel by a single consonant. Again, in words such as *added*, *rotten*, the letter represents little more than a voice glide.

In music, E is the fifth note of the musical alphabet and the third degree of the "natural scale" of C. Its syllabic name, employed in France and Italy, is mi.

EA (written by means of two signs signifying "house" and "water"), in the Babylonian religion, was the god of wisdom and patron deity of Eridu, situated in ancient times at the head of the Persian Gulf but now at some distance from the gulf. Eridu, "the good city," was one of the oldest settlements in the Euphrates valley, and is now represented by the mounds known as Abu Shahrein. Whether Ea (or A-e) represents the real pronunciation of his name we do not know. The name is rendered by Ἀός in the theogonies of Damascius, and by Ὡάννης in the fragments of Berossus. All attempts to connect Ea with Yah and Yahweh are idle conjectures without any substantial basis. The original Sumerian name of this god is En-Ki, "Lord of the earth," referring to his abode in the *Apsu*, or nether sea, from which springs and rivers were supposed to flow. He is never connected with the salt water seas. Ea is not found earlier than the 22nd century. He is figured as a man covered with the body of a fish, and this representation, as likewise the name of his temple E-apsu, "house of the watery deep," points decidedly to his character as a god of the waters (*see* OANNES). Of his cult at Eridu, which reverts to the oldest period of Babylonian history, nothing definite is known. Incantations, involving ceremonial rites, in which water as a sacred element played a prominent part, formed a feature of his worship. Eridu never played an important political rôle. The prominence of the Ea cult led to the survival of Eridu as a sacred city, long after it had ceased to have any significance as a political centre, *c.* 2200 B.C. Myths in which Ea figures prominently indicate that Ea was regarded as the protector and teacher of mankind. He is essentially a god of civilization, the creator of man and of the world in general. Traces of this view appear in the Marduk epic celebrating the achievements of this god, and the Ea cult at Eridu is connected with that of Marduk, since Marduk is generally termed the son of Ea who derives his powers from the voluntary abdication of the father in favour of his son.

Ea acquires his permanent place in the pantheon as the third figure in the triad, the two other members of which were Anu (*q.v.*) and Enlil (Bêl). To him was assigned the control of the watery element, and in this capacity he becomes the *shar*

apsi, i.e., king of the Apsu or "the deep," an ocean beneath the earth. Since the gathering place of the dead, known as Arālu, was situated near the confines of the Apsu, he was also designated as En-Ki, *i.e.,* "lord of that which is below," in contrast to Anu, who was the lord of the "above" or the heavens. The cult of Ea extended throughout Babylonia and Assyria. Temples and shrines were erected in his honour, *e.g.,* at Nippur, Girsu, Ur, Babylon, Sippar and Nineveh, and the numerous epithets given to him, as well as the various forms under which the god appears, alike bear witness to the popularity which he enjoyed from the earliest to the latest period of Babylonian-Assyrian history. The consort of Ea, known as Damkina, "lady of that which is below," or Nip-Ki, having the same meaning, or Damgal-nunna, "great lady of the prince," plays a part merely in association with her lord.

BIBLIOGRAPHY.—Tentative excavations were made at Eridu in 1919 by H. *R.* Hall, *see* "Ur and Eridu," *Journal of Egyptian Archaeology,* IX. (1923), and in 1918 by R. Campbell Thompson, *The British Museum Excavations at Abu Shahrein, Archaeologia LXX.* (1920).

EACHARD, JOHN (1636?–1697), English divine, was born in Suffolk, and was educated at Catharine Hall, Cambridge, of which he became master in 1675 in succession to John Lightfoot. He was twice *(1679* and *1695)* vice-chancellor of the university. He died on July *7, 1697.* In 1670 he had published anonymously a humorous satire entitled *The Ground and Occasions of the Contempt of the Clergy enquired into in a letter to R. L.* He attacked the philosophy of Hobbes in his *Mr. Hobb's State of Nature considered in a dialogue between Philautus and Timothy* (1672), and in his *Some Opinions* of *Mr. Hobbs considered in a second dialogue (1673).*

See his *Works* (3 vols., 1774). The *Contempt of the Clergy* was reprinted in E. Arber's *English Garner.*

EADBALD (ĕd'bawld) (d. 640), king of Kent, succeeded on the death of his father Aethelbert in *616.* He had not been influenced by the teaching of the Christian missionaries, and on his accession he followed the heathen custom and married his father's widow. After his subsequent conversion by Laurentius, archbishop of Canterbury, he recalled the bishops Mellitus and Justus, who had fled from his persecution, and built a church dedicated to the Virgin at Canterbury. He arranged a marriage between his sister Aethelburh and Edwin of Northumbria, on whose defeat and death in *633* he received his sister and Paulinus, whom he had sent with her, and offered the latter the bishopric of Rochester. After his conversion Eadbald ceased to live with his first wife, and married Emma, a Frankish princess. He died on Jan *20, 640.*

See Bede, *Historia ecclesiastica* (ed. *C.* Plummer, *1896);* *Saxon Chronicle* (ed. *J.* Earle and C. Plummer, *1899).*

EADMER or **EDMER** *(c.* 1060–1124), English historian and ecclesiastic, was probably of English parentage. At the monastery of Christ Church, Canterbury, he met Anselm, to whom he served as assistant when Anselm became archbishop of Canterbury in 1093. In 1120 he was nominated archbishop of St. Andrew's, but the Scots refused to recognize the authority of Canterbury. He died probably in 1124. His most important work is the *Historiae Novorum,* dealing with the history of England, mainly ecclesiastical, between 1066 and *1122.* It was first edited by John Selden in *1623.* Together with his *Vita Anselmi* (first printed in Antwerp in 1551) it was edited by M. Rule for the Rolls Series (London, *1884).* He also wrote lives of St. Dunstan and St. Oswald which are printed in Henry Wharton's *Anglia Sacra* part *2,* (1691), which has also a list of his works. Most of his mss. are in the library of Corpus Christi college, Cambridge.

See M. Rule, *On Eadmer's Elaboration of the first four Books of "Historiae novorum" (1886);* and Père Ragey, *Eadmer (1892).*

EADS, JAMES BUCHANAN (1820–1887), American engineer, was born at Lawrenceburg (Ind.), on May 23, *1820.* His first engineering work of any importance was in raising sunken steamers. In *1845* he established glass works in St. Louis. During the Civil War he constructed ironclad steamers and mortar boats for the Federal Government. His next important engineering achievement was the construction of the great steel arch bridge across the Mississippi at St. Louis upon which he was engaged from *1867* till *1874.* The work, however, upon which his reputation principally rests was his deepening and fixing the channel at the mouths of the Mississippi by means of jetties, whereby the narrowed stream was made to scour out its own channel and carry the sediment out to sea. Shortly before his death he projected a scheme for a ship railway across the isthmus of Tehuantepec, in lieu of an isthmian canal. He died at Nassau, in the Bahamas, on March *8, 1887.*

EAGLE, the name given to the larger diurnal birds of prey which are not vultures and which form the sub-family *Aquilinae.* They inhabit all regions of the world. Some seven or eight species inhabit Europe, of which only one is now resident in Britain.

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

AMERICAN EAGLE, THE NATIONAL EMBLEM OF THE UNITED STATES In the adult of this "bald" sea eagle, the head, neck and tail are white

The golden eagle *(Aquila chrysaetus)* inhabits the palaearctic and most of the nearctic regions. The plumage is dark brown, with the neck-feathers light tawny and the tail marbled with grey and lighter brown. It nests on cliffs, building a huge eyrie of sticks in which the female lays from two to four white eggs, mottled with red and purple. The same nest may be used year after year. The young are clad in white down. The Kirghiz Tartars use the golden eagle to capture antelopes. Allied species include the imperial eagle *(A. heliaca)* of Asia and south-east Europe; and *A. pennata* of southern Europe, Africa and India, which is the smallest of all eagles.

A second British species was the erne, sea-eagle or white-tailed eagle (*Haliaeetus albicilla*), which inhabits the whole of the northern part of the Old World, but has recently ceased to breed in Britain. The plumage is greyish-brown with a pale head, yellow beak and white tail. The nest resembles that of the golden eagle, but is more usually near water, for in addition to the hares, rabbits, grouse and other prey of *A. chrysaetus,* the erne eats fish and the refuse thrown up by the tide. Larger than either is *H. pelagicus* of eastern Asia, recognized by its white thighs and upper wing-coverts. Other species occur in south-east Europe, India, Malay, Australia, South Africa and Madagascar. All may be distinguished from the *Aquila* group by the bare, sealy tarsi.

In America the golden eagle is found from Labrador and interior Alaska to central Mexico, breeding in suitable localities throughout its range. The bald eagle (H. *leucocephalus*), the national emblem of the United States, is distributed from Maine to the coast of Alaska to northern Mexico, breeding throughout its range. Young birds in the first winter are streaked with brown and gray, much darker above. Later stages show heavy streaking of black and white on the under parts. Probably three years are required to attain adult plumage. Bald eagles are common in the lower Hudson valley when the river is frozen.

Local races of the bald eagle are *H. l. hypoleucus,* a paler subspecies found on Bering island, and the Alaskan H. *l. alascanus.*

The monkey-eating eagle (*Pithecophaga jefferyi*) is the largest of all eagles; it is related to the harpy (*q.v.*). It inhabits the Philippine Islands.

All eagles are remarkable for the power and stateliness of their flight, which is largely "soaring" in type, *i.e.,* the wings are not flapped, but kept stretched out, and the bird appears to float through the air.

See C. W. R. Knight, *The Golden Eagle (1927);* *F.* H. Herrick, *American Eagle* (1934).

EAGLE GROVE, a city of Wright county, Iowa, U.S.A., near the Boone river, 92 mi. N. by W. of Des Moines. It is served by the Chicago and North Western and the Chicago Great Western railways. The population in 1940 federal census was 4,024 It is

GOLDEN EAGLE WITH PREY

1 and **2.** A female golden eagle, trained for falconry, shown here killing a rabbit. Training an eagle is a formidable task. Owing to its extreme ferocity when deprived of its prey, and to its slowness in turning in the air, the attempt is seldom made to train the eagle for falconry

a railroad division point, and has car shops, cement works and butter and ice-cream factories.

EAGLEHAWK, a mining township of Bendigo county, Victoria, Australia, 105 mi. by rail N.N.W. of Melbourne and 4 mi. from Bendigo. Pop. (1933) 3,789. It stands on the Bendigo gold-bearing reef, and its mines are important. It has also spinning mills, a brewery, cordial works and a plaster sheet factory.

EAGLE OWL (Bubo bubo), a big owl inhabiting Europe and Asia, though only a straggler in most of Great Britain, and characterized by its large size and the two tufts of feathers on the head. It is allied to the great-horned owl (B. virginianus) of North America, but is larger. On the northwest coast of the United States the latter is represented by the dusky-horned owl (B. *v. saturatus*), a very dark-coloured race. The Arctic horned owl (B. v. subarcticus) is lighter coloured In Lower California there is a small, light-coloured race, the dwarf-horned owl (B. v. elachistus).

EAGLE PASS, a city of southwestern Texas, U.S.A., on the Rio Grande, opposite Piedras Negras, Mexico; a port of entry and the county seat of Maverick county. It is served by the Southern Pacific railway.

The population in 1920 was 5,765, of whom 2,711 were foreign-born white; in 1940 it was 6,459. Stock, feed and vegetables (notably spinach and onions) are raised in the surrounding country, and coal and gas are mined near by. The city was settled about 1846 and incorporated in 1908.

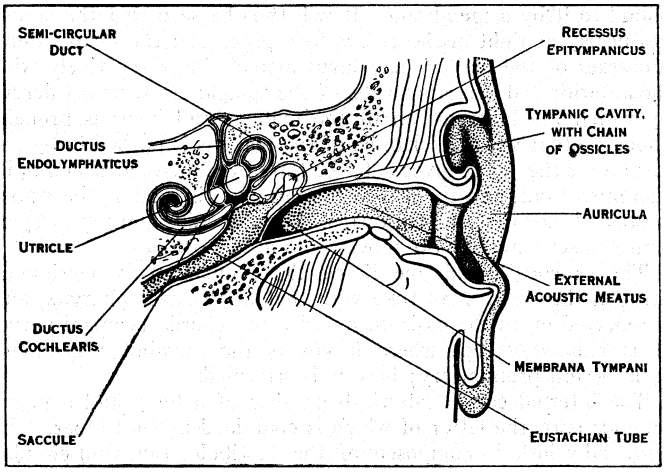
EAGRE: see BORE.

EAKINS, THOMAS (1844–1916), American portrait and figure painter, was born at Philadelphia, Pa., on July 25, 1844. A pupil of J. L. Gérôme, in the École des Beaux-Arts, Paris, and also of Léon Bonnat, besides working in the studio of the sculptor Dumont, he became a prolific portrait painter. He also painted genre pictures, sending to the Centennial exhibition at Philadelphia, in 1876, the "Chess Players," now in the Metropolitan Museum of Art, New York. A large canvas, "The Surgical Clinic of Professor Gross," owned by Jefferson Medical college, Philadelphia, contains life-sized figures. Eakins, with his pupil Samuel Murray (1870–1941), modelled the heroic "Prophets" for the Witherspoon building, Philadelphia, and his work in painting has a decided sculptural quality. He was for some years professor of anatomy at the schools of the Pennsylvania academy of fine arts in Philadelphia. A man of great inventiveness, he experimented in many directions, depicting on canvas modern athletic sports, the Negro, and early American life, but he is best known by his portraits. He died in Philadelphia on June 25, 1916.

EALPNG, a municipal and parliamentary borough of Middlesex, England, suburban to London, 9 mi. W. of St. Paul's cathedral, on the highroad to Uxbridge, served by the G.W.R. and the London Passenger Transport board. Pop. (est. 1938) 161,000. Area 13 98 sq.mi.

The borough was considerably enlarged in 1926 by the addition of the urban districts of Hanwell and Greenford, and further additions in 1928 made it one of the largest non-county boroughs. The parish church of St. Mary (rebuilt c. 1870) contains many interesting tombs. The church of All Saints (1905) commemorates Spencer Perceval, prime minister, who was assassinated in the house of commons in 1812 and who lived in Ealing. It was erected under the will of his daughter Frederica, a resident of Ealing. The tower of Holy Cross, Greenford, has a timber structure of the 12th century. Ealing has 979 ac. of parks, recreation grounds and open spaces under its control, including the ancient common (47 ac.), Walpole park (30 ac.), Pitshanger park (26 ac.) and others. Gunnersbury park (186 ac.), with two large mansions, was purchased in 1925 from the Rothschild family by the Ealing and Acton borough councils, with whom it is also shared by the borough of Brentford and Chiswick. Among former owners of the property was Princess Amelia, daughter of George II, who lived there from 1761 till her death in 1786. The name of Gunnersbury is said to be traceable to the residence here of Gunilda, niece of King Canute. The manor of Ealing early belonged to the see of London. Ealing, which was incorporated in 1901, has a technical institute and art school, It returns one member to parliament

EAR, ANATOMY OF. The human ear is divided into three parts—external, middle and internal. The external ear consists of the pinna and the external auditory meatus (fig. 1). The pinna is composed of yellow fibro-cartilage covered by skin. Round the margin in its upper three-quarters is a rim called the helix, in which is often seen a little prominence known as Darwin's tubercle, representing the folded-over apex of a prick-eared ancestor. Concentric with the helix and nearer the meatus is the antihelix which, above, divides into two limbs. In front of the antihelix is the deep fossa known as the concha, and from the anterior part of this the meatus passes inward into the skull. Overlapping the meatus from in front is a flap called the tragus, and below and behind this is another smaller flap, the antitragus. The lower part of the pinna is the lobule, which contains no cartilage. The pinna can be slightly moved by the anterior, superior and posterior auricular muscles. The external auditory meatus (fig. 1) is a tube about an inch long, its outer third being cartilaginous and its inner two-thirds bony. It is lined by skin in its whole length, the sweat glands of which are modified to secrete the wax or cerumen Internally it is closed by the tympanic membrane.



FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY," PERMISSION THE OXFORD MEDICAL PUBLICATIONS

FIG. 1.— DIAGRAMMATIC VIEW OF THE ORGAN OF HEARING, SHOWING THE RELATIONS OF THE EXTERNAL, THE MIDDLE AND THE INTERNAL EAR

The middle ear or tympanum (fig. 1) is a small cavity in the temporal bone. The Eustachian tube runs thence forward, inward and downward, to open into the nasopharynx, and so admits air into the tympanum. From the upper part of the posterior wall of the tympanum, an opening leads backward into the mastoid antrum and so into the air-cells of the mastoid process. Lower down is a little pyramid which transmits the stapedius muscle, and at the base of this is a small opening for the chorda tympani to come through from the facial nerve. The roof is formed by a very thin plate of bone, which separates the cavity from the middle fossa of the skull. Below the roof the upper part of the tympanum is somewhat constricted off from the rest, and to this part the term "attic" is often applied. The floor is a mere groove formed by the meeting of the external and internal walls. The outer wall is largely occupied by the tympanic membrane (fig. 1), which entirely separates the middle ear from the external auditory meatus; it is circular, and so placed that it slopes from above, downward and inward, and from behind, forward and inward. Externally it is lined by skin, internally by mucous membrane. while between the two is a firm fibrous membrane, convex inward about its centre to form the umbo.

The inner wall shows a promontory caused by the cochlea and grooved by the tympanic plexus of nerves; above and behind it is the fenestra ovalis, while below and behind the fenestra rotunda is seen, closed by a membrane. Curving round, above and behind the promontory and fenestrae, is a ridge caused by the aqueductus Fallopii or canal for the facial nerve. The whole tympanum is about half an inch from before backward, and half an inch high, and is spanned from side to side by three small bones, of which

the malleus is external. This is attached by its handle to the umbo of the tympanic membrane, while its head lies in the attic and articulates posteriorly with the upper part of the next bone or incus. The long process of the incus runs downward and ends in a little knob, the os orbiculare, jointed on to the stapes or stirrup bone. The two branches of the stapes are anterior and posterior, while the footplate fits into the fenestra ovalis and is bound to it by a membrane. It will thus be seen that the stapes lies nearly at right angles to the long process of the incus. Bony processes of the malleus and incus articulating respectively with the anterior and posterior walls of the tympanum form a fulcrum by which the lever action of the malleus and incus is brought about, so that when the handle of the malleus is pushed in by the membrane the head moves out; the top of the incus, attached to it, also moves out, and the os orbiculare moves in, and so the stapes is pressed into the fenestra ovalis. The stapedius and tensor tympanic muscles modify the movements of the ossicles.

The mucous membrane lining the tympanum is continuous through the Eustachian tube with that of the naso-pharynx, and is reflected on to the ossicles, muscles and chorda tympani nerve. It is ciliated except where it covers the membrana tympani, ossicles and promontory; here it is stratified.

The internal ear or labyrinth consists of a bony and a membranous part, the latter of which is contained in the former. The bony labyrinth is composed of the vestibule, the semi-circular canals and the cochlea. The vestibule lies just internal to the posterior part of the tympanum, and there would be a communication between the two, through the fenestra ovalis, were it not that the foot-plate of the stapes blocks the way. The inner wall of the vestibule is separated from the bottom of the internal auditory meatus by a plate of bone pierced by many foramina for branches of the auditory nerve (fig. 1), while at the lower part is the opening of the aqueductus vestibuli, by means of which a communication is established with the posterior cranial fossa. Posteriorly the three semicircular canals open into the vestibule; of these the external has two independent openings, but the superior and posterior join together at one end, while at their other ends they open separately. One end of each canal is dilated to form its ampulla. The superior semicircular canal is vertical, and the two pillars of its arch are nearly external and internal; the external canal is horizontal, its two pillars being anterior and posterior, while the convexity of the arch of the posterior canal is backward and its two pillars are superior and inferior. Anteriorly the vestibule leads into the cochlea (fig. 1, 4) which is

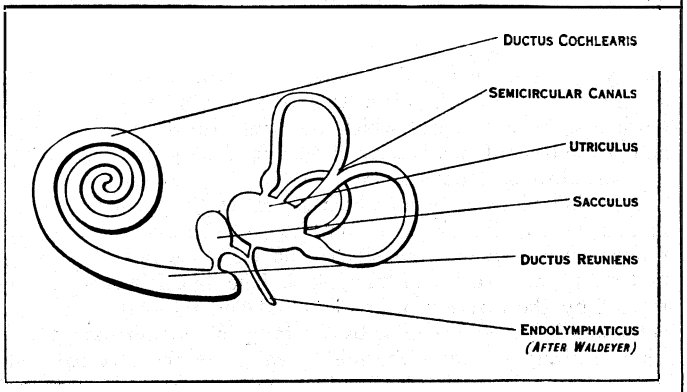


FIG. 2.— DIAGRAM OF THE DIFFERENT PARTS OF THE MEMBRANOUS LABYRINTH

twisted two and half times round a central pillar called the modiolus, the whole cochlea forming a rounded cone something like the shell of a snail though it is only about 5mm. from base to apex. Projecting from the modiolus is a horizontal plate (lamina spiralis) which runs round it from base to apex like a spiral staircase; it stretches nearly half-way across the canal of the cochlea and carries branches of the auditory nerve.

The membranous labyrinth lies in the bony labyrinth, but does not fill it; between the two is the fluid called perilymph, while inside the membranous labyrinth is the endolymph. In the bony vestibule lie two membranous bags, one of which, the saccule (fig. 2), is in front, and the other, the utricle, behind; each has a special patch or macula to which twigs of the auditory nerve are supplied, and in the mucous membrane of which are specialized hair cells (fig. 3).

Attached to the maculae are crystals of carbonate of lime called otoconia. The membranous semicircular canals are very much smaller in section than the bony; in the ampulla of each is a ridge, the crista acustica, which is covered by a mucous membrane containing sensory hair cells like those in the maculae. All the canals open into the utricle. From the lower part of the saccule runs a small canal called the ductus endolymphaticus (fig. 2). Anteriorly the saccule communicates with the membranous cochlea or scala media by a short ductus reuniens. A section obtained through each turn of the cochlea shows the bony lamina spiralis, already noticed, which is continued right across the canal by the basilar membrane (fig. 4), thereby cutting the canal into an upper and lower half, and connected with the outer wall by the strong spiral ligament. Near the free end of the lamina spiralis the membrane of Reissner is attached, and runs outward and upward to the outer wall, taking a triangular slice out of the upper half. There are now three canals seen in section; the upper is the scala vestibuli, the middle and outer scala media, ductus cochlearis or true membranous cochlea and the lower, the scala tympani. The scala vestibuli and scala tympani communicate at the apex of the cochlea, so that the perilymph can here pass from one canal to the other. At the base of the cochlea the perilymph in the scala vestibuli is continuous with that in the vestibule, but that in the scala tympani bathes the inner surface of the membrane stretched across the fenestra rotunda, and also communicates with the subarachnoid space through the aqueductus cochlea, which opens into the posterior cranial fossa. The scala media containing endolymph communicates with the saccule through the canalis reuniens, while, at the apex of the cochlea, it ends in a blind extremity of considerable morphological interest which is called the lagena.

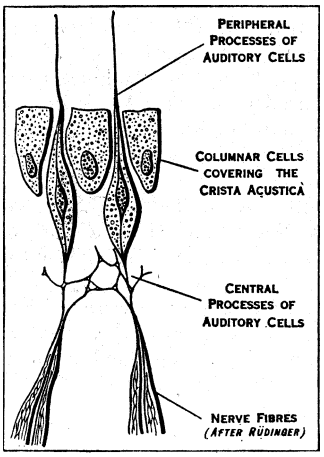

FIG. 3.— DIAGRAM OF AUDITORY NERVE CELLS AND PROCESSES

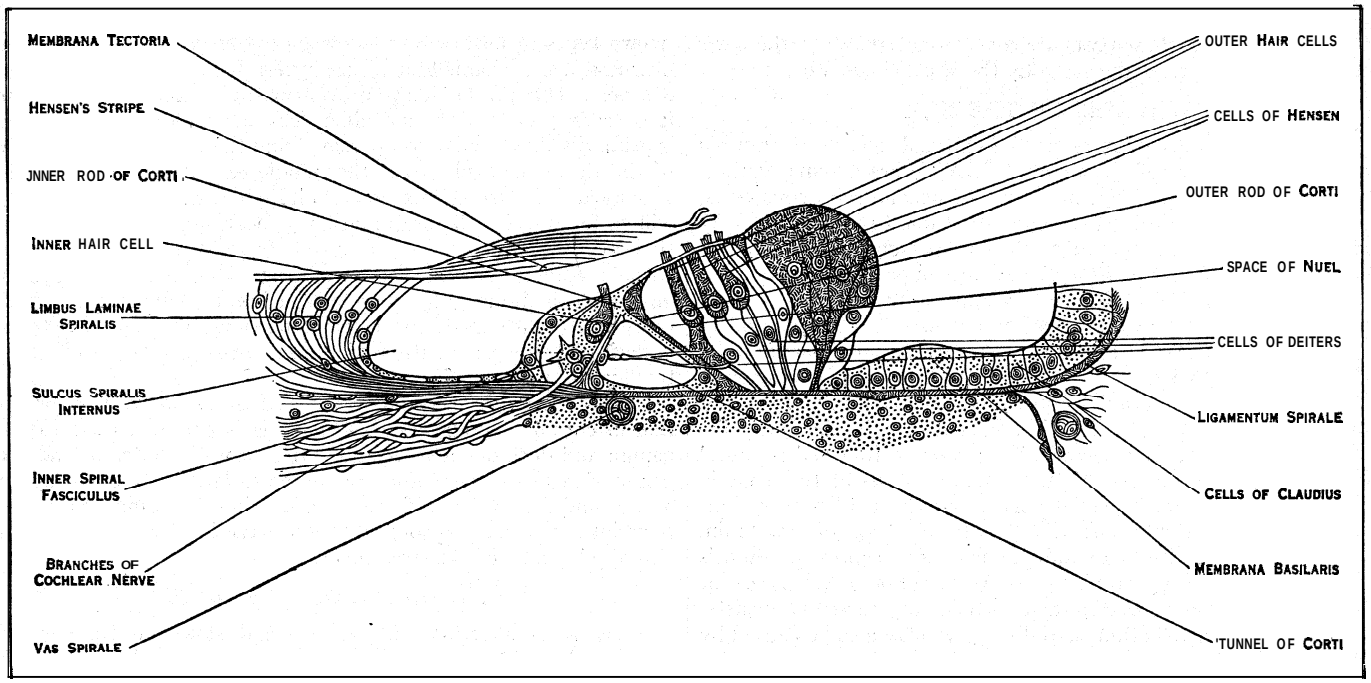
The scala media contains the essential organ of hearing or organ of Corti (fig. 4), which lies upon the inner part of the basilar membrane; it consists of a tunnel bounded on each side of the inner and outer rods of Corti; on each side of these are the inner and outer hair cells, between the latter of which are found the supporting cells of Deiters. Most externally are the large cells of Hensen. A delicate membrane called the lamina reticularis covers the top of all these, and is pierced by the hairs of the hair cells, while above this is the loose membrana tectoria attached to the periosteum of the lamina spiralis, near its tip, internally, and possibly to some of Deiters' cells externally. The cochlear branch of the auditory nerve enters the lamina spiralis, where a spiral ganglion (fig. 4) is developed on it; after this it is distributed to the inner and outer hair cells.

Embryology. — The pinna is formed from six tubercles which appear round the dorsal end of the hyomandibular cleft. Those for the tragus and anterior part of the helix belong to the first or mandibular arch, while those for the antitragus, antihelix and lobule come from the second or hyoid arch. The tubercle for the helix is dorsal to the end of the cleft where the two arches join. The external auditory meatus, tympanum and Eustachian tube are remains of the hyomandibular cleft, the membrana tympani being a remnant of the cleft membrane and therefore lined by ectoderm outside and entoderm inside. The origin of the ossicles is doubtful. H. Gadow's view is that all three are derived from the hyomandibular plate. The internal ear first appears as a pit from



FROM CUNNINGHAK, "TEXT-BOOK OF ANATOMY;" PERMISSION THE OXFORD MEDICAL PUBLICATIONS

FIG. 5. — TRANSVERSE SECTION OF CORTI'S ORGAN FROM THE CENTRAL COIL OF COCHLEA. SHOWING RODS AND HAIR CELLS

the cephalic ectoderm, the mouth of which in mammals closes up, to leave a pear-shaped cavity. The lower part of the vesicle grows forward and becomes the cochlea, while from the upper part three hollow circular plates grow out, the central parts of which disappear, leaving the margin as the semicircular canals. Subsequently constrictions appear in the vesicle marking off the saccule and utricle. From the surrounding mesoderm the petrous bone is formed by a process of chondrification and ossification.

Comparative Anatomy. — The ectodermal inpushing of the internal ear has probably a common origin with the organs of the

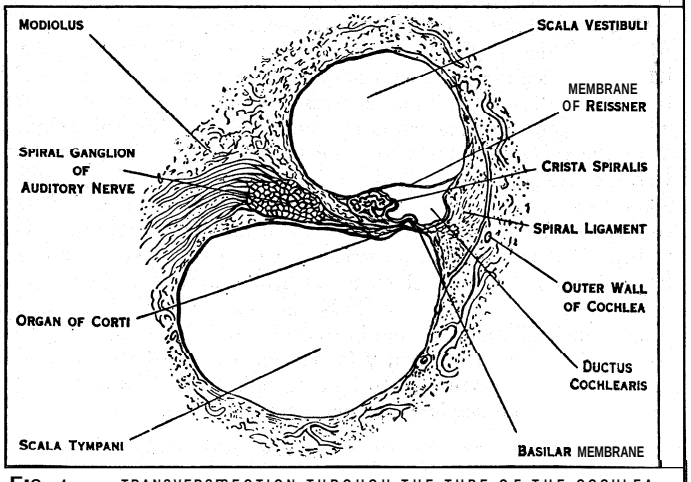


FIG. 4. — TRANSVERSE SECTION THROUGH THE TUBE OF THE COCHLEA, SHOWING PARTS

lateral line of fish. In the lower forms the ductus endolymphaticus retains its communication with the exterior on the dorsum of the head, and in some elasmobranchs the opening is wide enough to allow the passage of particles of sand into the saccule. In certain teleostean fishes the swim bladder forms a secondary communication with the internal ear by means of special ossicles. Among the Cyclostomata the external semicircular canals are wanting; *Petromyzon* has the superior and posterior only, while in *Myxine* these two appear to be fused. In higher types the three canals are constant. Concretions of carbonate of lime are present in the internal ears of almost all vertebrates; when these are very small they are called otoconia, but when, as in most of the teleostean fishes, they form huge concretions, they are spoken of as otoliths. One shark ***Squatina,*** has sand instead of otoconia. The utricle, saccule, semicircular canals, ductus endolymphaticus and a short lagena are the only parts of the ear present in fish.

The Amphibia (*q.v.*) have an important sensory area at the base of the lagena; it is probably the first rudiment of a true cochlea. The ductus endolymphaticus has lost its communication with the skin, but it is frequently prolonged into the skull and along the spinal canal, from which it protrudes, through the intervertebral foramina, bulging into the coelom. This is the case in the common frog. In this class the tympanum and Eustachian tube are first developed; the membrana tympani lies flush with the skin of the side of the head, and the sound-waves are transmitted from it to the internal ear by a single bony rod—the columella.

In the Reptilia the internal ear passes through a great range of development. In the Chelonia and Ophidia the cochlea is as rudimentary as in the Amphibia, but in the higher forms (Crocodilia) there is a lengthened and slightly twisted cochlea, at the end of which the lagena forms a minute terminal appendage. At the same time indications of the scalae tympani and vestibuli appear. As in the Amphibia the ductus endolymphaticus sometimes extends into the cranial cavity and on into other parts of the body. Snakes have no tympanic membrane. In the birds the cochlea resembles that of the crocodiles, but the posterior semicircular canal is above the superior where they join. In certain lizards and birds (owls) a small fold of skin represents an external ear. In monotremes the internal ear is reptilian, but above them the mammals always have a spirally twisted cochlea, the number of turns varying from one and a half in the Cetacea to nearly five in the rodent *Coelogenys.* The lagena is reduced to a mere vestige. The organ of Corti is peculiar to mammals, and the single columella of the middle ear is replaced by the three ossicles already described in man. In some mammals, especially Carnivora, the middle ear is enlarged to form the tympanic bulla, but the mastoid cells are peculiar to man.

EAR, NOSE AND THROAT, DISEASES OF THE. Though diseases of these parts are considered separately, the parts themselves are closely connected by the Eustachian tube.

I. DISEASES OF THE EAR

Diseases of the ear may affect the external, middle or internal ear. The commoner affections of the *auricle* are eczema, various tumours (simple and malignant), and serous and sebaceous cysts. Effusion of blood into the auricle is often due to injury, but may occur spontaneously, especially in insane persons. The chief diseases of the *external auditory canal* are impacted cerumen (or wax), boils, strictures due to inflammatory affections, bony growths, malignant disease, caries and necrosis, and foreign bodies.

Diseases of the *middle ear* are suppurative and non-suppurative, The former is either acute or chronic, and is accompanied by perforation of the drum-head and discharge from the ear. The chief importance of these affections, in addition to pain, deafness, discharge, etc., is that, if neglected, they may be followed by aural polypi, caries and necrosis of the bone, affections of the mastoid process, paralysis of the facial nerve, and the still more serious intracranial and vascular infective diseases of abscess in the brain, meningitis, subdural and extradural abscesses, septic thrombosis of the venous sinuses, and pyaemia. Acute suppurative disease of the middle ear is often due to the exanthemata, scarlatina, measles and smallpox, and to bathing and diving. It may also be caused by influenza, diphtheria and pulmonary tuberculosis.

Non-suppurative disease of the middle ear may be acute or chronic. In the acute form the inflammation is rarely accompanied by perforation. Chronic non-suppurative inflammations are moist, in which the symptoms are improved by inflation of the tympanum through the Eustachian tube, and dry (including sclerosis), which is intractable and not amenable to inflation. Diseases of the *internal ear* may be primary or secondary to an affection of the tympanum or to intracranial disease.

Injuries to any part of the ear may occur, among the commoner being injuries to the auricle, rupture of the drum head (from explosions, blows on the ear or the introduction of sharp bodies into the ear canal), and injuries from fractured skull.

Symptoms. — The chief symptoms of ear diseases are deafness, noises in the ear (tinnitus aurium), giddiness, pain and discharge. Deafness (or other disturbance of hearing) and noises may occur from disease in almost any part of the ear. Purulent discharge usually comes from the middle ear. Giddiness is more commonly associated with affections of the internal ear.

The researches of Arthur Cheatle have shown that in 80% of cases the mastoid process is composed very largely of air cells, that in the remaining 20% it is dense or acellular as in infants, that mastoid cells may develop in regions other than the mastoid process, and that persistence or excessive development of certain small veins in the inner wall of the mastoid antrum may favour the spread of infection leading to intracranial complications. These anatomical features may determine the symptoms and line of treatment to be adopted when disease attacks the temporal bone, particularly in inflammatory disease of the middle ear.

Of late the attention of otologists has been more than ever concentrated on the labyrinth, and particularly on its vestibular component. The internal ear or labyrinth comprises two essential structures, the cochlea which is to the ear what the retina is to the eye; the vestibular apparatus which subserves two important functions: (a) static (saccule and utricle) which has to do with the maintenance of equilibrium, (*b*) kinetic (saccule, utricle and semicircular canals) for the recognition and analysis of motion.

In health certain tests give results indicating a normal condition of the vestibular apparatus, *e.g.*, the pointing tests, nystagmic movements of the eyes after rotation of the patient and the employment of the caloric and electrical tests. These reactions are modified or absent when the vestibule is diseased. Hence the aural surgeon can explore the labyrinth and its immediate neighbourhood with minuteness. Consequently, certain types of vertigo, acute and chronic suppuration of the labyrinth with threatening symptoms of meningitis, and tumours of the auditory nerve, are often benefited by operation.

While little advance has occurred in the treatment of well-known types of insidious and slowly progressive forms of chronic deafness, it is probable that future generations will suffer less from deafness. This will be due to prevention rather than cure, because it is recognized that the so-called "chronic middle-ear deafness" is primarily due to infection passing from the nasopharynx by way of the Eustachian tubes into the middle ear cleft and its adnexa. Prophylactic measures in school clinics, child welfare centres, etc., will go far towards the preservation of hearing and in the prevention of complications apt to result from neglected acute and chronic suppuration of the middle-ear cleft, *e.g.*, meningitis, abscess of the brain and certain types of septicaemia. In the diagnosis and treatment of the latter conditions, valuable assistance is derived from examination of the cerebro-spinal fluid obtained by "lumbar puncture."

Finally, **A.** R. Friel has demonstrated the value of zinc ionization in chronic suppuration where sepsis is confined to the tympanum and does not involve the "attic" nor the antrum, and the perforation in the tympanic membrane is large enough to admit of the middle ear being filled with the ionizing fluid. Suppurations intractable and of long duration, have been cured by one or two applications of this treatment.

II. DISEASES OF THE NOSE

Apart from affections of the external skin and tumour-like overgrowth of the mucous membrane (polypi), deflection of the septum and plastic operations for correction of deformities, diseases of the nose are important from coincident infection of the air cells or sinuses.

In this connection also no organ or tissue of the body appears to be exempt from possible sub-infection by the organisms or their toxins if and when these are located in the antral, ethmoidal, frontal or sphenoidal sinuses. They gain entry into the system by inhalation or swallowing, or by the lymphatics or blood-vessels. This important subject was dealt with in the "Semon Lecture," University of London (1925), by Dr. Watson-Williams.

Treatment. — Formerly chronic suppuration involving the frontal sinus was treated by external operation; at present free and permanent drainage is attained through the nasal cavity and the result is much better.

One of the most intractable diseases of the nose is Foetid Atrophic Rhinitis (Ozaena). It is characterized by gradual wasting of the nasal mucous membranes and the bony structures which they cover. These atrophic changes are accompanied by the formation of foul-smelling crusts and not infrequently with a sinking in of the bony frame-work of the nose. Its cause has not been fully ascertained. Very similar effects are produced by syphilitic and tuberculous affections involving the bones of the nose. Hitherto surgeons have depended chiefly on local antiseptic applications and the daily use of cleansing washes. Recently better results have been obtained by surgical measures which aim at narrowing the nasal cavities by forcing inwards the inner walls of the antral sinuses and maintaining them in that position. Many cases appear to have been cured or greatly benefited. Lupus of the nasal mucous membrane has proved to be amenable to radium therapy.

(For hay fever, *see* **HAY** FEVER; ANAPHYLAXIS.)

III. DISEASES OF THE THROAT

The Tonsils. — This term is popularly applied to compact masses of lymphatic tissue situated between the anterior and posterior faucial pillars. Similar collections of lymphoid tissue are present in the nasopharynx and in the base of the tongue. The complete circle of this tissue is known as Waldeyer's Ring. It is present in all children and while it tends to undergo atrophy at puberty, this change often fails to take place.

Adenoids. — The term adenoids implies an overgrowth of the lymphoid mass in the nasopharynx which is sufficient in degree to produce symptoms. In health the collections of lymphoid tissue comprising Waldeyer's Ring are supposed to act as a first line of defence against invasion of the body by pathogenic micro-organisms. At the same time they offer an easy and open portal for infection. It is only necessary to mention the initial inflammation

of the tonsils and their immediate regions which herald an attack of scarlet fever, measles, diphtheria, influenza (frequently) and acute rheumatic fever. But when the components of the lymphoid ring become the seat of a chronic infection, or act as foci of sepsis, their potency for evil is equal to or even greater than that of the paranasal sinuses already referred to.

In respect of mental disease at the New Jersey State Hospital (Trenton) the number of discharged patients increased from 37 to 85% after removal of oral and tonsillar infections (H. A. Cotton, 1923). It is often forgotten that a small septic tonsil—especially in adults—frequently causes more definite symptoms in distant organs or tissues than large and prominent tonsils which are often only a cause of local discomfort. The modern practice of "enucleation" or complete rather than partial removal of the tonsils is based on the facts which are briefly outlined above.

Malignant Disease.—Both sarcomata and carcinomata are commonly met with. If left untreated they prove fatal, but if recognized and dealt with in their earlier stages they may be cured or afforded long periods of immunity from recurrence. Radiotherapy alone or combined with less radical surgery than formerly, has produced equally good if not better results than extensive surgical procedures by themselves *(see* RADIUM THERAPY).

Diathermy.—Under diathermy *(see* ELECTROTHERAPY) the operation is practically bloodless, the patient suffers no shock, scarring is slight and healing rapid. The coagulation by heat prevents dissemination of the cancer cells into the surrounding tissues which ordinary surgical manipulations may not be able to avoid. A dissection of the glands in the neck can be made before or after destruction of the primary growth.

Treatment by diathermy can only be carried out successfully when the growth is situated in readily accessible regions such as the mouth, soft palate, tonsillar regions, posterior wall of the pharynx and the epiglottis of the larynx. It is contra-indicated in the immediate neighbourhood of large blood-vessels, bone and cartilage. Hitherto "deep" X-ray therapy has not been successful for malignant disease in the throat or larynx.

Diseases of the Larynx.—Tuberculosis of the larynx is practically always secondary to a primary infection of the lungs, and its treatment has improved *pari passu* with that of the pulmonary lesion. Frequent inspection of the larynx, and the recognition of the earliest signs and symptoms of tuberculous laryngitis, followed by prolonged functional rest of the voice, have cured many patients whose general health and resistance have been maintained or improved by sanatorium treatment. In these circumstances and if prolonged functional rest of the vocal cords fails to cure small or limited tuberculous lesions in the larynx, application of the galvano-cautery will often produce rapid healing. Severe surgical measures for the removal of infected laryngeal tissues are rarely called for. The value of tuberculin in the treatment of laryngeal tuberculosis is still a matter of opinion. For fuller information on this subject *see* "the Mitchell Lecture" by Sir St. Clair Thomson *(Brit. Med. Journ.* Nov. *8,* 1924).

Malignant Disease.—Here again the essential for successful treatment is early diagnosis. Any adult suffering from an alteration of the normal speaking voice of more than a few weeks' duration should be examined by an expert laryngologist. The treatment of the disease in its early stages is surgical and aims at its complete removal. The records of cure or many years of freedom from recurrence are probably better than those in any other region of the body.

EARL, a title and rank of nobility (corresponding to Lat. *comes;* Fr. *comte),* now the third in order of the British peerage, between marquess and viscount. Earl is the oldest title and rank of English nobles, and was the highest until 1337, when the Black Prince was created duke of Cornwall by Edward III.

The nature of a modern earldom is readily understood, since it is a rank and dignity of nobility which, while it confers no official power or authority, is inalienable, indivisible, and descends in regular succession to all the heirs under the limitation in the grant until, on their failure, it becomes extinct.

The title is of Scandinavian origin, and first appears in England under Canute as *jarl,* which was englished as *eorl.* Like the *ealdorman,* whose place he took, the *eorl* was a great royal officer, who might be set over several counties, but who presided separately in the county court of each with the bishop of the diocese. Although there were counts in Normandy before the Norman Conquest, they differed in character from the English earls, and the earl's position appears to have been but slightly modified by the Conquest. He was still generally entitled to the "third penny" of the county, but his office tended, under Norman influence, to become an hereditary dignity and his sphere was restricted by the Conqueror to a single county. The right to the "third penny" is a question of some obscurity, but its possession seems to have been deemed the distinctive mark of an earl, while the girding with "the sword of the county" formed the essential feature in his creation or investiture, as it continued to do for centuries later. The fact that every earl was the earl of a particular county has been much obscured by the loose usage of early times, when the style adopted was sometimes that of the noble's surname (*e.g.,* the Earls Ferrers), sometimes that of his chief seat (*e.g.,* the Earls of Arundel), and sometimes that of the county. Palatine earldoms, or palatinates, were those which possessed *regalia, i.e.,* special privileges delegated by the Crown. The two great examples, which dated from Norman times, were Chester and Durham, where the earl and the bishop respectively had their own courts and jurisdiction, and were almost petty sovereigns.

The earliest known charter creating an earl is that by which Stephen bestowed on Geoffrey de Mandeville, in or about 1140, the earldom of Essex as an hereditary dignity. Several other creations by Stephen and the empress Maud followed in quick succession. From at least the time of the Norman Conquest the earl had a double character; he was one of the "barons," or tenants in chief, in virtue of the fief he held of the Crown, as well as an earl in virtue of his "belting" (with the sword) and his "third penny" of the county. His fief would descend to the heirs of his body; and the earliest charters creating earldoms were granted with the same "limitation." The dignity might thus descend to a woman, and, in that case, like the territorial fief, it would be held by her husband, who might be summoned to parliament in right of it. The earldom of Warwick thus passed through several families till it was finally obtained, in 1449, by the Kingmaker, who had married the heiress of the former earls. But in the case of "co-heiresses" (more daughters than one), the king determined which, if any, should inherit the dignity.

The 14th century saw some changes introduced. The earldom of March, created in 1328, was the first that was not named from a county or its capital town. Under Edward III. also an idea appears to have arisen that earldoms were connected with the tenure of lands, and in 1337 several fresh ones were created and large grants of lands made for their support. The first earldom granted with limitation to the male heirs of the grantee's body was that of Nottingham in 1383. Another innovation was the grant of the first earldom for life only in 1377. The girding with the sword was the only observance at a creation till the first year of Edward VI., when the imposition of the cap of dignity and a circlet of gold was added. Under James I. the patent of creation was declared to be sufficient without any ceremony. An earl's robe of estate has three bars of ermine, but possibly it had originally four.

Something should be said of anomalous earldoms with Norman or Scottish styles. The Norman styles originated either under the Norman kings or at the time of the conquest of Normandy by the house of Lancaster. To the former period belonged that of Aumale, which successive fresh creations, under the Latinized form "Albemarle" have perpetuated to the present day *(see* ALBEMARLE, EARLS AND DUKES OF). The so-called earls of Eu and of Mortain, in that period, were really holders of Norman *comtés.* Henry V. and his son created five or six, it is said, but really seven at least, Norman countships or earl-

doms, of which Harcourt (1418), Perche (1419), Dreux (1427) and Mortain (1430) were bestowed on English nobles, Eu (1419) and Tankerville (1419) on English commoners, and Longueville (1419) on a foreigner, Gaston de Foix. Of these the earldom of "Eu" was assumed by the earls of Essex till the death of Robert, the parliament's general (1646), while the title of Tankerville still survives under a modern creation (1714). An anomalous royal licence of 1661 permitted the earl of Bath to use the title of earl of Corbeil by alleged hereditary right. Of Scottish earldoms recognized in the English parliament the most remarkable case is that of the Lords Umfraville, who were summoned for three generations (1297–1380), as earls of Angus; Henry, Lord Beaumont, also was summoned as earl of Buchan from 1334 to 1339.

The earldom of Chester is granted to the princes of Wales on their creation, and the Scottish earldom of Carrick is held by the eldest son of the sovereign under act of parliament.

The premier earldom is that of Arundel (*q.v.*), but as this is at present united with the dukedom of Norfolk, the oldest earldom not merged in a higher title is that of Shrewsbury (1442), the next in seniority being Derby (1485), and Huntingdon (1529). These three have been known as "the catskin earls," a term of uncertain origin. The ancient earldom of Wiltshire (1397) was unsuccessfully claimed in 1869 by Mr. Scrope of Danby, and that of Norfolk (1312), in 1906, by Lord Mowbray and Stourton.

The premier earldom of Scotland as recognized by the Union Roll (1707), is that of Crawford, held by the Lindsays since its creation in 1398; but it is not one of the ancient "seven earldoms." The Decreet of Ranking (1606) appears to have recognized the earldom of Sutherland as the most ancient in virtue of a charter of 1347, but the House of Lords' decision of 1771 recognized it as having descended from at least the year 1275, and it may be as old as 1228. It is at present united with the dukedom of Sutherland. The original "seven earldoms" (of which it was one) represented seven provinces, each of which was under a mormaer. This Celtic title was rendered *jarl* by the Norsemen, and under Alexander I. (c. 1115) began to be replaced by earl (comes), owing to Anglo-Norman influence, which also tended to make these earldoms less official and more feudal.

In Ireland the duke of Leinster is, as earl of Kildare, premier earl as well as premier duke.

An earl is "Right Honourable," and is styled "My Lord." His eldest son bears his father's "second title," and therefore, that second title being in most cases a viscounty, he generally is styled "Viscount"; where, as with Devon and Huntingdon, there is no second title, one may be assumed for convenience; under all circumstances, however, the eldest son of an earl takes precedence immediately after the viscounts. The younger sons of earls are "Honourable," but all the daughters are "Ladies." In formal documents and instruments, the sovereign, when addressing or making mention of any peer of the degree of an earl, usually designates him "trusty and well-beloved cousin"—a form of appellation first adopted by Henry IV., who either by descent or alliance was actually related to every earl and duke in the realm. The wife of an earl is a countess; she is "Right Honourable," and is styled "My Lady." For the earl's coronet see CROWN AND CORONET.

See Lord's *Reports on the Dignity of a Peer;* Pike's *Constitutional History of the House of Lords;* Selden's *Titles of Honour;* G. E. C(okayne)'s *Complete Peerage;* J. H. Round's *Geoffrey de Mandeville* (1892). (J. H. R.)

EARLE, JOHN (*c.* 1601–1665), English divine, was born at York about 1601. He matriculated at Christ Church, Oxford, but migrated to Merton, where he obtained a fellowship. In 1631 he was proctor and also chaplain to Philip, earl of Pembroke, then chancellor of the university, who presented him to the rectory of Bishopston in Wiltshire; and in 1641 he was appointed chaplain and tutor to Prince Charles. Early in 1643 he was chosen chancellor of the cathedral of Salisbury, but was soon deprived as a "malignant," and in the same year was elected one of the Assembly of Divines at Westminster, but declined to sit. After Cromwell's victory at Worcester, Earle went abroad, and was named clerk of the closet and chaplain to Charles II., being appointed dean of Westminster at the Restoration and in 1661 one of the commissioners for revising the liturgy. In November 1662 he was consecrated bishop of Worcester, and was translated, ten months later, to the see of Salisbury, where he conciliated the nonconformists. He was on friendly terms with Richard Baxter and was strongly opposed to the Conventicle and Five Mile Acts. During the great plague Earle attended the king and queen at Oxford, and there he died on Nov. 17, 1665.

Earle wrote the witty work entitled Microcosmographie, or a Peece of the World *discovered,* in Essayes and Characters (1628), which ran through ten editions in the author's lifetime. He was employed by Charles II. to make the Latin translation of the Eikon Basilike, published in 1649; a similar translation of Hooker's Ecclesiastical Polity was accidentally destroyed.

See Philip Bliss's edition of the *Microcosmographie* (1811 and 1868).

EARL MARSHAL, in England, ranks as the eighth of the great officers of State, is the head of the college of arms, and appoints the kings-of-arms, heralds, and pursuivants. He attends the sovereign in opening and closing the session of parliament, walking at his or her right hand. He arranges State processions and ceremonials, especially coronations, royal marriages and funerals, and with the lord great chamberlain he assists in introducing newly-created peers in the House of Lords.

He exercised joint and co-ordinate jurisdiction with the constable in the court of chivalry, and afterwards became the sole judge of that tribunal till its obsolescence in 1737. The marshalship of England was formerly believed to have been inherited from the Clares by the Marshal family, who had only been marshals of the household. It was held, however, by the latter family as early as the days of Henry I., and passed to the Bigods. In 1306 it fell by inheritance to Edward I., and in 1316 was granted by Edward II. to his own younger brother, Thomas "of Brotherton," earl of Norfolk. As yet the style of the office was only "marshal." The office, having reverted to the Crown, was granted out anew by Richard II. in 1385 to Thomas Mowbray, earl of Nottingham, the representative of Thomas "of Brotherton." In 1386 the style of "earl marshal" was formally granted to him in addition. After several attainders and partial restorations in the reigns of the Tudors and the Stuarts, the earl marshalship was granted anew to the Howards by Charles II. in 1672 and entailed on their male line, under which settlement it has regularly descended to the present duke of Norfolk. Its holders, however, could not execute the office until the Roman Catholic emancipation, and were forced to appoint deputies. His Grace appends the letters "E.M." to his signature, and bears behind his shield two batons crossed in saltire, the marshal's rod (*virga*) having been the badge of the office from Norman times. There appear to have been hereditary marshals of Ireland, but their history is not well ascertained. The Keiths were Great Marischals of Scotland from at least the days of Robert Bruce, and were created earls marischal in or about 1458, but lost both earldom and office by the attainder of George, the 10th earl, in 1716. (See also MARSHAL; STATE, GREAT OFFICERS OF.)

See "The Marshalship of England," in J. H. Round, *Commune of London and Other Studies* (1899); G. E. C(okayne)'s *Complete Peerage.* (J. H. R.)

EARLOM, RICHARD (1742–1822), English mezzotint engraver, was born and died in London. In 1765 he was employed by Alderman Boydell, then one of the most liberal promoters of the fine arts, to make a series of drawings from the pictures at Houghton Hall; and these he afterwards engraved in mezzotint. His most perfect works as engraver are perhaps the fruit and flower pieces after the Dutch artists Van Os and Van Huysum. Earlom executed a series of 200 facsimiles of the drawings and sketches of Claude Lorraine, which was published in three vols., under the title of Liber veritatis (1777–1819).

EARLSTON (formerly ERCILDOUNE, of which it is a corruption), parish and market town, Bermickshire, Scotland. Pop. (1931) 1,689. It is on Leader Water in Lauderdale, 72½ m. S.E. of Edinburgh by the L.N.E.R. branch line from Reston Junction to St. Boswells, and about 4 m. N.E. of Melrose. Originally it was

called Arcioldun or "Prospect Fort," an ancient earthwork on Black Hill. In the 12th and 13th centuries the Lindsays and the earls of March and Dunbar were the chief baronial families The ivy-clad ruin of the ancient tower, "The Rhymer's Castle," is the traditional residence of Thomas Learmont, commonly called Thomas of Ercildoune, or Thomas the Rhymer, poet and prophet, and friend of the Fairies, who was born here about 1225. The Edinburgh Border Counties Association acquired this relic and surrounding lands in 1895. The leading manufactures are ginghams and tweeds, and the town is also an agricultural centre, stock and corn sales taking place at regular intervals and cattle and horse fairs being held every year. Some 3 m. away is Bemersyde, said to have been in the possession of the Haigs for 1,000 years, and presented to Field Marshal Earl Haig by the nation in 1921. The prospect from Bemersyde Hill was Sir Walter Scott's favourite view. The castle at Bemersyde was erected in 1535 to secure the peace of the Border.

EARLY, JUBAL ANDERSON (1816–1894), American soldier and lawyer, was born in Franklin county (Va), on Nov. 3, 1816, and graduated at West Point in 1837. He served in the Seminole War of 1837–38, after which he resigned in order to practise law in Franklin county, Virginia. He also engaged in State politics, and served in the Mexican War as a major of Virginia volunteers. He was strongly opposed to secession, but thought it his duty to conform to the action of his State. As a colonel in the Confederate army, he rendered conspicuous service at the first battle of Bull Run (*q.v.*). Promoted brigadier-general, and later major-general, Early served throughout the Virginian campaigns of 1862–63, and defended the lines of Fredericksburg during the battle of Chancellorsville. At Gettysburg he commanded a division of Ewell's corps. In the campaign of 1864 Early, who had now reached the rank of lieutenant-general, commanded the Confederate forces in the Shenandoah valley. After several successful actions in the Shenandoah and Potomac valleys (on July 11 he threatened the city of Washington), Gen. Sheridan arrived with Union reinforcements, forced Early to retreat, and defeated him at Winchester and Fisher's Hill. Finally, on Oct. 19, after inflicting at first a severe blow upon the Federal army in its camp at Cedar creek, he was decisively beaten by Sheridan. (See SHENANDOAH VALLEY.) Waynesboro (March 1865) was his last fight, after which he was relieved of his command.

Gen. Early was regarded by many as one of the ablest soldiers in the Confederate army.

After the declaration of peace he went to Canada; but in 1867 returned to resume the practice of law. For a time he managed the Louisiana lottery in conjunction with Gen. Beauregard. He died at Lynchburg (Va.), on March 2, 1894. Gen. Early was for a time president of the Southern Historical Society, and wrote, besides various essays and historical papers, *A Memoir of the Last* Year of *the War, etc.* (1867).

See *Lieutenant General Jubal Anderson* ***Early;*** *an Autobiographical Sketch and Narrative of the War Between the States* (1912).

EARLY CLOSING MOVEMENT. The Early Closing Association came into existence in Great Britain following a meeting of drapers' assistants held at the Commercial tavern, Holborn, in Oct. 1842. A resolution was then passed "that the present hours of business are longer than either the convenience or the necessities of the public require and that a judicious curtailment thereof may be effected, without injury to any of the principals concerned, which would be productive of the most beneficial results." In the period after 1842 great progress was made, including (1) the establishment of the Saturday half-holiday culminating in the Shops act, 1912, legalizing a weekly half-holiday for every shop assistant, (2) the Shops Seat act (1899), which stipulated for one seat to every three female assistants in shops, (3) the Shops act (1920), which provided compulsory closing of shops at eight o'clock weekday nights and nine o'clock Saturdays, in addition to the weekly half-holiday, and (4) improved shop conditions.

The Saturday half-holiday became a British national institution, and was adopted by almost every other country in the world. (A. LK.)

United States.—Laws limiting working hours of mercantile employees had been passed in most states prior to World War II, but actual openings and closings were determined by employers. Traditionally, Saturday became the chief shopping day of the week, with most stores remaining open later on that day, particularly in farm communities. After 1942, ho ever, the changed buying habits of the public, resulting from increased income and population shifts into war industry areas, caused merchants to experiment radically with store hours.

The department stores in some of the large cities eliminated the late Saturday closing and substituted instead certain weekdays.

Chain grocery stores and butcher shops in many of the bigger cities also eliminated the late Saturday closing. In the food trade the early closing policy was initiated by the meat cutters' trade union in San Francisco before 1920, and thereafter was generally adopted in other western cities. Labour's desire for improved working conditions became an increasingly important factor during the seven years previous to 1940 which saw the passage of the National Industrial Recovery act, the Wagner act and the Fair Labor Standards act.

Early closing hours for department stores were first demanded by the Working Women's society in 1891. This group enlisted the support of women consumers to secure better conditions for store employees by constructive legislation.

After its inception in 1891, the Consumers' league of New York helped bring about a shortened week for women employees, improved working conditions in retail stores, the closing of stores in the evening, half-holidays on Saturday, and advocated early Christmas shopping.

(R. GL.)

EARLY ENGLISH PERIOD, in architecture, the first of the three divisions into which the English Gothic style is usually divided. Although originally the term was applied to English Gothic up to the beginning of the 14th century (as by Rickman and R. P. Spiers), it is now more customarily limited to the first half of the 13th century. In the last quarter of the 12th century, partly through the influence of the Cistercian order and partly through that of the French design of the early Gothic parts of Canterbury cathedral (choir, c. 1175–78), pointed arches and other Gothic ideas became more and more common, so that by the end of the century the transitional period was over and the architecture of England completely Gothic. It is this earliest developed Gothic which is known as Early English. The chief characteristics of the style are: frequent use of high, slim openings, capped with steeply-pointed arches, known as lancets, often grouped in threes, fives (the "five sisters" in the transept of York cathedral) or even in sevens; simple four part church vaulting (see VAULT), often with a ridge rib in addition to groin, cross and wall ribs; arch mouldings, consisting of complex combinations of convex projections with deep, rounded hollows; nave and chapter house piers of a central core of stone surrounded by a number of black Purbeck marble shafts, tied together by occasional moulded bands; capitals, almost always consisting of a circular abacus with rich mouldings below, or sometimes with conventionalized foliage with many rounded lobes; frequent use of ball-flower (*q.v.*) and dog-tooth (*q.v.*) ornament. Toward the end of the period the use of tracery became general, lavishness of ornament increased, as in the diaper patterns in the arch spandrils of Westminster Abbey, and naturalism in the carving grew. Outstanding examples of the style are Salisbury cathedral, begun 1220; the nave and transept of Wells cathedral, end of the 12th century to 1242; parts of York cathedral transepts, 1230–60. (See GOTHIC ARCHITECTURE)

(T. F. H.)

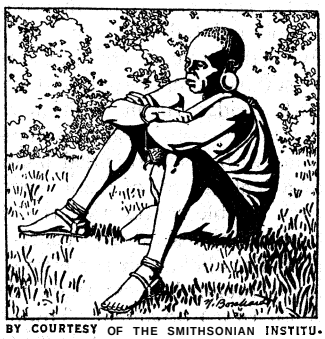
EARN, a loch and river, Perthshire, Scotland. The loch is 6½ m. long east to west and ⅘ m. in maximum breadth. It discharges by the river Earn. On its shores are Lochearnhead (at the southern extremity of Glen Ogle), which has a station on the railway from Perth to Balquhidder, and the ruins of St. Blane's chapel; Edinample Castle, an old turreted mansion belonging to the marquess of Breadalbane, situated in well-wooded grounds near the pretty falls of the Ample; Ardvorlich House, the original of Dar-

linvarach in Scott's Legend of Montrose, and the village of St. Fillans at the foot of the loch. The river, a notable fishing stream, flows out of Loch Earn eastwards with a gentle inclination towards the south, and reaches the Firth of Tay, 63 m. below Perth. The principal places of interest on the banks of the Earn are Dunira House; the village of Comrie; the town of Crieff; the ruined castle of Innerpeffray, founded in 1610 by the 1st Lord Maderty, close to which is the library founded in 1691 by the 3rd Lord Maderty, containing some rare black-letter books and the Bible that belonged to the marquess of Montrose; Gascon Hall, now in ruins, but with traditions reaching back to the days of Wallace; Dupplin Castle, a fine mansion in Tudor style; Forgandenny, and Bridge of Earn, a health resort situated amidst picturesque surroundings. Strathearn, as the valley of the Earn is called, extending from the loch to the Firth of Tay, is a beautiful and, on the whole, fertile tract, though liable at times to heavy floods. The earl of Perth is hereditary steward of Strathearn.

EARNEST, the payment of a sum of money by the buyer of goods to the seller on the conclusion of a bargain as a pledge for its due performance. It is almost similar to the *arrha* of the Roman law. Apart from its survival as a custom, its chief importance in English law is its recognition by the Statute of Frauds as giving validity to contracts for the sale of goods of a value exceeding £10. (See SALE OF GOODS.) It is in that statute clearly distinguished from part payment, consequently any sum, however small, would be sufficient as earnest, being given as a token that the contract is binding and should be expressly stated so by the giver. (See DEPOSIT)

EAR-RING, an ornament worn pendent from the ear, and generally suspended (especially among the more civilized races) by means of a ring or hook passing through the pendulous lobe of the ear. Among savage races the impulse to decorate, or at any rate to modify the appearance of the ear, is almost universal. The Berawan people of Borneo use plugs through the lobe of the ear $3\frac{3}{4}$ in. in diameter. More extraordinary still is an example of a stone ear-plug worn by a Masai, $4\frac{1}{2}$ in. in diameter and weighing 2 lb. 14 ounces. Among the superior races, though ear ornaments of extravagant size and elaboration are not unknown, moderation in size is commonly observed, and greater attention is paid to workmanship and fineness of material.

The general usage appears to have been to have ear-rings worn in pairs, the two ornaments in all respects resembling each other; in ancient times, or more recently among Oriental races, a single ear-ring has sometimes been worn. The use of this kind of ornament, which constantly was of great value, dates from the remotest historical antiquity, the earliest mention of ear-rings occurring in the book of Genesis. It appears probable that the ear-rings of Jacob's family, which he buried with his strange idols at Bethel, were regarded as amulets or talismans, such unquestionably being the estimation in which some ornaments of this class have been held from a very early period, as they still are held in the East. Thus in New Zealand ear-rings are decorated with the teeth of enemies, and with talismanic sharks' teeth. Among all the Oriental races of whom we have any accurate knowledge, the Hebrews and Egyptians excepted, ear-rings always have been in general use by both sexes; while in the West, as well as by the Hebrews and Egyptians, as a general rule they have been considered exclusively female ornaments. By the Greeks and Romans also ear-rings were worn only by women, and the wearing of them by a man is often spoken of as distinctively oriental.



BY COURTESY OF THE SMITHSONIAN INSTITUTION

A BANTU NEGROID

Among certain African tribes, ear-rings are worn not so much for ornament as for pulling the ear into a fashionable size and shape

In archaic art, ear-rings are frequently represented or their traces are left in the perforated ear lobes of early statues. After the 4th century such perforations occur seldom. In one instance, a Greek inscription records the weight of the detachable gold ornaments on a statue, among which a pair of ear-rings is included. Ear-rings of characteristic form are frequently discovered by excavation. In Egypt, a system of pendent chains is found hanging from a disc. In Assyria the decoration consists of pendants or knobs attached to a rigid ring. In the Mycenaean period, ear-rings are infrequent in Greece, but have been found in abundance in the Mycenaean finds of Enkomi (Cyprus) in the form of pendent bulls' heads, or of decorative forms based on the bull's head. In the tombs of the Greek settlers in the Crimea (4th century B.C.), ear-rings are found of marvellous complexity and beauty. The lexicographer Pollux, speaking of the names given to ear-rings, derived from their forms, mentions caryatids, hippocamps and centauresses. Jewels of the same class, of exquisite beauty and of workmanship that is truly wonderful, have been rescued from the sepulchres of ancient Etruria. Ear-rings of comparatively simple forms, but set with pearls and other stones, were the mode in Rome. Researches among the burial places of Anglo-Saxon Britain have led to the discovery of jewels in considerable numbers, which among their varieties include ear-rings.

These ornaments, which have never fallen into disuse, showed a considerable decline in Europe and America during the 19th century, but have been revived again in the 20th century to the extent that they are not uncommonly worn on the street or with evening dress. The more recent ones do not pierce the ear and are considerably smaller. (See also JEWELLERY.)

EAR-SHELL: see ABALONE.

EARTH. In the present article we shall treat the subject matter of the earth as a planet under the following headings:—(1) size, mass, density and form, (2) movements, (3) constitution, (4) age of the earth, and (5) earth's thermal history.

SIZE, MASS, DENSITY AND FORM

To primitive man the earth was a flat disk with its surface diversified by mountains, rivers and seas. The spherical form was asserted by Pythagoras, and Aristotle used arguments in its favour similar to those used to-day, viz., the ship gradually dis-

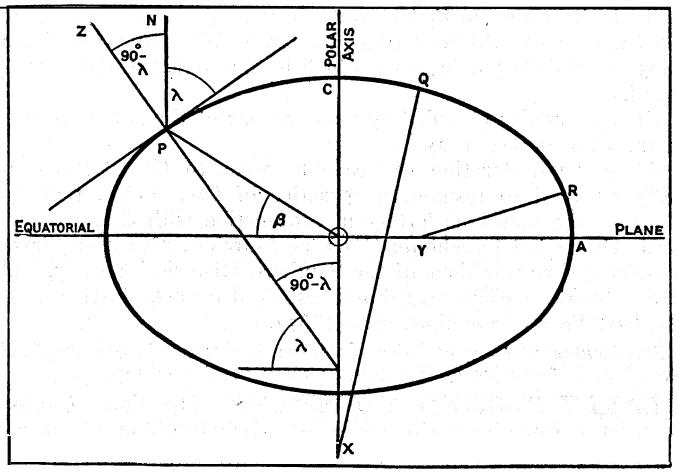


FIG. 1.— DIAGRAMMATIC SECTION OF EARTH THROUGH POLAR AXIS TO ILLUSTRATE LATITUDE

The latitude of a point P is the angle λ between PN parallel to the polar axis and a horizontal plane through P. The zenith distance of the pole is the angle NPZ=90°−λ. QX and RY are normals to the polar axis and the difference between CQ and RA represents the difference in length of a degree of latitude near the pole and near the equator

appearing, hull first, masts later, as it recedes beyond the horizon; the circular shadow cast on the moon during an eclipse; and the alteration in the appearance of the heavens as one passes from place to place on the surface. With regard to the last point, we may notice that if the earth were flat any star above it would be visible from every point of it. This is not true: many of the stars visible in England are never visible in South Africa or Australia, and conversely. On the other hand, an observer on the surface of a spherical earth would see every star that is above the tangent plane to the sphere at the point where he is. The direc-

tion of this plane varies with his position, and therefore the stars visible also depend on his position. The mean altitude (angular elevation above the horizon) of the Pole star is equal to the latitude of the place, for observers in the northern hemisphere.

The spherical form did not, however, become generally believed until after explorers had actually sailed around the earth; though this argument is not intrinsically so conclusive as any of the three first given. The distance a traveller has to proceed northwards to make the mean altitude of the Pole star increase by 1° is a "degree of latitude." Eratosthenes, in 250 B.C., was the first to measure this, by determining the difference of latitude between Alexandria and Syene, but there is some doubt about his measurement of the distance between these places. Picard, in 1671, obtained the first useful estimate. From the length of the degree of latitude the size of the earth can be calculated.

Actually, the length of the degree of latitude is found to vary slightly with latitude. This is because the earth is not exactly a sphere, a better approximation to its shape being an oblate spheroid (the surface swept out by an ellipse rotated about its shortest diameter). Such a surface is flatter near the pole than near the equator, and the degree of latitude is therefore longer in high latitudes than in low ones. Thus observation of the length of the degree in both high and low latitudes determines both the size of the earth and its polar flattening. The best determination yet made is that of J. F. Hayford, from observations in the United States, published in 1910. He gives:

$$a = \text{equatorial semi-axis} = 6{,}378{\cdot}388\text{km.}$$
$$b = \text{polar semi-axis} = 6{,}356{\cdot}909\text{km.}$$
$$a - b = 0{\cdot}18\text{km.}$$
$$\frac{a-b}{} = \text{ellipticity} = \frac{1}{297{\cdot}0 \pm 0{\cdot}5}$$

The distance from pole to equator, measured along the surface, is very nearly 10,000 kilometres.

The mass of the earth is found by comparing its gravitational attraction on a small sphere at its surface with that of a large sphere of known mass on the same small sphere. The attractive force satisfies the law of gravitation, namely, that the force produced on a given small body is proportional to $\frac{m}{r^2}$, where m is the mass of the attracting body and r the distance of its centre. If then the forces produced and the distances are known, we can find the ratio of the masses. Boys and Braun independently found the mass to be $5{\cdot}98 \times 10^{21}$ metric tons (1 metric ton $= 10^6$ grams $=$ 0·9842 British ton). This is the mass of a body with a volume equal to that of the earth, and with a density equal to 5·527 times that of water. The mean density of the earth is therefore 5·527 gm. per cubic centimetre.

MOVEMENTS

The motion of the earth is known if we know three things, which are independent or nearly so: first, the motion of its centre; second, its rotation about its centre; third, any variations of shape that may be taking place. These three types of motion may be described separately.

Movement of the **Earth** as **a** Whole.—The most important part of the movement of the centre is the revolution about the sun. The centre of mass (*i.e.,* centre of gravity) of the earth and moon together describes in the course of a year an elliptic path, with the centre of the sun at one focus. The mean distance from the sun is 149·4 million km., or 92.82 million miles. The eccentricity of the orbit is 0·016751 (eccentricity = difference of greatest and least distances ÷ sum of greatest and least distances).

The centre of the sun, however, is not fixed, but shares in the general motion of the solar system relative to the stars. The latter is a steady motion of the centre of mass of the whole system with a velocity of about 20km. per sec. towards a point in the constellation Hercules. It is found by statistical discussion of the apparent motions of stars. The sun's centre is close to the centre of mass of the solar system, but moves with regard to it on account of the attractive forces of the planets on the sun. The planets also attract the earth and moon. These forces introduce very complicated minor disturbances called perturbations.

The centre of mass of the earth and moon is about 4,800 km. from the centre of the earth; the latter moves about the former in the course of a month on account of the attraction of the moon for the earth, and on this account the earth gets alternately in front of and behind its mean position. This monthly inequality provides a means of determining the moon's mass.

Rotation.—The rotation of the earth about its polar axis is nearly uniform, the period being the sidereal day, which is 23h. 56m. 4·095s. of solar time. The revolution about the sun and the rotation were both established by Copernicus in 1543. In his great work De *orbium coelestium revolutionibus* it was shown that the common astronomical phenomena, such as the rising and setting of stars and the sun, the difference between the lengths of the sidereal and solar days, and the seasons, could be explained most simply by regarding the earth as revolving annually about a fixed sun, while rotating about an axis in itself. Later, the explanation of the revolutions of the planets was the greatest triumph of Newton's law of gravitation.

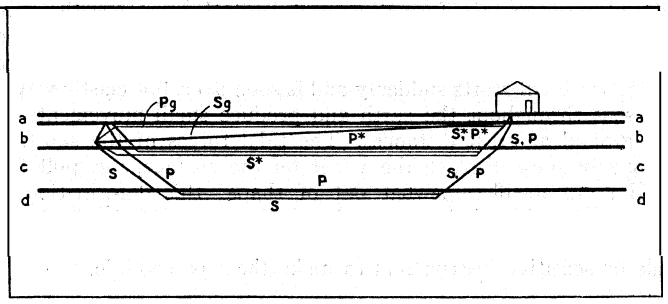

FIG. 2 — PATHS OF THE SIX PULSES OBSERVED IN NEAR EARTHQUAKES
aa, sedimentary layer; bb, granitic layer; cc, intermediate layer; dd, dunite base

The position of the axis, however, varies. The disturbances are known as precession, nutation and the variation of latitude. Precession (often called precession of the equinoxes) is a motion of the earth's axis in a cone whose axis is perpendicular to the plane of the earth's orbit, so that the celestial pole appears to move in a circle about the pole of the ecliptic. The time taken for the complete revolution is about 25,800 years. The phenomenon was discovered by Hipparchus (120 B.C.), and was first explained by Newton. The attraction of the sun and moon on the earth's equatorial protuberance tends to make it move so as to bring the equator into the plane of the orbit of the earth or the moon respectively. But the earth's rotation introduces a gyroscopic control, and the ultimate result is that each point of the earth's axis moves parallel to the plane of its orbit. The explanation is similar to that of the motion of the axis of a spinning top. Gravity tends to make the axis move downwards, but the spin of the top converts the disturbance into a revolution of the axis about the vertical. One effect of precession is that the equinoxes move around the ecliptic so as to be always moving to meet the sun. The rate is 50″·26 per year, enough to displace the equinoxes by 30° in 2,150 years. The vernal equinox, the point where the sun crosses the equator on its way north, was known in astronomy as the "first point of Aries"; but on account of precession it is now in Pisces. Also 4,000 years ago the star nearest the pole was **a** Draconis; but since the pole has moved it is now **a** Ursae Minoris; in 12,000 years it will be Vega.

The force tending to alter the tilt of the axis is not constant; when the sun or moon is crossing the equator, for instance, it has no effect. The path of the pole is therefore not described with uniform velocity, and is not quite a circle. The departures from the uniform circular motion are called "nutations." The largest of them, discovered by Bradley, is the lunar nutation, with a period of 18.6 years and an amplitude of 9″·2 in latitude. This arises because the plane of the moon's orbit revolves on the plane of the ecliptic in 18·6 years, so that the motion of the pole caused by the moon is not always about quite the same point of the sky. The variation of latitude consists of two small movements, one with a period of about 14 months, the other of a year. Both have amplitudes of about 0″·1. The existence of the former was predicted on dynamical grounds by Euler; it is a circular oscillation of the axis akin to the wobbling of a badly thrown quoit.

If the earth were quite rigid its period would be 306 days; actually it is about 428 days, the difference being due to the earth's elastic yielding. The annual movement is due to seasonal displacements of matter over the earth's surface. Both were discovered by Chandler in 1891; the qualitative explanation is due to Newcomb.

Deformations. — In addition to the above general movements, the earth is continually altering its shape. The movements involved in mountain formation and isostatic compensation are large but slow, taking millions of years for completion. The movement in a large earthquake may reach several metres close to the origin; it starts suddenly and is soon over, but elastic waves are sent throughout the earth and produce small movements of the ground at great distances. The tidal forces of the sun and moon not only displace the water on the surface, but pull the solid earth itself somewhat out of shape; this deformation is associated with an indirect one due to the weight of the displaced oceanic waters. All of these movements require either long intervals or sensitive instruments to make them perceptible.

CONSTITUTION

There are several different sources of information which are available concerning the constitution of the earth. Starting with the geological evidence, we know that most of the land surface is covered with a layer of sedimentary rocks. The chief of these are sandstones and shales, produced mainly by the weathering of granite and related rocks and redeposition of the resulting sediments in shallow water. In addition, large areas within the continents are covered with ancient rocks akin to granite, and granite is also a common intrusive rock. For all these reasons geologists (following Suess) have come to believe in a widespread granitic layer under all the continents. Another very common intrusive rock is basalt, which exists in several different forms, such as dolerite, gabbro, eclogite and tachylite. It is denser, in its commonest forms, than granite (3.0 against 2·7), and therefore has probably come from a greater depth. But the mean density of the earth is 5.5, nearly twice the density of basalt, and it has been shown that the high pressures in the interior of the earth are quite insufficient to compress basalt to such an extent. There must be much denser matter within the earth, and its density must be much greater than 5·5 to make up for the lighter stuff on the outside. This indicates an interior composed of heavy metals, especially iron, since this is the commonest heavy metal in the crust.

Upper Layers. — More detailed information is provided by seismology. As has just been mentioned, earthquakes send out elastic waves through the body of the earth, and the arrival of these at distant stations is recorded by instruments. Two types of bodily waves exist in a solid: first, a compressional wave like a sound wave, such that, as the wave passes, a particle vibrates *in* the direction of travel of the wave; and, second, a distortional wave, where the vibrating particle moves *at* right *angles to* the direction of travel of the wave. The two types are referred to, for brevity, as P and S. The letters stand for "primary" and "secondary" because the compressional wave travels faster. The velocities depend on the elastic properties of the material (incompressibility and rigidity, or resistance to change of shape) and on its density. When the substance is not uniform the energy of each wave behaves very much like that of light: that is, it travels in rays, which are curved in such a way that the wave travels from one end of the ray to the other in a shorter time than it would take if it travelled by any slightly different path. As in the case of light, again, if there is a sharp boundary between two different materials, a wave reaching the boundary is partly transmitted and partly reflected. A complication arises, however; in elastic waves, in a solid, four waves arise at a boundary, a compressional one and a distortional one in each medium. The distortional wave is entirely characteristic of solids: it does not exist in a liquid.

It is actually found, when the times of arrival of the waves from a near earthquake at different distances are compared, that a pair of waves can be traced, travelling with velocities of 5·4km. per sec. and 3·3km. per sec. respectively. The former velocity agrees with that found by L. H. Adams and E. D. Williamson, of the Geophysical laboratory at Washington, for the velocity of compressional waves in granite. This wave is consequently denoted by P_g and the other, which appears to be the corresponding distortional wave, by S_g. They travel wholly in the granitic layer from the origin to the observing station, apart from their short passage upwards through the sedimentary layer. These waves were first observed by A. Mohorovičić of Zagreb, Yugoslavia, in 1909.

If, however, a basalt layer underlies the granitic one it would be expected that some part of the waves sent out would be transmitted into this layer, travel through it, and be refracted up again when they return to the boundary. Now actually not one, but two other pairs of waves can be traced; they have been given specific symbols, and their velocities are: P*, 6·3km. per sec.; S*, 3·7km. per sec.; P_n (or simply P) 7·8km. per sec.; S_n (or simply S), 4·3km. per second. The curious fact is that none of these velocities fits that for compressional waves in crystalline basalt, as found in the laboratory, which is 6·9km. per second. The inference is that there is no widespread layer of crystalline basalt. The velocity of P* fits either tachylite, which is basalt in a vitreous, or glassy, condition, or diorite, a crystalline rock intermediate in composition between granite and basalt. P_n has a very high velocity; the only rock that transmits waves with so high a velocity is dunite, a rare rock at the surface, but consisting almost entirely of the mineral olivine (Mg_2SiO_4 and Fe_2SiO_4), which is fairly common as a constituent of mixed rocks. Eclogite, which has a similar composition to basalt, but a density of 3.3, may give a similar velocity, though it has not yet been examined for this purpose in the laboratory. There are thus two possible successions with increasing depth, both consistent with the seismological data, namely, granite-tachylite-dunite and granite-diorite-eclogite-dunite. The former was suggested by H. Jeffreys, the latter by Professor A. Holmes, and both views have arguments in their favour.

The six waves all appear to travel with uniform velocity, so long as the distance does not exceed about 900 kilometres. But their times of arrival are related as if they had started at times differing by a few seconds. If Δ is the distance of an observing station from the "epicentre" (the point of the surface vertically above the origin), T the time of arrival at the station, and v the velocity of travel of the wave, we have

$$T = T_o + \frac{\Delta}{v},$$

where T_o is the same for all stations for the same wave, so that the wave appears to have started at time T_o and travelled out with velocity v. But every wave has its own T_o, on account of the delay of the indirect waves in travelling down to the intermediate and lower layers, whereas the waves S_g and P_g come practically directly; just as walking to the next village may be quicker than travelling by train if one does not live near the station. These apparent delays in starting provide means of estimating the thicknesses of the granitic and intermediate layers, which are found to be about 10km. and 20km. respectively, under average continental conditions.

Below the ocean the structure must be somewhat different. Granitic rocks appear not to exist there, and basalt may come right up to the ocean bottom. On the other hand Holmes has suggested that there may be a thin upper layer of syenite, a rock resembling granite except that it contains no quartz. Direct seismological evidence is lacking, except that P_n and S_n seem to have the same velocities as under the continents. The chief difference between continents and oceans is, then, that under the oceans the granitic layer is absent or very thin.

Deeper Portions. — At distances over 900km. the four waves P_g, P*, S_g, S* have all disappeared or at least become unrecognizable. But P_n and S_n still exist. Their observed times of transmission give a means of finding their velocities of propagation at great depths, which has been employed by E. Wiechert, B. Gutenberg, S Mohorovičić and C. G. Knott. The velocities increase with depth, somewhat irregularly, to a depth of 0·45 of the radius, or 2,900km.; that of P varies within this range from 7.8 to 13km.

per sec.; the corresponding values for S are 4·35km. per sec. and 7km. per second. The increase is to be attributed mainly to an effect of the high pressure in increasing the stiffness of the material. There is no sudden change of velocity within this range of depth and the material is therefore probably of uniform composition, or at least its composition varies only continuously.

P waves just reaching a depth of 2,900km. emerge at an angular distance of 103° from the epicentre; that is, the line joining the epicentre to the point of emergence subtends an angle of 103° at the centre of the earth. At greater distances P and S cannot be detected. P reappears at a distance of 144°, and can be traced from there to the antipodes, but S never reappears at all. This is what would be expected if the earth had a liquid central core, for the fundamental property of a liquid is its inability to transmit distortional waves. But other alternatives are just possible, and we cannot decide that the central core is liquid without discussing other evidence.

P waves travel more slowly in the central core than just outside it, their velocity being about 9km. per second. These waves were first identified by R. D. Oldham in 1906, and further work on them has been done by Gutenberg and H. H. Turner. They emerge at minimum deviation at an angular distance of about 144°, and consequently have large amplitudes there. Between 103° and 144° only very small diffracted waves are recognizable. In addition, P and S waves incident on the central core are partly reflected and partly transmitted into the core as P waves. The reflected ones are spread out so much that they give rise to only small movements at the outer surface, but they have been identified by V. Conrad, the discoverer of P*. The transmitted waves are more conspicuous. That derived from S is again broken up when it returns to the boundary, giving three parts, denoted briefly by S_cP_cS, S_cP_cP and (S,P_c) (P_cS). The first two re-enter the outer shell when the wave has passed through the core; the three letters in each symbol indicate the type of the wave in the three parts of its path. The third wave is reflected on the inside of the core, and emerges after describing another path in the core as P and being transmitted into the shell as S. The existence of all these waves was predicted by Gutenberg, who calculated their theoretical times of transmission from the known velocities of P and S at various depths; and they have all been found by observation at the predicted times by Gutenberg himself and other workers, especially Prof. H. H. Turner. The wave reflected at the inside of the core is interesting because reflexion would not occur if the transition was gradual; it points to a sharp boundary between two quite different materials.

Density at Various Depths.—We have already seen that the high mean density of the earth also points to a difference of density between the interior and the exterior, comparable with that between metallic iron and ordinary rocks. There is reason to believe that the earth was once fluid, and in this state iron and silicates would not mix; thus a metallic core, sharply separated from a rocky shell, would be expected to exist. A correspondingly sharp change in properties with depth has been inferred, on entirely different evidence, from seismology. Seismology also indicates that there is no other sudden change. Hence we naturally infer that the two sudden transitions are identical, and that the thick outer shell, down to a depth of 2,900km., is composed of a silicate rock resembling olivine in composition, while the central core below that depth is made of metallic iron, probably in the liquid state.

The theory of the figure of the earth leads to another datum, involving the earth's "moments of inertia." The moment of inertia of a body about a line is obtained by multiplying the mass of every particle of the body by the square of its distance from the line, and adding up for all the particles. The moment of inertia of the earth about the polar axis is denoted by C, and that about any diameter in the plane of the equator is denoted by A. C is greater than A because the earth is spheroidal; particles, on an average, are farther from the polar axis than from one in the equatorial plane. Now the rate of precession contains as a factor the ratio $\frac{(C-A)}{C}$, which is therefore sometimes called the "precessional constant" or the "dynamical ellipticity." This rate being observed, and every other factor in the formula for it being known, we can therefore find the precessional constant, which is $\frac{1}{305\cdot6}$. But C—A can also be found absolutely, because it is the only unknown in the formula for the variation of gravity over the surface of the earth. Hence C can be found by simple division. It is conveniently expressed by the equation

$$\frac{C}{Ma^2} = 0\cdot334$$

where M is the earth's mass and a its equatorial radius. If the earth was a uniform sphere this ratio would have been 0·400; the difference gives new evidence that the earth is much denser near the centre.

The next step is to assume the earth to consist of a rocky shell and a metallic core, both of uniform density, and with the radius of the core equal to what seismology has revealed—0.55 of the outer radius. The densities of the shell and core are our unknowns, and can be found because we have two data, the mass and moment of inertia of the earth. The densities are found to be 4·5 and 12·0. They are much greater than those of dunite and iron at the earth's surface. But in the earth every layer is compressed by the weight of the matter above it, and if we allow for this we find that the average densities would be very close to those found for the uniform shell and core.

The Bodily Tide.—The density and the velocities of propagation of the P and S waves at any depth being by this time fairly accurately known, the elastic constants (the incompressibility and the rigidity) of the matter can be found. Hence it becomes, theoretically, possible to calculate how the earth as a whole would yield under known forces. The 14-monthly variation of latitude and the tides both provide data capable of being compared with theory. If the earth were perfectly rigid, the period of the variation of latitude would be 306 days; if it were a fluid, the variation

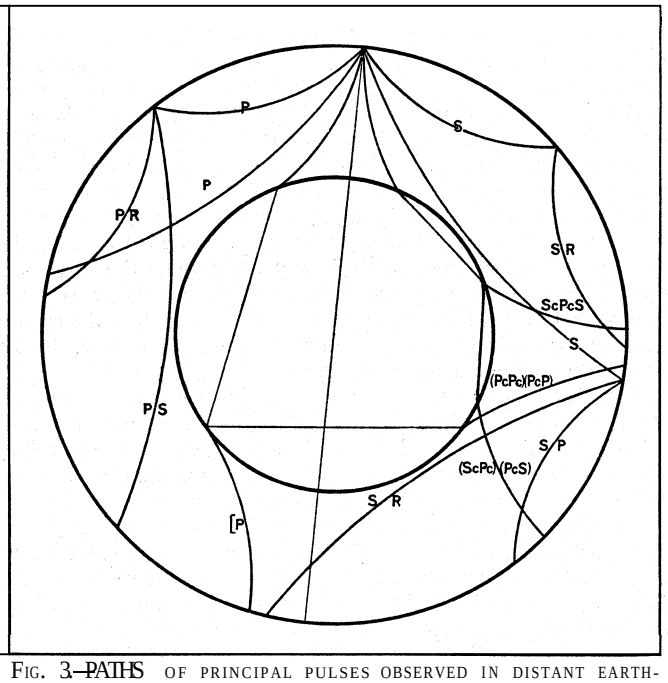

FIG. 3.—PATHS OF PRINCIPAL PULSES OBSERVED IN DISTANT EARTHQUAKES. THOSE STARTING AS P ARE SHOWN ON THE LEFT, THOSE STARTING AS S ON THE RIGHT

of latitude would not exist. If, again, the earth were fluid, the interior would yield so much to tidal force's that the ocean could yield no more, and there would be no visible tides. The actual tides are about 0·7 as high as they would be on a rigid earth. The two sources of information are closely related, but do actually give distinct checks on any theory. Lord Kelvin showed that the tidal yielding of the solid earth was no more than that of a globe of steel of the same size. We know now, however, that the dunite at a depth of 30–40km. is about two-thirds as stiff as steel, and the matter 2,900km. down is fully twice as stiff as steel. If the central

core were equally stiff, it can be shown that the earth as a whole would yield less than tides and the variation of latitude show it does. It has not yet been definitely shown that a liquid central core would give complete agreement, but it would certainly fit the facts much better than any reasonable hypothesis consistent with the solidity of the core.

Summary. — The structure of the earth, along a radius emerging at a typical point within a continent, would be as follows: —

	Thickness (km.)	Density
Sedimentary layer	0–5 (?)	a – 2.7
Granitic layer	10	2·7
Tachylite or diorite layer	20	2·9
Dunite shell (possibly with eclogite near the top)	2,900	3.3 (top) 5·0 (bottom)
Liquid iron core	3,500	11–11a

In oceanic regions the granitic layer may be absent, the sedimentary one thin and formed of deep-sea deposits, and the tachylite one replaced by matter of similar composition, but crystalline. The thicker shell and the central core are much the same below sea as below land.

THE AGE OF THE EARTH

The only theory of the origin of the earth that has hitherto survived quantitative test is the tidal theory. *(See* COSMOGONY.*)* This implies that the earth condensed from a filament, newly ejected from the sun under the gravitational attraction of a large star passing close to the sun's surface. The primitive earth would liquefy partly through loss of heat by radiation from the outside and partly by adiabatic expansion. The latter leads to the formation of liquid drops as in a liquid air machine, and the drops would gradually collect towards the centre. The formation of a liquid earth, probably with an atmosphere of some of its more volatile constituents, would be a matter of centuries. Further cooling would lead to solidification; the time needed for this would be longer on account of the reduced temperature and distension, but in a few thousand years at most the earth would have a thick solid shell on the outside. The further time taken for the outer surface to cool down, till its temperature was maintained almost wholly by the sun's radiation, would be only a few years. The temperature would then be near the present temperature, since the sun was in nearly its present state. The moon, if it originated in the same way as most of the other satellites, was formed a few years after the earth; if it was formed according to Sir G. H. Darwin's resonance theory, it still separated while the earth was liquid. Thus the intervals that have elapsed since the earth separated from the sun, since the moon was formed, or since the earth's outer surface became approximately as cool as it is now, do not differ by more than a few thousand years.

Denudation. — As soon as the outer surface became cool, an ocean could form — though possibly only a small one at first — and rain and rivers, denudation and sedimentary rocks came into existence. Several methods are available for estimating the age of the earth, but they are not all of equal accuracy, or reliability. The simplest, apparently, is that based bn denudation. If we know the total mass of sedimentary rocks over the earth's surface, and the annual amount of sediments carried to the sea by rivers, a simple division gives an estimate of how long the process has been going on. The transport of sodium to the sea in rivers, together with the present total amount of salt in the sea, gives another estimate. Both methods suggest ages of about 300 million years. But it is important to notice that many factors can vitiate both. In particular, purely geological evidence makes it clear that the present rate of denudation is considerably in excess of the average of the past, owing to the existence of many high and comparatively new mountain ranges and the large amount of easily denuded matter left by the last glacial period. These methods can, therefore, at most suggest an order of magnitude.

Kelvin's Arguments. — Two methods were given by Lord Kelvin, one based on the rate of supply of energy from the sun, and the other on the cooling of the earth's crust by conduction. In the former he supposed, following Helmholtz, that the sun's energy was maintained by contraction, and found that the whole energy liberated by the sun, in contracting from an infinite distension to its present size, would maintain radiation, at the present rate, for only about 20 million years. In the latter he considered the cooling of the earth from the state just after solidification, and found how the rate of increase of temperature with depth in the crust depended on the time the earth has been cooling This increase of temperature with depth is known by observation. The method, with modern data, gives about 27 million years for the age of the earth.

There is now an overwhelming amount of evidence that the earth and the sun are both very much older than Kelvin's numerical results would indicate. Yet the value of his attempts has not disappeared, though some current references might lead one to suppose that it had. Numerous astronomical sources of information have shown that the sun has been radiating as vigorously as now for hundreds of thousands of millions of years, and not merely for tens of millions, and we must infer that stars can draw on some source of energy much more provident than contraction under gravity. But Kelvin's argument will not be completely answered until this source can be definitely located and we can say under what conditions, and how fast, it gives up its energy; and although astrophysicists are making progress in studying it, its nature still remains largely a matter of speculation. At present we can only assert its existence.

Radioactivity. — The argument from the earth's thermal state was shown to require modification by the discovery of radioactivity. It was found that all surface rocks contained minute quantities of radioactive elements, but they were enough to indicate the probability that a large fraction of the heat being conducted out of the earth is of radioactive origin and does not arise from the original heat. But if so the original heat accounts for a smaller rate of increase of temperature with depth than was previously thought; in other words, cooling has proceeded to a greater depth and the time taken has been longer than Kelvin's theory indicates. Nevertheless, his theory is not done with. The earth is not so old that original heat has ceased to be important, and Kelvin's work shows how to estimate its importance. Its geophysical interest will not disappear till after the hot central core freezes.

Radioactivity not only showed the need of supplementing the old theory, but provided a new means of determining geological time; and this method is the best that is known. Radioactivity consists in the breaking up of elements with high atomic weights; in all known cases the disruption takes place by the loss of an a-particle, which is a charged helium atom, or by the loss of a β-particle, which is a free electron. In each case a certain amount

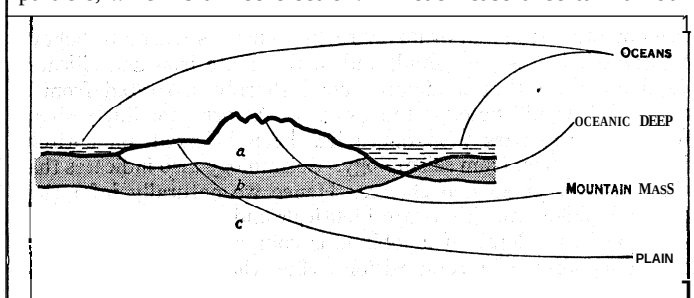

FIG. 4. — DIAGRAM ILLUSTRATING THEORY OF ISOSTASY. ACCORDING TO WHICH EQUILIBRIUM IN THE EARTH'S CRUST IS MAINTAINED BY FLOW OF ROCK MATERIAL BENEATH THE SURFACE UNDER GRAVITATIVE STRESS
a, granitic layer; b, intermediate layer; c, lower layer

of radiative energy is also liberated. The atomic weight of uranium is 238, that of helium is 4, and that of an electron, on the same scale, would be $\frac{1}{1800}$. Thus when an a-particle is lost the atomic weight decreases by 4; when a β-particle is lost it decreases by an insignificant amount. The products of the decay of uranium have therefore atomic weights of 234, 230, 226, 222, 218, 214, 210 and 206; but several may have nearly the same atomic weight owing to loss of β-particles. The most interesting

of the products, for our purpose, are those with atomic weights 226 and 206, namely, radium and lead. Radium breaks up at a known rate; in a given sample of radium 1 part in 2,280 breaks up every year. But in spite of its short life, radium is present in all uranium minerals, in a constant proportion corresponding to 36 atoms of radium per hundred million of uranium. The explanation is that uranium itself breaks up at such a rate as to replenish the radium as fast as this in its turn breaks up. For this to be possible one atom of uranium in 6,400 million must break up every year.

The final product is a kind of lead; that is to say, no chemical test will distinguish it from ordinary lead, but its atomic weight is 206 instead of 207·2. Lead is always found in uranium minerals, and when it was isolated it was actually found to have atomic weight 206. The different kinds of lead were the first examples discovered of isotopes, elements identical in chemical behaviour but differing in atomic weight; but numerous others are now known through the work of Aston.

Now, this lead is being produced from uranium at a known rate: for every 6,400 million atoms of uranium 1 atom of lead is produced every year, or, if we allow for the difference in atomic weights, 7,400 million parts by weight of uranium produce 1 part by weight of lead every year. Hence if a mineral contained no lead to begin with, and now contains x parts of lead to 1 of uranium, the age of the mineral is $7{,}400x$ million years, Petrologists can recognize when original lead must have been absent, and the method is therefore applicable to the determination of the ages of minerals, and hence to the absolute measurement of geological time. The element thorium behaves somewhat similarly to uranium, its final product being a lead of atomic weight 208. When uranium and lead are both present in a mineral the age can be calculated by the formula of Holmes and Lawson:—

$$\text{Age} = \frac{\text{Pb}}{\text{U}+0{\cdot}38\text{Th}} \times 7{,}400 \text{ million years.}$$

Holmes and Lawson give also a slightly more accurate formula, allowing for the variation of the amounts of uranium and thorium with time. The oldest known minerals to which this method is applicable have been found to have ages of about 1,500 million years. The coal measures were laid down about 250 million years ago. The former estimate is therefore a minimum estimate of the age of the earth.

The radioactive elements can be applied in another way, due to H. N. Russell, to find an upper limit to the age of the earth. The above method is based on the analysis of minerals specially rich in uranium and thorium. But these elements are present in all rocks, and the method could be applied to the earth's crust as a whole. A caution necessary is that some of the lead may have always been lead and not have been produced by radioactivity during the geological time. Consequently the method gives an upper limit. The amounts of the relevant elements, in parts by weight, shown by averages of analyses of rocks, are U, 6 parts per million; Th, 15 parts per million; Pb, 7·5 parts per million. The quantity of lead is too small to be consistent with the existence of the earth for more than about 3,000 million years, according to Holmes's latest revision. Thus radioactivity leads to the conclusion that the age of the earth is between 1,500 and 3,000 million years.

Evidence from Cosmogony: The Orbit of Mercury.—Two arguments from cosmogony also give evidence concerning the age of the earth. The first is based on the fact that planets formed by ejection from the sun would move originally in very elongated orbits, which must have been altered to their present circular form by some later influence. The only cause known that could produce such an effect is the resistance of the gaseous medium surrounding the sun, formed of the parts of the primitive filament that failed to condense into planets. The medium would meanwhile degenerate gradually on account of viscosity and diffusion. The time such a medium would take to reduce the eccentricity of the orbit of Mercury to its present value is inversely proportional to its density; the time it would take to become destroyed by viscosity and diffusion is directly proportional to its density. These times must be somewhere near equal, because, if the medium was not dense enough to begin with, it would have disappeared before it had produced its actual effect, while if it was too dense a large amount of it would still remain and would be visible. From a comparison of the two intervals of time it is found that the age must be of the order of magnitude of 3,000 million years. Great accuracy is not possible.

Tidal Friction.—An alternative method depends on the history of the earth and moon. The rotation of the earth is not absolutely uniform; the day is becoming longer by about one second in 120,000 years. The change affects the observed times of ancient eclipses to a measurable extent, and it is from these that the amount is determined. The explanation depends on the tides produced by the sun and moon. The tidal currents in shallow seas are resisted by friction over the bottom, and this leads to a certain amount of dissipation of energy and to a reaction on the tides in mid-ocean, giving a systematic disturbance of the times of high water. If no friction took place the attraction of either the sun or the moon on the tides raised by itself would act exactly through the centre of the earth, and would have no tendency to turn it; but the displacement of the times of high water causes the attraction to act along a line passing a little to one side of the centre, and consequently to alter the rotation of the earth. A reaction on the moon makes the moon go farther off, and explains how the moon can have receded to its present distance from its probable original close proximity to the earth's surface. The rate of change of the earth's speed of rotation due to lunar tidal friction varies inversely as the sixth power of the moon's distance, and must therefore have been much greater in the past. An estimate of the time needed to bring the moon to its present distance, based on the supposition that the phase lag of the oceanic tides has always been as at present, indicates an age of the order of 4,000 million years.

These two methods are much less accurate than those based on radioactivity. Their utility is that they both depend on theories that explain a large number of other facts, and that the agreement of their conclusions in order of magnitude with those drawn from radioactivity gives independent reason to believe that the latter are not vitiated by some fundamental error of principle.

THE EARTH'S THERMAL HISTORY

The primitive earth was presumably very thoroughly stirred up. But the heavy metallic constituents refused to mix with the rocky ones and quickly settled to the centre to form the core. At some stage during the solidification the granitic and basaltic layers separated from the dunite one, and, by some process so far very imperfectly understood, the granitic matter became collected into large patches, which we know now as the continents. In a few thousand years a thick solid crust formed, and subsequent cooling took place by conduction through it.

The later history is substantially modified by radioactivity. The amount of heat being conducted out of the earth per unit surface per unit time is the product of the thermal conductivity of the surface rocks, say 0·01 c.g.s., and the increase of temperature per unit depth, which is about 0·00032° C. per centimetre. Thus $3{\cdot}2\times10^{-6}$ calories per sq.cm. per sec. are being conducted out of the earth. But the experimental work of the present Lord Rayleigh, J. Joly, J. H. J. Poole and others has shown that average granite contains enough radioactive matter for 1 cu.cm. to produce $1{\cdot}4\times10^{-12}$ calories per second. Hence about $2{\cdot}3\times10^{6}$cm., or 23 km., of average granite would supply all the heat leaking out at the surface. The actual thickness of the granitic layer, as we have seen, is about 10km.; but other rocks are also radioactive. We are forced to suppose that unless the radioactivity is practically confined to a surface layer with a thickness comparable with 20km., the heat coming out of the earth would exceed its actual amount.

The temperature at any depth in the crust may be regarded as made up of two parts, one due to the original heat, the other to that developed by radioactivity since solidification. The age of the earth and the other relevant physical data being roughly known, the former part can be evaluated. Subtracting from the

rate of conduction out of the earth the portion due to original heat, we are left with the part due to radioactivity. This is found to be equivalent to the rate of generation of heat by about 15km. of granite, or by 10km. of granite with 20km. of basalt under it;—in excellent agreement, so far as we can tell, with the results of seismology. If we adopt the latter view, the present temperature at the base of the intermediate layer should be about 560° Centigrade. At a depth of about 300km. the rocks should have cooled by about 280° since solidification; below 600km. the present temperature in the rocky shell is nearly the melting point. We can now easily see why the central core is liquid. The melting point of dunite at ordinary pressures is 1,400°–1,600°; that of pure iron is about 1,500, but that of the material of the central core might be lower by some hundreds of degrees on account of impurities. In addition, the melting point of dunite is raised by pressure; that of iron, at any rate at low pressures, is lowered by pressure. Accordingly we should expect that the central core would be more fusible than the surrounding rock; and if the latter is near its melting point the iron must be liquid.

The foregoing discussion concerns mainly continental conditions. Radioactivity beneath the oceans must be less, and the cooling at great depths there may be up to 30% more. The upward concentration of radioactive matter requires an explanation. It is perfectly genuine, for, without it, it would be impossible to reconcile the radioactivity of the surface rocks with the rate of increase of temperature inwards. Also it can be shown easily that if the radioactive layers were twice as deep, or even if the total amount of radioactive matter were the same, but were uniformly distributed to a depth of 100km., the steady temperature at the base of the radioactive layer would be so high that the interior could never have become solid. A difficulty sometimes expressed about the concentration near the surface is that the elements concerned are heavy, and might have been expected to collect near the centre of the earth. But when the total amount of a substance is too small to affect the density of its solvent appreciably, the density is often of much less importance than solubility or volatility in determining the distribution.

Actually it is found that the radioactive generation of heat in basalt is under a third of what it is in granite, and in denser rocks such as dunite the amount is much lower again. This points directly to a strong upward concentration, especially as the dunites analysed are, of course, surface samples, and have probably been enriched by contact with the more radioactive rocks that surround them. Further, Holmes has called attention to the fact that in successive igneous outpours, even of material of similar composition, the material from the higher levels seems to have been enriched in radioactive materials at the expense of that lower down. The evidence that these substances actually do tend to collect upwards is very strong. The explanation is probably connected with the facts that they form volatile compounds, and that an important fraction of the water on the earth's surface has probably been extruded during geological time. The ascent of the water from rock magmas would carry the volatile constituents upwards. But it is to be noticed that the effect of radioactivity on deep-seated temperatures is proportional not only to the total amount of radioactive matter present, but also to its mean depth. The upward concentration of this matter would continue until it became too near the surface to prevent any farther solidification down below. Later denudation would tend to transfer the radioactive substances to the ocean bottom, as Joly has pointed out.

A further complication is the influence of change of state. If a liquid gradually solidifies by cooling from the top a solid crust forms and steadily thickens. The rate of thickening is largely controlled by the latent heat of fusion, which has to be conducted away before new matter can solidify. With a latent heat of 100 calories per gm., which is about correct for the few silicate rocks yet tested, it can be shown that solidification could not have reached a greater depth than 300km. during geological time. Yet the seismological evidence is clear that the earth is solid to nearly ten times this depth. It seems to follow that no change of state involving so great a latent heat has taken place at great depths; the change has possibly been from a liquid state to a glassy one, and not to a crystalline one.

The Effects of Cooling at Great Depths.—The fall of temperature since the solidification of the crust would be associated with a contraction in volume. But we have seen that, since the solid crust formed, the outer surface and the central regions have scarcely cooled at all; the greatest rate of cooling is at an intermediate depth, which is at present somewhere about 200 kilometres. The spherical shell of cooling matter becomes too small to fit the interior, but being plastic it stretches and becomes thinner. This makes its outer boundary move towards the centre, tending to leave the uncooled outermost regions unsupported. But they are not strong enough to support themselves, and collapse under their own weight. They have to accommodate themselves to too small a surface, and consequently crumple, fold and fracture. This is the thermal contraction theory of mountain formation. It is found that the total amount of reduction of surface to be expected is at least 2,000,000 square kilometres. The compression required to explain all known mountains is not accurately known, only a few great ranges having been fully surveyed geologically, but it appears to be of the same order of magnitude. The chief strength of the thermal contraction theory, however, is that it certainly accounts for a large fraction of the mountains of the globe, and as no other suggested theory has been proved so capable the presumption is that thermal contraction is the chief cause of mountain formation.

Further, the rocks beneath the oceans are more basic, and therefore are probably less radioactive and have cooled more than subcontinental rocks. Even at the same temperature basalt seems to be stronger than granite and when it is cooler it will be stronger still. Hence when an ocean floor is compressed against a continent, the latter will be the first to yield. This is the probable explanation of the Pacific type of mountains—the long series of the Rockies and Andes with the smaller ranges running nearly parallel to them and to the neighbouring coast.

Mountain formation, on almost any mechanical theory, would be expected to be intermittent in time and localized in position. The upper rocks are elastic solids, which have to be under a considerable stress before they give way, and when they do so the yield is at a definite place and becomes complete almost instantaneously. If then the stress is one that grows very slowly and gradually, there will be long quiescent periods when the stresses are accumulating, separated by short intervals when they are relieved by folding and fracture, with mountain formation as a result. This corresponds with the facts as known to geology.

The theory has, however, still to meet several difficulties in points of detail; while the phenomena of igneous activity, shown in volcanoes and intrusions, seem at present to stand right outside it. The temperatures that seem most probable within, the intermediate (basaltic) layer are enough to make a hard glass readier to flow than the basaltic layer actually is; nevertheless, basalt driven up to the surface seems to be much more completely fluid and, to judge by its effects on neighbouring rocks, at a much higher temperature. A curious fact noticed by Aston provides what looks like a promising clue. The "inert gases" (helium, neon, argon, krypton and xenon) are far scarcer on the earth than one might expect from comparison with the abundance of other elements of neighbouring atomic weights in the crust: the ratio is in all cases somewhere about a millionth. A very natural explanation is that when the primitive earth was highly heated and probably distended its gravitation was insufficient to control the freely-moving molecules of a gaseous atmosphere; consequently the truly gaseous constituents were mostly lost from the earth and transferred to the resisting medium. The present earth consists of the constituents, such as iron, that liquefied readily, and of the materials that formed liquid or solid compounds at the high temperature concerned. From this point of view it is interesting to note that the amount of oxygen in the earth's crust is within 1% of that needed to combine with all the other elements; and the rarity of the inert gases is to be attributed precisely to the fact that they are inert gases, and could not find even a temporary place of safety in the earth's interior. But if we adopt this explanation we must suppose that most of the water and carbon com-

pounds on the earth's surface at present have been expelled from the interior since the earth shrank to its present size. Now there is ample independent evidence that chemically active gases and water vapour are continually being expelled from volcanoes, and T. A. Jaggar and A. L. Day have given reason to believe that their reactions with one another and with the oxygen of the air are the principal factors in maintaining volcanic temperatures.

Continuous heating in the deeper crust would produce expansion and hence tension in the upper crust. This would lead to vertical cracks and violent igneous outpourings. On the views just given concerning the way radioactive materials become concentrated near the surface, the earth's crust must have had such a history in its earliest days, but denudation and other factors have obliterated all traces of it. On the moon, however, there has been no denudation, and an extensive system of fissures and craters is the moon's most prominent feature. Lunar vulcanism is then to be referred to the moon's earliest days and the upward movement of radioactive matter produced by it provides the reason why the internal heating ceased and there is no vulcanism on the moon to-day.

Isostasy. — It is clear from the geological evidence that the transport of large quantities of matter horizontally, so as to thicken or thin the crust locally by several kilometres, is a common feature of the earth's history. Now, all matter produces a gravitational field, and this redistribution would therefore be expected to produce disturbances of the direction and intensity of gravity. Numerical calculations of the amount of these disturbances can be made; but when they are compared with the actual local direction and intensity of gravity, as shown by the slope of the plumb-line and the period of a standard pendulum, they are always found to be wrong. It would actually be nearer the truth to say that additional matter does not appear to attract the plummet or the pendulum bob at all, and that matter removed appears not to have attracted them. The law of gravitation cannot be wrong; the only possibility is that there is really no excess or deficiency of mass in these places, addition or removal of matter on top being compensated by the outflow or inflow of an equal mass below. This result would follow physically if the earth's upper crust was an elastic solid, but so thin as to be readily flexible, and rested everywhere on a fluid interior.

This theory was actually suggested as an explanation by Sir G. B. Airy when attention was called to the facts by Archdeacon J. H. Pratt. Extra mass on top would force the crust down, the fluid below would flow out, and the process would continue until just enough had flowed out to restore the balance; in the "isostatic" state every vertical column of the same section would have the same mass inside it. Pratt did not accept this explanation, and proposed as an alternative the idea of a "depth of compensation"; according to him the extra mass of a mountain is compensated by a uniform reduction in density of all the matter below it, down to a fixed depth. This hypothesis requires that the matter should diminish in density when an extra pressure is placed on top of it, and therefore is physically unplausible; and there are also weighty geological arguments against it. But most geodesists, especially J. F. Hayford and W. Bowie in the United States, have adopted Pratt's view and found it to correspond well with the facts. It is only recently that W. Heiskanen has shown that the Airy theory fits the facts at least as well, and that H. Jeffreys has shown that this result was inevitable from the nature of the law of gravitation. The only modification needed in the Airy theory is that the substratum is not a fluid, but a very stiff solid, capable of transmitting distortional waves, but not of enduring great stresses for a long time. The weakness is, of course, to be attributed to its high temperature.

The variation of gravity over the outer surface depends somewhat on the thickness of the elastic outer layer, for this affects the depth where the outflow takes place. A horizontal displacement of a given mass at the surface would clearly affect gravity in a different way from a similar displacement at the centre of the earth. Heiskanen, on the hypothesis that the outflow was always vertically below the added matter, found that the thickness of the upper layer should be 40–80km. in different great mountain ranges. Actually the elastic bending of the upper layer will spread the compensation horizontally a little, and, when allowance is made for this, the most probable thickness is only about 30 kilometres. Thus the strong region extends at most to the bottom of the intermediate layer; all matter below that has a strength less than about a fiftieth of that of granite or basalt under surface conditions.

EARTH, FIGURE OF THE: *see* GEODESY.

EARTH CURRENTS. Our knowledge of earth currents dates from the introduction of telegraphy. Ordinary telegraph lines are traversed by natural electric currents which occasionally interfere seriously with their use. It is these currents which we shall mainly consider here. There are, however, electric currents arising from electro-chemical action in mineral deposits, electric waves due to natural causes such as thunderstorms or to wireless, and widely distributed artificial currents due to electric traction and lighting. The pioneers of our subject in England included W. H. Barlow and C. V. Walker, in charge, respectively, of the Midland and South-eastern telegraph systems. Barlow noticed the existence of a more or less regular diurnal variation, and the fact that earth currents proper occur in a line only when both ends are earthed. Walker collected statistics of large earth currents. His and Barlow's results indicated that the lines which suffer most from earth currents in England have the general direction north-east to south-west.

As Walker pointed out, it is the direction of the terminal plates relative to one another that is the essential thing. Thus in France, in 1883–84, E. E. Blavier, comparing continuous records from two lines, one aerial, the other underground, connecting Paris and Nancy by different routes, found an exact parallelism between the currents. The difference of electro-motive force between the two terminal plates is the cause of the current, but the intensity varies inversely as the total resistance of the wire. The currents in the ground must depend on the resistance of the soil, which will vary with the depth and the geological conditions. Observations on experimental lines can convey only a general idea as to the currents in the earth itself, but they may be expected to show their variations.

Our present knowledge owes much to practical men, but the fact that telegraph systems are primarily commercial undertakings is a serious obstacle to their employment for research. Some valuable observations have, however, been made on long telegraph lines. In addition to the French observations already referred to, mention may be made of important observations made from 1884 to 1888 in the case of two German lines, Berlin to Thorn and Berlin to Dresden, discussed by B. Weinstein, also of observations during 1921 and subsequent years on several Swedish lines, discussed by D. Stenquist.

Experimental Lines. — Amongst the earliest experimental lines were those instituted at Greenwich in 1865, one going to Dartford, distant about 10 m., in a direction somewhat south of east, the other going to Croydon, distant about 8 m., in a direction west of south. Perhaps the earliest of what may be considered modern installations was that set up by T. Moureaux at Parc St. Maur, near Paris, in 1892. There were three lines, one having terminal earth plates 14.8 km. apart in the geographical meridian, a second having earth plates due east and west of one another, also 14.8 km. apart, and the third, which did not measure earth currents, forming a closed circuit wholly insulated from the ground. In each of the three lines was a Deprez d'Arsonval galvanometer, and a continuous photographic record was devised.

Each galvanometer had a resistance of about 200 ohms, shunted by a resistance of only 2 ohms. The total effective resistances in the north-south and east-west lines were 225 and 348 ohms respectively. What is really measured by such apparatus is the voltage between the two earth plates. This voltage between the two earth plates as measured is usually stated in mv./km.: millivolts per kilometre.

Industrial currents put an end to the usefulness of the earlier installations. Of those still functioning the best known is that of the Ebro observatory, Tortosa, dating from 1910. One line, which we may call the N.′–S.′ line, has earth plates 1·28 km. apart, and the straight line joining them is inclined at 25°16′ to the geographical meridian, thus running roughly from north-north-west to south-south-east. The other, or W.′–E.′ line, has plates 1·415 km. apart, and is nearly perpendicular to the N.′–S.′ line, being inclined at 24°46′ to the geographical west-east line. The method of recording is similar to that described at Parc St. Maur. Other more recent installations are those of the Carnegie institution at Watheroo (Western Australia) and Huancayo (Peru).. The two lines at Watheroo run exactly north-south and east-west, each being about a mile long.

A source of uncertainty, especially in short lines, is the probable existence of polarization currents from the electrodes. These can be largely, if not entirely, avoided in temporary installations by the use of special non-polarizable electrodes. But difficulties still remain in permanent installations. For many purposes a constant polarization current is immaterial, but varying polarization effects might cause serious confusion. Provision for the detection of spurious electrode effects is thus desirable, and is included in the installation at the Carnegie institution which is situated at Watheroo (Western Australia).

Diurnal Variation. — The diurnal variation data in Table I. are all given as inequalities, *i.e.*, as algebraic departures from the mean value for the day. The inequality may be regarded as superposed on a "constant" value, which, in general, was so large that the direction of the total current was invariable. In cases like the Ebro, where the absolute difference of potential between the earth plates was known, the entries in Table I. represent millivolts per kilometre. In cases where the unit was arbitrary, the units employed in Table I. were such as to make the A.D., *i.e.*, the average numerical departure of the hourly values from the mean value for the day, equal 100. A few explanatory remarks will be found useful. The Greenwich data are based on a discussion by Sir G. B. Airy of results from 1865 to 1867. The Greenwich observations were among the earliest experimental studies made of the subject. Airy resolved the observed currents from the two lines in two directions, one N.′–S.′ in the magnetic meridian, the other W.′–E.′ perpendicular to it. Magnetic declination at the time was about 21° W. In every month the mean of the 24 hourly values represented a current from north to south in the magnetic meridian, and from east to west in the perpendicular direction. Col. 10 represents the inequality in the former current, + signifying increase in the current from north to south. Col. 13 represents the inequality in the latter current, but + signifies algebraic increase in the direction west to east, and so a numerical fall.

Col. 14 is based on a discussion by H. N. Dickson of hourly readings during a fortnight in Sept.–Oct. 1885 of the current in the telegraph cable between Ft. William and the Ben Nevis observatory. The "constant" part of this current was directed up the hill, nearly west to east. Thus in this case + represents numerical as well as algebraic increase.

Cols. 9 and 12 are based on Weinstein's discussion of the results from the German lines, Berlin to Thorn, 262 km. away, and Berlin to Dresden, 120 km. away. Relative to Berlin the geographical co-ordinates of the two other terminals were Thorn 0° 29′ N. lat., 5° 12′ E. long., and Dresden 1° 28′ S. lat., 0° 21′ E. long. The directions taken as + in Table I. are in each case the opposite of Weinstein's. His units being arbitrary, such (different) units were employed in cols. 9 and 12 as to make the A.D. in each case 100. But if we used the same absolute unit for the two directions, we should reduce the figures in col. 12 in the proportion roughly of 45 to 100.

Cols. 1 and 5, which refer to true geographical directions, are derived from the official Ebro publication for the year 1926, and are based on five days a month, mainly the international magnetically quiet (or Q) days selected at De Bilt; when the Ebro record was incomplete another quiet day was substituted. Cols. 2 and 6 also refer to the Ebro; they were calculated by D. Stenquist from all the available days, quiet or disturbed, of the six

years 1910, 1912, 1913, 1916, 1917 and 1918. Cols. 8 and 11, applying to the Ebro, reproduce the results in cols. 1 and 5 respectively, multiplied by the factors necessary to make the A.D.=100 in each case. In addition to the inequalities in cols. 1 and 5, obtained by combining results from the Ebro N.'–S.' and W.'–E.' lines, we have in cols. 3, 4 and 7 inequalities for the two lines separately, going only to the nearest mv./km. in the NS line. Cols. 3 and 7 are based like cols. 1 and 5 on the quiet day results of 1926 in the official publication. Col. 4 refers also to 1926, but is derived from the international magnetic disturbed (or D) days. Of the 60 disturbed days eight were omitted, as the trace was incomplete. No substitutes were used, and equal weight was given to each month.

Double Daily Oscillation. — A general feature in Table I. is a well marked double daily oscillation, best seen in the comparatively smooth data from Berlin and the Ebro. A key to the Ebro phenomena is supplied by cols. 3 and 7. The amplitude of the diurnal variation is some 15 times larger in the N.'–S.' line than in the W.'–E.' The phase of the W.'–E.' variation seems rather opposite than similar to that of the N.'–S.' variation, but the latter is so dominant as to decide the phase even in the west-east inequality, cf. cols. 8 and 11. The peculiarity of the phenomena may raise doubts respecting all the Ebro inequalities. But it will be seen that the results for the Ebro, in cols. 8 and 11, are remarkably similar to the corresponding results from the long German lines in cols, 9 and 12. The German data also agree in showing at least a close approach to agreement in the phase of the north-south and west-east diurnal inequalities. It was largely with a view to emphasizing this agreement in phase that W. to E. has been taken as the + direction in Table I.; this departs from the procedure adopted in the 11th edition.

The agreement between the Ebro results in cols. 1 and 2, and again in cols. 5 and 6, is good. The closeness of the amplitudes in the two cases must, however, be regarded as largely accidental. The amplitude really varies with the amount of disturbance and with the sunspot frequency. The six years on which cols. 2 and 6 depend had a mean sunspot frequency of only 44·2, as against 63.9 for 1926. The effect of disturbance on the regular diurnal variation at the Ebro can best be inferred from the corresponding quiet and disturbed day results in cols. 3 and 4 of Table I. Disturbance does not seem to have much influence on the type of the diurnal variation, but it largely increases the amplitude.

In view of the irregularities natural in inequalities from a single year, the A D. is probably a better measure of the amplitude than is the range in most cases in Table I. If we take the A.D as our measure, the ratio borne by the amplitude of the diurnal inequality in the west-east line to that in the north-south line is 0·43 at the Ebro (1926) and 0.45 at Berlin. According to observations by D. Stenquist, extending over several months of 1924 and 1925, the ratio was 0·54 at Lund (56° N.) and 1.84 at Lulea (66° N.). This tendency to a rise in the relative importance of the diurnal changes in the west-east direction as we go to higher latitudes in Europe was pointed out by Stenquist.

Irregular Changes. — Col. 15, Table I., stands by itself. It is based on an enumeration by Stenquist of the number of irregular changes exceeding a certain amplitude recorded in the Ebro N.'–S.' line during 1916, 1917 and 1918. The results are shown as an inequality representative of disturbance, the unit being selected to bring the A.D. up to 100. The changes really numbered 1645, the hourly totals varying from 12 to 168. We have here little if any trace of a double oscillation. The hour 9 P.M. of most frequent disturbance accords closely with the hour of greatest frequency of large magnetic disturbance in Britain; and, as is true of magnetic disturbance in Europe generally, the night is much more disturbed than the day. Stenquist also investigated the disturbances in the Ebro W.'–E.' line. They showed a decided double oscillation, but were relatively insignificant.

The fact that the amplitude of the regular diurnal inequality increases with sunspot frequency was first demonstrated by Weinstein for the German lines. Stenquist found a similarly large effect at the Ebro. L. A. Bauer also dealt with the matter in a discussion of Ebro data from 1910 to 1920. Employing all days with the exception of the highly disturbed, he found that the absolute daily range, *i.e.*, the excess of the absolute maximum over the absolute minimum of the day, in the N.'–S.' line was 53% larger in 1917, the year of sunspot maximum, than in 1913, the year of minimum.

Annual Variation. — Table II. illustrates the annual variation. Cols. 1 to 5 relate to the N.'–S.' line, cols. 6 to 10 to the W.'–E.' line at the Ebro. These data all refer to 1926, and are in mv./km. Cols. 1 and 6 give the ranges of the regular diurnal inequalities derived from five quiet days a month. Cols. 2 and 7 give the absolute daily ranges from the same quiet days. Cols. 3 and 8 give the absolute daily ranges from all available days, while cols 4 and 9 give the absolute daily ranges from the international magnetically disturbed days. Winter includes January, February. November and December; equinox includes March, April, September and October; and summer includes May to August. In all cases the yearly and seasonal results are arithmetic means from the included months. There is invariably a marked increase in amplitude as we pass from the inequality range to the absolute range, from the quiet day to the average day, and from the

average day to the magnetically, highly disturbed day.

The data in cols. 11, 12 and 13 are expressed in terms of units such that the mean from the 12 months is in each case 100. Col. 11 refers to Weinstein's value of the resultant current as derived from the diurnal inequalities in the German lines. Cols. 12 and 13 are derived from the all day absolute ranges in the Ebro N.′–S.′ line. Col. 12 is based on data given by Bauer for the 11 years 1910 to 1920. Col. 13 merely repeats the data in col. 3, but in a shape comparable with col. 12. Col. 14 is based on a table given by Stenquist of the number of disturbances from 1881 to 1884 in telegraph lines at four Norwegian stations, varying from 60° N. lat. to 70° N. The occurrences at the four stations, summed up as if independent, numbered 904. Each monthly sum was multiplied by —, so as to bring the monthly mean up to 100.

Cols. 11 and 14 may be regarded as representing respectively the regular and irregular daily changes. In col. 11 the maximum of activity occurs in the summer months, the minimum in the winter.

In col. 14, on the other hand, the maximum activity is in the equinoctial months, and the more conspicuous minimum occurs in summer. Cols. 12 and 13 agree with col. 14 in placing the maximum of activity in the equinoctial season. Cols. 3, 4, 8 and 9 agree with cols. 12 to 14 in making equinox the season of greatest activity. Cols. 1, 2, 6 and 7 agree with col. 11 in showing a tendency for the regular diurnal changes to be larger in summer than in winter.

Cols. 5 and 10 of Table II. represent the mean monthly values of the "constant" part of the current in the two Ebro lines. The difference between the results in the N.′–S.′ line from January to June and from August to November is extraordinary. A rapid fall occurred in July and a rapid rise in December. The phenomenon is almost equally prominent in the results given by Bauer for the resultant currents at the Ebro from 1914 to 1918, the chief difference being that in Bauer's average year the decline did not set in until August. His July values varied between 329 and 611, his September values between 13 and 33. The phenomenon is probably of local origin and might be a consequence of variable plate polarization. But there is nothing in the run of the figures in cols. 1 to 4 and 6 to 9 which suggests that the diurnal changes are affected.

Relations to Terrestrial Magnetism. — At the Ebro during 1926 the highest voltage recorded in the N.′–S.′ line was 0·754 v./km., but in one magnetically disturbed day the range exceeded 0·7 j v./km. Much larger voltages are sometimes encountered. In May 1921, during an outstanding magnetic storm, Stenquist calculated from the fusing of some copper wires and the non-fusing of others that the largest earth current voltage in Sweden lay between 6.3 and 20 volts per kilometre. In several cases the currents produced in telegraph wires exceeded 2·5 amperes. Under such circumstances potentials differing from that of the earth by several hundred volts may exist in a long line. Potentials of 700 or 800 volts are, in fact, said to have been met with in English lines during the autumn of 1859.

In dealing with the Ebro it has been assumed that quietness or disturbance in earth current phenomena can be safely inferred from the magnetic conditions. A striking confirmation is afforded by a table of Stenquist's which enumerates the days, 53 in number, between Nov. 1, 1906, and Oct. 31, 1909, when a current exceeding 15 milliamperes was recorded at the Stockholm Central Telegraph office, this representing the lower limit at which serious trouble was experienced. The magnetic character figure — the international measure of disturbance-exceeded 1·5 on 30 of the 53 days, and fell short of 1·0 on only two of them, the character on the average day being under 0·7. The three equinoctial months, March, September and October, supplied 28 of the 53 days, while June and July supplied none.

Close parallelism with magnetic phenomena is also shown in an investigation by W. J. Peters and C. C. Ennis of the 27 day recurrence interval. This is a well known magnetic phenomenon, conditions, whether specially disturbed or specially quiet, tending to recur after 27 days. Peters and Ennis employed the absolute daily ranges in the Ebro N.′–S.′ line from 1910 to 1924. Primary pulses were formed from selected disturbed and quiet days — usually five of each per month — and the adjacent days, in a similar way to that employed by Chree for terrestrial magnetism, and exactly as in the case of magnetism these were found to have associated pulses of disturbance or quietness, with their crests falling 27 days subsequent to those of the primary pulses.

All the phenomena mentioned here point to an intimate connection between earth currents and terrestrial magnetism. Many authorities have supposed it a case of cause and effect, differing, however, as to which is the cause and which the effect. So far as the limited data available enable us to judge, neither hypothesis suffices to explain the facts. It is practically certain that at least a substantial part of the regular diurnal changes in terrestrial magnetism is due to overhead electric currents, and the association of earth current with magnetic disturbances, and of both with aurora, points to the upper atmosphere as the ultimate seat of at least disturbance phenomena. The 27 day recurrence phenomenon supports the view, now generally held, that aurora and magnetic disturbance are due to electrical discharges from the sun. The exact nature of the discharge is still, however, a matter of speculation.

If the main cause of the daily magnetic variations is situated above the earth, this varying external field must necessarily induce electric currents within the earth. From consideration of the records of the diurnal variation of magnetic force at numerous observatories, Schuster showed that about two-thirds of the diurnally varying field is of external origin, the remainder coming from within. This implies that the induced currents in the earth are less than the primary currents in the atmosphere. According to Chapman the earth must be much more conducting below a depth of about 250 km. than in the layer above this. The specific resistance found for the core is 2,700 ohms per cm. cube. The core is about 1,000 times as conducting as dry earth, but only about $\frac{1}{100}$ as conducting as the salt water of the oceans.

Chapman and Whitehead have compared the diurnal variation of the horizontal potential gradient at Ebro with calculations based on the computation of the magnetic field. The agreement in phase is close enough to indicate that the theory is substantially correct; the observed variations are more than five times as great as the computed ones; but this is probably due to the local distribution of resistance in the rocks of the Ebro valley.

The movements of a magnetic needle being governed by the electric currents in the upper atmosphere as well as those under ground it is not to be supposed that magnetograms and records of the horizontal electric force will be very simply related. In general it is true that an increase in the flow of electricity under ground from north to south is accompanied by a movement of the compass needle to the west and a flow from east to west is accompanied by an increase in horizontal force. The ratio of the scales on which the variations of electric and magnetic force occur is much greater for rapid oscillations than for the regular diurnal changes. This may be due to the fact that the earth currents taking part in the rapid oscillations do not extend to any great depth.

In the case of Ben Nevis, as already remarked, the "constant" part of the potential difference indicated a current flowing up the mountain. A similar tendency has been described in other cases, but more evidence is needed to justify the conclusion that there is a general tendency for earth currents to flow up mountains.

Certain mineral deposits, e g., pyrites, especially when the surrounding material is damp, give rise to local earth currents of perceptible amount. This property may be utilized by prospectors, as is described by J. Bartels in the *Lehrbuch* der *Geophysik*, p. 575.

Uses of Artificial Earth Currents. — Artificial earth currents have been used in various ways by prospectors. To get a general idea of the problem, suppose a long 3 in. plank of wood, backed by 1 in. copper plating, and suppose holes drilled to a depth of 0·5 in. along the median line of the opposite face of the plank, to serve as points for the insertion of a pair of terminals, in a circuit furnished with a battery, and electrical measuring apparatus. Suppose measurements made of the electrical resistance of the wood between the terminals. So long as the distance between the termi-

nals is only 1 in. or 2 in., the presence of the copper backing is of little account, but as the distance between the terminals increases, so does the influence of the copper, until it becomes very large indeed. The presence of underground material differing much in electrical conductivity from the surrounding soil can be inferred in this way from judicious measurements of resistance, made with two terminals inserted in the ground at various distances apart. Other electrical methods have been tried, involving the use of alternating currents of high voltage, with periods such as 0·002 second, led into the earth. Equipotential surfaces may be mapped out with the aid of a telephone, and their shape supplies a key to the situation (cf. Bartels, l.c.).

As a specific example, reference may be made to investigations carried out by W. J. Rooney and O. H. Gish in the immediate neighbourhood of the observatories of Watheroo and the Ebro. Suppose four terminals sunk in the earth along a straight line, the distance between adjacent pairs being in each case a. The extreme pair of terminals are in a circuit containing a source of current. If I is the measured current in the circuit and V the potential difference found with a potentiometer between the inner pair of terminals, the resistivity of the earth ρ, assumed uniform, is given by $\rho = 2\pi a V/I$.

As regards the applications, in Rooney and Gish's words "The value of resistivity thus found must, however, in general be considered an average, in which the resistivity of the earth near the line of terminals is the more heavily weighted." They assume that material whose distance from the line of electrodes exceeds a may practically be left out of account.

The mean values calculated for ρ at Watheroo, from a series of sections and in different months, in ohms per cm.^{3}, varied from 580,000 when a was 2·5 metres, to 700 when a was 60 or 100 metres, and then increased to 5,000 when a was 600 metres. It was inferred that the sandy soil at the surface had a very high resistivity when dry, but beneath it at a comparatively small depth was a layer of low resistivity. This was confirmed. From the increase in the values obtained for ρ when a exceeded 100 metres it was inferred that below 100 metres there was a stratum of much higher resistivity.

At the Ebro the resistivity with $a = 2{\cdot}5$ metre, *i.e.*, near the surface, was much less than at Watheroo, in one case as low as 1,300; but with a as large as 60 or 100 metres it rose to 10,000, being then and for greater values of a much larger than at Watheroo. Rooney and Gish point out that the higher resistance of the deeper strata in the Ebro valley is accompanied by higher values of the potential gradient, so that the currents in the earth in the two localities are comparable.

Disturbances Due to Artificial Earth **Currents.**—Practically every kind of artificial use of electricity, traction, lighting, telegraphy, telephony and wireless, may set up earth currents of one kind or another.

The most important case is that of the disturbance caused by the use of direct current for electric traction. The currents are large, and even if there were a perfectly insulated return there would be a considerable resultant magnetic force at distances from the track which were not largely in excess of the distance apart of the direct and return currents. At a distance of $\frac{1}{2}$ m. or more from an ordinary electric railway the disturbance is usually much the largest in magnetographic records of changes in the vertical component of the earth's field. At Washington (D.C.), U S.A., sensitive instruments have shown disturbance effects at a distance of 12 miles. Practically all the magnetic observatories once functioning near large towns—including of late years Kew and Greenwich—have been put out of action.

As regards damage from electrolysis caused by the so-called "vagabond" currents to underground gas and water pipes, numerous observations have been made, especially in Germany and the United States. Owing, perhaps, to the conflicting interests involved, the extent of the damage has been variously estimated. However this may be, the prosecution of research into natural earth currents has difficulties to contend with which did not exist 100 years ago.

EARTHENWARE, a term generally associated with a coarser type of domestic pottery, although such cups and saucers and other table ware of thin pottery, are often called china (*q.v.*) in error. Earthenware can be made almost as thin as china, but it lacks translucency; it is opaque. Its chief feature is that it will absorb moisture *under* the glaze, whereas china will not. A test adopted by the British customs officials is the application of red ink to the ware at a point where the glaze has been removed. If the ink is absorbed then it is classed as earthenware.

Earthenware embraces a wide range of pottery known under a variety of names, which usually indicate the place where the ware was first introduced. William Burton, a well-known authority (*see* CERAMICS), writes: "The word earthenware in its widest sense might be used to cover all varieties of pottery, as they are all made from some form of earthen or mineral substance taken out of the ground. In this broad sense a brick, a drainpipe and a Chinese vase might be equally described as earthenware, but though the chemical differences between them are slighter than would be supposed, they are so far apart in technique and final result that the names earthenware, stoneware and porcelain are very conveniently used to differentiate between them. In this restricted sense, the title 'earthenware' covers all articles made from a single natural clay, or from mixtures of clay and other mineral substances which, *when sufficiently fired* for practical use, *still* remain porous, and need, therefore, if they are to be used for culinary, domestic, or decorative purposes, to be completed by the addition of an outer skin of glaze or glass melted on them. . . ." A handbook compiled by British experts in conjunction with the educational committee of the Pottery and Glass Trades' Benevolent Institution, gives the following definition of earthenware:—

"All ware may be termed earthenware which is porous in the material itself, and requires to be glazed before it can be applied to domestic use. Earthenware is opaque; it will not transmit light."

The porosity of the "body" (the pottery itself without a glaze) may give a wrong impression to those who are not familiar with the ceramic industry. For instance, Bourry, a noted authority on the industry, points out that terra-cotta and stoneware are quite distinct in their properties. One of the chief characteristics of stoneware is its impermeability, whereas terra-cotta has a porous body. If the distribution of the temperature of the kiln is irregular, some of the ware, says Bourry, will be impervious and rightly termed "stoneware," whilst other ware, in the same kiln, will have a porosity between that of terra-cotta and stoneware. Judged on the basis of porosity, an article, Bourry points out, might be defined as "stoneware" if viewed from one side and as "terra-cotta" if viewed from another! Therefore it will be seen that earthenware and other types are not easily defined; but for general purposes the term "earthenware" may be applied to pottery which is absorbent under the glaze.

Types of Earthenware.— Earthenware can, however, appear under several names, each chosen to distinguish a special type of ware. These are sometimes distinguished in the trade as agate ware, onyx ware, marbled ware, porphyry ware, that is, earthenware made to imitate these various natural stones by mixing different coloured clays and glazing with a rich soft glaze.

Delft ware is a general term applied to earthenware covered by an opaque tin enamel. It takes its name from Delft in Holland, where it was already largely made about 1600. Afterwards it was imitated at Lambeth, Bristol and Liverpool (England).

Faience ware is an earthenware with a soft rich glaze, generally decorated under the glaze; named after the place of its origin, "Fayence."

Majolica ware is the name given to an earthenware which is glazed with soft-coloured glazes. It takes its name from "Majorca."

Queensware is a yellow or cream-coloured English earthenware first made about 1750 by Josiah Wedgwood of Etruria (England). Many imitations of it have been made, which vary much in character, colour, hardness and quality.

Semi-porcelain and ironstone china are only trade names given to a harder form of earthenware. They are not in reality either porcelain or china.

The above descriptions cover in the main table ware and decorative pottery; but earthenware is also used for more prosaic purposes, such as sanitary utensils, and containers for food and drink. Earthenware is also produced in almost every civilized country of the world, but the quality varies considerably. In this respect Great Britain has an enviable reputation for its earthenware, just as it has for china.

Not only will the ware itself differin its quality, according to the country of origin, but the decorations also are in most cases characteristic of the nation that produces the earthenware, unless it is made specially for export. For instance, an eastern country like Japan expresses its artistic character in its pottery decorations, but to capture the trade in western countries forsakes its national decorative schemes and adopts those common in the Western Hemisphere.

The principal raw materials used in the manufacture of earthenware are: china clay, ball clay, flint and china stone.

China-Clay.—This mineral is found in many parts of the world, but the English mines at Cornwall and Devon are considered to produce the best clay for china-making. The clay is, of course, consumed largely by the British potters, but large quantities are exported, particularly to the United States, which have not a clay of the English quality, although quite good clays are found in Georgia.

The British trade returns do not show the exports of china-clay separately, but group them with china-stone. Of these two minerals 651,990 tons were sent abroad during 1926, more than half the quantity (361,797 tons) going to the United States. Belgium follows with 64,891 tons, and the Netherlands ranks third with 40,421 tons.

According to the last census of production, published in a series of preliminary reports during 1926, the output of British china-clay was 805,000 tons, valued at £1,448,000. The previous census taken in 1907 gave the production of china-clay and china-stone together, the total being 726,000 tons, valued at £542,000.

Perhaps the next most important deposits of china-clay are to be found in Czechoslovakia, where an output of 40,000 tons per year is obtained.' The best clay in Czechoslovakia is mined at Sedlice and Karlovy Vary. Czechoslovak clay is also exported to the extent of about 20,000 tons per year, a large part of this being sent to Germany.

China-clay is said to have resulted from the decomposition of granite through many centuries. Its main constituents are silica and alumina, and may be described generally as a white, amorphous powder. The clay is not usually mined in the ordinary way, but is washed down from the sides of the mine by huge jets of water thrown out of hosepipes at a high pressure. The water brings down the fine clay to the bottom of the mine, where any sand is allowed to settle out. The watery mixture of clay is then pumped up to the ground level, and run through a series of troughs, known as "micas," where it undergoes a process of levigation, which consists of running the mixture into a trough from which the clay and water overflow into another trough, and so on throughout the series. While the mixture is passing through the "micas," the heavier materials—the impurities such as mica --gradually settle out and are left behind. On emerging from the "micas" the clay, now pure, is run into settling pits. From here it will pass to storage tanks and then to drying kilns. Finally it travels, in the form of lumps, to the storage room or "linhay," from which it will be loaded into railway trucks or conveyed to ships. It is the china-clay that gives plasticity to the mixture of materials used by the potter.

Ball Clay.—This is found principally in Devon and in Dorsetshire, and is sometimes known as blue clay, owing to its greyish-blue colour, which is due to organic matter. When fired at a moderate temperature it becomes white and remains absorbent; but some clays, if subjected to intense heat, are, according to Sandeman, rendered so hard that they are not easily scratched with a knife. Under such conditions these clays turn a yellowish colour and become non-absorbent.

The clays vary, and the producer grades his clays into several qualities. Deposits will in some instances be found quite near the surface, while in other cases shafts will be sunk and the clay mined in branching "lanes," which vary in height according to the thickness of the vein of clay. It is necessary to "weather" the clay before sending it to the potter. To do this it is piled in heaps and exposed to the weather, and to the sun, rain and frost. probably for years, the whole being turned over at least once, so that all the clay may benefit from the exposure. This weathering is said to increase the plasticity of the clay, an important matter to the potter.

The production of ball clay in the United Kingdom according to the census published in 1926 was 146,000 tons, which had a selling value of £128,000. The United States bought 17,870 tons in 1926, more than half the quantity exported that year, Italy and Belgium following with 4,669 and 2,167 tons respectively.

Flint.—Almost everyone is familiar with the pebbles or pieces of flint which are washed smooth by the waves on the sea-shore. These find their way into the body of earthenware. Not all flints are equally suitable; the best are found in France, although there are many other sources of supply. To reduce the flints to a powdery mass so that they can be incorporated into the clay, the pebbles are heated (or calcined), a process which not only turns them white, but makes them more amenable to grinding. They are first of all crushed and then ground into very small particles in water, so that a white, or greyish, thin liquid paste is produced.

The flint can withstand very high temperatures and therefore makes what might be termed a framework for the clay and other materials in the earthenware. The census of production for the United Kingdom published in 1926 gives a total of 188,000 tons for flints (including crushed and broken flints).

China-Stone.—This is an important ingredient in pottery, and there are deposits of a high quality in Cornwall, England, where the stone is mined by inserting explosive charges in holes drilled by compressed air boring machines. The stone has four recognized qualities or grades: hard purple (a white, hard rock with a purple tinge); mild purple (similar but softer); dry white or soft (a soft white rock); buff (similar to dry white, but with a slight yellow tinge).

Silica is the principal constituent, amounting to about 74% in the dry white and over 80% in the three other varieties. Oxide of alumina is the next important ingredient, amounting to about 18% in the dry white and from 7 to 10% in the other varieties, The British output, according to the preliminary census reports published in 1926, was 51,000 tons, valued at £82,000. China-stone gives the china "body" its translucency.

Manufacture of Earthenware.—Earthenware may be "thrown" on the potter's wheel or made under semi-mechanical conditions. In the case of the potter's wheel the prepared ball or lump of clay, revolving at the will of the potter on a small circular platform, is moulded by hand into whatever shape is aimed at. But for commercial production on a large scale, the thrower may form the ware in a mould, which shapes the exterior, the clay being pressed inside until the desired thickness is attained; or the clay and other materials may be introduced in the form of "slip" (a mixture of the materials with water) into a plaster of paris mould.

A further method is that of "jolleying." In this process a mould forms one side of the article. If "flat" ware, such as saucers, plates, etc., is being made, the mould shapes the top or inside, and the under-side of the ware, which is on top in this process,

is fashioned by cutting away the clay, as it revolves, by means of a tool which is cut to represent the profile of article to be made. The lathe also plays a part in finishing raw, or "green," clay articles. These processes are described and illustrated under CHINAWARE (*q.v.*).

Unlike china, earthenware, has little beauty of its own; also, as already stated, it is necessary to cover it with a hard glaze before it can be used for domestic or most ornamental purposes. Its decoration may be applied by painting or printing designs under or over the glaze; or the decoration may consist of coloured glaze, in one colour or a variety of shades. A glaze is really a glass, and this may be coloured with various metallic oxides. The oxides produce different colours according to the temperature of the kiln and the method of heating. A variety of colour schemes is possible, but it is a speculative method of decoration for it is difficult accurately to predict what the colours will be when they emerge from the kiln. This element of chance is made use of by some potters, for it truthfully can be said that no two pots decorated in such a manner will be identical.

To perfect the decoration of pottery by the fusing of metallic oxides and a flus on the ware the potter needs to have a scientific knowledge; that is, he must understand the chemical and physical properties of the metallic compounds so that he may judge what their behaviour will probably be when subjected to heat in the kiln. With such knowledge some beautiful effects may be produced; but many glorious combinations of coloured glazes have been the result not of predetermined efforts, but of unforeseen happenings in the kiln.

When the "green" or raw clay article has been made, it is fired or heated in an "oven." The glaze is then applied and the ware is fired again.

These processes are illustrated under CHINAWARE.

Statistics.— The quantity of general earthenware, semi-porcelain and majolica produced in the United Kingdom, according to the census published in 1926, was 997,000 cwt., with a selling value of £2,691,000. These figures include only the returns in which weight was stated; other returns gave selling value only, and the total in this case was £3,288,000, making a selling value of £5,979,000 for the year. Sanitary earthenware had a selling value of £1,252,000. Returns regarding the weight of the ware produced were only partially made and gave a total of 360,000 cwt., with a selling value of £854,000. Imports of general earthenware (except high-grade earthenware resembling china), semi-porcelain and majolica into the United Kingdom during 1926 amounted to 291,232 cwt., the largest consignments coming from Germany (195,158 cwt.), Czechoslovakia ranking second with 53,744 cwt. and France, third, with 15,748 cwt. Exports for the same year amounted to 716,724 cwt., as compared with 825,513 cwt. in 1925. The United States is by far the best customer for British earthenware and china; for although earthenware is produced in America, English pottery is eagerly bought. Canada is not far behind the United States, the next most important market being Australia, while other countries in the British empire and South America take substantial proportions of the output of the British factories.

Czechoslovakia produces large quantities of pottery for export. China has been dealt with under CHINAWARE. Italy is well known for its majolica, and there is a moderate export trade; but of earthenware generally, Italy's imports are greater than her exports. Like other countries, France imports pottery as well as sending its own products overseas. Of faience and majolica the exports of French manufacture are considerable.

Classifications of pottery vary in almost every country. In the United States stoneware is grouped with earthenware and we get the record of imports in the table above.

The above countries are the principal sources of American import supply: smaller centres of production make up the grand totals.

FIG. I.— SCHEMATIC DRAWING OF EARTH INDUCTOR COMPASS, SHOWING THE THREE PRINCIPAL UNITS WHICH COMPOSE IT
For use on aircraft, this type is preferred to the ordinary magnetic compass. Its great advantage lies in the separation of the generator from the steering indicator, making it possible for the latter to be installed far enough from the engine to ensure freedom from magnetic disturbance

EARTH INDUCTOR COMPASS, THE, is related to the ordinary magnetic compass (*q.v.*) only in its use of the earth's magnetic lines as the directive force. There is no physical similarity between the two types of compass. The earth inductor compass comprises three principal units. That which reacts with the earth's field and therefore corresponds to the magnets of an ordinary compass is designated the *inductor generator.* This resembles an ordinary electric generator. except that it has no arti-

ficial field. It has an armature, commutator and brushes, and produces electromotive force by reaction with the earth's magnetic field. As in the case of any electric generator, the electromotive force depends upon the angle between the brushes and the field. In the earth inductor generator the brushes may be oriented about a vertical axis so that they may be set in any angular relation to the fore-and-aft line of the aeroplane. They may therefore be turned in relation to the earth's field, either independently or with the aeroplane. As the turning of the brushes in relation to the field discloses two positions of maximum potential and two positions of zero potential. In the earth inductor compass, use is made of one of these positions of no potential. The second unit is known as the *direction controller*. This carries a dial similar to an ordinary compass card and has a crank by which this dial may be turned to any position. There is a mechanical connection between the controller dial and the brushes of the generator, so that the angular position of the brushes is indicated upon the controller dial. The third unit of the compass, the *steering indicator* constitutes a sensitive zero-centre galvanometer, the dial of which is marked *left* and *right*. The indicator is electrically connected to the brushes. (*See* fig. 1.)

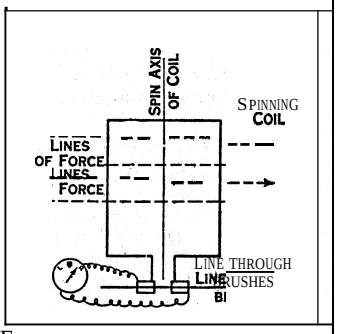

FIG. 2.—IF LINE THROUGH BRUSHES IS PARALLEL TO LINES OF EARTH'S MAGNETIC FIELD. GALVANOMETER SHOWS MAXIMUM DEFLECTION

When the compass is installed, the connection between the controller and the generator is made such that when the aeroplane is headed in the direction indicated on the controller, the brushes will be in a position of zero potential. The steering indicator hand will therefore remain in the centre of the dial. If the aeroplane is turned to the right, the generator brushes will be turned in relation to the earth's field and the generator will produce an electric current in such a direction as to cause the hand of the steering indicator to move to the right, showing the pilot that the aeroplane has turned to the right; turning the aeroplane to the left will put the generator brushes into such position that current in the opposite direction is generated, causing the steering indicator hand to move to the left. As the compass is ordinarily used, the desired "bearing" or direction is set upon the dial of the controller and the aeroplane is then turned until the steering-indicator hand comes to zero. Turns to the right or left away from this heading will cause the hand to move accordingly. When it is desired to change the direction, the controller dial is cranked to a new position and the aeroplane again turned to bring the steering indicator hand to zero. (*See* fig. 2 and fig. 3.)

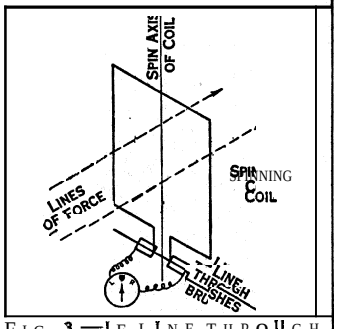

FIG. 3.—IF LINE THROUGH BRUSHES IS AT RIGHT ANGLES TO LINES OF EARTH'S MAGNETIC FIELD, GALVANOMETER READS ZERO

The earth inductor compass offers many advantages over the ordinary magnetic compass, particularly for use on aircraft (*see* AERIAL NAVIGATION). It is much easier to follow the hand of the steering indicator than it is to keep a certain mark on a swaying compass card opposite the lubber-line (*see* COMPASS). The outstanding advantage, however, is the dissociation of the direction-responsive element and the direction-indicating units. In the ordinary magnetic compass these cannot be separated, and in order that the pilot may see his compass it is frequently necessary to place it in a position where it is subject to strong local magnetic fields. With the inductor compass, on the other hand, the generator may be placed in a position which is practically free from magnetic disturbance, while the steering indicator is placed in the best position for observation by the pilot. The controller may be operated by the pilot or by a navigator. One form of the earth induction compass, the "Pioneer," is the invention of M. M. Titterington, and was used by the United States army fliers on their round-the-world and Pan-American flights, on Commander Rodgers's Hawaiian flight, Commander Byrd's North Pole flight, on the trans-Atlantic flights of Lindbergh, Chamberlin and Byrd, and on the flight of Brock and Schlee from New York to Tokyo.

(C. H. **C.**)

EARTH-NUT, the English name for *Conopodium denudatum,* a member of the family Umbelliferae, which has a brown, tuber-like root-stock the size of a chestnut. It grows in woods and fields, has a slender, flexuous, smooth stem 2 to 3 ft. high, much-divided leaves, and small white flowers in many-rayed, terminal, compound umbels. Though really excellent in taste and unobjectionable as food, it is disregarded in England by all but pigs and children. In Holland and elsewhere on the continent of Europe the rootstocks are generally eaten.

The name is applied also to the fruit of *Arachis hypogaea* (family Leguminosae) which is also known as the peanut, groundnut (*qq.v.*) or monkey-nut.

EARTH PILLAR, a column of soft rock, or earth, which has not a homogeneous structure throughout, but contains large blocks embedded in much finer material. By exposure to conditions of denudation, especially rain action, the large blocks protect the material beneath and so, by differential action, the earth pillars are produced. Glacial drift and morainic deposits are ideal substances in which earth pillars can be formed and these structures are therefore found in regions of recent glaciation.

Earth pillars are most likely to be found where the climate is semi-arid with precipitation concentrated. The "bad lands" of western North America furnish excellent examples, and there are specimens in Tirol and other parts of the Alps, in Scotland and in the Dead sea region.

EARTHQUAKE. Though, from very early times, the chief phenomena of earthquakes have been well-known, it was not until the middle of the 19th century that the science dealing with them received a name. In 1858, the term *Seismology* was introduced by Robert Mallet. "The observation of the facts of earthquakes and the establishment of their theory," he says, "constitute *Seismology* (from *σεισμός,* an earthquake, a movement like the shaking of a sieve)."

History.—Over the conceptions of the ancient writers, we need not linger. It was natural that the early Greek and Roman writers should be interested in earthquakes, for those phenomena are more frequent and more violent in Italy and Greece than in any other European countries. Earthquakes therefore find a place in many early works, especially those of Aristotle, Seneca and Pliny, but although these writers attempted to offer a rational explanation of earthquake phenomena, the hypotheses which their explanations involved are, as a rule, too fanciful to be worth reproducing. On the facts as described by them, however, most writers relied until the middle of the 18th century, and it was only when they had freed themselves from their authority and trusted to their more complete knowledge of (then) recent earthquakes, that seismology can be said to have existed as a science. For this release, we are indebted, more than to anyone else, to John Michell, for some years Woodwardian professor of geology at Cambridge. His well-known memoir on earthquakes, suggested by the Lisbon earthquake of 1755, was read five years later before the Royal Society. Except from an historical point of view, Michell's theory of the origin of earthquakes is now of little interest. It is otherwise with his direct contributions to science. He was the first to attribute the vibratory movement in earthquakes to elastic waves traversing the crust. He realized that the position of the origin could be determined by the directions of the shock at two or more places and also by observations of the time or of intervals of time. Its depth, in the case of the Lisbon earthquake, he supposed to be not less than 1 or 1½m. and probably not more than 3 miles. The Lisbon earthquake was succeeded in 1783 by a series of destructive earthquakes in southern Calabria. These were the first great earthquakes to be carefully studied, and the reports on them,

A SEISMOGRAPH, AND ITS RECORD OF AN EARTHQUAKE

1. Section of a seismograph record of the earthquake in Chile, 1922. 2. A seismograph. The horizontal pendulum, carrying a steady mass weighing 220 lb., registers earthquake motion (magnification: 80–100) on smoked paper, which rolls upon a drum, the paper being marked in convenient units of time. One such instrument is set in N–S direction to record E–W motion, and a second E–W to record N–S

by G. Vivenzio and by the committee appointed by the Neapolitan Academy are the earliest of a long series of important earthquake monographs. A succession of great earthquakes drew attention to many points of interest, and to none more significant than the changes of level that occurred during the New Madrid earthquake of 1811, the Kutch earthquake of 1819, and the Chilian earthquakes of 1822 and 1835.

In the first half of the 19th century, our knowledge of earthquakes received many additions. K. E. A. von Hoff, for instance, compiled a catalogue of earthquakes for the whole world. He also issued annual lists of earthquakes from 1821 to 1832. Von Hoff and others thus prepared the way for the general interest shown in the subject about the middle of the century. With this revival, the names of Alexis Perrey in France and Robert Mallet in England are chiefly associated. Perrey's work lay mainly in three directions. He published annual lists of earthquakes from 1843 to 1871, as well as a valuable series of regional memoirs, in which the greater part of the world was covered; but the subject to which he always turned with unfailing interest was the periodicity of earthquakes. He is now, perhaps, best known by the three laws in which he asserted that earthquakes are most numerous about the times of new and full moon, when the moon is nearest the earth, and when it crosses the meridian of the place of observation. The laws have been much criticized. It is possible that the third has no foundation; the others have not yet been definitely proved or disproved.

The impress left by Robert Mallet on the science has been much more lasting. In his first memoir (1846), he applied the laws of wave-motion in solids to the explanation of earthquake-phenomena and treated the subject "in a more determinate manner and in more detail than any preceding writer." He followed it up by his four reports to the British Association (1850–58). The third consists of his great catalogue of 6,831 earthquakes. In the fourth, he discussed this catalogue and published his valuable seismic map of the world. Mallet's last and most important work was his investigation of the Neapolitan earthquake of 1857, in which he applied several new methods of investigation. He determined the position of the epicentre and found the mean depth of the focus to be about 6½ miles. Mallet also advanced several terms still in use, such as seismic focus, angle of emergence, isoseismal line and meizoseismal area.

Development of Seismology.— While Mallet's work was drawing to a close, the study of earthquakes was continued in other countries. In Italy, L. Palmieri constructed his electro-magnetic seismograph in 1855, and installed it in the new observatory on Vesuvius. From 1869 to 1878, T. Bertelli observed and measured earth-tremors with unfailing diligence. In 1874, M. S. De Rossi founded the *Bollettino del Vulcanismo Italiano,* the first journal devoted solely to earthquakes and volcanoes. He also devised his scale of seismic intensity, to be combined a few years later with one proposed by F. A. Forel. In 1878, A. Heim and Forel founded the Swiss Seismological Commission, by which Swiss earthquakes were studied for more than 30 years. It was then merged in the existing Government department of the Swiss earthquake service.

Far more important was John Milne's foundation, in 1880, of the Seismological Society of Japan. It is not too much to say that. during its 12 years' existence, seismology became an exact science. Accurately recording seismographs were invented by J. A. Ewing, T. Gray and Milne, and, for the first time, revealed the real nature of the movements of the ground during an earthquake. Most of the society's work was done by Milne, who organized a system of observers throughout a large part of the country, catalogued the great earthquakes of Japan and studied their distribution in space. Shortly before the Seismological Society ceased its useful work, the provinces of Mino and Owari were visited by the destructive earthquake of Oct. 28, 1891. A few months later the Imperial Earthquake Investigation Committee was founded. The objects set before it were to discover means of predicting earthquakes and to fix the design of earthquake-proof buildings. The committee, however, wisely took all seismology for their province, extended the system of observers begun by Milne, even studying the volcanoes of the country, and accomplished valuable work.

Somewhat briefer references must be made to some other committees founded for the study of earthquakes. After the Ischian earthquake of 1883, the Italian meteorological office was extended so as to include a special section of geodynamics. In 1895, the Italian Seismological Society started its *Bollettino,* one of the most useful of seismological journals. The Laibach earthquake of 1895 led to the creation of the Austrian earthquake service. The Seismological committee of the British Association was appointed in 1895. The services of the International Association of Seismology, founded in 1903, were unfortunately ended in 1914. After the Californian earthquake of 1906, the Seismological Society of America began its promising career. In its *Bulletin,* many valuable memoirs have already been published.

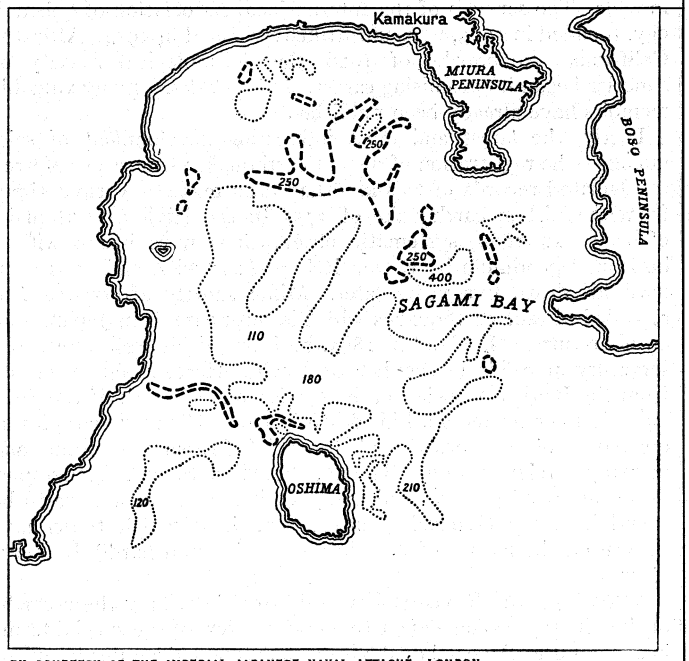
Lastly, the latest and most interesting development of seismology — the registration of distant earthquakes — must be referred to. Isolated records of this kind had been made at various times from the Lisbon earthquake of 1755 to the Riviera earthquake of 1887. In 1889, systematic observations were begun with a horizontal pendulum by E. von Rebeur-Paschwitz, and carried on until his death five years later. Milne shortly afterwards had recorded distant earthquakes with his seismograph in Japan, and, on his return to England in 1895, he founded his well known observatory at Shide in the Isle of Wight. Here, aided by grants from the British Association, he carried on the work of the Seismological committee until his death in 1913. His seismograph was erected at observatories in all the chief British possessions and st many foreign stations. To-day, the Milne-Shaw seismographs, of an improved pattern, and many similar instruments, are to be found in every civilized country. The light which these have thrown on the nature of the earth's interior, can hardly be overestimated.

Some Typical Earthquakes.— Before describing these earthquakes, it may be convenient to mention a few of the special terms in general use. An earthquake is due to some sudden displacement within the earth. The region within which this occurs is usually called the *seismic focus*, or simply the focus, sometimes also the origin, centre or hypocentre. The point on the surface vertically above the centre of the focus is the *epicentre.* A line drawn through all places at which the intensity of the shock is the same is termed an *isoseismal line.* The area within which the shock is strongest, say, that bounded by the innermost isoseismal line, is known as the *meizoseismal area,* and that within which the shock is perceptible without instrumental aid as the *disturbed area.* When earthquakes occur in series, the most important member is the *principal shock.* The others are divided into *fore-shocks* and *after-shocks* according as they occur before or after the principal shock.

Lisbon, 1755.—One of the greatest of all known earthquakes mas that which ruined Lisbon on Nov. 1, 1755. The epicentre was submarine and some distance to the west of Lisbon. How far the shock was actually felt is uncertain, for many observations, such as those reported in England, cannot refer to the earthquake. It seems, however, to have been felt all over Portugal and Spain, and in the south of France and the north of Africa, so that the disturbed area was probably more than a million sq. miles. The earthquake came without warning. Three great shocks in succession threw down all the houses in the lower part of Lisbon. Observers near the coast noticed that the sea retired, laying bare the bar, and then rolled in, it is said, to a height of qcft. above the ordinary level. For the whole of that day and the next night the sea continued to ebb and flow. Similar waves were observed along the coast of Spain, at Tangier and Funchal, along the coast of Holland, the south and east coasts of the British Isles, and even across the Atlantic to Antigua, Martinique and Barbadoes. Such waves occur with every great submarine earthquake. The feature of the Lisbon earthquake that is unique, or almost unique, among known earthquakes, is the agitation of inland waters far beyond the limits of the disturbed area. In Italy and Switzerland, lakes were set in oscillation, pools, rivers and lakes in Great Britain, as far as Loch Ness. 1,320m. from the epicentre, and even the lakes of Sweden and Norway, at a distance of 1,750m. In Loch Lomond (1,220m.), the water rose to a height of zft. 4in., then

subsided, and continued to rise and fall every ten minutes for an hour and a half.

Southern Calabria, 1783.—Less than 30 years later, in 1783, southern Calabria was desolated by a series of violent shocks. From Feb. 5 to March 28 there were six great earthquakes, and, up to Oct. 1, 1786, there were besides at Monteleone 38 very strong shocks, 198 strong, 303 of moderate strength and 642 slight shocks, a total of 1,187 earthquakes. The first great shock



BY COURTESY OF THE IMPERIAL JAPANESE NAVAL ATTACHÉ, LONDON

FIG. 1.—CENTRAL AREA OF JAPANESE EARTHQUAKE OF 1923. SHOWING MAIN ZONES; THE BOSO PENINSULA AND THE NORTH-WEST PORTION OF SAGAMI BAY. WHERE EARTHQUAKES WERE FREQUENT BETWEEN 1914 AND 1921

on Feb. 5 occurred without any warning, except for occasional slight shocks from 1780 onwards. Lasting about two minutes, with undulations vertically upwards and from every direction, all houses on the plain were destroyed within a few seconds, while those built on the firm ground of the hills escaped serious damage. The meizoseismal areas of the six great earthquakes were all of small size, and the intensity declined so rapidly outside them that one town might be entirely ruined while another only 1m. away suffered little. The disturbed areas were small, not one of them exceeding 100,000sq.m. From this, it is clear that the foci were situated close to the surface. The most interesting feature about these earthquakes was the rapid migrations of the foci. The first occurred on Feb. 5 near Palmi; the second on Feb. 6 near Scilla, 10m. to the S.W.; the third on Feb. 7, at 8.20 P.M., near Monteleone, 35m. N.N.E. of Scilla; the fourth, at 10 P.M. on the same day, near Messina and Scilla; the fifth, on March 1, near Monteleone again; and the sixth, which was as strong as the first, on March 28, near Girifalco, about 20m. E.N.E. of Monteleone. Thus the movements took place over a length of 65 miles.

Since 1783, many earthquakes of great interest have occurred, some of which have revealed to us new phenomena. It will be sufficient to refer here to the Assam earthquake of June 12, 1897, and the Japanese earthquake of Sept. 1, 1923, and to the slight shocks of Great Britain.

Assam, 1897.—On the Assam earthquake, we have an admirable report by R. D. Oldham. It was an earthquake remarkable for the vast extent of its meizoseismal area and the distortions of the crust within it. The shock itself was felt over about one and three-quarter millions sq.m., or nearly half the size of Europe. Serious damage to buildings occurred in a district containing about 160,000sq.m., or more than twice the size of Great Britain. The meizoseismal area, lying about 250m. N.E. of Calcutta, covered more than 6,000sq.m., *i.e.*, about the size of Yorkshire. From such figures, we can only conclude that, unlike the Calabrian earthquakes, the Assam earthquake originated at an unusually great depth. At Shillong, the ground vibrated visibly like a storm-tossed sea, only with more rapid undulations. At several places in the meizoseismal area, stones were projected from the ground, showing the maximum acceleration there must have been greater than 9,600mm. per sec. per sec. Within the meizoseismal area, distant places became clearly visible that before were hidden by intervening ridges. Changes in the slope of stream-beds led to the formation of pools. Fractures without superficial displacement occurred in the solid rock, one 7m. in length. Close to it, trees were snapped in two, and large blocks of stone were rent or dislodged. Besides these fractures, fault-scarps were formed, one 12m. long with a maximum throw of 35 feet. In many parts of the meizoseismal area, there were isolated centres of after-shocks, all, with the distortions described above, being evidently the results of some vast deeply-seated movement.

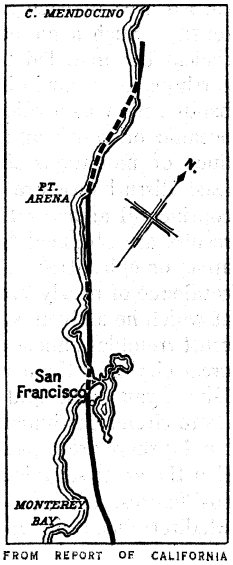
Japan, 1923.—In the present century, one of the greatest disasters known to us was the Japanese earthquake of 1923, though most of the loss to life and property was due, not to the earthquake, but to the great fires that followed it. From seismographic records at Tokyo and elsewhere, it was found that the epicentre lay beneath Sagami bay, a short distance to the north of Oshima (fig. 1), and that the mean depth of the focus was 30 miles. Soon after the earthquake, re-surveys were begun, both of the sea-bed and of the coastal regions of Sagami bay. The most remarkable changes were those in the bed of the bay. The broken lines in fig. 1 represent curves of elevation of 50 fathoms, and the dotted lines curves of equal depression. The figures within the curves give the greatest changes in fathoms. They reveal an uplift of more than 250 fathoms in one place, and, about a mile away, a depression of more than 400 fathoms, a difference of three-quarters of a mile. Clearly, a change of this magnitude could hardly occur without faulting. On land, the changes of elevation were much less marked. The main areas of uplift occurred along and beyond the north shore of Sagami bay and in the southern half of the Boso peninsula. In both, the greatest uplift measured was six and a half feet. Elsewhere, the change was usually one of subsidence, as a rule less than 16in., and only in one place reaching 5ft. 4in. In addition to the changes of level on land, the new survey revealed some horizontal movements. The island of Oshima was shifted 12ft. 5in. a little east of north, while the north shore of Sagami bay moved about 9ft. E.S.E. The displacements at these and other places show that the whole district made a clockwise twist about a vertical axis in Sagami bay.

British Earthquakes.—From 974 to 1916, the total number of earthquakes known in Great Britain is 1,190, of which 310 occurred in England, 822 in Scotland and 54 in Wales. Not more than 22 of them attained destructive intensity, 13 in England, seven in Scotland and two in Wales, the strongest known being that which occurred near Colchester on April 22, 1884. In Scotland, nearly all the earthquakes are connected with well known faults. Close to Inverness, four strong earthquakes have occurred from 1816 to 1901, probably through slips of the great fault that crosses Scotland along the line of the Caledonian canal. The most celebrated earthquake district in the country is the village of Comrie in Perthshire, which lies close to the Highland border fault. Here, from 1788 to 1921, 421 earthquakes were felt or heard, three-fourths of them between 1839 and 1846. A third region lies on the south side of the Ochil Hills. From Bridge of Allan to Alva, nearly 200 earthquakes have been observed during the present century. In England and Wales, there are many earthquake-centres, the most important being near-Hereford, in the midland counties of England, and in the southern counties of Wales. Some of the strongest earthquakes in England and Wales are those known as twin-earthquakes. In these, the shock consists of two distinct parts separated by an interval of two or three seconds. The impulses which cause them originate at some depth, in two detached foci from about 8m. to 20m. apart, and in many of them so closely together that the second focus is in action before the vibrations from the first have time to cross the intervening space.

Nature of Earthquake Motion.—In slight earthquakes, a low rumbling sound is usually heard, in a second or two, the sound becomes louder and with it a weak tremor is felt, the tremor rapidly merges into a few distinct vibrations and then movement and sound die away, the whole lasting from five to ten seconds. In great earthquakes, the order is the same, but the vibrations are strong oscillations, each of which may last a second or more, and the total duration may amount to four or five minutes. In the greatest of all, the ground may suddenly move as a whole and with such violence that no work of human hands can withstand the motion.

Seismographic records of earthquakes also reveal three stages of motion. In the preliminary tremor the vibrations are small in amplitude and short in period, from five to 12 occurring every second. It is succeeded by the *principal* portion, in which the vibrations are of much greater amplitude and from half to one or even two and a half seconds in period. In the end portion, the vibrations are of small amplitude but remain of long period. In most earthquakes, the range or double amplitude of the vibrations is less than 1mm.; in a semi-destructive earthquake, it may reach 73mm., and, in a destructive earthquake, 223mm. (about 9in.) or more. The intensity is usually measured by the maximum acceleration of the vibrations. In an earthquake that is just sensible, this is about 17mm. per sec. per sec. In destructive earthquakes, the maximum acceleration must exceed 300mm. per sec. per sec., but it often reaches much higher figures, such as 2,000mm. per sec. per sec. in the Californian earthquake of 1906 and the Messina earthquake of 1908, about 3,840mm. per sec. per sec. in the Japanese earthquake of 1923 and more than 9,600mm. per sec. per sec. in the Assam earthquake of 1897. These figures represent the intensity in the central areas of the earthquakes. To show how the intensity declines as the distance from the epicentre increases, series of isoseismal lines are drawn, the intensity along each depending on the degrees of some arbitrary scale, such as the Rossi-Forel or the Mercalli scale. The outermost isoseismal line bounds the disturbed area. In Great Britain, the largest disturbed areas known are about 100,000sq. miles. In destructive earthquakes the area may amount to as much as one and three-quarters or two million sq.m., as in the Assam earthquake and the Kangra earthquake of 1905.

The sound that accompanies an earthquake is a very deep rumbling noise, so deep that it may pass unheard by many observers. When it is heard, some of the vibrations may be inaudible, and thus the sound may be referred to different types, such as a lorry or train passing, thunder, wind or a chimney on fire, loads of stones falling, the fall of a heavy body, an explosion, etc. The variation in audibility throughout the disturbed area may be represented by a series of isacoustic lines, along each of which the same percentage of observers hear the sound. In great earthquakes, the sound-area occupies a rather small region surrounding the epicentre; in slight ones, it may extend beyond the disturbed area on one or all sides. Occasionally, the sound alone is heard, and series of such earth-sounds have been observed in the island of Meleda in the Adriatic sea, East Haddam in Connecticut and Guanajuato in Mexico.



FROM REPORT OF CALIFORNIA COMMISSION ON THE EARTHQUAKE OF 1906

FIG. 2.—MAP OF SAN ANDREAS RIFT AFTER EARTHQUAKE OF APRIL 18, 1906. HEAVY LINE INDICATES WHERE DISPLACEMENT OCCURRED

Dislocations **of the** Crust.—In some of the greatest earthquakes, there are no features more remarkable than the dislocations of the crust, the renewal of movement along the fault that may follow one general direction for many miles. The displacement along the fault may be mainly horizontal, as in the Californian earthquake of 1906, vertical as in the Assam earthquake of 1897, or partly vertical and partly horizontal, as in the Mino-Owari (Japan) earthquake of 1891. In a few earthquakes, such as the Messina earthquake of 1908, the movement takes the form of a warping of the crust, no actual fault being visible on the surface.

When the movement is horizontal, the fault may appear as a crack or fissure or may be revealed by the severing of roads, fences, etc., the ends of which may be separated by several feet. The Californian earthquake of 1906 was due in part to a movement along a remarkable fault, the San Andreas rift (fig. 2). The portion of the rift displaced runs close to the coast, and its total length is about 270 miles. The rift has been traced still farther to the south for another 300m. into the desert region of southern California. Here, the features of the rift retained their sharpness for many years, and there are clear signs of horizontal displacement in the past. For instance, in one place four deep ravines that descend the mountain slopes on the east side of the rift are displaced abruptly at the fault-line and reappear on the west side of the fault about 50yd. farther to the north-west. Such movements are no doubt the sum of many displacements. In 1906, the total horizontal shift varied as a rule from six to 15ft., in one place reaching 21 feet. From the shifting of fences, etc., it was unknown which side had moved, but a new survey of the; district proved that the rock on both sides had been displaced, that on the south-west side to the north-west, and that on the north-east side to the south-east. The movements decreased with increasing distance from the rift, ceasing at about 4m. on the north-east side, but at not less than 23m. on the other.

Much more remarkable in appearance, but less persistent in range, are the vertical displacements of the ground. When the throw is small, the result may be a mere slope of the surface; but, if it should exceed two or three feet, it appears as a low scarp or cliff. While the elevation is usually in one direction only, its amount is subject to wide and rapid variations. One of the faults of the Assam earthquake of 1897, the Chedrang fault, was about 12m. long. The movement was everywhere vertical, and the east side was invariably left the higher, except in two places where there was no throw. In the three portions into which the fault was thus divided, the maximum uplift was 25ft. in the southern portion, 35ft. in the middle and 32ft. in the northern. In this fault, it is unknown whether the east side was raised or the west lowered. In the Alaskan earthquakes of 1899, the measurements were all made with reference to the sea-level. Six years later, dead barnacles still clinging to the rocks showed that, on the west side of Disenchantment bay, there had been an uplift (the greatest known to us) of 47ft. 4in. Here again, there were rapid variations, from 42ft. on the same coast to 30ft. a mile to the west, and to 9ft. a quarter of a mile farther.

The displacements that are partly horizontal and partly vertical are more common than either of the others. One of the most remarkable examples is that which occurred with the Mino-Owari earthquake of 1891. This fault, which almost crosses the main island of Japan in a general north-westerly direction, was traced for a distance of 40m., and there can be little doubt that its total length was 70 miles. Its course is independent of the slope of the ground, for it cuts across hill and valley alike. Throughout its whole length, the ground on the north-east side of the fault **was** shifted to the north-west relatively to the other, usually 3ft. or 4ft., sometimes as much as 13ft. In some places, there has been no uplift, but, when it is perceptible, it is always a depression of the north-east side by from 3ft. to 20ft., except in one place, where the north-east side was left 20ft. above the other.

In a few earthquakes, a new series of levels has revealed a general bulging or subsidence of the crust without superficial fracturing. In the Kangra (India) earthquake of 1905, a slight rise of not more than 5in. was measured. In the Messina earthquake of 1908, there appears to have been a general subsidence, of as much as aft. at Reggio and 2ft. 4in. at Messina.

Sea-Waves.—When the origin of an earthquake is submarine, the shock along the coastal region may be followed by the inrush of a sea-wave, often, but erroneously, called a tidal wave. Estimates of the height of the wave are usually excessive, but, in the Messina earthquake of 1908, the height was certainly 28ft. on the

Sicilian coast and 35ft. on the other. In the Sanriku (Japan) earthquake of 1896, the height mas not less than 93 feet. So strong are the waves that vessels may be driven inland 200yd., trees may be uprooted, or a mass of concrete, 10cu.yd. in volume, may be torn from a pier and drifted 20yd. away. The sea-waves sometimes travel to great distances. The sea-waves of the Sanriku earthquake were registered at San Francisco (4,787m.), and those of South American earthquakes have been recorded in Japan after travelling distances of about 10,000 miles. After such journeys the water slowly sweeps up a beach and back again, like tides of short period, of 20 or 30m., the total rise and fall being as much as eight feet. There can be little doubt that the sea-waves are caused by some displacement of the ocean-bed, like that which occurs on land when fault-scarps are formed, for changes of level have occurred on land with many earthquakes followed by sea-waves. On the other hand, in the Californian earthquake of 1906, the fault was in part submarine, but the crust displacements were horizontal and no sea-waves were observed.

After-Shocks of Earthquakes. — After a great earthquake, the ground near the epicentre may remain for days in almost incessant motion. So frequent are the after-shocks, sometimes so continuous, that it may be impossible to count them without instrumental aid. After the Mino-Owari earthquake of Oct. 28, 1891, a seismograph at Gifu recorded 3,365 shocks by the end of 1893. Other Japanese earthquakes have been similarly followed, the earthquake of 1830 by 681 shocks in six months, that of 1847 by 930 in 31 days, and that of 1923 by 1,256 at Tokyo in the first month. Even in Great Britain, the Inverness earthquake of 1901 was succeeded by 16 shocks in less than two months. On the other hand, with the Californian earthquake of 1906, there were comparatively few after-shocks, the greatest number observed at any place in 14 months being 153. As there were vertical displacements of the crust in the Assam and Mino-Owari earthquakes, and none of any consequence in the Californian earthquake, it would seem that the number of after-shocks depends on the direction of the crust displacement. Usually, after-shocks are of slight intensity, but they sometimes reach destructive strength and are then followed by their own trains of after-shocks. After the first few days, they decline rapidly in frequency. At Gifu during the first week after the Mino-Owari earthquake, the daily numbers were 318, 173, 126, 99, 92, 81 and 78. Omori has shown that, if small variations are neglected, the decline in frequency may be represented by the formula $y = \frac{k}{x+h}$, where h and k are constants and y is the number of after-shocks within a given interval at time x after the earthquake. Their epicentres lay along all parts of the fault described above, they were frequent for some time near the terminal regions and finally were almost confined to the central district. A similar law governed the distribution of the after-shocks of the Inverness earthquake of 1901, and these were also marked by a continual approach of the foci towards the surface of the earth.

Secondary Effects of Earthquakes. — Whenever strong earthquakes occur in hilly districts, they may give rise to avalanches so large and so numerous that hillsides previously covered with forest are left bare. Avalanches along one side of a valley may divert a river-course, from both sides they may pond back the river into lakes. When the earthquakes occur among snow-covered mountains, as in Alaska in 1899, the descending glaciers may be shattered, and snow-avalanches may cause a temporary advance of the glaciers.

Even on level ground, many changes occur through the compression of the alluvium. Rice-fields in Assam and Bengal that were level before the earthquake of 1897 became gently undulated, the difference between crest and hollow being two or three feet. Railway lines are often buckled or twisted into loops. The ground is extensively fissured. When they occur near a river, the fissures run parallel to the bank, being due to the oscillation of ground unsupported on one side. Usually, they are a few hundred yards in length and two or more feet wide. They are distinguished from the permanent dislocations of the crust by their short length and variable direction. Others are formed on hillsides by incipient landslips and are horseshoe-shaped. They may also occur quite apart from any slope or excavation. They are then aligned in parallel series, and have been seen to open as the visible waves passed. The underground water-system is naturally disturbed by such changes. As a rule, the level of water in wells rises, but occasionally the supply is reduced, the variations being connected with changes in the width of the underground water-channels. When the surface-beds overlie water-bearing sands, the compression of the latter forces water through the fissures above in jets that may rise to a height of several feet and bring up sand and earth with them. As the current of water diminishes, the sand is left round the opening in the form of a shallow crater or saucer, sometimes zoft. in diameter.

Distribution of Earthquakes. — How unequally earthquakes are distributed over the world is well known. There are countries, like Italy, China, Japan or Peru, in which earthquakes are of frequent occurrence and of destructive strength. There are others, such as Switzerland, in which earthquakes are numerous but seldom cause damage; and there are a few, like Egypt or Brazil or the centre of Russia, in which they occur but rarely and are always weak. To give some numerical illustrations: in the years 1891–1920, 4,954 earthquakes were observed in Italy, an average of 165 a year; in the years 1893–98, 3,187 earthquakes were felt in Greece, or 531 a year; in the years 1885–92, 8,331 earthquakes were recorded in Japan, or 1,041 a year. In Switzerland, 998 earthquakes were felt in 1880–1909, an average of 33 a year; in Great Britain, 366 in 1889–1916, or 13 a year. In Brazil, 39 earthquakes were recorded during the 19th century. If we confine ourselves to the earthquakes that desolate cities, there were during the last century 39 in China, 22 in Japan, 21 in the Philippines, 19 in Greece, 16 in Italy, 11 in Chile and 8 in Peru.

In his earthquake-map of the world, Mallet coloured the disturbed area of each earthquake with a tint depending on its intensity. Such a method of mapping obscures details, but nevertheless the map led to results of general interest, namely, that earthquakes occur in bands of from 5° to 15° in width, that these bands follow as a rule the lines of elevation that divide the great oceanic or continental areas of the earth and so lie along the lines of mountains and volcanic vents, and that the areas of least disturbance are the central portions of great oceanic and continental areas or large islands in shallow seas. More detailed results are obtained from the methods of mapping meizoseismal areas or epicentres. Montessus' world-map is based on his great catalogue of nearly 160,000 earthquakes. The principal conclusion at which he arrived is expressed in the following law: The earth's crust trembles almost only along two narrow bands which lie along great circles of the earth, the Mediterranean or Alpino-Caucasian-Himalayan circle and the circum-Pacific or Ando-Japanese-Malayan circle. Earthquakes are not uniformly distributed along these bands; there are gaps in them in which few or no shocks occur. But that the great seismic zones cling to them is evident from Montessus' figures. Out of every 100 earthquakes, 53 occurred along the Mediterranean circle, 38 along the circum-Pacific circle and nine elsewhere. In this map, Montessus made use of all recorded earthquakes whatever their intensity. Milne relied only on earthquakes registered by seismographs over an area not less than about one-tenth of the whole surface of the earth. In essentials, his map is not unlike that of Montessus. There is the same great terrestrial region ranging west and east from Italy to the Himalayas and containing 21% of all the earthquakes. Six regions border the Pacific ocean with 68%, while four small oceanic regions include the remaining 11% of the earthquakes.

These maps show the distribution of earthquakes on a large scale. Coming to details, the most important law is that which Montessus expressed thus: "in a general way, we may say that, of two contiguous regions . . . the more unstable is that which presents the greater average slope." Milne, dealing with the earthquakes of Japan, came to a similar conclusion. The earthquakes of Japan, indeed, furnish one of the best examples of the law. Of the strong earthquakes from 1885 to 1905 (257 in number), Omori found that 145 originated in zones bordering the Pacific

coast and only nine on the Japan sea coast. The Japan sea occupies a depression in no place deeper than 1,646 fathoms, the gradient of the sea-bed ranging from 1 in 67 to 1 in 220. On the other side, the sea-bed slopes rapidly, with gradients of 1 in 27 and 1 in 16, into the basin of the Tuscarora Deep (4,376 fathoms).

One other law of distribution should be referred to. It is generally supposed that there is an intimate connection between earthquakes and volcanoes. Milne's seismic map of Japan shows, however, that "the central portions of Japan, which are the mountainous districts where active volcanoes are numerous, is singularly free from earthquakes." In Central America, the old town of Guatemala, built on the flank of an extinct or almost extinct volcano, was ruined seven times by earthquakes from 1541 to 1775. The new town, close to an active volcano, has never been destroyed.

Frequency of Earthquakes.—If we confine ourselves to earthquakes perceptible to man, one of our earliest estimates is that of Perrey, who in 1843 assigned a frequency of only 33 earthquakes a year to the whole of Europe and adjacent parts of Asia and Africa. For the first half of the 19th century Mallet recorded 65 a year. In 1900, Montessus estimated the annual number of earthquakes at about 3,830. Including slight tremors, Milne suggested that there were not less than 30,000 a year, or about two a minute. Of great earthquakes—those which reduce towns to ruins—Mallet recorded one a year in the first half of the 19th century, and Milne four a year during the last quarter. A noteworthy point about destructive earthquakes is their tendency to occur in groups. In Italy, according to G. Mercalli, from 1601 to 1881, 182 destructive earthquakes occurred in 103 years and 27 in the remaining 178 years. Similarly in Japan, as Omori remarks, the destructive earthquakes since 1301 have occurred in 41 groups separated by an average interval of about 13 years. This tendency to clustering, as Milne showed, is characteristic of the great earthquakes of the whole world. They occur in groups of two or three to 15 or more; the groups last from one to three days, seldom more than six days, and the interval between successive groups ranges from two to seven weeks. Milne also pointed out that, in widely separated regions, such as Italy and Japan or the opposite sides of the Pacific, alternations of activity were to some extent synchronous.

Periodicity of Earthquakes.—The clustering of earthquakes leads naturally to their periodicity, to the inquiry whether there is any regularity in the recurrence of clusters. Whatever the causes of such periodicity may be, it is not to be supposed that they produce the earthquakes, but merely that they tend to precipitate movements that are almost on the point of taking place. They may be more or less superficial in their action, or they may be deeply-seated within the earth or even quite outside it. We have thus two groups of periods, one of a year and a day, the other of 21 minutes, 429 days and 11, 19, etc., years.

Of these periods, the annual period has been longest known, since 1834, when P. Merian noticed that the earthquakes felt at Basle were more frequent in winter than in other seasons. This variation has been confirmed by many other seismologists. The chief result is that the maximum epoch, or epoch of greatest frequency, occurs in winter in both hemispheres. But there are many exceptions to this law. It does not apply to the most destructive of all earthquakes, and, in insular and peninsular regions, the frequency is greatest in summer. The diurnal period is less pronounced than the annual period, and can only be detected in earthquakes recorded by seismographs, for shocks are naturally felt more frequently during the quiet hours of the night. For ordinary earthquakes, the maximum epoch occurs near local noon in each district. For the after-shocks of strong earthquakes, it occurs at first shortly after midnight, but after a few months returns to noon. Several causes have been suggested for these periods, the variations of atmospheric pressure being the most probable.

The second group of periods, depending more or less on the structure of the earth or on its relations to the rest of the solar system, are of great interest. The shortest is one of 21 minutes. The period of 429 days was noticed by Milne in 1900. He showed that great earthquakes are frequent near the times when changes occur in the direction of the polar movements. Shortly afterwards, Omori found that the connection holds for strong, but not for slight, earthquakes in Japan. Recently, other periods have been added to the list. Making use of the destructive earthquakes from 1701 to 1899 recorded in Milne's great catalogue, it has been shown that there are periods of 11, 22, 33 and 19 years in the earthquakes of the northern hemisphere, the first maxima of which occurred in 1709, 1716, 1724 and 1715–16, respectively. The epochs are the same for different centuries, for different seasons of the year and for every large region of the northern hemisphere.

Position of the **Epicentre.**—The first element to be determined in the study of an earthquake is the position of its epicentre. Various methods have been suggested, depending on observations of the time, direction or intensity of the shock.

Time-records, as a rule, are not accurate enough for the purpose. They have been used by Seebach and others with results of doubtful value. It is easier to estimate the interval between two events than the precise time of either, and thus the only time-method used with profit is one proposed by Omori. This depends on the duration of the preliminary tremor at not less than three stations. If x is the duration in seconds of the tremor at a place not more than 1,000km. from the origin, Omori showed that the distance in kilometres between the station and the origin is $7{\cdot}27x+38$. Knowing, then, the distances of the origin from three stations, circles drawn with the stations as centres and the corresponding distances as radii, should intersect close to the epicentre. This method is much used in Japan, especially for locating the epicentres of submarine earthquakes. The second method, depending on the lines of direction of the shock at two or more places, was used by Mallet in his investigation of the Neapolitan earthquake of 1857. Most of the 78 lines of direction in this earthquake passed close to the village of Caggiano. Greater accuracy can be obtained by using the means of a large number of observations. In the Hereford earthquake of 1896, the position of the principal epicentre was fixed by the lines of mean direction in London and Birmingham. The last method, which makes use of the intensity of the shock, is the one most frequently applied. In a violent earthquake, the area of greatest destruction must include the epicentre. In weak or moderately strong earthquakes, the centre of the innermost isoseismal line cannot be far distant from it.

Depth of the Focus.—Up to the present time, though many attempts have been made to determine the depth of the focus—one of the most interesting problems of seismology—we can lay claim to no more than approximate results. The methods suggested for the purpose depend, as with the epicentre, on observations of the time or intervals of time, and on the direction and intensity of the shock. Seebach's method is of theoretical, rather than practical, interest, owing to the difficulty of obtaining exact time records. It has been used for five German earthquakes, giving depths ranging from seven to 24 miles. For near earthquakes, Omori's method, involving the duration of the preliminary tremor, is less open to objection. Knowing the distance of the focus by the duration of the tremor and also the distance of the epicentre, it is a simple matter to estimate the depth of the focus. In this way, he found the mean focal depth in 729 non-eruptive earthquakes of the volcano Asama-yama to be about 2m. below the base of the mountain. He also applied the method to 21 earthquakes felt in Tokyo, and found the depth to lie between 10 and 31½m., with an average value of 20 miles. The well known method devised by Mallet was the first in actual use. In his study of the Neapolitan earthquake, he measured the inclinations of fissures in many buildings. Assuming the direction of the shock to be at right angles to the fissures, he obtained 26 lines of direction which he took to point directly to some part of the focus. The position of the epicentre at Caggiano being known, he found the depth of the focus to lie between 3.2 and 9·3m., the mean value of all the estimates being 6.6 miles. Mallet's method has been employed in several later earthquakes, the results being about one-third of a mile for the volcanic Ischian earthquakes,

and from 6½m. to 10¾m. for four other earthquakes. Similar to Mallet's method is one used by Milne, in which the lines of direction were obtained from the horizontal and vertical components of the motion as given by seismographs. In the Yokohama earthquake of 1880, he found the depth to lie between 1½ and 5 miles. Two later estimates, by Omori, are 5.6 and 9.3 miles.

Of the methods depending on variations in the surface intensity, the best known is that devised by C. E. Dutton in his investigation of the Charleston earthquake of 1886. Assuming that the intensity of the shock varies inversely as the square of the distance from the focus, Dutton showed that the rate of decline in the intensity of the shock is greatest at a distance from the epicentre which, when multiplied by 1·732, gives the depth of the focus. In the Charleston earthquake, there were two foci, the depths of which were calculated in this way to be 12m. and 8 miles. In five later earthquakes, the depths were found by the same method to lie between 4m. and 21m. Dutton's method, apart from the difficulty of applying it, is open to the objection that it takes no account of the loss of energy that the waves suffer in traversing the crust. From a comparison of the intensities at the epicentre and along an isoseismal line, the objection has been partly met by R. D. Oldham, who found that of 5,605 recent Italian earthquakes, 90% originated at depths less than 6½m. and only 1% at depths greater than 19 miles.

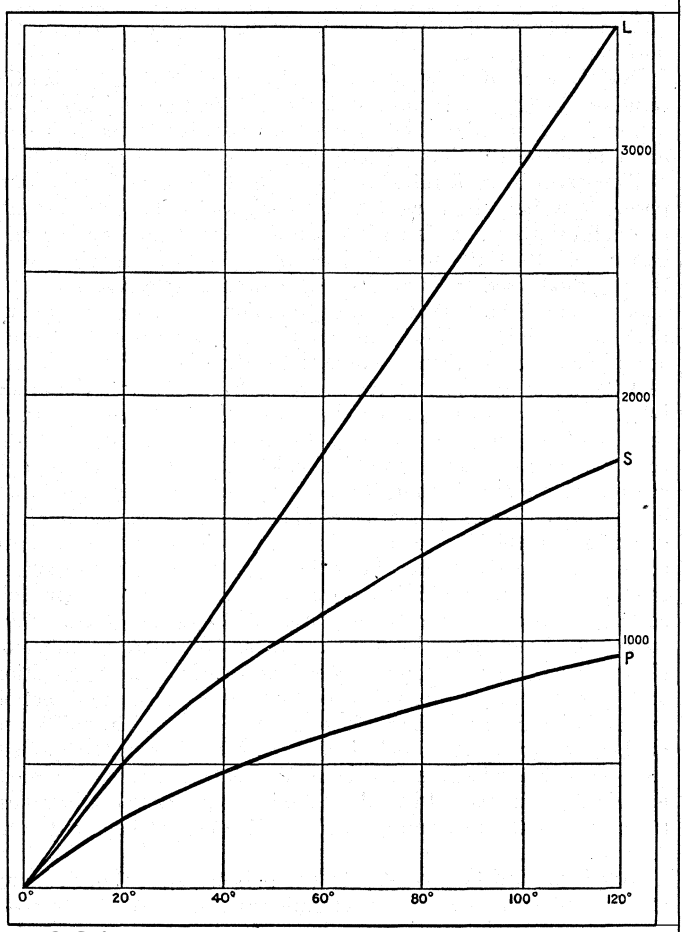


FIG. 3.—GRAPH OF TIME CURVES: PRELIMINARY TREMORS, P: SECONDARY WAVES. S; END (LARGER) WAVES. 12 TO 20 SECONDS IN DURATION, L
The abscissa measures distance of seismometer from epicentre; the ordinate, the time taken by seismio waves to travel from epicentre to recording station

Teleseismology.—We come now to the most recent and fascinating development of seismology—the registration of distant earthquakes. The instruments by which they are recorded are described under the heading SEISMOMETER (*q.v.*). Here, we are concerned only with the results obtained from a study of the seismograms or records. A brief glance at one of them shows a series of waves, small at first, then rapidly increasing in magnitude, and concluding with long, slow undulations—corresponding to the preliminary tremors, the "principal" portion and the "end" portion of the early writers on the subject. A closer inspection shows that the preliminary tremors consist of two phases. The first phase, known as the first preliminary tremors or primary waves, begins with a small but sudden displacement, followed by rapid vibration of a few seconds in period, and including at times reinforcements of the motion. The second preliminary tremors or secondary waves begin with a comparatively large vibration, succeeded by irregular vibrations, among which sudden reinforcements may appear as in the first phase. As the secondary waves end, the third phase, that of the long waves or large waves, begins, at first with large and irregular undulations of perhaps more than half a minute in period. Then come still larger waves, 12 to 20 sec. in period, concluding with smaller and irregular undulations forming the end portion. The whole movement may last one or two hours, sometimes more. In great earthquakes, after the end portion closes, a detached group of small long period waves may be seen, followed, perhaps, by a second group of still smaller range. There are other movements traceable in the records, but these are the principal features.

The first vibrations of the above phases are usually denoted by the letters P, S and L, respectively, the reinforcements in the earlier phases by PR, SR or PR_1, SR_2, etc., when there is more than one. The groups of small waves following the end portion are denoted by W_2 and W_3, W_1 referring to the first passage of the long waves.

One of the most interesting points about the P and S waves is that they do not travel with uniform velocity along the surface of the earth. The variations in velocity may be represented by time-curves or hodographs. In these, the distance of a station from the epicentre along the great circle joining them is measured along the horizontal axis of the diagram, and the time taken by the waves to travel this distance along a line at right angles to that axis. A time-curve may be drawn in this way for any earthquake. The curves in fig. 3 are average time-curves. In them points are plotted corresponding to the times of traversing given distances for a number of earthquakes, and the curves are drawn through or near these groups of points. The time-curve for a given earthquake may thus differ slightly from the average curves, the divergences depending in part on the depth of the focus, and, indeed, furnishing some clue as to that depth.

The first point to be noticed in these curves is that, while the line L is straight, the lines P and S are both so curved that, as the surface distance increases, the time required to traverse it does not increase in the same proportion. In other words, as the surface distance increases, the velocities of both P and S waves also increase. Near the epicentre, the velocities of these waves are, respectively, 7.1 and 4·0kilo. per sec. At distances of 30°, 60°, 90° and 120°, the velocities of the P waves along the surface are, respectively, 8.6, 10·9, 12.6 and 13·6kilo. per sec.; those of the S waves are 4.8, 6·0, 6.9 and 7·7kilo. per sec. The only inference that we can draw from these increases is that both waves travel, not along the surface, but along curved paths through the earth, and that the velocities increase generally with the depth below the surface.

Earthquake Waves.—From the straightness of the line L in fig. 3, we conclude that the time taken to travel any distance along the surface is proportional to that distance, that is, that the long waves travel along the surface with constant velocity, namely, 3·8kilo. per sec. Now, the great circle that passes through the epicentre and a given station is divided into two arcs, the minor and the major arcs. The first long waves that reach a station are of course those that travel with the above velocity along the minor arc. The waves continue their journey to the antipodes of the epicentre, cross there and pursue their way back towards the epicentre. They thus pass the given station a second time, that is, after traversing the major arc, and appear on the record there as the waves called W_2, the mean value of the velocity being 3·7kilo. per sec. Crossing at the epicentre, they again travel along the minor arc and, if strong enough, are recorded as the waves W_3, their mean velocity being 3·4kilo. per sec. The lower velocity for

the waves W_3 is no doubt due to the fact that they are the representatives of the most prominent but later of the long waves L. The mean time taken by the long waves to travel completely round the globe (that is, W_3-W_1) is 3hr. 20min. 46sec.

Returning to the P and S waves and their curved paths through the body of the earth, we have the valuable suggestion by R. D. Oldham, in 1899, that the primary waves consist of compressional vibrations and the secondary waves of distortional vibrations. It is now recognized that both types of vibrations (owing to repeated reflections and refractions in the outer layers of the crust) occur in both primary and secondary waves, but that compressional vibrations predominate in the former and distortional vibrations in the latter.

Estimates have been made by several seismologists as to the forms of the paths followed by the primary and secondary waves, those by C. G. Knott, founded on Turner's tables, being the most detailed. Assuming that the earthquake originates at a small depth below the surface, he has calculated the forms of ten curves or rays for the primary waves and seven for the secondary waves. He found that all the rays that emerge at the surface at distances less than 60° from the epicentre are concave towards the surface throughout. The ray that emerges at a distance of 73° is, in its deeper portion, slightly convex towards the surface, and this shows that, at a depth of about three-tenths of the earth's radius, the velocity has ceased to increase with the depth. This is further shown by the comparative straightness of still deeper rays in their central portions.

Two other points in connection with these waves must be referred to. The first is that, at distances of more than 120° from the epicentre, the secondary waves seem to disappear. The significance of this fact will be referred to later. The second is that, besides the waves either primary or secondary that proceed directly towards a station, there are others of the same types that reach the surface at some intermediate place, are reflected there, and, travelling on to the station, appear as reinforcements of the motion known by the letters PR, SR, etc.

Observational Methods.— Several methods have been used to determine the position of a distant epicentre. It will be sufficient to refer to two that are frequently employed. The first method, which is practically the same as Omori's for near earthquakes, depends on the duration of the primary waves; that is, on the interval S-P. For the average earthquake, this is shown to be constant at the same distance from the epicentre. For instance, if S-P were 6min. 42sec., then the distance measured along the surface would be 45" or 5,000km. If the distances were known for two other stations, the epicentre must lie near the point of intersection of the three circles drawn with the stations as centres and the corresponding distances as radii. In practice, it is found advisable to make use of the observations at several or many stations. By the second method, Galitzin's, the position may be determined from observations at one station only. The distance of the epicentre is given, as before, by the value of S-P. The direction of the epicentre is taken as that of the resultant of the N—S and E—W components of the first displacement. The epicentre must therefore lie at one end of the diameter in this direction of the circle of radius corresponding to S-P, which of the two ends is decided by the vertical component of the initial motion.

Seismographic observations on both near and distant earthquakes have thrown much welcome light on the nature of the earth's interior. They have shown that there is, first, an outer crust consisting of two layers, an upper granitic layer roughly 7½m. in thickness and a lower basaltic layer about twice as thick. Below the latter lies the homogeneous layer of great thickness. It probably reaches nearly half-way to the centre of the earth, for, at about this depth, the rigidity begins to break down. Within it is the central core. This allows the primary waves to pass, but with a velocity one-third less than that just outside it. It does not, however, transmit the secondary waves, as is shown by their disappearance at the distance of about 120" from the epicentre, and, on this account, it has been supposed that the core is fluid.

Origin of Earthquakes.— The distinction between volcanic earthquakes and earthquakes that occur far away from active volcanoes has long been recognized. In 1878, R. Hoernes divided earthquakes into rock-fall, volcanic and tectonic earthquakes. The first may be neglected as of little consequence, but lately an important addition has been made of very deep-seated movements, the origin of which may be at a depth that may be a perceptible fraction of the earth's radius. To these, Oldham has given the name of *bathyseisms*. The different classes, however, cannot always be kept distinct. Tectonic earthquakes may occur in immediate connection with a volcanic eruption, and bathyseisms may merge into tectonic earthquakes.

Volcanic earthquakes are confined to the neighbourhood of a volcano, which may be active (as Etna), dormant (as Monte Epomeo in Ischia) or extinct (as the Alban Hills near Rome). In the first case, they usually precede a volcanic eruption and decline in frequency as the eruption begins. The most significant features of volcanic earthquakes are their small disturbed areas (seldom more than 100 or 2000sq m.) and their great intensity near the centre. These point unmistakably to very shallow foci, as a rule, only a fraction of a mile; that is, to foci within or just below the mass of the volcano. With regard to the origin of most volcanic earthquakes, there can be little doubt. The slight shocks felt before or with the eruptions are due to explosions or to the injection of lava into fractures or cavities in the volcano. The sharp earthquakes that follow an eruption after some months or that occur near dormant or extinct volcanoes are probably caused by the slipping of the rock adjoining a fracture, the slipping being due to the contraction or displacement of the magma.

Coming next to the origin of tectonic earthquakes proper, by far the most numerous of all, it is generally held that they are due to the formation of faults. In some rare cases, perhaps, they may be caused by the actual fracturing, but nearly always by the growth of the faults. With every step in such growth, it is evident that an earthquake must occur—a slight tremor or earth-sound when the movement is a mere creep over a small section of the fault, a strong or destructive earthquake when the displacement is considerable over an area many miles in length. Such a connection is evident when there are permanent dislocations of the crust along a pre-existing fault. In slight earthquakes, such as those which visit Great Britain, the displacement may be no more than a small fraction of an inch, and it must die out far below the surface. In such earthquakes, the longer axes of the isoseismal lines are usually parallel to well-known faults, the centres of the curves lie on the downthrow side of the faults; and, when a series of earthquakes occur in a district, such as with the Inverness earthquake of 1901, the epicentres migrate to and fro within a narrow band parallel to the direction of the fault.

In every earthquake country, it is found that a prolonged interval of recovery follo s a great earthquake. The interval may extend to hundreds of years, even to 1,000 years or more. The Lisbon earthquake of 1755 has had no successor yet to compare with it in magnitude. Before an earthquake occurs, we may imagine a continual growth in the forces that will ultimately overcome all resistance. Here and there on the fault-surface, there are obstacles that must first be cleared away, and each such removal will give rise to a fore-shock. When the effective forces have become uniform over a large region of the fault-surface, it will then be possible for a general movement to take place, and it is to this movement that the principal shock is due. It is of course followed by a sudden readjustment of the stresses that produced the motion, to an increase chiefly along the lateral and upper margins of the focus. Thus it follows that after-shocks are at first more frequent near the terminal and central regions of the meizoseismal area, that they gradually forsake the former and become concentrated in the central portion, as in the Mino-Owari earthquake of 1891 and the Inverness earthquake of 1901.

In recent years, the conception of a simple focus has been extended for many earthquakes to that of a complex origin. The twin-earthquakes of Great Britain originate in two detached foci from 8m. to 20m. apart. Calabrian earthquakes belong to several foci, at some times successively in action, at others almost simultaneously. Foci more complex or more extensive than these are in many earthquakes the mere surface manifestations of deep-

seated movements or bathyseisms. In the Californian earthquake of 1906, the focus certainly reached up to the surface; the depth of the main portion has been variously estimated at from 12½m. to 67 miles. The Assam earthquake of 1897, with its vast meizoseismal area and its widely scattered movements, was probably due, as Oldham suggests, to a great bathyseismic displacement. How great may be the depth of these displacements is evident from their seismographic records. It has been variously estimated at from 30 to 800 miles. Even if we regard the latter figure as excessive, we have the conclusions drawn by H. H. Turner from many observations that the majority of these great movements originate at a depth of about 125m. and some even as far as 375 miles.

Destructiveness **of** Earthquakes. — To most persons, the loss of life and the damage to property are the chief features of a great earthquake. The number of persons killed within a few minutes is sometimes appalling, such as 50,000 in the Lisbon earthquake of 1755, 100,000 in the Messina earthquake of 1908, 180,000 in the Chinese earthquake of 1920, 200,000 in the Japanese earthquake of 1703, and, highest of all known, 300,000 in the Indian earthquake of 1737. Figures such as these may be exaggerated, but there can be no mistaking those for the Japanese earthquake of 1923, namely, 99,331 killed, 103,733 wounded and 43,476 missing, figures which of course include deaths by fire as well as by earthquake. If we reckon the loss by the percentage killed of the total number of inhabitants, the death-rates in the Japanese earthquake were only 2·7% in Tokyo and 5·5% in Yokohama. Far higher are the rates for some Italian earthquakes, for instance, 41% at Casamicciola in the Ischian earthquake of 1883, about 50% at Messina in the earthquake of 1908, 71% at Montemurro in the Neapolitan earthquake of 1857, and, in the Marsican earthquake of 1914, 91% at Avezzano and 94% and 97% in two neighbouring villages. In Great Britain, only one life is known to have been lost, an apprentice being killed in London by a falling stone during the earthquake of 1580.

We may endeavour to lessen the destructive power of earthquakes in two ways, by forecasting the occurrence of earthquakes, or, and at present more usefully, by a proper choice of site and modes of building. The prevision of earthquakes is as yet in its initial stage. One rather hopeful method depends on the study of the fore-shocks. As the obstacles to slipping are situated in all parts of a fault, it follows that the epicentres of the fore-shocks must mark out roughly the fault-system, or the part of it in which displacement is about to occur. In the case of the Mino-Owari earthquake of 1891, the whole region was so outlined within a year or two of the great earthquake. Another method has lately been put into practice. From a study of the earthquakes felt at Tokyo from 1914 to 1921, Omori outlined two zones in which earthquakes were then frequent, one covering the Boso peninsula (fig. 1), the other the north-west portion of Sagami bay and beyond. Between them lies part of the epicentral area of the earthquake of 1923. Omori inferred that activity would return to the intermediate region when the frequency of earthquakes in the others showed signs of lessening, as it did in the years 1920–21. Lastly, it has been suggested, that before sliding along a great fault takes place, the crust on either side would show signs of distortion that might be detected by the displacement of pillars erected along a line at right angles to the fault.

At present, more can be done to counter the destructiveness of earthquakes by the choice of a suitable site and the proper design of buildings. In every earthquake the damage to property is always least on hard rocks; it is more in houses built on soft ground; greatest of all on recently "made" land, especially on that filling up a marsh or creek. Sites on hard ground should therefore be selected, while the neighbourhood of unsupported openings, such as the edges of cliffs or river-banks, should be avoided.

In Japan and other earthquake countries, much attention has been paid to the proper form and structure of buildings. In ordinary works, yielding first shows itself at the base of a pier or wall, and thus such structures as the piers of bridges are made wider and stronger below and tapering upwards. In a so-called earthquake-proof house, the roofs are exceedingly light, chimneys are short and thick, arches are avoided, rafters run from the ridge pole to the floor-sills. The essential point, as was well shown in the Japanese earthquake of 1923, is that the building should be so framed and braced that it will move bodily as one block with its foundations. Thus, in 1923, brick buildings crumbled down at once into ruin. Wooden houses withstood the shock fairly well, but were an easy prey to the fires that followed. The modern steel-brick buildings offered a stout resistance to both earthquake and fire, and nearly half of those in Tokyo passed through the trial unharmed.

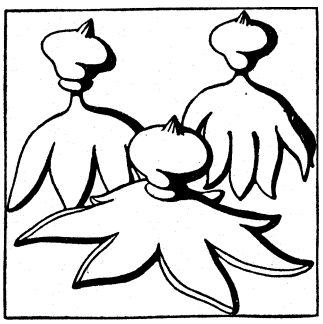
BIBLIOGRAPHY.—The only work dealing with the history of the science is C. Davison's *Founders of Seismology* (1927). Among textbooks may be mentioned F. de Montessus de Ballore's *La Science Séismologique* (1907); C. G. Knott's *Physics of Earthquake Phenomena* (1908); G. W. Walker's *Modern Seismology* (1913); and C. Davison's *Manual of Seismology* (1921). The most important monographs on earthquakes are those by R. Mallet, *The Neapolitan Earthquake of 1857* (1862); C. E. Dutton, "The Charleston Earthquake of Aug. 31, 1886," *U.S. Geol. Surv., Ninth Annual Rep.,* (1889); T. Taramelli and G. Mercalli, "Il terremoto ligure del 23 febbraio 1887," *Ann. dell'Uff. Centr. di Meteor. e di Geodin.,* vol. viii., pt. 4 (Rome, 1888); B. Koto, "The cause of the great earthquake in Central Japan, 1891," *Journ. Coll. Sci. Imp. Univ. Japan,* vol. v. (1893); R. D. Oldham, "Report on the great earthquake of June 12, 1897," *India Geol. Surv. Rep.,* vol. xxxix. (1899); R. S. Tarr and L. Martin, "The earthquakes of Yakutat Bay, Alaska, in September 1899," *U.S. Geol. Surv.* Prof. Paper No. 69, (1912); A. C. Lawson (ed.), *The Californian Earthquake of April 18, 1906* (Washington, Carnegie Institution, 2 vols., 1908–10); and M. Baratta, *La Catastrofe Sismica Calabro-Messine, 28 Dicembre 1908* (Soc. Geogr. Ital., Rome, 1910). Descriptions of various earthquakes are given by C. Lyell, *Principles of Geology,* 12th ed., (1875); C. Davison, *A Study of Recent Earthquakes* (1905); and F. de Montessus de Ballore, *La Giologie Sismologique* (1924). Many regional monographs have been published, including a long series by A. Perrey (1844–66), and a later series by F. de Montessus de Ballore, culminating in his *Géographie Siismologique* (1906). More detailed works are those by M. Baratta, I *Terremoti d'Italia* (1901), and C. Davison, *A History of British Earthquakes* (1924). The most important world-catalogues of earthquakes are those compiled by R. Mallet, "Catalogue of recorded earthquakes" (1606 B.C.-A.D. 1842), *Brit. Ass. Rep.,* 1852, 1853 and 1854; and J. Milne, "A catalogue of destructive earthquakes" (A.D. 1–1899), *Brit. Ass. Rep.,* 1911. Among the chief periodical works relating to seismology are the reports of the Seismological Committee of the British Association (from 1896), the *Bulletin* of the Seismological Society of America, the *Bollettino* of the Italian Seismological Society and the *Bulletin* of the Earthquake Research Institute (Tokyo).

(C. D.)

In late April and early May 1928 the modern city of Corinth was almost completely destroyed by repeated earthquake shocks of great intensity and thousands of citizens were rendered homeless. The country districts were also badly affected and in Bulgaria many towns and cities were shaken to their foundations. Smyrna and other cities in Asia Minor were very badly damaged.

A severe earthquake occurred in Burma (1930), killing several hundred and virtually obliterating Pegu. This was immediately followed by a shock of equal force in Persia. Another at Managua, Nicaragua (1931) brought death to hundreds and gave the United States marines a chance to employ themselves humanely in the succour of the thousands left homeless. In January 1934 a violent tremor shook all of India, destroying about 6,000 lives. (X.)

EARTHSHINE. The earth is a luminary to the moon as the moon is to the earth; consequently the portion of the moon's disc which is not illuminated by the sun is illuminated by earthshine analogous to moonlight. It is a familiar observation that when the moon is a crescent the earthshine is powerful enough to make the whole disc easily visible. The phases of the earth and moon are complementary, so that the earth is near "full" when the moon is near "new" and the earthshine is then strongest.



FROM LASZLO, "GASTEROMYCETES HUNGARIAE"
EARTH STAR (GEASTER GRANULOSUS), A KIND OF PUFF-BALL GROWING ON DECAYED LEAVES

EARTH-STAR *(Geaster),* in botany, a kind of puff-ball (*q.v.*), with a distinct outer coat which, on separating from the

inner, splits into several divisions, which become reflexed and spread like a star. The inner coat enveloping the spores is supported, like a ball, with or without a stalk on the upper face of the star. The spores generally escape by a distinct aperture which appears in the top of the ball. There are several species in Britain, found on the ground or on decaying leaves. They are generally distributed throughout America. *(See* FUNGI.)

EARTHWORM, the name of oligochaete worms found nearly all over the world. There are now more than 1,000 species known and the number is increasing. The earthworms of England belong almost entirely to the family *Lumbricidae,* which forms the prevalent earthworm fauna of the Palaearctic region and is also strongly represented in the Nearctic. Elsewhere they are replaced by the numerous genera of the families enumerated in the article ANNELIDA (*q.v.*). It is a remarkable fact that members of the family *Lumbricidae,* when introduced into tropical and other countries, thrive abundantly and oust the indigenous forms. In gatherings of earthworms from various extra-European countries it is always found that the worms of the cultivated ground and that near the coast are European species, the native forms being met with farther inland. The *Lumbricidae* from non-Palaearctic countries are mostly identical with Palaearctic species; and since they are impatient of sea-water, it seems clear that they must have been accidentally transported with plants, etc. Most earthworms live in the soil, which they devour as they burrow through it. A few, like their allies the river worms *(Limicolae),* habitually frequent streams, lakes, etc. Truly oceanic islands have no indigenous earthworm fauna, but are inhabited by forms identical with those of neighbouring continents, accidentally introduced.

Earthworms are hermaphrodite. Like the leeches (*q.v.*) they produce cocoons which are a product of the glandular epithelium of the clitellum. In pairing, earthworms come together with the head of one directed towards the tail of the other. The spermatozoa are then exchanged, passing into the *spermathecae* of the partner, whence they are transferred to the cocoon as the latter passes forward over the head. In these cocoons are previously deposited the eggs together with albumen upon which the embryos feed. So far as is known, the production of cocoons is universal among the *Oligochaeta.* The young hatch as fully formed earthworms. The work of earthworms in aiding the production of subsoil and in levelling the surface was first studied by Darwin, and has since been investigated by others. This work is partly carried out beneath the surface and partly on the surface, upon which the worms wander at night and eject the swallowed and triturated earth. Frequently castings of some height are formed of coiled ropes of agglutinated particles of mould. The British species, between 30 and 40 in number, do not grow to a greater length than 10in.; but in tropical countries there are species which reach a length of 4ft. Thus we have in Natal the gigantic *Microchaetus microchaetus;* in southern India, *Drawida grandis;* in Australia, *Megascolides australis;* and in South America, *Glossoscolex giganteus. See* ANNELIDA: *Oligochaeta.*

EARWIG, an insect belonging to the family *Forficulidae* of the order Dermaptera. It is characterized by the very short leathery fore-wings, or tegmina, and the large semi-circular membranous hind wings which have highly modified veins disposed in a radial manner. When the insect is at rest the hind wings are folded longitudinally in a fan-like fashion: there are also two other folds in a transverse direction and, in this way, they are tucked away beneath the tegmina. The body is terminated by a pair of horny forceps which exhibit evident differences of form in the two sexes. A remarkable fact about them is that the males fall into two sharply marked classes as regards the length of their forceps. It appears that the development of forceps of intermediate length is very unusual. The significance of this fact is still obscure. These forceps are highly modified cerci and, in the Ceylon genus *Diplatys,* the immature forms carry long jointed cerci, which are replaced by forceps only at the last moult. The function of the forceps is by no means clear, but in all probability they are mainly used as organs of offence and defence: when alarmed an earwig often uplifts the apex of the abdomen with the forceps widely opened in a threatening manner. The origin of the name earwig is uncertain: by some it is believed to be due to the fact that the insect has been known to use the human ear for purposes of concealment, but others claim it is a corruption of earwing in allusion to the form of the hind wings.

The family *Forficulidae* is almost cosmopolitan and the best known species is the common European earwig, *Forficula auricularia.* This insect is gregarious and nocturnal, hiding by day under loose bark, in hollow stems, under stones or in any suitable dark crevice. At night it becomes active, feeding upon tender foliage, flower petals, fruit, etc., and being especially partial to dahlias. The extent to which it partakes of animal food is uncertain but it is known to devour both living and dead insects. It is a curious fact that, in spite of the possession of well-formed wings, this insect has only on very rare occasions been seen to fly: also, the often repeated statement that the forceps assist in folding up the wings needs substantiation. The eggs are laid in masses up to 50 or more in number. They are deposited in a cavity in the soil where they are guarded by the female earwig, who rests over them until they hatch and the young nymphs are able to shift for themselves. The eggs are found during winter and early spring and the nymphs, after moulting four to six times, become mature during the summer. The European earwig has secured a footing on the Pacific side of N. America as well as in parts of New Zealand. In these localities it has become exceedingly numerous and destructive. Efforts are being made to control the insect by importing certain natural enemies from Europe into those lands which the earwig has adopted. The enemies known to parasitize the earwig are two species of flies of the family *Tachinidae* whose larvae live within and finally kill their host. Under ordinary circumstances earwigs are usually destroyed by means of traps or poison baits. Plant pots stuffed with straw and inverted on canes are a well known lure: in the United States the broadcasting of a poisoned bran mash bait has been recommended in places where the insect is very numerous. (A. D. I.)

EASEL, a support for a picture, painting or other work of art. Many types of ornate easels are also used for the display of works of arts, announcements, etc.

In construction, easels are divided generally into two classes: those of light construction, the so-called "sketching easels," and the heavier type, known as the "studio easels." Sketching easels are made to fold compactly so as to be conveniently carried for sketching purposes in the open. These easels should be as light in weight as possible but of very sturdy construction. There are a great many types, but practically all of them follow the tripod design, *i.e.,* three adjustable legs. When setting up the easel for use, the three legs spread apart and are adjusted to a height at which the artist may either sit or stand while painting. A tray is used to hold the painting on which the artist is working. The top of the picture is generally held fast with a clamp or attachment either attached to the third back leg or constructed into the easel between the front two legs. To keep the sketching easel rigid while working in a strong wind, a stout cord is tied to the head of the easel, to the other end of which a weight is attached and allowed to hang perpendicular, thereby maintaining the centre of gravity. Studio easels differ in construction from sketching easels in that they are of a heavier type. They do not follow any particular design, but are more or less elaborate both in finish and construction, according to the artist's preference. They may be obtained, finished in different kinds of wood, in keeping with the other furniture of the studio. The tray of the easel is adjustable, so that the artist may sit or stand while painting. There is also an attachment by which the painting may be tilted at different angles, to suit the artist's pleasure. The base of the easel is equipped with castors, permitting it to be turned or moved quickly to any part of the studio. (F. W. WE.)

EASEMENT, in law, signifies a right of accommodation. or limited right of use over land belonging to another. It is distinguished from *profit à prendre* since an easement confers merely a convenience to be exercised over the land of another without any participation in the profits of it. Thus a right of way is an

easement, a right of common is a profit. An easement is distinguishable also from a licence, which, unless it is coupled with a grant, is personal to both grantor and grantee, and is neither binding on the licensor, nor, in general, assignable by the licensee; while both the benefit and the burden are annexed to land.

The essential features of an easement, in the strict sense of the term, are therefore these: (i.) It is an incorporeal right; a right to the use and enjoyment of land—not to the land itself; (ii.) it is imposed upon corporeal property; (iii.) it is a right without profit; (iv.) it requires for its constitution two distinct tenements—the "dominant tenement" which enjoys the right, and the "servient tenement" which submits to it. This last characteristic excludes from the category of easements the so-called "easements in gross" (if such can subsist by English law), such as a right of way conferred by grant independently of the possession of any tenement by the grantee. The true easement is a right "appendant" or "appurtenant" to the dominant tenement.

Further classifications of easements must be noted. They are divided into (a) *affirmative* or positive, those which authorize the commission of an act by the dominant owner, *e.g.*, rights of way, and negative, when the easement restricts the rights of the servient owner over his own property, *e.g.*, prevents him from building on land so as to obstruct ancient lights (*q.v.*); (b) *continuous*, of which the enjoyment may be continual without the interference of man, *e.g.*, access to light, and *discontinuous*, where there must be a fresh act on each occasion of the exercise of the right, *e.g.*, a right of way; (c) apparent, where there are visible external signs of the exercise of the right, *e.g.*, a right to dam up a watercourse, and non-apparent, where such signs are absent, *e.g.*, a right to support of one house by another.

Acquisition of Easements.—Easements may be acquired (a) by express grant; (b) by an implied grant; (c) by express or implied reservation, *e.g.*, by the owner of land in selling the fee; (d) by prescription, either at common law or under the Prescription Act, 1832. An express grant, or express reservation (inter *vivos*), of an easement cannot be effected except by deed. An easement by implied grant usually arises under the principle that a grantor cannot derogate from his own grant. Thus a man builds two houses on a close with windows deriving light from the grounds of each other. If he sells one a grant of the light derived by it over the other's ground is implied.

Easements are acquired by prescription at common law by proof of "immemorial user" by the dominant owner and those through whom he claims. A "lost grant" is presumed on proof that an easement has been enjoyed uninterruptedly for 20 years before action brought unless the contrary is shown. To avoid the difficulties of proof of prescriptive right at common law, the Prescription Act, 1832, established more definite periods of use. In the case of easements other than light, the periods of prescription are 20 years to establish a prima facie, and 40 years to establish an indefeasible title. (As to light see ANCIENT LIGHTS.) The enjoyment of the easement by the dominant tenement must be open, *i.e.*, not hidden, and of right, *i.e.*, not by arrangement with the owner of the tenement affected by it (*Kilgour* v. Gaddes, 1904, 1 K.B. 457).

Easements may be extinguished (i.) by express release—here an instrument under seal is necessary; (ii.) by "merger," *i.e.*, where both tenements become the property of the same owner; (iii.) by abandonment through non-user. In the case of discontinuous easements, the shortest period of non-user may suffice if there is direct evidence of an intention to abandon.

A word may be added here as to the right to air. The owner of a dwelling-house may acquire a right to the passage of air through it by a defined channel. If it is claimed by prescription the proof required to establish it is the old common law proof, since the air easement is not one within the Prescription Act. It may also be acquired by grant, express or implied.

In Scots law the term "easement" is unknown. Both the name "servitude" and the main species of servitudes existing in Roman law (*q.v.*) have been adopted. The modes of their creation and extinction are similar to those of English law. The statutory period of prescription is 40 years (Scots Acts, 1617, c. 12), or 20 years in the case of enjoyment under any ex facie valid irredeemable title duly recorded in the appropriate register of sasines (Conveyancing [Scotland] Act, 1874). There are certain servitudes special to Scots law, *e.g.*, "thirlage," by which lands are "thirled" or bound to a particular mill, and the possessors obliged to grind their grain there, for payment of certain quantities of grain or meal as the customary price of grinding. Statutory provision has been made for the commutation of these duties (Thirlage Act, 1799), and they have now almost disappeared.

The French civil code and those of Belgium, Holland, Italy and Spain closely follow Roman law. French law is in force in Mauritius, and has been followed in Quebec (Civil Code, arts. 499 et seq.) and St. Lucia (Civil Code, arts. 449 et seq.). In India the law is regulated, on English lines, by the Easements Act, 1882 (Act v. of 1882). The term "easements," however, in India includes *profits à prendre*. In the South African colonies the law of easements is based on the Roman Dutch law. In most of the other colonies the law of easements is similar to English law. In some, however, it has been provided by statute that rights to the access and use of light or water cannot be acquired by prescription; but municipal bye-laws must be examined in this relation.

In the United States the law of easements is founded upon, and substantially identical with, English law. The English doctrine, however, as to acquisition of light and air by prescription is not accepted in most of the States.

Burge, *Commentaries on Colonial and Foreign Laws*, vol. iv., pt. 2 (new ed., 4 vols., 1907–27); Jacques Vollenweider, Étude sur les droits distincts et permanents en droit civil suisse, Lausanne (1923).

EAST, ALFRED (1849–1913), British painter and etcher, was born at Kettering, Northamptonshire, on Dec. 1j, 1849. He studied at the Glasgow School of Art and then in Paris at the École des Beaux-Arts, and under Robert Fleury and Bouguereau. He began to exhibit at the Royal Academy in 1883, and became R.A. in 1913 a few months before his death. In 1906 he became president of the Royal Society of British Artists. Many of his works are to be found in the English provincial galleries; his "Passing Storm" is at the Luxembourg, Paris; "The Nene Valley" at the Venice gallery; and "A Haunt of Ancient Peace" at the National gallery in Budapest. East visited Japan in 1889, and among his best works are the landscapes he painted there. From 1902 onwards he took a keen interest in etching, and produced a large number of plates. He also published a useful, practical book on landscape painting, The Art of Landscape Painting in Oil *Colour* (1906). Shortly before his death he presented a collection of his pictures to his native town, Kettering. He died in London on Sept. 28, 1913.

EAST AFRICA, OPERATIONS IN. When the World War broke out in 1914 the garrison of British East Africa, the territory immediately north of German East Africa, was scattered and engaged on punitive expeditions remote from the enemy frontier. In the case of each Protectorate the troops were native with European officers. The German forces, some 5,000 strong, including 260 Europeans, lay ready to the hand of their commander, Von Lettow-Vorbeck, a capable and determined soldier well able to employ them to full advantage. If it is remembered how keenly sensitive the native soldier is to any shortcoming in his superior and that Von Lettow had only been with his command for six months when hostilities began and kept that command efficient and formidable through four years of steadily declining fortune, some idea may be formed of the resolute nature and soldierly qualities of the German commander-in-chief. His operations consistently bore the clear imprint of his skill and personality, and there were advantages, other than his professional capacity and steady courage, upon which he could rely.

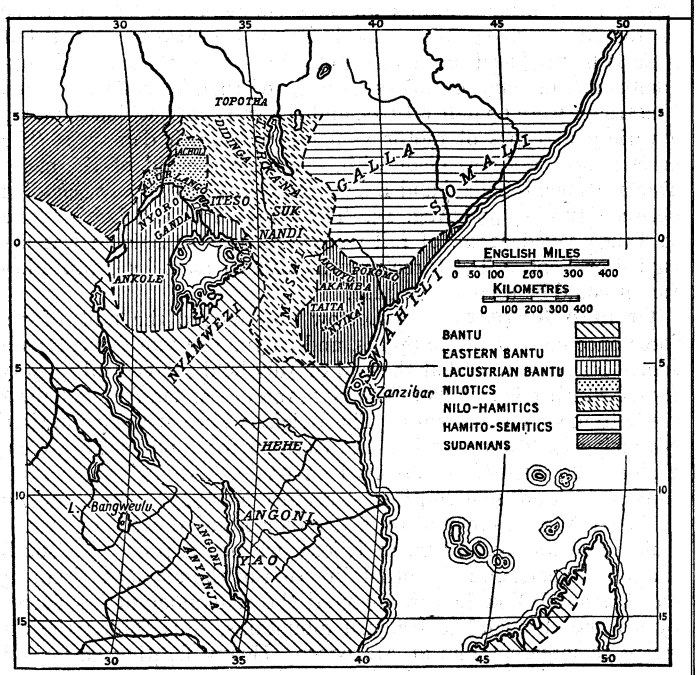
I. EARLY OPERATIONS.

The country—nearly double the size of Germany in 1914—which was the scene of operations, is for the most part covered by bush, dense as a rule, but occasionally thinning out to something like park land. High mountain ranges, thick with vegeta-

tion, rear themselves from bush and jungle which are fever stricken and liable to wholesale inundation during the rainy season. Rivers abound and malaria and dysentery of a malignant type, with other tropical diseases, combined to swell the casualty list of a European or Anglo-Indian force. Practically every animal imported into East Africa for the use of the British forces succumbed to the tsetse fly. The route of every British advance was marked by casualties due to diseases from which the rank and file of the enemy—askaris recruited from local tribes—were immune. Surprise by the attacker was as difficult as it was simple by the defender, who waited concealed and warned by the laborious approach of his adversary cutting roads and bridging rivers.

Supply and transport presented appalling difficulties to an advance through hundreds of miles of naturally impenetrable bush, while the defending force slowly fell back upon the magazines posted in its rear. Only an overwhelming preponderance in numbers made any advance possible, but a force starting with a strength adequate for an offensive enterprise constantly found itself reduced at best to an equality of strength on contact with the enemy. Many good cards were thus in the hand of the German commander; and he rarely failed to play them with full effect.

Naval Operations *and German* Advance.—On Aug. 8, 1914, two British cruisers, "Astraea" and "Pegasus," arrived opposite Dar es Salaam from Zanzibar, and, being unable to leave a garrison, the naval commander covenanted with the German governor that the latter should forbear from any hostile action in Dar es Salaam itself. Parallel to the southern frontier of British East Africa and about 50m. distant from it ran the Uganda railway from Mombasa to Lake Victoria. This tempting and exposed objective, for the protection of which the British troops at the outset were hopelessly inadequate, at once appealed to Von Lettow, who on Aug. 15 seized Taveta, which lay in British territory at the eastern end of the gap between the southern slopes of Mt. Kilimanjaro and the northern end of the Pare mountains in the German Pro-



RACE MAP OF EAST AFRICA

tectorate. An enemy force here was a standing menace to the British capital at Nairobi, and constantly raided the railway line.

In September the enemy cruiser "Königsberg" returned to Dar es Salaam and on Sept. 20 surprised and destroyed the "Pegasus" while undergoing repair in the Zanzibar roadstead. A combined enemy operation against Mombasa, for the execution of which the "Konigsberg" was to attack the port in conjunction with a land force moving north along the coast, failed, as the "Königsberg" was driven by the ships of the Cape Squadron into the Rufiji delta, where she was run aground. The land force began its march along the coast on Sept. 20, was repulsed at Gazi, 25m. from Mombasa, on Sept. 23, and retired to the frontier on Oct. 8. The crew of the "Konigsberg," which was blown up in July 1915, after being set on fire by the monitors "Severn" and "Mersey," joined the enemy land forces, with an armament of ten 4·1 guns.

German raids along the coast, on the Uganda railway, and into the frontier districts of Uganda, Belgian Congo, Rhodesia and Nyasaland were frequent in the opening months of the campaign. These small enterprises were much simplified by the central position of the enemy and the excellent lateral communication afforded by the central railway from Dar es Salaam to Kigoma, on Lake Tanganyika. This lake was under German control until Dec. 1915, when by the operations of motor boats specially brought from Capetown the enemy was deprived of the one lake which had not been in British hands since the earliest days of the campaign.

Reinforcements from India.—It soon became apparent that, unaided, the British Protectorate forces could not hold their own, and the Government of India consented to send an expedition. On Aug. 25 its leading unit reached Mombasa with Brig.-Gen. Stewart, who assumed command. The rest of the expeditionary force was directed on Tanga, the northernmost German port, at the southern extremity of the Usambara mountains, healthy highlands where the bulk of the German settlers resided. Coincident with an attack on Tanga an advance against Moshi by the north of Kilimanjaro was to be made by Stewart. The expeditionary force under Brig.-Gen. A. E. Aitken was about 7,000 strong and (except the 2nd Loyal North Lancs.) composed of Indian troops.

Failure of British Offensive.—The transports reached Tanga on Nov. 2, when the local commissioner represented the place as an open and undefended port and bombardment was deferred. Meanwhile, Von Lettow, advised of the plan by captured Indian mails, was hurrying reinforcements to the coast. When one and a half British battalions landed two miles east of the town on the evening of the arrival, they met with strong opposition and fell back. Von Lettow arrived on the evening of the following day, when British reinforcements had been landed and fighting resumed, and on Nov. 4 heavily defeated his opponent, whose casualties were 795. On the same day Stewart, checked at Longido, was compelled to retire. The British force at Tanga re-embarked and reached Mombasa on Nov. 5. The first British offensive had thus failed completely. Von Lettow's success at Tanga put an end for the time being to any general offensive against him, and it was not until 1916 that the next British advance was set in train.

The intervening period was occupied in raiding by both forces, with occasional engagements of a more ambitious nature. A British force was compelled to surrender on Jan. 17, 1915, at Jasin, in enemy territory, to a superior force, after 48 hours' fighting, which exhausted their ammunition and water. German losses, especially in officers, were serious, as was the shrinkage of ammunition. Maj.-Gen. M. I. Tighe assumed chief British command in April 1915 and in June, Bukoba, on Lake Victoria, was taken.

Reinforcements Arrive.—Aid was now sought from a different quarter, for, with the conquest of German South-west Africa by General Louis Botha in July 1915, the resources of the Union of South Africa became disposable to an extent which was impossible till the disappearance of the enemy from her own border. During the latter half of 1915 there was continuous preparation in South Africa of troops, depôts, supplies, medical stores, transport, animals and material of all kinds for use in East Africa. By Feb. 1916 one mounted brigade, two infantry brigades and one field artillery brigade, complete with all their auxiliary units, had arrived from South Africa to join Tighe. A second mounted brigade followed, together with a battalion of the Cape Corps (coloured men from the Cape Province). Tighe also had the following European units: the Calcutta Volunteer Battery, the 2nd Loyal North Lancs., 25th Royal Fusiliers, 2nd Rhodesians and two local settlers' corps; India sent him from her native army ten infantry regiments, one squadron of cavalry and two mountain batteries. The battalions of King's African Rifles were the original native Protectorate force. At the same time, Von Lettow's force had reached the highest limit which it attained in the campaign and was probably over 20,000. The exact combatant strength

is difficult to estimate, for there were many carriers of whom a percentage were armed and many trained as askaris. The askari in his own country is a soldier of high value. Such a force, with a strong leaven of Europeans, under a skilful and determined commander, was a formidable adversary in tropical bush country.

German Ammunition Supplies. — In April 1915 the mind of Von Lettow, which had been sorely exercised by his shortage of ammunition, was relieved in the following remarkable manner: A British ship, the "Rubens," seized at Hamburg, left that port loaded with arms and ammunition and appeared off Tanga on April 4, being sighted by H.M.S. "Hyacinth." Entering Manza Bay on fire and abandoned, she was boarded by bluejackets, who found her timbered up and battened down. After firing more rounds the "Hyacinth" steamed away on the assumption that her quarry would burn herself out. The Germans returned and salved almost the entire cargo, and a largely increased volume of enemy fire from the Mauser pattern 1898 rifles which the "Rubens" had brought was the result. This operation was repeated a year later.

II. OPERATIONS UNDER GENERAL SMUTS

The chief command in East Africa was assumed by General Smuts in Feb. 1916. He had previously declined the post, but when General Smith-Dorrien was compelled to relinquish the command in consequence of illness he accepted it. He reached Mombasa on Feb. 19 and found the railway completed from Voi to Serengeti, 5m. from Salaita Hill, the German advanced position from Taveta. A week earlier an attack on Salaita had failed. The rainy season was at hand and movement would then become impossible; Smuts telegraphed to Lord Kitchener that he was ready to carry out the occupation of the Kilimanjaro area at once. The proposal was agreed to and Smuts proceeded to advance.

British Advance on **Taveta.**—An attack, designed primarily to hold the enemy, was to be delivered on Salaita by a force under General Malleson, while Stewart was to repeat his attempt of 1914 to reach Moshi by the north of Kilimanjaro and thence to intercept any enemy retirement in his direction. General van Deventer with a mounted brigade, moving by Malleson's right, was to cross the Lumi river, and by way of the foothills of Kilimanjaro cut the enemy line of retreat between Taveta and Moshi. The execution of this movement unobserved was the only chance of surprising the enemy, for it was apparent to Von Lettow, who had made all preparations for retirement, that Taveta was Smuts' objective. This surprise was effected. Van Deventer moved on March 8 and on the following day his troops were astride the Moshi-Taveta road. On the same day the Germans evacuated Salaita and took up new positions on two hills, Latema and Reata, covering the gap between the Pare mountains and Kilirnanjaro. The main enemy force was posted at Himo, 5m. from the gap, whence it could move in any direction to attack or retire. The progress of Stewart's force was so slow that his movement was without effect.

The new enemy position was attacked on March 11 and, after severe fighting all day and the succeeding night, was occupied on the morning of the 12th by a general advance in support of detachments which had won their way to the two crests during the night and caused a retirement by the enemy.

German Withdrawal. — Von Lettow now withdrew his entire force to a position (Kahe-Ruvu) which stretched south of the Taveta-Moshi road from Kahe railway station eastward along the northern end of the Pare mountains. He was followed up and attacked on March 18 from Latema Nek by Brig.-Gen. Sheppard, and on March 20 van Deventer was sent from Moshi to turn the enemy at Kahe. He seized Kahe on March 21 and on the following night, after a very severe action with Sheppard, the enemy withdrew to Lembeni, zom. S. of Kahe. Von Lettow abandoned one 4·1 gun, and had expended ammunition to an extent which he could ill afford, but his force was intact and the timely arrival of the second blockade runner at this juncture with four 4.1 field howitzers, gun and small-arm ammunition, machine-guns, stores, provisions and clothing was an inestimable stroke of good fortune. Here the operations which had been undertaken before the rainy season were concluded and the British forces took up positions covering Taveta and Moshi and facing the enemy at Lembeni.

During the ensuing rains Smuts reorganized his force and prepared to resume the offensive at the earliest possible date. He could rely for assistance in his main operations upon the Belgians in the north-west and the British force under Maj.-Gen. Northey, operating from Nyasaland, to the south-west. For reasons fully recorded in his dispatches, Smuts decided at once to send van Deventer with a mounted force rapidly by Arusha to Kondoa Irangi and thence to the central railway and east along that line to Morogoro. His own force was to move south by the Pangani, and make for the same ultimate objective, Morogoro. It was hoped that Von Lettow would there be brought to bay by the two converging forces.

New British Offensive. — Van Deventer moved on April 3 and occupied Kondoa Irangi on April 19, capturing the enemy garrison at Lol Kisale en route. He reached Kondoa Irangi after heavy casualties in men and animals from disease and was there cut off and reduced to immobility as a consequence of his losses and the advent of the rainy season. Von Lettow concentrated a force against van Deventer and fighting ensued, but the German attacks, with one exception, lacked vigour and were all repulsed. Van Deventer's position was eased by the end of May, when Smuts began his advance down the Pangani and the Belgians moved on Tabora. Maj. Kraut was in command of the German force opposite Smuts when the latter set his troops in motion southwards from Moshi on May 18, Von Lettow having assumed direction of his concentration against van Deventer.

Systematically outflanked by his opponent, whose main advance along the Pangani was supplemented by flank movements by the Pare and Usambara ranges, Kraut found himself compelled to leave the Tanga railway and retire upon Handeni. This place was seized by Smuts on June 19, Korogwe having been occupied four days earlier. On June 24 the Germans were attacked simultaneously on three sides, but, after determined fighting, withdrew into the Nguru hills. Smuts was now compelled to halt his force on the Msiha river. In a month 250m. had been covered, but malaria had reduced the strength of all units, combatant and non-combatant, in some instances to 30% of their original numbers. The troops were on half rations, and the transport, which included a variety of types of motor vehicles, was much damaged. The coast region was now dealt with, and with the aid. of the navy, Tanga, Pangani, Sadani and Bagamoyo were successively occupied between July 17 and Aug. 15. The removal of the British base to Tanga saved zoom. of rail transport. Dar es Salaam was occupied on Sept. 4, but three months elapsed from its capture before it could be used as the base.

German Retreat. — Von Lettow now moved the bulk of his force once more opposite Smuts, and on June 24 van Deventer resumed his advance and at the end of July held the central railway from Kilimatinde to Kikombo, about 100 miles. On Aug. 9 he was ready to move on Morogoro. The Belgians were at the same time advancing on Tabora against the German force under Maj.-Gen. Wahle, who was left to do his best unaided, though some reinforcements were sent south-west against Northey. Smuts moved again on Aug. 5, opposed by a detachment of the enemy whose main force was withdrawn to Kilosa, whence it proceeded south towards Mahenge, the eventual direction of the enemy retirement on all fronts. Von Lettow directed the remainder of his forces by a route through the Uluguru mountains, thus foiling the attempt to intercept him at Morogoro. Heavy fighting ensued in these mountains but Kisaki fell into British hands on Sept. 15 and Von Lettow retired to Mgeta river and there entrenched himself. On this front, during the last three months of 1916, activity was confined to such minor affairs as are usual between opposite entrenched forces. Civil administration was instituted in the occupied area behind the British forces.

Belgian Operations. — The Belgian force (also native), under Maj.-Gen. Tombeur with European officers, was divided into two brigades, the Northern (Col. Molitor) and the Southern (Lt.-Col. Olsen) and operated in the north-west of German territory, opposed by Wahle, who was instructed to avoid a decisive action. The Belgian operations, well planned and successfully executed,

were of prime importance to the general campaign. Broadly described, they were as follows. Molitor invaded Ruanda by the north of Lake Kivu while Olsen co-operated south of him by the north of Tanganyika. The movements started on April 4, and by the end of May the Belgians were in possession of Ruanda. Molitor then sent columns south-west to join hands with Olsen and other columns south-west to Lake Victoria, which was reached on June 27.

In the middle of July, on a front between Tanganyika and Victoria, Molitor and Olsen moved south on the respective objectives of Tabora and Kigoma, the terminus of the central railway on Tanganyika. Olsen occupied Kigoma on July 28 and Ujiji on Aug. 2, and then moved east on Tabora. Co-operating with Molitor was a British column under Brig.-Gen. Sir C. P. Crewe, who captured Mwanza on the southern shore of Lake Victoria on July 14. On Sept. 19 Molitor occupied Tabora which Wahle had evacuated the previous day, leaving behind his sick with civilians and prisoners of war. Crewe reached the central railway a week later.

British Advance from Rhodesia.—By this time Northey had succeeded in interposing some of his forces, which were in three columns under Lt.-Cols. Hawthorn, Murray and Rodgers (the last a South African unit), between Tabora and Mahenge. His advance was on an original front between Lakes Nyasa and Tanganyika. Murray occupied Kasanga (Bismarckburg) at the south end of Tanganyika on June 8. The Germans were defeated at Malangali on July 24, and on Aug. 29 Iringa was occupied, Lupembe having been seized ten days earlier. Northey, ordered with van Deventer, now at Kilosa, to deal with the enemy in the Mahenge district, was much outnumbered by forces already in touch with him and Wahle's columns approaching from the north, and on the night of Oct. 21 most of Wahle's troops broke through him. On the same day Kraut was heavily defeated at Mkapira. Hawthorn secured the surrender of an enemy column at Ilembule. On Dec. 24 van Deventer and Northey attacked the Mahenge force. An enemy column surrendered to Northey, but the force engaged with van Deventer escaped him after fighting from Dec. 25 to 28.

Position at End of 1916.—By the beginning of 1917 Smuts had evacuated 12,000 to 15,000 white troops (South Africans), mostly victims to malaria, and they had been replaced by the Nigerian Brigade (Brig.-Gen. Cunliffe) and fresh battalions of the King's African Rifles. Kilwa and Lindi, south of Dar es Salaam, had been seized by the navy and a force under Maj.-Gen. Hoskins had been concentrated at Kilwa. On Jan. 1, 1917, an advance was made on the Mgeta position, but after heavy fighting the enemy retired across the Rufiji at Kibambawe. Smuts now went to England and Hoskins assumed the chief command. The rains ensued, and to clear the north bank of the Rufiji was all that could be barely accomplished before operations ceased perforce. Hoskins completely reorganized his command, but before operations were resumed he was ordered to Palestine. His successor was van Deventer, who assumed command at the end of May 1917.

III. VAN DEVENTER'S OPERATIONS

The enemy forces were disposed as follows: Von Lettow near Kilwa, Wahle in the Lindi area, Tafel at Mahenge, detachments between Kilwa and Lindi, and near the Ruvuma. Northey lay south and west of Tafel with another British force at Iringa, north-west of the enemy. The rest of van Deventer's troops were to act against Von Lettow. In pursuance of this decision an advance was made by the Kilwa force under Brig.-Gen. Beves on July 5 towards Liwale. The enemy fell back to Narungombe, where a severe engagement took place on July 19. The enemy retired south, but the Kilwa force was unable to move again until mid-September. In August the enemy was driven from the Lukuledi estuary to allow of an advance inland from Lindi. The Kilwa force (Hannyngton) was to move south and that at Lindi (Beves) west. These operations were marked by the hardest fighting of the whole campaign. Von Lettow fell back, under pressure by Hannyngton. towards Nyanga, 40 mi. S.W. of Lindi, Wahle retiring before Beves. On Oct. 15 a four days' battle began between Beves' force and the enemy under Von Lettow joined by Wahle. The latter retained their position and it was ten days before Beves' force under the command of Cunliffe could resume the offensive.

On Oct. 8 Tafel, pressed by Northey with Belgian co-operation from the north, had retired from Mahenge, and, breaking through two weak detachments on Nov. 16, moved south-east towards Von Lettow, whom he was debarred from joining by the Kilwa force. Vainly endeavouring to join the main body, Tafel reached the Ruvuma, but, unable to procure food, surrendered with his entire force on Nov. 28.

Germans Retire to Portuguese Territory.—On the night of Nov. 25–26 Von Lettow, having shed all weaklings, crossed the Ruvuma into Portuguese territory and thenceforward moved as the circumstances of his position, without bases and short of ammunition, dictated. Early successes in the new sphere of action, especially at Ngomano, gave the Germans food, ammunition, arms and clothing, and when the rainy season set in, in Jan. 1918, they were able to rest for a short time.

The operations during 1918 were carried out almost entirely by natives, the King's African Rifles, and Von Lettow fell back upon guerilla tactics. Against him in Portuguese territory were sent columns from the east and south shores of Nyasa; and another (Brig.-Gen. Edwards) advanced west from Porto Amelia midway between the Ruvuma and Mozambique. After various engagements Von Lettow marched in May south to the Lurio river, zoom. from German territory, captured Ille, and in June reached the coastal region near Quelimane. On July 1 he captured Nyamakura, 25m. from Quelimane, and in the middle of August at Chalana, eluded envelopment by converging columns. Turning north-west, he was engaged by Hawthorn (who had succeeded Northey) at Lioma, east of Lake Shirwa. After several encounters, the German force reached the Ruvuma again on Sept. 28 and, after resting at Ubena, where Wahle was left, set out for Rhodesia. On Nov. 1 Von Lettow made an unsuccessful attack on Fife and, turning south-west, took Kasama on Nov. 9. Advised on Nov. 13 of the Armistice, he accepted it the following day, and on Nov. 23 formally surrendered to General Edwards at Abercorn. With him were Dr. Schnee, the governor, and Maj. Kraut, together with a force of 30 officers and 125 other Europeans, 1,165 askaris and 2,891 other natives (including 819 women), 1 small field gun, 24 machine-guns and 14 Lewis guns.

Troops Engaged, Casualties, Etc.—The troops employed by the Allies in East Africa included 52,339 sent from India (5,403 British) and 43,477 South African whites. East African and Nyasaland settlers, Rhodesian volunteers and the 25th Fusiliers numbered about 3,000; African troops (King's African Rifles, Nigerians, Gold Coast Regiment, Gambia Company, Cape Corps) and West Indians about 15,000; an approximate total of 114,000 not reckoning Belgian native troops (about 12,000 in all), Portuguese and the naval force engaged. The greatest number in the field at any one time, May to Sept. 1916, was about 55,000; the lowest, in 1918, 10,000, all African, save administrative services. See also KENYA COLONY; TANGANYIKA TERRITORY.

British and Indian casualties were returned at 17,823; of these 2,762 were in the South African Forces. These figures are exclusive of casualties among carriers and of deaths and invaliding through sickness, which among the South Africans alone exceeded 12,000. The cost of the campaign to Great Britain, inclusive of Indian and South African expenditure and that of the local protectorates to March 1919, was officially estimated at £72,000,000.

EAST ANGLIA, one of the kingdoms into which Anglo-Saxon Britain was divided. Bede gives no information about its origin except that its earliest settlers were Angles. The kingdom of East Anglia comprised the two counties of Norfolk and Suffolk, with a western boundary probably formed by the fens of Cambridgeshire.

This kingdom first appears in Bede's narrative early in the 7th century, when its power was at its height. Towards the end

of the reign of Aethelbert, who died about 616, Raedwald of East Anglia began to win for himself the chief position among the Anglo-Saxon kings of his day. His position was assured, at least temporarily, in 617, when he decided to espouse the cause of the Northumbrian prince Edwin, then a fugitive at his court, and defeated Aethelfrith of Northumbria on the banks of the Idle, a tributary of the Trent, in Mercian territory. Raedwald had been converted to Christianity in Kent, but after his return home he relapsed. Bede states that he was the son of Tytil, the son of Wuffa, from whom the East Anglian royal family derived their name Wuffingas. According to the *Historia Brittonum* Guffa (Wuffa) was the son of (Guecha) Wehha, who first ruled the East Angles in Britain. This would put the organization of the kingdom in the first or second quarter of the 6th century. Eorpwald, the son of Raedwald, was converted to Christianity by Edwin, but was soon afterwards slain by Ricbert (627 or 628), whereupon the kingdom again became pagan for three years, when Sigebert, the brother of Eorpwald, became king and founded a see for Felix at Dunwich. Sigebert also founded a school in East Anglia, and on the arrival of an Irish missionary named Furšeus built him a monastery at *Cnobheresburg,* perhaps to be identified with Burgh Castle. Before 644, however, Sigebert resigned the crown in favour of his brother Egric and retired to *a* monastery. Shortly afterwards both brothers were slain by Penda of Mercia in his invasion of East Anglia, and Anna became king. This king was an enthusiastic Christian, and converted Coenwalh, king of Wessex, who had fled to his court. Two of his daughters, Saethryth and Aethelberg, took the veil; while another, Sexburg, was married to Earconbert, king of Kent; and a fourth, Aethelthryth, after two marriages, with Tondbert of the South Gyrwe and Egfrith of Northumbria, became abbess of Ely. In 654 Anna was slain by Penda of Mercia, and was succeeded by his brother Aethelhere, who was killed in 655 at the Winwaed, fighting for the Mercian king against Oswio of Northumbria. In 673 Archbishop Theodore divided the East Anglian diocese into two, Elmham being the seat of the northern, Dunwich that of the southern bishop. A long blank follows in the history of this kingdom, until in 792 we find Offa of Mercia slaying Aethelbert, king of East Anglia, who is said to have been his son-in-law. East Anglia was subject to the supremacy of the Mercian kings until 825, when its people slew Beornwulf of Mercia, and with their king acknowledged Egbert of Wessex as their lord. In 870 Edmund, king of East Anglia, was killed by the Danes under Ivarr and Ubbi, the sons of Ragnar Loðkbrok.

The following is a list of the kings of East Anglia of whom there is record:—Wehha; Wuffa; Raedwald, son of Tytil and grandson of Wuffa (reigning 617); Eorpwald, son of Raedwald (d. 627 or 628); Sigebert, brother of Eorpwald; Egric, brother of Sigebert (both slain before 644); Anna, son of Ene and grandson of Tytil (d. 654); Aethelhere, brother of Anna (d. 655); Aethelwald, a third brother; Aldwulf (succ. 663, d. 713), son of Aethelric and grandson of Ene; Elfwald, son of Aldwulf (d. 749); Hun Beonna and Albert; Aethelbert (792); Edmund (870).

After the death of Ragnar Loðkbrok's sons East Anglia was occupied by the Danish king Guthrum, who made a treaty with Alfred settling their respective boundaries, probably about 880. Guthrum died in 890. A later king named Eohric took up the cause of Aethelwald, the son of Aethelred I., and was slain in the fight with the Kentish army at the Holm in 905. A war broke out with King Edward the Elder in 913; in 921 a king whose name is unknown was killed at the fall of Tempsford, and in the same year the Danes of East Anglia submitted to Edward the Eider. From this time, probably, East Anglia was governed by English earls, the most famous of whom were Aethelstan, surnamed Half-King (932–956) and his sons, Aethelwold (956–962), and Aethelwine, surnamed *Dei amicus* (962–992).

EASTBOURNE, a watering place and county borough in the Eastbourne parliamentary division of East Sussex, England, 65¾ mi. S.S.E. of London by the Southern railway. Pop. (1938) 56,445 (augmented in the holiday season). Area 10 2 sq.mi. The long range of the South Downs terminates here in the lofty headland of Bcachy Head, 3 mi. S.W. of Eastbourne. Eastbourne once consisted of three parts—the village of East Bourne, a mile inland; South Bourne, lying back from the shore, and Seahouses, facing the beach. Owing to its modern extension, the part inland is now known as the Old Town. The church of St. Mary, a fine Transitional Norman building, is the ancient parish church of East Bourne. The marine parade, nearly 3 mi. long, is arranged in terraced promenades, and there is a pier with pavilion. There is a municipal orchestra. Hampden park (over 80 ac.) was acquired by the corporation; Devonshire park *(c.* 13 ac.) has recreation grounds and winter gardens. The principal buildings and institutions include the town hall, the corporation art gallery and technical institute, the Princess Alice Memorial and other hospitals and, among many high-class schools, Eastbourne college for boys, founded in 1867. The duke of Devonshire is one of the principal landowners, Golf links are laid out on the neighbouring downs, and Beachy Head is connected by a fine drive, which is continued through Birling Gap to the village of East Dean. which possesses an ancient Early English parish church with pre-Norman tower. The foundations of a Roman villa and other remains have been found at Eastbourne. The town was incorporated in 1883. The county borough was constituted in 1911, and the greater parliamentary division in 1918. The corporation consists of a mayor, 9 aldermen and 27 councillors. Eastbourne has its own commission of the peace and a separate police force. The council owns the electricity undertaking. At the end of 1941 air raids of World War II had damaged 3,700 houses.

EAST CHICAGO, a city of Lake county, Indiana, U.S.A., on Lake Michigan, adjoining Gary, Hammond and Whiting, and 20 mi. S.E. of the Chicago "Loop." It is served by the Baltimore and Ohio Chicago Terminal, The Chicago, South Shore and South Bend (electric), the Elgin, Joliet and Eastern, the Indiana Harbor Belt, the Pennsylvania, the New York Central, the Pere Marquette and the Wabash railways. Pop. 35,967 in 1920, of whom 14,663 were foreign-born white, and 54,637 in 1940.

East Chicago is one of the rapidly growing cities in the "Calumet region," an important manufacturing district. Indiana Harbor, the part of the city that lies along the lake, is connected with the Grand Calumet river by a 3m. ship canal. The commerce of the port in 1937 was 9,216,414 tons, consisting largely of incoming coal, iron ore and limestone, and shipments of gasoline and steel products. The city's factory output in 1937 was valued at $304,323,701. There are immense steel works and oil refineries and other important industries. The assessed valuation of property in 1940 was $86,131,860. East Chicago was founded in 1888; incorporated as a city in 1893. Its rapid growth began in the 20th century. Between 1900 and 1910 the population increased from 3,411 to 19,098, and, next decade, almost doubled.

EAST CLEVELAND, a city of Cuyahoga county, Ohio, U S.A., on the New York Central railroad, adjoining Cleveland. It is a rapidly growing residential suburb. The population increased from 2,757 in 1900 to 39,667 in 1930, and was 39,495 in 1940. It has a city-manager form of government.

EAST CONEMAUGH, a borough of Cambria county, Pa., U.S.A., on the Conemaugh river and the Pennsylvania railroad, 3m. N.E. of Johnstown. Pop. (1920) 5,256 (23% foreign-born white); 1930, 4,979; 1940, 4,810.

EASTER, the annual festival observed throughout Christendom in commemoration of the resurrection of Jesus Christ. The name Easter, like the names of the days of the week, is a survival from the old Teutonic mythology. According to Bede (De Temp. *Rat.* c. xv.) it is derived from *Eostre,* or *Ostâra,* the Anglo-Saxon goddess of spring, to whom the month answering to our April, and called *Eostur-monath,* was dedicated. This month, Bede says, was the same as the *mensis paschalis,* "when the old festival was observed with the gladness of a new solemnity."

The root *pasch,* from which so many other names for Easter are derived, is from the Hebrew *pisach* (Passover) from the verb form "he passed over."

There is no indication of the observance of the Easter festival in the New Testament, or in the writings of the apostolic Fathers. The sanctity of special times was an idea absent from the minds of the first Christians, who continued to observe the Jewish festivals, though in a new spirit, as commemorations of events which those festivals had foreshadowed. Thus the Passover, with a new conception added to it of Christ as the true Paschal Lamb and the first fruits from the dead, continued to be observed, and became the Christian Easter.

Although the observance of Easter was at a very early period the practice of the Christian church, a serious difference as to the day for its observance soon arose between the Christians of Jewish and those of Gentile descent, which led to a long and bitter controversy. The point at issue was when the Paschal fast was to be reckoned as ending. With the Jewish Christians, whose leading thought was the death of Christ as the Paschal Lamb, the fast ended at the same time as that of the Jews, on the fourteenth day of the moon at evening, and the Easter festival immediately followed, without regard to the day of the week. The Gentile Christians, on the other hand, unfettered by Jewish traditions, identified the first day of the week with the Resurrection, and kept the preceding Friday as the commemoration of the crucifixion, irrespective of the day of the month. With the one the observance of the day of the month, with the other the observance of the day of the week, was the guiding principle.

Generally speaking, the Western churches kept Easter on the first day of the week, while the Eastern churches followed the Jewish rule, and kept Easter on the fourteenth day.

A final settlement of the dispute was one among the other reasons which led Constantine to summon the Council of Nicaea in 325. At that time the Syrians and Antiochenes were the solitary champions of the observance of the fourteenth day. The decision of the council was unanimous that Easter was to be kept on Sunday, and on the same Sunday throughout the world, and "that none should hereafter follow the blindness of the Jews" (Socrates, *H.E.* i. 9). The correct date of the Easter festival was to be calculated at Alexandria, the home of astronomical science, and the bishop of that see was to announce it yearly to the churches under his jurisdiction, and also to the occupant of the Roman see, by whom it was to be communicated to the Western churches. The few who afterwards separated themselves from the unity of the church, and continued to keep the fourteenth day, were named *Quartodecimani,* and the dispute itself is known as the *Quartodeciman* controversy.

Easter day is the first Sunday after the full moon following the vernal equinox. This, of course, varies in different longitudes. A further difficulty occurred in the attempt to fix the correct time of Easter by means of cycles of years, when the changes of the sun and moon more or less exactly repeat themselves. At first an eight years' cycle was adopted, but it was found to be faulty, then the Jewish cycle of 84 years was used, and remained in force at Rome till the year 457, when a more accurate calculation of a cycle of 532 years, invented by Victorius of Aquitaine, took its place. Ultimately a cycle of 19 years was accepted, and it is the use of this cycle which makes the Golden Number and Sunday Letter, explained in the preface to the Book of Common Prayer, necessary. Owing to this lack of decision as to the accurate finding of Easter, St. Augustine tells us (*Epist.* 23) that in the year 387 the churches of Gaul kept Easter on the 21st of March, those of Italy on the 18th of April, and those of Egypt on the 25th of April; and it appears from a letter of Leo the Great (*Epist.* 64, ad *Marcian*) that in 455 there was a difference of eight days between the Roman and the Alexandrine Easter.

The ancient British and Celtic churches followed the cycle of 84 years which they had originally received from Rome, and their stubborn refusal to abandon it caused much bitter controversy in the 7th century between their representatives and St. Augustine of Canterbury and the Latin missionaries. These latter unfairly attempted to fix the stigma of the Quartodeciman observance on the British and Celtic churches, and they are even now sometimes ignorantly spoken of as having followed the Asiatic practice as to Easter. This, however, is quite erroneous. The British and Celtic churches always kept Easter according to the Nicene decree on a Sunday. The difference between them and the Roman Church, at this period, was that they still followed the 84 years' cycle in computing Easter, which had been abandoned at Rome for the more accurate cycle of 532 years. This difference of calculation led to Easter being observed on different Sundays, in certain years, in England, by the adherents of the two churches. To Archbishop Theodore is usually ascribed the credit of ending the difference in the rest of England in 669.

The Gregorian correction of the calendar in 1582 has once more led to different days being observed. So far as Western Christendom is concerned the corrected calendar is now universally accepted, and Easter is kept on the same day, but it was not until 1752 that the Gregorian reformation of the calendar was adopted in Great Britain and Ireland. Jealousy of everything emanating from Rome still keeps the Eastern churches from correcting the calendar according to the Gregorian reformation, and thus their Easter usually falls before, or after, that of the Western churches, and only very rarely, as was the case in 1865, do the two coincide.

Easter, as commemorating the central fact of the Christian religion, has always been regarded as the chief festival of the Christian year, and according to a regulation of Constantine it was to be the first day of the year. This reckoning of the year as beginning at Easter lingered in France till 1564, when, by an ordinance of Charles IX., the 1st of January finally took its place.

Four different periods may be mentioned as connected with the observance of Easter, viz., (1) the preparatory fast of the forty days of Lent; (2) the fifteen days, beginning with the Sunday before and ending with the Sunday after Easter, during which the ceremonies of Holy Week and the services of the Octave of Easter were observed; this period, called by the French the *Quinzaine de Piques*, was specially observed in that country; (3) the Octave of Easter, during which the newly-baptized wore their white garments, which they laid aside on the Sunday after Easter, known as *Dominica* in albis depositis from this custom; another name for this Sunday was Pascha *clausum,* or the close of Easter, and from a clipping of the word "close" the English name of "Low" Sunday is believed to be derived; (4) Eastertide proper, or the paschal season beginning at Easter and lasting till Whit Sunday, during the whole of which time the festival character of the Easter season was maintained in the services of the church.

The liturgical colour for Easter was everywhere white, as the sign of joy, light and purity, and the churches and altars were adorned with the best ornaments that each possessed.

Fixed Easter.—The Gospels record that our Lord celebrated the Passover on the Thursday, while Caiaphas and the Priesthood apparently celebrated it on the Friday, the day of the Crucifixion. As the Jewish day is counted from sunset to sunset there may be some explanation of the difference in this fact, but when the festival of Easter was established by the Church, there was a sharp controversy between those who celebrated the event on the 14th day and those who celebrated it on the 11th, the Quartodecimans, and the Quintodecimans (*v.* sup.), which led to much bloodshed.

The Council of Nicaea, held in A.D. 325, decided that Easter should be celebrated on a Sunday, but we are left with a method of fixing the date of Easter by which it can vary from year to year by no less than 35 days, between March 22 and April 25. The date is fixed in accordance with the tables prepared by Clavius for Pope Gregory XIII., when he reformed the calendar on Feb. 24, 1582, and is an attempt to reconcile the solar with the lunar year, on the Metonic system, with all the complications of the week, the month, the epact and an inexact calendar. The tables occasionally produce strange results. In 1923 the full moon of the heavens fell on the Sunday given by the tables for the celebration of Easter; and the Resurrection, going by the real moon, was being celebrated before the Crucifixion.

Proposals for Fixing Easter.—The inconvenience of an oscillating Easter is felt by all sections of the community, as school terms, university terms, law terms and the great holidays of Easter and Whitsuntide are all affected by a moving Easter. Chambers of Commerce, national and international, have since

1900 year by year passed resolutions in favour of a fixed date for Easter. At the International Congress of Chambers of Commerce held in Rome in 1923 such a resolution was re-affirmed and addressed to the Holy See. Not long afterwards the matter was referred to the League of Nations, and a conference was summoned at which the Roman, the Eastern Orthodox and the Anglican churches were represented, and it was agreed that there was a practically unanimous wish among the nations concerned that Easter should be fixed.

The Movement in Great Britain.--On April 27, 1921 Lord Desborough introduced a Fixed Easter bill in the House of Lords. Under this, Easter was always to be kept and observed on the second Sunday in April, which was the date in 1925. The three main arguments in favour of the date were: (1) That it is the nearest Sunday to the generally accepted date of the event which it commemorates; (2) that as the mean date of Easter for 100 years has been April 8.3, such a Sunday complies to the full with the requisition that any date selected should fall within the present limits of deviation, and (3) it divides the Christian year equally, and is a convenient date for the people.

As regards No. 1 it may be stated that, though the matter cannot be absolutely decided, the balance of opinion seems to be that the Crucifixion took place on Friday, April 7 A.D. 30, so calculating by Sundays, and in order to secure a date which can be very easily remembered, the second Sunday in April would appear to be an appropriate one, but it would be still more accurate to make Easter Sunday on April g, if that day were a Sunday, or on the Sunday following April 9. Certain ecclesiastical difficulties would then be avoided and there would always be 24 Sundays after Trinity, and the whole ecclesiastical calendar would be admirably fixed.

The supporters of the reform point out that the celebration of the Birth of our Lord was fixed in the 4th century by enactment for Dec. 25, thus consecrating the old Saturnalia of Rome to the new religion, and that, this having been done, there is no good reason why the celebration of the Death and Resurrection should vary 35 days in accordance with a fictitious moon.

In 1928 again the question of a Fixed Easter bill was raised in parliament and a referendum to various European countries was advised. As a result of the League of Nations Committee of 1923, the Easter Act was passed in England, Aug. 1928, fixing Easter day, conditionally upon international acceptance, as the first Sunday after the second Saturday in April. *(See* CHRONOLOGY.)

EASTER ISLAND, also known as Rapanui or Te Pito te Henua, situated in 27° 10′ S. lat. and 109° 26′ W. long., about 2,000m. from the coast of Chile and 1,100m. from Pitcairn, the nearest inhabited island to the west, is the most easterly and most isolated outpost of the Polynesian race. It was probably sighted by Capt. Davis in 1687; but the first European to land was the Dutch admiral Roggeveen on Easter day, 1722, whence its name. The name *Rapanui* is recent, and its various other native names, including *Te Pito te Henua,* really referred to particular localities, not to the island as a whole. Its abundant and remarkable stone monuments, and its unique ideographic script incised on wooden tablets have been the subject of much speculation (sometimes of an extravagant kind). The number of the monuments and their size, the smallness of the island and of the population, never more than 5,000 or 6,000 and estimated at only half that number at the time of discovery, indicate an extraordinarily intensive application to the arts of masonry and sculpture. The successful transportation of the huge monolithic sculptures and their erection in places remote from the quarries where they were made, are unexplained.

Archaeology. — Archaeology is here concerned almost exclusively with stone remains, together with a few small objects in shell and bone. Such skulls as have been collected from graves show no traces of high antiquity. Easter island is destitute of metal objects and pottery, although clay suitable for potting occurs in the craters. The stone remains include houses, platforms, semi-pyramidal cairns, circular towers, cisterns, statues, rock-carvings, adzes or chisels, obsidian spear-heads and fish-hooks.

The most striking monuments are the burial platforms, called *ahu,* and the statues surmounting them. Some 260 platforms have been counted in varying degrees of preservation, fringing the coast in almost unbroken succession, while a few are also found inland. Only about 100 of these were intended to support images.

A typical image *ahu* consists of a wall parallel with the sea, measuring up to 300ft. in length and 15ft. in height, and buttressed to landward with a slope of masonry. The images stood in a single row facing inland on the central portion of the wall, which projected towards the sea, and a single *ahu* might contain from one to 15 statues. The maximum extension of the landward slope was about 250ft., and beyond this was a paved area. The masonry, of huge polygonal or rectangular blocks, is sometimes beautifully finished and fitted together, but is more often of rough material. These *ahu,* which were still used within living memory, served for the exposure of dead bodies and contained vaults for the subsequent burial of the bones. There are also a number of rough semi-pyramidal cairns, up to 12ft. in height, containing burial vaults; these appear to be of more recent construction than the *ahu.*

All the statues belonging to the *ahu* have now been thrown down, and many broken. But by the accounts of the early voyagers the greater number of them were standing in the 18th century, and Roggeveen refers to religious ceremonies which appeared to him to indicate worship of the statues. The *ahu* were sacred places, corresponding to the Polynesian *marae,* and some, if not all, of the statues were erected in honour of ancestors.

The statues were cut from compressed volcanic ash, a soft and easily worked stone. All conform to a single distinctive type, representing only the upper half of the body with an upturned face and long ears, but vary in height from 3 to 36 feet. One example has even been found in the quarry with a length of 66ft., but it had never been moved. The usual height of the images on the *ahu* was from 12 to 20ft., and they were surmounted by tall cylindrical hats or crowns (as much as 6ft. high and 8ft. in diameter) in proportion. These consisted of a red volcanic tuff and were quarried in a different crater from the statues.

The quarry for the statues was both inside and outside the large crater of the volcano called Rano-Raraku at the north-east end of the island; here they are found in large numbers and in all stages of completion, as though the work had been suddenly interrupted and never afterwards resumed. The sculptors worked in niches surrounding the statues and the carving was completed before the back was detached by undercutting. The stone chisels used were found in *situ* and are of two main types; the rougher kinds somewhat resembling a European palaeolithic "handaxe," occur in large numbers and were evidently employed for roughing out the contours of the figures. The finer kinds, of hard stone, are without shaped butts and resemble the adzes of western Polynesia and New Zealand more closely than eastern Polynesian types. The tanged spear-heads of flaked obsidian are peculiar to the island. Apart from the statues on the *ahu* and in the quarry, there are a large number standing about the slopes of Rano-Raraku facing westwards, others in isolated positions, and a series placed at intervals along an ancient processional road, running westward from the quarry for six miles. This road, and two others less distinctly visible, probably served for transporting the statues. It is about 10ft. wide and levelled by shallow cuttings and embankments.

The means of transporting the larger images, the heaviest of which must have weighed about 50 tons, have never been satisfactorily explained. But a native account states that they were dragged into position (presumably with ropes, the native hemp and hibiscus fibre furnishing adequate materials) and that round pebbles were placed underneath to serve as rollers. Seaweed may also have been used to minimize friction with the ground. The statues were probably erected on the *ahu* by being hauled up an incline of earth or stones and then gradually "up-ended" into position by withdrawing the supporting material from under their bases.

Habitations, though generally constructed of perishable materi-

als, were sometimes provided with wrought foundation-stones, resembling kerb-stones, sunk into the ground and provided with holes in their upper surface for inserting the wooden rods which provided the framework of the houses. Their ground plan was long, narrow and boat-shaped, and they were large enough to accommodate from ten to 30 persons. There are also remains of stone chicken houses, and of round chambered towers on the coast used as fishing look-outs. Natural caves were extensively used as habitations, and some have been supplemented by frontal walls.

Apart from these houses, there is one "sacred" village at the south-west corner of the island, called Orongo, situated in a romantic position on a narrow and precipitous ridge between cliff and crater. It contains 48 houses built entirely of stone, the only examples of their kind in Polynesia. They were roofed by partial corbelling and a flat capstone, over which earth was heaped. Their low and narrow interiors, illuminated only by small doors, were often decorated with designs and figures in colour.

This village was connected with a bird-cult (still remembered) which played an important part in native life. A leading feature was an annual competition to secure the first egg laid on an outlying islet by the migratory sooty tern. Orongo was occupied by the competitors, and the numerous rock-carvings in the vicinity depicting a bird-headed man, sometimes holding an egg in his hand, presumably commemorate the victors. The rock-carvings, some much weathered, also depict faces and geometric designs.

There can be little doubt that the stone structures of Easter island are the work of the ancestors of the present inhabitants (now reduced in numbers to about 250). The statues and platforms were actually in use at the time of discovery, and some of the sculptors' names are still remembered. But apart from traditional evidence, the occurrence of certain peculiar designs carved on the backs of some of the stone statues, as well as on small wooden figures of recent date, furnishes an unquestionable link between the culture of past and present.

Date of Settlement.—The date of the earliest settlers' arrival, their point of departure and the question whether there was more than one migration are still uncertain. Tradition states that the ancestors arrived, under a chief named Hotu Matua, in two canoes coming from the west, but supplies no clear evidence of previous inhabitants or of subsequent immigrations. On the basis of the shortest recorded genealogy of 22 chiefs descended from Hotu Matua this migration can hardly be assigned to a period later than the 14th century A.D., and although the monuments contain no evidence for accurate dating, their number and the weathered condition of many of them indicate an age of many centuries. On the other hand, there is no evidence of a succession of cultures.

Racial and Cultural Affinities.—Racially and linguistically there is no doubt that the Easter islanders are predominantly Polynesian, with a considerable negroid admixture. The skulls collected from graves supply corroborative evidence. It seems simpler to account for the negroid element by presuming that the racial intermixture occurred in Melanesia previous to the arrival of the settlers than by postulating an earlier migration of Melanesians to Easter island. Nevertheless Hotu Matua's migration may have been preceded by another, also of Polynesian stock, but with a stronger infusion of Melanesian blood and culture. This would help to explain the social dichotomy and clan antagonisms to which some of the traditions bear witness. Attention has also been called to a number of remarkable resemblances in the bird-cult and the art associated with it as between Easter and the Solomon islands; these seem almost to amount to proof of a special cultural affinity.

Script.—The "writing" engraved on wooden tablets, unique in Polynesia and first noted in 1864, is undoubtedly of considerable antiquity. It takes the form of pictographs (or ideograms), representing stylized figures of men, birds, fish, etc., arranged in the inverted position in alternate lines ("boustrophedon"), so that the reader of a tablet is obliged to turn it upside down at the end of each line. The figures seem to have served as mnemonic symbols and cannot be translated word for word. Some of the stories which the tablets record have been obtained from living natives, but the exact meaning of the symbols and method of interpretation have been lost, probably beyond hope of recovery. (H. J. Br.)

EASTERN BENGAL AND ASSAM, a former province of British India, which was in 1905 constituted out of Assam and the eastern portion of Bengal, viz., the divisions of Dacca, Chittagong and Rajshahi (except Darjeeling, the district of Malda and the State of Hill Tippera [now Tripuna]). The capital was at Dacca. This province ceased to exist in 1912, when Assam was restored to its position as a separate province and the remainder of Eastern Bengal and Assam was retransferred to Bengal, which was created a presidency under a governor-in-council.

EASTERN QUESTION, THE. The expression used in diplomacy from about the time of the Congress of Verona (1822) to comprehend the international problems involved in the impending dissolution of the Turkish empire. Its use in this narrow sense is due to the conditions in which it was invented. In the early 19th century the Ottoman empire was still the only East with which European diplomatists were collectively brought into contact; for the questions of the Middle and Far East had not yet arisen.

The Eastern Question—though its roots are set far back in history: in the ancient contest between the cultures of Europe and Asia, the antagonism of Christian and Muslim, and the perennial rivalry of the Powers for the control of the trade routes to the Orient—dates in its modern sense from the treaty of Kuchuk Kainardji (1774), which marked the establishment of Russia as a Black sea power and formed the basis of her special claim to interfere in the internal affairs of the Ottoman empire. The actual right conceded was, however, very limited. Art. VII. of the treaty runs: "The Sublime Porte promises to protect firmly both the Christian religion and its churches; and also permits the Minister of the Imperial Court of Russia to make on all occasions representations in favour of the new Church in Constantinople, and of those who carry on its services." In view of later Russian claims, the wording of this article is important.

The compact between Napoleon and Alexander I. of Russia at Tilsit (1807) marked a new phase, which culminated in the Treaty of Bucharest (1812). By this instrument the Russian frontier was advanced to the Pruth and to the northern or Kilia branch of the Danube, and Russia's claim to intervene between the sultan and his orthodox subjects received a new sanction in Art. V., which confirmed "the contracts and conventions which had been counted among the privileges of Moldavia," and in Art. VIII., which stipulated for certain concessions to the insurgent Serbs.

The attitude of the various Powers in the Eastern Question was now defined. Russia, apart from her interest in the orthodox subjects of Turkey, aimed at owning or controlling the straits which were her only outlet to the Mediterranean and the ocean beyond. Austria, once the champion of Europe against the Turk, saw in Russia's advance a greater danger than any to be feared from the moribund Ottoman Power, and made the maintenance of Turkey's integrity a prime object of her policy; thus agreeing with Great Britain, whose traditional friendship with Turkey was strengthened by the rise of a new Power whose rapid advance threatened her communications with India and the stability of her rule there. But though Austria, Great Britain, and presently France, were all equally interested in maintaining the Ottoman empire, the failure of the Congress of Vienna (1815) to take action regarding the guarantee of Turkey[1] seemed to endorse Russia's claim to regard the Eastern Question as her "domestic concern" in which Europe had no right to interfere

[1] This was due to the sultan's obstinate refusal to ratify the Treaty of Bucharest. As Castlereagh put it, it was impossible to guarantee territories of which the boundaries were in dispute.

The Greek Revolt.—When, in March 1821, the news reached the Powers assembled at the Congress of Laibach that Prince Alexander Hypsilanti, a Greek officer in Russian service, had crossed the Pruth and raised the standard of revolt in the Danubian Principalities, it was feared that his claim to have Russian support was well founded. The Emperor Alexander I., however, yielding to Metternich's influence, repudiated Hypsilanti's action, and the revolt, unsupported by the Rumanian people, collapsed.

It was different, however, when, on April 2, Archbishop Germanos of Patras raised the standard of revolt in the Morea; here the Greek population rose en *masse,* massacred the Muslims and by September had completed the liberation of the peninsula by capturing the capital, Tripolitza. The revolt now spread north of the Isthmus, and, above all, to the Greek islands, whose loss—since they were the only recruiting grounds of the Ottoman navy—deprived Turkey of the command of the sea, thus frustrating all efforts to suppress the rising until the intervention of Mehemet Ali of Egypt at the end of 1824.

The unexpected success of the insurgents threatened to produce a European crisis; for the hideous reprisals of the Turks, culminating in the execution of the Orthodox Patriarch Gregorios (April 22, 1821), roused intense feeling in Russia and it needed the united effortsof Castlereagh and Metternich—who met at Hanover in October—to persuade the Emperor Alexander not to stultify his mission as the peace-maker of Europe by intervening in Turkey.

The accession of George Canning to office (Aug. 1822) made no immediate change in British policy; but in March 1823 he recognized the belligerency of the Greeks, in order to make their provisional Government responsible for their piracies. It was not, however, until Sultan Mahmud appealed to his vassal, Mehemet Ali of Egypt, to assist him with his trained army and fleet, that the Powers made any concerted effort to influence the situation.

The Emperor Alexander now proposed that the Powers should impose a settlement on the basis of Greek principalities tributary to the sultan. Metternich, who took this as implying an extension of Russian influence, countered by proposing an independent Greek State. A conference was summoned at St. Petersburg; but, as the majority favoured collective intervention, on a principle which Great Britain had always opposed, the British representative was withdrawn, and the meeting resulted in nothing but a futile offer of mediation (March 25, 1825).

Mehemet Ali Intervenes.—Meanwhile Ibrahim, Mehemet Ali's adopted son, had landed at Modon and begun the systematic conquest of the Morea. His fleet commanded the sea, and on land the Greek guerilla fighters had no chance against the trained Egyptian troops; only the heroic defence of Missolonghi (May 1825–April 1826) relieved the gloom of this terrible year. The death of the Tsar Alexander I. (Dec. 1, 1825), however, changed the European situation. His successor, Nicholas I., had begun his reign by quelling a serious mutiny of the troops, and a war with Turkey seemed an admirable way of restoring the morale of his army. A step in this direction was taken when, at the outcome of the Duke of Wellington's congratulatory mission to the new tsar (Jan. 1826), a protocol was signed at St. Petersburg under which Great Britain and Russia were to offer their mediation with a view to a settlement on the basis of tributary principalities, and if the mediation were rejected, the Powers might take action "jointly or separately."

Nicholas now sent an ultimatum to the Porte, demanding the execution of the terms of the Treaty of Bucharest; and since the sultan had just massacred the Janissaries (*q.v.*) Turkey could not resist. On Oct. 1 was signed the Treaty of Akkerman, which conceded all the Russian claims.

The Treaty of London.—This action of Russia, together with the barbarities of Ibrahim—who threatened to depopulate Greece and colonize it with fellaheen and negroes—stirred the other Powers to activity. A conference met in London and on July 6, 1827, the Protocol of St. Petersburg was turned into the Treaty of London. This treaty Austria and Prussia refused to sign, and the settlement of the Greek Question therefore passed into the hands of Great Britain, France and Russia, who engaged to procure the autonomy of Grerce under the sultan's suzerainty. There was to be no breach of friendly relations with Turkey; but should the sultan refuse mediation, the Powers were to send consuls to Greece. Meanwhile, an armistice was to be proposed to both sides, to be enforced by such means as might "suggest themselves to the prudence" of the contracting Powers. The readiest means seemed to be a "peaceful blockade" of Ibrahim in the Morea.

Navarino and the Russo-Turkish War.—On Oct. 20, in order to bring peaceful pressure on Ibrahim, who had rejected the armistice, Admiral Codrington sailed the allied fleet into the Bay of Navarino, where the Turco-Egyptian fleet lay at anchor. A chance encounter led to a general engagement and the total destruction of the Ottoman navy. The British Government tried to explain away this "untoward event"; but Sultan Mahmud refused to regard the demonstration as "peaceful," and proclaimed a holy war. The Emperor Nicholas seized the occasion and there followed the Russian invasion of Turkey, which ended with the Treaty of Adrianople (1829). The other Powers, meanwhile, feared that Russia would thus secure her influence over liberated Greece, and in July 1828 Britain, France and Russia signed the Protocol of London, by which France was entrusted with the task of ousting Ibrahim from the Morea. By the time the French troops arrived, however, this object had already been achieved by a naval demonstration by Codrington at Alexandria. By a protocol signed at London on Nov. 16, 1828, the conference placed the Morea and the Cycladees under the guarantee of the three Powers, this guarantee being extended on March 22, 1829—after General Church's victories over the Turks north of the Isthmus—to the mainland south of the line Arta-Volo and including the island of Euboea. These territories were to be erected into a tributary principality governed by a prince chosen by the Powers.

The Russian victory and the fact that the terms of the Treaty of London were embodied in the treaty of Adrianople led the other Powers to acquire merit by insisting on further concessions. On Feb. 3, 1830, a protocol of the London Conference settled that Greece should be an independent principality and be offered to Leopold of Coburg (afterwards King of the Belgians). Leopold having refused the honour another protocol laid down that Greece should be an independent sovereignty, extended the frontier to the line Arta-Volo and proposed Prince Otto of Bavaria as its ruler. King Louis of Bavaria accepted the offer on behalf of his young son, but stipulated that he should be king. This was agreed, and on May 13, 1832, another Treaty of London (antedated the 7th) was signed, placing the new Kingdom of Greece under the guarantee of the three Powers. (See GREECE: History.)

Revolt **of Mehemet Ali.**—The Greek question was still unsettled when a new phase of the Eastern Question was opened by the revolt of Mehemet Ali, pasha of Egypt. The immediate occasion, though not the pretext for his revolt, was the sultan's refusal to give him the pashaliks promised as the price of his intervention in Greece; he feared, too, that if he waited till the reform of the Turkish army was completed, he would share the fate of Hussein of Bosnia and Mustafa of Scutari, whom the sultan had crushed in the spring of 1831. On Nov. 1, 1831, accordingly, an Egyptian force entered Syria, met the fleet under Ibrahim at Jaffa, and at once besieged Acre. The garrison's resistance delayed the Egyptian advance; at Constantinople efforts were made to persuade the sultan to come to terms; and only in May 1833 was the ban of outlawry launched against Mehemet Ali. Meanwhile, Ibrahim had been pushing on. He had already occupied Gaza and Jerusalem before Acre fell (May 27). On June 15 he was in Damascus. On July 9 and 11 he defeated the Ottoman advance-guard at Homs and Hamah, and on the 17th crushed the main Turkish army, under Hussein Pasha, at the pass of Beilan. Pushing on into Anatolia, he gained a crowning victory at Konia over another Ottoman army under Reshid Pasha (Dec. 23), and advanced to Afium-Karahissar and Kiutayah. Nothing lay between him and Constantinople but the uncertain attitude of the Powers.

After the first defeats Sultan Mahmud, in his rage and despair, had turned first to Great Britain for aid. But, though Stratford Canning wrote from Constantinople, urging the necessity for upholding the sultan's authority even by arms, Palmerston was not prepared for an isolated intervention which would involve a breach

with France and Russia. The news that no active aid could be expected from England was followed by that of the disastrous defeat at Konia, which chanced to coincide with the arrival in Constantinople of a special Russian envoy, Count Muraviev, who at once renewed the tsar's previous offer of ships and troops to protect the capital. The sultan, in desperation, accepted, and on Feb. 20, 1833, a Russian squadron entered the Bosporus.

The French and British representatives had in vain tried to persuade Mahmud to reverse his fatal decision. They now agreed to take a new line, and induced the Porte to invite the Russians to withdraw by undertaking that France would persuade Mehemet Ali to accept the Sultan's terms. But the Emperor Nicholas sent peremptory orders for his fleet t9 remain until Ibrahim should have recrossed the Taurus mountains, and Mehemet Ali scornfully rejected the sultan's offers; he insisted on his full demands — Syria, Icheli, Aleppo, Damascus and Adana. The two Western Powers, intent on getting the Russians away, now pressed the Porte to yield; and, as the result of this combined pressure on both sides, and incidentally of a famine in the capital, an arrangement was reached. On April 8 was signed the Convention of Kutayah, under which all the Egyptian demands were conceded. The immediate result, for the Powers, was to throw Turkey wholly into the arms of Russia. Russia had given the sultan deeds, not words, and to Russia he committed himself. Before the Russian forces left there was signed in the palace of Unkiar Skelessi the famous treaty (June 8, 1833) which, under the guise of an offensive and defensive alliance, practically made Russia the custodian of the gates of the Black sea.

This temporary settlement was nowhere expected to prove permanent. Sultan Mahmud dreamed only of revenge, and engaged German officers — Moltke among them — to reorganize his army. The crisis came in 1838. In 1834 the Syrians had revolted against Mehemet Ali's tyranny; now the Arabs of the Hauran were in arms. The sultan, urging that he must rescue his subjects from oppression, could no longer be restrained, and on April 21, 1839, the Ottoman army invaded Syria, only to meet with a crushing defeat by Ibrahim at Nezib (June 23). Before the news reached Constantinople the old sultan died (July 1), leaving his throne to Abd-ul-Mejid, a lad of 16.

Finally, the news reached the capital that Ahmed Pasha, the Ottoman admiral-in-chief, had handed over his fleet to Mehemet Ali, on the pretext that the sultan's advisers were sold to Russia. So far as the Ottoman empire was concerned, Mehemet Ali was now master of the situation. He had, however, to walk warily.

At the outset these showed an apparently united front, the ambassadors of the five Powers on July 27 presenting a joint note to the Porte, in which they declared that an agreement had been reached in the Eastern Question and urged the Ottoman Government "to suspend all definite decision made without their concurrence." But the Powers were actually agreed only on the need for agreement. Britain, especially, insisted on this; for she feared isolated action by Russia under the Treaty of Unkiar Skelessi. Yet to preserve even apparent unity was almost impossible. France and Britain had hitherto acted together through fear of Russian designs, and Austria was now also reverting to her traditional policy of antagonism to Russia. Everything depended on the attitude of the Emperor Nicholas, and this was ultimately determined by his growing distrust of Austria and his hatred of the democratic régime in France. The first caused him to reject Metternich's proposal of a conference. The second led him to seek to loosen the Anglo-French *entente* by making direct overtures to Great Britain. In short, he announced through the Russian ambassador in London, Baron Brunnow, that he was prepared to accept the British views on the Turco-Egyptian question, to allow the Treaty of Unkiar Skelessi to lapse, and to act in the Ottoman empire only in concert with the other Powers, in return for an agreement closing the Dardanelles to the warships of all nations. Brunnow was empowered to arrange a coalition to settle the Egyptian question.

To this proposal all the Powers agreed, including France, and for nearly a year negotiations continued. In France public opinion violently supported Mehemet Ali's claims, while Palmerston believed that the Ottoman empire would never be secure until "the desert had been placed between the pasha and the sultan." The deadlock thus created developed into a crisis when, on Feb. 20, 1840, Thiers came into power in France. Not only did he reject a compromise which, on May 7, Guizot, as French ambassador, arranged with Palmerston, but it presently transpired that, without openly breaking with the concert, and without informing the other Powers, he was encouraging a "*direct* arrangement" between Mehemet Ali and the Porte. The discovery of what seemed an underhand intrigue by France to secure her "complete individual triumph" at Constantinople and Alexandria, led at once to a strong countermove from the other Powers, who on July 15, without the concurrence of France, signed with the Porte a Convention for The Settlement of the affairs of the Levant. By the instrument it was agreed that, the terms to be given to Mehemet Ali having been arranged with the Porte, the signatory Powers would force the pasha to accept them. If he yielded within ten days he was to receive the hereditary pashalik of Egypt, the administration of southern Syria for life and possession of the fortress of Acre. After ten days the offer of Syria was to be withdrawn, and after another ten days the sultan was to be free to take such action as his own interests and the counsels of his allies might suggest,

The news of this "mortal affront" caused immense excitement in Paris, and Thiers, declaring that the alliance with Great Britain was shattered, hurried on preparation for war. The immediate effect was that Mehemet Ali, confident of French assistance, maintained a defiant attitude. The unexpected outcome of the armed intervention of the Powers, however, soon changed the situation, The allied fleet, under Sir Charles Napier, had hardly appeared off Beirut (Aug. 11) when the Syrians rose in revolt against Ibrahim's tyranny. On Sept. 11, Suleiman Pasha not having obeyed the summons to evacuate the town, the bombardment of Beirut began. On Oct. 3 the town fell, and Ibrahim, cut off from his communications by sea and surrounded by a hostile population, began a hurried retreat. On Nov. 3, Acre surrendered to the allied fleet. The Legends of Mehemet Ali's invincibility and humane and enlightened rule were now pricked bubbles. The only question was whether he should retain Egypt,

Already, on Sept. 15, the sultan had, in accordance with the terms of the Convention of London, declared him deposed. But the news of this, and of the events in Syria, produced an exceedingly dangerous temper in France; there was loud clamour for war; and it looked as though the pacific Louis Philippe were faced by the alternative of war or revolution. To most of the British cabinet it looked as though concessions must be made to France for the sake of European peace. Therefore, when Guizot, on Oct. 8, presented to Palmerston what was practically a French ultimatum, "it was determined that this intimation should be taken in a friendly spirit," and that Palmerston should come to an agreement with the ministers of the other Powers jointly to persuade the Porte not to insist on depriving Mehemet Ali so far as Egypt was concerned. This did not at once stop the war fever in Paris; but Louis Philippe did not want war; the dismissal of Thiers, and the appointment of Guizot as foreign minister in the new Government under Marshal Soult, made for more moderate counsels, and by Dec. 4, the danger was past.

Nine days earlier Sir Charles Napier had appeared with the British squadron before Alexandria and had induced Mehemet Ali to submit to the sultan and restore the Ottoman fleet, in exchange for a guarantee of the hereditary pashalik of Egypt. Gentle pressure by the combined Powers on the Porte did the rest, On Feb. 13, 1841, the sultan issued a *firman* appointing Mehemet Ali hereditary pasha of Egypt, a second *firman* of the same date investing him with the government of Nubia, Darfur, Kordofan, Sennaar and their dependencies.

The Crimean War. — The Russian policy, initiated in 1829, of maintaining the integrity of Turkey while practically treating her as a vassal state, ended in 1841; the Emperor Nicholas reverted to the idea of expelling the Turks from Europe. The Eastern Question, however, slumbered for a while, the European Powers being fully engaged with the troubles which culminated in the revolutionary movements of 1848–49. In 1850, however, a new and fateful phase developed. Under the capitulations *sf*

1740 France held the right to protect the Catholics in Turkey and the guardianship of certain holy places in Palestine. These rights had been in abeyance since the French Revolution, and Russia had assumed the guardianship of the holy places. But Louis Napoleon, now Prince President of the French Republic, desiring to conciliate the clergy and to increase his prestige, instructed his ambassador in Constantinople to demand the restoration of French property and rights in the holy places. The Porte appointed a mixed commission to enquire into the matter; but since France objected to any documents being considered of later date than 1740 (which would have excluded the Treaty of Kuchuk Kainardji) and Russia peremptorily demanded that no change should be made, no mutually satisfactory solution was possible; and on Nov. 4, 1851, the British ambassador, Stratford Canning, reported to his Government that the question had "assumed a character of extreme gravity." It had developed into a struggle between France and Russia for influence in the East.

In vain the Ottoman Government suggested various compromises. Napoleon, now Emperor of the French, needed a war, and the Emperor Nicholas' refusal to recognize him as an equal embittered him against Russia. Nicholas, too, thought the moment opportune for carrying out his plans for ousting the Turks. He believed that he could rely on the neutrality of Austria, out of gratitude for his assistance to her in crushing the Hungarian insurrection in 1849. Great Britain's benevolence seemed to be assumed when the pacific Lord Aberdeen became prime minister in Dec. 1852. The tsar even revived his earlier idea of an arrangement with Great Britain for the partition of Turkey. In the famous conversations (Jan. 9 and 14, 1853) with the British ambassador at St. Petersburg, Sir Hamilton Seymour, he spoke of Turkey as the "Sick Man," and gave his ideas as to the disposal of his inheritance: the Balkans should be divided into a series of Christian States, Great Britain receiving compensation in Egypt, Cyprus and Crete. The comment on this by Lord John Russell, on behalf of the British Government, was to deny that Turkey was sick, and to insist that the whole question must be settled by general agreement. But Nicholas was deceived by the hesitations of Aberdeen, who was hopelessly divided between his fear of Russia and his dislike of the Turks; he was deceived, too, by his ambassador, Baron Brunnow, who reported that in England the pacifist influence of Bright and Cobden was supreme. Accordingly, after ordering the mobilization of his forces, he despatched Gen. Menshikov to Constantinople with an ultimatum demanding the preservation of the *status* quo as regarded the holy places and Russia's right to protect Christians in Turkey.

Menshikov, a blustering soldier, reached Constantinople on April 19, but the crisis was delayed by the diplomacy of Lord Stratford de Redcliffe, the British ambassador, who persuaded the Porte to yield respecting the holy places, but to resist the demand for a protectorate over the Christians.

On May 5, arguments and threats having failed, Menshikov presented the ultimatum; on the 22nd the Porte rejected it. This meant war, and on June 22 the Russians crossed the Pruth and proceeded to occupy the Principalities.

This was met by a collective protest of the Powers, and Austria concentrated her forces on the Serbian frontier. In these circumstances Russia agreed to a conference, which met at Vienna in August. The four points on which the other Powers insisted were: (1) the substitution of an international for a Russian protectorate of the Principalities; (2) freedom of navigation on the Danube; (3) maintenance of the integrity and independence of Turkey, and (4) renunciation by Russia of her claim to protect the orthodox subjects of Turkey. The conference drafted a convention, to be proposed to Russia by the Porte, confirming the rights granted by the treaties of 1774 and 1829 and by the *firmans* recently issued, and conceding to the orthodox rite a share in all privileges, etc., granted to other Churches under the Capitulations. Russia accepted this on condition that no modifications were made "under bellicose influences." But when, on Aug. 19, the Porte accepted the draft, it was with an amendment reserving to the sultan the right to protect the Christians. This amendment the tsar refused to accept; and, since this seemed to show that he intended to press his extreme claims, the British fleet was ordered to pass the Dardanelles, ostensibly to protect the sultan from the danger of a Muslim rising. The British Government announced that no aggressive action would be taken unless the Russians crossed the Danube or attacked an Ottoman port on the Black sea. The immediate *casus belli* which opened the Crimean War was the destruction by the Russian fleet of an Ottoman squadron in the harbour of Sinope on Nov. 3, 1853. On Jan. 3, 1854, a combined British and French squadron entered the Black sea; it was not, however, till March 27 that France and Great Britain declared war against Russia.

The Russians now advanced into the Balkan peninsula, but on June 3 an Austrian ultimatum forced them to retire not only from the Balkans, but from the Danubian Principalities which Austria occupied. Although the immediate menace to Turkey was thus removed, the Allies determined to continue the war and to secure the acceptance of the Four Points, and on Sept. 14 their combined armies landed in the Crimea. (See CRIMEAN WAR.) The initial disasters of the war bent the stubborn resolution of the "Iron Tsar," and on Nov. 28, strongly urged by Frederick William IV. of Prussia, he consented to accept the Four Points. It was too late. The successes of the Allies were bringing them fresh strength. On Dec. 2 Austria signed with them a formal defensive alliance, and in Jan. 1855 Cavour's determination to secure a position for the Kingdom of Sardinia in the councils of the Powers brought the Piedmontese into the Allied camp. On March 2 the Emperor Nicholas died, and the succession of Alexander II. seemed to promise peace. Conferences were resumed at Vienna; but honour and prestige were involved on both sides, and the war dragged on. The fall of Sevastopol (Sept. 9) might have been taken as decisive, but it was not till December that an Austrian ultimatum persuaded the tsar to yield. The terms of peace were to be settled by a congress in Paris.

The Treaty of Paris was signed on March 30, 1856. By this instrument the Eastern Question seemed to be settled, in the sense desired by the Allies. By the cession of a portion of Bessarabia, Russia was thrust back from the mouths of the Danube, of which the navigation was declared free; Russian naval power was destroyed in the Black sea, which was made neutral; the right of Russia to intervene in Turkey was formally repudiated, and the Ottoman empire, in return for elaborate promises of reform, was admitted to the concert of the Powers. Wallachia and Moldavia, with their existing privileges, were placed under the collective guarantee of the Powers, while remaining under the suzerainty of the Porte. It was not till three years later that the union of the Rumanian nation was accomplished by the election of John Alexander Cuza as prince in both principalities.

The Russo-Turkish War, 1877–78.—It was to be expected that Russia would seize the first opportunity of repudiating the humiliating terms thus imposed upon her. This came in 1870, and she took advantage of the collapse of France to denounce the Black sea clauses of the Treaty of Paris. The action of the Conference of London in regularizing this proceeding prevented any immediate critical developments. But though for five years longer the Eastern Question was to remain quiescent, beneath the surface it was exercising a strong and disturbing influence on the relations of the Powers. In spite of the League of the three Emperors, founded in 1872, Austria and Russia were once more hatching rival plans of aggression in the East: Russia was determined to seize the first opportunity for recovering the lost strip of Bessarabia and so removing the last tangible results of the Crimean War; while Austria, encouraged by Bismarck—who wished to reconcile her to her depositions as a German Power—was hoping to find in the Balkan peninsula compensation for her losses in Italy and Germany. Behind the Russian policy was the Pan-Slav ideal, which Russian agents were busy propagating among the Balkan peoples; behind the Austrian policy was the conviction that Serbia was already aspiring to play the part played by Piedmont in Italy, and to become the head of a Southern Slav empire built up out of the ruins of the Austrian and Ottoman empires. If the rivalry between Russia and Austria did not lead to a breach, this was because Russia saw that in the event of

war Germany would have to support Austria, now once more regarded as the bulwark of Germanism against the Slavs, while Austria feared that such an alliance would merely add to the overgrown power of Germany. As for Bismarck, who was preoccupied by the reviving power of France, the last thing he wanted was a war with Russia. It was such considerations as these which determined the attitude of the three Powers when the next critical phase of the Eastern Question began.

It opened in July 1875, when the Christian Slavs of Hercegovina rose against Turkish misrule. The failure of the Turks to suppress the insurrection and the consequent danger of a general conflagration led to the intervention of the Powers, and on Dec. 30, 1875, Russia, Germany and Austria-Hungary agreed to the terms of a joint note, drawn up by Count Andrássy, for presentation to the Porte. This declared that the time had come for joint action to compel Turkey to translate her promises of reform into acts. It demanded the formal recognition of the equal status of the Christian religion, and certain reforms in Bosnia-Hercegovina which were to be watched over by a mixed commission of Christians and Muslims. Great Britain and France having adhered, the "Andrássy Note" (*q.v.*) was presented to the Porte on Jan. 31, 1876.

The sultan, as usual, promised everything and performed nothing. Meanwhile the revolt spread. In May the signs were ominous; Serbia was arming, and Prince Milan gave the command of his troops to the Russian general Chernayev; Montenegro also was arming. The three emperors thought it time to take action, and on May 13 signed the Berlin Memorandum, which proposed combined action of the fleets, the enforcement of a two months' armistice, and further action if no settlement were reached. This broke down on the opposition of Great Britain, Disraeli arguing that it would only encourage the insurgents to go on. On May 24 the British fleet was ordered to Besika bay, for the defence of Turkey in case of need. On June 30 Serbia declared war on Turkey, and on July 2 Montenegro followed suit. On July 8 the Emperors Alexander II. and Francis Joseph met at Reichstadt and signed a convention defining the policy of Austria and Russia. There was to be no intervention so long as the contest was undecided. In the event of the defeat of Serbia, the two Powers would combine to preserve the status ***quo***. In the event of her victory, Austria-Hungary was to receive Bosnia-Hercegovina and Russia the ceded portion of Bessarabia. This agreement, which was significant in the light of later events, secured the neutrality of Austria-Hungary during the forthcoming Russo-Turkish War.

Meanwhile a fresh complication had arisen. In May the Bulgarian peasants had also risen and massacred many Turkish officials. The Turks, on their march northwards against the Serbs, took horrible vengeance, and the news of the "Bulgarian atrocities" caused immense excitement in England, and more especially in Russia. The Serbs, too, were soon in danger of being overwhelmed, and it was only a Russian ultimatum that prevented the Turks from advancing on Belgrade. In August the British Government, which wished to prevent the isolated action of Russia, persuaded Prince Milan of Serbia to ask for the mediation of the Powers, and took advantage of this to urge the Porte to come to terms with the Serbs and Montenegrins, for fear of a worse thing. This attempt at mediation, however, broke down at the obstinacy of both the Serbs and Turks. The Serbs were feeling increasingly certain of Russian support; as for the Turks, the deposition of Sultan Abd-ul-Aziz in May, and of his imbecile successor Murad in August, had infused a new spirit into their government; for the astute and ruthless Abd-ul-Hamid II. was now sultan. His policy was to pose as a reformer, and, for the rest, to procrastinate in the hope of splitting the European concert. He countered a British proposal for a comprehensive scheme of reforms in the Ottoman empire, to be embodied in a protocol concluded between the Porte and the Powers, by issuing an elaborate scheme himself (Oct. 12) But the patience of Russia was now exhausted; on Oct. 1j Gen. Ignatiev arrived in Constantinople, and on the 31st presented an ultimatum demanding the conclusion of an armistice with Serbia within 48 hours. On Nov. 2 the Porte yielded, and the field was cleared for fresh diplomatic action. On the 4th, Lord Derby proposed a conference at Constantinople on the basis of the integrity of Turkey. All the Powers accepted: but on the 8th the Emperor Alexander declared publicly that, if the Powers did not at once take effective measures in concert to enforce reforms, he would act alone.

The conference opened on Dec. 31, but it was soon clear that the Porte had no intention of accepting its decisions. On the 11th a constitution for the Ottoman empire was solemnly proclaimed, and the Porte rejected the demands of the conference on the ground that they must now be submitted to the new parliament. The case foreseen by the tsar had now arisen; the conference had proved abortive; and when on March 19, 1877, the new Turkish parliament met, almost its only act was to reject the demands presented by Russia. On April 24 Russia declared war.

The events of the war are described elsewhere. (*See* RUSSO-TURKISH WARS.) So far as the relations between the Powers were concerned, the most critical period was after Gen. Gurko's capture of Adrianople (Jan. 20, 1878), when the Russian advance threatened Constantinople and the straits. The British Government on Jan. 14 warned the tsar that any treaty between Russia and Turkey which might affect the engagements of 1856 and 1871 "would not be valid without the assent of the Powers who were parties to those treaties," and on the 23rd the British fleet was ordered to Gallipoli. On the 31st the preliminaries of peace between Russia and Turkey were signed at Adrianople, the terms of the armistice allowing the Russians to advance to within a few miles of Constantinople. The Grand Duke Nicholas now pushed forward to the lines of Chataldja; whereupon the British fleet was ordered to enter the Sea of Marmora. The situation was now extremely critical, for Austria-Hungary declared the terms of the Convention of Adrianople to be inconsistent with her interests, and it soon became clear that the only way of peace lay through a European congress. On Feb. 5 Count Andrássy formally invited the great Powers to a conference, and Russia, which was in no condition to continue the war with Great Britain and Austria ranged against her, had perforce to agree.

Before the final arrangements for the congress could be made, however, the Convention of Adrianople was converted into the Treaty of San Stefano (March 3). This seemed to realize the worst fears of the Powers. In default of the payment of a huge war indemnity, Turkey was to cede to Russia, Batum, Ardahan and Kars in Asia, and the Dobruja in Europe—this latter to be exchanged with Rumania for Bessarabia. Serbia, Rumania and Montenegro were to be independent States, Bosnia and Hercegovina were to receive autonomous institutions under the joint control of Russia and Austria-Hungary; above all, Bulgaria was to be erected into an autonomous principality, stretching from the Danube to the Aegean and embracing Eastern Rumelia and Macedonia, and its prince was to be advised for two years by a Russian commissioner supported by an army of occupation.

The news of the conclusion of this treaty, which seemed not only to bar Austrian advance in the Balkans but to be fatal to British interests by giving Russia a crushing preponderance in the East, again brought war very near. But in the end the strong representations of the Powers, backed by the diplomacy of Bismarck persuaded the tsar to consent to submit the treaty to the approaching congress.

This met in Berlin on June 13 and, after heated debates, arrived at a definite settlement a month later. By the Treaty of Berlin, signed on July 13, 1878, the terms of the Treaty of San Stefano were greatly modified. (See BERLIN, CONGRESS AND TREATY OF.) Its signature was hailed in Great Britain as a great diplomatic victory; the preponderance of Russia in the East had been checked; and Lord Beaconsfield boasted that he had secured "peace with honour," but the treaty represented, in fact, the starting-point of the latest and most disastrous phase of the Eastern Question which culminated in the World War.

Three new sovereign States were created by the treaty, Rumania, Serbia and Montenegro, but in the case of the former two at least the boundaries assigned to them left them bitterly dissatisfied. Rumania resented the enforced cession of Bessarabia to Russia in exchange for the less desirable Dobruja, and was

bound sooner or later to cast covetous eyes on Transylvania with its preponderantly Ruman population. Serbia mas in even worse case. She received indeed an increase of territory, at the expense of Bulgaria, but other terms of the treaty seemed to have been specially devised to make her dream of a Southern Slav union for ever unrealizable; for the Sanjak of Novi Pazar, which was to be garrisoned by the Austrians but still administered by the Turks, cut her off from Montenegro, while the permission given to Austria-Hungary to occupy and administer Bosnia-Hercegovina gave the Habsburg Monarchy what seemed likely to prove a permanent foothold in the Balkan peninsula. The foreign trade of Serbia (mainly pigs), cut off from access to the sea, was placed almost wholly at the mercy of Austria.

The Union of Bulgaria.— The most fateful of all the provisions of the treaty, however, was the splitting up of the greater Bulgaria created by the Treaty of San Stefano; for this not only kept the Balkan peninsula in a ferment for go years, but opened up a new problem, that of Macedonia, which was left to Turkey and, inhabited as it was and is by an inextricable mixture of races, was to become a bone of contention between Greeks, Serbs and Bulgarians (see MACEDONIA). As for Bulgaria herself, the artificial severance of East Rumelia could not long endure, and after a period of agitation on both sides of the Balkans, Prince Alexander accepted the offer of the crown of united Bulgaria (Sept. 20, 1885). Union was opposed by Russia, whose efforts to dominate the councils of Bulgaria had been frustrated by Alexander and his ministers, and for this very reason Great Britain now favoured the union, since she saw in a strong Bulgaria the best possible obstacle to the extension of Russian power. Austria-Hungary, on the other hand, had no wish to see a strong barrier erected between her and the coveted seaboard on the Aegean, and Serbia, more especially, resented a growth of Bulgarian power which threatened her own ambitious plans. This led to the Serbo-Bulgarian War of Nov. 1885, and when Prince Alexander crushed the Serbs at the battle of Slivnitsa, Austria-Hungary interposed to save Serbia from extinction. British influence at Constantinople, however, obtained from the sultan the formal recognition of the union of the Bulgarias. But the breach between Prince Alexander and the tsar was irreparable, and led to the abdication of the prince (Sept. 7, 1886) and the election of Prince Ferdinand of Coburg in his place. The new prince, who had been an Austrian cavalry officer, was not acceptable to Tsar Alexander III., who refused to recognize him; strained relations continued between Bulgaria and Russia; and it was not till 1898, under Tsar Nicholas II., that the two courts were reconciled. (See BULGARIA: History.)

The Greek War, 1897.—The union of Bulgaria had aroused among the Greeks too much excitement and heart-burning; the Cretans proclaimed their union with the kingdom; and only a blockade by the Powers prevented Greece from declaring war on Turkey. The crisis was thus tided over for the time; but in 1894 a secret society known as the Ethnikk Hetaireia (National Society) was founded, among whose objects were the union between the Greek islands and the kingdom, and the encouragement of the Greek movement in Macedonia, in order to prevent its absorption in Bulgaria. When, in 1896, the Cretans again revolted, the influence of this society was enough to compel King George of Greece to take up their cause. The naval forces of the Powers forced the submission of the Cretans to the arbitrament of Europe; but on the mainland the excitement continued; Greek irregulars were raiding into Thessaly; and in April 1897 the sultan, encouraged by the German emperor, declared war on Greece. The result was not long in doubt. The Greeks were no match for the Turkish forces, reorganized by German officers, and but for the Powers who imposed an armistice on both combatants (May 20), their ruin might have been complete. As it was, the war was a disaster for Greece. It discredited the dynasty, and by the terms of the peace treaty, signed in December, Greece had to cede a strip of Thessaly and pay a huge war indemnity. (See GREECE: History.) One gain, however, was made. Though Germany and Austria-Hungary had seceded from the European Concert in the Eastern Question, and in spite of the critical situation as between France and Great Britain arising out of the Fashoda incident (see AFRICA; FASHODA; SUDAN), France, Great Britain and Russia had continued to act together in the Cretan question, had forced the Porte to withdraw its officials from the island, and on Nov. 14, 1897, had invited Prince George of Greece to act as high commissioner.

German Influence in Turkey.— The breach in the Concert of Europe in the Cretan question was significant of profound changes in the grouping of the Powers. So far as the Eastern Question was concerned, a new factor of supreme importance had been introduced. Germany, so long as Bismarck was in power, had maintained a disinterested attitude so far as she herself was concerned, though she had consistently encouraged the eastward expansion of Austria. But with the accession of the Emperor William II. came a change of policy, the opening of which was marked by the State visit paid by the emperor and empress to Sultan Abd-ul-Hamid in Nov. 1889. More than 50 years earlier Moltke had pointed out the opportunities offered by Asia Minor for German exploitation, and the immediate object of the emperor was to forward German economic penetration, and for this and other purposes to establish his influence in Constantinople. His opportunity came in 1894, when the Turks, in their determination to stifle yet another incipient national revolt, began a systematic massacre of the Christian Armenians. All Europe stood aghast at these horrors, repeated year after year. By Art. LXI. of the Treaty of Berlin the Porte had undertaken to carry out reforms in the Armenian provinces, under the superintendence of the Powers; and a special responsibility attached to Great Britain in this matter under the secret treaty which had secured her Cyprus. But even without the despairing appeal of the Armenians to treaty obligations which had never been fulfilled, public opinion in England would have forced the British Government to take some action, and in 1896 Lord Salisbury induced the other Powers to unite in urging upon the Porte the carrying out of the promised reform. Since, however, these representations were not followed up by acts, the sole result was to alienate the Turks from Great Britain, and throw them into the arms of Germany. From Berlin there came, not protests, but a signed photograph of the emperor and his family as a birthday gift for the sultan. That was in 1896. The success of the German-trained troops in 1897 was followed in 1898 by a congratulatory visit of the emperor to Constantinople. The imperial pilgrimage to the Holy Land and Syria followed. It was inspired by a mixture of orthodox piety and *Realpolitik,* and was crowned on Nov. 8 by a speech at Damascus in which the emperor declared that he would at all times be the friend of the Sultan Abd-ul-Hamid, and of the 300 million Mohammedans who reverenced him as caliph. This, according to Pastor Friederich Naumann, was said with an eye on the time when a world war would break out, when the Caliph of Islam would once more raise the standard of a holy war and summon Egypt, the Sudan, East Africa, Persia, Afghanistan and India to war against England. The immediate outcome of the emperor's visit to Constantinople was more tangible: the concession of the port of Haidar-Pasha to the "German Company of Anatolian Railways." The idea of directing German capital and German emigration towards Asia Minor and Mesopotamia had takep definite shape. In 1902 it received a further development in the conclusion of a convention for the building of a railway from Constantinople to Baghdad. The contemplated extension of this line to Basra would have linked up Hamburg and Berlin with the Persian gulf, turned the flank of the British trade routes to the East, and secured the economic, if not the political, domination of Germany in the Ottoman empire. The ultimate idea, partly realized on paper during the World War, was the creation of a great Central European Customs Union, forming an "economic area" stretching from the Baltic to the Persian gulf, as a counterpoise to the United States and the British empire. (See Gratz and Schiiller, The Economic Policy of Austria-Hungary during the *War,* Eng. trans., 1927).

The Macedonian Question.--Meanwhile the question of what was to be done with Macedonia had become acute. All the

new Balkan States claimed the reversion of the lion's share of that country of inextricably mixed races, and in order to substantiate their respective claims Greeks, Serbs and Bulgars were busy exterminating each other. The efforts of the Turks to maintain order were worse than useless, and merely led to armed revolts. In 1903 a serious insurrection of Macedonian Bulgars led to the intervention of the Powers; Austria and Russia agreeing on the so-called Miirzsteg Programme, reluctantly accepted by the Porte, under which the three *vilayets* of Monastir, Salonika and Kosovo were placed under the supervision of Austrian and Russian civil agents and their gendarmerie was organized and commanded by officers appointed by the Powers. The experiment, which had but poor success, came to an end in 1908 with the breach of the *entente* between Russia and Austria and the attempt to substitute for it an Anglo-Russian programme was frustrated by the revolution in Turkey.

The Young Turk Revolution.—This revolution, by which in 1908 Abd-ul-Hamid and his régime were overthrown, made a profound change in the general situation. The programme of the Committee of Union and Progress, which had carried out the coup, appealed to the sentiment of Europe, which welcomed the birth of a liberalized Turkey, established on the basis of nationality without distinction of creed. It was soon clear, however, that the new liberalism was make-believe, while the new nationalism threatened to be more intransigent than the old Ottoman overlordship. The whole elaborate system of shams by which diplomacy had sought to disguise the disruption of Turkey was especially threatened; for in the new unified and Europeanized State there would be no room for provinces "occupied and administered" by foreign Powers, like Bosnia-Hercegovina (or possibly Egypt), or for "vassal" states like Bulgaria. Therefore, in order to forestall any attempt of a regenerated Turkey to reclaim what it considered its own, those interested took action. On Oct. 7, 1908, the Emperor Francis Joseph issued a rescript annexing Bosnia-Hercegovina to the Habsburg monarchy. Two days earlier Prince Ferdinand of Bulgaria had proclaimed his independence and assumed the title of king (tsar). In July 1909, after the withdrawal of the allied forces, the Cretans proclaimed their union with Greece, though the caution of King Constantine, disallowed this for the time being.

The Italian-Turkish War, 1911.—The annexation of Bosnia-Hercegovina, which had only been possible owing to the weakening of Russia in the war with Japan, revealed the breakup of even the pretence of a Concert of Europe in the Eastern Question. Here too the division of Europe between the Triple Entente and the Triple Alliance made itself felt. Russia and France joined in the protest of Great Britain against the annexation of Bosnia-Hercegovina as a violation of the treaties and a blow to the very foundations of international iaw; but the German emperor proclaimed his readiness to support his ally "in shining armour" and the protest began and ended in diplomatic notes.

The attitude of Italy was more doubtful. Though a member of the Triple Alliance, she resented the strengthening of Austria's position on the opposite coast of the Adriatic; for the rival ambitions of the Italians, the Serbs and the Habsburg monarchy were now adding an Adriatic question to all the others. Then, too, there was the question of Tripoli, the last remnant of the Ottoman empire in northern Africa still available for Italian expansion. The reversions of this had been reserved for Italy when France had occupied Tunis, but the disquieting activities of the Emperor William II. led to suspicions of German designs upon it. The result was a rapprochement between Italy and Russia, advertised in Oct. 1909 by the proposal of the Tsar Nicholas II. to pay a State visit to Rome.

The alarms of Italy were increased by the Agadir incident of July 1911, and she determined to take action at once. On Sept. 27, an Italian ultimatum was presented to the Porte demanding its consent to an Italian occupation of Tripoli under the sovereignty of the sultan; on the 29th she declared war on Turkey. But for fresh developments in the Balkans the war which followed might have dragged on indefinitely. But threatened by a new and more instant danger, the Porte suddenly came to terms. By the Treaty of Lausanne (Oct. 18, 1912), Tripoli, Rhodes and the Dodecanese archipelago were, under a thin disguise, ceded to Italy, which thus also obtained a foothold in the Aegean and was brought into conflict with Greek aspirations.

The Balkan League and Balkan Wars, 1912–13.—The new danger to Turkey which led to the hasty conclusion of the war with Italy was the formation of the often mooted league of the Christian States of the Balkan peninsula. In view of their clashing interests, especially in the matter of the reversion of Macedonia, such a league might well have seemed impossible; but the Young Turk revolution, with its threat of a revived spirit of Ottoman national aggression, drew them together, and the rapprochement was encouraged by the split in the concert of the Great Powers. The first step was the conclusion, on March 13, 1912, of a defensive alliance between Serbia and Bulgaria, in which they agreed to take common action in the event of an attack by a great Power upon Turkey and defined their respective claims in Macedonia. A military convention was also signed on May 29.

Meanwhile Greece too had, on May 10, concluded a defensive alliance with Bulgaria, though no mention was made in the treaty of Macedonia, and the Bulgarians, in the event of war arising out of the admission of the Cretan Deputies to the Greek parliament, only bound themselves to observe a benevolent neutrality. This treaty, too, was followed by a military convention (Sept. 22).

The crisis was provoked by a serious rising against the Young Turk régime in Albania. The movement rapidly spread into Macedonia; and the Albanians, flushed with victory, demanded the cession to them of the *vilayets* of Monastir and Skoplie, which Greece and Serbia had earmarked respectively as their own. Clearly, if their ambitions were to be realized, it was time for the new Balkan League to intervene. Bulgaria, violently excited by the news of a terrible massacre of Macedonian Bulgars by the Turks, was more than willing to take part. The Powers, appealed to by the League to join in demanding a drastic system of reforms in Macedonia, united only in urging concession upon the Porte and patience on the members of the League; and, when preparations for war continued, they contented themselves with threatening the Balkan States that, if they went to war, the Powers would see that they gained nothing by it. In view of the dislocation of the European Concert it seemed safe to ignore these warnings, and on Oct. 12 Montenegro declared war on Turkey.

The story of the Balkan wars is told elsewhere. (*See* BALKAN WARS.) Here it must suffice to note their outcome. The unexpected collapse of the Turks created a wholly new situation which forced the intervention of the Powers. On Dec. 3, 1912, an armistice was concluded, and on the 13th a conference of the belligerent States met in London to settle terms of peace, the ambassadors of the five Great Powers sitting simultaneously to watch over and direct the settlements. (*See* LONDON, CONFERENCES OF.) The conference broke up on Feb. 1, 1913, as the result of Enver Pasha's coup *d'état* of Jan. 23 which led the Balkan States to denounce the armistice. But one thing it had accomplished. It had been agreed by the Powers that Albania should be erected into an independent principality, and that Scutari should be placed under its sovereignty. Thus, so long as Austria-Hungary held the Dalmatian coast, Serbia would be effectually cut off from the Adriatic seaboard and forced into rivalry with Bulgaria and Greece for access to the coast of the Aegean at Salonika. This would lead to the breakup of the Balkan League, which threatened to be a barrier to the eastward pressure of the Central European Powers.

The Treaty of London, signed on May 30, 1913, under the mediation of the Powers, proved less a settlement than the cause of fresh dispute. Crete and all Turkey in Europe beyond the line Enos-Midia were ceded to the Balkan allies; the question of Albania and that of the islands were left to be settled by the Powers. It was inevitable that the victors should quarrel over the spoils, the more so as the creation of an autonomous Albania had profoundly modified the conditions under which the partition treaties between them had been concluded.

The quarrel was precipitated by the complete collapse of new Turkish efforts at resistance. Greece, Serbia and Bulgaria were

alike victorious; but Greece and Serbia, by the chances of war, now held the territories which Bulgaria coveted, and they showed no disposition to surrender them. Rumania, too, now joined in the scramble, demanding a rectification of the frontier of the Dobruja; and though on May 7 Bulgaria signed an agreement conceding this demand, Rumania concluded a military convention with Serbia and Greece. The rupture came on the night of June 29, with a sudden attack by the Bulgarians on the Serbs.

The war was soon over, and Bulgaria, utterly defeated, had to submit to hard terms. By the Treaty of Bucharest (Aug. 10, 1913) she ceded Rumania a considerable strip of the Dobruja, with the fortress of Silistria. In the south she received only a narrow strip to give her access to the Aegean at Dedeagatch. She restored Adrianople, Demotica and Kirk Kilissa to Turkey. Serbia and Greece, on the other hand, received large accessions of territory. Serbia acquired central Macedonia, including Okkrida and Monastir, Kosovo, and the eastern half of Novi Pazar, the western half going to Montenegro. Greece obtained Epirus, southern Macedonia, Salonika and the seaboard as far east as Mesta, thus including the port of Kavala. Crete, too, was soon afterwards assigned by the Powers to Greece, together with all the Turkish islands, except Imbros and Tenedos—which command the Dardanelles—and Rhodes and the Dodecanese archipelago, which were in the occupation of Italy.

The Crisis of 1914.—This settlement, as was inevitable, satisfied nobody. Greece desired to round off her territories to the north by acquiring southern Albania; she wished to complete her empire in the Aegean by adding to it Rhodes and the Dodecanese. This brought her into conflict with Italy, which held firmly to the islands and regarded the new Albanian principality as her peculiar interest. Bulgaria, of course, was profoundly dissatisfied; and her sense of grievance at the settlement-especially the loss of Thrace to Turkey—was not mitigated by the consciousness that the fault was her own. The most fateful outcome of the settlement, however, was the simultaneous strengthening and discontent of Serbia. Cut off from the Aegean by the Greek occupation of Salonika, it was inevitable that she should aspire to find an outlet to the Adriatic, which could only be done at the expense of the Habsburg monarchy. National irredentism—the vision of the oppressed Slavs of the dual monarchy united with their liberated brethren—combined with economic necessity to throw the Serbs into antagonism to Austria-Hungary. Hence the agitation which culminated in the crime of Sarajevo, the immediate occasion of the World War. Austrian statesmen now saw, or thought they saw, in the rise of the Serbian power, not only a bar to the expansion of the monarchy southwards, but an instant menace to its very existence, and so in July 1914 sent the fatal ultimatum to Belgrade. The nightmare vision which for more than a century had tormented the cabinets of Europe was now to become a reality. Hitherto it had been possible for the powers to suppress or to isolate the perpetual fires due to the shrinkage of Turkey. Now, suddenly, they had sent out a flame which lighted conflagration in all the world.

With the end of the World War the Eastern Question, in the sense defined, also came to an end; for the Ottoman empire had ceased to exist. It left, however, a plentiful aftermath of questions, some of which—like that of Albania and the Adriatic coast generally—remain dangerous sources of unrest.

EAST GRINSTEAD, a market town and urban district in the East Grinstead parliamentary division of East Sussex, England, 30 mi. S.E. of London by the S.R. Pop. (1938) 9,655. Area 10.3 sq.mi. East Grinstead is a junction station with branch lines to Groombridge (connecting with the Tunbridge Wells and Uckfield lines), Lewes, Hayward's Heath and Three Bridges. St. Swithin's church, rebuilt in the 18th century, occupies the site of a Saxon church, which later belonged to the priory of St. Pancras at Lewes, by whom its incumbents were appointed. Sackville college is an almshouse founded in 1608, and St. Margaret's home and orphanage was founded in the last century. Brewing and brick and tile making are carried on. The electricity undertaking is owned by the council. In the vicinity (near Forest Row station) is the golf course of the Royal Ashdown Forest Golf club. The hundred of East Grinstead (Grenestede, Estgrensted) was in the possession of the count of Mortain in 1086, and in the reign of Henry III. was part of the honour of Aquila, then in the king's hands. The honour was granted by him to Peter of Savoy, through whom it passed to his niece Queen Eleanor. In the next reign the king's mother held the borough of East Grinstead as parcel of the honour of Aquila. East Grinstead was included in a grant by Edward III. to John of Gaunt, duke of Lancaster, and it remained part of the duchy of Lancaster until James I. granted the borough to Sir George Rivers, through whom it was obtained by the Sackvilles, earls of Dorset. East Grinstead was a borough by prescription. In the 16th century it was governed by an alderman, bailiff and constable. It returned two members to parliament from 1307 until 1832, when it was disenfranchised. In 1285 the king ordered the market to be held on Saturday instead of Sunday, and in 1516 a yearly fair was granted.

EAST HAM, a municipal, county and parliamentary borough of Essex, England, 6 mi. E. by N. of London Bridge, on the District, L.M.S. and L.N.E. railways. Pop. (1938) 129,500, area 3.2 sq.mi. East Ham extends from Wanstead Flats on the north to the Royal Albert docks and the Thames at North Woolwich on the south. It is intersected by the two main highways out of east London, the Romford and Barking roads respectively; a by-pass road cuts off the southern angle of the borough nearer the river on the way to Grays and Tilbury. Its modern growth has been very rapid and it now forms, geographically, part of the eastward extension of London. It contains chemical, food and other factories, while the docks and river employ a large part of the population in the southern area. East Ham belonged before the Conquest to Waltham Abbey, whose possession of it was confirmed by Edward the Confessor The old parish church of St. Mary Magdalen retains Norman work in the chancel, and contains a monument for Edmund Nevill who claimed the earldom of Westmorland in the 16th century; William Stukeley, the antiquary (d. 1765), was buried in the churchyard. The ancient parish church of Little Ilford, now absorbed into Manor Park at the northern end of the borough, contains some interesting monuments. East Ham was incorporated in 1904, received a separate commission of the peace in 1906 and became a county borough in 1915.

Since 1918 it has been represented by two members of Parliament in the two constituencies of East Ham, North and South. The corporation owns the tramways and electricity undertakings and has a well-equipped technical college and public libraries. The Passmore Edwards hospital was founded in 1902.

There are over 200 ac. of open space and recreation grounds, including Wanstead Flats (100 ac.), Central and Manor parks (25 and 10 ac.), and other playing fields. A town planning scheme for the borough is in force. East Ham is included in the metropolitan police district of Greater London.

EASTHAMPTON, a town of Hampshire county, Massachusetts, U.S.A., in the Connecticut river valley, 17 m. N.W. of Springfield, just west of Mount Tom. It is served by the Boston and Maine and the New York, New Haven and Hartford railways Pop. (1930) 11,323; and in 1940 it was 10.316. Manufactures include elastic fabrics, felt, rubber thread, fireproof doors, men's shirts, slippers, metal furniture, mechanical rubber goods, advertising novelties, mercerized yarns and print goods. The manufacture of cloth-covered buttons (long a leading industry but discontinued) was built up by Samuel Williston (1795–1874) and his wife Emily Graves Williston, who first did the work by hand, then (1827) experimented with machinery, and in 1848 built a factory; and who in 1841 founded Williston academy, one of the oldest preparatory schools in New England. Easthampton was formed from parts of Northampton and Southampton in 1785 and was incorporated as a town in 1809.

EAST HAMPTON, a town of Suffolk county, New York, occupying the peninsula of Montauk at the E. end of Long island;

served by the Long Island railroad. The population in 1940 was 1,756. The scenery is varied and picturesque, and there are many summer homes and hotels. Montauk lighthouse, on Turtle hill, was first built in 1795. At Montauk Point a large military camp was established after the Spanish-American War. The principal villages are Sag Harbor (partly in the adjoining town), East Hampton and Amagansett. Most of the town was bought from the Indians in 1648 for about £30 by nine men from Massachusetts, who with 20 other families settled here in 1649; and until 1664, when all Long island passed to the duke of York, the settlement was practically independent. In 1683 Gardiner's island, settled in 1639, was made a part of East Hampton township. There are many tales of treasure buried by Captain Kidd on Gardiner's island and Montauk point. Sag Harbor (settled in 1730 and incorporated in 1803) was held by the British after the battle of Long island as a strategic naval and shipping point. It was an important whaling centre from 1785 until the embargo ruined the fisheries, and again from 1830 to 1870. "Home Sweet Home," the childhood home of John Howard Payne is at East Hampton. East Hampton is a summer resort.

EAST INDIA COMPANY, an incorporated company for exploiting the trade with India and the Far East. In the 17th and 18th centuries East India companies were established by England, Holland, France, Denmark, Scotland, Spain, Austria, and Sweden. The English, the most important of these, survived until it handed over its functions to the British government in 1858. It was founded at the end of the 16th century in order to compete with the Dutch merchants, who had obtained a practical monopoly of the trade with the Spice islands and had raised the price of pepper from 3s. to 8s. per lb. Queen Elizabeth incorporated it by royal charter, dated Dec. 31, 1600, under the title of "The Governor and Company of Merchants of London, trading into the East Indies." This charter conferred the sole right of trading with the East Indies, *i.e.,* with all countries lying beyond the Cape of Good Hope or the Straits of Magellan, upon the company for a term of 15 years. Unauthorized interlopers were liable to forfeiture of ships and cargo. There were 125 shareholders in the original East India Company, with a capital of £72,000: the first governor was Sir Thomas Smythe. The early voyages of the company, from 1601 to 1612, reached as far as Japan *(see* Purchas' narratives), and are distinguished

This building, on the site of the old house in 1726, was sold in 1859

as the "separate voyages," because the subscribers individually bore the cost of each voyage and reaped the whole profits, which seldom fell below 100%. After 1612 the voyages were conducted on the joint stock system for the benefit of the company as a whole. In 1610–11 Captain Hippon planted the first English factories on the mainland of India, at Masulipatam and at Pettapoli in the Bay of Bengal. In 1609 James I. renewed the company's charter "for ever," though with a proviso that it might be revoked on three years' notice if the trade should not prove profitable to the realm.

Meanwhile friction was arising between the English and Dutch companies. The Dutch traders considered that they had prior rights in the Far East, and their ascendancy in the Indian archipelago was indeed firmly established on the basis of territorial dominion and authority. In 1613 they made advances to the English company with a suggestion for co-operation, but the offer was declined, and the next few years were fertile in disputes between the armed traders of both nations. In 1619 was ratified a "treaty of defence" to prevent disputes between the English and Dutch companies. When it was proclaimed in the East, hostilities solemnly ceased for the space of an hour, while the Dutch and English fleets, dressed out in all their flags and with yards manned, saluted each other; but the treaty ended in the smoke of that stately salutation, and perpetual and fruitless contentions between the Dutch and English companies went on just as before. In 1623 these disputes culminated in the "massacre of Amboyna," where the Dutch governor tortured and executed the English residents on a charge of conspiring to seize the fort. Great and lasting indignation was aroused in England, but it was not until the time of Cromwell that some pecuniary reparation was exacted for the heirs of the victims. The immediate result was that the English company tacitly admitted the Dutch claims to a monopoly of the trade in the Far East and confined their operations to India and adjoining countries.

The need for good ships for the East Indian trade had led the company in 1609 to construct their dockyard at Deptford, from which, as Monson observes, dates "the increase of great ships in England." Down to the middle of the 19th century, the famous "East Indiamen" held unquestioned pre-eminence among the merchant vessels of the world. Throughout the 17th century they had to be prepared at any moment to fight not merely Malay pirates, but the armed trading vessels of their Dutch, French, and Portuguese rivals. Many such battles, usually with successful results, are recorded in the company's history.

It was not until it had been in existence for more than a century that the English East India Company obtained a practical monopoly of the Indian trade. In 1635, a year after the Great Mogul had granted it the liberty of trading throughout Bengal, Charles I. issued a licence to Courten's rival association, known as "the Assada merchants," on the ground that the company had neglected English interests. The piratical methods of their rivals disgraced the company with the Mogul officials, and a *modus vivendi* was only reached in 1649. In 1657 Cromwell renewed the charter of 1609, providing that the Indian trade should be in the hands of a single joint stock company. The new company thus formed bought up the factories, forts, and privileges of the old one. It was further consolidated by the fostering care of Charles II., who granted it five important charters. From a simple trading company, it grew under his reign into a great chartered company—to use the modern term—with the right to acquire territory, coin money, command fortresses and troops, form alliances, make war and peace, and exercise both civil and criminal jurisdiction. It is accordingly in 1689, when the three presidencies of Bengal, Madras, and Bombay had lately been established, that the ruling career of the East India Company begins. From this moment the history of the transactions of the East India Company becomes the history of British India (see INDIA: History). Here we shall only trace the later changes in the constitution of the ruling body itself.

The great prosperity of the company under the Restoration and the immense profits of the Indian trade attracted a number of private traders, both outside merchants and dismissed or retired servants of the company, who came to be known as "interlopers." In 1683 the case of Thomas Sandys, an interloper, raised the whole question of the royal prerogative to create a monopoly of the Indian trade. The case was tried by Judge Jeffreys, who upheld the royal prerogative; but in spite of his decision the custom of interloping continued and laid the foundation of many great fortunes. By 1691 the interlopers had formed themselves into a new society, meeting at Dowgate, and rivalling the old company; the case was carried before the House of Conimons, which declared in 1694 that "all the subjects of England have

equal right to trade to the East Indies unless prohibited by act of parliament." This decision led up to the act of 1698, which set up a new East India Company in consideration of a loan of two million to the state. The old company subscribed £315,000 and became the dominant factor in the new body; while at the same time it retained its charter for three years, its factories, forts, and assured position in India. The rivalry between the two companies continued both in England and in India, until they were finally amalgamated by a tripartite indenture between the companies and Queen Anne (1702), which was ratified under the Godolphin award (1708). Under this award the company was to lend the nation £3,200,000, and its exclusive privileges were to cease at three years' notice after this amount had been repaid. But by this time the need for permanence in the Indian establishment began to be felt, while parliament would not relinquish its privilege of "milking" the company from time to time. In 1712 an act was passed continuing the privileges of the company even after their fund should be redeemed; in 1730 the charter was prolonged until 1766, and in 1742 the term was extended until 1783 in return for the loan of a million. This million was required for the war with France, which extended to India and involved the English and French companies there in long-drawn hostilities, in which Dupleix and Clive became prominent.

OLD EAST INDIA HOUSE, LEADENHALL ST., LONDON. 1714

So long as the company's chief business was that of trade, it was left to manage its own affairs. The original charter of Elizabeth had placed its control in the hands of a governor and a committee of 24, the chairman and court of directors in London exercising unchecked control over their servants in India. But after Clive's brilliant victory at Plassey (1757) had made the company a ruling power in India, it was considered essential that the British government should have some control over the territories thus acquired. Lord North's Regulating act (1773) raised the governor of Bengal—Warren Hastings—to the rank of governor-general, and provided that his nomination, though made by a court of directors, should in future be subject to the approval of the crown; in conjunction with a council of four, he was entrusted with the power of peace and war; a supreme court of judicature was established, to which the judges were appointed by the crown; and legislative power was conferred on the governor-general and his council. In 1784 Pitt's India bill created a board of control, as a department of the English government, to exercise political, military, and financial superintendence over the British possessions in India. This bill first authorized the historic phrase "governor-general in council." From this date the direction of Indian policy passed definitely from the company to the governor-general in India and the ministry in London. In 1813 Lord Liverpool passed a bill which gave the board of control authority over the company's commercial transactions and abolished its monopoly of Indian trade. The monopoly of the valuable trade with China, chiefly in tea, was ended by Earl Grey's act of 1833. Its property was then secured on the Indian possessions, and its annual dividends of ten guineas per £100 stock were made a charge upon the Indian revenue. Henceforward the East India Company ceased to be a trading concern and exercised only administrative functions. Such a position could not, in the nature of things, be permanent, and the Indian Mutiny was followed by the entire transference of Indian administration to the crown on Aug. 2, 1858.

EAST INDIES, a name formerly applied vaguely, in its widest sense, to the whole area of India, Further India and the Malay archipelago, in distinction from the West Indies, which, at the time of their discovery, were taken to be the extreme parts of the Indian region. The term "East Indies" is still sometimes applied to the Malay archipelago (*q.v.*) alone, and the phrase "Dutch East Indies" is often used to denote the Dutch territories which constitute the greater part of that archipelago. The Dutch themselves use the term *Nederlandsch Indië* and, in English translation, "Netherlands Indies," a term generally accepted in official U.S. statements. Another name in use is INDONESIA.

NETHERLANDS INDIES

The Netherlands territories in Asia are an integral part of the Netherlands kingdom. Their status as colonies was abolished in 1922. They lie between 6° N., off Sumatra, to 11° 30' S., off Timor, and from 95° E., in Sumatra, to 140° E., in New Guinea. Politically they are divided into lands under direct government and subject native states. The islands are described officially as of two groups, Java and Madura forming one, and the other consisting of Sumatra, Borneo, the Riouw-Lingga archipelago, Banka, Billiton, Celebes, the Molucca archipelago, the Lesser Sunda islands, and a part of New Guinea—the outer provinces, as they are named collectively.

The governor-general represents the queen in the Indies and has the highest executive authority. He is assisted by an advisory council, the Council of the Indies, consisting of five members, of whom two are Indonesians. Together with the representative body—the *volksraad* (People's council)—the governor-general passes laws and regulations, except in a few instances in so far as these by their nature belong of right to the home government. He can veto legislation passed by the People's council, but in recent years this right was rarely used. He is bound by the constitutional principles, by which, according to the Netherlands Indies constitution of 1925, the Indies must be governed. The *volksraad* was established in 1918. It is a full co-legislative body, consisting of 60 members, of whom 30 are Indonesians, 25 Europeans and 5 Chinese or other "foreign Asiatics." There are eight departments of administration, each under a director who represents the government in the debates in the *volksraad.* These departments are: internal administration, justice, education and public worship, economic affairs, communications and public works, finance, navy and war. For administrative purposes the Indies are divided in six provinces: Sumatra, West Java, Middle Java, East Java, Borneo and the Great East, besides the four principalities in South Middle Java, two in Surakarta and two in Jokjakarta. These provinces are headed by Dutch governors, while the further territorial subdivisions in the outer provinces are in the hands of residents, assistant residents and *controleurs.* In Java these divisions are headed by residents and the Javanese chiefs of the internal administration, the regents, wedanas and assistant wedanas.

In local government a wide use is made of Indonesians, in the appointment of whom a primary consideration is that if possible the people should be under their own chieftains. In Surakarta and Jokjakarta in Java, also in many parts of the outer provinces, native princes preserve their position; they have limited power, and act generally under the supervision of a Dutch official.

In 1903 democratic government was introduced by the establishment of local councils in Java and some towns and regions in the outer provinces. Between 1926 and 1930 democratic institutions were extended in Java by the creation of provincial and regency councils, while in 1938 a similar reform was started in the outer provinces.

Population. — The accompanying table gives the area and population of Java and Madura, and of the outer provinces.

Since the Indonesian population increased 2.04% yearly from 1920–30, according to estimates the total population of the Indies

	Area	Population	
		Census 1920	Census 1930
	English sq. miles		
Java and Madura	50,745	34,984,171	41,719,524
Sumatra: Sumatra, West Coast	18,029	1,522,240	1,910,298

Total	4,072	49,281,787	69,747,919

*The New Guinea population, not separately computed for 1930, included under Amboina and Ternate.

in 1940 was 72,000,000. The population is divided legally into Europeans and persons assimilated to them, Indonesians and persons assimilated to them and foreign Asiatics. The first includes Eurasians, and also Armenians and Japanese. The total number of people classed as Europeans, in 1930, was 242,372, mainly Dutch and Eurasians, a large proportion of the Dutch being born in the Dutch East Indies. The remainder consisted of British, French, Belgians, Americans, Germans and Japanese. Foreign Asiatics numbered 1,344,878, mostly Chinese and Arabs, and mainly the former, but with many Indians; Indonesians numbered 59,143,775. A large proportion of the Europeans consists of government officials, or retired officials, for many of the Dutch, once established in the colonies, settle there for life. The remaining Europeans are mostly planters and heads of industrial establishments. The Arabs and Indians are quite generally traders; the Chinese are generally the middlemen and moneylenders, while many are plantation labourers in Sumatra and Borneo, and in the tin mines of Banka and Billiton. The natives are mainly agriculturists[1].

Religion and Education.— Entire liberty is granted to the members of all religious confessions. Apart from Christian converts and the Hindu Balinese and animistic tribes in the least-developed parts of the Dutch East Indies, the great majority of the Indonesians are Mohammedan, though not generally of a bigoted type, animistic practices being often in use together with Mohammedan rites, and particularly in regard to marriage customs, inheritance, and family life in general. Conversion to Islam among the animists means an upward step, hence Mohammedanism is gaining ground among such peoples. Islam was brought to the Indies from Gujarat (British India) in the 13th century by traders. At the end of that century several Mohammedan kings ruled in Sumatra (Achin), and gradually Islam spread over the islands, penetrating also to Java, where already in the 15th century many people, especially in the coastal regions, mere Mohammedans. The first followers of Islam in Java (wali's) are still worshipped. Of the four schools of Islam, the one founded by Mohammed ibn Idris ash-Shāfi'ī is generally accepted in the Indies. Mosques are found even in smaller towns, while in every village there is at least one chapel (langgar). Of the five fundamental obligations of Islam, the fast during the month Ramadān is observed most carefully. Another obligation is the haddj, the pilgrimage to Mecca, which was made by 40,000 to 50,000 people yearly shortly before the economic depression of the 1930s. In 1938 their number was 10,327.

The Protestant Church in 1939 had for its Netherlands-speaking community 45 ministers and 9 preachers and for its non-Netherlands-speaking community 31 assistant-ministers, 349 Indonesian preachers and 977 Indonesian assistants. The Roman Catholic Church had 554 European and 16 Indonesian priests. 474 European and 46 Indonesian brethren and 1,677 European and 164 Indonesian sisters. Before World War II there were numerous missionaries at work, Protestant. Roman Catholic and Salvation army; their progress may be gauged from the fact that in 1896 the Christian population was 280,065, while in 1939 it numbered 1,665,871 Protestants and 477,922 Roman Catholics (exclusive of 119,520 Protestant Europeans and 76,541 Roman Catholic Europeans), totalling 2,143,793 or about 3% of the total Indonesian population. The chief Christian church is the Dutch Protestant Church, to which most of the Protestant Europeans belong. Minahassa (North Celebes) proved the most fertile field for missionary enterprise, practically the whole population being Christian; Christianity by 1941 was making most headway in the Moluccas and New Guinea. The Indonesian Roman Catholic population is mostly in Manado, Amboina, Flores, Timor, Solor, Kei and Tenimbar Islands.

Both the government and missionaries maintain vernacular schools. Large sums were voted for the establishment of primary and secondary schools, and the government undertook to assist in the establishment of village schools, with the aim of providing one in each village at least in Java. A plan was put into effect by which 800 new village schools were opened yearly. There are schools for secondary education in all important towns, and schools for mechanical engineering and craft schools in Bandung, Batavia, Malang, Semarang and Surabaya. There are colleges for Indonesian school teachers, for Indonesian officials of the internal administration and special schools for Indonesian girls. Government schools exist for European education of Indonesian and Chinese children. There are commercial schools, navigation schools and training institutes for analysts and controllers of public health, pharmacists' assistants and municipal servants. There is a school for training sugar chemists in Suyabaya, a mining school at Sawah Lunto, and a training institution for veterinaries and an agricultural high school at Buitenzorg. On the university level are law and medical schools and a college of arts and sciences in Batavia; also an engineering college in Bandung. The educational policy is to increase the number of vernacular schools for the masses, create secondary schools adapted to the special requirements of the country (suitable for all races), and develop higher general scientific, technical and professional education. The percentage of literacy according to the census of 1930 was 7.2%. More than 40% of the children of school age receive instruction.

Justice and Finance.— As regards the administration of justice, a distinction is maintained between Europeans and persons assimilated with them and Indonesians, together with Chinese, Arabs, etc. The former are subject to laws closely resembling those of the mother country, while the customs and institutions (*adat*) of Indonesians are respected in connection with the administration of justice to the latter. The penal code, however, is the same for Europeans, Indonesians and foreign Asiatics. There is a high court of justice in Batavia for the whole of the Indies, and there are courts of justice in Batavia, Semarang, Surabaya, Padang, Medan (on Sumatra) and Makassar (Celebes). The court for the majority of the Indonesians and Chinese is the landraad, while there is the *landgerecht* for all groups for cases of minor offenses. In some regions in the outer provinces Indonesian courts and penal law are maintained. For minor cases of Indonesian common law in Java there are courts in the districts and regencies; matrimonial disputes among Indonesians are dealt with by courts of Mohammedan priests, while questions of suc-

[1]The density for the colony as a whole is 67 per sq. mi., and for Java and Madura, 815. There is over-population in Java, and emigration to Sumatra is encouraged by the government. Before World War II. 50,000 to 60,000 Javanese farmers moved yearly to the outer provinces Javanese coolies are employed as labourers in the Straits Settlements and Malay States, also in Surinam, but few settle Average mortality in Java and Madura is 18 per 1,000 It is higher than this in the crowded native and Chinese quarters of the largest towns: in some coolie lines on plantations with very modern organization it has been brought down to 12 per 1,000

cession among them are taken care of by the *landraad*.

The revenue is derived mainly from taxes on land and houses, customs and excise, import and export duties, corporation tax, income tax, land revenue and other duties; from government monopolies, *e.g.*, in opium, salt and pawnshops; and from government enterprises such as tin and coal mines, teak forests and rubber.

The condition of the monetary system before the Japanese occupation was sound. During the period 1922–31, annual expenditures and revenues of ordinary and extra-ordinary services together averaged 785,000,000 and 755,000,000 guilders respectively. The economic depression of 1929, however, was almost disastrous for the financial situation of the country, which was largely dependent upon the profits of western enterprise. A strong policy of curtailment, honever, kept public finances in order, though revenues fell to 466,000,000 guilders in 1935. The situation in world trade improved in 1936, while in the same year Holland and the Indies left the gold standard, with the result that a surplus of 29,000,000 guilders was shown. A few years later, however, the threat of war and the pressing need of defense made great demands on the public finances, reaching a climax in 1941 when the revenue amounted to 694,000,000 guilders and the expenditure to 829,000,000. The long-term public debt, 84,000,000 in 1913, reached a peak in 1924 of 1,124,000,000, diminished gradually to 983,000,000 in 1929 and rose again to 1,369,000,000 in 1934. From there on it decreased to 1,212,000,000 in 1940.

The monetary system is similar to that of Holland, the unit being the guilder (53 cents U.S.). The 5- and 10-guilder pieces are gold coins. Silver is usual, *i.e.*, 23, 1, ½, ¼ and 1/10 guilder pieces. There is a five-cent nickel piece, and there are copper, 2½, 1, and ½ cent pieces. Minting is at Utrecht, in Holland. The Java bank, established in 1828, with headquarters at Batavia, is the only bank issuing notes, two-fifths of the amount of which must be covered by specie or bullion. The government controls the bank. There is a postal savings bank and there are local native savings banks, and an extensive system of popular credit, *i.e.*, village rice credit banks, village money credit banks, and divisional, or district banks. There are also ample banking facilities, European and Asiatic (Chinese), throughout the archipelago.

Defense.—The army was organized as distinct from that of the Netherlands. Its strength in 1942 was about 40,000. In addition to this there were the legions of native princes in Jokjakarta and Surakarta—3,600 infantry; the Barisan, or native infantry of Madura, 1,400; the military police, nearly 10,000; and the colonial reserve and civic guard, to be mobilized for general service. In 1941 military draft was introduced for the Indonesian people. About a third of the regular army was composed of Europeans, mostly Dutch, some Eurasians; the remainder was made up, in order of numerical strength, of Javanese, Amboinese, Sundanese, Buginese, Alfurese, Manadonese, Timorese, Achenese and Bataks. No portion of the regular army of the Netherlands was allowed to be sent to the Indies, but individual soldiers were allowed to enlist in the colonial army, and they formed its nucleus. Native and European soldiers were mixed, but they were in separate companies. Officers, with very few exceptions, were Dutch from Holland, or born in the Indies. The artillery comprised field, mountain and siege batteries, with magazines, arsenals and workshops. There was a cavalry force, a flying corps and engineers corps. The threat of war that preceded the Japanese invasion in 1942 led to budget provisions for an enlargement and motorization of the army in all its fighting branches, and other new measures of a protective nature. The department of war was set up at Bandung, the military headquarters, with training schools, cavalry depot, motor artillery depot, air service depot, artillery construction shops, projectile factory, pyrotechnical factory, war stores depot, and a garrison. Most important other garrisons were at Magelang (Middle Java) and Malang (East Java). There were garrisons in Achin, Borneo and Celebes, while troops were stationed at many points in Sumatra and in Amboina and Ternate, Timor and New Guinea.

The naval service of the Indies had two branches: the squadron of the royal Netherlands navy and the so-called government navy. The former, while at the disposal of the governor-general, the commander in chief of the army and the navy in the Indies, was administered by the Netherlands minister of the navy at The Hague; the government navy, however, was a nonmilitary organization at the disposal of the local civil authorities and carried government employees and goods. Other tasks included patrol duty in the territorial waters and survey of coastal installations The most important naval base was Surabaya, while Amboina in the eastern part of the archipelago was an additional base. The usual squadron of the royal Netherlands navy is 4 cruisers, 6 destroyers, 18 submarines and several minelayers and motor torpedo boats.

Agriculture.— The agricultural industry is of two types, estate agriculture and native agriculture: the former is purely for export; the latter mainly to provide the necessities of life. Since the alienation to non-Indonesians of land in the hands of Indonesians is prohibited, uncleared land may be leased from the government or from native rulers; or may be rented voluntarily from native owners (with restrictions to protect native interests). There are some extensive private lands, dating from the time of the East India company, with manorial rights, but these are gradually being repurchased by the government. Estates are mostly European-owned and are situated mainly in Java and Sumatra. The main native-grown products are: rice, maize, cassava (tapioca), sweet potatoes, soya beans, groundnuts, cinnamon, cloves, nutmegs, pepper, tobacco, coconuts, rubber, coffee, tea, kapok, betel nuts and native fruits and vegetables of many kinds; estate products are: sugar cane, rubber, coffee, tea, tobacco, cinchona, tapioca, agava fibres, cocoa, coca, palm oil and lemon grass. Rice is the chief native crop, maize comes next in importance, then cassava. Sugar has been the chief estate product for a long time, grown principally in east and central Java. The yield is high and the quality first-class; the sugar is manufactured locally, in mills equipped with the latest scientific appliances. Production, about 3,000,000 tons in 1929, had to be restricted during the economic crisis, and Java in 1941 was producing only 1,500,000 tons yearly. Thus, one of the oldest commodities of the Indies, sugar, lost its predominant position to the newest, rubber. The systematic planting of the rubber tree (Hevea brasiliensis) did not start until about 1910. The planted area extended rapidly and in 1940, 1,640,000 ac. of estates were covered with rubber while the native rubber cultivation occupied at least 2,500,000 ac., according to estimates. In 1939 the Indies produced 383,000 tons or 37% of the uorld's rubber. Indonesians grew half of that production. Rubber is mainly grown on the islands of Sumatra and Borneo; Java's share was only 74,500 tons in 1939.

The collapse of the rubber market in 1927 was followed in 1934, after long deliberations, by an international regulation for the production and export of rubber signed by practically all rubber-producing countries. Each country had a basic quantity allotted while every three months the quantity to be exported was fixed in close co-operation with the consumers. This agreement worked satisfactorily and had a stabilizing influence on the price of rubber, which varied from $.09 to $.185 per pound after 1934. It was difficult to carry out the agreement with regard to the Indonesian rubber growers, but the problem was solved when, in 1937, the 715,000 Indonesian small holders were registered and export licences were issued. Most of the rubber is put on the market in yellow-brown smoked sheets weighing a little more than two pounds.

Rubber was the most valuable export commodity from the Indies in 1940, forming 40% of the total export value of the country.

Coffee no longer holds the pride of place it held formerly. The coffee industry had to combat an epidemic of disease in 1880, which led to much acreage being devoted to other cultures. Compulsory cultivation was abandoned in 1885, government cultivation in 1915, and the industry, relying largely on the Robusta variety of plant, which has shown little susceptibility to disease, instead of on *Coffea* arabica and *liberica*, is one of only moderate significance; production in 1939 was 121,000 tons. Tea (1939 crop, 83,000 tons) is grown principally in West Java and Sumatra East Coast. Tobacco is grown mostly in Sumatra (East Coast)

and Middle and East Java, the former being of superior quality: 1939 total production was 117,000 tons. Java, alone, produces more than 90% of the cinchona on the world market; it is grown in West Java, with a few estates in Sumatra. Palm oil is cultivated principally in East Coast Sumatra, and is one of the most promising of Dutch East Indian industries (production in 1939 was 244,000 tons). Kapok rose from about 3,000 tons in 1900 to 22,000 tons in 1939, the Java product being termed the best on the market. The Indies supply 72% of the world requirements of kapok, 90% of the total production is grown by Indonesians. Copra (1939 production, 537,000 tons) may be termed the "mainstay" of the archipelago, for it is produced everywhere, and, by ensuring a sure supply of cargo, enables steamers to call at very small ports and yet engage in profitable trade; coco nut cultivation is almost exclusively in Indonesian hands. Agave fibre cultivation is important in Java (Java sisal and Java cantala) and in Sumatra, and there has been a large extension of cassava cultivation, which has made the Dutch East Indies the most important tapioca-products' producer in the world. The output increased from 91,053 tons in 1921 to 200,000 tons in 1939. Other important products are pepper (1939, 71,000 tons, being 83% of the world's requirements) which is grown chiefly by Chinese and natives, in the Lampongs, Achin and west and southeast Borneo; spices, especially mace and nutmeg, grown in Java, Sumatra and the Moluccas; and essential oils, *i.e.*, citronella, lemon grass, patchouli and cajeput (4,000 tons annually) the two first-named grown mostly in Java, patchouli in Sumatra and cajeput principally in Buru and Ceram. Gutta-percha is also produced in small quantities. Forced labor exists no longer in the Dutch East Indies. Labour is cheap and plentiful in Java, and Javanese, with Chinese and other immigrants, aid cultivation in Sumatra. Elsewhere in the archipelago the scanty labour supply makes agricultural development possible by very slow stages only, and European capital fights shy of the uncertain situation. There can be little further expansion in Java; Sumatra is next most favourably placed for expansion, then Borneo and Celebes. Dutch New Guinea, with its very scanty Papuan population, is an agricultural problem. The government aided agriculture by means of irrigation and in every manner possible, maintaining agricultural training colleges and experts, experimental stations and advisers and keeping a constant watch for disease.

Next to agriculture, cattle breeding is of great importance in native life. Cows and buffaloes are raised generally, pigs in Bali. Madura and Bali cattle, being thoroughbreds, rank first; everywhere the indigenous breeds are crossed with Ongole and Hissar bulls, in order to obtain heavier specimens for draught and slaughter. Thoroughbred Dutch cattle are raised in Java. The total export of livestock in 1939 was: pigs, 83,692 and cattle, 16,600. An efficient veterinary service safeguards the industry. Fishing is of great importance. Motorboat fishing is done by Japanese, and in places the Chinese have developed sea fishing as an important industry. Motorboat fishing by Indonesians is gradually developing. Generally speaking, fishing is carried on in primitive fashion, by means of nets and traps and by spearing. Most of the fish is consumed fresh, but large quantities are dried and exported. Shells, pearl shell and tortoise shell are collected for export, also trepang and edible bird's nests. Another occupation is the collection of forest products, *i.e.*, timber, rattan, gums (copal, damar and benzoin), sago, bird skins, *atap*, wild cinnamon, wild rubber, gutta-percha and gutta jelutong. A forestry service, with experimental stations, watches over forest interests and restricts timber extraction. Chief among timber woods, and grown mostly in East Java, is teak, of which the production in 1939 was 10,876,949 cu. ft. of timber. Other valuable woods are ebony, sandalwood and ironwood, ebony averaging 8,000 tons in export.

Mining.— The mining industry is under the supervision of a bureau of mines of the department of communications and public works. The government grants prospecting licences and concessions, on certain terms, for all minerals and all kinds of bituminous coal and lignites, petroleum, asphalt and all other kinds of bituminous substances, solid as well as liquid and inflammable gases, with iodine and allied substances. Coal is mined by the government at the Ombilin mines, near Sawah Lunto, in the Padang highlands, Sumatra, the Bukit Asem mines, Palembang residency, Sumatra, and on the island of Pulau Laut, off the southeast coast of Borneo. production in 1939 was 1,222,406 tons. There are private concerns working coal in Sumatra and Borneo, with a production in 1939 of nearly 558,000 tons. Most of the coal is consumed locally. Tin is mined by the government on the island of Banka, which yields exceedingly pure tin, 99.9%. Banka production in 1939 was 17,035 tons. There is a large semiprivate tin-mining industry on the island of Billiton, in which the government has five-eighths of the profits (production in 1939, 9,929 tons), and another at Singkep, in the Riouw archipelago (production, 1,304 tons, 1939). There are gold and silver mines in Sumatra, Borneo, Celebes and Java which produced (1939) gold valued at 5,213,747 and silver at 463,076 guilders. Dutch Borneo yielded diamonds totalling 2,287 carats. An important oil industry has been developed in East Borneo, Palembang, Jambi, Achin and the East Coast of Sumatra, in East Java and in Ceram. The principal company is the Royal Dutch Petroleum company, while the Standard-Vacuum has large oil interests as well. The output of crude petroleum and of petroleum gas for 1939 was, respectively, 7,948,694 tons and 1,263,254 tons. Petroleum exports are in the form of kerosene, benzine, gasoline, liquid fuel, solar and Diesel oil, paraffin and lubricating oils; paraffin wax is made, also batik wax. Asphalt deposits are worked in the island of Buton, southeast Celebes. Bauxite has been exploited on the island of Bintan in the Riouw archipelago. Production in 1939 was 237,000 tons. In the Celebes some nickel has been mined.

Industry, Trade and Commerce.— Industry in the Dutch East Indies, especially in Java, developed rather rapidly after the economic depression of 1930. Apart from the industries connected with the manufacture of cane sugar, rubber, tea, cinchona, cocoa, essential oils and cassava products, and the petroleum and tin-mining industries, there are soap, ice, cigar and cigarette, aerated waters, cement, sulphuric acid, oxygen and explosives factories, paper mills, machine repair, metal construction, paint and varnish, tin packing, cement and brick and tile works, alcohol and arrack distilleries, potteries, tanneries, rice mills, coconut oil mills, lime kilns and cement tile factories, most in European, some in Chinese hands; in later years, a tire plant, an automobile assembly plant, beer breweries and shoe manufactures were established, while a weaving industry developed. The government gave special attention to the cottage industries. These industries are mainly on Java. The native plaited hat industry of Java produces bamboo and pandan hats.

Retail trade is carried on in native markets, and is almost entirely in native hands; Chinese and Arabs, with a few Indians, act as intermediaries. Wholesale trade is largely in European hands, but there are many Chinese and a few Japanese wholesale trade organizations. There are many trading associations, and chambers of commerce, and there is a government department of economic affairs.

The origin of the imports (totalling 529,900,000 guilders in 1939) was as follows (in millions of guilders): The Netherlands, 99.2; Japan, 85.0; United States, 63.7; Germany (including Austria), 41.2; Singapore, 33.8; Great Britain, 33.3. The destination of the total exports of 787,100,000 guilders in 1939 was as follows (in millions of guilders): United States, 146.0; Singapore, 125.0; The Netherlands, 109.0; Australia, 34.3; Great Britain, 34.1; Egypt (including Sudan), 25.1; Japan, 24.6; British India (including Burma), 23.9. Exports and imports for the year 1940 were as follows; Imports (in millions of guilders): textiles and yarns, 120.4; metals and metal goods, 72.9; foodstuffs, 66.4; chemical products, 47.9; machinery, 37.8; miscellaneous, 99.6; total, 445.0. Exports (in millions of guilders): rubber, 368.6; petroleum products, 169.6; tin and tin ore, 81.6; sugar, 52.0; tea, 48.9; deli tobacco, 31.7; cinchona bark and quinine, 27.1; tapioca products, 13.0; copra, 12.6; agave fibres, 10.3; palm oil, 9.6; coffee, 7.8; other leaf tobacco, 6.6; coal, 5.1; gums and resins, 3.8; pepper, 3.5; bauxite, 1.9; essential oils, 2.9; miscellaneous, 74.4; total, 931.0.

Shipping and Communications.—The principal steamship company operating almost exclusively in the archipelago is the *Koninklijke Paketvaart Maatschappij* (the Royal Packet Navigation company), Half the tonnage in Dutch East Indian waters is under the Dutch flag, other chief companies being the Netherlands Steamship company and Rotterdam Lloyd, plying between Europe and Java; and of other tonnage, British ships are by far in the majority. There are ordinarily frequent services between ports in Java and Sumatra and ports in the Straits Settlements, Australia, India, China, Japan, Europe and America; and Royal Packet vessels ensure constant communication between Java and Sumatra and the rest of the archipelago, while the company extended their lines to Australia, South Africa and South America. The total length of rail and tramways is 3,268 mi. in Java, 1,204 mi. in Sumatra. An air service between Batavia and Surabaya and the islands in the outer provinces, altogether 10 regular interinsular services, was established and a twice-weekly air service connected Amsterdam (Holland) and Bandung. Good motor roads exist in most parts of Java, and in several parts of Sumatra, and there are many motor services which link up with rail and tramways. There are rather good roads elsewhere. Good radio, cable and telegraph services exist, even in the remote islands; Java has one of the most powerful wireless stations in the world near Bandung, and numerous minor stations are scattered over the archipelago. There is an extensive and efficient telephone service (by the beam wireless system this was linked up with Amsterdam and London) also in some towns

and districts of Sumatra, Celebes and Manado, Borneo, Amboina, Bali and Lombok. There are regular programs of broadcasting for European as well as Indonesian listeners.

After a month of air and sea warfare the Japanese made their first landings in the Netherlands Indies on Jan. 10, 1942. On March 8 the last strategic points on Java fell to the enemy. (E. E. L.; J. O. M. B.)

EASTLAXE, SIR CHARLES LOCK (1793–1865), English painter, was born on Nov. 17, 1793, at Plymouth. Charles was educated (like Sir Joshua Reynolds) at the Plympton grammar-school, and in London at the Charterhouse. Towards 1809, partly through the influence of his fellow Devonian, Haydon, he determined to be a painter; he also studied in the Royal Academy school. In 1813 he exhibited in the British Institution his first picture, "Christ restoring life to the Daughter of Jairus."

In 1827 he was elected Associate of the Royal Academy and R.A. in 1830; and in 1850 succeeded Shee as president of the Royal Academy, and was knighted. In 1841 he had been appointed secretary to the royal commission for decorating the Houses of Parliament. In 1843 he was made keeper of the National Gallery, but resigned in 1847; in 1855 he became director.

In 1849 he married Miss Elizabeth Rigby, the author of *Letters from the Baltic* (1841), and other works. Lady Eastlake (1809–93) translated Waagen's *Treasures of Art in Great Britain* (1854–57), and completed Mrs. Jameson's *History of our Lord in Works of Art.* Eastlake died at Pisa on Dec. 24, 1865.

Sir Charles Eastlake was an accomplished scholar in matters of art, and published, in 1840, a translation of Goethe's *Theory of Colours;* in 1847 (his chief literary work) *Materials for a History of Oil Painting,* especially valuable as regards the Flemish school; in 1848, *Contributions to the Literature of the Fine Arts* (a second series was edited by Lady Eastlake in 1870, and accompanied by a Memoir from her pen); in 1851 and 1855, translated editions of Kugler's *History of the Italian School of Painting,* and *Handbook of Painting* (new ed., by Lady Eastlake, 1874).

See W. Cosmo Monkhouse, *Pictures by Sir Charles Eastlake, with biographical and critical Sketclz* (1875).

EASTLAND, a city of Texas, U.S.A., 90m. W. by S. of Fort Worth; the county seat of Eastland county. It is on Federal highway 80, and is served by the Eastland, Wichita Falls and Gulf and the Texas and Pacific railways.

In 1910 the population was 855; in 1920, at the height of the oil boom, 9,368; but in 1940 had fallen to 3,849 by the federal census.

It is the trade centre of a farming, stock-raising and oil-producing region, and ships large quantities of grain, peanuts, fruits, pecans and livestock. Numerous oil pools and large gas fields were discovered in 1927.

EAST LIVERPOOL, a city of Columbiana county, O., U.S.A., 44m. W. by N. of Pittsburgh, on the Ohio river, opposite Newell and Chester, West Virginia. It is on the Lincoln highway, and is served by the Pennsylvania railroad, interurban trolleys and motor buses and river steamboats. The population was 21,411 in 1920 (90% native white) and 23,555 in 1940 by the federal census.

It has large machine works, drawn steel plant and several small machine plants, electric porcelain plants and other diversified industries.

There are pottery plants in this city and in Chester and Newell; the latter two cities are served with two large passenger and traffic bridges.

The potteries employ 6,500 wage earners. The city is built on sloping ground, rising from the river bank, in the midst of beautiful scenery.

In 1798 Thomas Fawcett settled here, and in 1802 he laid out a town, which he named St. Clair hut others persisted in calling Fawcettstown. The name Liverpool was adopted in 1816, and in 1834, when the town was incorporated, East was prefixed, to distinguish it from another settlement in the State. The dominating industry dates from 1839, when James Bennett, an English potter, reached the small town, and judged that the clays in the surrounding hills would make an excellent quality of yellow ware. The manufacture of white ware began in 1872; of semi-vitreous china about 1890; while the production of porcelain electrical fixtures and supplies has developed in the present century. Local clays are still used for yellow ware by one plant, but with this exception all the raw materials needed by the potteries come from a distance: the clays from Florida, North Carolina, Kentucky and England; other minerals from distant States, Canada and Italy. Labour-saving machinery displaced the potter's wheel in East Liverpool at an early date.

EAST LONDON, a town of South Africa 33° 3' S., 27° 55' E. Its population, including that of the suburbs, such as Cambridge, 4 miles away, included 31,313 Europeans (1936) and, in 1921, about 11,600 natives, 2,006 coloured persons and 692 Asiatics. The town is situated at the mouth of the Buffalo river, 543 miles by sea from Cape Town, 253 from Durban, and 665 by rail from Johannesburg. The first settlement was a military post on the right bank of the river. It was established to serve as a base port during the Kafir Wars of 1846 and 1847 and was then known as Port Rex. When the railway was constructed on the opposite bank, the centre of gravity moved across the river, which is now spanned by a combined road and railway bridge. The main town is now built on a plateau, 150 to 200 feet high, overlooking the river and the sea coast. It is laid out in broad, straight streets, the principal one being Oxford street. There is also a large open square about which are banks and wool warehouses.

The climate is influenced by the warm Mozambique current off the coast. The mean minimum temperature is 57·1°, and the relative humidity about 87 per cent. The mean annual rainfall is about 30 inches, about 60% falling from October to March, inclusive. Owing to its equable climate, its facilities for surf bathing and to the attraction of its river, East London is one of the principal holiday resorts of the South African coast. Along the shore to the north-east of the river a fine weather esplanade has been made. There is also a park of 80 acres between the main town and the river, contaihing much indigenous hush, and laid out with drives, open lawns and beds of flowers.

The mouth of the river is constricted by a shifting sand bar. The river itself has been made narrower by the construction of training walls to increase the tidal scour. This, combined with dredging, has deepened the entrance, so that there is now a minimum depth of 22 to 23 feet at L.W.O.S.T. The range of spring tides is five or six feet. Vessels up to over 8,000 tons can enter the river, and ships, with a draught of up to 20 feet, can lie alongside the wharves, which extend for over a mile along the left bank. A wharf, now being constructed, will have a depth of 32 feet. The railway has been extended to the wharves so that ships can unload directly into the trucks. Five hundred yards of wharfage on the right bank of the river has a depth of 27 feet,

and is connected with the railway system. The repairing facilities include a shipway with a capacity of 1,000 tons dead weight. In 1928 larger vessels had to anchor in the bay, and load and unload by means of lighters. Important harbour works are however being undertaken with the intention of providing a fine enclosed harbour.

East London ranks as the fourth port of South Africa. It takes a large part of the trade of the eastern part of Cape Colony, of the Transkei and native territories, of Basutoland and part of the Orange Free State. As an exporter of wool and mohair it takes first place in the country. (R. U. S.)

EAST LOTHIAN or **HADDINGTONSHIRE,** a south-eastern county of Scotland, bounded north by the Firth of Forth, north-east by the North sea, east and south by Berwickshire, and south-west and west by Edinburghshire. It covers an area of 170,-971 acres. The sea coast measures 41 miles. On parts of it there are wide stretches of blown sand; on others grassy links, and there are several residential villages with such well-known golf courses as that of North Berwick. Traces of old raised beaches are seen. The Bass rock and Fidra isle belong to the shire, and there are numerous rocks and reefs off the shore, especially between Dunbar and Gullane bay. The northern half of the shire slopes gently to the coast, and the southern half is hilly. In the south the Lammermuir hills reach 1,733 ft ; the rocks here are of Silurian age mainly, bordered by Ordovician and broken by igneous intrusions. The more level tract, mainly of Carboniferous rocks, is broken by Traprain Law (724) in the parish of Prestonkirk, and North Berwick Law (612), both volcanic necks, and Garleton Hill (590) to the north of the county town. The river Tyne (28m.) rises south-east of Borthwick in Mid-Lothian, and reaches the sea just beyond the park of Tynninghame House. It is noted for a fine variety of trout, and salmon are sometimes taken below the linn at East Linton. The Whiteadder rises in the parish of Whittingehame, but leaves the shire to join the Tweed near Berwick.

Agriculture **and** Industries — Throughout nearly the whole of the 19th century East Lothian agriculture was held to be the best in Scotland, because of the enterprise of cultivators like George Hope of Fenton Barns (1811–76). East Lothian is famous for the richness of its grain and green crops, the size of its holdings and the good housing of its labourers. Much of the Lammermuirs is unproductive, though the lower slopes are cultivated. In the centre of the shire occurs a belt of tenacious boulder clay on a tilly subsoil not adapted for agriculture. The coast is sandy, but farther inland the rich loam is very fertile. The land about Dunbar is the most productive, yielding a potato — the "Dunbar red" — highly esteemed in the markets. Of the grain crops, oats and barley are the principal, and wheat also is grown. Turnips and potatoes are cultivated extensively. Many sheep are kept on the Lammermuirs.

Some fishing is carried on at Dunbar, North Berwick and Port Seton. Fireclay as well as limestone is worked, and there are some stone quarries. The chief industries are the manufacture of agricultural implements, pottery, bricks, woollens, and salt, besides brewing and distilling. Only a limited part of the Carboniferous limestone area includes the coal-measures, but coal is extensively worked at Tranent, Ormiston and near Prestonpans, the coalfield having an area of about 30 sq. miles. Ironstone is mined at Macmerry.

The county is served by the main line of the L.N.E R., with branches at Drem to North Berwick. at Longniddry to Haddington, and also to Gullane, at Smeaton (in Mid-Lothian) to Macmerry, and at Ormiston to Gifford.

Population and Government. — The population was 47,753 in 1938. The chief towns are Dunbar (pop. in 1938, 3,827), Haddington (4,664), North Berwick (3,165), Prestonpans (2,669), and Tranent (5,034).

The county, which returns one member to parliament. with Berwickshire, forms part of the sheriffdcm of Mid-Lothian, and a sheriff-substitute sits at Haddington, North Berwick and Tranent.

History. — Of the early Celtic inhabitants, traces are found in a few place-names and circular camps (in the parishes of Garvald and Whittingehame), and hill forts (in the parish of Bolton). Excavations at Traprain Law, carried on since 1914, gave evidence that this hill, a natural stronghold strengthened by earthworks, was in occupation nearly continually from the Bronze age to the beginning of the 5th century A.D. Most of the objects found are Celtic, but there was also a hoard of Roman silver plate of the 4th century, weighing over 770 oz., and believed to have been pillaged from Gaul by Saxon pirates. After the Roman occupation, of which few traces remain, the district formed part of the Saxon kingdom of Northumbria until 1018, when it was joined to Scotland by Malcolm II. It was comparatively prosperous till the wars of Bruce and Baliol, but from that period down to the union of the kingdoms it suffered from its nearness to the Border and from civil strife. The last battles fought in the county were those of Dunbar (1650) and Prestonpans (1745).

EASTMAN, GEORGE (1854–1932), American inventor, manufacturer, and philanthropist, was born at Waterville (N.Y.) on July 12, 1854. He was educated at Rochester and became interested in photography. In 1880 he began to manufacture dry plates, and four years later produced the first practicable roll film. In 1888 he invented the "kodak." He devoted the greater part of his fortune to the advancement of education, and had given by 1925 a total of over $58,000,000 for such purposes. Of this sum the university of Rochester received over $25,000,000, including upward of $5,500,000 for the medical school and $6,500,000 for the foundation and endowment of the Eastman school of music. He gave also $15,500,000 to the Massachusetts institute of technology and about $2,000,000 to the Hampton and Tuskegee institutes. He died Mar. 14, 1932. *(See* PHOTOGRAPHY.*)*

EASTMAN KODAK COMPANY, manufacturer of photographic equipment and materials, with plants in the United States, Canada, England, France, Germany, Hungary and Australia, and with distributing houses throughout the world, manufactures and sells Kodaks of many types; Ciné-Kodaks and Rodascopes, respectively used for making and projecting amateur motion pictures; photographic lenses and accessories; specialized photographic equipment for scientific, industrial and business uses; Kodak, Ciné-Kodak, X-ray, motion-picture and professional film; Kodachrome film for full-colour photography; film and plates for specialized purposes; photographic p in a wide range of varieties; photographic l nicals and photographic-laboratory equipment· approximately 3,5 synthetic organic chemicals; nonphotographic cellulose trat and cellulose-acetate ti s and sheeting; and Kodapak, a transparent packaging material.

The subsidiary Tennessee Eastman Corporation produces cellulose acetate for the manufacture of safety film and other purposes; acetate rayon yarn and staple fibre, including the crimped fibre, Teca; a cellulose-acetate molding composition, Tenite; and related products.

The industry came into existence with the photographic-plate business founded by George Eastman in 1880. It has grown from six employees to approximately 40,000. In 1889, Eastman and his associates introduced the first transparent film. .

The Kodak, the first compact, hand-held camera, had been invented the year before. In 1891, daylight loading was introduced; in 1923, the Ciné-Kodak; in 1931, the supersensitive panchromatic type of film, which revolutionized movie-studio technique and photography in other fields; and, in 1935, the Kodachrome colour process.

The Eastman Kodak Company has been a pioneer in research, in large-scale precision manufacturing, and in its comprehensive program for emplovee security. (F. C. E.)

EAST MQLINE, a city of Rock Island county, Ill., U.S.A., on the Mississippi river, adjoining Moline. It is served by the Burlington, the' Chicago, Milwaukee, St. Paul and Pacific, the Rock Island, and the Davenport, Rock Island and Northwestern railways. The population was 8,675 in 1920 (28% foreign-born white), and was 12,359 in 1940 by the federal census. It has important manufactures, similar to those of the neighbouring cities. including especially plows, scales. laundry machinery, harvesting machinery, steel playthings. pressed steel and voltage regulators. The city was incorporated in 1907.

EASTON, a city of eastern Pennsylvania, U.S.A., on the Delaware river, at the mouth of the Lehigh and Bushkill rivers, opposite Phillipsburg, N.J., 60 mi. N. of Philadelphia and 70 mi. W. of New York city; the county seat of Northampton county. It is on federal highways 22 and 611; is served by the Central of New Jersey, the Lehigh Valley, the Lehigh and Hudson River, and (through Phillipsburg) the Lackawanna and the Pennsylvania railways; and is at the junction of the Delaware and the Lehigh canals. The population was 33,813 in 1920 (91% native-born); 34,468 in 1930 and 33,589 in 1940 by the federal census; the population in the metropolitan area within 5 mi. of Centre square was 85,000.

The city is beautifully situated on rolling ground, commanding fine views of hills and rivers. The total bank resources are approximately $42,000,000 and building and loan resources, $5,000,000. On a hill overlooking the city is Lafayette college, a Presbyterian institution for men, opened in 1832, which has an enrolment of about 1,000. It was named after Gen. Lafayette, who was on tour through the United States when the movement to establish the college was launched in 1824.

Easton is the commercial centre of a region rich in mineral and agricultural resources. Abundant hydro-electric power is available, and the city has important and varied manufactures, with a total industrial pay roll of more than $15,000,000 annually. Among the principal products are steel, cement, silk, hosiery. paper cups, flour and feed, rope and twine, pumps, machinery of many kinds, plush, awnings, curtains, aluminum castings, auto springs, crayons, castings, men's clothing, railroad cars, steel bodies and showcases.

Easton was settled by Thomas and John Penn, brothers of William Penn, and was named after the family of Thomas Penn's wife. The land was acquired in 1752 from the Indians, who had had a trading post at that point, and several important treaties were negotiated with them there between 1756 and 1762, during the French and Indian war. The First Reformed church, built in 1776 and still standing, was used as a hospital during the Revolution. The bell rung to summon the people to the official reading of the Declaration of Independence on July 8, 1776, still hangs in the belfry of the courthouse, and the flag unfurled on that occasion is in the public library. The city of Easton was incorporated as a borough in 1789, as a city in 1887.

EAST ORANGE, a city of Essex county, New Jersey, 11 mi. W. of New York city, adjoining Newark. It is served by the Erie and the Lackawanna railways, and by interurban trolley and motor-coach lines. The population was 50,710 in 1920 (82% native white), 68,020 in 1930, and 68,945 in 1940 by federal census. East Orange and the adjoining municipalities of Orange, West Orange, South Orange and Maplewood (together known as "the Oranges") form a great residential suburban community, with a total population of about 165,000. The streets are broad and well shaded and there are many beautiful homes and several private schools, besides a public school system of high excellence. In East Orange is Upsala college (Lutheran, established 1893); and in South Orange, Seton Hall college (Roman Catholic, 1856). East Orange has an assessed valuation of $109,440,285 (1941). Its manufacturing industries are concentrated largely in the section called Ampere, and the principal products are sewer pipe, motors, dynamos, valves and pipe fittings and water-works supplies. The aggregate output in 1939 was valued at $6,026,103. In 1863 the township of East Orange was separated from the township of Orange, which had been set off from Newark in 1806; and in 1899 the city was incorporated.

EAST PALESTINE, a city of Columbiana county, Ohio, U.S.A., on the Pennsylvania railroad, near the eastern boundary of the state, 20 mi. S. by E. of Youngstown. Pop. (1930), 5,215; 1940 it was 5,123 by the federal census. Coal, fire clay and oil shales abound; it has manufactures of building tile, chinaware, electrical refractories and wiring devices, steel storage tanks for gas and oil, and various other articles. It is in the finest orchard district of the State.

EAST PITTSBURGH, a borough of Allegheny county, Pa., U.S A , on the Monongahela river, 12 mi. S.E. of Pittsburgh. It is served by the Bessemer and Lake Erie, the Pennsylvania, the Baltimore and Ohio, the Pittsburgh and Lake Erie, and the Union railways. The population was 6,527 in 1920 (30% foreign-born white), and was 6,079 in 1940 by federal census. The principal manufactures are electrical apparatus and dairy products. The borough was settled about 1871 and incorporated in 1894.

EAST POINT, city of Fulton county, Georgia, U.S.A.. $\frac{1}{4}$ mi. from the southern boundary of Atlanta; served by the Atlanta and West Point and the Central of Georgia railways. Pop., 9.512 in 1930 and 12,403 in 1940 by the federal census. It is a residential and industrial suburb, with a land area of 4.9 sq mi.

EASTPORT, a city of Washington county, Maine, occupying Moose island, in Passamaquoddy bay, a port of entry and the most easterly city of the United States. It is served by the Maine Central railroad and by steamer lines and ferries. The population was 3.466 in 1930; in 1940 it was 3,346. It has a large sardine-canning industry and important fisheries; has an airport; is the gateway to a fishing and hunting region; and is the site of the immense hydroelectric tidal power development, having the highest rise and fall of tides in the United States. The largest whirlpool in the western hemisphere forms off its eastern shore. Eastport was settled by fishermen in 1782; became a port of entry in 1790; was'incorporated as a town in 1798 and as a city in 1893. Under the Embargo acts of 1807 and 1808 it was a notorious place for smuggling. During the War of 1812 it was taken by the British (July 11, 1814), and after the close of the war was held under martial law until July, 1818, when it was surrendered to the U.S. in accordance with the provisions of the treaty of Ghent.

EAST PROVIDENCE, a town of Providence county, Rhode Island, U.S.A., on the east side of the Seekonk and Providence rivers, opposite Providence. It is served by the New York, New Haven and Hartford railroad. The population in 1940 was 32,165. There are four sections of the town: Watchemoket, the largest; Phillipsdale, containing most of the manufacturing; Rumford, which has a large chemical works; and Riverside, with attractive summer resorts. Oysters are shipped, and the output of the manufacturing works approximates $40,000,000 annually. Roger Williams established himself here in the spring of 1636, but left when he learned that he was within the jurisdiction of the Plymouth colony. Permanent settlement dates from 1644. In 1861 it was decided that the territory belonged to Rhode Island, and the town was incorporated in 1862.

EAST PRUSSIA, the easternmost province of the Land of Prussia, Germany, in 1939 bounded northwest by the Baltic sea, north and east by Lithuania, south by Poland, west by the territory of Danzig. Its area is 14,283 sq.mi. Population was (1939) 2,496,017, density 174 per sq.mi. It is part of the north German plain diversified in the south by morainic plateaus, thickly studded with small lakes. The dune coast is fringed by lagoons (Frisches Haff and Kurisches Haff) with eastward projecting sand spits to seawards. On the cultivated lands, which comprise about half the province, chiefly in the valleys of the north, are grown oats, rye, potatoes and flax (mainly in Ermeland) Horses and cattle are bred on the pastures. The south of the province is composed largely of forest, sterile moor, sand and bog, where a few wolves and lynxes still survive. Fishing is carried on in the lakes and haffs, while in Samland amber is found in great abundance. Foreign trade (main exports, timber and grain) is conducted through Konigsberg (*q.v.*), the capital. The population is predominantly German and Protestant except in Ermeland where Roman Catholics are in the majority and in the south where Poles have settled. In accordance with the Treaty of Versailles of 1919 plebiscites were held in the southern Marienwerder and Allenstein districts to determine whether they should remain with Prussia or go to Poland. By large majorities the population voted to remain with Prussia. By the Treaty also Memel (*q.v.*) was separated from East Prussia and created into a Free State under the League of Nations administration in order to provide Lithuania with a port. The so-called "Polish corridor" *(see* POMORZE) between East Prussia and Germany proper was forcibly annexed to the reich, along with other Polish territory and Danzig, in the first stages of World War II.

EAST SAINT LOUIS, a city of St. Clair county, Ill., U.S.A., on the Mississippi river, opposite Saint Louis, with which it is connected by three great steel bridges; one of the great railway centres of the country and an important manufacturing city. It is the focus of 21 railroads from the east, north and south, including the Baltimore and Ohio, Illinois Central, the Burlington, New York Central, the Louisville and Nashville, the Missouri Pacific, the Gulf Mobile and Ohio, the Nickel Plate, the Pennsylvania, the Saint Louis Southwestern, the Southern and the Wabash; is on federal highways 40, 50, 66 and 67; and is served by many local and transcontinental bus lines. The population in 1930 was 74,347 of whom 4,657 were foreign-born white and 11,536 were Negroes; and had increased to 75,609 in 1940 according to the federal census.

The city occupies 13.4 sq.mi. of the Mississippi bottom land, not much above the high-water mark of the river, but adequately protected by strong levees. The assessed valuation of property in 1940 was $42,908,014. Coal is mined at its doors (2,474,123 tons in the county in 1939).

The output of the factories within the city limits and in the adjacent metropolitan area in 1937 was valued at $162,000,000. Meat-packing houses employ 5,000 men. Other leading manufactures are aluminium ware, chemicals, glass bottles, paint pigments, railway equipment, roofing, brick, tile, pipe line valves and petroleum products. The stockyards are the second largest concentration point of livestock in the United States. Races are held regularly in the spring and fall.

East Saint Louis was laid out about 1808, and was chartered as a city in 1865. It grew most rapidly between 1900 and 1910, when the population practically doubled. There is a famous prehistoric mound (Monk's mound) near the city. The village of Cahokia, at the southern edge of the city, was one of the earliest French settlements in the Mississippi valley.

EAST STROUDSBURG, a borough of Monroe county, Pa., U.S.A., adjoining Stroudsburg (*q.v.*) and 20 mi. N. of Easton, surrounded by the beautiful scenery of the Kittatinny range and the Pocono mountains.

It is on federal highway 611 and is served by the Lackawanna and the Pennsylvania railways. The population was 4,855 in 1920 (93% native white), and was 6,099 in 1930 and 6.404 in 1940 by the federal census.

The borough has sundry manufacturing industries, has a progressive education system and is the seat of a state teachers' college (opened 1893).

EATON, DORMAN BRIDGMAN (1823–1899), American lawyer, was born at Hardwick (Vt.), June 27, 1823. He graduated at the University of Vermont in 1848 and at the Harvard law school in 1850, and in the same year was admitted to the bar in New York city. There he became associated in practice with William Kent, the son of the great chancellor. He was conspicuous in the fight against Tweed and his followers, by one of whom he was assaulted; he required a long period of rest, and went to Europe, where he studied the workings of the civil service in various countries. From 1873 to 1875 he was a member of the first United States civil service commission. In 1877, at the request of President Hayes, he made a careful study of the British civil service, and three years later published *Civil Service in Great Britain.* He drafted the Pendleton Civil Service Act of 1883, and later became a member of the new commission established by it. He resigned in 1885, but was almost immediately reappointed by President Cleveland, and served till 1886, editing the 3rd and 4th *Reports* of the commission. He was an organizer (1878) of the first society for the furtherance of civil service reform in New York, of the National Civil Service Reform Association, and of the national conference of the Unitarian Church (1865). He died in New York city, Dec. 23, 1899. Among his publications were: *Should Judges Be Elected?* (1873), *The Spoils System and Civil Service Reform* (1882), *Problems of Police Legislation* (1895) and *The Government of Municipalities* (1899).

See the privately printed memorial volume, *Dorman B. Baton, 1823-99* (1900).

EATON, MARGARET O'NEILL (1796–1879), better known as PEGGY O'NEILL, was the daughter of the keeper of a popular Washington tavern, and was noted for her beauty, wit and vivacity. About 1823, she married a purser in the United States navy, John B. Timberlake, who committed suicide while on service in the Mediterranean in 1828. In the following year she married John Henry Eaton (1790–1856), a Tennessee politician, at the time a member of the United States Senate. Senator Eaton was a close personal friend of President Jackson, who in 1829 appointed him secretary of war. This sudden elevation of Mrs. Eaton into the cabinet social circle was resented by the wives of several of Jackson's secretaries, and charges were made against her of improper conduct with Eaton previous to her marriage to him. The refusal of the wives of the cabinet members to recognize the wife of his friend angered President Jackson, and he tried in vain to coerce them. Eventually, and partly for this reason, he almost completely reorganized his cabinet. The effect of the incident on the political fortunes of the vice-president, John C. Calhoun, whose wife was one of the recalcitrants, was perhaps most important. Partly on this account, Jackson's favour was transferred from Calhoun to Martin Van Buren, the secretary of state, who had taken Jackson's side in the quarrel and had shown marked attention to Mrs. Eaton, and whose subsequent elevation to the vice-presidency and presidency through Jackson's favour is no doubt partly attributable to this incident. In 1836 Mrs. Eaton accompanied her husband to Spain, where he was United States minister in 1836–40. After the death of her husband she married a young Italian dancing-master, Antonio Buchignani, but soon obtained a divorce from him. She died in Washington on Nov. 8, 1879.

See James Parton's ***Life*** *of Andrew Jackson* (1860).

EATON, THEOPHILUS (*c.* 1590–1658), English colonial governor in America, born at Stony Stratford, Buckinghamshire, about 1590, settled in London, where he joined the Puritan congregation of the Rev. John Davenport. The pressure upon the Puritans increasing, Eaton, who had been one of the original patentees of the Massachusetts Bay Colony in 1629, determined to use his influence and fortune to establish an independent colony of which his pastor should be the head. He emigrated with Davenport to Massachusetts, and in the following year (March 1638) he and Davenport founded New Haven. In Oct. 1639 a form of government was adopted, based on the Mosaic law, and Eaton was elected governor, a post which he continued to hold, first over New Haven alone, and after 1643 over the New Haven Colony or jurisdiction, until his death at New Haven, Jan. 7, 1658. He was prominent in the affairs of the New England Confederation, of which he was one of the founders (1643). In 16 jS he and Davenport drew up the code of laws, popularly known as the "Connecticut Blue laws."

A sketch of his life appears in Cotton Mather's *Magnalia* (London, 1702); *see* also *J. B.* Moore's "Memoir of Theophilus Eaton" in the *Collections* of the New York Historical Society, second series, vol. ii. (New York, 1849).

EATON, WILLIAM (1764–1811), American soldier, was born in Woodstock, Conn., on Feb. 23, 1764. He was a school teacher for several years, graduated at Dartmouth college in 1790, and in 1792 entered the army as a captain, later serving against the Indians in Ohio and Georgia. In 1797 he was appointed consul to Tunis, where he arrived in Feb. 1799. In March 1799, with the consuls to Tripoli and Algiers, he negotiated alterations in the treaty of 1797 with Tunis. He rendered great service to Danish merchantmen by buying on credit several Danish prizes in Tunis and turning them over to their original owners for the redemption of his notes. In 1803 he quarrelled with the bey, was ordered from the country, and returned to the United States. In 1804 he returned to the Mediterranean as United States naval agent to the Barbary States with Barron's fleet. On Feb. 23, 1805, he agreed with Ahmet that the United States should undertake to re-establish him in Tripoli, that the expenses of the expedition should be repaid to the United States by Ahmet, and that Eaton should be general and commander-in-chief of the land forces in Ahmet's campaign. In making the arrangement Eaton far

exceeded his authority. On March 8 he started for Derna across the Libyan desert from the Arab's Tower, 40 m. west of Alexandria, with a force of about 500 men, including a few Americans, about 40 Greeks and some Arab cavalry. In the march of nearly 600 m. the camel-drivers and the Arab chiefs repeatedly mutinied, and Ahmet Pasha once put himself at the head of the Arabs and ordered them to attack Eaton. Ahmet more than once wished to give up the expedition. But on April 27, with the assistance of three bombarding cruisers, Eaton captured Derna—an exploit commemorated by Whittier's poem *Derne*. In May and again in June he successfully withstood the attacks of Tripolitan forces sent to dislodge him. On June 12 he abandoned the town upon orders from Commodore Rodgers, for peace had already been made (June 4) with Yussuf, the de *facto* pasha of Tripoli. Eaton returned to the United States, and received a grant of 10,000 ac. in Maine from the Massachusetts legislature. According to a deposition which he made in 1807 he was approached by Aaron Burr (*q.v.*), who attempted to enlist him in his "conspiracy." As he received from the Government, soon after making this deposition, about $10,000 to liquidate claims for his expense in Tripoli, which he had long pressed in vain, his good faith has been doubted. At Burr's trial at Richmond in 1807 Eaton was one of the witnesses, but his testimony was unimportant. He died on June 1, 1811, in Brimfield, Mass.

See the anonymously published Life of *the* Late Gen. William *Eaton* (Brookfield, Mass., 1813) by Charles Prentiss; C. C. Felton, "Life of William Eaton" in Sparks's Library of American Biography, vol. ix. (Boston, 1838); Gardner W. Allen's Our Navy and the Barbary Corsairs (Boston, 1905); and William Abbott, "A Forgotten Hero, William Eaton," Mag, of *Hist.*, vol. vi., pp. i.–ii. (1907). See also E. A. Powell, Gentlemen Rovers (1913); and M. Minnigerode, Lives and Times (1925).

EATON, WYATT (1849–1896), American portrait and figure painter, was born at Philipsburg, Canada, on May 6, 1849. He was a pupil of the schools of the National Academy of Design, New York, and in 1872 went to Paris, where he studied in the École des Beaux-Arts under J. L. Gérôme. He made the acquaintance of J. F. Millet at Barbizon, and was also influenced by his friend Jules Bastien-Lepage. After his return to the United States in 1876 he became a teacher in Cooper institute and opened a studio in New York city. He was one of the organizers (and the first secretary) of the Society of American Artists. Among his portraits are those of William Cullen Bryant and Timothy Cole, the wood engraver ("The Man with the Violin"). Eaton died at Newport (R.I.), on June 7, 1896.

EAU CLAIRE (ō′klār′), a city of north-western Wisconsin, U.S.A., 84 mi. E. of Saint Paul, on the Chippewa river at the mouth of the Eau Claire; the county seat of Eau Claire county. It is on Federal highways 10, 12 and 53, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific and the Soo Line railways.

The population was 30,745 in 1940, and was 26,287 in 1930 by Federal census. There is abundant waterpower, and the city has large and diversified manufacturing enterprises, with an aggregate output in 1940 valued at $29,172,523. It is the principal jobbing centre for the prosperous Chippewa valley. Since 1912 the city has operated under a commission form of government. It is the scat of a State teachers' college, a county tuberculosis hospital and a county hospital for the insane. There are six musical organizations and a municipal auditorium seating 2,000. A State fish hatchery assures good fishing in the vicinity.

Eau Claire was settled about 1847; chartered as a city in 1872; and grew rapidly with the development of the north-uestern lumber trade in the decade 1870–80. A serious strike in 1881 necessitated the calling out of the State militia.

EAU DE COLOGNE, a perfume, so named from the city of Cologne, where its manufacture was first established by an Italian, Johann (or Giovanni) Maria Farina (1685–1766), who settled at Cologne in 1709. The perfume gained a high reputation by 1766, and Farina associated himself with his nephew, to whose grandson the secret was ultimately imparted; the original perfume is still manufactured by members of this family under the name of the founder. The manufacture is, however, carried on at Cologne, and also in Italy, by other firms bearing the name Farina, and the scent has become part of the regular output of perfumers. The discovery has also been ascribed to a Paul de Ferninis, who is supposed to have brought his recipe from Milan to Cologne, of which he became a citizen in 1690, and sold the perfume under the name Eau admirable, leaving the secret at his death to his nephew Johann Maria Farina. It was prepared from an alcoholic infusion of certain flowers, pot-herbs, drugs and spices, distilling and then adding definite quantities of several vegetable essences. The purity and thorough blending of the ipgredients are of the greatest importance, The original perfume is simulated and even excelled by artificial preparations. The oils of lemon, bergamot and orange are employed, together with the oils of neroli and rosemary in the better class. The common practice consists in dissolving the oils, in certain definite proportions based on experience, in pure alcohol and distilling, the distillate being diluted by rose-water.

EAU DE VIE: see **BRANDY**.

EAUX-BONNES, a watering-place of southwestern France, in the department of Basses-Pyrénées, 3½ mi. S.E. of the small town of Laruns, the latter being 24 mi. S. of Pau by rail. Pop. (1936) 181, commune 462. Eaux-Bonnes stands at a height of 2,460 ft. at the mouth of a fine gorge, at the confluence of two torrents, the Valentin and the Sourde. Its sulphurous and saline mineral waters (famous from the 14th century), are beneficial in affections of the throat and lungs. They vary between 10° and 90° in temperature, and are used for drinking and bathing. There are two thermal establishments, a casino and fine promenades.

The watering-place of LES EAUX-CHAUDES is 5 mi. by road south-west of Eaux-Bonnes, in a wild gorge on the Gave d'Ossau. The springs are sulphurous, varying in temperature from 52° to 97°, and are used in cases of rheumatism, certain maladies of women, etc. There is fine mountain scenery in the neighbourhood of both places. The valley of Ossau, one of the most beautiful in the Pyrénées, before the Revolution formed a community which, though dependent on Béarn, had its own legal organization, manners and costumes.

EAVES (not a plural form as is sometimes supposed, but singular), in architecture, the projecting edge of a sloping roof, which overhangs the face of the wall so as to throw off the water.

EAVESDRIP or **EAVESDROP,** that width of ground around a house or building which receives the rain water dropping from the eaves. By an ancient Saxon law, a landowner was forbidden to erect any building at less than aft. from the boundary of his land, and was thus prevented from injuring his neighbour's house or property by the dripping of water from his eaves. The law of eavesdrip has had its equivalent in the Roman *stillicidium,* which prohibited building up to the very edge of an estate. This prohibition has been adopted by some States which follow the Roman civil law.

From the Saxon custom arose the term "eavesdropper," *i.e.,* any one who stands within "the eavesdrop" of a house, hence one who pries into others' business or listens to secrets. At common law an eavesdropper was regarded as a common nuisance, and was presentable at the court leet, and indictable at the sheriff's tourn and punishable by fine and finding sureties for good behaviour. Though the offence of eavesdropping still exists at common law, there is no modern instance of prosecution or indictment.

EBBW VALE, urban district, Monmouthshire, England, 21 m. N.W. of Neuport, on the G.W. and L.M.S. lines. Pop. (1938) 29,750. The town lies near the head of the Ebbw valley, nearly 1,000 ft. above sea-level. Its position on the northern outcrop of the South Wales coalfield made it, first of all, an important iron-smelting area, and subsequently a coal-mining centre. The extended use of coal and new processes in smelting brought about the establishment of one of the most important steel works in South Wales. Distance from the coast and trade depression after the World War have caused decline and distress.

EBEL, HERMANN WILHELM (1820–1875), German Celtic scholar, studied at Berlin and Halle, and, after holding other professional posts, became professor of comparative philology at Berlin. He died at Misdroy on Aug. 19, 1875. His most

important contribution to Celtic philology was his revised edition (1871) of Zeuss's *Grammatica Celtica.* A selection of his papers was published in English as *Celtic Studies* (edit. Sullivan, 1863).

EBEL, JOHANN GOTTFRIED (1764–1830), author of the first real guide-book to Switzerland, was born at Zullichau in Prussia on Oct. 6, 1764. He first visited Switzerland in 1790. As a result of three years' study he published *Anleitung auf die nützlichste und genussvollste Art in der Schweiz zu reisen* (Zurich, 1793). This was the best Swiss guide-book till "Murray" (1838). In 1801 he was naturalized Swiss and settled in Zurich. He died on Oct. 8, 1830.

Ebel's other works include *Schilderungen der Gebirgsvölker der Schweiz* (2 vols., Leipzig, 1798–1802); *Über den Bau der Erde im Alpengebirge* (2 vols., Ziirich, 1808).

EBENACEAE, a family of dicotyledonous trees and shrubs including the ebony (*q.v.*) and other valuable timber-trees. It has seven genera, with about 320 species, chiefly tropical or subtropical, and especially abundant in Malaya. The fruit is usually a berry. Several tropical species are cultivated for their edible fruits, while the Chinese persimmon *(Diospyros kaki)* is one of the most important fruits of China and Japan, also cultivated in various parts of North America. The family is represented in the United States by two species of persimmon (*q.v.*).

EBER, PAUL (1511–1569), German theologian, was born at Kitzingen in Franconia, and was educated at Nuremberg and Wittenberg, where he became the close friend of Philip Melanchthon. In 1541 he was appointed professor of Latin grammar at Wittenberg, and in 1557 professor of the Old Testament. He published a handbook of Jewish history, a historical calendar intended to supersede the Roman Saints' Calendar, and a revision of the Latin Old Testament. In the theological conflict of the time he sought to mediate between the extremists. From 1559 to the close of his life he was superintendent-general of the electorate of Saxony. He died at Wittenberg on Dec. 10, 1569.

EBERBACH, a town of Germany, in the *Land* of Baden, romantically on the Neckar, at the foot of the Katzenbuckel. 19 mi. E. of Heidelberg by the railway to Wiirzburg. Population 6,973. It manufactures barrel-hoops, chemicals and cigars, and carries on by water an active trade in timber and wine. Eberbach was founded in 1227 by the German king Henry VII, who acquired the castle (now ruined) from the bishop of Worms.

EBERBACH, a famous Cistercian monastery of Germany, in the Prussian province of Hesse-Nassau, situated near Hattenheim in the Rheingau, 10 m. N.W. from Wiesbaden. Founded in 1116 by Archbishop Adalbert of Mainz, as a house of Augustinian canons regular, it was bestowed by him in 1131 upon the Benedictines, but was shortly afterwards repurchased and conferred upon the Cistercian order. The Romanesque church (consecrated in 1186) was despoiled during the Thirty Years' War and secularized in 1803.

EBERHARD (?–939), duke of the Franks, brother of Conrad, duke of Franconia and German king (911–918). In 915 Eberhard supported his brother against the rebel, Henry the Fowler of Saxony, but was defeated, and when Conrad died (918), Eberhard, at his brother's wish, carried to Henry the royal crown and sceptre, obtaining, however, for his support, almost complete independence for his own dukedom of Franconia. In 938 Eberhard rebelled against the new king, Otto the Great. He was defeated and fined, and his abettors condemned to carry dogs through the streets of Magdeburg. In the following year Eberhard, allied with the king's brother Henry and Gilbert of Lorraine, rebelled again, but was surprised and slain at Andernach on the Rhine.

EBERHARD, surnamed IM BART *(Barbatus),* count and afterwards duke of Württemberg (1445–1496), was born on Dec. 11, 1445, the second son of Louis I., count of Wurttemberg-Urach (d. 1450) and succeeded his elder brother Louis II. in 1457. In 1468 he made a pilgrimage to Jerusalem. He visited Italy, became acquainted with some famous scholars, and in 1474 married Barbsra di Gonzaga, daughter of Lodovico III., marquis of Mantua. In 1482 he made with his cousin Eberhard VI., count of Württemberg-Stuttgart, the treaty of Munsingen, by which the districts of Urach and Stuttgart into which Wiirttemberg had been divided in 1437 were again united. The country was declared indivisible, and the right of primogeniture established. *(See* WÜRTTEMBERG.) At the diet of Worms in 1495 the emperor Maximilian I. guaranteed the treaty, and raised Eberhard to the rank of duke. Eberhard was one of the founders of the Swabian League in 1488. He gave charters to the towns of Stuttgart and Tubingen, and introduced order into the convents of his land, some of which he secularized. He took a keen interest in the new learning and founded the university of Tübingen in 1476. In 1482 he again visited Italy and received the Golden Rose from Pope Sixtus IV. He died at Tiibingen on Feb. 25, 1496. The succession passed to his cousin Eberhard, who became Duke Eberhard II.

See Rösslin, *Leben Eberhards im Barte* (Tiibingen, 1793); Bossert, *Eberhard im Bart* (Stuttgart, 1884).

EBERHARD, CHRISTIAN AUGUST GOTTLOB (1769–1845), a versatile German writer, was born at Belzig, near Wittenberg, on Jan. 12, 1769. His best works are *Hannchen und die Küchlein* (1822), a narrative poem in ten parts, and an epic on the Creation, *Der erste Mensch und die Erde* (1828). He died at Dresden on May 13, 1845.

His collected works *(Gesammelte Schriften)* appeared in 20 volumes in 1830–31.

EBERHARD, JOHANN AUGUSTUS (1739–1809), German theologian and philosopher, was born at Halberstadt, Lower Saxony, where his father was singing master at the church of St. Martin's, and teacher of the school of the same name. He studied theology at the university of Halle, and took orders. At Berlin he formed a close friendship with Nicolai and Moses Mendelssohn. His *Neue Apologie des Socrates* (1772) hindered his preferment. But in 1774 he was appointed to the living of Charlottenburg, and in 1778 became professor of philosophy at Halle. He died on Jan. 6, 1809.

His works include: *Amyntor, eine Geschichte in Briefen* (Berlin, 1782)—written to counteract the influence of those sceptical and Epicurean principles in religion and morals then so prevalent in France, and rapidly spreading in Germany; *Über die Zeichen der Aufklärung einer Nation,* etc. (Halle, 1783); *Theorie der schonen Künste und Wissenschaften,* etc. (Halle, 1783, 3rd ed., 1790); *Allgemeine Geschichte der Philosophie,* etc. (Halle, 1788; 2nd ed. with a continuation and chronological tables, 1796); *Versuch einer allgemeinen-deutschen Synonymik* (Halle and Leipzig, 1795–1802, 6 vols., 4th ed., 1852–53), long reckoned the best work on the synonyms of the German language (author's abridgment, 1 vol., Halle, 1802); *Handbuch der Aesthetik* (Halle, 1803–05, and ed., 1807–20).

See F. Nicolai, *Gedachtnisschrift auf* J. *A. Eberhard* (Berlin and Stettin, 1810); also K. H. Jordens, *Lexicon deutscher Dichter und Prosaisten.*

EBERLEIN, GUSTAV (1847–1926). A German sculptor born on July 14, 1847, at Spickershausen, Hanover. He studied at the Academy of Nuremberg and at Berlin under Blaeser, a follower of the classicist Rauch. After a visit to Rome in 1873 where he was attracted to the Baroque he joined the group of sculptors led by Reinhold Begas. In 1887 he became a member of the Berlin academy, in 1893 he was made professor and in 1897 he held an important exhibition of his work at the Berlin academy. His reputation rests chiefly upon his numerous public monuments, such as those of the emperor William I. (Mannheim, Elberfeld and Altona); Bismarck (Krefeld); Richard Wagner (Berlin); Goethe (Rome); Queen Luise (Tilsit). He also executed religious pieces such as the groups representing the life of Adam and Eve; and mythological pieces such as Pygmalion and Galatea. In 1898 he presented the Eberlein museum to Münden in his native Hanover, which contains a representative collection of his work. In 1892 he published *Aus eines Bildners Seelenleben, Plastik, Malerei und Poesie.*

See A. Rosenberg, *Eberlein* (Bielefeld, 1903).

EBERLIN, JOHANN ERNST (1702–1762), German musician and composer, was born in Jettingen, Bavaria, on March 27, 1702, and became court organist to the prince-archbishop of Salzburg, where he died on June 21, 1762. Most of his compositions were for the church (oratorios, etc.), but he also wrote some important fugues, sonatas and preludes, and his pieces were at one time highly valued by Mozart.

EBERS, GEORG MORITZ (1837–1898), German Egyptologist and novelist, was born in Berlin on March 1, 1837. At Gottingen he studied jurisprudence, and at Berlin oriental languages and archaeology. He became in 1865 *docent* in Egyptian language and antiquities at Jena, and from 1870 to 1889 he was professor at Leipzig. He had made two scientific journeys to Egypt, and his first work of importance, *Ägypten und die Bucher Moses,* appeared in 1867–1868. In 1874 he edited the medical papyrus ("Papyrus Ebers") which he had discovered in Thebes (tr. by H. Joachim, 1890). Ebers early conceived the idea of popularizing Egyptology by means of historical romances. *Eine ägyptische Konigstochter* (1864) had a great success. His subsequent works of the same kind—Uarda (1877), *Homo sum* (1878), *Die Schwestern* (1880), *Der Kaiser* (1881), of which the scene is laid in Egypt at the time of Hadrian, *Serapis* (1885), *Die Nilbraut* (1887), and *Kleopatra* (1894), were also popular. Ebers also turned his attention to other historical periods—especially the 16th century *(Die Frau Bürgermeisterin,* 1882; *Die Gred,* 1887)—without, however, attaining the success of his Egyptian novels. His other writings include a descriptive work on Egypt (*Ägypten in Wort und Bild,* 2nd ed., 1880), a guide to Egypt (1886) and a life (1885) of his old teacher, the Egyptologist Karl Richard Lepsius. He died at Tutzing, Bavaria, on Aug. 7, 1898.

Ebers's *Gesanzmelte Werke* appeared in 25 vols. at Stuttgart (1893–1895). Many of his books have been translated into English. For his life *see* his *Die Geschichte meines* ***Lebens*** (Stuttgart, 1893); also R. Gosche, *G. Ebers, der Forscher und Dichter* (2nd ed., Leipzig, 1887).

EBERSWALDE, a town of Germany, in the province of Brandenburg, 28mi. N.E. of Berlin by rail; on the Finow canal. Pop. (1939) 40,985. It received its municipal charter in 1257, but was sacked during the Thirty Years' War. In 1747 Thuringian cutlers came to the town, but the cutlery industry has died out. About 4 mi. to the north lies the Cistercian monastery of Chorin.

The town has a 14th-century church. Industries include iron-founding and the making of roofing material and bricks. Trade is in grain, wood and coal. In the immediate neighbourhood are an important brass-foundry and a Government paper-mill, in which paper for note money is manufactured.

EBERT, ADOLF (1820–1890), German romance philologist, was born at Kassel on June 1, 1820. He was professor of romance languages in Marburg, and from 1862 onwards in Leipzig, where he died on July 1, 1890. He wrote a standard work on mediaeval literature, which is still indispensable to the student and has been the basis of much subsequent work by later writers, *Allgemeine Geschichte der Literatur im Abendlande* (3 vols., 1884–87). From 1859–63 he edited, with F. Wolf, the *Jahrbuch fur romanische und englische Literatur.*

EBERT, FRIEDRICH (1870–1925), German politician, was born in Heidelberg on Nov. 4, 1870, the son of an impecunious tailor. He was an early recruit to the Socialist movement, becoming a fluent speaker and a first-class trade union organizer, suffering persecution and boycott for the cause. He moved to Hanover, and later on to Bremen, where he joined the staff of the local paper of the party, and, having dropped his trade as a saddler, became labour secretary for Bremen. From 1905 Ebert played an important part in the direction of the Socialist Party. He entered the *reichstag* in 1912. A year later he became chairman of the party, which at that time was torn between the Orthodox and Revisionists; his common sense was considered a guarantee for keeping the party together.

At the outbreak of the World War, Ebert, deeply impressed by the danger of Russian victory, led the bulk of the party who voted for war credits. His common sense repudiated the optimistic pacificism of Haase and his followers, who later became the Independent Socialist Party. He continued to strive, however, at home and abroad, especially at the Stockholm Conference in June 1917, for a just peace. He became leader of the Majority Socialists in 1916 and chairman of the budget commission of the *Reichstag* in 1918. Though disapproving of the Peace of Brest-Litovsk, he opposed strikes to bring about peace. In Feb. 1918 he tried hard and fairly successfully to put an end to the Berlin strike, which threatened to become a national calamity. For the part he played at that time he was attacked later on by the Independents as well as by the representatives of the old order.

After Ludendorff's collapse in Sept. 1918 Prince Max of Baden formed the first parliamentary cabinet. Ebert induced his party to join at a time when Ludendorff's insistence on an immediate demand for an armistice was already known. The negotiations about the armistice continued over a month. The suffering working classes began to be restless. When the plans to force a great naval battle became known, a mutiny took place at Kiel. Acting on Ebert's advice, Prince Max sent Noske to Kiel who succeeded in re-establishing order.

Ebert, knowing the historical attachment of the German people to monarchy, wanted a democratic parliamentary government, on English lines, but no republic. When the organized working men began to follow the Independents, Scheidemann intimated to Prince Max (Nov. 7) that the Socialists must withdraw from the cabinet, and that if the emperor did not abdicate by the 9th one of his sons, not the crown prince, should take his place. The emperor vacillated. By the 9th the masses had got out of hand. The monarchy collapsed, but the knowledge of the abdication had not the desired effect. Scheidemann proclaimed the German republic, and Prince Max offered Ebert the chancellorship, which he accepted. He formed a Provisional Government consisting of three Independents and two Majority Socialists besides himself.

From Nov. 1918 to Feb. 1919 it was touch and go whether Germany would be a democratic country or a soviet republic. The small group of German Bolshevists, the Spartacus Union, led by Karl Liebknecht and Rosa Luxemburg, insisted that Russia's example should be followed, whilst the Independents did lip service to democracy, but wanted to postpone the elections. Ebert insisted on early elections for a constituent assembly, to give Germany a Democratic constitution. For nearly two months the Government had no power. The Spartacists had armed their adherents and repeatedly tried to imprison Ebert and his colleagues. Ebert called Noske to Berlin, who succeeded in quelling the December and the January risings by means of quickly organized volunteers. When the struggle was over, the elections to the national assembly took place quietly. Democracy had won the day, thanks to Ebert and the Moderate Socialists. It was but fitting that the assembly elected him the first provisional president of the German republic. Ebert stuck to his post when the Treaty of Versailles had to be signed and later when (March 1920), a military rising, the Kapp Putsch, took place. He left Berlin with his Government to return after the general strike had forced the leaders to surrender.

Ebert's appointment as president was provisional. He wanted to withdraw from office at the appointed time (1922) and to subject himself to a proper election. He bowed, probably unwisely from his point of view, to the wishes of the majority of the *Reichstag,* including the People's Party, who asked him to accept office for a second term from their hands until 1925. When that term drew near its end, reactionary and radical forces had gained strength in Germany. This was shown by the result of the general election of May 1924. But by 1925, after stabilization had done its work, the situation had improved considerably; there appeared to be quite a fair chance that Ebert, if he chose to stand, might be re-elected.

By that time Ebert had dropped the party leadership. He remained on friendly terms with his party, but he considered himself the representative of the German people as a whole. He wielded the great but rather veiled power of the German president with consummate tact. His attitude when forming cabinets, and when reaching decisions was correct, constitutional and wise. He had gained the confidence of all persons with whom he came in contact. He had made the office of the president influential, though not conspicuous. This artisan who had not had the academic training so greatly valued in Germany succeeded in getting a firm grasp on foreign affairs. He saw a point quickly and he knew how to deal with men. Singularly modest and unassuming, his was the dominant influence, nevertheless, in the many crises the German republic had to pass through in the years that.

followed the peace.

But the fact that a plain man of the people was the head of the state did not commend itself to the reactionary elements of German society. A campaign of calumny was organized against him, accusing him of having fomented sedition and broken the back of the German army. He was forced to bring an action for libel against Herr Rothard, who had published in the *Mitteldeutsche Zeitung* a letter and footnote accusing Ebert of treasonable conduct in connection with the munition workers' strike in Jan. 1918. Rothard was found technically guilty, but the judge's finding was unfavourable to Ebert. As the judge's political bias was scarcely denied, the public, including the cabinet sided with Ebert. The central government and many state governments passed votes of confidence; the public assured him of their sympathy, but the strain practically killed Ebert, who had been suffering from repeated attacks of appendicitis. He did not wish to be operated upon before the case was over, and then it was too late. He died on Feb. 28, 1925, at Charlottenburg.

Ebert was a very fortunate combination of the lighthearted spirituality and sober shrewdness of the south German. He had faith in ideas and ideals, but he believed in action and in organization as well. There was passion in him, but there was common sense; there was strength in him, and there was sober suavity. He was by no means a genius towering head and shoulders above his fellow men. He was rather one of them, sharing their feelings and their qualities so that they could trust him completely, being just far enough ahead of them to make them follow him, the true leader for an incipient democracy.

EBERT, FRIEDRICH ADOLF (1791–1834), German bibliographer, was born at Taucha, near Leipzig, on July 9, 1791, the son of a Lutheran pastor. In 1813 he was attached to the Leipzig university library, and in 1814 was appointed secretary to the Royal library of Dresden and, in 1827, after a short period of absence, chief librarian. The rich resources open to him in the Dresden library enabled him to undertake the work on which his reputation chiefly rests, the *Allgemeines bibliographisches Lexikon* (2 vols 1821–30). This was the first work of the kind produced in Germany, and the most scientific published anywhere. Ebert was a contributor to various journals and took part in the editing of Ersch and Gruber's great encyclopaedia. He died at Dresden on Nov. 13, 1834, in consequence of a fall from the ladder in his library.

See the article in *Ersch und Grubers Encyclopadie,* and that in the *Allg. deutsclze Biog. by* his successor in the post of chief librarian at Dresden, Schnorr von Carolsfeld.

EBERTH, KARL JOSEPH (1835–1926), bacteriologist, was born in Würzburg where he studied under Kolliker and Virchow (*qq.v.*). He was called in 1874 to Ziirich, and in 1881 to Halle. He made numerous important contributions to bacteriology and pathology, and is still commemorated in the so-called "Eberth's bacillus," the organic cause of typhoid fever, which was first distinguished by him in 1880.

See R. Renecke's biography in *Berliner Klinische Wochenschrift,* 1915, *LTI,* 1010–1012; works given in J. Page, *Biographisches Lexikon hervorragender Aerzte* (Vienna) 1901.

EBINGEN, a town of Germany, in the *Land* of Württemberg, on the Schmiecha, a left-hand tributary of the Danube, 37 mi. W. of Ulm by rail. It manufactures velvet and cotton-velvet ("Manchester") goods, stockings, stays, hats, needles, tools, etc. There are also tanneries. Pop. (1939) 14,881.

EBIONITES (Heb. אֶבְיוֹנִים "poor men"), a name given to the ultra-Jewish party in the early Christian church. It is first met with in Irenaeus (Adv. *Haer.* i, 26, 2), who sheds no light on the origin of the Ebionites, but says that while they admit the world to have been made by the true God (in contrast to the Demiurge of the Gnostics), they held that Christ was a miraculously endowed man, and rejected Paul as an apostate from the Mosaic law to the customs and ordinances of which, including circumcision, they steadily adhered. A similar account is given by Hippolytus *(Haer.* vii, 35), who invents a founder named Ebion. Origen *(Contra Celsum,* v. 61; *In Matt.* tom. xvi, 12) divides the Ebionites into two classes according to their acceptance or rejection of the virgin birth of Jesus, but says that all alike reject the Pauline epistles. This is confirmed by Eusebius, who adds that even those who admitted the virgin birth did not accept the pre-existence of Jesus as Logos and Sophia. They kept both the Jewish Sabbath and the Christian Lord's day, and held extreme millenarian ideas in which Jerusalem figured as the centre of the coming Messianic kingdom. Epiphanius with his customary confusion makes two separate sects, Ebionites and Nazarenes; both names, however, refer to the same people (the Jewish Christians of Syria), the latter going back to the designation of apostolic times (Acts xxiv, 5), and the former being the term usually applied to them in the ecclesiastical literature of the 2nd and 3rd centuries.

The origin of the Nazarenes or Ebionites as a distinct sect is very obscure, but may be dated with much likelihood from the edict of Hadrian which in 135 finally scattered the old church of Jerusalem. While Christians of the type of Aristo of Pella and Hegesippus, on the snapping of the old ties, were gradually assimilated to the great church outside, the more conservative section became more and more isolated and exclusive. "It may have been then that they called themselves the Poor Men, probably as claiming to be the true representatives of those who had been blessed in the Sermon on the Mount, but possibly adding to the name other associations." Out of touch with the main stream of the church they developed a new kind of pharisaism. Doctrinally they stood not so much for a theology as for a refusal of theology, and, rejecting the practical liberalism of Paul, became the natural heirs of those early Tudaizers who had caused the apostle so much annoyance and trouble. Though there is insufficient justification for dividing the Ebionites into two separate and distinct communities, labelled respectively Ebionites and Nazarenes, we have good evidence, not only that there were grades of Christological thought among them, but that a considerable section, at the end of the 2nd century and the beginning of the 3rd, exchanged their simple Judaistic creed for a strange blend of Essenism, Gnosticism—as in the Clementine literature (*q.v.*) of the 3rd century—and Christianity.

See W. Beveridge, art. "Ebionism" in Hastings *Encyclopaedia of Religion and Ethics,* with refs.; articles "Ebioniten," "Elkasaiten," "Clementinen," in Herzog-Hauck, *Realenzyclopädie,* with refs.; F. J. A. Hort, *Judaistic Christianity* (still valuable); Harnack, *History* of *Dogma* (Eng. tr., vol. i); Lightfoot, "St. Paul and the Three" in *Commentary on Galatians;* Ottley, *Doctrine of the Incarnation,* pt. iii, § 2; and the general church histories.

EBNER-ESCHENBACH, MARIE, FREIFRAU VON (1830–1916), Austrian novelist, was born at Zdislavič in Moravia, on Sept. 13, 1830, the daughter of a Count Dubsky. She lost her mother in early infancy, but received a careful intellectual training from two slepmothers. In 1848 she married the Austrian captain, and subsequent field marshal, Moritz von Ebner-Eschenbach, and resided first at Vienna, then at Klosterbruck, where her husband had a military charge, and after 1860 again at Vienna. Her first essay was with the drama *Maria Stuart in Schottland,* which *P.* E. Devrient produced at the Karlsruhe theatre in 1860, but she found her true sphere in narrative. Commencing with *Die Prinzessin von Banalien* (1872), she graphically depicted in *Bofena* (1876, 4th ed. 1899) and *Das Gemeindekind* (1887, 4th

ed. 1900) the surroundings of her Moravian home, and in *Lotti, die Uhrmacherin* (1883, 4th ed. 1900), *Zwei Comtessen* (1885, 5th ed. 1898; Eng. trans. 1893), *Unsühnbar* (1890, 5th ed. 1900) and *Glaubenslos?* (1893) the life of the Austrian aristocracy in town and country. Later books are *Neue Erzahlungen* (1881, 3rd ed. 1894), *Aphorismen* (1880, 4th ed. 1895), *Parabehz, Märchen und Gedichte* (2nd ed. 1892), *Aus Spatherbsttagen* (1901) and *Agave* (1903). Frau von Ebner-Eschenbach's incisive wit and masterly character-drawing give her a foremost place among the German writers of her time. She died in Vienna on March 12, 1916.

See A. Bettelheirn, "Marie von Ebner Eschenbach und Julius Rodenberg," *Deutsche Rundschau.* Jahrg. *46,* pp. 6–23 (Berlin, 1920); A. Bettelheim, *Marie von Ebner Eschenbach's Wirken und Vermächtnis* (Leipzig, 1920).

EBONITE, a substance manufactured by over-vulcanizing rubber. Pure rubber is mixed with about 40% of sulphur by rolling, and the resulting mass heated for from six to ten hours at a temperature of 150°. The valuable material thus obtained is a non-conductor of electricity and resists many chemical reagents. *(See* RUBBER: PRODUCTION AND MANUFACTURE.)

EBONY, the wood of trees of the genus *Diospyros* (family Ebenaceae), widely distributed in the tropical parts of the world. The best kinds are very heavy, deep black, and consist of heartwood only. On account of its colour, durability, hardness and susceptibility of polish, ebony is much used for cabinet work and inlaying, pianoforte-keys, knife-handles and turned articles. The best Indian and Ceylon ebony is furnished by *D. Ebenum,* which grows in abundance throughout the flat country west of Trincomalee in Ceylon. The tree is distinguished by the inferior width of its trunk, and its jet-black, charred-looking bark, beneath which the wood is perfectly white until the heart is reached. The wood is stated to excel all other varieties in the fineness and intensity of its dark colour. Although the centre of the tree alone is employed, reduced logs 1 to 3ft. in diameter can readily be procured. Much of the East Indian ebony is yielded by *D. melanoxylon* (Coromandel ebony), *a* large tree attaining a height of 60 to 8oft., and 8 to 1oft. in circumference, with irregular rigid branches, and oblong or oblong-lanceolate leaves. The wood of *D. tomentosa,* a native of north Bengal, is black, hard and of great weight. *D. montana,* another Indian species, produces a yellowish-grey soft but durable wood. *D. quaesita* is the tree from which is obtained the wood known in Ceylon as *Calanzander.* Its closeness of grain, great hardness and fine hazel-brown colour, mottled and striped with black, render it valuable for veneering and furniture making. *D. dendo,* a native of Angola, is a valuable timber tree, 25 to 35ft. high, with a trunk 1 to 2ft. in diameter. The heart-wood is very black and hard and is known as black ebony, also as billet-wood, Gabun, Lagos, Calabar or Niger ebony. What is termed Jamaica or American ebony, and the green ebony of commerce, is produced by *Brya Ebenus,* a leguminous tree or shrub, having a trunk rarely more than 4in. in diameter, flexible spiny branches, and orange-yellow, sweet-scented flowers. The heart-wood is rich dark brown, heavier than water, exceedingly hard and capable of receiving a high polish.

Ebony was among the articles of merchandise brought to Tyre (Ezekiel xxvii. 15), and Herodotus states (iii. 97) that the Ethiopians every three years sent a tribute of 200 logs of it to Persia. By the ancients it was esteemed of equal value for durability with the cypress and cedar *(see* Pliny, *Nat. Hist.* xii. 9, xvi. 79). According to Solinus (*Polyhistor,* Paris, 1621), it was employed by the kings of India for sceptres and images, also on account of its supposed antagonism to poison, for drinking-cups. The hardness and black colour of the wood appear to have given rise to the tradition, alluded to by Southey (*Thalaba,* i. 22), that the tree produced neither leaves nor fruit, and was never seen exposed to the sun.

EBRARD, JOHANNES HEINRICH AUGUST (1818–1888), German theologian, was born at Erlangen on Jan. 18, 1818. Educated in his native town and at Berlin, he became *Privatdocent* at Erlangen (1841) and then professor of theology at Zürich (1844). From 1847–61 he held a similar post at Erlangen, where in 1875 he became pastor of the French reformed church. His chief works were *Christliche Dogmatik* (2 vols., 1851), *Vorlesungen über praktische Theologie* (1864), *Handbuch der Christ. Kirchen- u. Dogmengesch.* (4 vols. 1865–66), *Apologetik* (1874–75, Eng. trans. 1886). He also edited and completed H. Olshausen's commentary, himself writing on the Epistle to the Hebrews, the Johannine Epistles and Revelation. He died at Erlangen on July 23, 1888.

EBRO (anc. *Iberus* or *Hiberus*), the only one of the five great rivers of the Iberian Peninsula which flows into the Mediterranean. The Ebro, approximately 465 m. in length, rises at Fuentibre, a hamlet among the Cantabrian mountains, in the province of Santander; at Reinosa, 4 m. E., it is joined on the right by the Hijar, and thus gains considerably in volume. It flows generally east by south through a tortuous valley as far as Miranda de Ebro. The chief cities on its banks are Logroño, Calahorra, Tudela, Saragossa and Caspe. Near Mora in Catalonia it forces a way through the coastal mountains, and, passing Tortosa, falls into the Mediterranean about 80 m. S.W. of Barcelona. It drains an area of nearly 32,000 sq.m. Its principal tributaries are—(right) the Jalon with its affluent the Jiloca, the Huerva, Aguas, Martin, Guadalope and Matarraña; (left) the Ega, Aragon, Arba, Gallego and the Segre with its system of confluent rivers. The Ebro and its tributaries have been utilized for irrigation since the Moorish conquest; the main stream becomes navigable by small boats about Tudela; but seafaring vessels cannot proceed farther than Tortosa. The great Imperial Canal, begun under the emperor Charles V., proceeds along the right bank from a point about 3 m. below Tudela, to El Burgo de Ebro, 5 m. below Saragossa; the irrigation canal of Tauste skirts the opposite bank for a shorter distance; and the San Carlos or New Canal affords direct communication between Amposta at the head of the delta and the harbour of Los Alfaques.

EBROÏN (d. 681), Frankish "mayor of the palace," was a Neustrian, and wished to impose the authority of Neustria over Burgundy and Austrasia. In 656, at the moment of his accession to power, Sigebert III., the king of Austrasia, had just died, and the Austrasian mayor of the palace, Grimoald, was attempting to usurp the authority. The great nobles, however, appealed to the king of Neustria, Clovis II., and unity was re-established. But in spite of a very firm policy Ebroïn was unable to maintain this unity, and while Clotaire III., son of Clovis II., reigned in Neustria and Burgundy, he was obliged in 660 to give the Austrasians a special king, Childeric II., brother of Clotaire III., and a special mayor of the palace, Wulfoald. His efforts to maintain the union of Neustria and Burgundy were opposed by the great Burgundian nobles, who rose under St. Leger (Leodegar), bishop of Autun, defeated Ebroin, and interned him in the monastery of Luxeuil (670). Soon, however, Leger was defeated by Wulfoald and the Austrasians, and was himself confined at Luxeuil in 673. Ebroi'n and Leger then left the cloister. Each looked for support to a different Merovingian king, Ebroi'n even proclaiming a false Merovingian as sovereign. Leger was besieged in Autun, was forced to surrender and had his eyes put out, and, on Oct. 12, 678, he was put to death after undergoing prolonged tortures. The church honours him as a saint. After his death Ebroi'n became sole and absolute ruler of the Franks, imposing his authority over Burgundy and subduing the Austrasians, whom he defeated in 678 at Bois-du-Fay, near Laon. He was assassinated in 681.

Latina,* vol. xcvi.); "Vita metrica" in *Poëtae Latini aevi Carolini,* vol. iii. (*Mon. Germ. hist.*); J. B. Pitra, *Histoire de Saint Léger* (1846); and J. Friedrich, "Zur Gesch. des Hausmeiers Ebroi'n," in the *Proceedings of the Academy of Munich* (1887, pp. 42–61).

EBURĀCUM or EBORĀCUM (probably a later variant), Roman name of York (*q.v.*) in England. Established about 75–80 as fortress of the Ninth legion and garrisoned (after the annihilation of that legion about A.D. 118) by the Sixth legion, it developed outside its walls a town of civil life, which later obtained Roman municipal rank and in the 4th century was the seat of a Christian bishop. The fortress and town were separated by the Ouse. On the left bank, where the minster stands, was

the fortress, of which the walls can be partly traced. At the west corner a bastion of the 4th century type (the so-called Multangular Tower) survives, while at the east corner an internal tower of earlier date has been uncovered. The municipality occupied the right bank near the present railway station. The place was important for its garrison and as an administrative centre. The name is preserved in the abbreviated form Ebor in the official name of the archbishop of York, but the philological connexion between Eboracum and the modern name York is doubtful and bas probably been complicated by Danish influence. (S. N. M.)

EÇA DE QUEIROZ, JOSE MARÍA (1843- goo), Portuguese novelist, was born at Villa do Conde, his father being a retired judge. Entering the consular service in 1872, he went to Havana, and, after a tour in the United States, was transferred two years later to Newcastle-on-Tyne and in 1876 to Bristol. In 1888 he became Portuguese consul-general in Paris and died there in 1900.

Queiroz in 1870, in collaboration with Ramalho Ortigão, wrote a sensational story, *The Mystery* of *the Cintra Road,* but the first publication which brought him fame was *The Farpas,* a series of satirical and humorous sketches of various phases of social life. At this period French literature and French politics interested Queiroz profoundly, while he ignored the *belles-lettres* of his own country and its public affairs. He founded the Portuguese Realist-Naturalist school, of which he remained for the rest of his life the chief exponent, by a powerful romance, *The Crime of Father Amaro,* written in 1871 at Leiria but only issued in 1875. During a stay in England he produced two masterpieces, *Cousin Basil* and *The Maias,* but they show no traces of English influence, nor again are they French in tone, for his disillusionment progressed and was completed when he went to Paris and had to live under the régime of the Third Republic. Settling at Neuilly, the novelist became chronicler, critic and letter-writer as well, and in all these capacities Queiroz displayed a spontaneity, power and artistic finish unequalled in the literature of his country since the death of Garrett. Many of his pages descriptive of natural scenery, such for instance as the episode of the return to Tormes in *The City and the Mountains,* are classic examples of Portuguese prose. He manifested a predilection for middle-class types, but his portrait-gallery comprises men and women of all social conditions.

Queiroz also wrote a number of short stories, some of which have been printed in a volume under the title of *Contos.* The gems of this remarkable collection are perhaps *The Peculiarities* of *a Fair-haired Girl, A Lyric Poet, José Matthias* and *The Corpse.*

One of Queiroz's romances and two of his short stories have been published in English. **An** unsatisfactory version of *Cousin Basil,* under the title *Dragon's Teeth,* appeared at Boston, U.S.A., in 1889, while *Sweet Miracle* has had three editions in England and one in America, and there is also a translation of *O Defunto (The Corpse),* under the name of *Our Lady of the Pillar. See* J. Pereira de Sampais, *A Geração Nova — Os Novellistas* (Oporto, 1886), and Senhor Batalha Reis's preface to some prose fragments of Queiroz edited by him and named *Prosas Barbaras* (Oporto, 1903).

ECARTE (Fr. for "separated," "discarded"), a game at cards, of modern origin, probably first played in the Paris *salons* in the first quarter of the 19th century. It is a development of a very old card game called *la triomphe* or *French-ruff.* Écarté is generally played by two persons, but a pool of three may be formed, the player who is out taking the place of the loser, and the winner of two consecutive games winning the pool.

The small cards (from the two to the six, both inclusive) are rernoved from an ordinary pack. The players cut for deal, the higher having the choice. The king is highest, the ace ranking next below the knave. The dealer gives five cards to his adversary, and five to himself, by two at a time to each and by three at a time to each or vice versa. The eleventh card is turned up for trumps. If it is a king, the dealer scores one, at any time before the next deal. The non-dealer then looks at his cards. If satisfied with them he plays, and there is no discarding; if not satisfied he "proposes." The dealer may either accept or refuse. If he accepts, each player discards, face downwards, as many cards or "stock," first to complete the non-dealer's hand to five, cards as he thinks fit, and fresh ones are given from the undealt then to complete the dealer's. To ask for "a book" is to ask for five cards. Similarly a second proposal may be made, and so on, until one player is satisfied with his hand. If the dealer refuses, the hand is played without discarding. If the non-dealer announces that he holds the king of trumps, he scores one; similarly. if the dealer holds the king and announces it, he scores one. The announcement must be made before playing one's first card, or if that card be the king, on playing it. The non-dealer, being satisfied with his hand, leads a card. The dealer plays a card to it, the two cards thus played forming a trick. The winner of the trick leads to the next, and so on. The second to play to a trick must follow suit if able, and must win the trick if he can.

The scores are for the king and for the majority of tricks. The player who wins three tricks scores one for the "point"; if he wins all five tricks, he scores two for the "vole." If the non-dealer plays without proposing, or the dealer refuses the first proposal, and fails to win three tricks, the adversary scores two, but no more even if he wins the vole. The game is five up. The points are conveniently marked with a three-card and a two-card, as at euchre. The three is put face upwards with the two face downwards on the top of it. When one or two or three points are scored the top card is moved so as to expose them. At four, one pip of the two-card is put under the other card. Games may be recorded similarly.

Hints to Players. — The following hints may be of service to beginners:—

Do not announce the king until in the act of playing your first card.

The hands which should be played without proposing, called *jeux de rigle* (standard hands), ought to be thoroughly known. They are as follows:—

1. AH hands with three or more trumps, whatever the other cards.
2. Hands with *two trumps* which contain also:—
   (*a*) Any three cards of one plain suit;
   (*b*) Two cards of one plain suit, one being as high as a queen;
   (*c*) Two small cards of one suit, the fifth card being a king of another suit;
   (*d*) Three high cards of different suits.
3. Hands with *one trump,* which contain also:—
   (a) King, queen, knave of one suit, and a small card of another;
   (*b*) Four cards of one suit headed by king;
   (*c*) Three cards of one suit headed by queen, and queen of another suit.
4. Hands with *no trump,* which contain three queens or cards of equal value in different suits, *e.g.,* four court cards.
5. Hands from which only two cards can be discarded without throwing a king or a trump.

Holding cards which make the point certain, propose. If you hold a *jeu de règle,* and one of the trumps is the king, propose, as your adversary cannot then take in the king.

When discarding, throw out all cards except trumps and kings.

If your adversary proposes you should accept, unless you are guarded in three suits (a queen being a sufficient guard), or in two suits with a trump, or in one suit with two trumps. Hence the rule not to discard two cards, unless holding the king of trumps, applies to the dealer.

The hands with which to refuse are the same as those with which to play without proposing, except as follows:—

1. Two trumps and three cards of one plain suit should not be played unless the plain suit is headed by a court card.
2. One trump and a tierce major is too weak, unless the fifth card is a court card. With similar hands weaker in the tierce major suit, accept unless the fifth card is a queen.
3. One trump and four cards of a plain suit is too weak to play.
4. One trump and two queens is too weak, unless both queens are singly guarded.
5. One trump, queen of one suit, and knave guarded of another should not be played unless the queen is also guarded, or the card of the fourth suit is a court card.
6. One trump, a king and a queen, both unguarded, should not be played, unless the fourth suit contains a card as high as an ace.
7. Four court cards without a trump are too weak to play, unless they are of three different suits.

Refuse with three queens, if two are singly guarded; otherwise, accept.

Lead from your guarded suit, and lead the highest.

If the strong suit led is not trumped, persevere with it, unless with king of trumps, or queen (king not having been announced), or knave ace, when lead a trump before continuing your suit.

You should not lead trumps at starting, unless you hold king or queen, knave, or knave ace, with court cards out of trumps.

The score has to be considered. If the dealer is at four, and the king is not in your hand nor turned up, play any cards without proposing which give an even chance of three tricks, *e.g.*, a queen a guarded knave, and a guarded ten. The same rule applies to the dealer's refusal.

At the adverse score of four, and king not being in hand or turned up, any hand with one trump should be played, unless the plain cards are very small and of different suits.

If the non-dealer plays without proposing when he is four to three, and the dealer holds the king he ought not to mark it. The same rule applies to the non-dealer after a refusal, if the dealer is four to three.

At the score of non-dealer three, dealer four, the dealer should refuse on moderate cards, as the player proposing at this score must have a very bad hand.

At four a forward game should not be played in trumps, as there is no advantage in winning the vole.

Laws of Écarté.—The following laws are abridged from the revised code adopted by the Turf club: A cut must consist of at least two cards. Cards exposed in cutting, fresh cut. Order of distribution of cards, whether by three and two, or vice versa, once selected, dealer must not change it during game. Player announcing king when he has not got it, and playing a card without declaring error, adversary may correct score and have hand over again. If offender wins point or vole that hand, he scores one less than he wins. Proposal, acceptance, or refusal made cannot be retracted. Cards discarded must not be looked at. Cards exposed in giving cards to non-dealer, he has option of taking them or of having next cards; dealer exposing his own cards, no penalty. Dealer turning up top card after giving cards, cannot refuse second discard. Dealer accepting when too few cards in stock to supply both, non-dealer may take cards, and dealer must play his hand. Card led in turn cannot be taken up again. Card played to a lead can only be taken up prior to another lead, to save revoke or to correct error of not winning trick. Card led out of turn may be taken up prior to its being played to. Player naming one suit and leading another, adversary has option of requiring suit named to be led. If offender has none, no penalty. Player abandoning hand, adversary is deemed to win remaining tricks and scores accordingly. If a player revokes or does not win trick when he can do so, the adversary may correct score and have hand replayed.

ECBATANA (Old Persian *Hangmatána*), situated at the foot of Mount Orontes (Alwand), was the capital of Media and the summer residence of the Achaemenian kings, being afterwards also the Parthian capital. According to the Greeks (*e.g.*, Herodotus, i., 96 ff.), it was founded by Deioces the Mede, but it appears to be mentioned in an inscription of Tiglath-Pileser I., who was much earlier. Though surrounded by seven walls and possessing a citadel, that was at the same time a treasure-house, it was captured by Cyrus from Astyages in 550 B.C., and was taken from the last Achaemenian by Alexander in 330 B.C. Amongst the Achaemenian relics found in the city in recent times is a trilingual inscription in which Artaxerxes Mnemon celebrated the building of a palace. The Ecbatana at which, according to Herodotus (iii., 64), Cambyses died, is probably a blunder for Hamáth.

Geiger and E. Kuhn, *Grundriss der Iranischen Philologie*, ii. (1896–1904). *See* also HAMADAN and PERSIA: *Ancient History*. (R. LEV.)

ECCARD, JOHANN (1553–1611), German composer of church music, was born at Miihlhausen, Thuringia, in 1553. He studied at Munich, under Orlando Lasso, in whose company he is said to have visited Paris. In 1583 he became assistant conductor, and in 1599 conductor, at Konigsberg, to Georg Friedrich, margrave of Brandenburg-Anspach, and in 1608 he was called by the elector Joachim Friedrich to Berlin as chief conductor. He died at Konigsberg in 1611. Eccard's works consist exclusively of vocal compositions, such as songs, sacred cantatas and chorales for four or five, and sometimes for seven, eight, or even nine voices. Their polyphonic structure is remarkable and still excites the admiration of musicians. At the same time his works are instinct with a spirit of true religious feeling. Eccard and his school are inseparably connected with the history of the Reformation and "Ein' feste Burg" is only one of many Lutheran hymns for which he provided memorable settings.

See K. G. A. von Winterfeld, *Deu Evangelische Kirchengesang* (1843); and G. Reichmann, *Joh. Eccards weltliche Werke* (Heidelberg, 1922).

ECCELINO DA ROMANO (1194–1259), Ghibelline leader, and supporter of the emperor Frederick II., was born on April 25, 1194, of a German family settled in Italy in the first half of the 11th century. They were lords of Romano, near Padua. In 1226, at the head of a band of Ghibellines, Eccelino seized Verona and became *podestà* of the city. He lost Verona, but regained it in 1230; and in 1232 Frederick II. issued a charter confirming him in his possessions. In 1236–37 the emperor gave him the government of Vicenza, Padua and Treviso; and on Nov. 27, 1237, he shared in the victory over the Lombards at Cortenuova. In 1238 he married Frederick's natural daughter, Selvaggia; in 1239 was appointed imperial vicar of the march of Treviso; but in the same year was excommunicated by Pope Gregory IX. After Frederick's death in 1250 he supported his son, the German king Conrad IV. His cruelties had, however, aroused general disgust, and in 1254 he was again excommunicated. In 1256 Pope Alexander IV. proclaimed a crusade against him, which was led by Philip, archbishop of Ravenna. Eccelino lost Padua, but on Sept. 1, 1258, he defeated his enemies at Torricella. At Cassano on Sept. 27, 1259, Eccelino was wounded and taken prisoner. Enraged at his capture, he tore the bandages from his wounds, refused to take food and died at Soncino on Oct. 7, 1259. In the following year his brother Albert was put to death, and the Romano family became extinct. Eccelino, sometimes called the tyrant, acquired a reputation for cruelty that gained him a place in Dante's Inferno; but his unswerving loyalty to Frederick II. contrasts favourably with many of his contemporaries. Eccelino is the subject of a novel by Cesare Cantu and of a drama by J. Eichendorff.

See J. M. Gittermann, *Ezzelino da Romano* (Freiburg, 1890); S. Mitis, *Storia d'Ezzelino IV. da Romano* (Maddaloni, 1896); and F. Stieve, *Ezzelino von Romano* (Leipzig, 1909). *See* also Hampe, *Mittelalt. Geschichte* (1922).

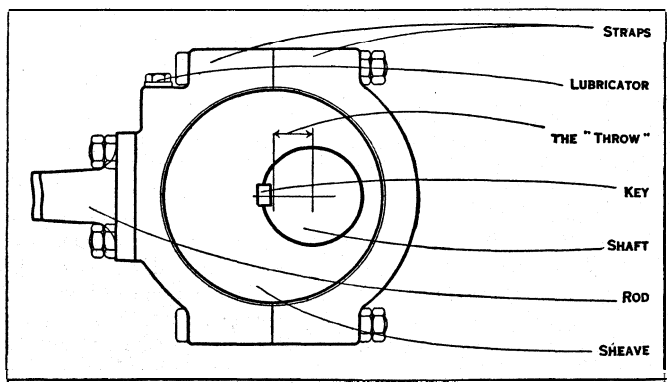

DIAGRAM OF AN ECCENTRIC USED IN STEAM ENGINES, SHOWING PARTS
The eccentric converts rotary into reciprocating motion and moves the valve controlling the flow of steam and the exhaust to and from the cylinder

ECCENTRIC, from two Greek words, meaning literally "out from the centre," and thus used to connote generally any deviation from the normal. In ancient astronomy the word denotes a circle round which a body revolves, but whose centre is displaced from the visible centre of motion. In early times the ellipses in which the planets revolve around the sun as focus could not be distinguished from circles, but the unequal angular motion due to ellipticity was observed. A point, however, can be found on the major axis of the ellipse (namely the empty focus) such that the angular velocity of the planet about it is nearly

constant. It was therefore supposed that the deferent of the epicycle of the planet moved uniformly in a circle about this point. For eccentric angle see ELLIPSE.

In engineering, an eccentric is a disc mounted out of centre on a shaft, to give reciprocating movement to a lever; it is an agent much used in steam-engines and other mechanisms. It is fixed with a key or screw on to the crankshaft and moves the valve-rod to and fro to control the flow of steam and the exhaust. Using two eccentrics with link-motion, the engine can be reversed, and the steam used expansively, *e.g.*, in locomotives, when a good rate of speed has been reached. A reversing eccentric is one with a slotted fitting whereby it can be moved in relation to the shaft, thus reversing the action of the valve to run the engine in the opposite direction. This is but little used, however, the link motion having preference. Eccentrics are also fitted on the popular drop-valve steam-engines, being located then on a shaft running parallel with the cylinder. An eccentric is often employed to work a pump, and operate the slides of certain machines, such as those for shearing and punching. Eccentrics are used to work the jaws of powerful rock- and stone-crushers, and to'close quick-acting clamps and safety mechanisms that check slipping.

ECCHELLENSIS (or ECHELLENSIS), **ABRAHAM** (c. 1600–1664), a learned Maronite, was born at Eckel, Syria. Educated at Rome, he became professor of Arabic and Syriac in the college of the Propaganda at Rome, and in 1646 professor at the Collège de France. Invited to take part in the preparation of an Arabic version of the Bible, Ecchellensis returned in 1652 to Rome, where he died. Of his Latin translations of Arabic works, the most important was the Chronicon *Orientale* of Ibnar-Rāhib (Paris, 1653), a history of the patriarchs of Alexandria. With Giovanni Rorelli he wrote a Latin translation of the 5th, 6th and 7th books of the Conics of Apollonius of Perga (1661). He also published *Eutychius vindicatus*, sive *Responsio* ad *Seldeni* Origines (Rome, 1661). To Le Jay's polyglot Bible he contributed the Arabic and Latin version of Ruth and the Arabic version of the third book of Maccabees.

ECCLES, municipal borough, Eccles parliamentary division, Lancashire, England, 4 m. W. of Manchester, of which it forms practically a suburb. Pop. (1938) 42,550. It is served by the L.M.S. railway. The Manchester Ship canal passes through. Before the Reformation the monks of Whalley abbey had a grange here at what is still called Monks' Hall; and in 1864 many thousands of silver pennies of Henry III. and John of England and William I. of Scotland were discovered near the spot. From early times "wakes" were held at Eccles, and bull-baiting, bear-baiting and cock-fighting were carried on. Under Elizabeth these festivals were abolished, but were revived under James I., and maintained until late in the 19th century. The church of St. Mary, believed to date from the 12th century, has been much restored. There are several modern churches and chapels, a town hall and numerous cotton mills, while silk-throwing and the manufacture of fustians and ginghams are also among the industries, and there are also large engine works. Eccles cakes have a wide reputation. Eccles was incorporated in 1892. The borough maintains the tramway service, etc., but water and gas are supplied from Manchester and Salford respectively.

ECCLESFIELD, township, Wortley rural district, Penistone parliamentary division, West Riding of Yorkshire, England, 5 m. N. of Sheffield on the L.M.S. and L.N E. railways. Population 22,944. The church of St. Mary is Perpendicular, with a central tower. It contains excellent woodwork, and formerly bore the familiar title of the "Minster of the Moors." Ecclesfield was the seat of a Benedictine priory, which passed to the Carthusians in the 14th century. Cutlery and tools are largely manufactured, and there are coal-mines, paper-mills, and iron and fire-clay works.

ECCLESHALL, market town, Stone parliamentary division, Staffordshire, England; 7 mi. N.W. from Stafford, and 140 mi. from London. Pop. (1931) 3,532. Holy Trinity church is principally Early English and has fine stained glass. Several bishops of Lichfield are buried there, as Eccleshall castle, of which only the walls enclosing the moat remain, the main building being relatively modern, was the episcopal residence from the 13th century until 1867. Blore Heath was the scene of a defeat of the Lancastrians by the Yorkists in 1459.

ECCLESIA, the general assembly of freemen in Athens (ἐκκλησία). In the primitive state the king was absolute, though his great nobles in council (see BOULE) were able to influence him considerably. In the earliest times the free people, *i.e.*, the fighting force of the state, were called together to ratify the decisions of the king. In Athens, as in Rome, where the Plebs obtained the codification of the laws (the Twelve Tables), it was owing to the growing power of the people meeting in the agora that Dracon was entrusted with the task of publishing a code of law.

The precise powers which Solon gave the people are not known. The executive power (see ARCHON) was still vested in the Eupatrid class (see EUPATRIDAE). It seems that, though the officials of the state were still Eupatrid, the Ecclesia elected those of the Eupatrids whom they could trust, and had the right of criticizing their official actions. Solon admitted the Thetes (see SOLON) to the Ecclesia, thus recognizing them as citizens. Under Cleisthenes (*q.v.*) the Ecclesia remained the sovereign power. The relation of Boule and Ecclesia in the Cleisthenic democracy was of the greatest importance. The Ecclesia alone, a heterogeneous body of untrained citizens, could not have drawn up intelligible measures; the preliminary drafting was done by the Boule (*q.v.*). In the 5th century the functions of the Ecclesia and the popular courts of justice were increased by the exigencies of empire. At the beginning of the 4th century B.C. the system of payment was introduced (see below). Under Roman rule the powers of the Ecclesia and the popular courts were much diminished. They still assembled to elect strategi, and, under Hadrian, had some small judicial duties, but as a governing body the Ecclesia died when, Athens became a civitas *libera* under Roman protection.

Constitution and Functions.—Throughout the period of Athenian greatness the Ecclesia was the sovereign power. The regular place of meeting was the Pnyx. From the 5th century it met sometimes in the theatre, which in the 3rd century was the regular place. Special meetings were held at times at Peiraeus. Certain meetings, however, for voting ostracism (*q.v.*) and on questions affecting individual status took place in the agora. Meetings were (1) ordinary, (2) extraordinary, and (3) convened by special messengers (kuriai *sunklētoi* and katakldtoi), these last being called when it was desirable that the country people should attend. At ordinary meetings the attendance was practically confined to Athenian residents. According to Aristotle there were four meetings in each of the prytanies; probably only the first of these was called *Kuria*. In the kuria *ekklēsia* of each month took place the Epicheirotonia (monthly inquiry) of the state officials, and if it proved unsatisfactory a trial before the Heliaea (supreme court) was arranged; the council reported on the general security and the corn supply. In the sixth prytany of each year at the *kuria* ekkldsia the question whether ostracism should take place that year was put to the vote. On occasions of sudden importance the herald of the council summoned the people with a trumpet, and sometimes special messengers were despatched to "bring in" the country people (katakalein).

All Athenians over the age of 18 years were eligible to attend the assembly, save those who for some reason had suffered atimia (loss of civil rights). The introduction of pay, which belongs to the early years of the 4th century, was a device to secure a larger attendance. The rate rose from one to two obols and then to three obols, while at the time of Aristotle it was one and a half drachmas for the kuria ekkldsia and one drachma for other meetings.

Procedure.—The proceedings opened with formalities: the purification; the curse against all who should deceive the people; the report as to the weather omens. The assembly was always dismissed if there were thunder, rain, or an eclipse. These formalities over, the Prytaneis communicated the probouleuma of the council, without which the Ecclesia could not debate. This recommendation either submitted definite proposals or merely brought the agenda before the assembly. It explained the business

in hand, which otherwise must often have been beyond the grasp of a miscellaneous assembly. After the reading, a preliminary vote was taken on the question whether the council's report should be accepted *en* bloc. If it was decided to discuss, the herald called upon people to speak. Any person, without distinction of age or position, might obtain leave to speak; any member of the assembly (1) might propose an amendment, (2) might draw up a new resolution founded on the principal motion, (3) might move the rejection of the motion and the substitution of another, (4) might bring in a motion asking the council for a recommendation on a particular matter, (5) might petition the council for leave to speak on a given matter to the assembly. Voting usually was by show of hands and the decision of the assembly had absolute validity. These decisions were deposited in the *Mētrōon* where state documents were preserved; peculiarly important decrees were inscribed also on a column (*stēlē*) erected on the Acropolis. The power of the council was far from sufficient. The real check on the vagaries of amateur legislators was the graphd paranomdn. Any man was at liberty to give notice that he would proceed against the mover of a given resolution. A trial in a Heliastic court was then arranged, and the plaintiff had to prove that the resolution in question contravened an existing law. If this contention was upheld by the court, the resolution was annulled and the defendant had to appear in a new trial for the assessment of the penalty, which was usually a fine. Three convictions under this law involved a certain loss of rights; the loser could no longer move a resolution in the Ecclesia. After the lapse of a year the mover of a resolution could not be attacked. In the 4th century the *graphē* paranomdn took the place of Ostracism.

Revision **of** Laws.—In the 4th century the assembly annually took a general vote on the laws, to decide whether revision was necessary. If the decision was in favour of alteration, any private citizen might put up notice of amendments. The nomothetai, a panel selected by the *prytaneis* from the Heliaea, heard arguments for and against the changes proposed and voted accordingly; new laws so passed were liable to the graph5 paranomdn.

Judicial Functions.—The Ecclesia heard cases of *probolē* and eisangelia (impeachment—see GREEK LAW). The *probolē* was an action against sycophants and persons who had not kept their promises to the people or had disturbed a public festival. The verdict went by show of hands, but no legal consequences ensued; if the plaintiff demanded punishment he had to go to the Heliaea, which was not bound by the previous vote in the Ecclesia. Cases of eisangelia in which the penalty exceeded the legal competence of the council came before the Ecclesia in the form of a *probouleuma.* To prevent vexatious accusations, the accuser who failed to obtain one-fifth of the votes was fined 1,000 drachmas (£40).

Summary.—The Ecclesia had absolute power save for the graph5 paranomdn, which constituted the dicasteries (jurymen) in one sense the sovereign power in the state. It dealt with all matters, home and foreign. It was in practice by no means a representative assembly. The phrase used to describe a special assembly (katakldtos *ekklēsia*) shows that ordinarily the country members did not attend. Thucydides says that 5,000 was the maximum attendance, though he is referring to the time when the number of citizens was reduced owing to the plague and the Sicilian expedition. The Ecclesia did not exercise the power of law-making (*nomothesia*) in the strict sense but passed *psephismata*, which would in many cases be regarded as law in the modern sense. The Ecclesia also was concerned with the supervision of administration.

ECCLESIASTES, one of the Wisdom Books of the Old Testament (see WISDOM LITERATURE). The book, as it stands, is a collection of discourses, observations and aphorisms. The precise meaning of the Hebrew title is not certain. The Greek *ecclesiastes* means one who takes part in the deliberations of an assembly (ecclesia), a debater or speaker in an assembly (Plato, *Gorgias,* 452 E), and this is the general sense of the Hebrew word. Koheleth is employed in the book as the name of a sage. It is intended to represent him as a member of an assembly (Kahal) —not the Jewish congregation, but a body of students or inquirers, such as is referred to in xii, 9–11, a sort of collegium, of which he was the head; and as instructor of this body he gives his criticism of life. The author begins, indeed, by identifying his sage with King Solomon (i. 12, ii. 11, 12*b*); but he soon abandons this literary device, and speaks in his own name. The rendering "preacher" has a misleading connotation.

Contents.—In the book as we have it there is no orderly exposition of a theory; it rather has the appearance of a collection of extracts from a sage's notebook. It is, however, characterized throughout (except in some later additions) by a definite thought, and pervaded by a definite tone of feeling. The keynote is given in the classic phrase with which the discussion opens and with which it closes: "Vanity of vanities (*i.e.,* absolute vanity), all is vanity!" Life, says the author, has nothing of permanent value to offer. His attitude is not one of bitterness but of calm hopelessness, with an occasional tinge of disgust or contempt. He fancies that he has tried or observed everything in human experience, and his deliberate conclusion is that nothing is worth doing. He believes in an all-powerful but indifferent God, and is himself an observer of society, standing aloof from its passions and ambitions, and interested only in pointing out their emptiness.

This general view is set forth in a number of particular observations.

1. His fundamental proposition is that there is a fixed, unchangeable order in the world, a reign of inflexible law (i. 4–11, iii. 1–11, 14, 15, vii. 13, viii. 5–9); natural phenomena, such as sunrise and sunset, recur regularly; for everything in human experience a time has been set; all its phenomena are to be regarded not as utterances of a living, self-directing world, but as incidents in the work of a vast machine that rolls on for ever; there is an endless repetition—nothing is new, nothing is lost; God, the author of all, seeks out the past in order to make it once more present; it is impossible to add to or take from the contents of the world, impossible to change the nature of things; the result is unspeakable weariness—a depressing series of sights and sounds. No goal or purpose is discoverable in this eternal round. To what end was the world created? It is impossible to say. Such is Koheleth's view of life, and it is obvious that such a conception of an aimless cosmos is thoroughly non-Jewish, if we may judge Jewish thought by the great body of the extant literature.

2. Further, says Koheleth, man is impelled to study the world, but under the condition that he shall never comprehend it (iii. 11, vii. 23, 24, viii. 16, 17). God has made the world an object of man's thought, yet so that man can never find out the work that God has done (iii. 11). The reference seems to be not so much to the variety and complexity of phenomena as to the impossibility of construing them rationally or in such a way that man may foresee and provide for his future. Man is in the clutches of fate (ix. 11, 12); there is no observable relation between exertion and result in life; the race is not to the swift nor the battle to the strong.

3. Human life, Koheleth declares, is unsatisfying. He inquired, he says, into everything that is done by men under the sun (i. 12–16); God has inflicted on men a restless desire for movement and work, yet life is but a catalogue of fruitless struggles. He gives a number of illustrations. In his character of king he tried all the bodily pleasures of life (ii. 1–11); all these he set himself to enjoy in a rational way, but, when all was done, he surveyed it only to see that it was weary and unprofitable. Dropping the rôle of Solomon and speaking as an observer of life, the author declares (iv. 4) that the struggle for success is the result of rivalry among men, which has no worthy outcome. The securing of riches is a fallacious achievement—naked man comes into the world, naked he goes out,

If wealth be thus a vain thing, yet a sage might be supposed to find satisfaction in wisdom, that is, practical good sense and sagacity; but this also the author puts aside as bringing no lasting advantage, since a wise man must finally give up the fruit of his wisdom to someone else, who may be a fool, and in any case the final result for both fools and wise men is the same—both are forgotten (ii. 12–23). The whole constitution of society, in fact, seems to the sage a lamentable thing; the poor are oppressed, the earth is full of their cries, and there is no helper (iv. 1); strange social upheavals may be seen; the poor set in high places, the rich cast down, slaves on horseback, princes on foot (x. 5–7). He permits himself a sweeping generalization (vii. 25–28); human beings as a rule are bad; one may occasionally find a good man, never a good woman—woman is a snare and a curse.

4. The natural outcome of these experiences of the author is that he cannot recognize a moral government of the world. He finds, like Job, that there are good men who die prematurely notwithstanding their goodness, and bad men who live long notwithstanding their badness (vii. 15); and in general there is no moral discrimination in the fortunes of men (viii. 14, ix. 2).

5. There is no sacredness or dignity in man or in human life; man has no pre-eminence over beasts, seeing that he and they have the same final fate, die and pass into the dust, and no one knows what becomes of the spirit, whether in man's case it goes up to heaven, and in the case of beasts goes down into Sheol—death is practically the end-all; and so poor a thing is life that the dead are to be considered more fortunate than the living, and more to be envied than either class is he who never came into existence (iv. 2, 3). It is a special grievance that the wicked when they die are buried with pomp and ceremony, while men who have acted well are forgotten in the city (viii. 10).

6. That the author does not believe in a happy or active future life appears in the passage (iv. 2, 3) quoted above. The old Hebrew view of the future excluded from Sheol the common activities of life and also the worship of the national god (Isa. xxxviii. 18); he goes even beyond this in his conception of the blankness of existence in the underworld. The living, he says, at least know that they shall die, but the dead know nothing—the memory of them, their love, hate, envy, perishes, they have no reward, no part in earthly life (ix. 5, 6); there is absolutely no knowledge and no work in Sheol (ix. 10). His conclusion is that men should do now with all their might what they have to do; the future of man's vital part, the spirit, is wholly uncertain.

7. His conception of God is in accord with these views. God for him is the creator and ruler of the world, but hardly more; he is the master of a vast machine that grinds out human destinies without sympathy with man and without visible regard for what man deems justice—a being to be acknowledged as lord, not one to be loved. There can thus be no social contact between man and God, no communion of soul, no enthusiasm of service. Moral conduct is to be regulated not by divine law (of this nothing is said) but by human experience. The author's theism is cold, spiritless, without influence on life.

If now the question be asked what purpose or aim a man can have, seeing that there is nothing of permanent value in human work, an answer is given which recurs, like a refrain, from the beginning to the end of the book, and appears to be from the hand of the original author; after every description of the vanity of things comes the injunction to enjoy such pleasures as may fall to one's lot (ii. 24, 25, iii. 12, 13, 22, v. 18, 19, viii. 15, ix. 7–10, xi. 7, xii. 7). The opportunity and the power to enjoy are represented as being the gift of God; but this statement is not out of accord with the author's general position, which is distinctly theistic.

There are many sayings in the book that appear to be at variance with its fundamental thought. For example, wisdom is praised in a number of passages (iv. 13, vii. 5, 11, 12, 19, viii. 1, ix. 16, 17, x. 2, 3), though it is elsewhere denounced as worthless. It may be said that the author, while denying that wisdom (practical sagacity and level headedness) can give permanent satisfaction, yet admits its practical value in the conduct of life. This may be so; but it would be strange if a writer who could say "in much wisdom is much grief" should deliberately laud wisdom. It may be added that there are in the book a number of aphorisms about fools (v. 3 [4], vii. 5, 6, x. 1–3, 12–15) quite in the style of the book of Proverbs, some of them contrasting the wise man and the fool; these appear to be the insertions of an editor. Further, it may be concluded with reasonable certainty that the passages that affirm a moral government of the world are additions by pious editors who wished to bring the book into harmony with the orthodox thought of the time.

Many practical admonitions and homely aphorisms are scattered through the book: iv. 5, quiet is a blessing; iv. 9–12, two are better than one; iv. 17 (Eng. v. 1), be reverent in visiting the house of God (the temple and the connected buildings)—to listen (to the service of song or the reading of Scripture) is better than to offer a foolish (thoughtless) sacrifice; v. 1 (z), be sparing of words in addressing God; v. 1–5 (2–6), pay your vows—do not say to the priest's messenger that you made a mistake; vii. 2–4, sorrow is better than mirth; vii. 16–18, be not over-righteous (over-attentive to details of ritual and convention) or overwicked (flagrantly neglectful of established beliefs and customs); here "righteous" and "wicked" appear to be technical terms designating two parties in the Jewish world of the 2nd and 1st centuries B.C., the observers and the non-observers of the Jewish ritual law; these parties represent in a general way the Pharisees and the Sadducees; viii. 2–4, x. 20, it is well to obey kings and to be cautious in speaking about them, for there are talebearers everywhere; vii. 20, no man is free from sin; vii. 21, do not listen to all that you may overhear, lest you hear yourself ill spoken of; ix. 4, a living dog is better than a dead lion; xi. 1–6, show prudence, and decision in business; do not sell all your goods on one venture; act promptly and hope for the best.

Composition of the Book.—If the analysis given above is correct, the book is not a unit; it contains passages mutually contradictory and not harmonizable. Various attempts have been made to establish its unity. Other of the biblical Wisdom books (Job, Proverbs) are compilations—why not this? It is not necessary to multiply authors, as is done, for example, by Siegfried, who supposes four principal writers (a pessimistic philosopher, an Epicurean glossator, a sage who upholds the value of wisdom, and an orthodox editor) besides a number of annotators. Nor is it worth while to attempt a logical or symmetrical arrangement of the material.

A simple and adequate view of the growth of the book has been formulated by A. H. McNeile and followed by Barton. Its essence may be briefly stated. The original Koheleth, as has been indicated, was a very heretical work, nevertheless it was so brilliant and so in keeping with the mind of the Greek period that it obtained a firm hold upon the intelligence of the age. Orthodoxy, however, could not allow it to continue unchallenged or unopposed. Two sets of additions, therefore, were attached to it. One of them consists of a series of conventional aphorisms of the sages inserted to give the work a more Hebraic tone and colouring. Examples of this sort are seen in iv. 5*b*, 6, vii. 1–14. The second series is more positively and directly orthodox. It is in flat contradiction to the cold lifeless scepticism of Koheleth. It sets forth the traditional, positive and constructive view of life. It may be seen in such passages, for example, as iii. 17; iv. 17; xi. 9*d*, xii. 1*a*, 13. Had it not been for the mollifying effect of such additions, it is hardly conceivable that Koheleth would ever have entered the Canon, or held its place there long if it had found entry.

Date.—As to the date of the book, there is a gradual approach to a consensus of opinion. The Solomonic authorship has long since been given up; the historical setting of the work and its atmosphere—the silent assumption of monotheism and monogamy, the non-national tone, the attitude towards kings and people, the picture of a complicated social life, the strain of philosophic reflection—are wholly at variance with what is known of the 10th century B.C. and with the Hebrew literature down to the 5th or 4th century B.C. The introduction of Solomon, the ideal of wisdom, is a literary device of the later time and probably

deceived nobody. The decisive considerations for the determination of the date are the language, the historical background and the thought. The language belongs to the post-classical period of Hebrew. More than this, there are many resemblances between the dialect of Koheleth and that of the Mishna. Not only are new words employed, and old words in new significations, but the grammatical structure has a modern stamp—some phrases have the appearance of having been translated out of Aramaic into Hebrew. It is improbable that such Hebrew as that of Koheleth would have been written earlier than the and century B.C. (for details see Driver's Introduction). The general historical situation, also, presupposed or referred to, is that of the period from the year zoo B.C. to the beginning of our era; in particular the familiar references to kings as a part of the social system, and to social dislocations (servants and princes changing places, x. 7), suggest the troublous times of the later Greek and Maccabean rulers, of which the history of Josephus gives a good picture.

The conception of the world and of human life as controlled by natural law, a naturalistic cosmos, is alien not only to the prophetic and liturgical Hebrew literature but also to Hebrew thought in general. Whether borrowed or not, it must be late; and its resemblance to Greek ideas suggests Greek influence. The general air of Greek reflection seems unmistakable. The scepticism of Koheleth differs from that of Job in quality and scope; it is deliberate and calm, not wrung out by personal suffering; and it relates to the whole course and constitution of nature, not merely to the injustice of fortune. Such a conception has a Greek tinge, and would be found in Jewish circles, probably, not before the 2nd century B.C.

A precise indication of date has been sought in certain supposed references or allusions to historical facts. The mention of persons who do not sacrifice or take oaths (ix. 2) is held by some to point to the Essenes; if this be so, it is not chronologically precise, since we have not the means of determining the beginning of the movement of thought that issued in Essenism. So also the coincidences of thought with Ben-Sira (Ecclesiasticus) are not decisive: *cf.* iii. 14 with B.S. xviii. 6; 2-6 (3–7) with B.S. xxxiv. 1–7, vii. 19 with B.S. xxxvii. 14; x. 8 with B.S. xxvii. *26a*; xi. 10 with *B.S.* xxx. 21; xii. 10, 11 with B.S. xxxix. 2 ff., xii. 13 with B.S. xliii. 27; if there be borrowing in these passages it is not clear on which side it lies, and it is not certain that there is borrowing—the thoughts may have been taken independently by the two authors from the same source. In any case since Ben-Sira belongs to about 180 B.C., the date of Koheleth, so far as these coincidences indicate it, would not be far from 200 B.C. The contrast made in x. 16 f. between a king who is a boy and one who is of noble birth may allude to historical persons. Such identifications as have been proposed, however, do not fix the date of the book precisely; the author may have referred to events that happened before his time. The reign of Herod, a period of despotism and terror, and of strife between Jewish religious parties, is preferred by some scholars (Graetz, Cheyne and others) as best answering to the social situation depicted in the book, while still others (as Renan) decide for the reign of Alexander Jannaeus (104–78 B.C.). The data are not numerous and distinct enough to settle the question beyond determining general limits; for reasons given above the book can hardly have been composed before 200 B.C., and if, as is probable, a Septuagint text shows the influence of Aquila, it is to be put earlier than 50 B.C. Probably also, its different parts are of different dates.

Of the author nothing is known beyond the obvious fact that he was a man of wide observation and philosophic thought, of the Sadducean type in religion, but non-Jewish in his attitude toward life. He was, doubtless, a man of high standing, but neither a king nor a high priest, certainly not the apostate priest Alcimus (1 Macc. vii. ix.); nor was he necessarily a physician—there are no details in ch. xii. or elsewhere that any man of good intelligence might not know. The book is a mixture of prose and poetry, in about equal proportions.

The fortunes of the book are not known in detail, but it is clear that its merciless criticism of life and its literary charm made it popular, while its scepticism excited the apprehensions of pious conservatives. Possibly the *Wisdom* of *Solomon* (*c.* 50 B.C.) was written partly as a reply to it. The claim of sacredness made for it was warmly contested by some Jewish scholars. In spite of the relief afforded by orthodox additions, it was urged that its Epicurean sentiments contradicted the Torah and favoured heresy. Finally, by some process of reasoning not fully recorded, the difficulties were set aside and the book was received into the sacred canon; but not until the synod of Jabneh in A.D. 90 was its right to remain in the canon officially and finally allowed. Jerome (on Eccl. xii. 13, 14) declares that the decisive fact was the orthodox statement at the end of the book; the one important thing is to fear God and keep His commandments. It is not certain that it is quoted in the New Testament, but it appears to be included in Josephus' list of sacred books.

McNeile, Introduction to Ecclesiastes (1904); G. A. Barton in the Internal *Crit. Comm.* (1908). M. Jastrow, *A* Gentle Cynic (1919); H. Ranston, Ecclesiastes and the Early Greek Wisdom Literature (192j). (C. H. T.; J. M. P. S.)

ECCLESIASTICAL COMMISSIONERS, in England, a body corporate, whose full title is "Ecclesiastical and Church Estates Commissioners for England," invested with very important powers, under the operation of which extensive changes have been made in the distribution of the revenues of the Established Church. Their appointment was one of the results of the vigorous movements for the reform of public institutions which followed the Reform Act of 1832. In 183; two commissions were appointed "to consider the state of the several dioceses of England and Wales, with reference to the amount of their revenues and the more equal distribution of episcopal duties, and the prevention of the necessity of attaching by commendam to bishoprics certain benefices with cure of souls; and to consider also the state of the several cathedral and collegiate churches in England and Wales, with a view to the suggestion of such measures as might render them conducive to the efficiency of the established church, and to provide for the best mode of providing for the cure of souls, with special reference to the residence of the clergy on their respective benefices." And it was enacted by an Act of 1835 that during the existence of the commission the profits of dignities and benefices without cure of souls becoming vacant should be paid over to the treasurer of Queen Anne's Bounty. In consequence of the recommendation of these commissioners, a permanent commission was appointed by the Ecclesiastical Commissioners Act 1836 for the purpose of preparing and laying before the king in council such schemes as should appear to them to be best adapted for carrying into effect the alterations recited in the act. The new commission was constituted a corporation with power to purchase and hold lands for the purposes of the act, notwithstanding the statutes of mortmain. The first members of the commission were the two archbishops and three bishops, the lord chancellor and the principal officers of state, and three laymen named in the act.

The constitution of the commission was amended by the Ecclesiastical Commissioners Acts, 1840–41, and 1868. The commission consists of the two archbishops, all the bishops, the deans of Canterbury, St. Paul's and Westminster, the lord chancellor, the lord president of the council, the first lord of the treasury, the chancellor of the exchequer, one of the principal secretaries of State, the lord chief justice, the master of the rolls, and certain lay members of the Church of England appointed by the crown and by the archbishop of Canterbury. The crown also appoints two laymen as church estates commissioners, and the archbishop of Canterbury one. These three are the joint treasurers of the commission and form, with two members appointed by the commission, the church estates committee.

The commission presents an annual report to parliament in which full information is given as to its activities. Its main function at the present time is the management of the estates of the church in order to augment or endow benefices, etc. The following is a summary of the receipts and expenditure for the years 1924, 1925 and 1926:—

Receipts

	1924	1925	1926
	£	£	£
Forward	262,000	300,000	320,000
Estates . . .	1,609,000	1,625,000	1,502,000
Dividends and interest	1,015,000	1,087,000	1,120,000
	2,886,000	3,012,000	2,942,000

Expenditure

	1924	1925	1926
	£	£	£
Benefices, Archbishops, Bishops, Administration, etc. .	1,881,000	1,970,000	1,987,000
Appropriation for future Augmentations, etc. .	625,000	642,000	605,000
Depreciation fund .	80,000	80,000	80.000
Balance forward . .	300,000	320,000	270,000
	2,886,000	3,012,000	2,942,000

ECCLESIASTICAL JURISDICTION. The jurisdiction exercised by ecclesiastics, in taking cognizance of and deciding causes, over other ecclesiastics and over the laity. Before its union with the State, the power of the Church in this direction, as in others, was only spiritual. Coercive authority over their bodies or estates could only be given by concession from the secular power.

The fundamental principle of ecclesiastical jurisdiction with its "sanction" of excommunication will be found in the words attributed to Christ in Matt. xviii. 15–18. These injunctions indicate the customs of the Christian Churches at an early stage in their history. After the time of the Apostles, we find this criminal jurisdiction exercised by bishops individually over their respective "subjects" — doubtless with the advice of their presbyters according to the precept of St. Ignatius (c. 110). As neighbouring dioceses coalesced into "provinces" and provinces into larger districts (corresponding to the civil "dioceses" of the later Roman Empire), the provincial synods of bishops and the synods of the larger districts acquired a criminal jurisdiction, still purely spiritual, of their own. The theory, as expressed in legal phrase by Cyprian in the 3rd century, was that the apostolic power of delegated sovereignty from the Lord, alike legislative and judicial, was held in joint-tenancy by the whole body of Catholic bishops.

Even before the edict of Milan, at least as early as the latter half of the 3rd century, the spiritual sentences of deposition from office had sometimes indirect temporal consequences recognized by the secular courts. The classical example is the case of Paul of Samosata, bishop of Antioch. It would seem that, in the intervals of persecution, some rights of property were recognized in the Christian Church and its officers; although the Church was an illegal society. After some previous abortive trials, Paul of Samosata was deposed and excon~municated in 269, by a great synod of the Antiochene district. Paul, notwithstanding his deposition, kept possession of the episcopal residence. The local church sought recovery of it before the tribunals of the Empire. The judicial authorities requested a rescript from the emperor Aurelian for the decision of the cause. Aurelian referred the matter to the bishop of Rome and the bishops of Italy, who gave their award in favour of the Antiochene Church.

Roman Empire from Constantine. — With the "Nicene period" came a great development on the criminal side. A system begins to be formed, and the secular arm supports the decrees of the Church. The first trace of system is in the limited right of appeal given by the first oecumenical council of Nicaea and its provision that episcopal sentences or those of provincial synods on appeal were to be recognized throughout the world. Still examination must be had whether persons have been expelled from the congregation by any episcopal small-mindedness (μικροψυχία), or contentious spirit, or such-like harshness (ἀηδία). That this may be conveniently inquired into, synods are to be held every year, in each province, and questions of this kind examined. And as regards the secular arm. the practice arose of superadding banishment by the emperor to synodical condemnation. The dogmatic decrees of Nicaea I. were at once enforced in this manner. On the other hand, the Arian reaction at court worked its objects by using the criminal spiritual jurisdiction of synods against the Catholics—often packing the synods for the purpose. The acts of councils of this age are full of the trials of bishops not only for heresy but for immorality and common law crimes. The accusations are frequently unfounded; but the trials are already conducted in a certain regular forensic form. The secular authorities follow the precedent of Nicaea I. and intervene to supplement the spiritual sentence by administrative penalties. Sometimes an imperial officer of high rank is present at the synod, as an assessor to maintain order and advise upon points of procedure.

The trial of Athanasius shows a further stage in the development of ecclesiastical jurisdiction. Its significance is seen in the council of Sardica (347), a council of practically the whole West save Africa. which acquitted Athanasius after a full judicial inquiry. This council endeavoured to set up a system of appeals in the case of bishops, in which the see of Rome was made to play a great part. "Out of honour to the memory of St. Peter," a condemned bishop may ask the intervention of Rome. If the bishop of Rome thinks the cause should be heard again, he is to appoint judges; if otherwise, the original judgment is to be confirmed. Pending appeal, the appellant's see is not to be filled up.

The tendency to give pre-eminence to Rome appears again in an imperial letter to St. Flavian, who, in the judgment of the East, was bishop of Antioch, but who was rejected by the West and Egypt, summoning him to Rome to be there judged by the bishops of the imperial city—a summons which St. Flavian did not obey.

The story of the administrative development of the Church in the 5th century is mainly the story of the final emergence and constitution of the great "patriarchates," as authorities superior to metropolitans and provincial synods. In consequence of the occupants of the thrones of Constantinople and Alexandria falling successively into opposite heresies, the question arose how "patriarchs" were to be judged. In both cases, as it seems, an attempt was made by the bishop of Rome to depose the erring patriarch by his authority as primate of Christendom, acting in concert with a Western synod. In both cases, apparently, an oecumenical synod ignored the Roman deposition and judged the alleged offences of the respective patriarchs in first and last instance. The third and fourth oecumenical synods (Ephesus, 431; Chalcedon, 451) were primarily tribunals for the trials of Nestorius and Dioscorus; it was secondarily that they became organs of the universal episcopate for the definition of the faith, or legislative assemblies for the enactment of canons. Nothing is more remarkable than their minute care as to observance of rules of procedure. In both cases, imperial assessors were appointed. At Chalcedon, on the other hand, the imperial commissioners decided points of order, kept the synod to the question, took the votes and adjourned the court. The fifth oecumenical council came near to sitting in judgment over the pope. Vigilius, although in Constantinople, refused to attend the sittings of the council. He was cited three times, in the canonical manner, and upon not appearing was threatened in the third session with anathema (Hefele, Councils §§ 268 *ff.*). After the council, Justinian banished the pope, until he accepted the council, which he ultimately did.

The constitution of the patriarchal system resulted in the recognition of a certain right of appeal to Rome from the larger part of the West. Britain remained outside that jurisdiction, the Celtic churches of the British islands, after those islands were abandoned by the Empire, pursuing a course of their own. In the East, Constantinople, from its principality. acquired special administrative pre-eminence, naturally followed, as in the case of Rome, by judicial pre-eminence. An example of this is found in the ninth canon of Chalcedon, which also illustrates the enforcement upon a clerical plaintiff in dispute with a brother cleric of recourse to the arbitration of their ecclesiastical superior. The canon provides that any clerk having a complaint against another clerk must not pass by his own bishop and turn to secular tribunals, but first lay bare his cause before him, so that by the sentence of the bishop himself the dispute may be settled by

arbitrators acceptable to both parties. In the next century Justinian put the other patriarchates on the same footing as Constantinople. But the growth of a special "original" jurisdiction at Constantinople, which perhaps developed earlier than the corresponding institution at Rome, may be traced to the fact that bishops from all parts were constantly in Constantinople. The bishop of Constantinople, even before he became properly "patriarch," would often assemble a synod from these visiting bishops, which acquired the technical name of *σύνοδος ἐνδημοῦσα*, the synod of sojourners. This synod frequently decided questions belonging to other patriarchates.

Theodosius I. began the system of giving secular authority to Church tribunals. But it appears definitely in 425, when a constitution of Theodosius II. provides that a recent decree of the usurper John should be disregarded and that clerks whom he had brought before secular judges should be reserved for the episcopal jurisdictions, "since it is not lawful to subject the ministers of the divine office to the arbitrament of temporal powers." Justinian has a clearer perception of the demarcation between the spheres of spiritual and temporal law. His system is based on the principle that if the offence be ecclesiastical, needing ecclesiastical correction, the bishop shall take cognizance of it; but if a cleric be accused of a secular crime he shall be first accused before his bishop, who may depose him from his office and order, and then the competent judge may take him and deal with him according to the laws.

Certain enactments of later Saxon times in England have been sometimes spoken of as though they united together the temporal and spiritual jurisdictions into one mixed tribunal deriving its authority from the State. In the latter part of the 10th century, laws of Edgar provided that the bishop should be at the county court and also the alderman, and that there each of them should put in use both God's laws and the world's law (Johnson's *English* Canons, i. 411). This probably was, as Johnson suggests, that the bishop might enforce secular laws by ecclesiastical censure and the alderman ecclesiastical laws with secular punishment. But the two jurisdictions were kept separate; for by another law of Edgar it was provided that "in the most august assembly the bishop and alderman should be present, and the one should interpret to the people the law of God, the other the laws of men." In the meantime, however, on the Continent, Charlemagne under the mistaken belief that he was following the authority of Constantine I. and Theodosius I., had taken the serious step of empowering bishops to act as real judges; and causes could be taken from lay cognizance and transferred to the bishop's tribunal.

The Mediaeval System. — With the later 9th century we enter upon a new epoch, and by the time of Gregory VII., in the 11th century, the tribunals have fallen into the hands of a regular class of canonists who are in fact professional church-lawyers in orders (see CANON LAW). The changes due to the adoption of the False Decretals by Nicholas I. and the application of their principles by Hildebrand (afterwards Gregory VII.) are discussed elsewhere (see HILDEBRAND; INVESTITURE; and kindred articles). The mediaeval system, thus inaugurated, may be considered (1) in its hierarchy, (2) in the subject matter of its jurisdiction, (3) in its penalties.

(1) It is a system of courts. Much that had been done by bishops is now done in the course of regular judicial procedure; the court takes the place of the synod, which ceases to have judicial work. The court of the metropolitan takes the place of the provincial synod, except possibly for the trial of bishops, and even this becomes doubtful.

At first the bishop was the only judge in the diocesan court and he always remains a judge. But just as the king appoints judges to hear *placita* coram rege *ipso*, and the feudal lord appoints his seneschal or steward, so the bishop appoints his official, the "vicar-general" or "chancellor" (see CHANCELLOR). It was gradually established that as a king should not hear causes but commit them to his judges, so a bishop should not hear causes but appoint an official to hear them. In France the "parlements" were constantly insisting on the independence and irremovability of the official.

The ecclesiastical and secular courts are kept distinct. The charter of William the Conqueror abrogated the laws of Edgar. No bishop or archdeacon "shall any longer hold pleas in the Hundred concerning episcopal law nor draw a cause which concerns the rule of such to the judgment of men of the world" (Stubbs, Select Charters, part iii.). In France, where the bishop was a temporal baron, his feudal and his spiritual courts were kept by distinct officers. From the bishop, or his official, appeal lay to the metropolitan, who again could hear causes by his official. The Constitutions of Clarendon recognize this appeal (c. viii.). An appeal lay from the court of the metropolitan to that of the primate. There were many disputes as to the existence of these primates (see Maitland, Canon Law in the *Church* of *England,* p. 121). In England the dispute between Canterbury and York was settled by making them both primates, giving Canterbury the further honour of being primate of all England. In France the primatial sees and the course of appeals to them were well established.

In England the Constitutions of Clarendon added a provision for appeal to the king, "and if the archbishop shall have failed in doing justice recourse is to be had in the last resort (postremo) to our lord the king, that by his writ the controversy may be ended in the court of the archbishop; because there must be no further process without the assent of our lord the king." The last words were an attempt to limit further appeal to Rome. It will be observed that the king does not hear the cause or adjudicate upon it. He merely corrects slackness or lack of doing justice (Si *archiepiscopus* defecerit in *justitia exhibenda*) and by his writ (precepto) directs the controversy to be determined in the metropolitan's court. As Bishop Stubbs says (Report of Eccl. Comm. vol. i. *Hist. App.* i.): "The appeal to the king is merely a provision for a rehearing before the archbishop, such failure to do justice being not so much applicable to an unfair decision as to the delays or refusal to proceed common at that time" (cf. Joyce, The Sword and the Keys, 2nd ed., pp. 19–20). The *recursus* ad *principem,* in some form or other of appeal or application to the sovereign or his lay judges, was at the end of the middle ages well known over western Europe. This recourse in England sometimes took the form of the appeal to the king given by the Constitutions of Ciarendon, just mentioned, and later by the acts of Henry VIII.; sometimes that of suing for writs of prohibition or mandamus, which were granted by the king's judges, either to restrain excess of jurisdiction, or to compel the spiritual judge to exercise jurisdiction in cases where it seemed to the temporal court that he was failing in his duty. The *appellatio tanquam* ab *abusu* (*appel* comme *d'abus*) in France was an application of a like nature.

Lastly there was the appeal to the patriarchs, *i.e.* in the West to Rome. The distinguishing feature of this appeal was that the rule of the other appeals did not apply to it. In the regular course of those appeals an appellant could not leap the intermediate stages; but he could at any stage go to this final appeal, *omisso medio,* as it was technically called. Van Espen says: "The whole right of appeal to the Roman pontiff *omisso* medio had undoubtedly its origin in this principle, that the Roman pontiff is ordinary of ordinaries, or, in other words, has immediate episcopal authority in all particular churches, and this principle had its own beginning from the False Decretals." There was an alleged original jurisdiction of the pope, which he exercised sometimes by permanent legates, whom Gregory VII. and his successors established in the chief countries of Europs, and to whom were committed the legislative, executive and judicial powers of the spiritual "prince" in the districts assigned to them. After legates came special delegates appointed by the pope to hear a particular cause. It was the general practice to appoint two or three to sit together (Van Espen, pars iii. tit. v. c. 2, 37). These might sub-delegate the whole cause or any part of it as they pleased (ibid. 9–18). These courts were convenient, since it was the custom to appoint delegates resident in the neighbourhood, and the power of sub-delegation, general or limited, simplified questions of distance. In Belgium causes appealed to Rome had to be committed to local delegates (Van Espen, pars iii tit. v. c. 3, tit. x. c. 2).

There could be an appeal from these delegates to the pope and from the pope himself to the pope "better informed" (Van Espen, pars iii. tit. x. c. 2, 13). So personal had the system of jurisdiction become that even the trials of bishops ceased to be necessarily conciliar. Generally they were reserved to the pope (Van Espen, pars iii. tit. iii. c. 5, 17–19); but in England the archbishop, either in synod, or with some of his comprovincial bishops concurring, tried and deposed bishops *(see* case of Bishop Peacock and the other cases cited in *Read* v. *Bishop of Lincoln,* 14 *P.D.* 148, and Phillimore, *Eccl. Law,* pp. 66 *et seq.).* The matrimonial cause between Henry VIII. and Catharine of Aragon was the most famous English cause tried by delegates under the "original" jurisdiction of the pope, and was ultimately "evoked" to Rome. The foreseen adverse termination of this long-drawn cause led to Henry's legislation.

When the temporal courts interfered to prevent excess of jurisdiction, they did so by prohibiting the ecclesiastical court from trying and the suitor from suing in that court. The pope could not be effectively prohibited, and no instance is recorded of a prohibition to papal delegates. But suitors have been prohibited from appealing to the pope *(see* per Willes, *J.,* in *Mayor of London* v. *Cox,* L.R. 2 H.L. 280). Whatever may have been the law, it is certain that, notwithstanding the statutes of Edw. III. and Rich. II., appeals to Rome and original trials by papal delegates did go on, perhaps with the king's licence; for the statute 24 Hen. VIII. c. 12 recites that the hearing of appeals was an usurpation by the pope and a grievous abuse, and proceeds to take away the appeal in matrimonial, testamentary and tithe causes, and to hinder, by forbidding citation and process from Rome, all original hearings also. The statute 25 Hen. VIII. c. 19 follows this up by taking away appeals in all other subjects of ecclesiastical jurisdiction.

In 1438 the council of Basel took away all papal original jurisdiction (save in certain reserved cases), evocation of causes to Rome, appeals to Rome *omisso medio,* and appeals to Rome altogether in many causes. Such appeals when permissible, except the "greater," were to be tried by delegates on the spot (31st Session; Mansi, *Concilia, in loco).* These proceedings at Basel were regarded at Rome as of no effect. Nevertheless this decree and others were adopted by a French national council at Bourges and promulgated by the king as a "Pragmatic Sanction" (*q.v.*). The parlements registered the Sanction and the effect was permanent in France. Louis XI. and Charles VIII. sought to revoke it; but both parlements and states-general refused to recognize the revoking decrees. In 1499 Louis XII. ordered the Pragmatic to be inviolably observed. The parlements thereupon condemned several private persons for obtaining bulls from Rome. In 1516 a Concordat between Leo X. and Francis I. settled all these questions in the sense of the Pragmatic, substantially according to the Basel canon. By this Concordat, by an ordinance of Francis I. in 1539, by two or three other royal edicts, and (above all) by the practice of the parlements, explanatory of this legislation, and their *arrêts,* the conflict of secular and ecclesiastical jurisdictions was settled until the Revolution.

(2.) The subject matter over which the ecclesiastical courts had jurisdiction was no longer purely "criminal" with a civil quasi-jurisdiction by way of arbitration. In the later middle ages these courts had jurisdiction over most questions, except indeed the then most important ones, those relating to real property. This civil jurisdiction was sometimes concurrent with that of the secular courts, sometimes exclusive. In England, for example, in reference to marriage, it included the right to decide in questions of the legitimacy of offspring; in reference to inheritance, the right to examine the administration of bequests of personal property and to intervene in cases of intestacy; the right of intervention to enforce contractual promises made by oath or pledge of faith; as well as in many questions where the church as an organization was directly concerned, as in the tenure of church lands, and questions of fitness or unfitness in the case of presentation to a benefice. The actual working of these wide extensions of ecclesiastical jurisdiction, and their reaction on the social and political life of the country, may be studied in F. W. Maitland's *Canon Law in the Church of England* (1898), in F. Pollock and F. W. Maitland's *History of English Law Before Edward I.* (1898), and J. F. Stephen's *History of the Criminal Law of England* (1883).

In regard to "clerks," the great question at issue in England was whether the ecclesiastical courts had exclusive jurisdiction in the case of criminous clerks, or the king's court, or whether there was a concurrent jurisdiction. The Constitutions of Clarendon, in which the general aim of Henry II. was to restore the rights of the crown over the clergy, ordered that in all civil matters, and in cases of dispute with laymen, the clergy shall be amenable to the royal courts (for text, *see* Mansi, *Concilia,* vol. xxi. pp. 1187 *sqq.;* E. H. Landon, *Manual of Councils,* pp. *132 sqq.).* The sympathies of the English church and nation were divided, for Becket was both violent and inconsistent in his conduct of the case of the church against the Constitutions. But the king's ungovernable temper broke out in a cry of rage that inspired four of his knights to steal away from his court and murder his enemy in Canterbury Cathedral; and the wave of reaction caused by this appalling deed deprived the State of many important rights only recovered at the Reformation. One of the worst evils of the later middle ages was the "Benefit of Clergy." "Not only monks and parish priests, but professional men, and an enormous crowd of menials and minor officers of clerical establishments, and in later times anyone who could make some show of being able to read, were safe from the dread of any serious penalty for such crimes as burglary, rape, and homicide, at any rate for the first offence. It was only too easy to obtain minor orders, and the attraction to baser spirits of such privileges and protection was great" (G. M. Trevelyan, *History of England,* bk. ii. ch. ii.).

The history of ecclesiastical jurisdiction on the continent of Europe during the middle ages is inseparable from the history of the Roman Catholic Church, of which indeed it is an essential part. The larger questions at issue are indicated in the articles dealing with that subject: and the details may be studied in P. Fournier, *Les officialités au moyen âge* (1880), *M.* Gaudry, *Traité de la législation des cultes* (1856), *J. P.* Migne, *Dictionnaire de droit canonique* (1844), and Tillemont, *Mémoires pour servir à l'histoire ecclésiastique* (1701–12).

(3.) The penalties inflicted by ecclesiastical courts were technically divided into punishments *(poenae)* and censures (*censurae*), purely spiritual and remedial *(see* Van Espen, pars iii., tit. xl. c. 1, 3; Phillimore, *Ecclesiastical Law,* p. 1064). The *poenae* were of various kinds. Apart from the case of heresy and kindred offences, the most extreme punishments were imprisonment for life, in the bishop's prison, or, on the other hand, deposition or degradation from the ministry. In the cases of heresy, apostasy and sorcery, the ecclesiastical courts sought the aid of the secular jurisdiction to superadd the punishment of death. Incorrigible offenders on these matters were "left" to the secular power. This provision of the fourth Lateran Council in 1215 was always interpreted to mean death *(see* Van Espen, *Observationes in concilium Lateranense IV.;* and, as to English law and practice, Maitland, *op. cit.,* Essay vi., and pp. 161, 176). The "capital" punishment was generally (always in England) by burning. Burning was an English punishment for some secular offences.

The Concordat with Francis I. by which the pope gave up the right of hearing appeals from France was not many years before the legislation of Henry VIII. in England. Both monarchs proceeded on the same lines; but Francis I. got the pope's consent: Henry VIII. acted *in invitum,* and in time went further.

Ecclesiastical Jurisdiction in England.— The Statute of Appeals (24 Hen. VIII. c. 12) took away appeals to Rome in causes testamentary and matrimonial and in regard to right of tithes and oblations. A final appeal is given to the archbishop of the particular province; but in causes touching the king a final appeal is given to the Upper House of Convocation of the province. The "Act of Submission of the Clergy" (25 Hen. VIII. c. 19) took away *all* appeals to Rome and gave a further appeal, "for lack of justice," from the several courts of the archbishops

to the king in chancery. Thence a commission was to issue to persons named therein to determine the appeal definitely. Henry VIII. exercised his jurisdiction as Supreme Head through a vicar-general. Edward VI. exercised original jurisdiction in spiritual causes by delegated commissions (see Archdeacon Hale, *Precedents* in *Criminal* Cases, p. xlviii.). Unless the king was to be regarded as an ecclesiastical person, they were not properly ecclesiastical courts; although spiritual persons might sit in them, for they sat only as royal commissioners. The same point has been taken by large bodies of clergy and laity in regard to the court of final appeal created by 25 Hen. VIII. c. 19 and its present successor, the judicial committee of Privy Council. At any rate the "original" jurisdiction claimed for the monarch personally and his delegates, under Henry VIII. and Edward VI., has not permanently remained. In theory, Hooker's contentions have been conceded that "kings cannot in their own proper persons decide questions about matters of faith and Christian religion" and that "they have not ordinary spiritual power" (Ecc. Pol. vii. 8, 1, 6; cf. xxxix. Articles, Art. 37). In the case of an "established" church, and in particular, of the Church of England as by law established, Hooker's theory meets with important qualifications (see article ECCLESIASTICAL LAW).

The legal position of the clergy of the Church of England has been affected by a series of enactments of which the most important are the following: the "Church Discipline Act" (3 and 4 Vict. c. 86) creating the "consistory court"; the "Public Worship Regulation Act" (37 and 38 Vict. c. 85); and the "Clergy Discipline Act" (55 and 56 Vict. c. 32). The last remains of the old powers of ecclesiastical jurisdiction in reference to secular causes, have been removed during the 19th century. (1) All matrimonial, testamentary and ab intestate jurisdiction has been taken away by 20 & 21 Vict. c. 77 (testamentary, etc., England), c. 79 (testamentary, etc., Ireland), c. 85 (matrimonial. England); 33 & 34 Vict. c. 110 (matrimonial, Ireland). Matrimonial jurisdiction was taken from the bishop of Sodor and Man in 1884. (2) Since 6 & 7 Will. IV. c. 71, tithe has become, except in a few rare cases, tithe rent charge, and its recovery has been entirely an operation of secular law. Most kinds of offerings are now recoverable in secular courts. (3) Administration of pious gifts has passed to the court of chancery. (4) The enforcement of contractual promises has long been abandoned by the courts Christian themselves. (5) Church rates can no longer be enforced by suit (31 & 32 Vict. c. 109). (6) Defamation was taken away in England by 18 & 19 Vict. c. 41, and in Ireland by 23 & 24 Vict. c. 32. (7) Laymen can no longer be tried in the spiritual courts for offences against clerks. (8) The jurisdiction for "brawling" in church, etc., is taken away by 23 & 24 Vict. c. 32 in the case of the laity (see A. J. Stephens, Ecclesiastical Statutes, i. 336). On the other hand the "Church of England Assembly (Powers) Act, 1919," defined the powers of the Church in reference to internal affairs and facilitated Parliamentary sanction where this is required (see ENGLAND, CHURCH OF).

The position of a disestablished or an unestablished Church is comparatively modern, and has given rise to new jural conceptions. These Churches are collegia *licita* and come within the liberty of association so freely conceded in modern times. The relations of their bishops, priests or other ministers and lay office-bearers inter se and to their lay folk depend upon contract; and these contracts will be enforced by the ordinary courts of law. A consensual ecclesiastical jurisdiction is thus created, which has to this extent temporal sanction. (See ECCLESIASTICAL LAW.)

The case of Scotland presents special features. The Church had the same jurisdiction in Scotland and exercised it through similar courts to those which she had in England and France, till about 1570. As late as 1566 Archbishop Hamilton of Glasgow, upon his appointment, had restitution of his jurisdiction in the probate of testaments and other matters (Keith, History of the Scottish Bishops, Edinburgh, 1824, p. 38). There was an interval of uncertainty, with at any rate titular bishops, till 1592. Then parliament enacted a new system of Church courts which, though to some extent in its turn superseded by the revival of episcopacy under James VI., was revived or ratified by the act of 1690, c. 7, and stands to this day. It is a Presbyterian system, and the Scottish Episcopal Church is a disestablished and voluntary body since 1690 (see PRESBYTERIANISM; SCOTLAND, CHURCH OF; SCOTTISH EPISCOPAL CHURCH).

Protestant Continental European States.—With the Reformation in the 16th century, Church courts properly speaking disappeared from the non-episcopal religious communities which were established in Holland, in the Protestant states of Switzerland and of Germany, and in the then non-episcopal countries of Denmark and Norway.

Discipline over ministers and other office-bearers was exercised by administrative methods in the form of trials before consistories or synods. To this extent ecclesiastical jurisdiction is still exercised in these countries. Consistories and synods have exercised discipline of a penitential kind over their lay members; but in later times their censures have generally ceased to carry temporal consequences. Ecclesiastical jurisdiction on the civil side for the trial of causes soon disappeared.

The matter is now determined for all countries which have adopted codes, whether after the pattern of the Code Napoleon or otherwise. These countries have created a hierarchy of temporal courts competent to deal with every matter of which law takes cognizance, and a penal code which embraces and deals with all crimes or delicts which the state recognizes as offences. Hence, even in countries where the Roman Church is established, such as Belgium and Italy, the most of the Latin republics of America, and the province of Quebec, and a fortiori where this Church is not established, there is now no discipline over the laity, except penitential, and no jurisdiction exercised in civil suits, except possibly the matrimonial questions of princes (of which there was an example in the case of the late prince of Monaco). In Spain causes of nullity and divorce a fhoro, in Portugal causes of nullity between Catholics are still for the court Christian (non-secular).

BIBLIOGRAPHY.—The subject of ecclesiastical jurisdiction in modern times inevitably links itself onto the ecclesiastical and civil history of the countries concerned. On the general subject, *see* ECCLESIASTICAL LAW; and, for further references, articles "Law, Christian" in Hastings' *Encyclopaedia of Religion and Ethics*, vol. vii.: "Roman Catholic" and "Eastern" by Adrian Fortescue, and "Anglican" by A. J. Maclean. For the history of the principal codes *see* CANON LAW. On the development of ecclesiastical jurisdiction in the Church of Rome *see* ROMAN CATHOLIC CHURCH, and (from other points of view) TRENT, COUNCIL OF; VATICAN COUNCIL; and ULTRAMONTANISM. With reference to the Eastern church, *see* ORTHODOX EASTERN CHURCH; also Landon, *Manual of Councils* (1893), s.v. "Constantinople" and "Rome"; Mouravieff, *History of the Russian Church*, Eng. tr. 1842; Hackett, *Orthodox Church in Cyprus* (1901); Milasch, *Das Kirchenrecht der morgenlandischen Kirche* (1905). With reference to the Anglican Church, *see* Blunt, Phillimore and Jones, *Book of Church Law*, 1899; W. E. Collins, *Nature and Force of the Canon Law* (Church Historical Society, no. xxsiv., 1898); and the classical statement of Hooker, *Ecclesiastical Polity*, bk. viii. With reference to the middle ages, *see* the relative parts of the *Cambridge Mediaeval Wtstory* and the classical works of van Espen (Louvain, 1720): *Jus ecclesiasticum universum; Observationes in Concilium Lateranense iv.; De recursu ad Principem.* *See* also other works mentioned in the course of the foregoing article.

(X.)

ECCLESIASTICAL LAW, in its broadest sense, the sum of the authoritative rules governing the Christian Church, whether in its internal polity or in its relations with the secular power. Since there are various churches, widely differing both in their principles and practice, it follows that a like difference exists in their ecclesiastical law, which is the outcome of their corporate consciousness as modified by their several relations to the secular authority. At the outset a distinction must be made between churches which are "established" and those that are "free." The ecclesiastical laws of the latter are, like the rules of a private society or club, the concern of the members of the church only, and come under the purview of the State only in so far as they come in conflict with the secular law (*e.g.*, polygamy among the Mormons, or violation of the trust-deeds under which the property of a church is held). In the case of "established" churches, on the other hand, whatever the principle on which the system is based, or the difference in its practical application, the essential conditions are that the ecclesiastical law is also the law of the land, the decisions of the church courts being enforced by the

civil power. This holds good both of the Roman Catholic church, wherever this is recognized as the "State religion," of the Oriental churches, whether closely identified with the State itself, or endowed with powers over particular nationalities within the State, and of the various Protestant churches established in Great Britain and on the Continent of Europe.

Writers on the theory of ecclesiastical law, moreover, draw a fundamental distinction between that of the church of Rome and that of the Protestant national or territorial churches. This distinction is due to the claim of the Roman Catholic church to be the *only* church, her laws being thus of universal obligation; whereas the laws of the various established Protestant churches are valid—at least so far as legal obligation is concerned—only within the limits of the countries in which they are established. The practical effects of this distinction have been, and still are, of enormous importance. The Roman Catholic church, even when recognized as the State religion, is nowhere "established" in the sense of being identified with the State, but is rather an *imperium in imperio* which negotiates on equal terms with the State, the results being embodied in concordats (*q.v.*) between the State and the pope as head of the church. The concordats are of the nature of truces in the perennial conflict between the spiritual and secular powers, and imply in principle no surrender of the claims of the one to those of the other.

Protestant ecclesiastical law, then, is distinguished from that of the Roman Catholic church (1) by being more limited in its scope, (2) by having for its authoritative source, not the church only or even mainly, but the church in more or less complete union with or subordination to the State, the latter being considered, equally with the church, as an organ of the will of God. The ecclesiastical law of the church of Rome, on the other hand, whatever its origin, is now valid only in so far as it has the sanction of the authority of the Holy See. And it must be noted that the "canon law" in its old sense is not identical with the "ecclesiastical law" of the Roman Catholic church. By the canon law used to be meant the contents of the *Corpus iuris canonici,* which have been largely superseded or added to by, *e g.,* the canons of the Council of Trent and the Vatican decrees. The long projected codification of the whole of the ecclesiastical law of the church of Rome, was completed in 1917 in the pontificate of Benedict XV. (*See* also CANON LAW and ECCLESIASTICAL JURISDICTION.)

The ecclesiastical law of England is in complete dependence upon the authority of the State. The convocations of York and Canterbury are provincial assemblies possessing no legislative or judicial authority; even such purely ecclesiastical questions as may be formally commended to their attention by "letters of business" from the Crown can only be finally settled by act of parliament or, under the Church of England Assembly (Powers) Act 1919, by a measure passed by the church assembly and then assented to by a separate resolution in each house of parliament and submitted for royal assent. The ecclesiastical courts are for the most part officered by laymen, whose subordination to the archbishops and bishops is purely formal, and the final court of appeal is the Judicial Committee of the Privy Council. In like manner changes in the ecclesiastical law have been made directly by parliament in the ordinary course of legislation, and in point of fact a very large portion of the existing ecclesiastical law consists of acts of parliament.

The first principle of the ecclesiastical law in England is the assertion of the supremacy of the Crown, which in the present state of the constitution means the same thing as the supremacy of parliament. This principle has been maintained ever since the Reformation. Before the Reformation the ecclesiastical supremacy of the pope was recognized, with certain limitations, in England, and the church itself had some pretensions to ecclesiastical freedom. The freedom of the church is, in fact, one of the standing provisions of those charters on which the English constitution was based. The first provision of Magna Carta is *quod ecclesia Anglicana libera sit.* By the various enactments of the period of the Reformation the whole constitutional position of the church, not merely with reference to the pope but with reference to the State, was definitely fixed. The legislative power of convocation was held to extend to the clergy only, and even to that extent required the sanction and assent of the Crown. The common law courts controlled the jurisdiction of the ecclesiastical courts, claiming to have "the exposition of such statutes or acts of parliament as concern either the extent of the jurisdiction of these courts or the matters depending before them. And therefore if these courts either refuse to allow these acts of parliament, or expound them in any other sense than is truly and properly the exposition of them, the king's great courts of common law may prohibit and control them."

The design of constructing a code of ecclesiastical laws was entertained during the period of the Reformation but never carried into effect. It is alluded to in various statutes of the reign of Henry VIII., who obtained power to appoint a commission to examine the old ecclesiastical laws, with a view of deciding which ought to be kept and which ought to be abolished, and in the meantime it was enacted that "such canons, institutions, ordinances, synodal or provincial, or other ecclesiastical laws or jurisdictions spiritual as be yet accustomed and used here in the church of England, which necessarily and conveniently are requisite to be put in ure and execution for the time, not being repugnant, contrarient, or derogatory to the laws or statutes of the realm, nor to the prerogatives of the royal crown of the same, or any of them, shall be occupied, exercised, and put in ure for the time with this realm" (25 Henry VIII. c. 19, 35 c. 16).

The work was actually undertaken and finished in the reign of Edward VI. by a subcommittee of eight persons, under the name of the *Reformatio legum ecclesiasticarum,* which, however, never obtained the royal assent. Although the powers of the 25 Henry VIII. c. 19, were revived by the 1 Elizabeth c. 1, the scheme was never executed, and the ecclesiastical laws remained on the footing assigned to them in that statute—so much of the old ecclesiastical laws might be used as had been actually in use, and was not repugnant to the laws of the realm.

The statement is, indeed, made by Sir R. Phillinore (*Ecclesiastical Law,* 2nd ed., 1895) that the "Church of England has at all times, before and since the Reformation, claimed the right of an independent church in an independent kingdom, to be governed by the laws which she has deemed it expedient to adopt." This position can only be accepted if it is confined, as the authorities cited for it are confined, to the resistance of interference from abroad. If it mean that the church, as distinguished from the kingdom, has claimed to be governed by laws of her own making, all that can be said is that the claim has been singularly unsuccessful. From the time of the Reformation no change has been made in the law of the church which has not been made by the king and parliament, sometimes indirectly, as by confirming the resolutions of convocation, but for the most part by statute. The list of statutes cited in Sir R. Phillimore's *Ecclesiastical Law* fills 11 pages. It is only by a kind of legal fiction that the church can be said to have deemed it expedient to adopt these laws.

The terms on which the church establishment of Ireland was abolished, by the Irish Church Act of 1569, may be mentioned. By s. 20 the present ecclesiastical law was made binding on the members for the time being of the church, "as if they had mutually contracted and agreed to abide by and observe the same"; and by s. 21 it was enacted that the ecclesiastical courts should cease after Jan. 1, 1871, and that the ecclesiastical laws of Ireland, except so far as relates to matrimonial causes and matters, should cease to exist as law. (*See* also ENGLAND, THE CHURCH OF.)

BIBLIOGRAPHY.—The number of works on ecclesiastical law is very great, and it must suffice here to mention a few of the more conspicuous modern ones: Ferdinand Walter, *Lehrbuch des Kirchenrechts aller christlichen Konjessionen* (14th ed., Bonn, 1871); G. Phillips, *Kirchenrecht,* Bde. i.–vii. (Regensburg, 1845–72) incomplete; the text-book by Cardinal Hergenrother (*q.v.*); P. Hinschius, *Kirchenrecht der Katholiken und Protestanten in Deutschland,* 6 Bde. (1869 *sqq.*), only the Catholic part, a masterly and detailed survey of the ecclesiastical law, finished; Sir Robert Phillimore, *Eccl. Law of the Church of England* (and ed., ed. by Sir Walter Phillimore, 1895). For further references *see* CANON LAW, and the article "Kirchenrecht" in Herzog-Hauck, *Realencyklopädie* (ed. Leipzig, 1901); C. F. S. Zollman, *Amer. Civil Church Law* (1917); P. Gillet, *La personnalite juridique en droit ecclesiastique* (Malines, 1927).

ECCLESIASTICUS (abbreviated to *Ecclus.*), an alternative title of the apocryphal book otherwise called "The Wisdom of Jesus the son of Sirach." The Latin word ecclesiasticus means "churchly," and might be used of any book which was read in church or received ecclesiastical sanction. The name of the book appears in the authorities in a variety of forms. The writer's full name is given in l. 27 (Heb. text) as "Simeon the son of Jeshua (*i.e.,* Jesus) the son of Eleazar 'the son of Sira." In the Greek text this name appears as "Jesus son of Sirach Eleazar of Jerusalem." The name is shortened sometimes to *Ben* Sira in Hebrew, Bar Sira in Aramaic, and sometimes to Sirach. The work is variously described as the Words (Heb. text), the Book (Talmud), the Proverbs (Jerome), or the Wisdom of the son of Sira (or Sirach).

Of the date of the book we have no certain indication. It was translated by a person who says that he "came into Egypt in the 38th year of Euergetes the king" (Ptolemy VII.), *i.e.,* in 132 B.C., and that he executed the work some time later. The translator believed that the writer of the original was his own grandfather (or ancestor, πάππος). Arguments for a pre-Maccabean date may be derived (a) from the fact that the book contains apparently no reference to the Maccabean struggles, (b) from the eulogy of the priestly house of Zadok which fell into disrepute during these wars for independence.

In the Jewish Church Ecclesiasticus hovered on the border of the canon. The book contains much which attracted and also much which repelled Jewish feeling, and it appears that it was necessary to pronounce against its canonicity. In the Talmud (Sanhedrin 100 b) Rabbi Joseph says that it is forbidden to read (*i.e.,* in the synagogue) the book of Ben Sira. In the Christian Church it was largely used by Clement of Alexandria (c. A.D. 200) and by St. Augustine. Jerome (c. A.D. 390–400) writes: "Let the Church read these two volumes (Wisdom of Solomon and Ecclesiasticus) for the instruction of the people, not for establishing the authority of the dogmas of the Church" (*Praefatio in libros* Salomonis). In the Vulgate Ecclesiasticus immediately precedes Isaiah. The council of Trent declared this book and the rest of the books reckoned in the Thirty-nine Articles as apocryphal to be canonical.

The text of the book raises intricate problems which are still far from solution. The original Hebrew (rediscovered in fragments and published between 1896 and 1900) has come down to us in a mutilated and corrupt form. There are marginal readings which show that two different recensions existed once in Hebrew. The Greek version exists in two forms—(a) that preserved in cod. B and in the other uncial mss., (b) that preserved in the cursive codex 248 (Holmes and Parsons). Owing to the mutilation of the Hebrew the Greek version retains its place as the chief authority for the text.

The restoration of a satisfactory text is beyond our hopes, for we cannot doubt that the translator amplified and paraphrased the text before him. It is probable that at least one considerable omission must be laid to his charge, for the hymn preserved in the Hebrew text after ch. li. 12 is almost certainly original. Ancient translators allowed themselves much liberty in their work, and Ecclesiasticus had no reputation for canonicity in the 2nd century B.C. to serve as a protection for its text.

The uncertainty of the text has affected both English versions unfavourably. The A.V., following the corrupt cursives, is often wrong. The R.V., on the other hand, in following the uncial mss. sometimes departs from the Hebrew, while the A.V. with the cursives agrees with it. Thus the R.V. omits the whole of iii. 19, which the A.V. retains, but for the clause, "Mysteries are revealed unto the meek," the A.V. has the support of the Hebrew. Sometimes both versions go astray in places in which the Hebrew text recommends itself as original by its vigour; *e.g.,* in vii. 26, where the Hebrew is:—

> Hast thou a wife? abominate her not.
> Hast thou a hated wife? trust not in her.

Again in ch. xxxviii. the Hebrew text shows its superiority over both English versions.

	Hebrew	R.V. (similarly A.V.)
Ver. 1.	Acquaint thyself with a physician before thou have need of him.	Honour a physician according to thy need of him with the honours due unto him.
Ver. 15.	He that sinneth against his Maker will behave himself proudly against a physician.	He that sinneth before his Maker, let him fall into the hands of the physician.

In the second instance, while the Hebrew says that the man who rebels against his Heavenly Benefactor will a fortiori rebel against a human benefactor, the Greek text gives a cynical turn to the verse, "Let the man who rebels against his true benefactor be punished through the tender mercies of a quack." The Hebrew text is superior also in xliv. 1: "Let me now praise favoured men;" *i.e.,* men in whom God's grace was shown. The Greek text of v. 1 "famous men," is nothing but a loose paraphrase.

In character Ecclesiasticus resembles the book of Proverbs. It consists mainly of maxims, moral, utilitarian and secular. Occasionally the author attacks prevalent religious doctrines, *e.g.,* the denial of free-will (xv. 11–20), or the assertion of God's indifference towards men's actions (xxxv. 12–19). Occasionally he touches the highest themes, and speaks of the nature of God: "He is All" (xliii. 27); "He is One from everlasting" (xlii. 21, Heb. text); "The mercy of the Lord is upon all flesh" (xviii. 13). The book contains several passages of force and beauty; *e.g.,* ch. ii. (how to fear the Lord); xv. 11–20 (on free-will); xxiv. 1–22 (the song of wisdom); xlii. 15–25 (praise of the works of the Lord); xliv. 1–15 (the well known praise of famous men). Many sayings scattered throughout the book show depth of insight or practical shrewdness. A few examples may be cited. "Call no man blessed before his death" (xi. 28); "He that toucheth pitch shall be defiled" (xiii. 1); "God hath not given any man license to sin" (xv. 20); "Man cherisheth anger against man; and doth he seek healing from the Lord?" (xxviii. 3); "All things are double one against another: and He hath made nothing imperfect" (xlii. 24, the motto of Butler's Analogy); "Work your work before the time cometh, and in His time He will give you your reward" (li. 30). It cannot be said, however, that Ben Sira preaches a hopeful religion. Though he prays, "Renew Thy signs, and repeat Thy wonders. . . . Fill Sion with Thy majesty and Thy Temple with Thy glory" (xxxvi. 6, 14 [19], Heb. text), he does not look for a Messiah. Of the resurrection of the dead or of the immortality of the soul there is no word. In his maxims of life he shows a frigid and narrow mind. He is a pessimist as regards women: "From a woman was the beginning of sin; and because of her we all die" (xxv. 24). He does not believe in home-spun wisdom: "How shall he become wise that holdeth the plough?" (xxxviii. 25). Artificers are not expected to pray like the wise man: "In the handywork of their craft is their prayer" (v. 34). Merchants are expected to cheat: "Sin will thrust itself in between buying and selling" (xxvii. 2).

BIBLIOGRAPHY.—A useful summary of the literature of Ecclesiasticus is found at the end of Israel Levi's article, "Sirach," in the Jewish Encyclopaedia. The most important edition in English is that of G. H. Box and W. O. E. Oesterley in R. H. Charles, Apocrypha and Pseudepigrapha of the O.T. (1913). (W. E. **BA.**)

ECGBERT or **ECGBERHT** (d. 766), archbishop of York, was made bishop of that see in 732 by his cousin Ceolwulf, king of Northumbria, succeeding Wilfrid II. on the latter's resignation. The pall was sent him in 735 and he became the first northern archbishop after Paulinus, none of his predecessors having received the vestment. He was the brother of Eadberht, who ruled Northumbria 737–758. He was the recipient of the famous letter of Bede, dealing with the evils arising from the corrupt state of the monasteries. Ecgbert himself wrote a *Dialogus Ecclesiasticae* Institutionis, a Penitentiale and a Pontificale. He was a correspondent of St. Boniface. His brother Eadberht succeeded to the throne of Northumbria in 738, and Ecgbert, whose power was certainly increased by this relationship, used his authority wisely for the welfare of his see. He gave generously to the churches of his diocese, and, in particular, founded the Cathedral School of York. He died on Nov. 19, 766.

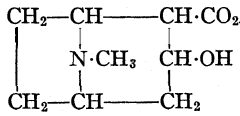
See Bedc, *Continuatio,* sub. ann. 732, 735, 766, and *Epistola* ad *Ecg-*

berctum (ed. Plummer, 1896); Chronicle, sub. ann. 734, 735, 738, 766 (ed. Earle and Plummer, 1899); Haddan and Stubbs, Councils and *Ecclesiastical* Documents (1869–78), iii. 403–431; Proceedings of *Surtees* Society (Durham, 1853).

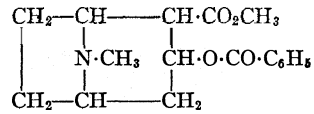
ECGBERT or **ECGBERHT** (d. 839), king of the West Saxons, son of Ealhmund, succeeded to the throne in 802 on the death of Beorhtric. It is said that at an earlier period in his life he had been driven out for three years by Offa and Beorhtric. In 815 Ecgbert ravaged the whole of the territories of the West Welsh, which probably at this time did not include much more than Cornwall. In 825 he joined the men of Devon against the West Welsh, who were again defeated at Camelford. The next important occurrence in the reign was the defeat of Beornwulf of Mercia at Ellandun, probably near Winchester, in 821. Ecgbert sent his son Aethelwulf against Kent; he drove Baldred, king of Kent, across the Thames, and Kent, Surrey, Sussex and Essex submitted to Wessex; while the East Anglians, who slew Beornwulf shortly afterwards, acknowledged Ecgbert as overlord. In 829 the king finally conquered Mercia, and Northumbria, which accepted him as overlord. Ecgbert was the first king to hold the whole of England under his overlordship. He also increased his power by reversing the Mercian policy of resisting the authority of the archbishops, and by making an agreement of perpetual alliance with the church of Canterbury. In 830 he led a successful expedition against the Welsh. In 836 he was defeated by the Danes, but in 838 he entirely routed them and their allies the West Welsh at Hingston Down (Hengest dune) in Cornwall. Ecgbert died in 839, after a reign of 37 years, and was succeeded by his son Aethelwulf.

See Anglo-Saxon Chronicle (ed. Earle and Plummer, 1899); W. de G. Birch, *Cartularium Saxonicum* (1885–93). Also a paper by Sir H. H. Howorth in Numismatic Chronicle, 3rd series, vol. xx. pp. 66–87 (reprinted separately, 1900), where attention is called to the peculiar dating of several of Ecgbert's charters, and the view is put forward that he remained abroad considerably later than the date given by the Chronicle for his accession. On the other hand a charter in Birch, Cart. Sax., purporting to date from 799, contains the curious statement that peace was made between Coenwulf and Ecgbert in that year.

ECGONINE, a white crystalline alkaloid of the tropine group, is chiefly of interest because of its relation to cocaine. Ecgonine is a tropine carboxylic acid $C_9H_{15}NO_3,H_2O$, and cocaine is its benzoyl methyl ester:



Ecgonine



Cocaine

l-Ecgonine results from the alkaline hydrolysis of I-cocaine (the naturally occurring form); it melts at 205° when anhydrous α-Ecgonine is an isomeride, having its CO_2H group attached to the same carbon atom as the OH group. (See CHEMISTRY: ORGANIC, HETEROCYCLIC DIVISION.)

ECHEGARAY Y EIZAGUIRRE, JOSE (1832–1916), Spanish mathematician, statesman and dramatist, passed out at the head of the list of engineers in the Escuela de Caminos at Madrid, and, after a brief practical experience at Almeria and Granada, was appointed professor of pure and applied mathematics in the school where he had lately been a pupil. Between 1867 and 1874 he acted as minister of education and of finance; upon the restoration of the Bourbon dynasty he withdrew from politics and under the pseudonym of Jorge Hayaseca won a new reputation as a dramatist with El Libro talonario (1874). Later in the same year Echegaray achieved a popular triumph with La *Esposa* del vengador, in which the good and bad qualities—the clever stagecraft and unbridled extravagance—of his later work are clearly noticeable. From 1874 onwards he wrote, with varying success, a prodigious number of plays. Among the most favourable specimens of his talent may be mentioned En el *puño* de la *espada* (1875), *O locura ó* santidad (1877) and En el seno de la muerte (1879). El gran Galeoto (1881), perhaps the best of Echegaray's plays in conception and execution, has been translated into several languages. The humorous proverb, ¿ Piensa *mal* y *acertarás?* exemplifies the author's limitations, but the attempt is interesting as an instance of ambitious versatility. His susceptibility to new ideas is illustrated in such pieces as *Mariana* (1892), *Mancha que limpia* (1895), El Hijo de Don Juan (1892) and El Loco Dios (1900); these indicate a close study of Ibsen, and El Loco Dios more especially might be taken for an unintentional parody of Ibsen's symbolism.

Echegaray enjoyed exceptional popularity for over 30 years, but his vogue is now over. He had valuable gifts: in artful construction, in the arrangement of dramatic scenes, in mere theatrical technique, in the focusing of attention on his chief personages, few writers excel him. He had, moreover, a powerful, gloomy imagination, which is momentarily impressive. But in the drawing of character, in the invention of felicitous phrase, in the contrivance of verbal music, he is deficient. He alternates between the use of verse and prose; and his hesitancy in choosing a medium of expression is amply justified, for the writer's prose is not more distinguished than his verse.

See L. Anton del Olmet and A. Garcia Carraffa, Echegaray (1912).

ECHELON, in military tactics and drill, a formation of troops composed of successive and parallel units facing in the same direction, each on a flank, and to the rear of, the unit in front of it (Fr. frpm échelle, ladder). The disposition of the whole thus resembles the steps of a staircase. To form echelon from line, the units forming the line move off, each direct to its front, in succession, so that when the formation is completed the rightmost body, for example, is farthest advanced, the one originally next on its left is to the left rear, a third is to the left rear of the second, and so on. The word is also used more loosely in tactics and strategy to express the successive parts of a unit or force, *e.g.,* forward, reserve or rear echelon, irrespective of distances and relative positions; and in military organization to indicate parts of the headquarters organization which are left in rear of the fighting zone.

ECHIDNA or **SPINY ANT-EATER** (Echidna aculeata), one of the Monotremata (*q.v.*) the lowest subclass of Mammalia. It is a native of Australia, burrowing in sand, or hiding in rock crevices. In size and appearance it resembles a hedgehog, its upper surface being covered over with strong spines directed backwards and inwards, so as to cross each other on the middle line. The tail is very small. It has a long tubular snout with a small mouth; its tongue is long and slender, lubricated with a viscous secretion, by means of which it seizes the insects on which it feeds. It has no teeth. Its legs are short and strong and form powerful burrowing organs. The male echidna has its heel provided with a sharp hollow spur, connected with a gland. It is a nocturnal animal. When attacked it seeks to escape either by rolling itself into a ball or by burrowing rapidly into the sand. Two eggs are laid and these are carried, as are the young at an early stage, in an abdominal pouch, into which open the mammary glands. The echidnas are restless in confinement and constantly endeavour to effect their escape by burrowing.

There are two varieties, the Port Moresby echidna and the hairy echidna. The latter is found in south-eastern New Guinea, Australia, and Tasmania. In all the spines are mixed with hair; in the Tasmanian race they are nearly hidden by the long harsh fur. Of the three-clawed echidnas (Proechidna) confined to New Guinea there are two species.

ECHINODERMA (Echinoderms), a group of animals that live in the sea and constitute one of the great branches (phyla) of the animal kingdom. Familiar examples are the sea-urchin (Echinoid), the sea-star or starfish (Asteroid) and the brittle-star (Ophiuroid). Less familiar are the feather-star and sea-lily (unstalked and stalked Crinoid), and the sea-cucumber (Holothurian) (figs. 1–j). These forms represent the five classes into which the Echinoderma now living are usually divided. In the older periods of the world's history there were other classes, none of which have survived.

The recent forms are of such diverse appearance, and for the most part so unfamiliar, that there is no vernacular English name for the branch. "Echinoderma" is a Greek word and means "prickle-skinned" ("animals" being understood). The Greeks gave

the name "Echinus" to two animals of very different nature, but both protected by a coat of prickles: one the hedgehog or urchin of the land; the other the sea-urchin, which the French call *oursin*. Both urchin and *oursin* are connected with the French *hérisser*, to bristle. The name Echinus has been continued in use for a kind of sea-urchin. The name "Echinodermata," often applied to the whole branch, means "sea-urchin skins," and was

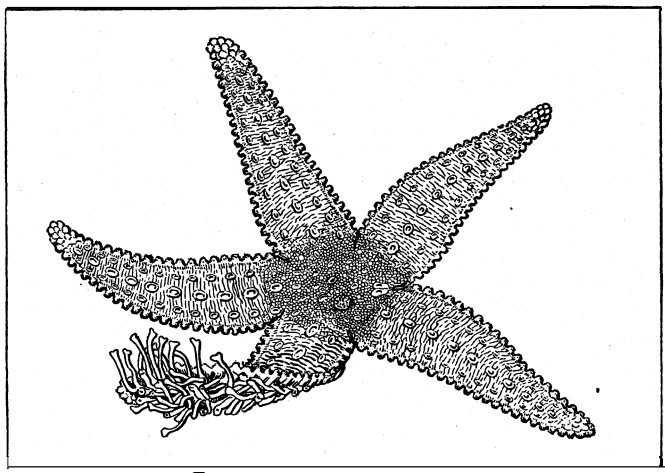


FIG. 1.—SEA-STAR OR ASTEROID

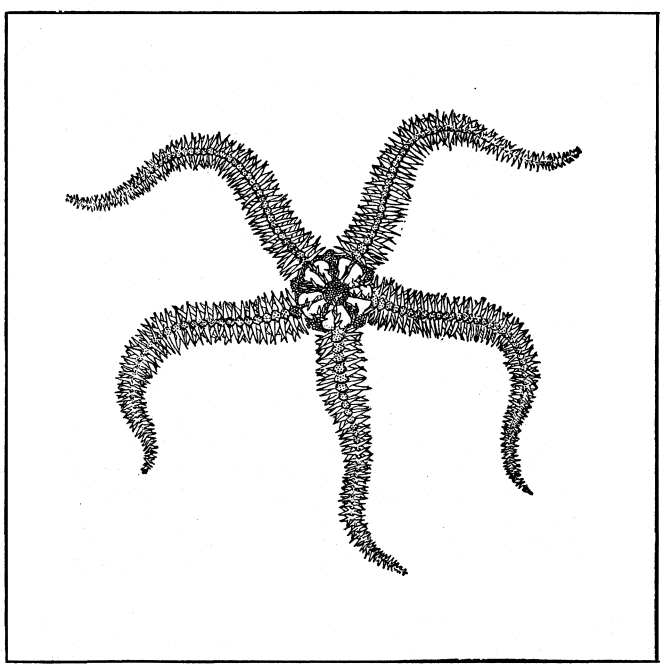
invented in 1734 by J. T. Klein to denote only the empty shells or tests of sea-urchins.

CHARACTERS AND RELATIONS

Diverse though recent echinoderms are, all possess certain characters, some of which they hold in common with other groups of animals, while others are distinctive of the branch. The common characters may be mentioned briefly. The substance of an echinoderm is built of many cells; the animals are multicellular (Metazoa, as opposed to Protozoa). An echinoderm differs from

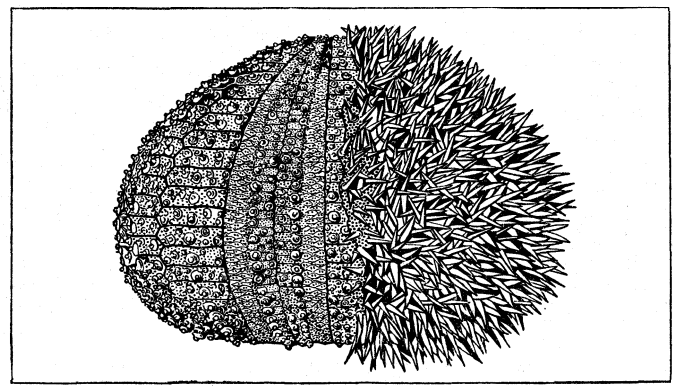


FROM "THE CAMBRIDGE NATURAL HISTORY" (MACMILLAN)

FIG. 2.—BRITTLE-STAR OR OPHIUROID

such animals as sea-anemones and jelly-fish, which are little more than sacs (Coelentera = hollow guts), in having the inside of the sac divided into a gut or digestive tube and a body-cavity or coelom (=hollow); in this it resembles molluscs, flat-worms, arthropods and vertebrates: such animals are called Coelomata. The fundamental plan of an echinoderm, as in all Coelomata, is bilateral, and any appearance of radial symmetry is secondary.

Radial Arrangement. — Recent Echinoderma are distinguished from the other Coelomata by the following characters: — Nearly all show a division of some of the bodily organs into five rays. The rays may fork, may increase, or may be partly suppressed; but the number five governs the plan, though it is not really primitive. The middle line of each ray is termed a radius; a line drawn midway between two adjoining radii is termed an interradius: thus the body-surface may be mapped into five



FROM "ROYAL NATURAL HISTORY" BY PERMISSION OF F. WARNE & CO.

FIG. 3.—SEA-URCHIN OR ECHINOID

radial areas alternating with five interradial areas. In recent echinoderms the organs that show the radial arrangement most clearly are numerous sacs, canals and tubes which carry water through the body and constitute a hydraulic apparatus (water-vascular system). In its most typical form (fig. 6) this consists

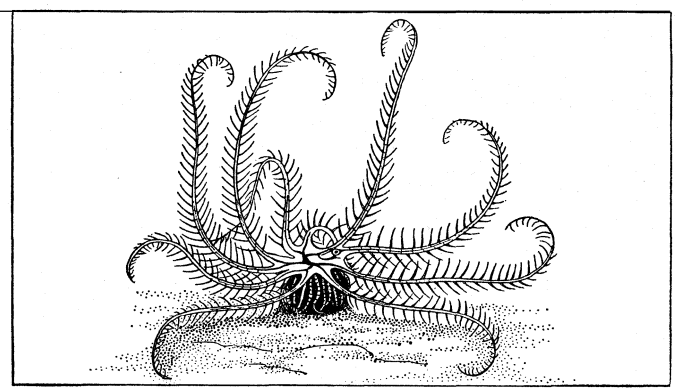


FIG. 4.—FEATHER-STAR OR UNSTALKED CRINOID

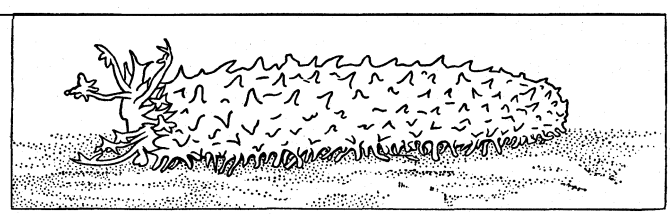
of a ring-canal round the mouth, indirectly connected with the water outside, and sending a canal down each of the radii. From each side of this radial water-vessel small branches are given off, and their ends project from the surface of the animal as closed tubes with muscular walls; since in the sea-urchin and sea-star



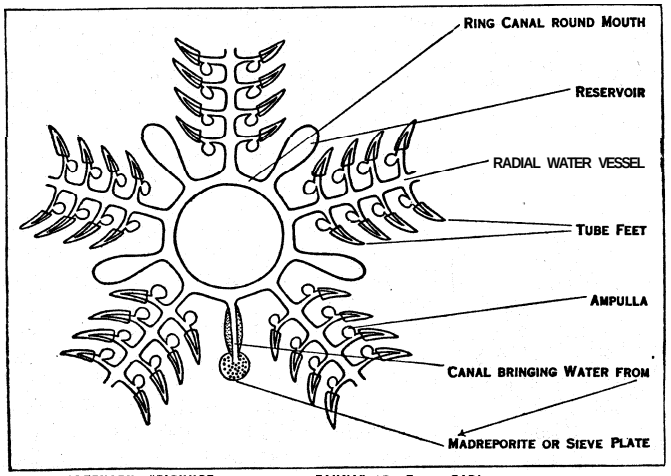
FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 5.—SEA CUCUMBER OR HOLOTHURIAN

these tubes end in suckers and aid locomotion, they are called tube-feet or podia (fig. 1). The podia, as they stand up on each side of the radial canal, look like flowers bordering a garden-walk (Lat., *ambulacrum*); hence that radial area of the test is called an ambulacrum, and the interradial areas are called inter-ambulacra.

In the older and more primitive classes of Echinoderma, the hydraulic ambulacral system does not subserve locomotion, but only sensation and respiration. The five-rayed structure did not originate in this system, but was due to the extension from the

mouth of five grooves lined with minute lashes (cilia), which by constant whipping drive a stream of water with food-particles towards the mouth. The food-collecting area was increased by the elongation or branching of the grooves, as in crinoids and sea-stars; and the water-vessels followed the food-grooves. In crinoids and sea-stars the food-grooves are open and in use; but in brittle-stars, sea-urchins, and holothurians they have become



FROM MORTENSEN, "PIGHUDE; DANMARK'S FAUNA" (G. E. C. GAD)

FIG. 6.— HYDRAULIC APPARATUS OF SEA-STAR

closed over, while the ambulacral system continues to send out its podia (fig. 7).

Spicular Structure of Skin.—The name Echinoderma expresses one of the chief characters of the branch. Prickles, it is true, are not so well developed in the other classes as they are in sea-urchins, though they are to be found more or less frequently in most of them. The essential feature is the presence in the deeper layers of the skin of minute spicules of crystalline carbonate of lime (calcite), which usually grow together into plates, or small bones, or prickles, all so interpenetrated with the connecting fibres of the skin that they constitute a beam-and-rafter work (fig. 8). Under the microscope a thin section of this looks like a net. Wherever the mid-layer or mesoderm occurs in the body, and not only in the skin, its cells have this power of deposition of lime; they can also re-absorb it and redeposit it, so that the shape and structure of the skeleton change as the animal grows. In all these respects the skeletal tissue of Echinoderma is paralleled only by the bone of Vertebrata; but it differs from

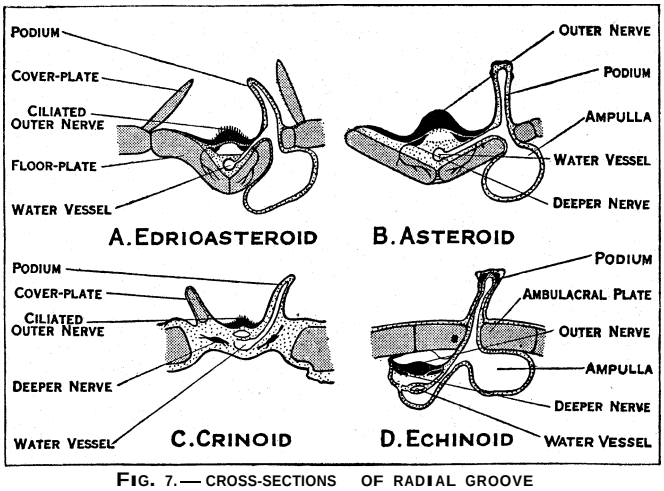


FIG. 7.— CROSS-SECTIONS OF RADIAL GROOVE

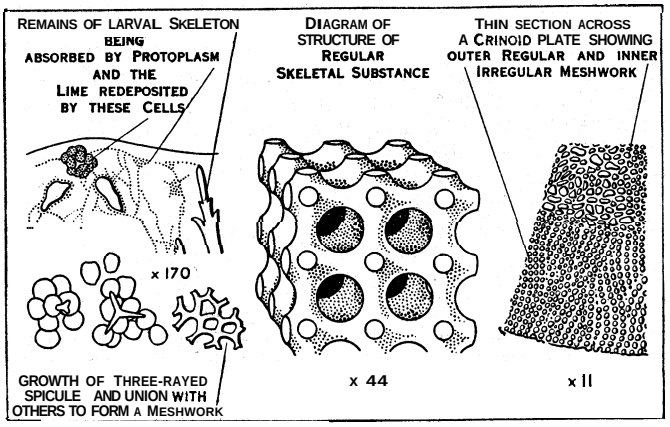
bone in chemical composition, in the formation of the spicules within the cells and not outside them, and in the retention of a crystalline character so that each plate acts as an individual crystal. By the cleaved surface characteristic of calcite and the net-like appearance, even minute fragments of echinoderm skeleton embedded in the rocks can be distinguished from the remains of molluscs, corals, arthropods and other animals.

Other Common Characters.— The following characters of less obvious nature are also common to all recent echinoderms:— The egg develops first into an elongate, two-sided larva (figs. 9 and 21), with an untwisted gut, and with the body-cavity essentially arising as three pairs of pouches (coeloms); all or part

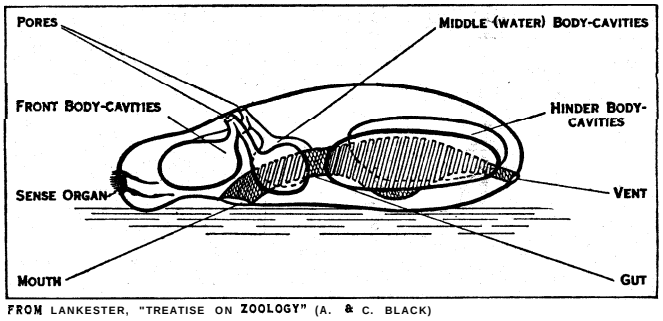


FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 8.— SKELETAL SUBSTANCE OF ECHINODERMA

of this is somewhat abruptly changed into a radial creature with coiled gut. This characteristic metamorphosis is described later. The nervous systems are three: (1) the outer oral sensory system, chiefly composed of a ring round the mouth, and radial nerves, lying outside the water-vessels, and derived from the epithelium; (2) the deeper oral motor system, lying just below the former, supplying the muscles in the oral side of the body-wall, and derived from the mesoderm; (3) the apical motor system, most pronounced in crinoids; its centre is where the stem originates, and its cords pass down the stem and the rays to work their muscles; it is in all classes except holothurians, and is derived from endothelium. The blood system consists of a number of spaces rather than definite vessels, without heart or regular circulation; its contents differ from the general fluid of the body-cavity only in containing more albumen. In all the internal fluids float various bodies: some are red with haemoglobin (like human blood-corpuscles), and aid respiration; others are white, wandering amoeba-like cells, which serve many purposes, some eating the various waste-products and then squeezing their way to the exterior, for there is no definite excretory system.

Relationships.— The Echinoderma, as we have seen, differ from other radial animals, but agree with many other branches, in the separation of a body-cavity (coelom) from the primitive hollow, which persists as the gut. The various branches of the



FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 9.— SIMPLIFIED DIAGRAM OF THE DIPLEURULA

Coelomata may have sprung independently from the Coelentera, and if there was any connection between them it must have been through forms whose existence we can only infer from a study of the oldest fossils and of the earliest stages in the life-history of their living descendants. Thus we find the mode of origin of the coelom and its early division into three pairs of sacs paralleled only in that great branch of the Coelomata which includes all animals with a backbone or with its cartilaginous precursor termed "notochord." The lower Chordata (as the branch is named) comprise the lancelet (*Amphioxus*), the sea-squirts or

ascidians, and some less-known, often worm-shaped creatures named Enteropneusta. All Chordata, except sea-squirts, show traces of this triple division of the coelom; and the growth of its middle division into lobes and tentacles is seen also in some Enteropneusta. The larva of one of the Enteropneusta (*Balanoglossus*) was originally described as an independent animal *(Tornaria)* and supposed to be related to the Echinoderm larval forms—the presence of a water pore accentuates the outer similarity. The mouth of the developing echinoderm, when it shifts from the original median position, invariably moves to the left not to the right; in the lancelet the mouth appears first on the left side. The central nervous system of Chordata, like the outer oral nervous system of Echinoderma, is derived from the outer epidermis and sinks below the surface in the same manner; this indicates that the ancestral forms responded to certain outer stimuli by a similar mechanism. The resemblances and differences between echinodermal and vertebrate skeletal tissue have already been emphasized. All these facts suggest that the Echinoderma and the Chordata were derived from a common ancestor, differing from the ancestors of other Coelomata, but itself not yet either an echinoderm or a chordate.

CLASSIFICATION

The five classes into which, as said at the outset, Echinoderma now living are usually divided, are not of equal value, for the Asteroidea and Ophiuroidea diverged in a comparatively late geological period, so that the differences between them are not so profound as those that distinguish the other classes; the difficulty is met by merging them in a super-class, Stelliformia. In early Palaeozoic times there existed other classes, all of which became extinct before the Mesozoic era began. Most of those creatures resembled the crinoids in being attached to the sea-floor and in feeding on minute organisms, which they swept along ciliated grooves into their usually upturned mouths. They have therefore been grouped with the crinoids as Pelmatozoa (stalk-animals), while the remaining classes, which are free-moving and generally feed with down-turned mouth on larger organisms, have been opposed to them under the name Eleutherozoa (free animals). These names conveniently connote definite facts of structure and habit, but do not imply any closer relationship between the classes included under them. The classification here adopted embodies a few recent advances. Certain Pelmatozoa that, in editions of the *Encyclopædia Britannica* after 1900, have been placed under Cystoidea as an order Carpoidea are now distinguished as a class. On the other hand the Blastoidea, though numerous and rather sharply defined, are a relatively late offshoot from the Cystoidea, and if they are retained here as a class, it is only because authorities disagree upon their point of origin. W. J. Sollas has proposed a class Ophiocistia for a few rare Silurian fossils, of which the structure was long misunderstood, though correctly given in the *Encyclopedia Britannica* (1911); they may be modified Stelliformia or Echinoidea, but cannot be maintained as a separate class. Recently some Palaeozoic fossils, usually regarded as Cirripedia, have been referred by T. H. Withers (1926) to the Echinoderma, and F. A. Bather has accepted that view, while keeping them apart as a sub-branch. Machaeridia The larger divisions of the Echinoderma here accepted may be tabulated, without implication as to their mutual affinities, thus:—

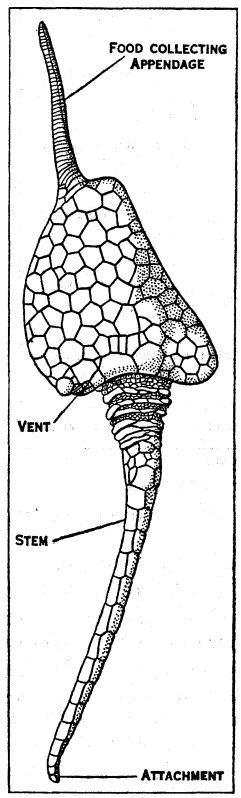
The † denotes that the group became extinct before the Mesozoic era.

COMPARATIVE ANATOMY AND PHYSIOLOGY

Machaeridia.—Of the Machaeridia only the skeleton is known, and it is mainly because its plates have shown the crystalline cleavage characteristic of echinoderms that they have been placed in this branch. In the simpler forms the plates are in two rows, hinged down the back, and opening on the other side (fig. 10); scars on their inner face indicate the presence of muscles that would pull the two sides together. One infers that the animal was elongate, flexible, symmetrically two-sided, with a mouth and some sensory organ at the fore-end, and a vent at or near the hind-end; it may have been such a creature as study of recent larvae has led several authors to imagine as a probable ancestor under the name *Dipleurula* (little two-sides) (fig. 9). In that the two front pairs of coeloms would have opened to the exterior by a pore apiece, but no trace of such a pore has yet been seen in machaeridian plates. More advanced forms had four rows of plates, two on each side. At one end a plate was often modified in a way that suggests temporary fixation.



BY COURTESY OF THE ROYAL SOCIETY OF EDINBURGH. FROM BATHER "CARADOCIAN CYSTIDEA"

FIG. 11.—A CARPOID. DENDROCYSTIS

Carpoidea.—All Carpoidea bear traces of a stem by which the body was attached to some object on or near the sea-floor (fig. 11). In most the skeleton shows some two-sided symmetry, if only in a part of the stem; this may have originated in the symmetry of the *Dipleurula,* but its gradual increase in various series of the class is due to adaptation. Nearly all Carpoidea are flattened in a plane parallel to the sea-floor, and either the whole body-wall is flexible or one side remains flexible, so that it could expand and contract as the animal drew in or expelled water for food or aeration. The positions of intake and vent relative to the stem and to each other vary according to the particular habitat and mode of life of each genus; originally, perhaps, they were at opposite ends of the body and the stem arose between them; in any case the arrangement differed from that of all other Pelmatozoa. In the apparent absence of water-pore, genital pore and any trace of radial symmetry, the Carpoidea and Machaeridia differ from all other classes.

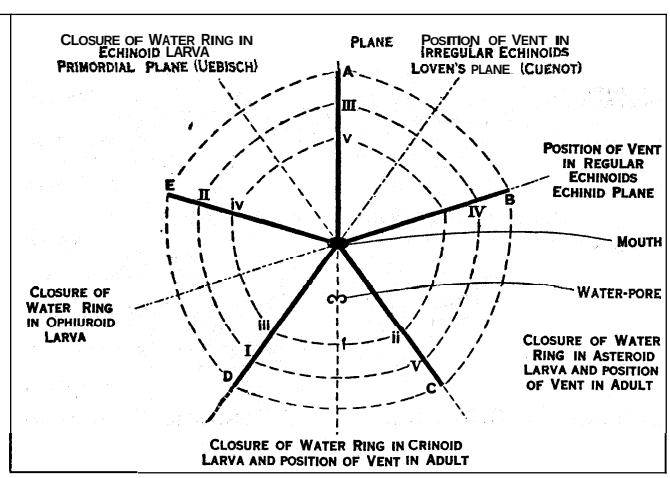


FIG. 12.—THE SYMMETRIES OF THE CHIEF CLASSES

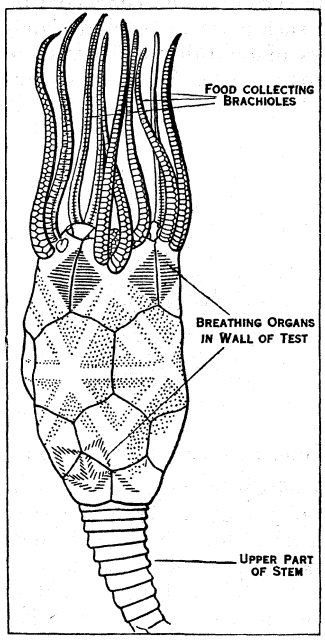
Cystoidea.—The Cystoidea, like all other echinoderms. have a

two-sided symmetry, but in them we see the rise of radial symmetry. Study of this enables one to draw a plan by which the symmetries in other classes can be compared (fig. 12). Normally the cystoids are attached to the sea-floor by one pole of the body and take in food through a mouth at the opposite, upper pole. Near the mouth is a water-pore, and close to it, but further from the mouth, is a genital pore; the vent is usually in the same line, at the side of the body. Thus the body can be divided into similar halves by a plane passing through the mouth or oral pole, the apical hole, and the water-pore. This plane is termed the **M** plane (because in other classes the water-pore is broken up into many, and the perforated plate is called a *madreporite*) and it can always be identified. The rays originate by the extension of the ciliated lining of the gullet over the body-surface; it stretches out in the form of grooves, the first, naturally, away from the vent, towards the front or anterior part of the body, the second and third towards the free space on each side; later, these three grooves become five by the forking of the right and left grooves. The food-collecting surface was usually increased by the extension of the grooves on little jointed appendages (brachioles), which did not contain prolongations of the body-cavity or of the generative system (fig. 13). The water-system may have sent branches through the mouth-opening along the food-grooves, but did not subserve locomotion. Aeration of the body-fluids was effected through thinner portions of the test, and according to the structure of these the Cystoidea may be grouped in two subclasses:—(1) Rhombifera or Dichoporita, in which the breathing organs are folds of the test-wall, crossing the sutures of the plates (fig. 13); (2) Diploporita, in which the breathing organs are canals of **U**-shape within the test wall and not crossing the sutures (fig. 14). There are other differences between these subclasses.



AFTER JAEKEL IN "STAMMESGESCHICHTE DER PELMATOZOREN" (JULIUS SPRINGER, BERLIN)

FIG. 13.—A RHOMBIFEROUS CYSTOID, CHIROCRINUS, NAT. SIZE

Blastoidea.—The Blastoidea proper (fig. 15) have a body-skeleton of 13 main plates arranged in three circlets, according to a marked five-rayed symmetry, viz., five radials, which support the five main food-grooves; five orals, which surround the mouth and lie between the food-grooves; the basals, which lie beneath the radials and form a facet for the stem. The vent lies in one of the interradii, either adjoining, or enclosed by, an oral; the water-pore and genital pore are probably associated with it. Respiration was effected through thin portions of the test wall, strongly folded so as to increase the surface; these *hydrospires* cross the sutures between the radial and oral plates. Each food-groove, after passing between the orals, lies not on the radial plate, but on a special plate in the radial line called, from its shape, the lancet-plate; this is bordered by small side-plates, to which brachioles are attached.

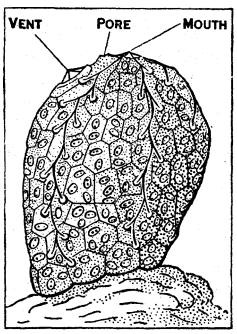


FIG. 14.—A DIPLOPORITE CYSTOID

Crinoidea.—The body of the Crinoidea (fig. 16) is normally borne on a stem, has the food-collecting system upwards, and the vent in the **M** plane at the side or raised away from the intake on a sort of chimney (anal tube). The food-grooves are extended on five arms or hrachia, which are not, like brachioles, mere appendages to the test, but actual outgrowths of the body (fig. 7j containing throughout extensions of the body-cavities, the generative organs, and the apical nervous system, as well as bearing the usual water-vessels with their side-branches and podia, and nerves from the two oral systems. The arms, which are built of successive plates (brachials), may fork or branch repeatedly, and the smaller branches may become arranged along the sides of the larger, forming pinnules. O. Jaekel, however, holds that the pinnules of certain forms represent the brachioles of cystids. The body with its arms is termed the crown; that portion of it below the free part of the arms is the dorsalcup; the covering or lid of the cup, above the free part of the arms, is the tegmen. In the simpler crinoids the cup consists of only two or three circlets of plates: the five radials, from which spring the arms; the (primitively) five basals, beneath the radials and alternating with them; and often the (primitively) five infrabasals, beneath and alternating with the basals. Infrabasals are wanting in some groups (monocyclic), present in others (dicyclic), but may be overgrown by the basals or may atrophy in the adult (cryptodicyclic). The cup may be enlarged by the incorporation of the lower parts of the arms, between which other plates (interbrachials) often arise; to make room for the vent, or to support it, special anal plates may be added. The gut, as viewed from the oral surface, is coiled in a clockwise direction (solar).

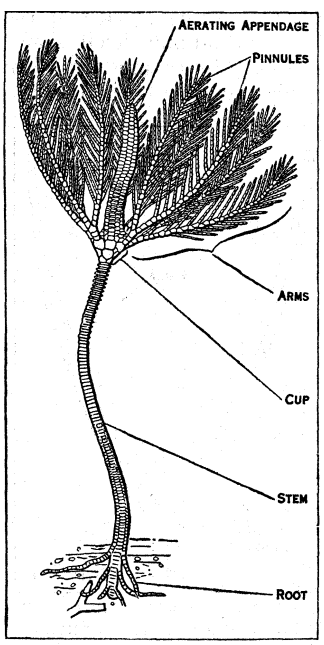
FIG. 15.—A BLASTOID, OROPHOCRINUS FUSIFORMIS



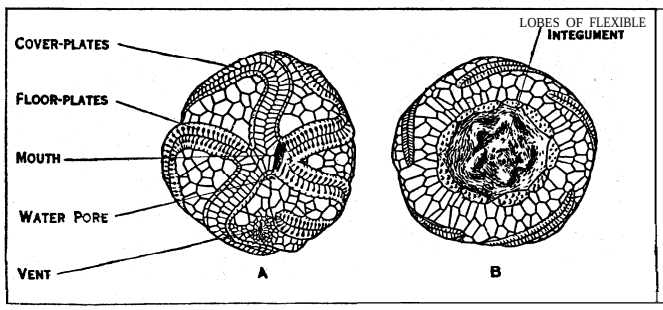
BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

FIG. 16.—BOTRYOCRINUS DECADACTYLUS, OF SILURIAN AGE

Edrioasteroidea.—The Edrioasteroidea (fig. 17) had a circular test composed of an indefinite number of irregular plates. They were either permanently attached to the sea-floor, or adhered like a limpet with some power of movement. From the upturned mouth five food-grooves stretched over the upper face; these were usually borne on a series of alternating floor-plates and protected by hinged cover-plates. From the structure of the fossils (fig. 7) it is inferred that a water-canal passed from a ring canal round the mouth, beneath each groove but outside the floor-plates, and that it gave off branches, each of which ended in a podium stretching outwards and a swelling (ampulla) stretching inwards between the floor-plates to form a reservoir; no other Pelmatozoa show such a structure. There were no brachioles. The gut seems to have had a solar coil; its vent and madreporite lay on the same side as the mouth. In some genera the depth of the food-grooves impressed a five-rayed symmetry on the generative organs.

Stelliformia.—The Stelliformia (sex-stars, brittle-;Lars. *et al.*)

live as a rule with the mouth downwards; from it radiate five ciliated grooves with a superficial nervous tract, as in Pelmatozoa; the structure of these grooves and of their associated water system is as just described for Edrioasteroidea (fig. 7). The creature indeed resembles an *Edrioaster* turned upside-down, but differs in that both vent and water-pore are on the apical face, which is now uppermost; they are, moreover, no longer both



FROM LANKESTER, "TREATISE OH ZOOLOGY" (A. & C. BLACK)

FIG. 17.—EDRIOASTER (SESSILE STAR) COMBINES ASTEROID STRUCTURE WITH CRINOID HABIT. A UPPER, B. UNDER SURFACE

in the same interradius: while the madreporite, as shown in fig. 12, still marks interradius C/D of the M plane, the vent has moved into B/C. In correlation with the overturn, food-collecting by ciliated grooves has given place to active search for and ingestion of animal food, alive or dead, in larger portions; this again has led to modification of plates round the mouth into jaws, and to prolongation of the ambulacra on radial extensions of the body, giving the animal first the star shape (fig. 1), then the form of a disc with five arms (fig. 2). The terminal plate of each ray is separated from the apical pole by a stretch of plated integument; the grooves never bend round on to the upper surface. Since each terminal bears an organ sensitive to light, it is also called an ocular. According as they move by crawling or wriggling recent Stelliformia fall into two classes: Asteroidea and Ophiuroidea.

In the Asteroidea (fig. 1) the ambulacral grooves remain open and the podia change into tube-feet, each with a sucker at the end, by which the sea-star clings to objects and pulls itself along; a podium can be withdrawn into the groove by its muscles, when its fluid contents pass into the ampulla; contraction of the am-

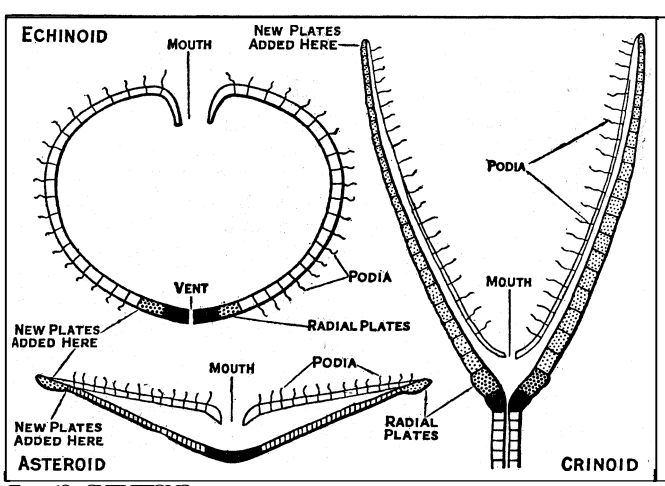


FIG. 18.—SKELETONS OF AN ECHINOID. ASTEROID AND CRINOID PLACED WITH MOUTH UPWARDS AND CUT ACROSS. RADIAL PLATES=OCULARS

pulla squeezes the fluid again into the podium, swelling it out for use. The arms are not, as a rule, sharply distinguished from the body, and they contain both genital glands and blind extensions of the digestive system (caeca). The body-fluids are aerated through thin-walled outgrowths of the body-cavity (papulae) which pass between the plates of the upper surface. Podia and papulae are protected by thorns or spikes, which are sometimes clumped (paxillae), sometimes branched and bearing a membrane, sometimes modified into small grasping organs (pedicellariae). Many sea-stars have more than five arms, but the arms never fork.

The Ophiuroidea (the name means snake-tail forms) owe their name to the long, thin, flexible arms, which spring abruptly from the central disc (fig. 2). The arm-groove is covered, the podia cease to act as tube-feet, the floor-plates are thickened and joined by pairs into solid bones shaped like vertebrae and connected by strong muscles. No room is left in such arms for genital glands or digestive caeca. The outer plates of both disc and arms are broad shields, without interspaces for papulae. Sometimes aëration is through clefts at the bases of the arms. The thorns remain small and usually of simple structure. No ophiuroid has more than five arms, but in one order (basket-fish) the arms may fork several times and the animals cling to branched corals.

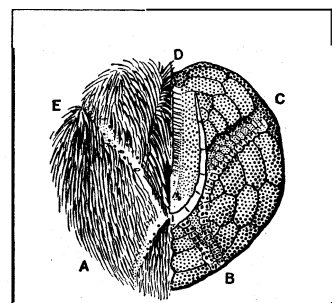

FIG. 19.—IRREGULAR ECHINOID

Echinoidea.—The Echinoidea (sea-urchins, figs. 3, 19) also live mouth downwards. A simple regular echinoid may be compared to an asteroid in which the vent is at the apical pole, and the grooves have grown round on to that face of the test (fig. 18), so that their terminal ocular plates encircle the vent and are separated from it only by five other plates of rather larger size, each pierced by an opening for the extrusion of the genital products (hence called genital plates), and one also pierced by numerous water-pores (madreporite). The test having become rigid as well as globular, the soft structures of the grooves have sunk beneath it, and the podia emerge through the plates (fig. 7). The absence of papulae from the close-built test throws more respiratory work on the podia, and to aid this the canal of each is divided, and cilia sweep a current up one half and down the other; thus the pores for the podia are double like the diplopores of cystoids. The plates through which the podia pass are called ambulacrals; new evidence suggests that they correspond to the floor-plates of Asteroidea and Edrioasteroidea, not to the cover-plates or to any structure in Crinoidea, Cystoidea or Blastoidea. The genital glands are much branched, and here remain interradial.

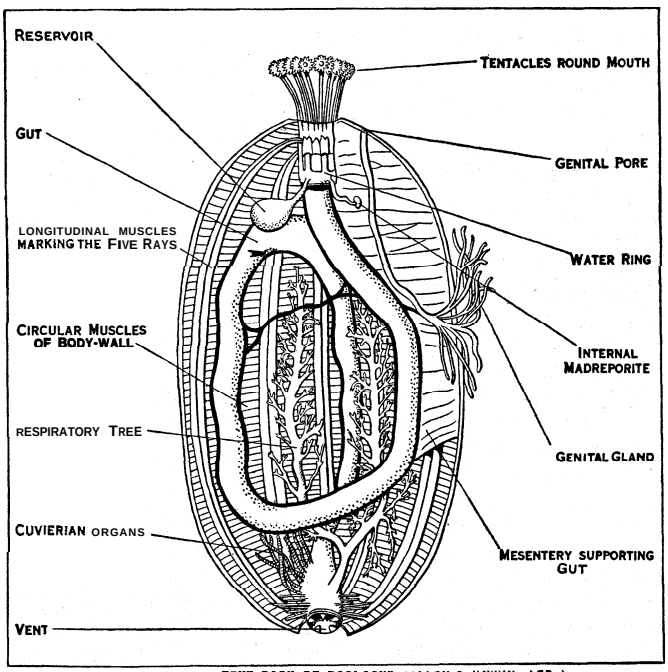
In a regular echinoid (fig. 3) the madreporite and vertical axis mark the M plane; the vent is not precisely at the apical pole, but is shifted in the direction of radius B (fig. 12). According to S. Lovén, the plates of the five interradii are symmetrical with regard to the plane B-D/E, which therefore is called the echinoid plane. In a large number of later sea-urchins the vent moves towards the under-side of the test, whence such forms are called irregular echinoids (fig. 19). In most the vent passes along interradius B/A, while the mouth moves in the other direction along radius D; the plane thus marked is known as Lovén's plane. In such urchins the groove D is termed anterior, and, with the adjacent C and E, forms the trivium, while grooves A and B form the bivium. These are not the same rays as form the so-called trivium and bivium in the other classes. The change to irregular is connected with a change in the mode of feeding. Regular echinoids have five teeth, interradially placed and held in a frame of 20 pieces, which Aristotle compared to a ship's lantern. In those later forms that take to feeding on ooze or minute food, these structures are gradually lost.

It is in the urchins that the spikes or prickles of the skin are most highly developed. They are generally called spines (Lat. *spina,* a thorn), but as "spine" has a different meaning in English and anatomy, the term "radiole" is preferable. They are attached to round-headed tubercles on the test by a ball-and-socket joint, and are moved by muscles. Primarily radioles serve for protection, but the larger radioles may be used like stilts for locomotion or for digging. Some radioles are minute, clothed with cilia, and arranged in narrow bands (fascioles), which are supposed to sweep currents of water for aeration or sanitation. Pedicellariae

are always present, and are of five different types.

Holothuroidea.—The Holothuroidea (holothurians, sea-cucumbers) resemble the Echinoidea in that the outer skin covers the grooves and is pierced by the podia. But, whereas a sea-urchin moves sideways in any direction, a normal holothurian (fig. 5) moves only in the direction of its mouth, with the body stretched along the sea-floor, and the vent at the other end. The surface turned to the sea-floor is always the same, and is usually flattened; down its middle line is one of the radii (A), with radius B to its right and E to its left (fig. 12), the podia of these radii serve as sucking feet, but those of radii C and D, on the upper surface, are used only for feeling and aëration. Near the front or mouth end of the middle upper interradius C/D opens the duct from the single genital gland, while the water-pore opens just in front of it in the larva and in the adult too in some species; in others the pore closes and the water-system obtains its fluid from the body-cavity through openings in the stone-canal. There is no apical system of plates, and no terminal plate or special tentacle at the end of each ray. In these respects and in the symmetry of the rays the holothurians depart from other Eleutherozoa and approach such early Pelmatozoa as *Edrioaster*.

The following special features are found in most holothurians (fig. 20). The mouth is surrounded by the ten front podia, which have become prominent tentacles. Outside these is a rim, which can close over both mouth and tentacles. The body-wall has two sets of muscles: a transverse, circular layer, which, on contraction, compresses the contained fluids and thus elongates the body; five pairs of longitudinal muscles, alongside the radii, which on contraction shorten the body (it is hard to hold a holothurian). The gut passes from the mouth, below interradius C/D to the hinder end of the body, then forwards along interradius D/E, then downwards along A/B to the vent; thus it has a solar coil as in crinoids and echinoids. Most holothurians suck in water through the vent for aeration; to accommodate this the rectum is enlarged and, in numerous species, gives off two many-branched tubes with



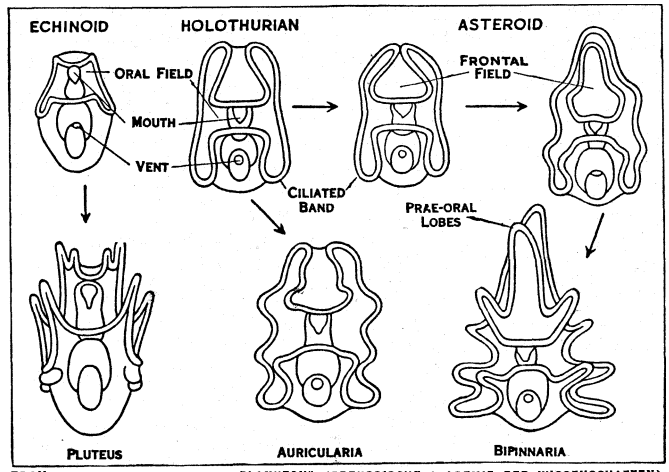
FROM SEDGWICK, "STUDENT'S TEXT BOOK OF ZOOLOGY" (ALLEN & UNWIN, LTD.)

FIG. 20.—A HOLOTHURIAN OPENED ALONG THE BACK

blind ends, termed the respiratory trees. In most holothurians the skeleton is greatly reduced. Round the gullet is usually a ring of five radial and five interradial pieces, which may correspond to the mouth-frame of echinoids. There are no regular plates in the body-wall, but throughout the skin and the connective tissue are scattered minute spicules, which have different shapes characteristic of the various genera and species; in one or two genera some of these are enlarged to form irregular plates, and in one or two they are absent altogether.

REPRODUCTION AND DEVELOPMENT

In most echinoderms the sexes are separate, but not distinguished by any external character. The genital products are discharged into the water, where the eggs are fertilized by the sperm. The egg then divides into a number of cells, which form a hollow ball. One end of this grows inwards, and the result is an open-mouthed sac with a double wall. From the walls cells migrate

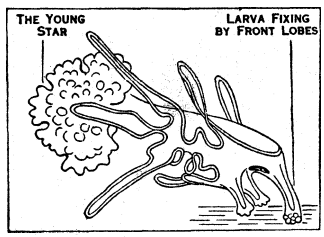


FROM MORTENSEN, "NORDISCHE PLANKTON" (PREUSSISCHE ACADEMIE DER WISSENSCHAFTEN)

FIG. 21.—THE EARLY STAGES OF LARVAE OF VARIOUS ECHINODERMS

into the space between, forming a middle layer. This stage corresponds to the structure of the jelly-fish, etc. (Coelentera). The body-cavity arises from the hollow of the sac as a single pouch growing out into the loose middle layer. By repeated division of this pouch arise the three pairs of coeloms shown in the diagram of the dipleurula (fig. 9). Meanwhile the sac lengthens and is flattened on one side, towards which the original cavity bends down and breaks through to form the larval mouth, leaving the original opening as the larval vent.

The larvae are free-swimming, and are modified from this ground-plan in five directions according to the class to which each belongs. They used to be regarded as distinct animals, and so received special names. Of the four types of pelagic larvae of Eleutherozoa the simplest is the holothurian, of which an early stage is shown in fig. 21. The primitive mouth is surrounded at a little distance by a band of cilia, which by their vibration move the larva. A smaller ciliated band immediately round the mouth sweeps in food. The oral field, within the main band, is shaped like a broad H; in later stages the two side portions are folded on their borders and look like a pair of human ears, whence this larva has been called *Auricularia*. The vent lies in the middle below the cross-piece of the H, and the gut runs through the curved body to it, swelling on its way into a stomach but showing no twist. This larva has no skeleton, only some wheel-shaped spicules scattered through its substance. The larvae of brittle-stars and sea-urchins have a skeleton, in which long rods push out the side-folds and so increase the length of the ciliated band; early stages are shown in fig. 21. A fancied resemblance of later stages to a painter's easel led J. Müller to called the larva *Pluteus* (easel). In the arrangement of the rods the *Ophiopluteus* differs somewhat from the *Echinopluteus*. The asteroid larva has no skeleton. It differs from the auricularia in the meeting of the two upper limbs of the H, so that the oral field is like an A, and there are two complete ciliated bands (fig. 21); their apices are drawn out into long prae-oral lobes, and their margins are folded into narrower lobes or pinnae, whence the larva was called *Bipinnaria*. In the recent unstalked crinoids and some other echinoderms with large yolky eggs, the larva grows within the egg till it emerges as



FROM MORTENSEN, "NORDISCHES PLANKTON" (PREUSSISCHE ACADEMIE DER WISSENSCHAFTEN)

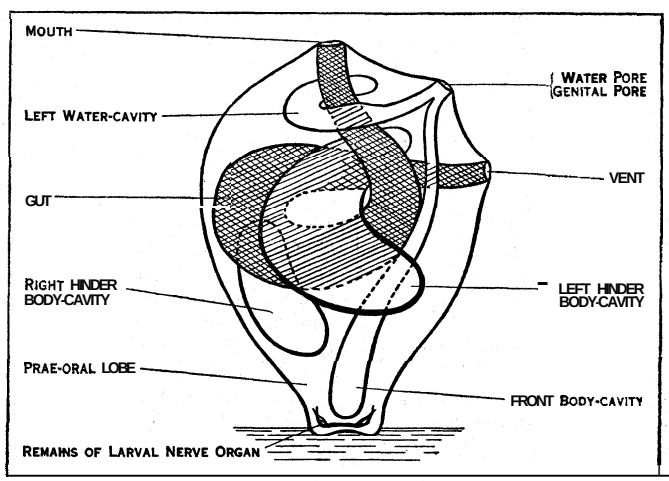
FIG. 22.—LARVA FIXED TO SEA FLOOR AND YOUNG STAR

a barrel-shaped form with five bands of cilia like the hoops of the barrel; the primitive mouth, being unused, closes.

Between the larva and the adult is a series of complicated changes, during which the larval skeleton is absorbed and redeposited as the permanent skeleton, while portions of the creature are often cast aside as worn out trappings. Such a marked change is called a metamorphosis (*q.v.*). It is best known in some of the sea-stars, where it takes about 12 days. The larva sinks and attaches itself to the sea-floor by a portion of the prae-oral lobe (fig. 22); this is pulled out into a stalk, and the future star developed within the body of the larva. The essential change is the curving of the left hydrocoel and the left hinder coelom round the gut, till each becomes a ring. In the asteroid the oral face of the star bends downwards towards the stalk and the floor, and the water-ring closes round the stalk, which then disappears (fig. 24). In the crinoid the oral face is bent upwards, so that the water-ring does not enclose the stalk (fig. 23). As shown in fig. 12 the water-ring closes in a different interradius with reference to the M plane in each class; this is connected with the torsions that occur during metamorphosis.

The later stages of growth are often of interest to the evolutionist as suggesting the ancestry of the present form and the origin of its special structures. The classical instance is the rosy feather-star (*Antedon bifida*). This was thought to be an asteroid, but in 1823 J. V. Thompson, a Cork surgeon, discovered that when quite young it was fixed by a stalk like a crinoid; the growing animal breaks away from the root, and the upper part of the stalk is condensed into a knob bearing numerous stem-tendrils or cirri. This process recapitulates the race-history traced in Jurassic fossils.

Protection of the Brood.—Free-swimming larvae probably represent an ancient stage in echinoderm history, retained in the life-history to ensure the dispersal of creatures that are slow-moving or fixed in the adult. The fixed larval stage that intervenes demands food-yielding and quiet waters. When, as on ice-bound coasts or in ocean abysses, such conditions do not obtain, the eggs are furnished with yolk, and both they and the developing young remain with the mother. Brood-chambers or nurseries may be formed. The thorns of some sea-stars expand like umbrellas over

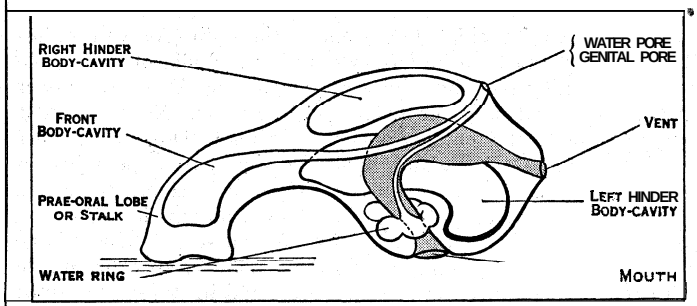


FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 23.—DIAGRAM SHOWING THE INTERNAL STRUCTURE OF THE PRIMITIVE PELMATOZOON. PRODUCED WHEN THE DIPLEURULA FIXED ITSELF BY THE HEAD CAUSING THE MOUTH TO MOVE UPWARDS AND SO THROW THE GUT INTO A COIL AND BEND THE BODY-CAVITIES

the young; in some sea-urchins the ambulacral grooves are sunk to receive the eggs; many brittle-stars have pouches hollowed in the sides of the body between the arms; the plated holothurian, *Psolus*, has a nursery roofed by large plates on its back; in some other holothurians the young cling by their podia to the parent's back; the stem and root of a crinoid present a natural surface of attachment for the young.

Self-division and Regeneration.—Many echinoderms can break off portions of themselves, generally under the stimulus of danger or to get out of a difficult situation. The stem and arms of the later crinoids have special breaking-planes; the brittle-star snaps off its arms when seized and disintegrates before the distressed naturalist; holothurians, when attacked, eject portions of their viscera, and to this habit the cotton-spinner owes its name. The discarded portions can be grown again; it has even been claimed that in some cases they can themselves grow fresh bodies and become complete individuals. A sea-star *(Linckia)* commonly



FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 24.—DIAGRAM SHOWING CHANGE FROM FIXED ECHINODERM TO FREE

avails itself of this faculty, and one may find big arms with a small body at one end, and four little arms growing out of it; these are known as comet-forms. The power of regeneration is probably due to the extension of all the systems of the body into the arms, but it seems that in general a portion of the central disc must also be present. A development of this power is reproduction by spontaneous division, as practised by many sea-stars, brittle-stars and holothurians; it is indeed the usual method in the British holothurian *Cucumaria lactea*. Sea-stars found with groups of arms of different sizes must have divided in this way.

GEOGRAPHICAL DISTRIBUTION

Echinoderms are confined to the sea, and differ in this from all but one or two branches of the Animal Kingdom. The limitation is probably connected with the density of the water, since echinoderms depend largely on their hydraulic system, and there is besides a constant interchange between the internal fluids and the outer water through the thin membranes. Any sudden change would be particularly fatal to the larval stages, which transport the species to other localities. Some species tolerate a change better than others, but few are found even in brackish water. Within the sea, however, echinoderms may occur from anywhere between tide-marks down to 6,000 metres ($3\frac{3}{4}$ miles). Those between tide-marks are generally buried in moist sand; some urchins bore holes in rock, and these retain a little water; few can stand being left high and dry. In littoral waters examples of all classes are numerous, but the greatest abundance and variety occur between 1,000 and 2,000 metres; in the greater depths both species and individuals are fewer. Most species have a limited range of depth, but a few have considerable extension; thus, the brittle-star *Ophiacantha bidentata* ranges from 5 to 4,450 metres. No order and no family is exclusively either littoral or abyssal, but two highly modified kinds of holothurian occur only floating in the open sea.

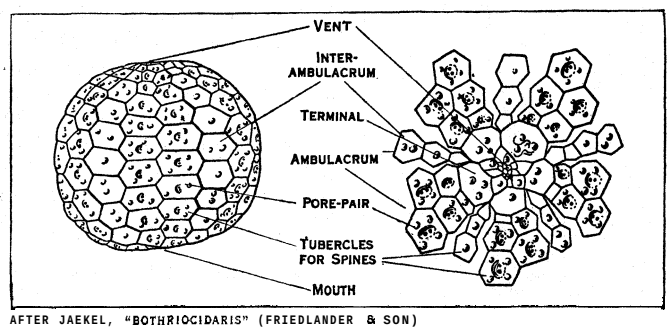
Since the depths of the sea are connected and their conditions uniform, species inhabiting them map be found in any of the oceans. The conditions of coastal waters are varied, and so, consequently, are the species, few having a really wide distribution; the chief exceptions are circum-polar species, which may stretch down the Pacific and Atlantic coasts. Some Arctic species appear to be represented in the Antarctic by similar forms, a phenomenon also observed in other groups of marine animals. Attempts have been made to map out various regions, each characterized by its echinoderm fauna, and from these to infer past migrations and possible changes of land and sea; but knowledge is still incomplete and opinions too diverse for summary here. Echinoderms have been said to abound more in the tropics, where certainly they are more striking in colour; but modern dredging shows that they occur in the same enormous quantities and rich variety in polar and temperate seas. In the Atlantic brittle-stars may be brought up by hundredweights, and the "Challenger" dredged 10,000 unstalked crinoids at a single haul.

GEOLOGICAL HISTORY AND EVOLUTION

Geology gives only a succession of fossil forms; the relation of these to one another is interpreted through facts of anatomy and development, and seen to be an evolution. In its main lines the race-history is now thought to have been as follows. We start with a dipleurula larva (fig. 9), still free-floating and with none of the peculiarities of the modern adult echinoderm. The event that originated the branch was the discovery of the sea-floor, on which followed the adoption of a stationary life and the deposition of lime spicules in the skin. The three-rayed spicules grew into star-shaped plates loosely joined, such as are scattered in Lower and Middle Cambrian rocks. As the plates grew, they were more firmly united, and completer skeletons were preserved. These, at the outset, show a divergence. The Machaeridia (fig. 10) may represent the elongate stage before fixation. If the elongate form became fixed by the middle of its body, the mouth and the vent would be on the two sides of the base of attachment, and from such a creature all the nonradiate Carpoidea (fig. 11) may have descended. They are found only from Middle Cambrian to Devonian.

Origin of Radiate Forms. — Radiate forms had a different origin. The dipleurula, apprehending the floor by its sensory front end. fixed itself, not by the ciliated pole, but a little to one side, the right side being chosen for a reason we cannot yet fathom. The result was the passage of the mouth to the upper surface (fig. 23). As it passed up along the left side, the gut caught hold of the left water-sac and pulled it upwards, curving it in the process. Since this was attached to the left duct from the front body-cavity, that structure was also pulled up and its pore came to lie between mouth and vent, while the stretched part of the front cavity formed a canal lying along the outer wall. The gut, as it coiled, drew the left hinder coelom also upwards in a curve, while the stomach pressed the right hinder coelom down to the fixed end, where it was involved in the elongation of that region. Not only can these changes be traced in the developing *Antedon* today, but several of the older cystoids had the structure of such a primitive pelmatozoon. Notably they retain the pore by which the genital products, formed from the canal alongside the body-wall, were extruded. At this stage no radiate structure was visible, but, unlike Carpoidea and Machaeridia, these forms had the fundamental plan on which the radiate types were built.

Radiation arose from the mode of feeding combined with the effect of gravity. Fixed to the sea-floor, with its mouth upturned to the food-bearing waters, which it swept inwards by the cilia of the gullet, the primitive pelmatozoon extended its food-collecting surface by the outgrowth of ciliated channels from its mouth



AFTER JAEKEL, "BOTHRIOCIDARIS" (FRIEDLANDER & SON)

FIG. 25.—SUPPOSED ANCIENT ECHINODERM. BOTHRIOCIDARIS, SHOWING (RIGHT) ARRANGEMENT OF PLATES ROUND THE VENT

as already described under Cystoidea. A limit was set to this increase by the size of the body itself.

Crinoids and Feather-stars. — Another class, based on a better plan, appeared first at the close of Cambrian time and by the close of Devonian time had taken the place of the cystoids; this class was the Crinoidea. Here the length of the food-grooves was increased by the actual outgrowth of the body-wall in the direction of the five rays, but upwards; the outgrowths became jointed, and repetition of the process led eventually to the long and many-branched arms of the crinoids, in which the grooves sometimes reach the combined length of a quarter of a mile. The Crinoidea early blossomed into some half-dozen orders and became adapted to every habitat which the sea provides. A single instance may be taken from certain shore-dwellers which in Jurassic times found safety by shortening their stem while retaining the whorls of cirri; with these, when torn away by the waves, they could grasp the nearest object. Eventually the stem was fused with the lower part of the cup into a hemisphere covered with cirri. Acquiring some power of free locomotion, this type spread into the group of Comatulida (feather-stars), which today comprises hundreds of species, divided among 98 genera (fig. 4).

Sea-stars and Brittle-stars. — Among the oldest known echinoderms is a genus of Edrioasteroidea, a class in which radiation had affected not only the food-grooves but the hydraulic system. Though clearly Pelmatozoa, they provide a starting-point for all classes of Eleutherozoa. Most adhered by a sucking action of the flexible under-side to smooth surfaces. Through the thin skin of that side, the genital products, it is suggested, were extruded. At that time, if at no other, the creatures were liable to be overturned, and those that could use their podia for locomotion would have an advantage. A sea-star is little more than an overturned *Edrioaster*, and some even now retain the power of feeding in the pelmatozoan way. The anatomical changes in adaptation to the new mode of life have been explained under Stelliformia (fig. 24). Fossils of the crawling asteroid type are known from the top of the Cambrian, but are rare until the Upper Silurian and Lower Devonian, when some adopted a wriggling habit and a structure tending towards the ophiuroid type. Genera with arm-grooves completely closed and with all their floor-plates turned into "vertebrae" are of doubtful occurrence earlier than the Carboniferous. Ophiuroids with elaborate vertebrae of modern type appear first in the Trias.

Sea-urchins. — The first echinoids may also have been derived from overturned edrioasteroids; the vent, as it passed up, was dragged a little farther back, leaving room for the madreporite, with which it became closely associated at the apical pole. The earliest known are from the top of the Ordovician. For half-a-century *Bothriocidaris* (fig. 25), a small fossil from Esthonia, has been regarded as an ancestral echinoid, but T. Mortensen, after fresh examination, refuses to accept it. This leaves in the Ordovician and Silurian only many-plated forms with flexible test; they cannot be derived immediately from *Edrioaster* since they already have well-developed jaws. The family Lepidocentridae, to which they belong, continues to the Carboniferous. Nearly all Palaeozoic echinoids have more than the 20 columns of plates found in later genera; among them the Archaeocidaridae, apparently existing in the Devonian, are nearest the simple cidarid type, which has a solitary representative in the Carboniferous and another in the Pdrmian. The early cidarids retained some flexibility in the union between ambulacral and interambulacral ares; in the Triassic period this gradually gave place to a rigid union, and at the same time appeared the diademoid type, with external gills, close-set podia, and more numerous radioles. Cidaroida and Diademoida have persisted to our own day, the former relatively unchanged, the latter giving rise to successive suborders. Among these, some Jurassic genera show the beginning of that movement of the vent towards the margin which characterizes the irregular urchins. A side-branch originating in Cretaceous times was the Clypeastroida (shield-urchins) as an adaptation to life just below the sand of the shore. Another modification led to elongate urchins in which the jaws were gradually lost as the animal took to extracting nutriment from ooze. The extreme of this line is reached in the modern Spatangidae (heart-urchins).

Sea Cucumbers. — The coiled gut and radiate hydraulic system of the Holothuroidea suggest that this class also was derived from a primitive pelmatozoon. At an early stage the creature took to locomotion in the direction of the mouth, with consequent worm-like lengthening of the body, possibly facilitated by the less calcified integument. Already in Middle Cambrian shales are found the compressed imprints of soft-bodied animals with apparent holothurian structure. The closure of the food-grooves, the elaboration of mouth-tentacles. the suppression of the unused podia on the back, and the retention of the single genital gland with its

pore, were all natural consequences of this mode of life. Spicules ascribed to holothurians have been found fossil from the Carboniferous onwards, but the general absence of other skeletal structures prevents one from tracing the history of the class.

NATURAL HISTORY

Echinoderms are sluggish and frequently immobile for considerable periods. The brittle-stars are the most rapid movers. Free forms shun the light, and hide or bear a cloak of sea-weed by day. Their often brilliant colouring can rarely have protective value. Some sea-stars light the depths with glorious phosphorescence, and many littoral brittle-stars phosphoresce when stimulated. This also may be a useless by-product of some activity. The general mode of life and nutrition have been mentioned under the various classes, and further details are given under STAR-FISH and SEA-URCHIN. Holothurians feed by sweeping minute creatures into the mouth with large shield-shaped tentacles, or by catching them with the slimy surface of bushy tentacles, which they push into the mouth and withdraw cleansed. Abyssal holothurians live in and feed on the ooze, breathing by the podia of the back, which are often monstrously developed. In some holothurians portions of the respiratory trees consist of slime-secreting cells; when irritated, the animal compresses its body and forces the tubes out of the vent; the slime absorbs water and swells enormously, finally splitting into sticky threads in which an enemy can be hopelessly entangled. Many animals live in or on echinoderms as messmates: among them are protozoans, sponges, annelids, arthropods, molluscs, and, most notably, a fish, Fierasfer, which enters the respiratory trees of holothurians. Parasites are even more numerous. Besides the groups mentioned, they include nematodes, trematodes, a myxomycete, and the myzostomes, of uncertain affinity, found chiefly on crinoids. Many of these uninvited guests assume the livery of their host, and frequently compel structural changes.

Economic Aspects.—In the economy of Nature, echinoderms play a larger part than in that of man. The crinoids and other Pelmatozoa seem useless; yet they have extracted from the sea millions of tons of lime and built up huge masses of rock. Derbyshire marble, Belgian petit granit, the *Trochiten-kalk* of Germany, and many of the Oolitic freestones are largely formed of their remains. Holothurians in the sea, like earthworms on land, pass the loose detritus perpetually through their bodies, extracting the organic nutriment, and thus acting as cleansers. The same task is performed by many heart-urchins, while most of the other free-moving forms, especially the sea-stars, are scavengers on a larger scale. An ocean without echinoderms might become a putrid cesspool. Unfortunately sea-stars do not confine themselves to carrion, but attack living molluscs, among them oysters and mussels, doing terrible damage (see STAR-FISH). On the other hand some of the smaller kinds are eaten by bottom-fishes, and thus help to turn Nature's waste into marketable food. For the immediate food of man most echinoderms are unsuitable, but some holothurians are used in the East (see BÊCHE-DE-MER), and in various parts of the world the ovaries of the larger regular sea-urchins are much appreciated. The ease with which the eggs of echinoderms can be fertilized and the early stages of development reared in the laboratory has led to their extensive use as material for research into fundamental problems of life and growth.

History.—During the 18th and first half of the 19th centuries, echinoderms were described by many eminent naturalists: Echinoidea by J. T. Klein, C. Linnaeus, N. G. Leske, E. Desor and L. Agassiz; Stelliformia by J. H. Linck; Crinoidea by J. S. Miller; Cystoidea by L. v. Buch; but it was the researches of Johannes Miiller (1840–50) that laid the foundation for a scientific treatment of the branch. For the host of later writers on this large and varied group, reference must be made to the works cited in the bibliography.

BIBLIOGRAPHY.—An annual index to all publications on Echinoderma has for many years appeared in Zoological Record (London, Zool. Soc.). General works are:—H. Ludwig and O. Harnann, "Echinodermen" in Bronn's *Klassen* und Ordnungen *des* Tierreichs (1889–1907), full bibl., exhaustive accounts of recent forms; F. A. Bather, E. S. Goodrich, J. W. Gregory, "Echinoderma" in Lankester's Treatise on Zoology (1900), bibl., recent and fossil, full on Pelmatozoa; E. W. MacBride, "Echinodermata" in Cambridge Natural History, I. (1906), good on habits; T. Mortensen, Handbook of the Echinoderms *of* the *British* Isles (1927), bibl., good for the zoologist on both sides of the Atlantic. Special Groups are approached on broad lines in:—T. H. Withers, Catalogue of the Machaeridia (1926), Nat. Hist., bibl.; O. Jaekel, "Phylogenie und System der Pelmatozoen," *Palaeont. Zeitschr.* (1918); A. H. Clark, Monograph of existing Crinoids (1915); F. A. Bather, *Studies* in Edrioasteroidea (1915); W. K. Spencer, Monograph on *Palaeozoic Asterozoa* (1914), Stelliformia; H. Matsumoto, "Monograph on Japanese Ophiuroidea," *Journ. Coll.* Sci. Tokyo (1917) new classification. (F. A. B.)

ECHINOIDEA, a class of the Echinoderma (*q.v.*), comprising the sea-urchins (*q.v.*).

ECHINUS, in architecture, a convex moulding! under the abacus of a column capital, so called from its resemblance, in form, to a sea urchin (Greek ἐχῖνος, *echinos*). It is universal in both Greek and Roman Doric orders, in which it usually has a profile of circular or elliptical curvature; occasional Roman examples have a cyma recta, double curved (see CYMA) profile. The convex moulding between the volutes of the Ionic order is also termed an echinus, as is any similar form in a capital of any style. (See ORDER.)

ECHIUROIDEA. The echiuroids are a small group of exclusively marine animals which live in tubes or galleries in the rock. They are of moderate size (*Ikeda* is recorded with a length of two metres) with a sac-like body surmounted by a large preoral lobe or proboscis, with which they explore their surroundings in search of food. In almost all species there is a pair of bristles, strictly comparable with the bristles of the annelids or segmented worms, on the ventral surface a short distance below the mouth; by means of these the animals can enlarge the walls of their burrows. They can also drag themselves from place to place by fixing the proboscis to a stationary object and by its contraction drawing the body forward. *Echiurus* is capable of swimming freely, which it probably does at night; this would account for the occurrence in certain places of large numbers of these animals thrown up on the beach on the morning after a storm.

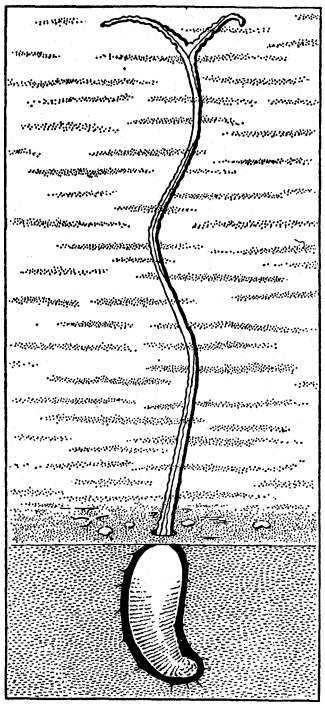


FIG. 1.—BONELLIA VIRIDIS, SHOWN WITH ITS BODY IN ITS HOLE. AND THE LONG DIVIDED PROBOSCIS, OFTEN A METRE LONG. PROTRUDED

Phylogeny.—The precise relation of the echiuroids to other animal groups still remains obscure. Many authorities consider them closely allied to the annelids, but certain primitive features in their development make it preferable to regard them as an early offshoot of the same branch as that which gave rise to the annelids rather than as members of that group that have lost their segmentation.

Anatomy.—The body-wall consists of a cuticle, glandular epidermis, a cutis and three layers of muscle. There is a roomy body cavity or coelom which communicates with the exterior by a varying number of nephridia or ducts, which serve both for excretion and for the passage of the genital products. The coelom is filled with corpuscles and in some species also contains haemoglobin. The ciliated proboscis leads by a simple mouth into the alimentary canal, which is divided into regions according to their function in digestion. The mid-gut is provided ventrally with a ciliated groove and a collateral intestine. From the rectum two large sacs are given off which communicate with the coelom by a number of ciliated funnels and to the exterior by the terminal part of the rectum. These are absent in *Hamingia* sibogae.

Except in Urechis, there is a closed vascular system, consisting of a dorsal and a ventral vessel joined medially by the neuro-intestinal vessel and in front by a vessel which loops round the proboscis. The gonad is a solid cord of cells on the posterior extremity of the ventral vessel, and the genital products develop free in the coelom and escape by way of the nephridia. The nervous system consists of a ventral nerve cord without ganglia, from which the nerves come off at irregular intervals. In front there is a large nerve ring looping round the proboscis.

Embryology. — The larva is a trochophore possessing transitory evidences of segmentation in the arrangement of the pigment and of the cilia. The development is characterized by the enormous elongation of the pre-oral lobe.

Classification. — The echiuroids may be divided into two families, the *Echiuridae* in which the male and female are similar and the Bonelliidae in which the male, lacking both mouth and anus, is a minute parasite on the female. All the *Echiuridae* except Thalassema and its allies have bristles round the anus. Nearly all the *Bonelliidae* have paired ventral hooks and a bifid proboscis, except Hamingia which has no ventral hooks and an undivided proboscis.

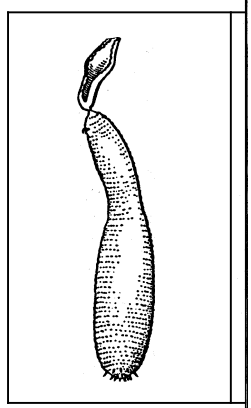

FIG. 2.—ECHIURUS ECHIURUS SHOWING SAC-LIKE BODY AND PRE-ORAL LOBE

Habits.—*Echiurus* forms a tube cemented with mucus; Thalassema and *Bonellia* live in holes in the rock. In *Bonellia* the sex of the adult depends on the mode of life of the larva. The larvae that live a free existence unattached to an adult female develop normally into females. Those that are to become males settle on the proboscis of an adult female; after three days they creep inside, develop male characteristics and eventually come to rest in the uterus of the female. The determining factor seems to be a water-soluble substance secreted by the proboscis and the gut-wall of the female; for Baltzer by feeding an extract of these organs to the free-living larvae has obtained a high percentage of males, which, however, do not reach full development. By removing the larva from the proboscis of the female before the completion of the sex-determining process intersexes can be produced. In *Pseudobonellia* there is a special tube in the body wall in which the male lives.

See W. K. Fisher and G. E. MacGinitie, "The Natural History of an Echiuroid Worm," *Am. Mag. Nat. Hist.* (1928). (C. C. A. M.)

ECHMIADZIN, (1) a monastery in the Armenian S.S.R., in 40° 12' N., 44° 19' E., the seat of the Catholicus or primate of the Armenian church. It is situated close to the village of Vagarshapat, in the plain of the Aras, 2,840 ft. above the sea, 12 m. west of Erivan and 40 north of Mount Ararat. The monastery comprises a complex of buildings, surrounded by brick walls 30 ft. high, which with their loopholes and towers present the appearance of a fortress. Its architectural character has been considerably impaired by additions and alterations in modern Russian style. On the western side of the quadrangle is the residence of the primate, on the south the refectory (1730–1735), on the east the lodgings for the monks, and on the north the cells. The cathedral is a small but fine cruciform building with a Byzantine cupola at the intersection. Its foundation is ascribed to St. Gregory the Illuminator in 302. Of special interest is the porch, built of red porphyry, and profusely adorned with sculptured designs somewhat of a Gothic character. The interior is decorated with Persian frescoes of flowers, birds and scroll-work. It is here that the primate confers episcopal consecration by the sacred hand (relic) of St. Gregory; and here every seven years he prepares the holy oil which is to be used throughout the churches of the Armenian communion. Outside the main entrance are the alabaster tombs of the primates Alexander I. (1714), Alexander II. (1755), Daniel (1806) and Narses (1857), and a white marble monument, erected by the English East India Company to mark the resting-place of Sir John Macdonald Kinneir, who died at Tabriz in 1830, while on an embassy to the Persian court. The library of the monastery is a rich storehouse of Armenian literature (see Brosset's Catalogue de la *bibliothèque d'Etchmiadzin*, St. Petersburg, 1840). Among the more remarkable manuscripts are a copy of the gospels dating from the 10th or 11th century, and three bibles of the 13th century. A type-foundry, a printing-press and a bookbinding establishment are maintained by the monks who supply religious and educational works for their co-religionists.

To the east of the monastery is a modern college and seminary. Half a mile to the east stand the churches of St. Ripsime and St. Gaiana, two of the early martyrs of Armenian Christianity; the latter is the burial-place of those primates who are not deemed worthy of interment beside the cathedral. From a distance the three churches form a fairly striking group, and accordingly the Turkish name for Echmiadzin is *Uch-Kilissi,* or the Three Churches. The town of Vagarshapat dates from the 6th century B.C.; it takes its name from King Vagarsh (Vologaeses), who in the 2nd century A.D. chose it as his residence and surrounded it with walls. Here the apostle of Armenia, St. Gregory the Illuminator, erected a church in 309 and with it the primacy was associated. In 344 Vagarshapat ceased to be the Armenian capital, and in the 5th century the patriarchal seat was removed to Dvin, and then to Ani. The monastery was founded by Narses II., who ruled 524–533; and a restoration was effected in 618. The present name of the monastery was adopted instead of Vagarshapat in the 10th century. At length in 1441 the primate George brought back the see to the original site.

(2) An administrative district of the Armenian S.S.R., with an area of 3,009 sq km., and a population (1926) of 113,930, mainly rural. Vagarshapat (see above) is the centre, pop. (1926) 8.035. The district suffers severely from drought, but a scheme of irrigation is now being inaugurated which should greatly increase the cotton production of the region.

ECHO. A sound reflected from an obstacle. Personified in later Greek mythology, as a mountain nymph or Oread (not before Euripides). In Ovid (*Metam.* III., 356 ff.) she offended Hera by keeping her talking and thus preventing her spying on an amour of Zeus; in punishment, she was deprived of speech, save the power to repeat the last words of another. A hopeless love for Narcissus (*q.v.*) made her fade away to a voice only. In Longus (III., 23), she rejected Pan's advances; he thereupon drove the shepherds mad, and they tore her in pieces; Earth buried her limbs and allowed them still her power of song.

See Roscher's *Lexikon,* art. ECHO.

ECHTERNACH. The oldest town in the old duchy of Luxembourg on the Sûre, close to the Prussian frontier, and the centre from which the English saint Willibrord converted the people to Christianity in the 7th century. A Benedictine abbey is represented mainly by an old Romano-Gothic church. The hospital-almshouse is said to be the oldest in Europe save the Hôtel-Dieu in Paris. The Benedictine abbey has been greatly shorn of its original dimensions, but the Basilica remains a fair monument of Romano-Gothic art.

The Church of SS. Peter and Paul contains the remains of St. Willibrord and stands on an isolated mound; it is reached by 60 steps which are the scene of a remarkable ceremony on Whit-Tuesday. The archbishop of Trier attends on behalf of Germany and holds a religious ceremony on the Prussian side of the Sûre before the procession crosses the bridge into the grand duchy, where it meets a procession of Luxembourgeois, partly religious, partly popular, to go through the streets of the town to the steps of SS. Peter and Paul. The religious procession (300 singers) under the bishop of Luxembourg, chants St. Willibrord's hymn; it is followed by a miscellaneous band which plays the old German air "Adam had seven sons." Next come the dancers who take three steps forward and two steps back up the 60 steps. The procession is thus a considerable strain on those who partake but, as the saint is reputed to cure epilepsy and St. Vitus dance, and other illnesses, many sick persons try to reach the church and may be in danger of being trampled by the throng if they collapse on the way up. It is said that the ceremony dates from a cholera epidemic of the 13th century. The abbey was of old

the goal of the procession. King William I. of the Netherlands tried to change the day from a Tuesday to a Sunday, so as to avoid loss of a full working-day, but the old order re-established itself. In spite of changes of political relations following the war of 1914–18, the ceremony still takes place as of old.

Students of folk-lore have tried to trace a connection between the dancing procession of Echternach and the spring dance of the heathen races, but at any rate it invests the little town with importance.

ECIJA, a town of southern Spain, province of Seville, on the Cádiz-Córdoba railway. Pop. (1930) 29,884. Ecija on the left bank of the river Genil, which is navigable to this point, is the centre of a fertile district producing olives, cereals, wine and some cotton. The heat in summer is so great that the spot is known as *El Sarten,* or the "Frying-pan" of Andalusia. Long famous for its shoe-makers, Ecija also manufactures olive oil, soap, candles, wine, starch, straw-hats, cloth and pottery. The city, once enclosed by walls, now in ruins, is chiefly remarkable for its Moorish gateways, its church towers studded with glazed tiles, its many fine balconied and decorated mansions and its chief square surrounded by colonnades and planted with acacias. It also possesses 20 convents, now mostly secularized. Ecija, called *Estadja* by the Arabs, is the ancient *Astigis,* which was raised to the rank of a Roman colony with the title of *Augusta Firma* and became so flourishing a centre that Pliny and Pomponius Mela, writing in the 1st century A.D., described it as the rival of Córdoba and Seville. Local tradition maintains that it was visited by the apostle Paul, who converted his hostess Santa Xantippa; and, according to one version of his life, it was the see of St. Crispin in the 3rd century.

ECK, JOHANN MAIER (1486–1543), German theologian, the most indefatigable and important opponent of Martin Luther, was born on Nov. 13, 1486, at Eck, Swabia. His father, Michael Maier, was a peasant and bailiff (*Amtmann*) of the village; his uncle Martin Maier, parish priest at Rothenburg on the Neckar, sent him at the age of twelve to the university of Heidelberg, later on to Tubingen, Cologne and Freiburg-im-Breisgau. At the age of 24 he was already doctor and professor of theology. During this period he was known as an opponent of the scholastic philosophy; and, though he did not go to all lengths with the "modernists" (*moderni*) of his day, his first work—Logices *exercitamenta* (1507)—was on their side, an attitude which brought him into conflict with the university senate. His position in Freiburg becoming intolerable he accepted in 1510 an invitation from the duke of Bavaria to fill the theological chair at Ingolstadt, where he was destined for thirty years to exercise a profound influence as teacher and vice-chancellor *(Prokanzler).*

A ducal commission, appointed to find a means for ending the interminable strife between the rival academic parties, entrusted Eck with the preparation of fresh commentaries on Aristotle and Petrus Hispanus, and between 1516 and 1520, in addition to his other duties, he published commentaries on the *Summulae* of Hispanus, and on the *Dialectics, Physics* and lesser scientific works of Aristotle, which became the text-books of the university. These commentaries are inspired with much of the scientific spirit of the New Learning, but he had no sympathy with the revolutionary attitude of the Reformers. He had won laurels in a public disputation at Augsburg in 1514, when he had defended the lawfulness of putting out capital at interest; again at Bologna in 1515, on the same subject and on the question of predestination; and these triumphs had been repeated at Vienna in 1516. These successes gained him the patronage of the Fuggers, and he found himself fairly launched as the recognized apologist of the established order in church and state, the first-fruits of this new position being a quite gratuitous attack on his old friend, the distinguished humanist and jurist Ulrich Zasius (1461–1536), for a doctrine proclaimed ten years before, and a simultaneous assault on Erasmus's *Annotationes in Novum Testamentum.*

Luther sent to Eck in 1517 copies of his celebrated 95 theses. Eck made no public reply; but in 1518 he circulated, privately at first, his *Obelisci,* in which Luther was branded as a Hussite. Luther entrusted his defence to Carlstadt, who answered Eck in 400 distinct theses, and declared his readiness to meet him in a public disputation, which took place at Leipzig in 1519. On June 27 and 28 and on July 1 and 3 Eck disputed with Carlstadt on the subjects of grace, free will and good works, ably defending the Roman standpoint; from July 4 to 14 he engaged with Luther on the absolute supremacy of the papacy, purgatory, penance, etc., showing a brilliant display of patristic and conciliar learning against the reformer's appeals to Scripture. The arbitrators declined to give a verdict, but the general impression was that victory rested with Eck. He made Luther admit that there was some truth in the Hussite opinions and declare himself against the pope. He induced the universities of Cologne and Louvain to condemn the reformer's writings, but failed to enlist the German princes, and in Jan. 1520 went to Rome to obtain strict regulations against those whom he called "Lutherans." He was created a protonotary apostolic, and in July returned to Germany, as papal nuncio, with the bull *Exsurge Domine* directed against Luther's writings. He now thought he could crush not only the Lutheran heretics but also his humanist critics. The effect of the publication of the bull, however, soon undeceived him, and he was glad to escape from Saxony with a whole skin. In his wrath he appealed to force, and his *Epistola ad Carolum V.* (Feb. 18, 1521) called on the emperor to take measures against Luther, a demand soon to be responded to in the edict of Worms. In 1521 and 1522 Eck was again in Rome, reporting on the results of his nunciature. On his return from his second visit he was the prime mover in the promulgation of the Bavarian religious edict of 1522, which led to years of persecution. In return for this action of the duke, Eck obtained for him, during a third visit to Rome in 1523, valuable ecclesiastical concessions. Meanwhile he published eight considerable polemics between 1522 and 1526.

Luther declined to answer his arguments, and Eck turned his attention to Switzerland and the Zwinglians. At Baden-in-Aargau in May and June 1526 a public disputation on the doctrine of transubstantiation was held, in which Eck and Thomas Murner were pitted against Johann Oecolampadius. Though Eck claimed the victory in argument, the only result was to strengthen the Swiss in their memorial view of the Holy Communion, and so to diverge them further from Luther. At the Augsburg diet in 1530 Eck was charged by Charles V. to draw up, in concert with twenty other theologians, the refutation of the Protestant Confession. He was at the colloquy of Worms in 1540 and at the diet of Regensburg (Ratisbon) in 1541. At Worms he showed some signs of a willingness to compromise, but at Regensburg he persuaded the Catholic princes to reject the Interim.

Eck died at Ingolstadt on Feb. 10, 1543. He was a powerful debater, but his victories were those of a dialectician rather than a convincing reasoner, and in him depth of insight and conviction were ill replaced by the controversial violence characteristic of the age. Moreover, even after discounting the bias of his enemies, there is evidence to prove that his championship of the Church was not wholly due to zeal for Christianity; for he was notoriously drunken, unchaste, avaricious and almost insanely ambitious. His chief work was *De primatu Petri* (1519); his *Enchiridion locorum communium adversus Lutherum* ran through 46 editions between 1525 and 1576. In 1530–35 he published a collection of his writings against Luther, *Opera contra Ludderum,* in 4 vols. *See* also LUTHER, MARTIN.

See T. Wiedemann, Dr. Johann ***Eck*** (Regensburg, 1865).

ECKERMANN, JOHANN PETER (1792–1854), German poet and author, best known owing to his association with Goethe, was born at Winsen, Hanover, on Sept. 21, 1792, and was brought up in penury. After serving as a volunteer in the War of Liberation (1813–14), he became a clerk in the War Department at Hanover. In 1817, although 25 years of age, he went to school at Hanover and then, for a year, to the University of Gottingen. His acquaintance with Goethe began in 1823, when he sent him the manuscript of his *Beiträge zur Poesie* (1823). Soon afterwards he went to Weimar, where he instructed the son of the grand duke. In 1830 he travelled in Italy with Goethe's son. In 1838 he was given the title of grand-ducal councillor and appointed librarian to the grand-duchess. Eckermann is chiefly remembered for his

contributions to the knowledge of Goethe contained in his *Conversations with Goethe* (1836–48). To Eckermann Goethe entrusted the publication of his *Nachgelassene Schriften* (posthumous works) (1832–33). He was also joint-editor with Friedrich Wilhelm Riemer (1774–1845) of the complete edition of Goethe's works in 40 vols. (1839–40). He died at Weimar on Dec. 3, 1854.

Eckermann's *Gesprache mit Goethe* (vols. i. and ii., 1836; vol. iii., 1848; 7th ed., 1899; edit. by L. Geiger, 1902) have been translated into almost all the European languages, not excepting Turkish. (Eng. trans. by Margaret Fuller, Boston, 1839, and John Oxenford, London, 1850.) His "remains" were edited by F. Tewes in vol. i. of *Aus Goetlzes Lebenskreise* (1905). *See* Petersen, *Die Entstehung der Eckermannischen Gespräche . . .* (1924); Houden, J. P. *Eckermann, Sein Leben für Goethe* (1925), based on recently discovered letters and diaries.

ECKERNFÖRDE, a town of Germany, in the Prussian province of Schleswig-Holstein, on a fjord of the Baltic, 20 mi. by rail N.W. from Kiel. Pop. (1939) 13,676. It has a good harbour, fishing, trade in agricultural products, and manufactures of tobacco, salt and iron goods. There is a technical school of buildings. Eckernforde was taken by Christian IV. of Denmark in 1628 from the Imperial troops. In 1813 the Danes were defeated here. The place lost most of its trade after the union with Germany in 1864, and suffered severely from a sea-flood in 1872. In the immediate neighbourhood is Borby, popular for sea-bathing.

ECKERSBERG, KRISTOFFER (1783–1853), Danish painter, was born at Warnitz on Jan. 2, 1783. He studied in Paris under J. L. David, and then went to Rome, where he worked until 1816 in close fellowship with Thorwaldsen. His paintings from this period—"The Spartan Boy," "Bacchus and Ariadne" and "Ulysses"—testify to the influence of the great sculptor. After his return to Denmark his chief work was done in landscape and sea-painting. It is claimed for Eckersberg by the native critics that "he created a Danish colour," that is to say, he was the first painter who threw off conventional tones and the pseudo-classical landscape, in exchange for the clear atmosphere and natural outlines of Danish scenery. Ecltersberg died on July 22, 1853, at Copenhagen, where he was professor at the academy.

ECKHART, JOHANNES ["MEISTER ECKHART"] (1260?–1327), German philosopher, the first of the great speculative mystics of the West, was born at Hochheim, near Gotha. He entered the Dominican order and in 1302 became a master of theology at Paris. Two years later he was made provincial of his order for Saxony, and in 1307 vicar-general for Bohemia. In both provinces he was distinguished for his practical reforms and for his power in preaching.

Released from his offices in 1311, Eckhart taught in Paris until 1314, when he was sent to Strasbourg. Later he was transferred to Cologne, where, in 1326, the archbishop took proceedings against his doctrines. In the following year, that of his death, Eckhart publicly declared his orthodoxy and appealed to Pope John SSII. In 1329, 28 of his propositions were condemned by the Holy See.

Eckhart has been termed a scholastic mystic, rather than a mystical scholastic, because he colours the Aristotelian elements in Aquinas with the mysticism of the pseudo-Dionysius. The two most important doctrines in his, as in all mystical systems, are those of the Divine nature and of the relation between God and creatures, especially the human soul.

For Eckhart, God is the absolute and infinite Being best characterized as nothing on the ground that His simplicity is irreconcilable with a plurality of predicates. If any attribute could be ascribed to Him, it would be the *esse* implied in the scriptural *Ego sum qui sum,* though strictly speaking, God is, rather than has, *esse.* In spite of this assertion that the Divine essence and existence are identical, Eckhart goes on to declare that apart from the Divine existence there is nothing. *Ens tantum unum est et Deus est.* Every creature has its own essence, but its existence is that of God, and God and the creature are more closely related than matter or form or than the parts and the whole. In addition to this pantheistic leaning, the statement that at the same time that God engendered His Son, co-eternal and equal to Himself, He created the world, brought Eckhart's orthodoxy under suspicion. The statement may not apply to the exterior effect of the eternal act of God, but Eckhart's interpretation of the in *principio* of Genesis as the *nunc aeternitatis* suggests that it does.

Although the Divine existence permeates all being, it is regarded by Eckhart as especially manifested in the human soul, whose end is union with God. This union is to be accomplished through knowledge. The soul must first understand that creatures in themselves are nothing, and then, having perceived the continuity of its being with the Divine being, it can dispense with the external means of salvation and abandon itself to God, Who finds in it His own existence.

Eckhart's style is unsystematic and abounding in symbolical expression, but his successful exposition of scholastic doctrines in an undeveloped tongue has made him the father of German philosophical language.

ECKHEL, JOSEPH HILARIUS (1737–1798), Austrian numismatist, born at Enzersfeld, lower Austria, was for over 20 years professor of antiquities and numismatics at the university of Vienna, and keeper of the imperial cabinet of coins. Eckhel's great work is the *Doctrina numorum veterum* (8 vols., 1792–98). Out of the mass of previously loose and confused facts Eckhel constituted a true science. A volume of *Addenda,* prepared by Steinbiichel from Eckhel's papers after his death, was published in 1826. He died at Vienna on May 16, 1798.

ECKMÜHL or **EGGMUHL,** a village of Germany, in Bavaria, on the Grosse Laaber, 13m. S.E. of Regensburg by the railway to Munich. It is famous as the scene of a battle fought here on April 22, 1809, between the French, Bavarians and Württembergers under Napoleon, and the Austrians under the archduke Charles, which resulted in the defeat of the latter. Napoleon, in recognition of Marshal Davout's great share in the victory, conferred on him the title of prince of Eckmiihl. For an account of this action and those of Abensberg and Landshut *see* NAPOLEONIC CAMPAIGNS.

ECLECTICISM, a term used specially in philosophy and theology for a composite system of thought made up of views chosen from various other systems (from Gr. ἐκλέγω, I select). Where the characteristic doctrines of a philosophy are not thus merely adopted, but are the modified products of a blending of the systems from which it takes its rise, the philosophy is not properly eclectic. Eclecticism always tends to spring up after a period of vigorous constructive speculation, especially in the later stages of a controversy between thinkers of pre-eminent ability. Their respective followers, and more especially cultured laymen, lacking the capacity for original work, seeking for a solution in some kind of compromise, and possibly failing to grasp the essentials of the controversy, take refuge in a combination of those elements in the opposing systems which seem to afford a sound practical theory. Since these combinations have often been as illogical as facile, "eclecticism" has generally acquired a somewhat con-

temptuous significance. At the same time, the essence of eclecticism is the refusal to follow blindly one set of formulae and conventions, coupled with a determination to recognize and select from all sources those elements which are good or true in the abstract, or in practical affairs most useful *ad hoc*. Theoretically, therefore, eclecticism is a perfectly sound method, and the contemptuous significance which the word has acquired is due partly to the fact that many eclectics have been intellectual trimmers, sceptics or dilettanti, and partly to mere partisanship. On the other hand, eclecticism in the sphere of abstract thought is open to this main objection that, in so far as every philosophic system is, at least in theory, an integral whole, the combination of principles from hostile theories must result in an incoherent patchwork. Thus it might be argued that there can be no logical combination of elements from Christian ethics, with its divine sanction, and purely intuitional or evolutionary ethical theories, where the sanction is essentially different in quality. It is in practical affairs that the eclectic or undogmatic spirit is most valuable, and also least dangerous.

In the 2nd century B.C. a remarkable tendency toward eclecticism began to manifest itself. The longing to arrive at the one explanation of all things, which had inspired the older philosophers, became less earnest; the belief, indeed, that any such explanation was attainable began to fail. Thus men came to adopt from all systems the doctrines which best pleased them. In Panaetius we find one of the earliest examples of the modification of Stoicism by the eclectic spirit; about the same time the same spirit displayed itself among the Peripatetics. In Rome philosophy never became more than a secondary pursuit; naturally, therefore, the Roman thinkers were for the most part eclectic. Of this tendency Cicero is the most striking illustration—his philosophical works consisting of an aggregation, with little or no blending, of doctrines borrowed from Stoicism, Peripateticism, and the Scepticism of the Middle Academy.

In the last stage of Greek philosophy the eclectic spirit produced remarkable results outside the philosophies of those properly called eclectics. Thinkers chose their doctrines from many sources—from the venerated teaching of Aristotle and Plato, from that of the Pythagoreans and of the Stoics, from the old Greek mythology, and from the Jewish and other Oriental systems. Yet it must be observed that Neoplatonism, Gnosticism, and the other systems which are grouped under the name Alexandrian, were not truly eclectic, consisting, as they did, not of a mere syncretism of Greek and Oriental thought, but of a mutual modification of the two. It is true that several of the Neoplatonists professed to accept all the teaching both of Plato and of Aristotle, whereas, in fact, they arbitrarily interpreted Aristotle so as to make him agree with Plato, and Plato so as to make his teachings consistent with the oriental doctrines which they had adopted, in the same manner as the schoolmen attempted to reconcile Aristotle with the doctrines of the church. Among the early Christians, Clement of Alexandria, Origen and Synesius were eclectics in philosophy.

The eclectics of modern philosophy are too numerous to name. Of Italian philosophers the eclectics form a large proportion. Among the German we may mention Wolf and his followers, as well as Mendelssohn, J. A. Eberhard, Ernst Platner, and to some extent Schelling, whom, however, it would be incorrect to describe as merely an eclectic. In the first place, his speculations were largely original; and in the second place, it is not so much that his views of any time were borrowed from a number of philosophers, as that his thinking was influenced first by one philosopher, then by another.

In the 19th century the term "eclectic" came to be applied specially to a number of French philosophers who differed considerably from one another. Of these the earliest were Pierre Paul Royer-Collard, who was mainly a follower of Thomas Reid, and Maine de Biran; but the name is still more appropriately given to the school of which the most distinguished members are Victor Cousin, Théodore Jouffroy, J. P Damiron, Barthélemy St Hilaire, C. F. M. de Rémusat, Adolphe Garnier and Ravaisson-Mollien. (See COUSIN, VICTOR).

ECLIPSE. One heavenly body is said to be eclipsed by another when the second body passes between the observer and the first body so as to obscure part or all of it. Thus an eclipse (from Gr. ἔκλειψις, failing to appear) of the sun occurs when the moon comes between the earth and the sun. If the more remote body be completely obscured by the nearer body the eclipse is said to be total, otherwise it is termed partial. If the distant body be visible all round the nearer body at any moment the partial eclipse is then termed annular.

We shall divide the consideration of eclipses as follows:

I. General considerations.
II. Eclipses of satellites of Jupiter.
III. Eclipsing binary stars.
IV. The calculation and prediction of eclipses (explained in detail for eclipses of the sun) laws and cycles of eclipses of the sun and moon.
V. Phenomena of eclipses of the sun.
VI. " " " " " moon.
VII. Table of eclipses in the 20th Century.

I. GENERAL CONSIDERATIONS

A convenient way of regarding an eclipse is to consider the shadow cast by a dark body (such as the earth or moon) into the space surrounding a bright body (such as the sun). Thus if fig. 1 represents a section through the centres S and M of a bright body S and a dark body M, and AA', BB' be the exterior and CC', DD' the interior common tangents respectively we see that to an observer situated, as at O_1, outside the cone formed by CC', DD', there will be no obscuration of S; from an observer situated within the cone, as at O_2 part of S will be hidden; and if he be within the cone formed by AA', BB' and between its apex P and M, as at O_3, the whole of S is hidden from him.

If we know the sizes of S and M and their motions we can determine the form and position of the shadow cones at any moment, and hence can say whether any other body (*e.g.*, the earth or a particular point on it) falls within them.

In fig. 2 if S represents the sun, M the moon and E the earth we have in (1) the configuration necessary for an eclipse of the moon, in (2) that required for an eclipse of the sun.

If all the members of the solar system revolved in orbits which were in the same plane, then there would be an eclipse at every revolution of a satellite around its primary. Thus once a month we should have an eclipse of the sun when the moon was between us and the sun (*i.e.*, at a time of new moon) and an eclipse of the moon a fortnight later when we were between the sun and moon (*i.e.*, at a time of full moon). The orbits are not coplanar but slightly inclined to one another, and so it can happen that the axis of the shadow cones passes above or below the more distant body and no eclipse visible on the planet may occur. We shall explain the matter in detail for eclipses of the sun, and it will be seen that the considerations advanced apply *mutatis mutandis* to eclipses of the moon or other bodies. The planets between the earth and the sun (Venus and Mercury) clearly may pass between us and the sun. These occurrences are technically termed transits, but the calculations concerning them are essentially the same as for eclipses.

FIG. 1.—DIAGRAM DEMONSTRATING THE NATURE OF AN ECLIPSE
A dark body (M), the moon, casts shadow cones into the space surrounding a bright body (S), the sun. No eclipse is seen in the unshaded region (O_1); in the lightly shaded area there is a partial eclipse (O_2); at O_3, there is a total eclipse; and at O_4 an annular eclipse

II. ECLIPSES OF SATELLITES OF JUPITER

In fig. 2 (3) we have a representation of eclipses of one of the outer planets, Jupiter say, and its satellites. Satellite I. is drawn inside the umbral cone of Jupiter and so, since it is not self-luminous, is temporarily (*i.e.*, while passing through the cone) invisible from the earth (E). Satellite II. is drawn passing between Jupiter and the sun and so casting a shadow on Jupiter. If

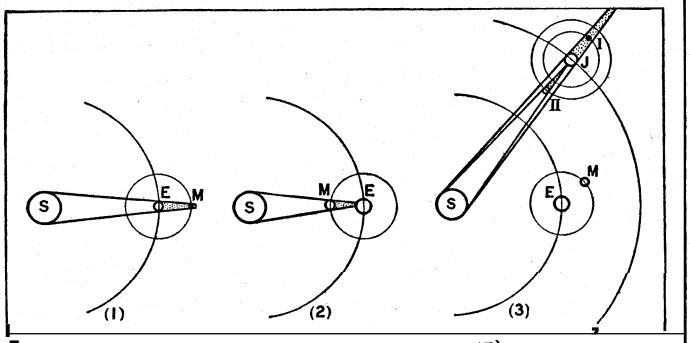

FIG. 2.— RELATIVE POSITIONS OF SUN (S), EARTH (E), MOON (M), AND JUPITER (J) IN AN ECLIPSE
1. An eclipse of the moon; the moon is drawn inside the umbral cone, so the eclipse is total
2. An eclipse of the sun; part of the earth's surface is inside the umbral cone; over this region of the earth a total solar eclipse takes place
3. Eclipses of Jupiter's satellites visible from the earth. Satellite I is eclipsed and therefore invisible temporarily. Satellite II is casting a shadow on the surface of Jupiter, which is visible through a telescope as a round dark spot

the umbral cone be long enough to reach the surface of Jupiter there will be a dark spot on the surface (the shadow of its moon) visible from the earth if it falls on the half of Jupiter visible to us.

The eclipses of the satellites of Jupiter provide a frequent and interesting spectacle (of which details are given in the *Nautical Almanac*) and are of considerable astronomical interest. Historically they are important inasmuch as they provided one of the earliest proofs of the finite velocity of light. It is possible to calculate with considerable precision the times of disappearance and reappearance of one of the satellites undergoing eclipse (as I.) and it was found by Romer that there were discrepancies between the observed and calculated times that could be explained if we supposed that we saw the eclipse a little early or a little late depending upon whether the earth was at a point in its orbit nearer to or further from Jupiter than the sun; the difference between the extreme variations being the time needed for light to travel the distance across a diameter of the earth's orbit.

III. ECLIPSING BINARY STARS

Eclipsing Binaries are stars which vary in brightness periodically. The most famous of these is Algol or β Persei, and the explanation of the changes is that there are two stars revolving round one another in an orbit whose plane intersects the earth, or does so very nearly. Thus from time to time one star passes in front of or behind the other as seen from the earth and the light from one of them is temporarily lost to us. From the way in which the light from the double systems varies it is possible to calculate the shapes and relative sizes of the components of the binary system and to obtain certain other information (see STAR).

IV. CALCULATION OF ECLIPSES OF THE SUN

We can divide our calculations into two parts. In the first part we seek to determine if an eclipse can occur and in the second to determine its circumstances (*i.e.*, whether or no it is visible at a given point on the earth's surface, its type [total or partial], duration, etc.). It is most convenient to suppose the earth fixed and the sun and moon revolving around it.

We will suppose first that the observer is situated at the centre of the earth. Then the state of affairs can be represented on a "celestial sphere" as in fig. 3. In this diagram PP' is the earth's axis and the position of celestial objects is marked on the general sphere of the sky in the same way as countries are marked on an ordinary globe of the earth, looking at the celestial sphere from the "outside" as we do at the countries on a globe. Thus O the centre of the sphere (MEQM'E'Q') is the observer, the circle QQ' is the equator. The motion of the sun can then be described thus. It moves round a great circle QQ′ called the ecliptic, which is inclined at $23\frac{1}{2}°$ nearly to the equator, once in a solar or ordinary year. The moon likewise describes once a lunar month an orbit represented by the great circle MM′ which is inclined to the ecliptic at about 5° (instead of being the same circle EE' as it would be if the orbits were coplanar). The daily motion is represented by a revolution of the whole sphere and everything on it round P'P once a sidereal day. The sun can be represented by a small circle X centre on EE' about $\frac{1}{2}°$ in diameter, and the moon by a small circle Y, nearly the same size, centre on MM′. The sizes and distances of the sun and moon are such that they subtend very nearly the same angle (about $\frac{1}{2}°$) at the earth, but their apparent sizes are not constant. The earth goes round the sun not in a circle but an ellipse, and the sun is further from us in summer (in the northern hemisphere) than in winter, thus its apparent size (the circle X) varies and also its speed of motion around EE' is faster in winter than in summer. The moon also moves around the earth in an ellipse and so its distance and speed vary so that the apparent size (*i.e.*, the circle Y) varies. It is for these reasons that the duration and magnitude of an eclipse vary. For an eclipse to occur the sun and the moon must be so situated that the circles X and Y overlap. Clearly since they are only about $\frac{1}{4}°$ in radius and the circles EE' and MM' are inclined at about 5° this can only happen when the moon and sun are near one of the two points ☊ and ☋ of intersection of EE' and MM' called the node; of the moon's orbit. The moon's nodes revolve in the ecliptic from east to west once in about 19 years. The interval of time between two successive passages of the sun through one of the nodes is termed an "eclipse year" and since the moon's node moves to meet the advancing sun this interval is about 18·6 days less than a tropical (or ordinary) year. Nineteen eclipse years (6585·7806 days) are very nearly the same as 223 ordinary months (6585·3211 days). This interval of 18 years 11 days (or 18 years 10 days if February 29 has occurred five times) is termed the Saros, and is the simplest relation useful in predicting eclipses. After this interval the moon and sun come very nearly to the same relative position again. Thus the eclipse of 1923 (September 10) was a repetition of that of 1905 (August 30). The coincidence of the two periods is not exact and so while there is an eclipse again after a Saros the circumstances of it will be different. If a new moon fell exactly at a node then after 18 years 11 days the new moon occurs before the node is reached. The difference between the two periods is 0·4595 days and so the moon is 28′ farther west. If new moon happens within 18" of the node an eclipse of the sun may take place; if it is an ascending node the eclipse will be visible in high northern latitudes on the earth; at the next return the new moon will be 28′ nearer the node and the eclipse will be visible a little south of the first position. When the new moon is within about 11° of the node the eclipse becomes central (*i.e.*, there is a line on the surface of the earth from any point of which the centres of the sun and moon appear coincident) and may be annular or total depending on the distance of the moon and sun from the earth. Total eclipses now occur every 18 years 11 days passing south each time till the limit of 11° is passed on the other side of the node and there remains a series of partial eclipses tailing off to the south pole. In such a series there are from 68 to 75 eclipses of which abbut 18 are total.

One other important relation is that 239 returns of the moon to perigee are 6585.5574 days, so after 223 lunations the moon returns not only very closely to its original position with respect to sun and node but also with respect to line of apsides so that the distance from earth to moon is nearly the same. Thus the duration is altered but little and the perturbations of the moon's orbit are almost unchanged with but little effect then on the time of the eclipse. The fraction ·3211 days in the period of the Saros has the effect of making each eclipse occur about 110° of longitude further west and after three Saroses it has nearly returned to its original position but farther N. or S. Since there are two nodes the sun will come into a region where eclipse is likely twice a year. giving the two "eclipse seasons" each about one month in duration, in which at least one eclipse or possibly two small partial

eclipses may happen. Generally, but not necessarily, one eclipse of the moon will occur in a season. There is possible as a maximum five eclipses of the sun in a year. Solar eclipses occur oftener than lunar ones, but since a solar eclipse is visible only over a very limited region of the earth and a lunar one over a whole hemisphere, lunar eclipses are more often seen at any one place.

Having determined that an eclipse will take place it remains to find its circumstances at a given place on the earth's surface. For this purpose we make use of the conception of the moving shadow cones. A plane passing through the centre of the earth and perpendicular to the axis of the moon shadow is chosen as a plane of reference and termed the fundamental plane, and the co-ordinates x and y of the point in which the axis of the shadow cones cuts it are determined and also the declination d and the hour angle μ of the axis. The radii l_1(penumbra) and l_2 (umbra) of the section of the shadow cones by the fundamental plane are then found. and all these quantities together with the angles of the cones and the rates of change of x, y and μ are given in the Ephemerides. These quantities (termed the Besselian elements) can be used to determine the circumstances at any place in the following way. Knowing the position of the observer on the earth we have his co-ordinates referred to the fundamental plane at any instant and so can find the position relative to him of the shadow cones. If he is always outside them the eclipse is invisible to him. If he be nearer the central line there will be a time when he just touches the circle formed by the penumbra. The moon is then just beginning to touch the sun (1st contact), and if he be near enough there will also be a moment when he just touches the umbral circle and totality commences (2nd contact). The moon now touches the sun internally at one point and later he will be just on the edge of the shadow circle as it is leaving him (3rd contact) and totality ends. The end of the eclipse is when the further rim of the penumbra reaches him and the other edge of the moon is just touching the edge of the sun externally (4th contact). Likewise the bearings of the points of contact may be found and so the position in the sky of the points of the crescents during the partial phase can be calculated. Thus it is possible to determine the form of the shadow cast on the earth's surface and the path over which it moves. In the Ephemerides maps are given showing the part covered by the shadow as it moves over the earth's surface and the region within which the eclipse is total if anywhere (*i.e.*, if there are any points on the earth's surface near enough to the moon to fall in the cross-hatched region in fig. 1), and lines are drawn joining those places where the eclipse begins and ends at certain times, *e.g.*, sunrise or sunset. The most important information is the track of the line of central eclipse (the locus of the intersection of the line of centres of the sun and moon with the surface of the earth) and the northern and southern limits of the region of totality. Since the moon moves through its own diameter in about an hour there will be about an hour between the 1st and 2nd contacts and also between the 3rd and 4th. The duration of totality (the interval between the 2nd and 3rd contacts) is greatest on the central line and may be anything up to about $7\frac{1}{2}$ mins. The longest duration will clearly occur when the moon is near perigee and the sun near apogee and also if the eclipse occur near mid-day on the earth's equator for then the surface of the earth is nearly perpendicular to the shadow cones and their rate of motion over it is slowest. It is possible with the aid of modern tables to predict eclipses a few years ahead with an accuracy of a few seconds. The chief difficulty lies in the uncertainty of the moon's motion.

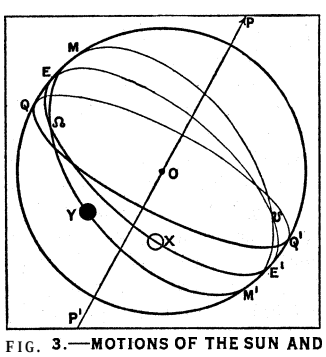

FIG. 3.—MOTIONS OF THE SUN AND MOON ON THE CELESTIAL SPHERE
P-P¹ is parallel to the earth's axis, Q-Q¹ is the celestial equator. X, the sun, moves around E E¹ the ecliptic, once a year Y, the moon, moves around MM¹, its orbit, once a month. The intersections (nodes) Ω—℧ of the moon's orbit and the ecliptic rotate once in 19 years. The black circle Y and the clear circle X must overlap to produce an eclipse; thus X must be near a node, and the moon new

Eclipses can of course be "predicted backwards" as well as forwards, and the calculation of ancient eclipses has been of value in historical research in fixing the dates of certain events. The main difficulty is in identifying an eclipse with certainty since often details such as the time of day of the eclipse, or even the season, are lacking. The earliest date thus accurately determined is the year 911 B.C., from an eclipse in Assyria. The eclipse mentioned in Amos viii., 9 seems to have been the one in 763 B.C. There was no eclipse visible in the neighbourhood of Samaria in 787 B.C., the date set down opposite this passage in some Bibles.

V. PHENOMENA AND INFORMATION YIELDED BY OBSERVATION OF SOLAR ECLIPSES

In general little or nothing of astrophysical importance can be learnt from a partial eclipse of the sun, but during the few minutes of totality of a total eclipse much information about the physical nature of the sun has been obtained that is not available under any other circumstances. The observation of the times of occurrence of the various phases of any eclipse is useful in improving our knowledge of the motions of the sun and moon and of the figure of the earth, but the value of a total eclipse is that we can then observe the solar atmosphere and surroundings which are invisible to us ordinarily on account of the great brilliance of the general sky-light, *i.e.*, sunlight scattered by the molecules of the earth's atmosphere. The moon acts as a screen outside the earth's atmosphere and cuts off the direct light of the sun and the scattered light at the same time, thus for instance the Corona (*q.v.*) has never been seen or photographed except during an eclipse.

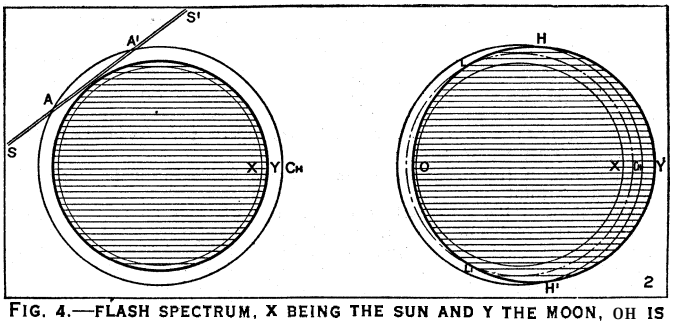

FIG. 4.—FLASH SPECTRUM, X BEING THE SUN AND Y THE MOON, OH IS THE TOP OF THE CHROMOSPHERE. WHICH IS LEFT WHOLLY OR PARTLY UNCOVERED AFTER THE DISC OF THE SUN IS COVERED BY THE MOON
1. shows the slit, SS¹, of a spectroscope placed to measure the wave lengths of the flash spectrum
2. Shows the way in which the "crescents" of the flash are formed and that the length of the crescent HOH¹, formed by an element high in the chromosphere, is greater than the crescent LOL¹, formed by an element low in the chromosphere

The apparent diameter of the sun is very roughly 1,800 sec. of arc and its atmosphere, or the Chromosphere (*q.v.*), extends about 10 sec. only above the surface (photosphere); that is to say the sun as seen from the earth is a disc surrounded by a narrow ring of atmosphere somewhat over $\frac{1}{2}\%$ of a solar diameter in thickness. This atmosphere consists of many elements in the gaseous condition at a high temperature. We cannot in ordinary circumstances see it although it is very bright, but during a total eclipse the moon covers up the disc of the sun, and when the last crescent of the disappearing sun has vanished the narrow ring or crescent of chromosphere becomes visible. It is found that this atmosphere yields an emission spectrum which is the reversal, or counterpart of the ordinary solar absorption spectrum. On account of the fact that this spectrum flashes out at the instant totality commences it is termed the "flash spectrum." The study of it is one of the most important aims of eclipse observers. First of all it is of prime importance to have an accurate knowledge of the wavelengths of the lines in this spectrum. For this purpose an image of the sun is focused on the slit of a suitable spectrograph, and a suitable comparison spectrum may be photographed alongside the flash spectrum. In this way the bright lines in the flash spectrum are identified line for line with the dark lines in the Fraunhofer spectrum.

Date at noon point	Duration of totality minutes	Node and series	Regions swept by shadow
1900 May 28	2·1	D 5	United States, Spain, N. Africa.

1999 Aug. 11	2·6	A 11	Central and Southern Europe, touching England.

From fig. 4 (1) it is clear that the length of the line in the spectrum, *i.e.*, the length of slit (SS') illuminated (AA') depends on the height of the chromosphere. This method has also been used to estimate the heights to which the elements concerned reach in the chromosphere since the intensity diminishes as the height increases, but it is open to serious objections. Firstly there exist lines of any one element of greatly different intensities at any one level and the length of a line in the spectrum will depend on whether or not the light is strong enough to produce any effect during the exposure given. Secondly the scale of image possible renders it almost impossible to make a really accurate setting of the slit at a given height, and as a corollary of this it is usually entirely unknown to what extent the moon has cut out the central part of the line during the exposure. Lastly the slit is by no means narrow compared with the chromosphere itself and the optical definition obtainable may be such as to confuse the image seriously.

The chromosphere is so narrow that its spectrum can be obtained with an objective prism spectroscope (*i.e.*, one without slit of collimator). Fig. 4 (2) shows the way in which the moon leaves a crescent of chromosphere uncovered at a given instant. The lengths of the crescents again depend on the height of the element concerned. This method is used to determine heights in the chromosphere. It is open to the first objection raised against the slit method, but not to the others, and enables us at any rate to fix a minimum height. It is found that most elements extend to a height of about 500 km. (310 miles) but some, *e.g.*, H and Ca are found as far up as 14,000 km. (8,700 miles). The best method for investigating the variation of intensity with height is undoubtedly that known as the "falling plate method." For this purpose an objective prism or grating is used giving in the usual way a spectrum of crescents, but a part of this only is used, namely a narrow strip of it which is allowed to pass through a slit running along the spectrum area placed close to the plate. The plate is caused to move uniformly during the period of exposure and thus each small piece of crescent (virtually a dot) is spread out into a long line perpendicular to the direction of dispersion in the spectrum. Since as the exposure proceeds the chromosphere is gradually covered up at a known rate from the bottom by the moon (or uncovered if third contact be used) the variation of intensity along the line so produced can be used to determine accurately the law of variation of intensity of the radiation of the wave-length concerned with height.

It is only recently that modern spectro-photometric methods have been applied to the study of the flash spectrum, but the results are most promising and photometric investigations will form an important part of future observations. One serious difficulty is to compare the intensities of lines that are not so close together that the variation of the absorption of light in the earth's atmosphere can be neglected. since the precise value of the absorption at different wave-lengths is unknown. It should be remarked that the method of obtaining flash spectra with a slit can be used

when the eclipse is not total, by setting the slit on a part that will be covered by the moon.

There appears to be a faint general continuous background to the flash spectrum, but near the head of the Balnier series there is a marked continuous spectrum due to the capture of free electrons by the ionized hydrogen atom. The Balmer series of hydrogen is extraordinarily well developed in the flash and if the lines be numbered in order taking H_α as H_1, H_β as H_2 and so on we can detect lines as far as H_{36}. This confirms our ideas of the very low density in the chromosphere.

Prominences. — When totality commences an irregular fringe of crimson flame-like objects is often seen around the limb of the sun. These are the prominences, and are found to consist of masses or clouds of gas mainly hydrogen (hence the red colour) and calcium in rapid motion above the solar surface. They vary very much in size and profusion, being found mostly in the sun-spot zones and in greatest profusion and usually largest near a time of maximum sun-spot activity. During a long eclipse changes may be found in the prominences, but the study of their behaviour is carried out mostly with the spectroheliograph, an instrument which allows them to be photographed without an eclipse. Pl. II., in the article SUN shows a prominence photographed in 1919. The same prominence was observed with the spectroheliograph at the Solar Physics Observatory, Cambridge, on the day preceding the eclipse and was photographed at intervals of an hour throughout the day of the eclipse whereby remarkable changes were observed and it was found that this giant prominence reached a height of 150,000 miles above the solar surface, attaining a velocity of over 55,000 miles per hour and a maximum length of 361,000 miles.

The Deflection of Light by a Gravitational **Field.**—One of the most famous, and the first, of the tests of Einstein's theory of relativity was that of observing the bending of a ray of light passing close to the sun. During a total eclipse the brighter stars are visible to the naked eye and many more can be photographed near the sun. If Einstein's theory be true the stars near the sun should be found not in their true places but displaced away from the sun by a small, but measurable, amount varying inversely as the distance from the centre of the sun. This test was first carried out in 1919 and has been repeated since with results on the whole in favour of the theory (see RELATIVITY).

Other Phenomena. — Baily's Beads. — It is found that totality does not begin or end quite suddenly as it should were the sun and moon of perfectly smooth outline, but that there exists for a moment or two a crescent of minute gleaming points of light, called Baily's Beads. These are due to the irregular outline of the moon (*i.e.*, its mountains and valleys) whereby the sun is left uncovered here and there for a moment after the disc representing the size of the moon if smoothed out would have covered it.

Shadow Bands. — When totality is nearly due and there remains but a small crescent of sun left there can often be seen on the ground or on the walls of buildings striations of light and shade, not very definite in outline but something like a sheet of corrugated iron, moving moderately rapidly perpendicular to their length. These are termed the shadow bands and are due to corrugations introduced into the nearly plane waves of light reaching us from the sun owing to irregularities in the refraction of the earth's atmosphere.

VI. ECLIPSES OF THE MOON

The phenomena attending eclipses of the moon are not of great astrophysical interest nowadays. Owing to the earth's atmosphere there is never complete darkening of the lunar surface. Even at mid-eclipse there is sufficient light refracted to make it visible as of a dull ruddy hue. The reddening is due to the absorption of the blue rays in our atmosphere. The brightness of the moon in eclipse varies considerably presumably owing to the variability of our atmospheric conditions, cloudiness and suspended dust, etc.

VII. TABLE OF THE PRINCIPAL TOTAL ECLIPSES OF THE SUN IN THE 20TH CENTURY A.D.

We omit those eclipses which are visible only in polar regions or are of excessively short duration. The first column gives the date of the eclipse, the next the duration of totality, the third the node near which the eclipse occurs and the number of the Saros series to which it belongs, repeated eclipses having the same number. The last column states where the eclipse is visible.

ANCIENT ECLIPSES

It is not surprising that, in ancient times when eclipses were regarded as portents, a large number of eclipses should have been mentioned in history or in literature, in addition to those which are recorded in astronomical treatises or on astronomical tablets.

The value of these records may be classified as follows: (1) Literary *and* historical, depending on the interest which they aroused, the notice taken of them, and their connection with events. (2) *Chronological,* in so far as they enable us, by computing their dates, to verify chronological systems resting on other evidence and to supply dates for events connected with the eclipses. (3) Astronomical, including the determination by ancient astronomers of the periods and motions of the sun and moon, and by modern astronomers of the mean rate of change of those motions, which, in astronomical terminology, is called secular acceleration.

Literary and Historical References. — (I) Chinese. In the *Shu* King or Book of Historical *Documents* it is stated that Hsi and Ho (the hereditary astronomers) had neglected the duties of their office and were abandoned to drink in their private cities. The king, Chung K'ang, placed the marquis of Yin in command of an army with instructions to punish them. The marquis issued a florid address to his troops in which he referred to Hsi and Ho having neither heard nor known anything on a recent occasion when "the sun and moon did not meet harmoniously in Fang." The phrase is taken by all Chinese scholars. ancient and modern, to mean an eclipse. It would therefore appear that a military expedition was sent to punish the two astronomers for failing to observe an eclipse. There are good reasons for believing that this part of the *Shu* King is a literary restoration, made to take the place of books that were burned by imperial order in 213 B.C., but sufficient is found in a quotation made by Tso before that disaster and in the statements in the Bamboo Annals also made before that date, to prove that the reference to the eclipse is authentic, though its relation to the supposed offence of Hsi and Ho is doubtful. Attempts have been made to identify this eclipse, but the necessary data are wanting. It may easily have been a small eclipse, and the number of the month is given differently in different texts. The received Chinese chronology places the accession of Chung Kang in 2159 B.C. The Bamboo Books, where chronology is probably nearer to the truth, place that event in 1952 B.C.

The Shih King, or Book of Poetry, contains a lamentation caused by an eclipse of the moon, followed by an eclipse of the sun. The dates are clearly defined and are found to agree with the lunar eclipse of Aug. 21 and the solar eclipse of Sept. 6 in 776 B.C.

The eclipses recorded in the Spring and *Autumn Annals* possess a chronological and astronomical rather than a literary interest.

(2) Assyrian. — The Assyrian eponym canon, which preserves the names of the annual magistrates who gave their names to the years, records under the year which corresponds to our 763–762 B.C.:—"Insurrection in the city of Assur. In the month Sivan the sun was eclipsed" The reference must be to the eclipse of the sun on June 15 in 763 B.C. A reference to the same eclipse has been found in Amos viii. 9, "And it shall come to pass in that

day, saith the Lord God, that I will cause the sun to go down at noon, and I will darken the earth in the clear day."

(3) Greek.—In the Odyssey Homer twice makes the unrecognized Odysseus predict that Odysseus will return "as the old moon wanes, and the new appears," that is, at new moon, when alone an eclipse of the sun is possible. In one of these passages he predicts vengeance on his wife's suitors. On the day when Odysseus was to become known and slay the suitors, the seer Theoclymenus notes among other portents of gloom that "the sun has perished out of heaven, and an evil mist has spread over all." This was interpreted by Plutarch and Eustathius as a total eclipse of the sun. Some modern scholars have regarded it as merely a vision of the seer. Schoch (the Observatory, xlix. [1926] pp. 19–21) has suggested an identification with the solar eclipse of April 16 in 1178 B.C., which was total in or near Ithaca. But it is not improbable that the story of the eclipse belongs to legend rather than to history.

In a fragment of a lost poem by Archilochus occur the words:—"Nothing there is beyond hope, nothing that can be sworn impossible, nothing wonderful, since Zeus, father of the Olympians, made night from mid-day, hiding the light of the shining sun, and sore fear came upon men." According to Aristotle the words come from a passage, abusing a lady, probably Archilochus's former *fiancée* Neobule, who is supposed to have belonged to Paros. The life of Archilochus was divided between Paros and Thasos. The phenomenon described has been identified as the total eclipse of the sun on April 6 in 648 B.C.

Small fragments survive of other poetic descriptions of eclipses. and the ninth paean of Pindar, addressed to the Thebans, takes an eclipse of the sun as its theme. Sandys translates the opening lines as follows:—

"Beam of the sun! O thou that seest afar, what wilt thou be devising? O mother of mine eyes! O star supreme, reft from us in the daytime! Why hast thou perplexed the power of man and the way of wisdom, by rushing forth on a darksome track?"

Pindar then proceeds to speculate on the meaning of the eclipse as a portent. The poem probably refers to the solar eclipse of 463 B.C., April 30, which was nearly total at Thebes.

The most fampus of ancient eclipses was a total eclipse of the sun which happened according to Herodotus during a battle between the Lydians and Medes. The portent induced them to cease from fighting and conclude peace. Herodotus further informs us that Thales of Miletus predicted this eclipse to the Ionians for the very year in which it happened. Babylonians were certainly predicting eclipses about this time by means of the 18 years' cycle known as the Saros. But, as that cycle gives eclipses for every year, the statement about Thales must, if true, mean that he predicted that an eclipse of the particular year would attain a great magnitude. Such a prediction can be made by the 18 years' cycle without any mathematical computation. The eclipse was certainly that of 585 B.C., May 28, and must have been predicted by means of the eclipse of 603 B.C., May 18. Several ancient writers have preserved 585 B.C. or some neighbouring year as the date of the eclipse.

Thucydides comments on the frequency of eclipses during the Peloponnesian war. The most interesting of these were the solar eclipse of 431 B.C., Aug. 3, when, we are told, "the sun assumed the shape of a crescent and became full again, and during the eclipse some stars became visible," a statement that agrees well with modern computation, and the lunar eclipse of 413 B.C., Aug. 27. That date had been selected by the Athenian commanders, Nicias and Demosthenes, for the departure of their armament from Syracuse. All preparations were ready, but the signal had not been given, when the moon was eclipsed. The soldiers and sailors clamoured against departure and Nicias in obedience to the soothsayers resolved to remain thrice nine days. This delay enabled the Syracusans to capture or destroy the whole of the Athenian fleet and army.

The year 310 B.C., Aug. 15, is the date of a total eclipse of the sun, which, as we are informed by Diodorus and Justin, was seen by Agathocles and his men the day after he had sailed from Syracuse on his way to Africa. Modern computations of the eclipse track render it probable that he sailed to the north of Sicily.

In Plutarch's Dialogue on the Face which appears in the Orb of *the* Moon, one of the characters, called Lucius, deduces from the phases of the moon and the phenomena of eclipses a similarity between the earth and the moon and illustrates his argument by means of a recent eclipse of the sun, "which, beginning just after noon, showed us plainly many stars in all parts of the heavens, and produced a chill in the temperature like that of twilight." A little further on Lucius refers to a certain brightness which appears round the moon's rim in total eclipses of the sun. Nicolaus Struyck identified this eclipse with that of A.D. 71, March 20, and the identification has been confirmed by Ginzel after a very exhaustive discussion. There are numerous other references to eclipses in Greek literature.

(4) Roman.—There is a very large number of eclipses recorded in Roman history. One which has attracted the attention of students alike of astronomy and of the Roman calendar is stated by Cicero to have occurred in the 350th year from the foundation of Rome and to have been described by the poet Ennius as follows:—"On the Nones of June the sun was covered by the moon and night." This would appear to have been the solar eclipse of 400 B.C., June 21, which reached a total or almost total phase at Rome a few minutes after sunset. It seems to show that in that year the calendar month of June began 16 days later than in the calendar as reformed by Julius Caesar.

The eclipse of the moon in 168 B.C., June 21, has attracted much attention. The Romans were at that time at war with Macedon, and Polybius informs us that the eclipse of the moon was interpreted as an omen of the eclipse of a king and thus encouraged the Romans and discouraged the Macedonians. Cicero states that Sulpicius Gallus explained the eclipse on the following day, while Livy states that the eclipse was predicted by Gallus and took place on the night before the battle of Pydna, which, according to him, was fought on Sept. 4 of the Roman calendar of that time. It seems clear that the story has grown with repetition and that there is no evidence that the eclipse was predicted or that it was on the night before the battle of Pydna.

Use of Eclipses for Chronological Purposes.—Although no continuous era has been used since ancient times, dates are frequently expressed in terms of regnal years, or are named after consuls or other officials of whom lists have been preserved. In these cases it is important to be able to equate certain specific years thus defined with years before the Christian era. This can be done whenever the date of an eclipse or other identifiable and calculable astronomical phenomenon is given in an ancient record.

The received Chinese chronology can be confirmed accurately by eclipses from 719 B.C. onwards. The chronology of Ptolemy's canon of kings, which gives the Babylonian series from 747 to 539 B.C., the Persian series from 538 to 324 B.C., the Alexandrian series from 323 to 30 B.C., and the Roman series from 30 B.C. onwards, is confirmed throughout by eclipses. The eclipse of 763 B.C., recorded in the eponym canon, enables us to carry the chronology back with certainty through the period covered by that canon, to 893 B.C. Assyrian, Babylonian and Persian chronology provide a stable chronology for the countries with which Assyria, Babylon and Persia came into contact, but there is no check from eclipses on Greek or Egyptian historical chronology before the Persian period. Identifiable eclipses recorded under named Roman consuls extend back to 217 B.C. The dated eclipses of Ennius and Pydna and one in 190 B.C. can be used to determine the position of Roman calendar months in the natural year, and occasionally eclipses help us to fix the precise dates of a series of events, such as those connected with the Athenian disaster at Syracuse.

Use of Eclipses for Astronomical Purposes.—(I) *In Ancient* Astronomy. It would appear that at least from the time of King Nabonassar (747 B.C.) a dated canon of astronomical observations was preserved at Babylon, including all eclipses. This rendered it possible to determine accurately the intervals between eclipses and must have facilitated the discovery of the 18 years' cycle, more exactly the cycle of 6,5853 days, which Suidas calls the saros, and its multiple, the 54 years' cycle of 19,756 days.

These cycles govern the recurrence of eclipses. It has been seen that Thales probably used such a cycle. In a Babylonian observation tablet of 568 B.C. mention is made of failure to observe a predicted eclipse of the moon. The eclipse is found by computation to have been real, but invisible at Babylon. It was doubtless predicted by cycle. Tables based on the saros go back to the 4th century B C. Eclipses of the moon give more accurately than any other kind of observation the actual time when sun and moon are in opposition. From an early date the Babylonian astronomers must have deduced from them not only the mean interval between two conjunctions, but the principal inequality in the motion of the moon and the similar inequality in the motion of the earth, or, as on their geocentric theory they conceived it, of the sun, and they were able to define the periods of these inequalities, which astronomers call the anomalistic month and year.

In the same way, since eclipses happen only when the two luminaries are stationed at intersections of their orbits called nodes, and since the path of the shadow in a lunar eclipse depends on the position of the centre of the sun in relation to the node, they were also able to determine the position and motion of the nodes. By assuming, what is approximately true, that the saros of 6,5853 days contained an exact number (a) of synodic months, or revolutions of the moon measured from the sun, (b) of anomalistic months, or revolutions of the moon measured from her apogee or perigee, that is, from her furthest removal from and closest approach to the earth, and (c) of draconic months or revolutions of the moon measured from her node, the early astronomers, perhaps in the 6th century B.C., computed the relative motions of the sun and moon, the lunar perigee and apogee, and the nodes. About 500 B.C. Naburiannu, apparently from a more accurate study of eclipse observations, obtained improved values which for the motion of the moon from the sun were 10″ per annum too small, for the moon from her perigee 20″ per annum too great, and for the moon from her node 5″ too small. Still more accurate values were obtained by Kidinnu about 383 B.C., from whom they passed to the Greek astronomer Hipparchus. In the system of Naburiannu the distance of the moon from her node was used for the prediction of the magnitude of lunar eclipses.

(2) *In Modern* Astronomy.—Ancient eclipses are of the highest value for the determination of "secular accelerations," that is, for the determination of the progressive, as distinct from the periodic, changes in celestial motions. Edmund Halley asserted in 1695 his belief that the moon's motion was subject to acceleration, but did not specify the amount of the acceleration. In 1749 Richard Dunthorne demonstrated from a comparison of the recorded with the computed times of eclipses distributed over 2,000 years that such an acceleration existed and assigned to it the value of 10″ a century. By this is meant that the effect of the acceleration is to produce an advance of 10″ in the moon's longitude in the course of a century. Laplace in 1786 discovered that such an acceleration should be the gravitational effect of the secular diminution in the eccentricity of the earth's orbit. But J. C. Adams showed in 1853 that the acceleration due to this cause amounts to 6″ only in a century. The residue must be explained by other causes.

The most recent values are 11″ a century acceleration of the moon, of which 5″ is unexplained, and about 1·5″ a century for an acceleration of the earth's motion suggested by P. H. Cowell in 1905. It is usual to regard the latter as an apparent effect of a retardation of the earth's rotation, which is our standard of time. This should produce an apparent acceleration of the Moon 13·4 times as great as that of the earth. But, since the unexplained acceleration of the moon is only about 3·3 times as great as that of the earth, it becomes necessary to suppose that there is a real secular retardation of about 15″ a century in the moon's motion. It is commonly supposed that tidal friction is the main cause of both retardations. (*See* MOON.)

ECLIPTIC, in astronomy, is the great circle on the celestial sphere which forms the apparent path of the sun in the course of the year. The twelve constellations or signs of the zodiac are arranged along the ecliptic. The plane of the ecliptic is the plane of the earth's orbit, or more strictly the plane in which the centre of gravity of the earth and moon revolves round the sun; it meets the celestial sphere in the great circle above mentioned.

ECLOGITE, in petrology a typical member of a small group of rocks now recognized as including both igneous and metamorphic representatives, and of special interest on account of the variety of minerals they contain and their geological relationships. The eclogites (from Gr. ἐκλογή, a selection) are mostly coarse-grained and massive aggregates of green monoclinic pyroxene and red garnet, but some varieties possess green hornblende wholly or partly replacing the pyroxene, thus giving rise to the two important groups—the pyroxene and the hornblende eclogites. The minerals associated with these essential constituents include rutile, apatite and iron ores, and, less commonly, quartz, muscovite, zoisite, cyanite, albite, bronzite, olivine and chlorite. The eclogites correspond closely in bulk composition with the gabbros and dolerites, but are characteristically assemblages with high density (3·2–3·6 as compared with gabbro 2·9–3·0).

The pyroxenes show considerable variation in composition, and include both non-aluminous and aluminous varieties. The latter contain significant proportions of the jadeite and aegirine molecules and correspond to true omphacite. The red garnet is a pyrope-rich variety containing almandine and grossular, but is not so magnesia-rich as the garnet found in serpentines and peridotites. The hornblende is usually a green variety—smaragdite, or alkali-hornblende sometimes approaching glaucophane in composition.

Whether of metamorphic origin or considered as igneous rocks consolidating under excessive pressures, the almost complete absence of plagioclase felspar makes these rocks of peculiar interest. The omphacite-garnet assemblages have undoubtedly crystallized under high pressures, in place of augite, olivine and plagioclase in accordance with the principle of Van't Hoff and Le Chatelier. Magnesian garnet appears in place of the olivine-anorthite pair, and a jadeite-chloromelanite-bearing pyroxene in place of the augite-plagioclase combination of the heteromorphous gabbros.

Under the name griquaite, eclogites are found as blocks or boulders in the kimberlite "pipes" of the diamond fields of South Africa. This pyroxene-eclogite is of special interest inasmuch as diamonds have been found as enclosures of the garnet of the rock, and according to one prevailing view eclogite is the parent rock of the diamonds of the South African fields, the diamonds of the "pipes" being derived from the explosive disruption of deep-seated masses of diamantiferous griquaite.

That some eclogites are of metamorphic origin is clearly revealed by their geological associations and microscopic structures. Such often appear as lenses intercalated among crystalline schists and show unmistakable crystalloblastic structures.

Others, such as those of western Norway, occur as lenticular masses in granite gneiss or bands in olivine rocks (peridotites, dunites or their serpentine derivatives). These rocks possess no true crystalloblastic structure, and are believed to be unaltered igneous rocks. Probably some eclogites from other areas previously believed to be transmuted gabbros are of similar origin.

The amphiboles of the eclogites may represent either a direct crystallization from the magma, or arise by metamorphic processes from original pyroxene, and it is not improbable that many of the so-called "garnet-amphibolites" of archaean tracts are transformed eclogites. The clear recognition of eclogites as primary magmatic consolidations under high pressures has led to the conception of an eclogite zone in the earth's crust immediately below the more acid silicate shell. At depth magma of basaltic

or gabbroid composition may exist stable as solid eclogite, and it is possible that in this zone is to be discovered the source of the eclogite blocks of the kimberlite "pipes."

The chief localities for eclogites are archaean and palaeozoic metamorphic-igneous complexes. They are known from Sutherlandshire, western Norway, Saxony, Bavaria, the Alps, Austria, Greece and California. Glaucophane and jadeite-eclogites occur in Italy. The following analyses represent the compositions of some typical eclogites:

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O	TiO_2
	57·10	11·66	2.84	3.22	6.37	13·80	2·21	0·81	
	48·22	16·51	2.64	5.78	8.26	13·46	3·23	0·47	1·07
3	44·91	17·15	1·68	6·45	14·27	11·28	1·01	0·89	0·46
4	44·15	15·68	1·81	15·88	5·70	7.37	2·70	1·89	3·21

1. Cyanite-bearing eclogite, Eppenreuth, Fichtelgebirge, Bavaria.
2. Hornblende eclogite, Burgstein Otztal, Tirol.
3. Griquaite, Premier Mine, Kimberley, South Africa.
4. Glaucophane-bearing eclogite, San Martin, California.

(C. E. T.)

ECLOGUE, a short pastoral dialogue in verse. The word is conjectured to be derived from the Greek verb ἐκλέγειν, to choose. Another derivation traces it to αἴξ, goat, and λόγος, speech, and makes it a conversation of shepherds. The idea of dialogue, however, is not necessary for an eclogue, which is often not to be distinguished from the idyll. The grammarians, in giving this title to Virgil's pastoral conversations (Bucolica), tended to make the term "eclogue" apply exclusively to dialogue. The Eclogues of the Spanish poet Garcilasso de la Vega (1503–36) are still admired. See also BUCOLICS; **PASTORAL.**

ECOLOGY, ANIMAL. Animal ecology is rather a difficult subject to define, because it lies on the borderlines of so many other subjects, and also because comparatively little work has so far been done on it, so that its exact scope and limits still remain to be established. In a general way animal ecology seeks to give some definite form to the vast number of observations which have been accumulated during the last few hundred years by field naturalists and various other people interested in wild animals. It was Haeckel who first invented the word "oecology" in the year 1869; but, owing to the predominantly morphological and physiological interest which was taken in animals during the latter half of the 19th century, the subject that he so named was largely ignored by zoologists. It was the botanists who developed further the idea of studying scientifically the relations between the plants and their environment, and when American botanists, and later, American zoologists, began to produce a great deal of important work in ecology during the beginning of the 20th century, the "o" was gradually dropped and the word was adopted in its present form, although the older spelling is still widely used on the Continent. "Ecology" corresponds to the older terms "Natural History" and "Bionomics," but its methods are more accurate and precise, and, while much of the earlier work was centred upon the study of adaptations with the idea of proving the theory of natural selection, the modern trend is in a different direction. Ecology is now concerned more with an attempt to reduce and co-ordinate into some scientific scheme the existing information (which is enormous, but appallingly scattered) on the habits, life histories, and numbers of all the different animals, with a view to solving some of the urgent practical problems which are cropping up everywhere as a result of man's becoming civilized and interfering with the animal and plant life around him. Professor **J. A.** Thomson has rather aptly called animal ecology "the New Natural History," and has pointed out that, although it can never reach in its methods "the icy perfection of comparative anatomy" yet it has nevertheless an important gap to fill in biological work. To say that animal ecology deals with "the relations of animals to their environment" is to give a formal definition that conveys no idea whatever of the manifold and exciting problems with which the ecologist has to deal. Instead, therefore, of endeavouring to force the subject into a strait-waistcoat, it will be more to the point to begin by describing a few examples, selected more or less at random, of the type of problem which may confront the animal ecologist working in the field. We can then proceed to inquire what stock of information we possess at the present time; the uses which can be made of it; and then we may be in a position to suggest the most desirable methods of classifying this information, and the lines along which research upon the ecology of animals may best be directed in the immediate future.

During the winter of 1910–11, a deadly epidemic of pneumonic plague broke out in Northern China, and killed off about 60,000 Chinamen. This outbreak originated from a previous epidemic amongst the tarbagans or wild marmots (Arctomys bobac) which inhabit the semi-desert steppes of Mongolia, and are the most dangerous reservoir of plague in that region. We now know, through the researches of Wu Lien-Teh and others, that this marmot only suffers from really severe outbreaks of plague at comparatively long intervals (about every ten years), at times when the numbers of the animals have for some reason become too great, and the population in consequence too dense. This overcrowding favours the spread of the plague bacillus, and produces suitable conditions for epidemics in the marmots; when these occur, any accidental contact, causing infection to spread to a man, enables the bacilli to spread through the Chinese population, which in its turn is usually overcrowded. From this point, the epidemic spreads from one person to another by the breathing of infected air, after the manner of influenza. A climatic factor comes in here, for it is only in countries with a moist cool climate that widespread epidemics of pneumonic plague occur; in hotter and drier regions the bacilli of plague cannot be successfully carried about in the droplets of moisture breathed out by infected people. In these hotter countries, *e.g.,* India and South Africa, plague occurs in the bubonic form, and is transmitted by the bites of fleas, which in turn have become infected with bacilli from rats or other rodents.

The complete cycle of events in China is not, however, entirely to be explained by the marmots, for it is an interesting fact that before about 1890 severe epidemics of plague in man were much less frequent in that region. The increase in modern times has probably been due to two other factors: the arrival of a great many Russian immigrants from the west, partly as a result of the establishment of the Trans-Siberian railway, which runs for part of its way straight through the marmot country; and also the penetration of Mongolia in recent years by an increasing number of Chinese colonists from the south-east. These new arrivals, being ignorant of the deadly nature of sick marmots, appear often to have handled them carelessly or eaten them, and so contracted plague, in some cases starting huge epidemics in the human population, like the one mentioned above, or like that which took place in 1921 and killed about 9,000 Chinamen.

The example just given illustrates the varied nature of the knowledge required for the complete solution of problems in animal ecology. Here the problem touches on zoology, medicine, bacteriology, climatology, history, human population problems, ethnology—to mention only the most obvious subjects involved.

The example of plague in Chinamen also illustrates the fact that man's relation to his environment (especially to his animal environment) may become suddenly strikingly altered when he migrates to a new part of the world. Most primitive peoples have settled down into a more or less harmonious relationship with the animals and plants of their own country. The Red Indians of North America, or the natives of Siberia, usually took care not to kill too many of the animals upon which they depended for food, so that the stock would not become exhausted—any failure to follow this principle would result in starvation and extinction of the tribe; and according to Percival the Masai of Central Africa have long been aware that malaria is carried by mosquitoes—in fact, their word for catching malaria means literally "I have been bitten by a mosquito." In England we have been here long enough to have settled down into a fairly comfortable balance with the animal community of which we are privileged members; but in the newer colonies, we see the effect of man's interference

with the balance of nature demonstrated in very remarkable ways.

The Hawaiian islands afford a number of very interesting cases of this sort. The sugar-cane leaf-hopper (Perkinsiella *saccharicida*) was introduced by accident towards the end of the 19th century, and, having no natural enemies, it flourished greatly. It was first noticed as a pest about 1887, and by 1902 it had increased to an enormous extent, so that on one plantation the sugar production fell in three years from 19,000 tons to 7,000. Perkins and other workers studied the insect in its native haunts in Australia, and after trying several different natural enemies, succeeded in almost completely controlling the leaf-hopper by introducing into Hawaii a Chalcid wasp (Paranagrus *optabilis*) from Queensland, with an allied species from Fiji, both of which parasitize it. Eighteen months later the leaf-hopper damage fell to about half its former proportions, and next year about three-quarters of the plantations were under control. Later on, a Capsid bug (*Cyrtorrhinus mundulus*), which sucks the eggs of the leaf-hopper, was also successfully introduced from Queensland. There are now comparatively few sugar-cane leaf-hoppers left in Hawaii, although in some years revivals in numbers tend to occur, and these have to be checked again.

A third example of an ecological problem is that of the rype or willow grouse (*Lagopus lagopus*) in Norway. Of late years this bird has become increasingly scarce in Norway, and since it is an important game bird a number of people have investigated its ecology with a view to finding out why it has become so much reduced in numbers. It appears that in earlier times (until about 1900) the willow grouse used to be subject to very marked and at the same time very regular fluctuations in numbers, and that one of the factors producing this was a coccidian protozoan (*Eimeria avium*) which gave rise to epidemics among the willow grouse whenever the latter became overcrowded. Some other factors appear to have been at work in controlling the actual years of abundance also, since the willow grouse cycle coincided very closely with the similar three or four year cycle in lemmings and mice in Norway, which also have periodic epidemics, but of an entirely different nature. It appears that in recent years the epidemics in grouse have become much more frequent and severe, so that the population is kept permanently at a very low ebb, and increase up to the abundance of former "crown years" is no longer possible. The explanation of this state of affairs which has been put forward by Brinkmann is this: normally the number of sick individuals in the coveys of willow grouse is kept down by birds of prey, for the heavy infestation by the parasite has the effect of reducing the flying power of birds, so that the sick are more easy to catch than the healthy. In this way the proportion of heavily infected birds, even in epidemic periods was always kept below a certain level; but in recent years birds of prey have been persecuted and greatly reduced in numbers, owing to the damage they do to poultry, etc., on farms. In consequence it seems that the ground occupied by the willow grouse has become very heavily infected with the spores of *Eimeria*, and the density of the parasites has increased to such a point that the grouse have epidemics nearly every year, instead of every four years. Besides being interesting in other ways, this example illustrates how the obvious idea of enemies being hostile to their prey fails to hold good when we are dealing with the regulation of numbers. Here the hawks were by their actions increasing the density of the willow grouse, instead of merely tending to reduce it.

It would be possible to give an indefinite number of similar examples all tending to show the immense importance to mankind of a knowledge of the means by which the numbers of animals are controlled, or of the factors in the environment which affect the life histories and distribution of the various species. It is not surprising to find that man's inter-relations with other animals bulk very large in the picture, since man himself is only one animal in a huge community of other ones, and is still subject to many of the same influences as the wild species. Malaria and mosquitoes; sleeping sickness and tsetse flies; earthworms in the soil; the control of nitrogen bacteria by protozoa in the soil; the enemies of crops, of timber and of other resources; the conservation of the supply of game, or of marine fisheries; the ravages of hookworms among tropical peoples; rats as reservoirs of diseases such as plague and jaundice, or as the destroyers of produce; the control of insect pests by birds; the effects of climate upon man himself—all these are ecological problems, requiring for their solution a background of ecological principles, and an ordered and skilfully organized knowledge of animal ecology. Human civilization is faced in many parts of the world with grave economic and medical problems, which can only be solved successfully along ecological lines, and it seems quite possible that unless they are solved in time, the civilization will be in danger of sinking gradually and collapsing under the strain, or at any rate of becoming too unpleasant to be worth retaining. At the very least, animal ecology has an important and very urgent contribution to make towards the world's happiness. This is probably not widely realized: five years ago an eminent zoologist remarked that ecology was only playing with science, while an equally famous entomologist was heard to say that ecologists were an obscure sect of the followers of Lamarck.

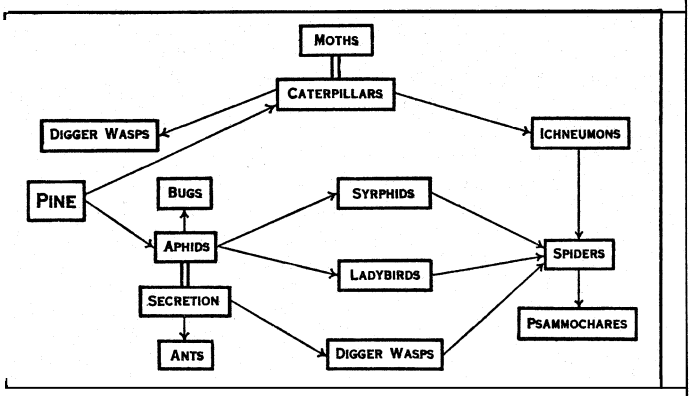
Having to some extent made clear the scope of animal ecology, we may now proceed to take stock of our general knowledge. What information is there about wild animals? Animal ecology is in rather a peculiar position, for there is an enormous amount of information in existence about the habits, distribution and numbers of wild animals, but much of it is either recorded in an unsuitable way and is therefore useless, or else only to be found in an extremely scattered form. A great many of the facts about animal life are never published at all, either because the observers have not the opportunity or training to describe them, or because they do not realize the value or significance of the data. The subject thus resembles a large nebula floating round in space: it will be some time before all the separate particles become condensed into a solid body. Another peculiarity of animal ecology is that many of the most interesting observations are made by people who are not scientifically trained at all—gamekeepers, fishermen, lighthouse keepers, clergymen, country gentlemen, amateur naturalists (but most of these are collectors only) or travellers; or if they are scientists, they are often not actually zoologists, but probably doctors, experts in forestry or agriculture, or travellers with an eye for the interesting and unusual. As a result, there exists, as we have said, a very large, but peculiarly diffuse body of facts about the life and manners of wild animals. There is hardly any journal which is not capable of being of some use to the ecologist. Periodicals on meteorology contain elaborate analyses of the behaviour of animals during thunderstorms, or the times of arrival of migrant birds in spring; the daily press often records "plagues" of animals like ants and mice, which pass unnoticed by more sober journals; engineering magazines may record examples of pests which attack marine timber works, or describe the animals found in water supplies, or cases of caterpillars holding up railway trains. The key fact for which the ecologist is looking may be firmly embedded in the middle of a work of travel mainly devoted to railway systems, or the songs of the Copper Eskimos, or the religion of the Bhotias. The immediate tendency (at any rate the immediate need) in ecology is for the co-ordination of these scattered facts, for the digestion of these gigantic boluses of unassimilated first-hand observations; and lastly, and most urgently of all, we require ideas, to link up all these stray facts into an effective whole. The proportion of facts to ideas in animal ecology is at present indigestibly high; the journals of ornithology and entomology are swollen fat and heavy with such valuable, but unassimilated matter.

What, then, are the lines along which this organization should proceed? In the following pages an attempt will be made to indicate the most promising of these lines, and at the same time to describe the more important principles which have already been established. The general thread running through this account is as follows. Animal ecologists doing pure research have carried out a number of ecological surveys, established the habitats of a number of animals, and gained some insight into the nature and workings of their environment, together with some idea of the ways in which environmental factors affect a few species. At

the other end of the subject, there are hundreds of economic entomologists and other zoologists, who are studying problems concerned with the number of animals, and who are in need of a basis of principles upon which to work. The gap between these two groups of ecologists will have to be bridged by professional ecologists studying the organization of animal communities. For it is found that by analyzing the lists of animals from different habitats and arranging the species according to their food-habits, it is possible to obtain just the kind of data required for the solution of the more practical problems connected with animal numbers and their control. One of the tasks of ecologists at the present time is to provide a system of basic principles which can be used by other people such as medical investigators, or evolutionists, or botanists, or economic zoologists working in the field.

ECOLOGICAL SURVEYS

The first step in the study and consideration of the animal ecology of any region is the carrying out of a primary ecological survey; this involves (a) the collection and listing of all the species of animals found in the district and (b) the description, in as accurate a way as possible, of the exact habitats of all the animals which have been collected. The first part of this task is more easy than the second. For many countries we now have a fairly clear idea of the species which occur there, and of the general distribution of each. In some countries (England among them) this sort of work has rather tended to run to seed, and has often degenerated into the accumulation of lists which refer to districts which may have quite arbitrary limits, bearing no relation whatever to the ecological habitats of the various animals. For instance, natural history societies frequently spend considerable energy in making lists of animals for counties, or for the country within a certain radius of some town. Such lists are almost, if not altogether, useless. They show how a means can easily be confused with an end. The second point is the importance of collecting, with all specimens, ecological notes about the habitats of the animals. In order to do this properly, it is of course necessary to have good topographical and geological maps, together with maps of, or at any rate organized information about, the plant associations, and also if possible meteorological and climatological data for the district. With such information at hand, it is possible to define in a rough, but useful, preliminary



FROM O. W. RICHARDS, IN THE 'JOURNAL OF ECOLOGY" (OXFORD UNIVERSITY)

FIG. 1.— DIAGRAM OF FOOD-RELATIONS ("FOOD-CYCLE") IN AN ANIMAL COMMUNITY LIVING UPON YOUNG PINE TREES, IN THE SOUTH OF ENGLAND

The arrows point from the organism eaten to that eating it, and the parallel lines indicate different stages or products of the same animal

way the general habitats and distribution of the different species of animals. Fortunately the necessity of recording the exact habitats of animals is becoming widely recognized, even among collectors of insects. Organized ecological surveys have been started in many places during recent years. The fine work of the American Bureau of Biological Survey, both in the U.S.A. and in Canada; Wesenberg-Lund's comprehensive studies of the freshwater animals of Denmark; the work of Annandale in India, and of Johansen in Arctic Canada and Greenland; these are examples of the movement for obtaining an organized knowledge of the ecological distribution of animals. In England, very few such surveys have as yet been carried out with anything approaching completeness, but we may mention the survey by Richards of animal communities living in various habitats on Oxshott common; that of freshwater Crustacea in the English lakes by Gurney; of freshwater animals in Welsh streams by Carpenter; and certain valuable work on marine plankton communities in the North sea, by Hardy and others. But the general ecological distribution of English animals has at present often to be left to the imagination, or to be deduced from analogy with what is known from the Continent. This applies more particularly to our knowledge of the *animal* environment (food, enemies, parasites, etc.) of species. The numerous local natural history societies (over 50 in number) which exist all over the British Isles, form a skeleton organization for this sort of enterprise, which, like the tides, has still to be harnessed and directed along the most useful lines. For details of carrying out surveys, and collecting animals, the reader is referred to the relevant sources at the end of this article.

When the preliminary stage of making lists has been reached and completed certain facts about the distribution of animals in nature begin to emerge. The first is that the habitats of animals —those various combinations of environmental factors which affect them and control their occurrence and numbers—can be classified and arranged in a large number of ways. Secondly, each different habitat possesses its own characteristic community of animals. The number of different habitats in which animals can be found living is at first sight bewilderingly great. Almost wherever one looks animals can be found in greater or less variety; on the bottom of the sea at a depth of several miles; in the throats of turkeys; in the baleen plates of a whale; in hot springs; on the snow of high mountains; living and feeding on the algae which, in turn live among the hairs of the sloth; on the bottoms of ships; in stores of food (there is a moth whose larva lives on tobacco and strychnine); on the surface film of water; in the pools of acid water found in tree-holes; in lichens on the surface of windswept rocks; not to speak of the vast number of more obvious habitats afforded by vegetation, soil, and water. How are we to classify these different habitats in a convenient way, so as to avoid the reproach usually levelled at ecologists, that the subject is nothing but a chaotic mass of unrelated facts? It is obviously imperative to have some scheme in order to provide a common system to which all the detailed records of animals by habitats can be referred, and in order to understand their distribution in nature. There are three useful ideas which help to reduce the chaos to order:

Gradients in the Environment.— There are a number of clearly marked gradients in important or controlling environmental factors which enable us to arrange some of the habitats, and therefore their animal communities, in definite series. A good example of this is the gradient in temperature and light which runs from the poles to the equator. Along this gradient the conditions change gradually through arctic, subarctic, and other zones to tropical conditions, and at the same time produce corresponding changes in the animal and plant communities. A fact which immediately emerges is the enormous influence that vegetation has upon the nature of the animals' habitats. Climatic factors do, of course, act directly on animals, but a great deal of their influence is felt indirectly through plants, which frequently change the whole character of the climate, as far as the animals are concerned. For instance, the light intensity inside a pine wood may be only about half that outside, with the result that animals living among pine needles occupy, in the daytime, conditions similar to those at dusk outside in the open. Another effect of plants is to create a much wider variety of "climatic" conditions (*e.g.*, humidity) than would otherwise exist, so that a more varied choice of habitats is open to animals, with consequent multiplication of the number of species. Again, plant associations are usually rather sharply marked off from one another, owing to the way in which dominant plants compete for light and food, so that the animal communities within them tend also to be rather more sharply separated from one another than they would otherwise be. This separation is well shown in the zones

found up the sides of mountains, where we find altitude corresponding to latitude—a phenomenon seen at its best in the Himalaya, where a traveller can sometimes listen to English and tropical birds calling at the same time in their different zones. These have been termed "life zones" by American ecologists, and the animal communities living in them have been more fully studied in North America than anywhere else, partly owing to the grand scale upon which they can be seen on the sides of the Rocky Mountains. In this connection the work of Grinnell and Storer on the life zones of the Yosemite region in the Sierra Nevada should be consulted, as one of the best examples of the way in which preliminary surveys can be carried out. The method of zoning animal communities with reference to some master factor in the environment is a useful one, and many such gradients can be found in nature. For instance, there is the vertical gradient in light and oxygen in the sea, or in freshwater lakes; the vertical gradient in salt content of water as we pass from alpine lakes down to the sea; gradients in water content of the soil, which are responsible for well-defined zones dominated by different species of plants; many more examples of this nature could be quoted.

Ecological Succession.—The second important idea which can be profitably used in arranging animal communities, is an extension of the one just described. This is the idea of ecological succession or orderly changes of the habitats from one into another. Important changes, usually rather slow ones, are continually taking place in the environment—rivers change their course, with corresponding destruction of existing land and formation of new; the climate changes from a temperate one to an arctic one, with the advance of an ice-sheet; the land rises or falls; valley lakes become silted up, or filled with vegetation and formed into marsh, and finally dry land. Such changes are happening everywhere, so that any one habitat seldom stays as it is for any length of time; but the most important kind of ecological succession is that caused by the "development" of vegetation. Ecological succession or development of plant communities occurs usually in a definite orderly, and predictable way, the changes being brought about mainly by the growth and decay of the plants themselves. These, by depositing humus, change the character of the soil, and are driven out and replaced by other species. There are other processes at work also (see PLANTS: Ecology *and* Distribution). The work of botanists has enabled plant communities to be arranged in series which represent their relationships both in space and time; and, in so far as animals also depend on the plants, these systems are of great importance to the animal ecologist and form a convenient means of classifying communities. The works of Tansley and Clements should be consulted in this connection. A number of papers and a few books on the classification of animal communities have been published; of the latter the most useful are Shelford's Animal Communities of Temperate America, and Haviland's Forest, Steppe and Tundra.

Communities at Different Times.—The third important principle to be used in the classification of animal communities is the fact that the character of the community in any place is always changing in a more or less periodic way. Thus in a birch wood or in a freshwater stream an almost entirely different set of species will be found active by day and by night. In the same way, the composition of the community changes according to the weather, or the tides (in the case of marine intertidal animals), or the passage of the seasons, and so on. This time-factor is an important one, and enables the field ecologist to simplify a great deal of his work, since the long lists of species with which he starts can be split up into smaller units—a great asset when he comes to work out the inter-relations of the animals. For instance, if one were studying the animals of a slow stream in England, one might find two common Crustacea, *Gammarus pulex* and *Asellus* aquaticus, living with several species of fish. The problems centring round the food supply of the different fish become simpler, when we find that Gammarus is mainly nocturnal, hiding by day under weeds and stones, while *Asellus* is quite active during the daytime.

THE FACTORS WHICH AFFECT ANIMALS

So far we have considered the surroundings of animals from a broad point of view, in order to reach a general orientation about them. It is necessary now to go a stage farther and try to analyze these general habitats (*e.g.*, "The Alpine zone," "an Oak wood," "the bottom of a lake") into their constituent factors. We are immediately brought up with a jerk against the fact already pointed out, that the animal ecologist requires a variegated and rather queerly assorted knowledge of subjects which are not biological at all, and many of which may never have been encountered during his training as a scientist. He is in the position of having to correlate the behaviour and occurrence of animals with botanical or inanimate phenomena which are studied by specialists, highly trained in their own lines of work. There is in existence a rather rich literature on the subject of the physical and chemical environments of animals, much of which has been accumulated by ecologists (see "Ecology" passim, and such works as Whipple's Microscopy of Drinking Water and Murray's Depths of the Ocean). The distribution and numbers of animals can be correlated with climatic factors, the gas content of waters, the soil temperature, and other such factors. Theoretically a very large amount of this work lies within the province of the meteorologist, the chemist, or the hydrographer, but unfortunately the data which are accumulated by these specialists are seldom exactly those required by the biologist. For this reason the animal ecologist is frequently delayed and even completely sidetracked on fundamental work which has little direct bearing on animals, although it is necessary for the ultimate solution of the problems upon which he started to work when he was younger. This obstacle is an important one from the point of view of progress in animal ecology; it explains the peculiar (and to the outsider, rather pointless and disconnected) nature of the literature upon the subject, the fact being that animal ecologists are really trying to do everyone else's work as well as their own, without realizing that such a feat is impossible. To attempt this is also undesirable, since there are specialists studying these other questions, while there is no one but the ecologist to study the equally urgent purely biological problems met with in the field. Progress in animal ecology will therefore probably lie along the lines of friendly co-operation with other specialists, so that ecologists themselves will have time left to study animals.

The factors which influence animals may be divided conveniently into three main groups (a) physical and chemical, (b) plants, (c) other animals. Any of these factors may affect the distribution or numbers of a species, and much scattered work has been done on different animals. This is often of great value in indicating the nature of the environment of animals and the processes going on in it, but, as far as the animals themselves are concerned, only one or two principles of importance have emerged, partly owing to a failure to appreciate the difference between ordinary factors and limiting factors. An example will make this difference clear. It has been shown that in certain parts of France the distribution of the freshwater crayfish is determined by the amount of calcium carbonate in the waters of the streams which form its habitat. This in turn is determined by the nature of the rocks which go to form the country through which the streams flow. Granite areas support few or no crayfish, while regions with enough calcium carbonate in the rocks are able to supply the material required by the crayfish for the formation of its skeleton. In this case calcium carbonate is the limiting factor to the distribution of the crayfish. No amount of work upon the oxygen requirements of the crayfish would have thrown any light upon its distribution, although it would tell us something about its physiology. Another example is that of the elf-owl (Micro*pallas* wkitneyi) which occurs in the deserts of California and Arizona This bird makes its nests exclusively in the holes made by two woodpeckers (Centurus *uropygialis* and *Colaptes chrysoides mearnsi*) in the stems of a giant cactus (Cereus giganteus). Its range in the desert is determined by these two biotic factors—cactus and woodpeckers. But the woodpeckers are not like the owl confined to the one cactus for nesting; they can also use other plants or trees, so that to them the cactus is not a limiting

factor. Returning to the owl, it will also be obvious that in part of its range it might be limited by the absence of cactus (even though woodpeckers were there); while, elsewhere, the cactus might be present but not available for nesting purposes owing to the absence of the woodpeckers. This idea of limiting factors is one of the most important ones which is used by ecologists in the course of field work; failure to realize its significance may often result (and has done in the past) in a great deal of work which is useless, ecologically speaking. (We owe the discovery of this idea to the plant ecologists.) It has often been the custom for animal ecologists to tabulate a list of the factors which act on animals, and then to pick out any one of them and study their exact quantitative mode of operation. From what has already been said it is clear that such a method will not necessarily throw any light upon the distribution of the animal under consideration. although it may reveal interesting facts about its physiology, and about the environment itself. After all, the object of ecology should be mainly to discover why animals occur in particular numbers at particular places: this can only be done by finding out the *limiting* factors and studying them.

At this point it is desirable to go back for a moment in order to reconsider the question of habitats and the best method of recording the data about them, when engaged on primary ecological surveys. What has just been said about limiting factors puts the idea of a habitat in rather a different light. Before, we were considering it as a complex one composed of numerous factors, all of equal importance or value to the animals living among them. But although all these factors exist, from the point of view of the animal's distribution and numbers the limiting factors are the ones which are of paramount importance, But in practice it is not possible to tell at a glance what are the limiting factors at work on each species, so that what actually happens is that we try to record any feature in the animal's environment with which it is constantly associated. This feature may or may not be the real limiting factor; usually it is only correlated with it. When we say that an aphid occurs on the under sides of oak leaves at a certain distance from the ground, we are only describing in a rough shorthand way the fact that it is confined to that place by, say, conditions of humidity or the nature of the plant juices produced in the leaves at that point. It should always be remembered, however, that the ultimate aim of ecological work of this sort is to be able to describe exactly the limiting factors acting on an animal, so that we may be in a position to predict what it will do under any given circumstances. It is at this point that ecology links up with physiology; for there is really no sudden break between the chain of causes leading from the soil to the oak tree, to its leaf juices, to the aphid digestion, and then to the utilization and excretion of the matter that it absorbs. Of course, in practice. it is not usually necessary to follow up the action of environmental factors upon animals any further than the rough correlation between the outer limiting factor and the animal's behaviour. Elaborate physiological explanations only become necessary in the case of man and his domestic animals, where we wish to apply medical measures. The confusion between physiological and ecological work is one of the many snags which have held up the progress of ecology a good deal during the last 20 years, and clear thinking on the matter is desirable.

We divided the environmental factors into three groups: the first two groups (physical and chemical, and plants) form great sciences of their own, and will not be treated here in detail. The influence of animals upon one another demands a much fuller consideration, and will, in fact, occupy most of the remainder of this article. The subject has been comparatively neglected by professional ecologists although it has been the chief interest of countless naturalists, especially of the older school, and more recently of a fairly considerable army of economic zoologists. The reason for this one-sided development of ecology appears to have been that plant ecology was made into a science before animal ecology had got properly under way, so that most of the earlier animal ecologists automatically followed the tendencies of plant ecology, and their interest came to be focussed upon the effects of soil, climate, and water upon species. and also upon the effects of plants, especially those due to succession. Hence, the centre of ecological interest drifted away from animal inter-relationships, which, however, carry with them the key to the understanding of animal numbers. Indeed, the subject of animal numbers has hardly figured at all in ecological literature until quite recently, although it was being intently investigated by biologists who did not term themselves ecologists, and who were working often in isolation, perhaps at some remote tropical station. It was Carr-Saunders's Population *Problem* (a study of the numbers in man) which helped to direct attention again to the regulation of numbers in animals and, of course, more particularly in man.

The fascinating problems presented by the inter-relations of animals have attracted naturalists since the earliest times. There has been in consequence a colossal amount of literature published on this subject, which has been approached from a great many points of view. Such work falls conveniently into two sections (1) the inter-relations of members of the same species (*e.g.*, the social habits of ants or of antelopes, the courtship of birds or of insects, co-operation in all its stages of evolution, etc.); (2) the inter-relations between animals belonging to different species (*e.g.*, food relations, parasitism, mimetic associations). We do not propose in this article to go over in any detail the work which has been done in the first sphere, although it comes quite logically under the heading of ecology. The fact is that with most animals, members of the same species do not act as limiting factors to one another's distribution, although in a sense they can act as limiting factors to numbers (see BIRDS, Reproductive Habits). Therefore much of the work on the subject bears very little relation to the questions of distribution and numbers with which the ecologist is mainly occupied. This statement applies to a great deal of the work on flock tactics, on the pairing habits of birds and insects, and on caste-systems in insects like ants and bees.

(a) It must be sufficient to mention some of the more important sources of information on these questions, and to indicate rhe points at which they illuminate general ecological problems. The problems concerning the inter-relations of animals of the same species again fall into two well-defined groups: (1) relations between the sexes, and (2) other relationships (flocking, co-operation, caste-systems, etc.). Most of these complicated inter-relationships have been brought about by the tendency of animals to evolve means of producing some division of labour which enables the species as a whole to maintain itself more effectively in the face of competition. The formation of two sexes with a suitable division of labour, is the most widespread example of this tendency, and since this division of labour has as its result the more successful production or upbringing of the young, we find that among many of the higher forms of animals the sexual relationship has become mixed up with more or less elaborate systems of territory which are required for the proper provision of a sufficient supply of food for the developing young. This phenomenon is especially well-marked in birds and mammals, and in some of the social insects. Eliot Howard (Territory in Bird Life) gives a good summary of the problem as seen in birds, and his theories have been criticized and developed further by Nicholson (How Birds Live). These two books give a clear idea of the ways in which sex relations may have a direct bearing on the population problems of a group of animals. The problems presented by the sex relations of insects have been fully reviewed from certain points of view by Richards, but it is at present uncertain what precise part is played by these relations in the other aspects of insect economics.

(b) Division of labour takes other forms in some of the more specialized social animals. Definite castes (workers, often soldiers, occasionally more remarkable types like living honey-pots, thread-spinners, etc.) occur amongst many ants, termites, and bees. This subject has been very fully treated by Wheeler (Ants; *Social Life* among Insects) and more briefly by Alverdes (Social Life in the Animal World). The division of labour may also take the form of temporary occupation of different jobs by different individuals (*e.g.*, sentries in antelopes and flamingos; crêche-minders in giraffes and penguins). The book by Alverdes sums up a number of facts bearing on these and other aspects of co-operation among

social animals. All these points are mentioned here because it has been shown (*e.g.*, by Wheeler, for insects) that increased co-operation and division of labour between members of the same species usually have the effect of enabling a denser population to exist on a given area, and this fact has, of course, a direct bearing on the problems concerning the numbers of animals, which we shall have to consider later on. Finally, it is worth mentioning that a perversion of the caste system has in certain cases resulted in the existence of robbers within the species. This is an ecological problem, to which little attention has been paid, but which has an important bearing upon the evolution of certain kinds of parasitism.

(c) We now come to the second type of animal inter-relation, that between members of different species. The inter-relations between different animals have been studied very intensively, but with the exception of work upon parasitism, organic symbiosis. mimicry, and colour adaptation, the facts discovered have been chiefly of a rather disconnected and unorganized nature. Also they have usually been recorded with one particular purpose in view—to prove or at any rate to illustrate Darwin's theory of adaptation through natural selection. In consequence, there has been a tendency to focus attention upon the strange and unlikely habit, the curious adaptation, the attractive resemblance, or the triumph of some successful parasite over its host. This tendency was a natural result of the wave of enthusiasm which followed the fruitful ideas of Darwin and Wallace, but at the present time ecological work upon the inter-relations of animals is tending in rather a different direction. It is being realized gradually that these remarkable examples of inter-relations between different species are only special cases of a very common phenomenon—the fact that animals frequently depend for their living upon their ability to catch other animals for food, a fact referred to by Darwin as "the almost universal law of 'consume or be consumed'." Animal communities are not simply unorganized assemblages of animals which happen to live in the same habitat—they are intimately connected together in a most complex manner, and the tie that binds them together is the tie of food. Food and eating are so familiar that it is possible to miss their enormous importance in ecology, and to forget that most of the problems which centre around animal numbers depend for their solution upon an adequate knowledge of the food-relationships of animals; since it is in this way that the numbers of one species are kept down by another. We shall not consider in any detail here the work which has been done upon animal coloration, commensalism, and symbiosis, since these subjects form only a comparatively small part of the whole study of food-relations among animals, and since, further, many of the conclusions which can be drawn from such work must be left in a rather indefinite state until a more settled idea is obtained of the exact way in which species arise and the part which adaptation really plays in this process.

THE STRUCTURE OF ANIMAL COMMUNITIES

An enormous amount of work has been done upon the food habits of animals, but scarcely half-a-dozen pieces of research upon the food-relations of a whole community. The complete food cycle for a community has only been worked out in one or two cases (very simple ones like those of arctic animals, or the community of animals living on one plant); but as a result of the work which has been done so far, several generalizations can be made. First, it is found that animals are usually arranged in "food-chains" leading from herbivorous or scavenging species up to terminal animals, through several stages formed by carnivores. For instance, in the sea, flagellated protozoa of various species are eaten by copepods, the latter by pteropod mollusca, the pteropods by herrings, and finally the herrings are preyed on by sea birds such as gannets, or by human beings. Again, in a pine wood, the young pine trees support a community of animals which are arranged in various food-chains, all radiating from herbivorous insects such as aphids and moth caterpillars; aphids are eaten by hover flies (syrphids), which are in turn eaten by spiders, and the spiders are preyed on by wasps, which use them as a food store for their larvae. In this community, there are also insectivorous birds, which are eaten by hawks. The part of this food cycle which refers to insects is shown in fig. 1, and it illustrates very well a typical animal community, containing a number of different food chains, all radiating from plants through herbivorous animals and several carnivores. This form of organization or structure of animal communities is universal, and it will be evident that the study of animals, as limiting factors to the distribution or numbers of a species, is an exceedingly difficult one. No animal can be said to be dependent upon only one other species, since all are bound up together by food connections into one complex organization. The result of this state of affairs is that any upset or interference with the existence or numbers of species may have, and usually does have, very unexpected effects upon other species which one would not at first sight expect to be affected at all. For instance, it is said that the increase of the manufacture of bicycles affected the walrus-hunting industry in arctic regions, and that any shortage of walrus leather (which is used in polishing metals) is in turn followed by an increase in the amount of tuberculosis in certain French factories, which are then compelled to use felt instead of walrus leather (the felt producing a noxious kind of dust). Or there is the case of two species of blue butterfly (Agriades coridon and *A. thetis*) which formed a local colony on one place upon the Downs, but were wiped out through a temporary over-increase in the numbers of rabbits, which ate up completely all the plants of the horse-shoe vetch (*Hippocrepis comosa*) upon which the butterfly caterpillars depended for food. Instances of this sort could be multiplied.

It is clear from what has been said, that in order to understand the way in which any animal is affected in its numbers or distribution by the other animals living with it, it is necessary to study the *whole* animal community living in one habitat, and that it is useless to treat the animal as if it were completely isolated and acting as a separate unit. A general knowledge of the complete food cycle of an animal community is accordingly of great value to anyone who is investigating the biology of a particular species belonging to that community, since, armed with such knowledge, he is enabled to see at a glance a number of the points at which that animal is connected with other ones amongst which it lives, and this in turn throws light upon the manner in which its numbers are kept down and controlled. Supposing one is studying some insect which is becoming a dangerous pest among crops or in timber, a knowledge of its food relationships, gained from previous work upon the food cycle of the community to which it belongs, makes it possible at once to try various experiments with counterpests (enemies or parasites) without it being necessary to wait for several years in order to work out these food relations—by which time the damage might have become colossal or possibly even uncontrollable. It seems clear, then, that the study of food relations of animals should form the next important step in any biological survey, after the first lists of species from different habitats have been made. It is at this point that the ways of animal and plant ecology part quite definitely: plants are living in communities where competition is usually for the same kind of food, whereas animals feed in infinitely more diverse ways than plants, and consequently have developed the complex communities which we find everywhere, and which require special methods for their study.

At present, only in a few cases have surveys of animal communities been carried to this further stage. The preliminary listing is in itself a long and formidable task, and furthermore, the systematics of many groups of animals have only been properly worked out within the last decade. Or, again, they have not been reduced to a simple and convenient system of reference which can be used by the ecologist, who is usually busy on other things. For this reason a number of the best ecological surveys up to date have been done by people who have paid attention mainly to one group of animals, in which they themselves are expert at identifying the different species (*e.g.*, birds or beetles or molluscs); but it is obvious that such surveys cannot, by their nature, apply the food cycle method of study at all widely, since any one group of animals usually has rather similar food habits (*e.g.*, butter-

flies). This kind of survey, although of very real value in many other ways, is yet of limited application to fundamental research upon the numbers of animals. It seems likely, therefore, that future ecological surveys, which attempt to carry their work beyond the preliminary phase which has now been reached in many cases, will either have to employ teams of experts in different groups (either in the field or by sending the material to be examined afterwards), or else will have to concentrate upon very simple communities, which contain few species and which have the minimum of complications in other respects. It is probable that the latter type of work will yield the most useful results, as far as the discovery of general principles is concerned.

Looking over the literature on the subject, one notes that food cycles have only been worked out with anything approaching completeness in a handful of cases: the land animal communities of arctic and high arctic regions (Elton); the animals of Calluna heath, pine woods, and associated habitats in the south of England (Richards), some of the land communities of temperate North America (Shelford); and the plankton community of the North Sea (Hardy). Otherwise, attention has been confined to single food-chains, or to the chains radiating from one species, followed out to a certain distance. (Of course, these, if followed farther, would give the food-cycle for the whole community, and this, as we have explained, is the whole point of doing such work.) There is, accordingly, a rather big blank space in our organized knowledge of the food relations of wild animals, and even if we examine the few cases in which the food-cycle has been made out at all, it is found that the food habits of the different animals are only slightly known and indicated in a very rough way, that quantitative data are usually lacking, and that all consideration of the parasites has had to be omitted. The value of this work, however, lies in certain ideas which have resulted from it, and which do reveal to some extent the way in which an animal community is constructed and how it works.

The first of these ideas is concerned with the size of animals and of their food. Every carnivorous animal is limited to a certain definite range of size in the matter of food, since on the one hand it cannot seize and overpower any animal above a certain size, while on the other hand it cannot find a sufficient number of animals below a certain size, to be worth while or provide it with enough food in the time available. Small spiders catch springtails, willow wrens eat caterpillars, the red-backed shrike attacks bumble bees, the merlin preys on the meadow pipit, and the eagle lives on ptarmigan—in all cases the size as well as the other qualities of the food comes into question. This rule applies also in many cases to herbivorous animals, but is less widely in operation, owing to the fact that plants are to a large extent defenceless. However, the lower limit of size often plays a part in determining the food of seed or fruit-eating birds. In all cases the abundance of food is also an important consideration, since a small animal, if very numerous, may be obtained in sufficiently large numbers to attract animals which usually feed on things of a greater size. The significance of this idea about the size of food is that it explains to a large extent why food-chains exist at all in animal communities. Each stage in the chain has the effect of turning small food animals into larger ones, and since there are wider limits to the sizes of animals than to the size of the food of any one animal, we usually find some three or four stages forming the food chain. Sometimes there are more, often fewer, but there seem hardly ever to be more than six or seven stages in a chain leading from a vegetarian animal to the terminal carnivorous species. This leads us to ask why there should be a limit to the number of stages in such a chain. The answer is partly that animals themselves have limits of size; but there is another important reason, which holds good for most animal communities. This depends upon the relative numbers of the individuals forming the various stages in a chain. For instance, suppose we take the chain of freshwater animals: copepod-insect-fish-bird. It will be found that the number of individuals in each species decreases very rapidly as we pass from the copepod to the bird. There might be, in a single lake, millions of copepods, many thousands of insects, several hundred trout, and half-a-dozen grebe. Another way of putting it is to say that one grebe requires so many fish to supply its food requirements, each fish needs so many insects, and each insect so many copepods. At the same time there must be a certain number of each animal produced to perpetuate its own species in the face of old age and of checks other than being eaten. Thus each species is supporting, in addition to itself, a very great burden in the form of enemies. The copepod is supporting all the rest, and therefore has to be the most abundant of them all; but this it is, in fact, enabled to be on account of its smaller size, and consequent ability to grow up and breed more quickly. It is clear that as each stage in this chain is reached a smaller margin of living matter is left over to support any further species. The amount of transmuted copepod gradually diminishes, like a suit of old clothes which passes from one person to another, losing its substance by degrees until there is nothing left but a single patch. It can be seen that the size limits to the food of animals produce food-chains, and that these chains are able to exist because the smaller animals, which have the greater burden to bear, are by their smaller size enabled to support it the more effectively. We have not at present the necessary data for solving in a quantitative manner these fascinating problems about the balance between size, rate of increase, and density of numbers; but presumably animal ecology will some day be in a position to present the phenomena of animal inter-relations in almost as accurate a form as those of chemistry. A beginning along these lines has been made by Chapman, who has worked upon populations of weevils kept at standard temperatures, and with controlled conditions of food and breeding rates.

We have dealt with food chains, the food cycle, and with the idea which may be conveniently termed the "pyramid of numbers" in animal communities. Another useful conception is that of niches. We can divide up animals into different classes according to their food habits, *e.g.*, herbivores, carnivores, etc. But it is possible to go farther than this, and divide the herbivores into those of different sizes, or belonging to different plants, *e.g.*, aphids, grasshoppers, mice, rabbits, grouse, sheep, cows, etc., or, on the other hand, aphids of grass, of trees, and so on. Then we can classify carnivorous animals according to the size and nature of their prey. When we begin to classify the food-habits of animals in some such manner it becomes gradually clear that there are in each animal community a great many different occupations, jobs, or niches (just as there are in a human community), and that each niche is filled by a particular species. If we now turn to another animal community, occupying a different habitat, we find that although many of the same niches occur there, the actual species filling them are different in most cases. For instance, there is one mouse (Microtus) in grassland, which is preyed upon by the kestrel; in woods there is another kind of mouse (*Apodemus*) which is preyed on by owls and weasels; while in houses there is a third kind of mouse (Mus) which is preyed on by the domestic cat and by human beings. In this example, the same niche (small mouse) is filled by three different species, whose habits and numbers, and size are to a large extent similar. The term "niche" is meant to be an elastic one, and it is hardly worth while attempting to define it exactly; but in spite of this, the idea is a useful one, since it emphasizes the fundamental similarity of all animal communities—a fact which is of some importance, since it is probable that any general principles which may be found out about the workings of animal inter-relations in any one community will be found to have a wide application elsewhere. It would therefore seem likely that intensive work, carried out completely on very simple communities such as those of arctic regions or deserts, would afford the strongest chance of discovering the fundamental laws governing the inter-relations of animals and therefore the regulation of their numbers. The fifth idea of importance in the study of animal communities is concerned with the significance and place of parasites in the general scheme. It has been customary in the past to treat parasites as if they were really different from carnivorous animals. In their morphology and in the fact that they get free transport on their host, they undoubtedly differ in many ways profoundly from the ordinary free-living animals. But the resemblances are really much more than

these differences; parasites feed in essentially the same manner as carnivores, and a complete graded series can be traced from typical parasites which are completely dependent upon their host for food, lodging and transport, leading to species which lead an entirely free-living, carnivorous existence. Fleas are a good case of the transitional type of animal, while mosquitos and lampreys and jackals are other examples. From an ecological point of view, the chief significant difference between these two classes of predatory animal is that a carnivore usually destroys its prey at once, whereas a parasite usually confines itself to abstracting little bits of its host, which are often scarcely missed by their owner. The principle followed is the same as that employed by a manufacturer who sells to an enormous number of people a very small article (like matches or pins) and by making a very small profit on each, amasses a huge fortune without harming his clients to any great extent. Another way of putting it is that a carnivore employs the method of a burglar, the parasite those of a blackmailer. In making out a complete scheme of the food relations in a community it is clearly necessary to include parasites as well as carnivores; but, in practice, it is often possible to manage without this, owing to the small absolute bulk of the parasites, and the fact that they are often eaten at the same time as their host, and so in a sense can be considered to be part of it. However, ecological work on numbers, especially medical work, has shown the profound inter-dependence of the two classes of animal, carnivore and parasite, especially where they carry any smaller parasite (bacterial or protozoan) which is capable of generating epidemics in the host species.

ANIMAL NUMBERS

Although the intensive study of the structure of animal communities has not so far been carried beyond the very earliest stages, yet it is obvious that farther research in this branch of ecology affords a good prospect of throwing light upon the mode in which the numbers of animals are regulated during normal times, and the reasons for the breaking down of this system of regulation—a breakdown which is quite frequent in nature, and which manifests itself in the form of plagues of animals (*e.g.,* mice, locusts or aphids), or, in the case of parasites, as epidemic diseases. Even in the present state of our knowledge of the social structure of the animal world, we are in a position to make certain suggestions along these lines. For instance, there is the fact that every animal community, whether it be living under the bark of a dead pine tree, on the shores of a mountain lake, or in the wainscot of an old house, seems to be constructed fundamentally in the same way. This fact enables us to conclude that the means by which animal numbers are regulated may be similarly uniform in their action in all habitats. It seems very probable that if a suitable team of ecologists settled down like locusts on one very small, simple animal community, and studied it intensively from every point of view for a good many years, they might discover almost all the important laws about animal numbers—laws which may elude one if the community studied is very complicated (*e.g.,* tropical rain-forest or marine plankton) or if observations are not carried out consecutively for a number of years.

Up to this point we have dealt chiefly with the relative numbers of different species in a community. Before proceeding farther, we must say something about the absolute density of numbers; in other words, it is necessary to inquire whether any censuses have been made of animal numbers. To carry out a census in practice is not at all simple, for a variety of reasons; but there have been a number of beginnings made in this direction during the last 20 years. The most successful and accurate census results have been obtained with marine or freshwater plankton animals, since these are the easiest to deal with. On the Continent and in America a number of quantitative surveys have been carried out, and these give an interesting and clear-cut picture of the density of various Crustacea, Rotifera, etc., in the water. On land a certain amount of census work has been done on soil animals, since these lend themselves to much the same sampling methods as are employed with aquatic animals. Otherwise, little progress has as yet been made with accurate censuses of land animals, except in the case of birds (Nicholson, Cook, Grinnell and Storer) and certain mammals; the work on the latter is of a sporadic nature, and chiefly applies to species which have some special economic or sporting interest (*e.g.,* an annual census is taken of the baboons on the Rock of Gibraltar, and a similar one of the fur seals on the Pribiloff islands of Alaska). In addition, census methods have frequently been applied, though usually in rather a rough way, to various insects which are of economic significance. In the present state of our knowledge, it is not possible to draw any very far-reaching conclusions from this side of ecology, except that it appears that most species are a great deal more numerous than one would expect. We must therefore confine ourselves to pointing out the importance of accurate figures for density of numbers of animals, and the fact that it is rapidly coming into prominence in ecological work.

In spite of this general lack of precise quantitative data about the actual numbers of animals in a given area, there are several important principles which have been discovered about numbers of animals. We shall conclude this article by giving an account of them. We have already noted that the number of individuals of a species is often extremely great in any given area—for instance, one acre of arable soil has been estimated to contain over two million springtails and about 800,000 earthworms. Now coupled with this is the fact that any species of animal is, in nine cases out of ten, endowed with powers of multiplication which are enormously greater than it can actually realize in practice, at any rate during normal times. If a species over-increases, it runs a definite danger of over-eating its food supply, but at the same time, if it does not produce a very large number of extra individuals in each generation it will be in danger of extinction through the operation of checks other than starvation, of which the most important are enemies. The position of nearly all animals is therefore this; they are always tending to increase enormously, but are prevented from doing so by various checks—mainly by carnivorous or parasitoid enemies ("parasitoids" meaning those Hymenoptera and other insects which have parasitic larvae but free-living adults). In this way the population is prevented from eating out its food supply; but the system also involves a dangerous tendency for the numbers to oscillate a great deal about their average density. If any species allows its numbers to fall below a certain density it is in danger of being blotted out by any unusually severe check such as occasional droughts or bad winters, or an unusually large number of enemies We find, therefore, that each species tends to approach an optimum density for its population; both below this optimum and above it the conditions become disadvantageous to the species. The limits of this optimum may be rather wide, thus differing to some extent from the rather precise optimum density which is found in a human population. Nevertheless the optimum exists for each species, and unless the latter is able to maintain its numbers somewhere near this, it is liable to become locally extinct. In fact, it is very probable that the limits to the range of any animal are often fixed by factors acting on its numbers, rather than directly upon the animal itself.

We have next to inquire whether animals do succeed in keeping their numbers at the density which suits them best. Anyone who has kept a watch on the animals in his own district continuously for a stretch of years must have noticed that there is a great variation in the numbers of most animals from year to year; often it is impossible to predict whether a species (a butterfly or a wasp or a slug or a bird) will be abundant or not. Notes of this sort are continually being made in a scattered way, such as that "this year we had very few long-tailed tits, but jays were unusually abundant" or that "this was a good year for *Vanessidae,* but not for other butterflies." A survey of a portion of the vast sea of literature bearing on this question leaves no doubt that the numbers of most species vary considerably from year to year, but that most of them do not usually become either extraordinarily numerous or extremely scarce. It is clear, then, that the conception of an optimum density as applied to animals, like that of niches in animal communities, must be an elastic one, and that in practice the desirable density is not a point, but ranges over a fairly good distance either way. Even then, it is not always realized

or even approached. One of the reasons for this is that what we call the optimum is itself varying, since the food supply varies, and the enemies and the climate and other factors also vary. The impression of anyone who has studied animal numbers in the field is that the "balance of nature" hardly exists, except in the minds of scientists; it seems that animal numbers are always tending towards some ideal stability and communities are always tending to settle down into a smooth and harmonious working mechanism, but that something always happens before this happy state is reached. This liability to upsets of the "balance of nature" is as much a property of animal communities as is that of a boiling pot of water to overflow if left unattended. It is not merely a phenomenon characteristic of regions or habitats which have been interfered with by man. Even in places completely untouched by civilization, *e.g.*, in the barren grounds of arctic Canada, or in a tropical forest, the occasional unbalance of animal communities is a normal thing, and the numbers of animals are found to vary to a greater or less extent—witness the periodic flights of sandgrouse from the Gobi, or of painted lady butterflies from the Sahara, plagues of mice and lemmings in the barren grounds, or of aphids in the northern coniferous forests of Europe. Perhaps the most striking account of this kind of thing is that given by Cabot in the appendix to his book on Labrador, where he describes the extraordinary cycle of events accompanying a year of mouse abundance in the interior of that country; after reading that account no one can remain in doubt about the natural variability of animal communities in places almost untouched by man except as a rare native animal. Are these fluctuations in numbers, these failures of the regulating mechanism of animal increase, caused by internal changes, after the manner of an alarm clock which suddenly goes off, or the boilers of an engine blowing up, or are they caused by some factors in the outer environment—weather, vegetation, or something like that? It appears that they are due to both, but that the latter is the more important of the two, and usually plays the leading part.

The environment of animals is so exceedingly unstable itself that it would be surprising if some of its irregularities were not reflected in animal communities, which form such delicate indices of any changes in the outer world. We cannot describe the various rhythms which are going on in the weather, in the tides, or the various accidental circumstances which play a part in causing upsets in nature. But it may be worth while to examine a little more closely what actually happens when a plague of animals occurs, since this is one of the most important practical ecological problems met with in the field. The trouble usually starts with an excessive increase of some herbivorous animal, which is favoured in a particular year by unusual conditions of food or climate or some other factor. Now, the carnivore, which is nearly always larger than its prey, is in normal times able to destroy all the extra herbivores which are produced; that is the ordinary balance of numbers in a community. But we have to remember all the time that the smaller animal is increasing at a faster rate than the large carnivore, so that if the herbivore once gets out of control of its enemies, the latter are never able to catch up by increasing themselves, since their powers of increase are relatively so much less. For instance, if there is a plague of field mice in progress we should find that while the mice were having about four or five litters in a year, the foxes which prey on them could not have more than one or two, and the young foxes would not be in a fit condition to breed until the following spring, whereas the mice, which had been born in the previous spring would already be producing young by the autumn, and adding to the total numbers. So, if unusually favourable conditions have enabled the herbivore (mouse, sandgrouse, aphid, crossbill, or oakmoth) once to escape from the control of its carnivorous enemies, increase goes on at a rapidly faster and faster rate, and the conditions of a "plague" are reached. In the summer of 1924 enough aphids were blown from the spruce forests of northern Europe, over 800 miles of sea, to cover in a broad belt the whole ice-cap of North-East Land, an arctic island about as big as Wales. With them were found the syrphid flies which are among their most important enemies. but these were very much less abundant. This gives some idea of the scale attained by a really big plague of animals. It is obvious that, as enemies are no longer a serious check to numbers, starvation will follow, unless something else happens to avert this disaster.

Examination of the cases of plagues about which we know anything, shows that the situation is met by animals in several different ways, some animals doing one thing, and some another. In mammals and game birds, and also in certain birds and insects, the increasing density of population favours the spread of parasites-bacteria (as in the case of the marmot plague described earlier), or Protozoa (as in the willow grouse), or tapeworms (as in certain fresh-water fish). When the numbers of the host reach a certain point, the rate of circulation of the parasites increases and speeds up very suddenly, and the infestation of the host animal becomes serious, and usually leads to death. Just as the herbivore can increase faster than its enemies, so can the parasite, owing to its smaller size, increase faster than its host. The parasite in this case acts as a sort of emergency check on numbers, and we see therefore that it is absurd to consider the enemies and parasites of an animal as hostile, for the whole association stands or falls together as one unit. If the mouse is wiped out, the foxes and weasels, the tapeworms and the protozoa and bacteria will be wiped out also. It is difficult to imagine exactly how natural selection acts on such a unit; if the argument be carried to its logical conclusion, it would seem that natural selection either acted on everything from bacteria and mice to thunderstorms and sunspots or upon nothing. This case of mammal fluctuations in numbers illustrates very well how ecology throws light on, or at any rate raises problems in connection with, evolution and adaptation. The increase in numbers resulting from a breakaway from control by enemies is sometimes partly relieved by migration, but this does not necessarily do any more than transfer the problem elsewhere. However, migration usually implies concentration of the animals into swarms or flocks, and so favours the generation of epidemics, and also makes it more likely that enemies will kill more of them. During "lemming-years" in Norway, the migrating animals are eaten by all manner of unusual enemies including reindeer, trout in lakes, and cod out at sea. Migration may also lead to other kinds of destruction, as in the aphids which were blown on to the ice-cap of North East Land but perished in a blizzard three days later. Migration and epidemics seem to be the usual check when enemies fail; where these in turn cannot control the numbers, starvation occurs, but so numerous are the ways in which animal communities react to variations in their environment that starvation seems to occur curiously seldom, although plagues of animals on a greater or lesser scale are quite common in all communities.

It is impossible to treat the various problems of animal numbers in any detail here, since apart from the general ideas outlined above, our knowledge is mostly unorganized and empirical, and the literature on the subject immense. It may be noted however, that the question of numbers has an intimate connection with migration and with the spread of species, since at the limits of their range animals are always fluctuating in numbers in a very marked way, and problems of distribution often turn out to be really problems in numbers. Dispersal is another subject which cannot be treated fully here, and we shall merely point out that the psychology of animals comes in and assumes great importance in connection with dispersal, and that the manner in which animals actually find the habitat suited to their needs is a subject which has not been adequately studied. It would seem that this is the most natural field for people working upon the instincts and tropisms of animals.

BIBLIOGRAPHY.—Only a few of the most important works are mentioned in this list. The text books by Elton and Pearse contain fairly full bibliographies. General works of reference: C. C. Adams, *Guide to the Study of Animal Ecology* (1913); V. E. Shelford, *Animal Communities in Temperate America* (1913); A. S. Pearse, *Animal Ecology* (1926); R. N. Chapman, *Animal Ecology; with Especial Reference to Insects* (Minneapolis, 1926); C. S. Elton, *Animal Ecology* (1927). Surveys and collecting: H. B. Ward and G. C. Whipple, *Freshwater Biology* (1918); *Handbook of Instructions for Collectors*, issued by the British Museum (Natural History). General

accounts of animal communities: P. *A.* Buxton, *Animal Life in Deserts* (1923); *T.* Hesse, *Tiergeographie auf oekologischer grundlage* (1924); *M. D.* Haviland, *Forest, Steppe and Tundra* (1926). *Food cycles.*—*V.* Summerhayes and *C.* S. Elton, *Journal of Ecology*, vol. xi. (1923); *A.* C. Hardy, *Ministry of Agric. and Fish., Fishery Investig.*, series 2, vol. vii., No. 3. (1924). O. W. Richards, *Journal of Ecology*, vol. xiv., p. 246 (1926). Relations within the species: W. M. Wheeler, *Ants* (1913); *H.* E. Howard, *Territory* in *Bird Life* (1920); *W.* M. Wheeler, *Social Life among the Insects* (1923); Fr. Alverdes, *Social Life in the Animal World* (1927). Numbers: *E.* M. Nicholson, *How Birds Live* (1927); *A.* M. Carr-Saunders, *The Population Problem* (1922). (C. S. E.)

ECOLOGY OF PLANTS: *see* PLANTS.

ECONOMIC ARTICLES. The large subject economics is dealt with in this work under many headings. The article ECONOMICS is a general survey of the development of economic theory. Further discussions of different branches of the subject will be found in the articles entitled CAPITAL, CAPITALISM, LAND, LAND TENURE, LAND NATIONALIZATION, LABOUR, RENT, SUPPLY AND DEMAND, DEMAND, VALUE, PRICE, PRICES, UTILITY, WEALTH, PROFIT, DISTRIBUTION, WAGES, WAGE SYSTEM IN INDUSTRY, MINIMUM WAGE, DIMINISHING RETURNS, ECONOMIC MAN, ECONOMIC FREEDOM and COMPETITION.

Various schools of economic thought are treated in the articles which are entitled MERCANTILE SYSTEM, LAISSEZ FAIRE, SOCIALISM, SOCIALISM (PRINCIPLES AND OUTLOOK), COLLECTIVISM, COMMUNISM, CO-OPERATION, COPARTNERSHIP, MUNICIPAL TRADING, PROFIT SHARING, ANARCHISM, BOLSHEVISM, SYNDICALISM and SINGLE TAX. A special article is devoted to FASCISM in its economic aspect.

For a key to the many articles relating to banking, money, finance and taxation, *see* the conclusion of the article FINANCE.

The department of fiscal policy is treated under the headings FREE TRADE, PROTECTION, FAIR TRADE, RECIPROCITY, TARIFF, TARIFF REFORM, IMPERIAL PREFERENCE, SAFEGUARDING OF INDUSTRY, CUSTOMS, CUSTOMS UNION and COMMERCIAL TREATIES.

For related articles of importance *see* SOCIOLOGY, RURAL DEPOPULATION, URBANIZATION, HOUSING, USURY, COST OF LIVING, LUXURY, TRADE CYCLE, PROFITEERING.

There is a group of articles relating to industrial and commercial combinations under the headings TRUSTS, COMBINES, COMBINATION IN INDUSTRY, COMPETITION, PRICE-MAINTENANCE, MONOPOLY, etc. For associations of traders *see* TRADE ORGANIZATION, ASSOCIATIONS (INDUSTRIAL), INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES and IXTERNATIONAL CHAMBERS OF COMMERCE. The organization of labour is treated under TRADE UXIONS and THE INTERNATIONAL. For the relations of capital and labour, *see* INDUSTRIAL RELATIONS.

The problems of poverty are dealt with in the articles POOR LAW, VAGRANCY, WORKHOUSE, CHARITY, UNEMPLOYMENT, SWEATING SYSTEM, SLUM and POVERTY LINE. Under INSURANCE ARTICLES will be found reference to various methods of insuring.

As to economic practice and the actual production and distribution of wealth, reference should be made to the economic sections under the heading of each country, and in addition, to the articles COMMERCE, TRADE (WORLD STATISTICS), AGRICULTURE, (a special key will be found under the heading AGRICULTURAL ARTICLES), RAW MATERIALS, IMPORTS, EXPORTS, MANUFACTURES (COMMERCE IN), RATIONALIZATION OF INDUSTRY, SCIENTIFIC MANAGEMENT, RESEARCH (INDUSTRIAL), INDUSTRIAL RELATIONS, STANDARDIZATION, SALESMANSHIP, STORE and AGENTS IN BUSINESS.

For the discussion of questions of population, in which all economic endeavour may be said to be summarized, *see* the articles POPULATION, BIRTH RATE, DEATH RATE, MARRIAGE RATE and BIRTH CONTROL.

ECONOMIC FREEDOM, in economics, **a** term applied to a condition of society in which free competition obtains. The term connotes the emergence of society from slavery and serfdom. In complete economic freedom, every man is at liberty to work as he will, unfettered by law or regulation, and uncontrolled by any customary obligation to an overlord; at liberty to enter into contracts, to sell his services or his products, to move about freely, and to engage in the enterprise of his choice.

For the rise and modification of the concept of economic freedom the history of ancient and modern states should be consulted, and in particular the articles SLAVERY; SERFDOM; FEUDALISM; INDUSTRIAL REVOLUTION; ECONOMICS; TRADE UNIONS; CO-OPERATION; INSURANCE; NATIONAL INSURANCE; COMBINATION; TRUSTS, etc.

ECONOMIC MAN. The term *homo economicus* has often been employed, with an ironical significance, by critics of political economy, and has been especially directed against the English economists who founded the Classic school, such as Ricardo and Senior. Critics reproach them with having based a science of economics on the conception of an "abstract man," a creature moved solely by exclusively economic motives. The German economists, in particular, have opposed to this conception a rival method, the so-called "historical" or "realist" school, which studies *men* (not man) under the sundry aspects evolved in different ages and countries. They maintain that this method alone is fruitful and capable of indefinite renewal, while the conception of the *homo economicus* can lead only to a few general formulae devoid of any practical application.

It must, however, be admitted that the science of economics could never have been developed, had it not seen men as something more than different individuals; had it not first regarded the characteristics common to all. Long ago Aristotle said, "there is no science except of the general"; individuals, objects, facts, being, so to speak, merely accidents, deviations from the true type. The existence of a science of economics implies that men generally, if not invariably, behave in the same fashion when placed in the same circumstances. If they are purchasers, they will always prefer the cheaper of two products of equal quantity, or, if price is equal, that of better quality. If they are workers, they will seek the kind of work which is least laborious and best remunerated. If they are owners of an object, they will not part with it or lend it without return.

The real failing of the early economists was their habit of too wide generalization. The French economists of the late 18th and early 19th centuries, such as the physiocrats and Jean Baptiste Say, declared that political economy is possible only if every distinction of time and nationality is suppressed. The historical school was right in protesting against this conception of a universal and eternal national order, and substituting for it that of economic systems differentiated by time and circumstance. It does not study the "typical man," but the man of the 20th century or of the first; the bourgeois or the workman; the man of the west or him of the east; the town-dweller and the country-dweller, and restricts its concentric circles progressively to approach reality through successive approximations. Nevertheless, these remain generalizations, although increasingly narrow ones. The individual case, the conduct of John or William, so far as it is isolated, "excentric," as it has been well termed, is of no interest for the economist, unless this individual case, by generalizing itself, becomes the starting-point for a new generalization, and inaugurates a new column to a statistical table.

The dispute between the economists of the *homo economicus* school and those of the realist and historical school is a revival of the great conflict which divided the mediaeval scholastics for several centuries, between the "Universals" and the "Nominalists," the former affirming, with Aristotle, the reality of abstract and general ideas, the latter seeing in them nothing but words, names, categories, corresponding to no reality.

The Nominalists were ultimately victorious, and founded modern science, the product of observation and experimentation. The latter is directed towards the particular, and, indeed, the most minute facts, which were considered negligible by the Universals, are most highly prized by the students of to-day. It has been said that the domain of discovery begins beyond the fourth decimal point; which is to say that it is only at this point that a universal law can be shaped, unless a sagacious observer sees a new vista open before him. Only when observations, pressed to the last limit of precision, revealed certain discordances in the movement of luminous rays, could Einstein's theory be formulated.

Nevertheless, the rôle of deduction in physical science is far from played out; for while students struggle to relate phenomena to unity, others work unceasingly to discover divergences in that unity. It is the same in the science of economics.

The Abstract Man.—The general expression "homo economicus" has, hcwever, a further signification. It is not merely the individual, the "average man"; not merely the typical man who unites within himself all the characteristics of the human race. On the contrary, it is man stripped of all characteristics other than the purely economic, that is to say, impelled by no motive other than that of interest. It is here, above all, that this view of the science of economics lends itself to criticism, and seems to merit Carlyle's virulent description of "the dismal science." This criticism is, however, misplaced, for it is obvious that after having reduced man, *ex hypothesi,* to a skeleton, one cannot expect to find in him a heart.

Here, too, we must grant science, even in the case of a social science, the right, even the necessity, of elimination. If a physicist studying mechanics must eliminate all phenomena capable of affecting the motion, such as friction, so much the more may the economist, to clear his way in the tangle of social facts, simplify them by eliminating from his field of vision everything not concerned with the desire of gain.

In the introduction to his "Theory of Political Economy," Stanley Jevons said:

"The theory which follows is entirely based on a calculus of pleasure and pain, and the object of Economics is to maximise happiness by purchasing pleasure, as it were, at the lowest cost of pain."

This was the origin of the so-called "hedonist" school. Thus political economy becomes a sort of mechanical science, and can even be expressed in mathematical formulae.

Pure Economy.—Attempts have been made to constitute an exact science, known as "pure economy," which was promoted by Cournot and Walras in France, Stanley Jevons in England, Gossen in Germany, and to-day has a certain number of adherents. This method appears to us to have a perfect right to a place in instruction, although we cannot think that it has yet enriched knowledge by any very important contributions, except, perhaps, Leon Walras's theory of economic equilibrium.

Pure economy cannot, however, claim to exhaust all political economy. These social mechanics can but give a schematic representation of political economy which is a science as living and as complex as man himself. As in the vision of the Prophet Ezekiel, who saw dry bones live, these skeletons must have restored to them the flesh and blood removed by elimination. Man is not a creature governed solely by his interests, but also by his feelings, his convictions, his passions. Besides, it must be remarked that his so-called "interests" include very various motives; for there is not only pecuniary interest, the desire of profit; there is also the desire of leisure, that factor which has proved so potent in the struggle for the limitation of the working day; there is the desire for independence, which revolts the working class against the wage-system; there is the desire for security, which creates in every country the immense apparatus of social insurance. Personal interest expands progressively, and becomes family interest, corporative interest, class interest, national interest, and even, reaching its last limit, the interest of humanity.

It is impossible to explain economic evolution if no factors outside egoism are considered, and the action of altruism is not also regarded. The so-called institutions of social service, solidarity, and mutual assistance—communal conditions inspired by collective interest—grow more numerous every day. Family allowances, for example, supplementary to the wage, occupy a growing place in modern economy. Consumers' co-operatives transform commerce by eliminating all purposes of profit.

If demography is admitted as part of political economy, then the sexual interest must be placed beside and above the personal interest. It is not "economic man" that begets children, for his individual and class interests often conflict with his sexual interest.

Most economists, however, consider that this progressive extension should not pass beyond the limit which should divide political economy from ethics. Their provinces should remain separate; in the one case interest, in the other duty; in the one utility, in the other justice. We think, however, that it is neither possible nor desirable to respect this dividing-line, which we consider to be arbitrary. No doubt, from the point of view of classification, it may be well to distinguish the two provinces, just as in a library it is proper to separate the books dealing with the two sciences. Yet neither can be ignored in explaining social facts. Study of modern economic questions—social questions, as they are called—shows that one almost always arrives at an *impasse* where political economy fails, and only ethics can afford a solution. The ethics of political economy are justice.

According to pure economy, any price, any wage is just if it has been determined by the interplay of supply and demand under conditions of unrestricted competition. This is the tenet of the hedonist school, and they are right, if the word "just" be taken as meaning "exact," as when one says that a weight "just balances" when the two scales are in exact equilibrium. But what sort of political economy is that which in determining prices and wages eliminates "justice" in its true, ethical sense, and how can it give any solutions to the problems of the present generation, the problem of high prices, or of the remuneration of labour? When the authors of the Treaty of Versailles solemnly proclaimed in art. 427: "labour should not be regarded merely as a commodity or article of commerce" (one of the principles of which the International Labour Office is the embodiment), they meant that labour conditions cannot be treated solely by the principles of pure economy. When the governments of every country endeavour to limit the rise of prices and lower the cost of living, this is because they believe that there is a conception of a just price which stands above that evolved from the blind caprice of the law of supply and demand, and that this higher law ought to prevail.

If we consider the history of labour, we see that it has passed through many stages. Formerly it was impelled by constraint, when slavery was current; later in the stage of wage-labour, this constraint still exists, on account of the necessity imposed on the proletariat of earning its bread; but by degrees, as the working class becomes stronger and better organized, forced labour is replaced by interested labour—already a great progress, not only from the moral point of view, but also from that of the return. Yet another stage may be foreseen—a stage already reached in the liberal professions—where interested labour becomes a social service, a public function, in the noble sense of this term; that is to say, its motive will be duty.

Similarly, as regards consumption, how can the economist set aside every moral consideration regarding the use of wealth; refuse to distinguish between that whose only aim is pleasure, such as the consumption of alcohol, and that which meets the public interest, such as the education of children?

In conclusion, then, it must be said that *homo economicus* has a justification in existing, and may form the object of the abstract science of pure economics, but that the object of political economy is social man—a fact which is, indeed, sufficiently indicated by the very adjective "political." (C.G.)

ECONOMICS. Because economics has to do with the wealth-getting and wealth-using activities of men, it is often defined as "the science of wealth." This is not a wholly satisfactory definition, for the special characteristics of economics are determined not so much by its subject-matter as by the particular interests which have prompted the inquiries of economists and the particular questions which they have tried to answer. We define economics better, therefore, when we say that it is a science which is concerned with the communal problems of economic life. The ordering of the economic affairs of the household and the planning and management of business undertakings come alike under its purview, but its interests and problems are not the interests and problems of either household economy or business enterprise. How men acquire wealth and how they use it are matters of fundamental importance for economics. but its principal concern is with the intricate interrelations of various wealth-getting and wealth-using activities and with the ways in which these activities affect the welfare of the community. The attention which economics

gives to the general or social aspects of the interplay of economic activities is born of its central interest in the wisdom or unwisdom of measures which governments take or which conceivably they might take with a view to regulating, controlling or participating in them or to directing them into one channel rather than another. The older name, "political economy," still gives a right impression of the kinds of problems with which economics is mostly concerned.

Like every science, economics proceeds upon the assumption that there is some sort of order in the phenomena with which it deals. Just as and because the economic activities of men are not altogether aimless or directed wholly by chance, so the economic life of the community, viewed as a whole, is not sheer confusion, but has a discernible ordered pattern, showing itself in dependable "laws" or "tendencies" which are discoverable by means of careful observation and analysis. That there is some measure of regularity and predictability in economic phenomena is a commonsense assumption, one upon which men act in the daily conduct of their affairs. But there was only a very small field for economic science so long as the economic order, in its larger features, merely reflected the social or political order—so long, that is, as men's different economic activities and their economic relations were determined largely by their political status, by the position in the general institutional structure of society into which they were severally born or which they might be able to attain. Under such circumstances economic problems appeared in the guise of juristic and ethical problems. Economic activities were rated good or bad, not so much by their ultimate effects upon the economic welfare of the community as by their consistency with some supposedly rational or "natural" view of the general structure of society. Thus Aristotle's conclusion that trading for gain, as contrasted with trading to exchange goods, is "unnatural" was merely a corollary of his views of the nature and the functions of the family and the state. In the middle ages economic matters were discussed by some of the patristic writers and later by the schoolmen, but both groups were concerned almost wholly with the ethics of trade and of money-lending, and their criteria were drawn either from authority or from their own systematic philosophies.

The New Economic Order and Its Problems.—What made the development of a science of economics possible was that transformation of the economic structure of society which, better than anything else, marks off the modern period from the mediaeval. This transformation is referred to, with emphasis upon one or another of its aspects, as the rise of modern capitalism, or of the competitive system, or of the system of free business enterprise. The dominating factor in it was the growth of trade, especially the growth of inter-town and inter-regional trade. With the growth of trade and the widening of markets the advantages of the division of labour and of local and regional industrial specialization became more and more pronounced. With the increasing ramifications of the market men were brought into a new nexus of relations, more intricate and more impersonal than the mediaeval system of prescriptive rights and duties, and giving the individual man more freedom of choice and action than that system had given him. Men became more dependent upon one another, not in any direct personal way, but in the sense that with the expansion of markets and the progress of the division of labour the welfare of each became intricately related to the activities of an increasing number of others. They came to realize that they had common economic interests and oppositions of economic interest as well. What were these interests and how best cauld the interests of the community or of a particular group or class within the community. be furthered? Such questions created problems of public policy for the new national states which the transformation of economic life had helped to bring into being, and out of the discussion of such problems the new science of political economy was born. There was need of such a science, because the mechanism of economic life had become so intricate that the deeper-reaching as contrasted with the surface effects of particular economic policies were difficult to discern. The task of eronomics was that of finding whatever dependable ordered relations might lie beneath the baffling complexity of the surface of economic life, so that public policies might be based upon knowledge and understanding.

Long before there was anything deserving the name of economic science, however, there was much writing, mostly controversial, as there has been ever since, about such matters as the monetary, fiscal and commercial policies of governments. Among the participants in these early controversies were some of the ablest men of their time—philosophers, public administrators and successful men of affairs. At one point or another the best of them probed deeply into the mysteries of the world's economic mechanism and reached conclusions which the economists of a later day have reaffirmed. For the most part, however, the early writers were too heavily handicapped by the lack of a scientific organon. They had no consistent general view of economic processes taken as a whole, so that their views of particular issues were likely to be partial and short-sighted. Take for example the writings which had the purpose of expounding or defining the principles of that general system of governmental economic statecraft known as "mercantilism," which flourished from the 16th century down to the 19th, and which was exemplified in the restrictive policies of such statesmen and rulers as Colbert, Burleigh, Cromwell and Frederick the Great. Whether mercantilistic measures met the immediate needs of the times, whether they helped or hindered the task of nation-building, are disputed questions; but there can be no doubt respecting the weakness of the grounds upon which the case for such measures was commonly supposed to rest. It is not quite true that, as their critics have often said, the mercantilists held that money alone is wealth; but as a group they concerned themselves largely with the ways in which a country might secure and maintain a favourable balance of trade so as to conserve and increase its stock of money. They identified the economic interests of the nation with the interests of its merchants and they looked mostly at the immediate rather than the enduring interests of the mercantile classes themselves. The things which they thought conducive to national welfare were those they thought would stimulate trade and increase profits: plentiful supplies of money. low interest rates and low wages. Some of them appear to have thought of the nation as though it were itself a great trading firm, profiting from the excess of its foreign sales over its foreign purchases. Mercantilism, as the reader may have observed, is even now not wholly dead, but its errors were exposed long ago.

The Beginnings of Economic Science.—Sharply contrasted with the mercantilists' naïve confusion of economic welfare and money profits were the conceptions employed by a small but influential group or philosophical sect which flourished in France in the second half of the 18th century. They called themselves *les Économistes*, but the world now calls them the Physiocrats. Compared with the tracts of the mercantilists, who used the language of the world of trade, their writings seem abstract and doctrinaire. Their principal tenets were erroneous, and the modern economist finds less that has permanent value in their work as a whole than in that of some of their predecessors (*e.g.*, Richard Cantillon, whose *Essai sur le* commerce was written between 1730 and 1734). But though they saw the processes of economic life imperfectly, they saw them as a whole. Not the buying and selling of the marketplace, but the continuing flow of goods through various channels from producer to consumer, was what they fixed their attention upon. The welfare of the community, in their view, was measured, not by the profits of trade. but by the excess of the community's annual product over its cost. In commerce and manufactures, they thought, there is no net product or surplus, for those activities add no more to the aggregate product than is required to support the people who are engaged in them. But in agriculture more is produced than is required to support the cultivators, and the surplus, which goes to the landowners as rent, is the only true net product which the community reaps from its efforts. Upon this disposable surplus the burden of all public expenditures, through the shifting of taxes from one producer to another, must inevitably fall. The Physiocrats were mistaken, for there were inconsistencies in their ways of measuring product and costs; they are important in the

history of thought, not because they gave the right answers, but because they asked important questions,—questions which in themselves were a challenge to the naïve assumptions of mercantilism; and they had a considerable influence upon thoughtful men of their own day and of the period immediately following. Turgot, renowned for his courageous but abortive economic and fiscal reforms, fell just short of discipleship. His work, *Reflexions sur la formation et la distribution des richesses* (1766), is an exceedingly able treatise.

In 1776 Adam Smith published *An Inquiry into the Nature and the Causes of the Wealth of Nations,* a work in which wisdom, learning and power of analysis were joined as they are in few books. Sharing the physiocratic prejudices ("in agriculture nature works with man"—as though she did not work with him in his every pursuit!) and holding that the interests of business men, as a class, are more often opposed to the interests of the community than the interests of landowners are, Adam Smith nevertheless gave the world a new interpretation of the advantages of trade, a new "philosophy of commerce." But he saw in commerce a means to welfare, not an end, and his book was, in effect, a formidable tract directed against mercantilism. Money, from the communal point of view, he held to be merely an instrument, a "wheel of trade." The real source of a country's wealth, he said is its "annual labour," and its wealth could be increased only by making its labour more effective and by husbanding and accumulating the products of labour. The division of labour, *i.e.,* the specialization of tasks, is the principal factor in its effectiveness, and the degree in which the division of labour is practicable depends upon the extent of the market. These were Adam Smith's fundamental principles. We elaborated them with extraordinary skill, always discussing concrete problems, showing unusual powers of fresh observation in his selection and use of illustrative material, and passing large sections of economic history and the whole range of the contemporary commercial and fiscal problems of Great Britain under survey. Although the book is the most powerful brief ever formulated for unimpeded trade, neither hampered nor coddled by governments, its greatest importance is not to be found in that circumstance, but in the general picture, at once simple and comprehensive, which it gives of the economic life of a nation. The apparent chaos of competition, the welter of buying and selling, are resolved or transmuted into an orderly system of economic co-operation by means of which the community's wants are supplied and its wealth increased. This general picture has been in the minds of economists ever since, whatever their opinions with respect to the efficiency of the competitive system. Despite some sweeping phrases which invite a different interpretation, Smith's real concern was for the establishing and maintaining of competitive conditions rather than for a vigorous observance by governments of a hands-off policy in respect of economic matters. He was discussing a special set of problems. He was opposed to monopoly, to exclusive combinations, and special privileges of all kinds, quite as much as to the type of legislation which aims at fostering a country's prosperity by restricting its trade. Often styled the "apostle of self-interest," he took no pains to conceal his dislike for some of the forms in which self-interest manifests itself in trade and industry. What his attitude would have been under the later conditions of the 19th and 20th centuries towards the factory acts, social insurance, and measures intended to help onward equality of competitive opportunities, we cannot tell. But there is very little in these newer types of legislation which runs counter to his principal contentions or is inconsistent with his general economic philosophy.

The Older Political Economy.--Adam Smith's work had a profound influence, not in Britain alone, but in almost every part of the western world. It was probably partly responsible for some radical changes in the commercial policies of governments, although one cannot be certain about this, for the current of the times was moving in a direction favourable to Smith's contentions. Its effect upon scientific thought and upon the character and quality of public discussions of economic questions was unmistakable. Men like J. B. Say in France and K. H. Rau in Germany based their own work very largely on Smith's and helped to diffuse his influence. Say, however, was more than a mere popularizer. He had some clear-cut views of his own, and developed Smith's work in directions other than it took in the hands of Smith's British successors. In the United States, Say's work came to be about as widely read as Smith's.

The particular trend which the development of economics took in Great Britain was determined very largely by the character of the economic problems which confronted the nation, partly by reason of swiftly progressive changes in its own industrial structure and partly in consequence of the Napoleonic wars. The rapid growth of population, the extension of agricultural cultivation and the rise of land rents, the expansion of industrial activities, the depreciation of the currency, the variations of prices, of interest rates and of profits, and, after the wars, the depression in both agriculture and industry, were phenomena at once conspicuous and important. Some of these developments commanded the attention of Parliamentary committees; all of them attracted the interest of thoughtful men. With Adam Smith's impressive picture of the mechanism of organized economic life in their minds, it was natural that men should think of such phenomena as interrelated and as susceptible of being explained in some consistent and comparatively simple way. At any rate, out of the discussions of the period, out of the pamphlets and the controversial tracts, there emerged a coherent system of political economy, owing much, of course, to Adam Smith, but putting stress on matters to which he had given little or no attention, and emending his views at a number of important points. This newer political economy was more formal and systematic than Adam Smith's, and was concerned more largely with abstract general relations, but it dealt with real problems and dealt with them in what was intended to be a practical way. There is an appearance of paradox, but only an appearance, in the circumstance that the particular type of economics which grew out of attempts to deal intelligently with the problems of a period of economic storm and stress should be one which gave particular attention to "normal tendencies" and to the conditions of economic equilibrium rather than to the causes of economic maladjustments. A parallel may be found in the way in which the study of pathology has contributed to men's knowledge of normal physiology.

For convenience the period of which we are now speaking may be taken as having definitely begun when David Ricardo's *Principles of Political Economy and Taxation* was published (1817) and as having culminated with the publication of John Stuart Mill's *Principles of Political Economy* (1848). One who compares the economic tracts and the systematic treatises of that period with the *Wealth of Nations,* will be impressed with the increased importance given to a group of problems which have remained ever since among the principal concerns of economics, problems now commonly grouped under the head of "the theory of value and distribution." The theory of value, of course, has to do with the explanation of why goods exchange at particular ratios, why some goods are expensive and other goods are cheap. The theory of distribution is really an extension of the theory of value so as to explain the magnitude of the shares of the total national product which are secured by those who contribute either their own services or the use of their property to the communal task of production. With the problem of personal distribution, the problem, that is, of why some men are rich and some are poor, economic theory, of the type which we are now discussing, has not directly concerned itself. Its problem has been that of the distribution of the product among the so-called factors of production. These factors and their respective shares were classified as labour and its wages, capital and its profits, and land and its rent. Later on the conception of a fourth share, the profits of enterprise, or of the successful direction of production, was taken over from the French economists, the earnings properly imputable to capital, as distinct from enterprise and direction, being put down as interest. But British economists, more than those of other countries, still continue to speak, in realistic fashion, of "the profits of capital," and there is no general agree-

ment among economists anywhere that enterprise should be treated as a separate factor in production, even though the profits of enterprise be conceded to be a separate distributive share. The three-fold, or four-fold, classification of factors is in some respects arbitrary. Some economists use a two-fold classification, treating land as a particular form of capital, while others hold that a really adequate classification would take account of many different kinds of capital and of various grades or qualities of labour. The truth is that the three-fold classification is adequate in the analysis of some problems (the simple contrast between labour and capital, taken as including land, is all that is needed to bring certain important problems into clear relief), and inadequate in the analysis of others. It has been suggested that the three-fold classification was in its origins merely a reflection of the actual political and social structure of the society of the day. Be that as it may, the classification still corresponds very closely to the way in which some of the most important of communal economic problems present themselves.

An element in the theory of value which for a long time was stressed to the comparative neglect of almost everything else was the tendency for the exchange values or relative prices of goods produced and sold under competitive conditions to be equal or at any rate proportionate to the respective costs of producing them, as a result of the continuous shifting of productive resources from less profitable to more profitable channels. By costs were meant not the money outlays of employers but "real" or communal sacrifices. At first these real costs were conceived to be measured by or proportionate to the amounts of labour required to produce different goods, but later the "abstinence" or waiting involved in accumulating capital by using resources so as to get a larger future product instead of using them in providing for immediate wants was held to be a distinct and separate cost. This innovation was first suggested by N. W. Senior in 1836. At this point, it may be observed, the economic theory of the "scientific" socialists, including the predecessors as well as the followers of Karl Marx, branches off from that of the more orthodox economists, for the socialists refused to adopt the innovation.

The distribution of the product was held also to be determined in considerable part by costs. Thus the doctrine that in the long run the standard of living of the labouring people determined their wages was in effect a cost-of-production theory of the value or price of labour. This doctrine rested upon the theory of population generally associated with the name of T. R. Malthus, and particularly with the revised form which Malthus gave his theory in the second edition (1803) of his famous Essay *on* Population. In its revised form the theory was to the effect, not that population would normally increase faster than the means of subsistence could be increased, but that it would normally increase at least as fast as the means of subsistence would permit. For "means of subsistence" read "standard of living," understanding by that term the general scale or standard which labourers think must be maintained if a family is to be supported, and the essential basis of the standard-of-living theory of wages is obvious. If wages fall below that level, it was thought, the rate of growth of the population will fall off, the supply of labour will be relatively smaller, and wages will rise. If wages rise above that same fixed point, the increase of the population will be quickened (except so far as a better standard of living may become effective) and wages will fall.

The rent of land, however, was held not to be governed or determined by the principles of cost. This was because (1) the supply of land is fixed, so that a rise of rents does not tend to counteract itself by stimulating supply, and because (2) the prices of agricultural products cover the costs of cultivation on lands which, prices and wages being what they are, are barely worth using, and hence yield no rent. Rent, from the communal point of view, was held to be neither determined by cost nor itself a determining element in the prices of commodities, but to be a surplus arising from the circumstance that the value of the produce of the better lands is more than enough to pay the cost of cultivating them. Closely connected with the doctrine of rent — although in point of historical fact preceding it instead of deriving from it — was the law of diminishing returns. With the growth of population and the extension of cultivation, the theory ran, resort must be had to poorer lands, or lands already in use must be cultivated more intensively, or more probably both things must occur. In any case the increase of product would not be proportionate to the increase of the amount of labour required. In manufactures, it was thought, increasing returns were normally operative, because a larger population, with a larger demand for goods, affords larger opportunities for the economies of the division of labour, and for the inventions and the applications of the fruits of scientific progress to industry which the division of labour facilitates. Agriculture, too, benefits by technical progress, but here the possibility of improvements in methods were thought to be somewhat smaller and to be more than counterbalanced by the increasingly disadvantageous proportioning of labour and land which comes as an inevitable result of the growth of population. Some of the older economists, including both Ricardo and Mill, went so far as to hold, in what is perhaps the most vulnerable part of their analysis, that with the increase of the amounts of labour required to produce the labourer's own subsistence, coupled with advance of land rents, the profits of capital must decline. This would dampen men's desire to accumulate capital, and finally the growth of population and of wealth would come to an end. In the law of diminishing returns, taken as a statement of a tendency, there was nothing fallacious. Taken as a prophecy, however, it was, or has been thus far, mistaken. The possibilities of improvements in agricultural technique were underestimated, and the rapid extension of the cultivation of new lands of good quality, brought nearer to the world's industrial centres by cheap transport, was unforeseen.

It was recognized, of course, that at any given time the prices of goods and of productive services might be considerably out of line with the norms established by long-run tendencies. But these deviations were held to be self-correcting, and for the most part the older economists were content to attribute them to "variations of supply and demand." In some instances, however, they pushed their analysis of the factors which control the temporary state of the market a little further. Thus, for the time being, the supply of labour is determined by the present numbers of the working population. The demand for labour was held to be determined, not by the demand of final consumers for the products of labour, but (since most labour has to be paid for and the labourers supported before their products are ready for the market) by the amount of capital that can be devoted to the making of "advances" to labour. This was the famous wages-fund doctrine. It was found to be so misleading, however, that it has been pretty generally abandoned, the elements of truth which it contained being taken account of in other ways. Again, the equally famous doctrine (which has withstood criticism better) that the value or purchasing power of money at any given time depends, other things being equal, upon its quantity as compared with the volume of production and trade, may be regarded as a supply-and-demand theory of money. It was supplemented by the doctrine that the "normal" value of money, *i.e.*, its value in the long run, is determined, when gold or silver is the monetary standard, by the marginal costs of mining, that is, by the costs of producing that portion of the supply which would not be produced if the metal were a little less valuable. Similarly, and quite naturally, short-lived fluctuations of the rate of interest were ascribed to temporary changes in the supply of and demand for loanable funds.

It would be an error, however, to think of these earlier economists as altogether preoccupied with theories of value and distribution, and it would also be an error to fail to recognize that their interest in those theories was born of their interest in practical problems. In general moreover they were not such uncompromising opponents of any sort of interference by the government in industry as some of their critics and some of the lesser writers who pretended to expound their views might lead one to think. Their attitude towards legislation intended to improve the condi-

tion of the working classes was sometimes sceptical but rarely hostile.

The Critics.—Before reviewing the later progress of economics it will be helpful to look at the principal types of criticism which have been directed against the older political economy and which are still maintained as against some of the newer developments of economics. In the first place, romanticists like Adam Müller and John Ruskin and their followers disliked the new modern economic mechanism, into the workings of which the economists were trying to probe, and they also disliked the economists' conception of communal welfare, which, one might say, involves no challenge of the particular conception of individual economic welfare which prevails in a competitive society, but merely substitutes the point of view of the community for that of the individual. They preferred an ordered society with economic subordinated to religious, moral or aesthetic values—such as some of them thought was implied, even if not fully realized, in the social structure of the later middle ages. Work, some of them insist, is not merely a means to an end, particularly when the end is what is commonly called wealth, for good work is worth doing for its own sake and for its effect upon the character of the worker. What the romanticists offer is a moral or aesthetic creed, not a science. They do not impugn the fitness of economics to serve as an instrument of attack upon its own problems, but they belittle its problems.

Another group of writers, for whom there is no better general descriptive name than "the critical school," come much closer to meeting the economists of the orthodox line upon their own grounds. One of the earliest and easily the most influential of them was Sismonde de Sismondi (*Nouveaux principes d'économie politique*, published in 1817, and other works). Other able writers, often without any conscious discipleship, have taken a position much like Sismondi's. These critics urge that insufficient attention is given to the defects of the existing economic mechanism, even if it be viewed merely as a means of providing for the material needs of the community. They suggest that the economists, in their contemplation of such things as "long-run" or "normal" tendencies, the advantages of the division of labour, and the seeming perfections of the automatic processes by means of which the things men do in the pursuit of their own economic interests become knit together into a vast scheme of communal economic co-operation, forget how often the mechanism breaks down and the "normal" progress of the community's economic life is interrupted by a crisis; how unemployment, partly chronic and partly epidemic, is a persisting disease of the present economic order; how unequally the aggregate product is distributed among the members of the community; and how many of the things which men do in pursuit of their own economic advantage are, in point of fact, inimical to the economic interests of the community. As some contemporary critics put the matter, men to-day are interested first of all in making money, and only incidentally in making goods. To look at the activities of a competitive, acquisitive, society as though such activities constituted, in their entirety, a communal process of wealth production, requires, it is urged, rather more rationalizing and sophisticating of the facts than the orthodox economists and their followers realized. Such criticisms undoubtedly go too far. They give an incorrect impression of the place of the more abstract parts of the older economics in the general view of the community's economic activities which one finds in the works of the economists. No economist of the first rank has ever been a devotee of the "economic harmonies." The critical school, nevertheless, has had a wholesome influence upon the progress of the science. This school, it may be observed, occupies a position midway between that of the economists of the more orthodox line and that of the socialists who denounce the parts of economics that are inconsistent with their tenets as being merely an apologetic for and a product of the existing economic order.

Another angle of attack was adopted by the "historical school"—using that term broadly so as to include critics who might easily be put into several different groups. This school has had and still has adherents in all countries, but it has been especially influential in Germany. The most important of the early exponents of its views were Friedrich List (*Nationales* System der *politischen* Oekonomie, 1841) and Wilhelm Roscher (Grundlagen der Nationaloekonomie, 1854, and other works). The structure of a nation's economic life, said these critics, is a "historical category," something peculiar to a given nation at a given time, a product of its past, and to be understood, therefore, only by the study of that past. The wisdom of particular economic policies is relative to place and time, and the general or supposedly universal "laws" of abstract economics need to be supplemented by or even subordinated to an analysis of the concrete facts of each nation's economic growth. If they had gone no further these critics would have found many to agree with them. But the founders of the school (Karl Knies, whose work, Die *politische Oekonomie vom Standpunkte* der *geschichtlichen Methode,* appeared in 1853, is a notable exception) made of what they called the historical method something peculiarly arbitrary and doctrinaire. Instead of looking to history for the particular antecedents of those concrete differences of economic structure in which they professed to be interested, they proposed to derive from history universal and binding laws, akin to the laws of the physical sciences. In naming certain stages of economic development through which they thought every nation must pass they were really elaborating suggestions which they got, not from historical research, but from the Greeks. Like some of their followers, they regarded the forms which economic life has taken in the past as inevitable products of historical forces, while at the same time they contended for a rather heavy-handed control of economic activities by the state. The French and British economists had looked upon the way in which the economic life of the community is organized as being shaped and determined by the interplay of the activities and interests of individual men, and they had treated the state as though it were an instrument of men's purposes, a utilitarian device. The spokesman of the historical school, on the other hand, strongly influenced by Hegel, ascribed a prior and independent value to the state, and looked upon the economic activities of individuals as though moving in grooves determined by the general structure of society and expressing at the same time the controlling purposes of the state. Despite the extremes to which they pushed their contentions, the historical economists gave a needed emphasis to what may be called the institutional as contrasted with the free or contractual aspects of economic activities. Their work and that of their successors has made economists more mindful of the way in which institutions are the masters as well as the servants of men. and less ready to asume that the particular economic order with which their analysis is mostly concerned is inevitably permanent or final. The historical economists also gave a needed impetus to the study of economic history—a most valuable complement to the study of economic theory. With the growth of careful and painstaking historical research the old dogmatism of the historical economists has pretty generally given way to a realization of the variety and complexity of the fabric of economic history, and the new schools of historical economics under the leadership of such scholars as Gustav Schmoller in Germany and George Unwin in Great Britain (to name only men who are no longer living) are, as they should be, schools of historical research.

The Methods of Economics.—Not only its critics but also some of its expounders have held that economics (*i.e.,* analytical economics, allied in its methods and its aims, even if not in all of its findings, to the older political economy) is essentially abstract and deductive, proceeding from the premise that men's activities are prompted mostly by self-interest, and that it posits an "economic man," whose behaviour under given circumstances is completely rational or predictable. Economics is indeed abstract, as any science must be, but it has never been in any real sense deductive or a *priori,* and the "economic man" will be found upon scrutiny to be a fairly complex sort of person, whose behaviour is taken to be strictly self-regarding only in respect of certain aspects of the relationships into which he enters as buyer or seller, borrower or lender. In fact it might be urged plausibly that the older political economy, of which the Malthusian theory

of population was an integral part, erred by underestimating the part which the rational prevision and weighing of economic consequences plays in human conduct. When we say that economics is abstract, we mean merely that economists do not pretend to take account of all of the factors which, in their entirety, might be supposed to account completely for every happening and every outcome in economic life. Their principal interest is in uncovering factors and relationships which are so general and important that the community cannot afford to remain in ignorance of them.

Economics makes use of two general classes of data: (1) observed facts respecting the behaviour of men in their various economic activities and relationships, including all classes of activities that have economic consequences; (2) such economic phenomena or events as movements of population, production, trade, incomes, prices, wages, profits, interest rates, etc. The most trustworthy evidence respecting the characteristics of human behaviour is often supplied by its results, and so the second class of data has often been drawn upon for knowledge respecting the first class. In the actual processes of constructive thought men doubtless pass forward and backward from one sort of knowledge to the other. The earlier economists, however, presented their findings in such a manner as to show that the known phenomena of the second class could be explained by (*i.e.*, were consistent with) the known facts of the first class—the known characteristics of human behaviour. This circumstance undoubtedly accounts for the mistaken impression that they "deduced" their findings, including the second class of facts, from the first. What they really did, of course, was to examine such experience as was at hand and seemed relevant to their problems, with a view to discerning the systematic relationships which ran through it and to explaining the more puzzling or apparently more complicated happenings in terms of their relationships to what was familiar or more easily understood.

The growing accumulations of precise numerical information covering a wide variety of economic facts, coupled with the advance of statistical technique, bids fair to accomplish a notable change in the character and content of economics. More and more it is found that records of measurable economic phenomena, carefully interpreted, may be used to provide a basis for more reliable and in some respects more sensitive accounts of the economic activities of the community than can possibly be derived from even the most careful observation of how individual men conduct their affairs. The economic science of the immediate future, it is safe to say, will give a relatively larger place to the study of the movements of averages and aggregates. It should not be supposed, however, that this means that economics will be or can be altogether statistical—a new kind of "political arithmetic." Every average or aggregate is in some measure unique, the resultant of the play of a particular combination of circumstances, such as may never be encountered again. In order that me may know just how dependable and how significant the variations of these statistical magnitudes are, we need to analyse them so that we can explain them. That is, we need to weave them into the general texture of our knowledge, so as to relate them to other things which we know. In short, although economics is beginning to utilize new materials effectively, and although some of these new materials call for the use of a new technique, it cannot change its general logical method, for outside the field of the experimental sciences there is no other method of getting useful and reliable knowledge.

The Progress of Economic Theory.—"Economic theory" is the rather misleading name now commonly given to the more general and abstract parts of economics. These more general parts are no less practical than what is sometimes called "applied economics," but the problems with which they have to do are less immediate and particular. The general problems of value and distribution, referred to above, have continued to hold a place among the central concerns of economic theory, but there has been a notable change in the general character of the analyses. The older economists, as we have seen, had a special interest in the long-run relations between value and costs, and, save in a few notable instances, were content to dispose of the other factors governing the variations of prices and values by invoking the formula of supply and demand. One of the tasks which a newer generation of economists set for themselves was the careful examination of the mechanism of supply and demand, with special emphasis on what had been the relatively neglected factor of demand. One of the most important steps in the new analysis was taken independently but almost simultaneously (towards the end of the third quarter of the 19th century) by W. S. Jevons (England), Carl Menger (Austria) and Léon Walras (France and Switzerland), although it came to be known later that they had been anticipated by some earlier but forgotten writers. Adam Smith, in a famous passage, had contrasted "value in use" (high for water and relatively low for diamonds) with "value in exchange" (high for diamonds and low for water). The new analysis found a definite relation between value in use (or "utility") and exchange value. The point was that neither use value nor exchange value is an attribute of things conceived generally or abstractly, but only of specific units or increments. Water, for example, has a variety of different uses, and its exchange value at a particular time and place is directly related to the importance of its marginal uses, *i.e.*, the uses which would have to be foregone if the supply of water were just a little smaller. Under conditions of scarcity the value of water might be exceedingly high, but only because its marginal uses were exceedingly important. In this way many an ingenious theory of value was built up by the economists whom we have named and their followers in Europe and America. Some of these writers also took another and more doubtful step. Having explained values by relating them to the choices and preferences of consumers, they pictured the economic behaviour of men, including the choices which they make as consumers, as governed by the aim of maximizing pleasure and avoiding pain, so that the fullest possible satisfaction of consumers' wants was held to yield "maximum happiness." This, it is now pretty generally agreed, is dubious psychology.

Starting with this new way of explaining the values of the goods and services which consumers buy and use, a new type of explanation of the distribution of the aggregate product among the various productive factors was developed. The central point in this new analysis was the thesis that the value of productive agents, including labour, capital and land, is derived from or, we might say, merely reflects the value which consumers attach to the final products of such agents. The problem of distribution, viewed from this particular angle, is the problem of discovering the general relations between the values of the final products of trade and industry and the values of the productive agents. If the demand of consumers for finished products could be construed to be a demand for definite quantities of land, labour and instruments, combined in fixed proportions, the problem would be relatively simple. But because, in fact, goods can be produced in different ways, and because, within limits, one factor can be substituted for another (as a given amount of agricultural produce can be grown by using more labour and less land or more land and less labour, or as simple and direct or highly roundabout methods, requiring small or large amounts of capital, may be used in industry) the problem is really exceedingly complex.

One general principle which has been found to help towards clarifying the problem is nothing more than an extension or generalization of a principle which the older economists had taken account of in their doctrine, previously noted, that the expansion of agricultural production is attended by diminishing returns. It came to be seen that if it is true that the amount of product dependent upon the efforts of any one labourer or any one day's labour becomes smaller when the amount of labour "applied" to or combined with a given amount of land is increased, it must also be true that the amount of product dependent upon the use of any one particular acre of land becomes smaller when the available supply of land of equal quality and accessibility is increased more rapidly than the supply of labour. Similarly, the larger the supply of capital as compared with the supply of labour and land, the smaller is the amount by which the product would be decreased if any one unit of capital were not available. How

much of the aggregate product will have to be assigned to any one labourer or to the owner of a certain productive instrument or a certain piece of land will be determined, if competition is free and frictionless, by the extent to which the product really depends upon the work of that particular labourer or the use of that particular productive agent. The individual labourer, for example, counts for more, and indeed produces more, when there is a plentiful supply of productive agents other than labour. He produces less — for less depends upon his own efforts — when labour is relatively plentiful and other productive agents relatively scarce. What he earns will depend, of course, upon the value of what he produces, and his real wages — what he is able to buy — will depend as well upon the values of other products. But — assuming again that competition is unimpeded and frictionless — labour, like capital and land, will move or be moved away from employments where the value of its product is relatively small, and will move or be moved into employments where the value of its product is relatively large. There is thus a tendency — effective in a measure, though never working itself out completely — towards an equality of the values of the products attributable in different employments to labourers of comparable efficiency and to other productive agents of comparable kinds. The significant outcome of this newer analysis is not the doctrine that everyone who contributes to the communal product tends to get as his allotted share an amount equal to "what he produces." It must be remembered that differences in respect of training and of opportunity still affect men's productive capacities; that institutions, such as inheritance, help to determine how the products imputed to capital and land shall be distributed; that the swift process of industrial change often robs men of the advantages of acquired skill; that impediments of one kind or another often prevent men from transferring their labour to employments in which its product would have a higher value; that capital once fixed or invested in permanent forms is generally irretrievably committed to the fortunes of a particular type of enterprise, whatever those fortunes may prove to be. No, the doctrine that "rewards tend to be proportionate to products." taken by itself, has no particular significance, except as a corrective to the even more misleading notion that rewards are in no manner related to or dependent upon productivity. The real significance of this new way of sketching the outlines of the problem of distribution is that it brings clearly into view the general form, at least, of some very important relations between production and distribution and between one distributive share and another. Relations such as these have to be kept in mind when analysing the probable repercussions of almost any projected scheme for economic betterment.

Any short summary is bound to make economic theories appear thinner and more remote from the concrete facts of economic life than they are. The structure of abstract general relations which constitutes the framework of modern economic theory has been built up, not like pure geometry, by a wholly intellectual process, but by a patient and persistent scrutiny of the complicated facts of economic life. In what is generally called "mathematical economics," however, one finds a comparatively high degree of abstraction. The one great advantage of the use of mathematics in economics is that in that way alone is it possible to depict the variety, the complexity and most of all the interdependence of the factors which determine prices, costs, supply, demand and distributive shares. Elaborate mathematical formulations of the conditions of "general economic equilibrium" have been devised, notably by Léon Walras (*Éléments d'économie politique pure, 1874,* and later editions) and Vilfredo Pareto *(Manuel d'économie politique,* 1909, and other works). The principal value of these elaborate and highly abstract systems is that they put the enquirer on his guard against over-simplifying his problems, as for example, by forgetting that a change of almost any economic variable has its indirect as well as its direct effects. Other writers, notably Alfred Marshall *(Principles of Economics,* 1890, and later editions) have shown that it is possible to put a proper emphasis upon the interdependence of economic phenomena while yet examining more closely and realistically into the operations of the different parts of the cionomic mechanism, and while taking account of factors which make for change as well as of factors which make for stability.

Among the economic phenomena to which a largely increased amount of attention has been given are interest and profits. In connection with interest two different though related types of questions present themselves. First, is interest a necessary or in any sense an "earned" income? For what sort of productive service or sacrifice is it a payment? Is there any perceptible relation between the amount of the payment and the amount of service or sacrifice? Second, what factors govern the fluctuations of interest rates, and what determines their general level or their movements, upward or downward through longer periods of time? The first of these two types of problems was brought into prominence by the attacks of the socialists upon the private receipt of income from capital. Profits, as the term is used in the world of affairs, are generally a mixed form of income, containing elements of interest and sometimes of wages (as for superintendence or managerial direction) along with a special element (which may be positive or negative) of what the economist calls "pure profits." The distinguishing characteristic of profits is that they are not paid in accordance with any contract or agreement, but are contingent upon the success of particular undertakings. Pure profits are what is left after allowance is made for the interest and wages which would have to have been paid for capital and management upon a contractual instead of a contingent basis. Pure profits, therefore, are determined by all of the factors which make for the success of an undertaking, such as foresight, fortune, quickness to see opportunities for gain and to take advantage of them. In a completely stationary and unchanging economic order, it is pretty generally agreed, the advantages of different employments of capital and of managerial ability would be so completely equalized by competition that there could be no pure profits.

The Problems of Modern Economics. — The more general and abstract parts of economics cannot be taken to be completely true and adequate accounts of the mechanism of modern economic life. They are at best serviceable approximations to partial, though important, aspects of truth. There are other true generalizations which might be made. Some of these are obvious but unimportant; others, doubtless, are important, but require further scrutiny of the facts or a more penetrating insight to bring them to light. But even in their present imperfect and incomplete state the generalizations which the economist has at his hand constitute an organon of proved effectiveness, an instrument by means of which some of the results of economic changes, whether planned or not planned, may often be predicted with a fair degree of certainty. The practical problems of communal economic life are many and various. At any given time they appear to fall into a number of fairly well defined groups or classes, but as new problems challenge attention and new interests emerge, new groups appear and some of the old problems fall into new relations. Each group or class of problems has its special literature, and each engages the attention of a corps of specialists.

Among the classical problems of economics are such subjects as the mechanism of money and credit and its proper management, the incidence and the effects of various kinds of taxation, the nature of international trade and the economic consequences of protective tariffs and other devices for controlling it. In none of these fields is the ground completely explored or all of the issues definitely settled. But in each field important findings have been reached which appear to have permanent value. The outcome of the various fiscal and monetary measures to which governments resorted during the World War, and the results of the various restrictions imposed at that time upon trade and industry were in general just about what competent economists predicted they would be. Post-war experience, too, in respect of such problems as reparations and monetary stabilization, were such as to give new confirmation of some long-established economic principles.

The general form which economics took at first was determined very largely by its preoccupation with certain special types of problems, notably problems of national commercial policy. But as new types of economic problems have forced themselves upon

the attention of the community, economics has had to deal with them, and in the process not only its scope but its general pattern has inevitably been altered. The way in which a new group of "labour problems" has emerged from the labour movement of the 19th century is a case in point. Up to the last quarter of that century there was very little careful analysis of those problems, apart from discussions of the general theory of wages. Now, however, there is hardly a field of economic inquiry which is more thoroughly cultivated. The trades union movement and its significance, the possible gains of collective bargaining, the length of the working day, factory legislation, profit-sharing, the organization of control within the factory and its administration, labour turnover, the minimum wage, the prevention and settlement of industrial disputes, compulsory arbitration, the causes and possible cures of unemployment and social insurance in its various forms are subjects which suggest the increasing range of this new field of economic interest. It is important to observe that the attention now given to these subjects marks a change of interest rather than a change of attitude. The earlier economists, interested as they were in the exploding of popular fallacies with respect to the ways in which the prosperity of the community can best be secured and (with that end largely in view) in showing how the economic activities of individuals are so inter-related that they constitute, in their entirety, a great communal economic mechanism, often give the impression—an impression which careful study of the writings of the ablest of them will dispel—that they regarded that mechanism as self-sufficient, needing neither interference nor any sort of direction on the part of the community. They concerned themselves more with what governments could not do than with what they could wisely attempt. Modern economics strikes a different note. Its tone is less negative; it is more insistent in its search for and scrutiny of possible ways of altering the organization of the community's economic life for the better. Almost every gain has its cost, and accordingly almost every such problem resolves itself into a question of a balance of advantage. The advantages and disadvantages are hardly ever purely economic, and no purely "scientific" analysis, therefore, can completely dispose of such questions. The economist, however, may be able to gauge the general character of the probable effects of a specific change upon the production of wealth or its distribution, so that the wisdom of proposed changes can be discussed upon the basis of some knowledge of their probable consequences.

Questions associated with monopoly—its roots, its various types, its effects, its possible advantages in some circumstances, the ways in which it may be controlled—are matters with which economics have long been concerned. Economists have learned, for one thing, to distinguish between the types of monopolies which are inevitable, and have to be recognized and treated as such, and the types of monopolies which might be prevented or suppressed, in so far as the maintenance of competitive conditions in fields where competition is feasible is held to be a sound public policy. Changing methods of business organization and particularly the rise of the limited liability company have created new problems for economics. On the one hand there is a new opportunity for large numbers of people, not merely to put their savings out at interest, but to participate in the profits (and losses) of large undertakings. On the other hand, along with this larger diffusion of industrial ownership, there are new opportunities for the concentration of industrial control. This situation gives rise to new communal problems, and these, in turn, create new fields for economic inquiries. The general theory of economic equilibrium, which includes an analysis of how exchange values and distributive shares "tend" to be determined under the operation of the forces which make for a general balancing of supply and demand, retains its importance in economics. But in recent years economists have come to give increased attention to the factors which make for economic change and to the persistence of maladjustments in the mechanism of production and trade. The recurring phenomena known as industrial fluctuations or business cycles, with their attendant costs and wastes, are receiving a very much larger amount of study than was formerly given to them.

The most striking and possibly the most important characteristic of the newer work in economics, as contrasted with the older, is its greater realism. Not that it manages to do without abstract conceptions, but that it takes its conceptions, so far as it can, from the world of affairs. The older economists, for example, in their efforts to dig beneath that surface view of economic life which had deceived the mercantilists, held that money was merely a convenient instrument or tool. From their point of view, which remains a significant point of view, they were right. They also held that money prices were "exchange values" expressed in terms of money, making value the basic and price the derived conception, and thus inverting their real relation. This procedure, again, was not without reason, and in some special types of economic analysis it remains convenient to assume that trade is conducted by barter, without the use of money. In general, however, modern economists find it better to deal with money prices rather than with "exchange values." They have observed that modem processes of price-making and distribution depend upon the use of money and credit, not only in the sense that processes so complex would be unthinkable otherwise, but also in the further sense that the use of money and credit has certain special and discernible effects upon the outcome. Reliable records of economic activities—or at any rate of their results—are now brought together and published by governments or made public by business organizations on a scale, in respect of both volume and variety, which would have excited the envy of the older economists. A much wider range of economic experience is now available for study and analysis. In dealing with this new material—virtually a by-product of the activities which it records—economics again has to accommodate itself to a more realistic view. It has to deal with economic events in the forms in which they really occur, and it has to search for the systematic relations which run through these masses of real events. But although the interests of economics have become more varied and concrete, and although its conceptions have become better adapted to the handling of the facts of economic life in the form in which those facts present themselves, economics remain a communal or political science. Particular findings or tenets have been discarded, and new ones have been set up in their stead But the general picture of a scheme of communal economic life, sufficiently ordered to make an analysis of it possible, and imperfect enough to give point and purpose to such an analysis in spite of changes of view-point and method, remains.

BIBLIOGRAPHY.—A. E. Monroe (ed.), *Early Economic Thought* (1924), a compilation of well chosen selections from economic literature prior to Adam Smith; Paul Gemahling (ed.), *Les grandes tronomistes* (1925), with excellent bibliographies, covers the subsequent period also. For the history of the earlier period the best single reference is *A.* Onclien, *Geschichte der Nationalökonomie* (3rd ed., 1922); for the later period the *Histoire des doctrines économiques* by Charles Gide and Charles Rist (5th ed., 1926) is similarly useful. An English translation, *History of Economic Doctrines* (1915) of an earlier edition of the last-named work is available. Recent developments are treated in detail in Theo. Surányi-Unger, *Die Entwicklung der theoretischen Volkswirtschaftslehre in ersten Viertel des 20. Jahrhundert* (1927); a more accurate though less complete survey will be found in *Die Wirtschaftstheorie der Gegenwart* (4 vols., 1927–29), ed. by Hans Mayer and others. *See* also for special branches, Edwin Cannan, *A History of the Theories of Production and Distribution in English Political Economy from 1776 to 1848* (3rd ed., 1917); Jan St. Lewiński, *The Founders of Political Economy* (1922); James Bonar, *Philosophy and Political Economy* (3rd ed., 1922); Walter Bagehot, *Economic Studies* (1879); S. *P.* Altmann and others, *Die Entwicklung der deutschen Volksmirtslehre im neuneehnten Jahrhundert* (2 vols., 1908); G. H. Bousquet, *Essai sur l'évolution de la pensée économique* (1927); and the following standard treatises: J. K. Ingram, *A History of Political Economy* (new ed., 1919); L. H. Haney, *History of Economic Thought* (1911); *A.* Dubois, *Précis de l'histoire des doctrines tconomiques* (1903); Hector Denis, *Histoire des systèmes économiques et socialistes* (2 vols., 1904, 1907); René Gonnard, *Histoire des doctrines tconomiques* (3 vols., 1921–27); J. Rambaud, *Histoire des doctrines tconomiques* (2 vols., 1907–08); J. Schumpeter, *Epochen der Dogmengeschichte* (in *Grundriss der Socialokonomik*, 1913). Articles on various special topics, with bibliographies, will be found in the *Handworterbuch der Staatswissenschaften* (4th ed., 8 vols., 1923–08) and in the *Dictionary of Political Economy*, edited by Sir R. H. I. Palgrave (revised ed., edited by Henry Higgs, 3 vols., 1926). (A. Yo.)

ECONOMICS, PRIMITIVE. Comparatively little is known about the economic organization of savage peoples. Being apparently one of the simplest and least interesting aspects of their social life, it has been the last to receive attention from the anthropologist, though in reality it presents complex problems of vital concern for native welfare. Most of our knowledge of the principles of savage economic life is due to the work of German scholars. The earliest studies in economic anthropology were largely of an evolutionary nature, attention being concentrated on the somewhat barren aim of fitting phenomena into schemes of stages of progress and constructing theories of development from one stage to another. Best known of all is the *Dreistufenschema,* the three-stage scheme of society by which mankind, having first lived as hunters and fishers, advanced through the pastoral grade of existence to attain the state of agriculture, which represented the final achievement of primitive industry. This scheme of the economist Friedrich List persisted for several decades, though the idea of a universal course of evolution for all mankind soon disappeared. Rival theories, as that of the barter, money, credit periods of development of Bruno Hildebrand, were also advanced. In time the old three-stage pattern of economic progress was abandoned, owing to the destructive criticism of geographers such as Friedrich Ratzel and anthropologists like Eduard Hahn. Other schemes of classification of culture, associated with the names of Hahn, Ernst Grosse, Alfred Vierkandt and Heinrich Schurtz, came in rapid succession, but the value of such work lay in the collection of data and the incidental analysis of native economic conditions — as in Hahn's distinction between hoe-cultivation and agriculture proper with plough and domesticated animals — rather than in the actual theories propounded.

The writings of Karl Biicher, by drawing the economy of primitive man into relation with that of our civilization, have done much to provoke interest in the subject. His classification, however, of all savage economic life as being either a selfish individual hunt for food or at best a sharing of goods within the closed circle of the household, does not conform to the facts as now known, nor do his theories of the development of exchange from the custom of giving presents and the origin of work in play find much modern support.

Exponents of the *kulturhistorische* method in anthropology, notably Wilhelm Koppers, have also laid due stress on the economic factor as a prime determinant of culture. But their study of economic life is made subservient to their attempt to establish certain theories regarding the history of mankind which involve a hypothetical scheme of *kulturkreise* or stages of culture. This interest in the problematical origins of native custom has led to a neglect of its real place in native life.

Studies by such writers as M. Marcel Mauss, Prof. Richard Thurnwald and Dr. Bronislaw Malinowski have done much to retrieve the position. The attempt to establish evolutionary sequences has been discarded, and the imagined history of institutions left on one side. Primitive economic organization is studied for its relation to the existing social mechanism, for the ends which it serves in the present, not for what it may have been in past ages. In short, the "functional method" of inquiry is employed. The institution of the exchange of gifts, for example, is shown to be part of the native economic system, not in virtue of being a transition stage from gift-making to trade, but because it satisfies certain practical needs and allows for the expression of social sentiments — ideas of rank, prestige, liberality and fulfilment of obligation. Recent work of this type in primitive economics has thrown light upon such questions as the character of leadership in native labour, the social stimuli involved, the part played by co-operation, the nature of economic reward, the action of the principle of reciprocity in exchange, the value of magic in industry, and the influence of wealth upon chieftainship and rank.

Such problems are concerned with vital issues, and the investigator here is grappling with the reality which lies at the foundation of the life and work of the native. Such study, apart from its interest *to* the economic historian in throwing light on the nature of less developed forms of institutions, has also a practical value. An adequate knowledge of the economic organization of a native people is essential before we can govern them, trade with them, utilize their labour, secure their co-operation in political affairs, or preserve them from the worst effects of contact with white civilization.

ECONOMIZER. An important adjunct to a steam-generating plant. Instead of being allowed to escape to the chimney direct from the furnaces, the waste gases are led through passages in which are placed sets of vertical tubes. Water passes through the tubes and the heat of the gases raises it to a useful temperature for various purposes, not merely to supply the feed for the boilers, but also for supply where a large quantity of hot water is required, as in laundries, hotels, breweries, dyeworks and so on. At the same time, strains on the boiler plates and parts through exposure to an inflow of cold water are prevented. Scale trouble in the boiler is also greatly reduced, because the scale forms instead inside the economizer tubes, and these are readily cleaned. Some 15% to 20% of coal is saved on the installation of an economizer. Evidence of this is the fact that if the gases leave the boiler at 650° F, the feed-water entering the economizer at 100° F will leave it at 272° F, reducing the temperature of the gases to 330° F. The Green economizer consists of a number of vertical cast-iron tubes, $4\frac{9}{16}$ in. external diameter, made up in sections, and connected with branch pipes at top and bottom. The outside of each tube is kept clean by encircling scrapers, which travel slowly up and down all the time, actuated by automatic mechanism at the top. The soot falls into a pit for convenient removal. There is also a horizontal type of economizer which is mounted above a water-tube boiler. In some designs of economizers tubes with gills are used, to obtain the maximum heat transference, and the soot is cleaned off by steam blowers.

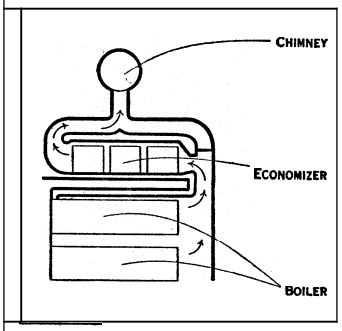

DIAGRAM TO SHOW PASSAGE OF WASTE GASES FROM BOILERS WHICH ARE MADE TO HEAT WATER IN ECONOMIZER BEFORE ESCAPING BY CHIMNEY

ECONOMY, the thrifty management of the financial resources of a household or of an individual, hence a "saving," not only of money, but of time, labour or effort, and generally, the least expenditure of means to attain a required end. "Economy" is also used in theology in such expressions as "Mosaic" or "Christian economy" as a synonym of "dispensation," for the administration of the world by God at particular times or for particular races. From the meaning of organization or administration of a house or State the word is applied more widely to the ordered arrangement of any organized body, and is equivalent almost to "system"; thus the "economy" of nature or of animal or plant life may be spoken of. "Political economy" is the science dealing with the production, distribution and consumption of wealth *(see* ECONOMICS).

ECORSE, a village of Wayne county, Michigan, U.S A., on the Detroit river, 7m. S.S.W. of Detroit. It is served by the Detroit, Toledo and Ironton, the Michigan Central and the New York Central railways. The population was 3,394 in 1920 (81% native white) and was 13,209 in 1940 by the federal census. It is a rapidly growing industrial suburb, manufacturing steel, castings salt and motor engines. The village was founded about 1812 and incorporated in 1902.

ECOSSAISE, in music, the French name, which has also been adopted in Germany, for a certain Scottish dance and corresponding music. Originally this dance was a slow one in duple time, but the term nowadays signifies one of a quicker and livelier character in 2-4 time. Beethoven and Schubert both left examples. The écossaise, it should be noted, is not the same as the schottische (*q.v.*), although the names might suggest that it is.

ECSTASY, a term applied to an abnormal mental condition, in which the mind is entirely absorbed in the contemplation of one dominant idea or object, and loses for the time its normal self-control (Gr. ἔκστασις, from ἐξίστημι, put out of its place, alter). With this there is commonly associated the prevalence of some strong emotion, which manifests itself in various ways, and with varying degrees of intensity. This state resembles in many points that of catalepsy, but differs from it sufficiently to constitute it a separate affection. The patient in ecstasy may lie in a fixed position like the cataleptic, apparently quite unconscious, yet, on awaking, there is a distinct recollection of visions perceived during this period. More frequently there is violent emotional excitement which may find expression in impassioned utterances, and in extravagant bodily movements and gesticulations. Ecstasy usually presents itself as a kind of temporary religious insanity. and has frequently appeared as an epidemic. It is well illustrated in the celebrated examples of the dancing epidemics of Germany and Italy in the middle ages, and the *Convulsionnaires* of St. Médard at the grave of the Abbé Paris in the early part of the 18th century, and in more recent times has been witnessed during periods of religious revivalism. (See also INSANITY and NEUROPATHOLOGY.)

ECUADOR (officially **La** *República del* Ecuador), a republic of South America, bounded on the north and north-east by Colombia and Peru, on the east-south-east and south by Peru, and on the west by the Pacific Ocean. The northern boundary (about 680 m.) begins on the Pacific coast at the mouth of the Rio Mataje, 1° 30' N. and ascends this stream to about 1° 18' N. where it crosses the ridge into the Rio Mira. The boundary ascends this stream to the confluence with the Rio San Juan, ascends the latter to its source, crosses the summit of the Andes in about 0° 45' N. and then descends the east slope of the Andes via the Rio Carchi, crossing to the Rio Aguarico and descending

THE BRIDGE OF EL VADOR Y SAN ROQUE. AT CUENCA. ECUADOR

this to 0° 23' N. where it crosses to the Rio San Miguel and descends this stream to the confluence with the Rio Putumayo in long. 75° 52' W. of Greenwich. It then turns south-west overland to the top of the divide between the Rio Putumayo and Rio Aguarico, about 0° 4' S. and 76° 15' W. a surveyed distance of about 310 m. from the Pacific. From this point the boundary follows the divide between the Rio Putumayo and Río Napo to the source of the Ria Ambiyacu which river it follows to the Amazon at 3° 19' S. and 71° 50' W. The boundary along the divide between the Putumayo and the Napo is not surveyed, but the approximate distance from the Pacific to the Amazon is about 680 miles.

In 1927 Colombia ceded to Peru a narrow strip of territory, about 430 m. E. and W., just N. of the Ecuador boundary as established by Colombia and Ecuador in 1916. The southern boundary follows the centre of the main channel of the Amazon from the mouth of the Rio Ambiyacu, to that of the Rio Huancabamba 78° 38' W. (about 520 m.). It then ascends the Rio Huancabamba to its source and crosses the Andes at 4° 40' S. to descend the Macara to the Catamayo. It then descends this river to the confluence with the Alamor which it ascends to the Quebrada de los Pavas. Ascending this the line then crosses *a* divide into the Rio Túmbez which it follows to the Pacific. This boundary is undisputed by Peru from the Pacific at the mouth of the Rio Tumbez to the headwaters of the Rio Huancabamba.

The area of Ecuador (not including the Galapagos islands, *q.v.*, with approximately 3,028 sq.m.), is variously estimated. Official Ecuadorian claims are 337,392 sq m., but well over 100,000 sq.mi. is in dispute with Peru (q v.). Attempts to settle the boundary question with Peru, in existence since colonial days, have failed. In 1894 the dispute was referred to the King of Spain as arbiter, but no results came. Since 1924, and especially since 1934, through the good offices of the President of the United States. negotiations have been carried on intermittently at Washington. In 1936 and 1937 especially, and to a less degree since then, relations between the two countries have been quite strained.

PHYSIOGRAPHY

Andean Region. — Ecuador is largely mountainous. It is traversed from N. to S. (500 m.), by the Andes Mountains (maximum elevation: Chimborazo, 20,j76 feet). The lowest divide in the cordillera, 6.888 ft., is on the Peruvian boundary.

The Andes are narrowest in Ecuador, which is divided into three regions: the Andean highlands, the coastal region between the Andes and the Pacific, and the Amazon region, or Oriente, on the east of the high Andes. The Andean region ends on the west in elevations of about 1,500 ft. above the sea. In the south, around the gulf of Guayaquil there is only a narrow belt of low coastal region. From a point a few miles east of Guayaquil, however, to just south of the Equator, the Andes terminate along the east side of the Guayas basin. **A** line from the head of the Guayas basin at Sto Domingo de los Colorados on the Rio Toachi north to a few miles east of San Lorenzo terminates the western boundary of the Andean region in Ecuador. On the east, however, the base of the Andes may be taken at points such as Macas (3,580 ft.) and Mera (3.808 ft.). In general the 4.000 ft. unbroken contour from the Colombian to the Peruvian border bounds the Andean region on the east.

The width of this mass from base to base varies from a minimum of 73 m. (Bucay to Macas), to a maximum of 183 m. (Zapotello and Santiago). The average width is about 100 m. (Sto. Domingo de los Colorados-Tena, 1,680 ft.). The longitudinal profile of the Andean summits from north to south, coinciding with the watershed between the Atlantic and Pacific varies from 20,576 ft. in Chimborazo to about 6,900 ft. in the south near the Peruvian boundary.

That portion of the Andes from about 2" S. to the Colombian frontier is characterized by lofty, volcanic peaks, many covered with perpetual snow and ice, some active. Beginning with Cumbal (15,711 ft.) and Chiles (15,678 ft.) just north of the Colombian boundary, the most important are Yanaurcu (14,881), Cotocachi (16,328), Imbabura (15,028), Mojanda (14,038), Cayambe (19,186), Saraurcu (15,502), Pichincha (15,918). Antisana (18,715), Cotopaxi (19,613), Corazón (15,871), Iliniza (17,405), Quilindana (16,174), Carihuairazo (16,51j), Chimborazo (20,-576), Tunguragua (16,690), Altar (17,730) and Sangay (17,464). These are irregularly distributed on a basal plateau and viewed from a great distance each volcanic unit is only a small mass having a prominence of but 3.000 or 4,000 ft. above the general level of the upland. Antisana, for example, can be described as a mass about 4 m. in diameter at its base and rising from an elevation of 15,000 ft. to 18,715 ft. above the sea.

In the volcanic part of the Ecuador Andes the streams flow in old valleys often several miles wide filled with hundreds of feet of ash and lava. The streams arc therefore rejuvenated and

flow in narrow canyons with steep walls.

The streams of the Andean highland region are all torrential and flow both to the Atlantic and Pacific. The largest drainage basin on the Andes is the Pastaza system, which is composed of the south-flowing Patate and the north-flowing Chambo. The longitudinal valley in which these flow is about 100 m. long. The two streams unite at the middle of this section near Baiios (6,000 ft.) to form the Pastaza and eventually reach the Amazon. To the north of the Patate-Chambo basin, about 40 m. of the upper part of the Guallabamba is in a valley which has the same north-south trend as its neighbour to the south. These two units, totalling a length of 140 m. in the most populous part of Ecuador and separated by an east-west divide of an elevation of only 11,650 ft. form a strikingly narrow, longitudinal depression and it has been customary to refer to the higher portions of the Andes to the east and west of this as the eastern and western cordillera. But the Andes are so narrow in Ecuador that it seems best to recognize them as one mountain mass. The Mira in the north flows to the Pacific and has a considerable portion of its drainage on the Andean highlands. This is often referred to as the Ibarra basin.

The Andes of southern Ecuador are pretty well and irregularly cut up by both Pacific and Atlantic tributaries whose headwaters are interlocked. Among the main streams of the former class are the Paute, the Zamora and the Chinchipe. To the latter belong the Naranjal, the Jubones, the Tumbez and the Catamayo. There are no large lakes in Ecuador.

All of the Andean highlands with the exception of the eastern and western slopes are treeless and highly suitable for agriculture. The forests of the east and west slopes are nearly uninhabited. The central part of the Andes which is also the most elevated and has the best climate has such cities as Ibarra (*q.v.*), Quito (*q.v.*), Latacunga (*q.v.*), Ambato (*q.v.*), Riobamba (*q.v.*), Cuenca (*q.v.*) and Loja.

Pacific Coastal Region.—The coastal region forms an area in places 115 m. wide extending from the Andes to the Pacific and from the Peruvian boundary in lat. 3° 30′ S. to Colombia, 1° 30′ N. This is mostly lowland formed of the basin of the Guayas and the coastal plain but in the south-east is a mountainous ridge called the cordillera de Colonche which is narrow and in the form of a half circle extends from near Guayaquil where it is named "cordillera de Chongón," to just south of Puerto Viejo where it is called cordillera de Puca. It is about 84 m. long and sometimes reaches 2,600 it. altitude.

The "montaiias de Cojimies" in the western part of the province of Esmeraldas, lie between the Pacific and the Rio Quinindé. These "mountains" are a narrow ridge about 35 m. long and reaching 1,000 ft. altitude. Just south-east of the town of Esmeraldas is a narrow ridge called "montaiias de Atacames." It is about zo m. long and its summits attain an elevation of nearly 1,000 ft. above the sea.

Scarcely anything is known of the coastal region between the rivers. Esmeraldas province is supposed to be a tableland having summits of about 1,000 ft. elevation and valleys dissected to nearly sea-level. The Guayas river and its tributaries form a large part of the coastal region. The river is in part an estuary extending north from the gulf of Guayaquil and is the largest navigable stream on the Pacific coast of South America. At Guayaquil to which sea-going vessels ascend it is about 2 m. wide. The river rises near the equator, and its main tributaries are the Daule, the Vinces, Rio Zapotal and Rio Chimbo, all navigable on their lower courses and having extensive swamp areas. Steamboats go regularly from Guayaquil up the Rio Bodegas to Babahoyo 80 m. above Guayaquil and for 40 m. up the Daule. The navigable channels of the Guayas and its tributaries are computed to be 200 m. long; the drainage basin is said to cover about 14,000 sq. miles. The second large river system of the coastal region is the Rio Esmeraldas, which like the Guayas has tributaries whose sources are in the snows of the Andean highlands. The Rio Esmeraldas is formed by the Guallabamba and Blanco about 42 m. from its mouth and discharges into the Pacific at 1° N. and 79" 40′ W. through a narrow and precipitous gorge. The most northerly important coastal river system is the Santiago, formed by the Cayapas and the Santiago. The Cayapas is navigable by canoe for a long distance, the Santiago for only a few leagues above its junction with the Cayapas. Below La Concepción, the Santiago is a broad, deep stream. Near its mouth it divides and forms many islands, chief of which are La Tola, Santa Rosa and San Pedro. The Mira, north of the Santiago, forms for a part of its course the boundary between Colombia and Ecuador.

Bays.—The coast extends from about 1° 30′ N. and 78° 52′ W. to lat. 3° 30' S. and curves west ard to 81° W. Most prominent headlands are La Puntilla, Cabo de San Lorenzo, Cabo Pasado and Punta Galera. The bays are commonly broad indentations with the exception of the gulf of Guayaquil, and the rivers discharging into them are generally obstructed by bars so that the small ports of the coast do not afford much protection to shipping. The most northerly of these bays is Ancón de Sardinas, lying south of the Mira delta. The head of the bay is fringed with islands and reefs behind which is the mouth of the Mataje, the boundary between Colombia and Ecuador, and that of the Santiago. The small bay of San Lorenzo would form an excellent port terminus for Quito. The coast for about 80 m. E. and W. of the mouth of the Esmeraldas consists of rocky promontories and of high cliffs broken here and there by short river ravines. The Esmeraldas has a wide mouth with islands and shoals constantly altered by the swift current. The port of Esmeraldas is on the left bank of the river. As the mouth is obstructed by a bar and the river current is swift, the anchorage for ships is outside in an open roadstead with slight protection. Between Cabo Pasado and Cabo de San Lorenzo is a broad indentation in which is the Bahía de Caráquez, a small bay, now the terminus of a railway which runs inland 473 m. to Chone. The southern portion of the broad indentation is called Bahia de Manta and on this is a small port served by a railway extending inland 37 m. to Santa Ana. The Bahia de Santa Elena is formed by a broad curve from Punta Ayangue to La Puntilla. At Salinas a small settlement on the end of the point "La Puntilla" is the landing place of the All-America cable. A pipe line terminates on the shore east of Salinas bringing petroleum from the wells of the Anglo-Ecuadorian Oil Co., situated on the south coast of the peninsula. Ships anchor with little protection in the roadstead between Salinas and Ballenita. The gulf of Guayaquil is the largest on the Pacific coast of South America. Its mouth is 140 m. wide between La Puntilla on the N. and Cabo Blanco on the S. and it penetrates the land eastward with a slight curve northward at its head for a distance of about 100 m., terminating in the Guayas estuary and river on which is the port of Guayaquil. The upper end of the gulf and its northern shores are fringed with swamps through which numerous estuaries penetrate for some distance inland. Of these, the Estero Salado, W. of the Guayas, formed of many shallow tide water channels penetrates as far inland as Guayaquil, but is used only by canoes Near Guayaquil in the Estero Salado is good bathing. The upper end of the gulf of Guayaquil is filling up with the silt brought down from the Andes. It is divided midway by the large island of Puná, at the eastern end of which is the anchorage for steamers too large to ascend the Guayas. The steamship channel passes between this island and the Peruvian coast and is known as the Jambeli channel. The Morro channel, west of Puná, is obstructed by shoals and dangerous for shipping. In the Jambeli channel on the south-east shore of the gulf is the small port of Puerto Bolivar, serving Machala and the Zaruma mining district. A railway runs inland to Machala and thence to Paraje. Another is being built from Puerto Bolivar via Santa Rosa to Zaruma.

Islands.—There are few islands off Ecuador, and only one of any considerable size, that of Puná in the north-east part of the gulf of Guayaquil. This is 29 m. long by 8 to 14 m. wide. Puná generally is low and swampy and its shores, except on the east, are fringed with mud banks. It is densely wooded, in marked contrast to the opposite Peruvian shore and is unhealthy the greater part of the year. It has a population of about 3.000, about 800 living in the village of Puná at its north-east extremity. Pilots are taken on here to ascend to Guayaquil. Twelve miles south-

west of Puná island and 80 m. from Guayaquil is Amortajada (or Santa Clara) island, whose resemblance to a shrouded corpse suggested the name which it bears. It rises to a considerable elevation, and carries a light 256 ft. above sea-level. There are some low, swampy islands, or mud flats, covered with mangrove thickets, in the lower Guayas, but they are uninhabited. On the coast N. of the Gulf of Guayaquil there are only two small islands of more than local interest. The first of these is Salango, in 1" 35′ S., which is about 2 m. in diameter and rises to a height of 524 feet. It is well wooded, and has a well-sheltered anchorage formerly frequented by whalers in search of water and fresh provisions. The next is La Plata, in 1° 16′ S., which rises to a height of 790 ft., and has a deep anchorage on its eastern side where Drake is said to have anchored in 1579 to divide the spoils of the Spanish treasure ship "Cacafuego." The Galápagos islands (*q.v.*) belong to Ecuador, and form a part of the province of Guayas.

The Amazon Region.—The region east of the Andes mountains or the Amazon region is called the "Oriente" and is entirely forested. It begins at the eastern base of the Andes mountains which may be taken at about 4,000 ft. above the sea and extends to the eastern boundary with Peru (see above on boundaries).

The land surface in general slopes eastward, at first rapidly until at about 850 ft. above the sea it becomes a part of the Amazon lowland. Very little is known of the interstream areas. Immediately east of the Andes the general surface is deeply dissected by rivers, but in a measure as one proceeds eastward the land surface tends in general to meet the level of the rivers. Near the Andes are here and there mountainous masses like the volcano Sumaco (12,700 ft. above the sea) and the cordillera Galeras which in reality belong to the Andean region for they are connected to the Andes by the 4,000 ft. contour. A few detached mountain masses such as the Lumbaki mountains on the equator in longitude 77" 20′ west of Greenwich are known to exist and doubtless others will be discovered later.

The main rivers of the Oriente originate on the Andes. All flow into the Atlantic and those whose sources are in the Andes emerge in great gorges on to the Amazon lowland. They are torrential and not navigable till they reach a low elevation when they suddenly become navigable, not only for canoes, but for launches and steamers.

This uppermost point of navigation, or "fall line" is clearly marked. The streams for about 100 m. east of the Andes are torrential and full of rapids. Their courses in this part are usually "braided," *i.e.*, choked with debris from the Andes so that there are many channels and islands. The beds are of boulders which decrease in size eastward. At the "fall line" which on the Río Napo for example, is 850 ft. above the sea, in longitude 77° 00" W. of Greenwich, and about 3,000 m. from the Atlantic, the braided character disappears and the rivers become deep, sluggish and wide, with low mud banks.

Tributaries.—The streams are all tributaries of the Amazon (*q.v.*), divided into two classes, those which rise in the Andes and those which have their entire courses east of the mountains. In the first class are the Rio Napo, Rio Pastaza, Rio Santiago and Rio Chinchipe. To the second subdivision belong the Rio Tigre and the Rio Morona. The Rio Napo, the tributaries of which rise on the Andean slopes from Cotopaxi north to Tulcán, is the largest of these rivers. Its total length is about 700 m. and it enters the Amazon at about 385 ft. above the sea, in latitude 3° 20′ S. and 72° 40' W. of Green ich. From the village of Napo near the base of the Andes where it has an elevation of 1,580 ft. above the sea, it descends in 90 m. to an elevation of about 900 ft. above the sea, at the mouth of the Rio Coca. From here it drops 515 ft. in about 464 m. or about one foot per mile In the stretch between Napo and the mouth of the Rio Coca, the river is shallow and canoes can be used, but going upstream against the current and with bad rapids, it is slow work, about 1½ m. per hour. The descent from Napo to the mouth of the Coca is done by canoe and by shooting the rapids, in two days, *i.e.*, at the rate of about 5 m. per hour. At the mouth of the Coca, the Napo is about 1,500 ft. wide; at its mouth it is nearly one mile wide. Steam launches can ascend to a point several miles above the mouth of the Rio Coca. The principal tributaries of the Napo are the Aguarico and the Coca from the north, and the Curaray from the south. The Coca unites with the Napo in lat. 0° 30' S. and 77° 00′ W. of Greenwich and is about 150 m. long. This river has been recently explored by Sinclair who finds that at Papallacta it is about 10,333 ft. above the sea and at Baeza 20 m. farther east, 5,863 ft. having a fall of about 223 ft. per mile in this distance, a total of 4,470 ft. About 50 m. farther east the Coca debouches from deep canyons on to the lowlands and for the remainder of its course, 54 m. it is a shallow, braided stream of strong current with many islands and channels. Its average fall in the lower 54 m. is 18 ft. per mile and although the current is swift and there are many dangerous rapids, canoes can be poled 50 m. above the mouth.

The Rio Aguarico joins the Napo about 312 m. from its mouth and about 590 ft. above the sea, and is about 200 m. long. Little is known about its course or the country through which it flows. A part of the river near its source forms the boundary between Ecuador and Colombia.

The main tributary of the Napo from the south is the Rio Curaray. This stream rises east of the Andes 18 m. north of Canelos, in hills about 2.000 ft. above the sea. It is about 400 m. long and joins the Napo about 143 m. from the Amazon. Near its headwaters it is a creek with a very serpentine course and it is described as having this feature all the way to its mouth. It is said to be navigable on account of its sluggish current as far as Canónico, about 300 m. from its confluence with the Napo. Sinclair crossed it in 1921 in long. 77° 40' W. of Greenwich and gives its elevation there as 2,000 ft. above the sea with a fall of about 5 ft. per mile.

The Rio Pastaza which is about 450 m. long enters the Amazon at a point 76" 20′ W. of Greenwich and about 4" 55' S. lat. The upper portion of this river, 127 m. long lies on the Andean highlands and has been described above as far as Mera, 3,808 ft. above the sea where the river enters the Amazon lowland. From Mera the river drops at the rate of 40 ft. per mile to the mouth of the Rio Pindo (2,700 ft. above the sea), where it is still a very torrential stream. Apparently the river is not navigable for canoes above Andoas, a settlement about 68 m. below the Pindo, for the usual route of Indians and travellers eastward leaves the Pastaza near the mouth of the Pindo, to proceed overland to Canelos (1,690 ft. above the sea, in lat. 1° 35′ S. and 77° 45' W. of Greenwich) on the Rio Bobonaza where canoes are taken to its confluence with the Pastaza at Andoas, a point about 216 m. from the Amazon. It is said that boats of a draft not exceeding 4 ft. may ascend about 110 m. from the Amazon.

The Tigre is an affluent of the Amazon and rises east of the Andes. Its length is a little over 400 miles. It joins the Amazon in 73° 55′ W. of Greenwich and in 4" 20′ S. lat. It is navigable for boats drawing 6 ft. at high water from the confluence of its tributaries, the Cunambo and the Pintuyacu, to its mouth, a distance of about 400 m. About 104 m. from its mouth it receives the Rio Corrientes, an affluent from the west which is navigable for about 100 miles. The Rio Pucacuru joins it from the north about 152 m. from its mouth and this latter stream is navigable it is said for about 37 m. above its mouth. The width to the mouth of the Corrientes is 650 to 980 ft. and its depth from 25 to 30 feet. The current is said to flow at about 1½ m. per hour. The ascent of 400 m. can be made in about 67 hours, there being only two bad places, the Island of Tacuma and at Piedra Lisa.

The Morona is an affluent of the Amazon, whose course is also entirely on the lowlands east of the Andes. Its sources are said to be in the Rio Cumasi and other streams north of Macas at elevations of about 4,000 ft. above the sea. Its length is about 340 m. It joins the Amazon at 485 ft. elevation in longitude 77° 02′ W. of Greenwich and 4° 45′ S. lat. It is a very meandering river and at 243 m. from its mouth is only 660 ft. above the sea; 203 m. farther down its elevation is 515 ft. and the fall is thus only 144 ft. in 203 miles. From here to the mouth, 41 m., the drop is only 30 feet. It is navigable from its mouth to the Manhauasisa, 310 miles upstream at all times and for two-thirds of its length by steam launches drawing 4 feet. Its depth is from 40 to 50 feet and its width from 260 to 490 feet.

The Rio Santiago empties into the Amazon in 77° 38' west of Greenwich and 4° 25′ S. lat. at an elevation of 580 ft. above the sea. Its mouth is just above the Pongo de Manseriche. Its total length following the tributary, Rio Zamora is 281 m., the Rio Zamora being 150 m. long. From Macas, 3,580 ft. above the sea, on the Rio Upano, to the mouth of the Santiago, 580 ft. elevation, the distance is about 182 m. and the drop 3,000 ft., *i.e.*, about 16 ft. per mile.

The Rio Chinchipe is about 88 m. long and is almost entirely in the Andes. It joins the Amazon in 5° 27' S. lat. and 78° 32' west of Greenwich at an elevation of about 1,209 ft. (J. H. SR.)

Geology.—The Andes reach great heights in Ecuador, where they include several lofty volcanic peaks. The volcanoes are of Tertiary or later origin and are most numerous in the northern half of the country. Cotopaxi, Chimborazo, and Cayambe are volcanoes that rise more than 19,000 ft. above sea-level, and these and other snow-covered and ice-capped peaks form the culminating points of the mountain mass. This has been divided into the Eastern Cordillera, composed of gneiss, mica schist and other old crystalline rocks, and the Western Cordillera, composed of porphyritic eruptive rocks of Mesozoic age and of Mesozoic sedimentary beds, mainly Cretaceous. Between these ranges are recent deposits that contain plant remains. Northward this depression is in large part filled with lava, tuff and agglomerate from the volcanoes, which stand either upon the folded Mesozoic beds of the Western Cordillera, on the old rocks of the Eastern Cordillera or on the floor of the depression. The lavas and ashes are mostly Andesitic. Ecuador is more subject to volcanic disturbances than any other South American country, excepting, perhaps, Chile.

The mineral resources of Ecuador have been only slightly developed. Gold, mercury, copper, iron, and lead are mined. Silver deposits have been found, but are not worked. Platinum has been discovered in the Santa Elena peninsula, north of Guayas Gulf. The largest development is that of gold, centring around Zaruma in the province of El Oro. Some sulphur deposits exist in the Pichincha and Chimborazo districts, and in the Galapagos islands. Coal in the interior of the republic is as yet unmined.

Ecuador has three important petroleum fields: the coastal region of the Santa Elena peninsula, the Amazon country in the east, and the Andean plateau. Only the first-named has been developed, although concessions in both the other areas were granted in 1938. (G. McL. Wo.; X.)

Climate.—Were it not for its lofty mountains and the Humboldt current the climate of Ecuador would be entirely tropical, for it is traversed by the equator. But, inasmuch as the elevations extend from sea-level up to 20,576 ft., the climates vary from the tropical of the lowlands east and west of the Andes, through the temperate of the higher slopes, to the Arctic climate of the peaks of Chimborazo, Cayambe, Antisana, etc.

The tropical lowlands are along the Pacific coast and the tributaries of the Amazon, east of the Andes. The former are comparatively dry; the latter extremely humid because of the Atlantic trade winds in their south-west course across the low and extremely wet basin of the Amazon.

The Pacific coast is one of transition between the arid climate of the coast of Peru to the south and the northerly humid one of Colombia. The former climate is caused mainly by the presence of the Humboldt current which flows from the coast of Chile north, and the latter by the warm south-flowing waters of the Central American current. These two currents, with a difference of temperature of from 6 to 8° F, meet off the coast of Ecuador and flow west to the Galapagos islands. Only at rare intervals is their relative strength altered, as in 1925 when the Central American current flowed farther south than had ever been known and the Humboldt current appeared to be missing entirely. Consequently the deserts of Peru and of southern Ecuador were visited by large quantities of rain for the first time in many years. The Santa Elena peninsula, for example, received a rainfall in the period Jan. 21 to May 1, 1925 of 40 in. and this decreased in the period Jan. 11 to April 5, 1926 to 27 in. and in the 12 months of 1927 to nearly normal, viz., a total of 4 inches.

Under normal conditions, the inner shores of the gulf of Guayaquil, the island of Puná, the valley of the Guayas and all the coast of Ecuador north of Cape San Lorenzo have considerable rainfall, while the coast from the Santa Elena peninsula north to Cape San Lorenzo, including the island of La Plata, is a region of scanty rainfall. From Cape San Lorenzo south there appear to be four climatic provinces. In the Montecristi region the climate is normally semi-arid but the hills receive a typical heavy Scotch mist. In the cordillera de Colonche, a ridge about 1,800 ft. high south of the above region, there is more humidity and very thick vegetation. In the Santa Elena peninsula there are no hills and the climate is extremely arid. Finally along the shore of the gulf of Guayaquil south-east from Santa Elena the climate is tropical with luxuriant and profuse vegetation. The Santa Elena climate is characteristic of the arid type. In 1927 the maximum temperature averaged 86.3° F, the minimum 65.4° F. The hottest months were Jan., Feb., March and April. The total rainfall for the year 1927 amounted to 4 in. and took place in the months of February and March.

No rainfall data are available for the humid part of the coast north of Cape San Lorenzo. At Recreo, a humid region on the coast in 0° 27' S. there was (July 1893-June 1894) a mean annual temperature at 6 A.M. of 72.3° F, at noon 77.1° F, at 3 P.M. 77.1° F and at 8 P.M. 74½° F, the average for the year amounting to 75° F. At another point on the coast in the humid zone, viz., La Maria (2° 54' S.) on the east coast of the Jambeli channel, north of Machala, the averages for the period January to May 1892 were: 6 A.M. 74.4° F, noon 82.8° F, 4 P.M. 85.8° F, 8 P.M. 81.3° F, the average being 81.1° F. At Guayaquil, which is 33 m. above the entrance of the Guayas river into the gulf, the mean annual temperature varies between 82° and 83° F and the rainfall for February and March 1882 is reported as being 3.1 and 6.1 in. respectively.

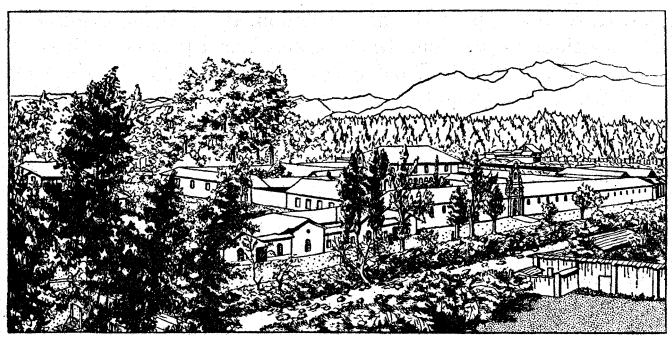
There seems to be a clearly marked division in the Pacific coastal region into cooler months from July to November and warmer months the rest of the year.

The tropical region east of the Andes is the zone of greatest rainfall. The average minimum temperature at Mera on the Pastaza (3,800 ft.) for the years 1923, 1924, 1926 and 1927 was 57.7° F; the average maximum 79.9° F and the mean annual temp. 68.8° F. The rainiest months were May in 1922, 1924 and 1925 and April in 1923 and 1927. The heaviest rainfall in any month was in April 1927 with 27 in. and the driest month was Feb. 1923 with 4.8 inches. There are few weather stations in Ecuador and figures of average, maximum and minimum rainfall through the whole country vary greatly in the different regions, coastal belt, the plateau and the eastern lowlands.

There does not appear to be any pronounced division into rainy and dry seasons. At Tena (1,700 ft.), another point east of the Andes, observations during 1925–27 show an average yearly minimum temperature of 65.3° F and an average maximum of 81.3° F. The mean annual temperature here is about 73.3° F. The rainfall in 1925 totalled 147.2 in. (12.2 ft.). Eleven months of observations in 1926 gave a total of 6.66 in. per month, which would be equal to a total of 80 in. for the year. But during the period Jan.–June 1927 there was a total of 107.2 in. averaging 18 in. per month, which if continued the entire year would amount to 201 inches. The best series of observations, and in fact the only ones available to show the climatic conditions in the temperate zone of the Andes is that for which we are indebted to Mr. J. W. Mercer of the South American Development Co., owners of the Zaruma mines, 2,500 ft. above the sea. These observations carefully made over a period of 30 years (1897–1927) show an average daily minimum temperature of 64.4°, an average daily maximum temperature of 81.5° F. In addition, the records for the hour 8 P.M. show for the 30 years an average temperature of 69.8° F. The hottest temperature recorded was 93° F, the lowest 51° F. The average temperature for the 30 years is 72.9° F. The rainfall takes place almost totally in the months from December to May. The average yearly total for the 30 years is 66.9 inches.

Flora.—The flora varies from that of the tropics to that of icy mountains; from vegetation characteristic of humid and arid

regions on the Equator to lichens on the snows at *18,400* ft. above the sea. Corresponding to the broad climatic divisions the vegetation is classified into five types: *(1)* that of the arid regions on the low-lying Pacific coast; *(2)* that of the humid regions on this same coast and in the low-lying Amazon region east of the Andes; *(3)* that of the forests on the east and west slopes of the Andes up to about 10,000 ft. altitude; *(4)* that of



BY COURTESY OF THE PAN AMERICAN UNION

THE HOSPITAL OF ST. VINCENT DE PAUL, AT CUENCA, ECUADOR

the so-called "cereal" zone, a treeless region on top of the Andean plateau; and (5) the *"páramo"* or Alpine region which terminates in the region of perpetual ice and snow. Because of this great diversity of climate, the flora of Ecuador is exceedingly rich, and species before unknown from this region are constantly being discovered. J. N. Rose has recently raised the number of known species of cacti from *12* to *30*. Hitchcock has extensively studied the grasses which extend in great diversity from the lowlands to the snow line. W. Popenoe has described about 100 species of fruits. Ferns are abundant and of many types ranging from the filmy ferns of the fog-covered forests to the giant tree ferns of the tropical valleys. The genus *Eupatorium* occurs in many forms, more than 50 species being reported. Numerous species of the heath family are found in the forested mountains and the high *páramos*.

Among the more common economic plants are the *corozo* or ivory-nut palm (*Phytelephas macrocarpa*), which furnishes vegetable ivory for manufacturing buttons; the cocoa tree (*Theobroma cacao*), from which the cocoa bean is gathered; the fibre plant *Carludovica palmata* (not a palm), used for making "Panama" hats, the balsa tree or corkwood *(Ochroma lagopus)*, furnishing the lightest timber *(30* lb. per cu.ft.) in the world; and the cinchona tree which yields quinine. Wheat grows at elevations of from 4,500 ft. to *9.800* ft. and barley up to 11,500 feet. More than 100 kinds of useful woods have been described.

Mammals.—While in general mammals are comparatively scarce, according to Tate they are represented by a very wide range of species. In the forests east of the Andes the Primates are numerous, but on the west coast only three genera occur: spider-monkeys, howlers and capuchins. The Carnivora include the jaguar, puma, ocelot, foxes, weasel, *Tayra*, otter, skunk, grison, racoon, coatimundi and kinkajou. The Ungulates comprise the tapir, two kinds of deer and two sorts of peccaries. Among the rodents are the amphibious capybara (east of the Andes), paca, agouti and the rare *Dinomys;* the smaller forms include squirrels, rabbits, cavies and numerous rats and mice. There are numerous species of bats, including the blood-sucking vampire. Representatives of the sloths, anteaters and armadillos are not rare. The opossums, with half a dozen genera, include the web-footed *Chironectes*, and the curious little *Caenolestes*, the so-called "living fossil," of the high Andes.

The chief governing factor in the distribution of these animals is the Andes Mountains which run north and south through the country causing wide variations in the climate. Broadly speaking the climates are tropical from sea-level up to 5,000 ft.; sub-tropical from 5,000 to *11*,000 ft.; and temperate, from *11*,000 ft. up to snow-line. These conditions, modified by rainfall, act directly upon the vegetation and the animal life within the several zones, resulting in the evolution of specially adapted forms. The only indigenous animals under domestication are the llama and alpaca. Neither is abundant. But horses, cattle, sheep, goats and pigs are now raised everywhere. In the high plateaux, sheep and cattle thrive particularly well. A whaling enterprise, the Compañia Ballenera del Ecuador, operating from Santa Elena, was started in 1925. In *1926*, according to a report of the U.S. Consul, a catch of 370 whales was made which yielded 9,500 barrels of oil.

Remains of extinct vertebrates, such as mastodons and horses, are found in the Pleistocene deposits of the highlands and also of the Pacific coast. The natives at the time of the arrival of Pizarro, in 1527, ascribed these to a race of giants which formerly inhabited the country.

Birds.—Dr. Frank Chapman states that about 1,500 species of birds have been found in Ecuador. This is approximately one-fourth of the South American avifauna and is doubtless a larger number of birds than has been recorded from any other area of similar size. Ecuador owes its exceptional abundance of bird-life primarily to the extent and altitude of its mountains, which add to the lower or Tropical Zone, three additional zones, each of which has species that are restricted to it (endemic). They are the Sub-tropical Zone (alt. from *3,000* or 4,000 ft. to 9,000 ft.) with *237* species, the Temperate Zone (alt. 9,000–12,000 ft.) with 142 species and the Páramo Zone (alt. 12,000 ft. to snow line) with 33 species. These endemic zonal species have been derived from the Tropical Zone at the base of the Andes and also from both the south Temperate and the north Temperate Zones. Their existence affords an admirable illustration of the stimulating effects of change of environment on the evolution of species. For example, Ecuador is known as the land of humming birds, but it is not generally realized that only *66* of its 147 species are found in the Tropical Zone, while *81* are confined to the upper life zones and in large part at least, have therefore been evolved since the latter part of the Tertiary when the mountains they occupy were elevated.

The brilliantly coloured Tanagers (*Tanagridae*) are also commonly considered as characteristic of the American tropics, but of the 106 species found in Ecuador only *52* are known from the Tropical Zone, while *46* are confined to the Sub-tropical, and *18* to the Temperate Zone. Other families of birds with numerous species in Ecuador are the Pigeons *(Colztmbidae)* 26 species; Parrots *(Psittacidae) 38* species; Toucans (*Rhampastidae*) 19 species; Woodpeckers *(Picidae)* 37 species; Antbirds (*Formicariidae) 114* species; Woodhewers (*Dendrocolaptidae*) *31* species; Flycatchers *(Tyrannidae) 160* species; and Wrens (*Troglodytidae) 32* species.

Sixty-six species of birds that nest in North America visit Ecuador in winter. Among this number are the Carolina Rail, or Sora *(Porzana carolina)*, Blue-winged Teal *(Querquedula discors)*, Kingbird (*Tyrannus tyrannus*), Barn Swallow (*Hirundo erythrogaster)*, Red-eyed Vireo *(Vireosylva olivacea)*, Redstart *(Setophaga ruticilla)*, Rose-breasted Grosbeak (*Zamelodia ludoviciana*) and Scarlet Tanager (*Piranga erythromelas)*.

Fishes.—When compared with the Amazonian fauna, the freshwater fish fauna of the Pacific slope of Ecuador *(see* C. H. Eigenmann, *Mem*. Carnegie Mus., vol. ix., pp. 1–350), is relatively meagre, only about *60* species being included. The fishes of the eastern part of Ecuador are as yet practically unknown. Although the species and many genera are now different, all of the fishes of the Pacific slope streams are similar in character to their Amazonian relatives and were evidently derived from them before the uprising of the Andes. This Pacific slope fauna is characterized by the lack of certain usual Amazonian types such as the electric eel and the piranha. One of the most remarkable of Ecuadorian fishes according to Dr. Henn of the Carnegie Museum is the "raspabalza" *(Plecostomus spinosissimus*), which is a sort of plated catfish, so well protected by its spiny covering that, if care is taken not to frighten it, it may be picked up by hand from the sandbars. In the same waters, the Guayas system, occurs a blind catfish, the "ciego" (*Cetopsis occidentalis*), the eyes of which are covered with thick skin.

Another celebrated Andean species found in Ecuador is the so-called volcano fish *(Astroblepus grixalvii)*, which, by means

of its disk-like, sucking mouth and prickly fins, is enabled to live in torrential mountain streams. Formerly this fish was erroneously said to be thrown in great quantities during eruptions from subterranean lakes within volcanoes.

Reptiles. — All the major groups of reptiles are known. According to Ruthven there are fresh-water and land turtles, crocodilians, lizards and snakes. Among the lizards, the beautiful "fan-Iizards," "American chameleons" or Anoles are conspicuous for their delicate changeable colours and flashing throat fans. Other interesting lizards are the *Ameivas,* active and conspicuous on bright warm days; the blind lizard, *Amphisbaena,* frequently found in ant and termite nests; the spiny Echinosaura; and several geckos. The snakes of Ecuador vary in size from thread-like *Helminthophis,* which burrows in decaying wood, to the large boa *(Constrictor constrictor).* There are fresh-water snakes, sea snakes, tree snakes, ground snakes and burrowing snakes. Many are harmless, but there are numerous venomous species. Among the latter are several opisthoglyph snakes. several protoglyph snakes, coral snakes (*Elaps* or *Micrurus*) and the dangerous solenoglyph pit-vipers, notably the *fer de lance* (*q.v.*). There are also various tree snakes, such as *Oxybelis,* interesting for their attenuated form and habit of resembling vines. The crocodilians are represented by a true crocodile and the broad-snouted caiman. A few fresh-water turtles and the large land tortoise *(Testnrdo denticulata)* are known.

Insects.—While the insect inhabitants of Ecuador embrace numerous genera and species representing the most important orders, no comprehensive survey has been completed. Campos enumerates some 1,550 known species, chiefly butterflies and moths (*Lepidoptera*); beetles *(Coleoptera);* grasshoppers and their allies (*Orthoptera*); and bees and ants (*Hymenoptera*). Of beetles alone there are estimated to be 8,000 species. In general it may be said that for each 1.500 ft. of elevation there is a new province of insect life. *Lepidoptera* have been collected on the slopes of Antisana at 16,000 ft. altitude. A giant beetle (*Dynastes hercules*) attains a length of five inches. Certain click beetles and fireflies are noted for their phosphorescent light. Among the *Diptera* is found or rather was found the mosquito *Aedes argenteus,* the carrier of the yellow fever germ, known also as *Stegomyia fasciata.* Below 1,500 ft. elevation also occurs the mosquito (*Anopheles albimanis*), carrier of the malaria germ. Numerous parasitic insect pests abound among the Indians.

POPULATION, GOVERNMENT, ETC.

Population. — No complete census of Ecuador has ever been made. The total population is variously estimated from two to four millions. An official estimate in 1941 gave 3,011,062. Probably 60% or even more is pure Indian, 25 to 30% mestizo, and at most 15% white There are a few Negroes on the coast. Guayas is the most populous province, with Manabí, Pichincha, Chimborazo, Azuay and Tungurahua following in order. The language of the whites and mestizos is Spanish; that of most of the Indians is Quéchua, although some speak Spanish; in the forest region to the east of the Andes the Jibaro language is spoken among the wild Indians.

Some attempts to attract European immigration have been made, but with little success. In the early 1930s some Jewish colonists entered the country. All in' all, however, there has been probably a smaller proportion of new blood brought into Ecuador since independence than into any other country of South America.

Government. — Under the constitution of March 29. 1929, Ecuador is a centralized republic with the customary legislative, executive, and judicial branches of government. Freedom of worship and of the press is granted, and the civil rights of women assured. Public credit is guaranteed, and funds set aside for payment of the public debt cannot constitutionally be diverted to other purposes. The Congress, consisting of a senate and a chamber of deputies, meets, in theory, on August 10 of each year. The senate is composed of one senator for each of the 15 interior and coast provinces, one for the eastern provinces jointly, and 15 functional senators representing groups, as the universities, the journalists and scientific academies and societies, industry. labour etc. The chamber of deputies is composed of one deputy for each 50,000 inhabitants in each province. Senators are elected for four years, deputies for t o. Suffrage is granted all literate men and women over 21 years of age.

The president, elected by popular vote, serves four years and cannot be re-elected. In addition to a cabinet appointed by the president, there is a council of state which comprises various high functionaries. The cabinet comprises seven members: the ministers of Government and social welfare, foreign relations, education, public works, agriculture and promotion, finance and public credit, national defence. The supreme court is the highest tribunal and consists of 10 justices and an attorney general elected by congress for a term of six years. Eight superior courts have regional jurisdiction. In actual practice during recent years the Government has been a dictatorship under one individual or a group, and constitutional guarantees have been suspended. In 1937 a constituent assembly met at Quito to draw up a new constitution, but was dissolved after a dispute with the provisional president.

There are 17 provinces, 67 cantons, and 498 parishes. Each province is ruled by a governor, each canton by a *Jefe Politico* and each parish by a *Teniente Politico.* The Galápagos islands are under a Territorial Chief. The Oriente is divided into the two provinces of Napo-Pastaza and Santiago-Zamora.

Army, **Navy,** and Aviation. — In 1935 the army consisted of 702 officers and 6,833 men. Military service is compulsory for one year for men on reaching the age of 20. Lots are drawn to determine who undergoes special training at that time. All men from 18 to 50 years of age are part of the reserves. There is, in addition, a national police force, with a personnel of 3.433, charged with maintaining internal order. One military hospital is at Quito, another at Guayaquil. The 1939 budget allotted 29,414,000 sucres, or 22% of the total, to national defence. The Ecuadorian Government maintains at the aviation base at Guayaquil a school of aviation where young Ecuadorians are trained as pilots and in the mechanics of ground air service. It is here that numbers of men have become proficient in the various branches of air service. The navy has one cruiser, with a personnel of 394 officers and men.

Religion. — Of the pre-Inca religions the only one remaining is possibly that of the Jibaro Indians of eastern Ecuador, which Karsten says is wholly unaffected by Christianity. In this there is no notion whatsoever of a supreme being and creator of the Universe, but it is by no means a pure demonology. The Inca religion has apparently entirely disappeared *(see* INCA**).**

The Spaniards made the conquest of Peru not only a territorial extension of their power but a means of conversion of the aborigines to the Roman Catholic religion. The capitulation of July 26, 1529 made Hernando de Luque bishop of Peru. and Pizarro, when he returned from Spain after having made this contract, took with him a number of Dominican priests, among them,, Fray Vicente de Valverde. Soon more priests, this time Mercedarians, arrived and the campaign to convert the Indians was well started. Luque never went to Tumbez to take over his charge but Valverde was made bishop at Cuzco over all of Peru. González Suárez states that by the end of the 17th century there were in Ecuador alone 42 convents belonging to the Dominicans. Franciscans, Augustinians, Mercedarians, Jesuits, and barefooted Carmelites. The number of priests was very large, Quito alone having, as he states, about 1,000 priests. Great discord reigned and "great damage was caused to the moral advancement of the people by the bad example not only in lack of virtue among the priests, but by their lack of good manners." González Suárez concludes, however, that the convents were the cradle of culture. It is certain that. by the end of the 17th century. no part of the Andean region remained unvisited by the missionaries In 1767 the Jesuits were expelled from all the Spanish dominions in America.

The opposition to the official religion was intended to restrict clerical influence in political affairs. The growth of liberalism resulted in 1889 in the church tithes (10% of the value of the production of the farms) being abolished; a tax of 3 per mill on the value of the farms was substituted In 1902 civil marriage was permitted and in 1904 the Church was placed under State control,

the foundation of new religious orders was forbidden and new religious communities were denied entrance. In addition all members of the episcopate had to be Ecuadorians. The State took over the landed property of the religious orders and administered it under a board of charities which now gives a pension to the friars. The excuse for this latter action was stated to be the great wealth of the church, gained largely through participation in legacies and by labour which received no "earthly" pay.

In recent years a few Protestant missionaries have penetrated the country and are at work among the Indians east of the Andes (Tena and Macas). There is now absolute freedom of religion in Ecuador. The Catholic Church has an archbishop at Quito and bishops in Ibarra, Riobamba, Cuenca, Guayaquil and Puerto Viejo.

Education. — The Ministry of Public Instruction exercises supervision over all educational institutions whatsoever. Higher education is provided at the Central university of Quito, the University of Cuenca, the University of Guayaquil, and the Junta universitaria of Loja, all of them Government-supported. The Central university has faculties of law and social sciences, physical and natural sciences, philosophy and letters, and medicine. The national veterinary school, a school for nurses, and a vaccination institute come under the last; a school of agronomy under the faculty of physical and natural sciences, and a section of pedagogy under that of philosophy and letters. The University of Cuenca has faculties of medicine, and of law and political and social science, along with a school of painting and art, and the superior school of mining engineering. Faculties of law and social science, medicine, pharmacy, and odontology, and physical sciences and mathematics, and a school for nurses come under the University of Guayaquil. The Junta universitaria has only a faculty of law and political and social sciences. Teacher training is provided in four normal schools, two in Quito, and one each in Cuenca and Guayaquil. In addition, short elementary normal courses have been established in seven cities. Despite the financial vicissitudes which the country has gone through in recent years, valiant efforts have been made to improve educational facilities.

A committee consisting of experts in educational methods, school architecture, public health, etc., known as the National Council on Education, was appointed by the Government in 1935 to reorganize primary and secondary educatiop along modern lines, by issuing pamphlets to interpret the ideals of the new type of school, by building experimental schools, organizing demonstration schools for Indians, and establishing welfare centres for underprivileged children of pre-school age. Some of the results of the increased emphasis on education are already evident.

The national appropriation for education in 1938 was $1,211,800 U.S., about 13.6% of the total budget. In 1937 there were 2,580 elementary schools, with 209,000 enrolment, and 17 secondary schools, with 5,124.

The 1937 enrolment figures showed a 6% increase in attendance over 1936 and 17% over 1935. To provide necessary funds for education the Government is requiring municipal governments to increase their contributions toward defrayment of school costs. Revolutionary changes in secondary school requirements were made during 1937 and 1938, with radical changes in the curricula which break down the rigidity of the old system and its excessive pre-requisites and, through enlargement of the number of elective courses, makes for flexibility. Further efforts at school improvement are being made by encouraging teachers to improve themselves. In 1938. over 50% of the Ecuadorian teachers held no diplomas or certificates of any sort, and only 16% had adequate professional training in normal schools. In a campaign against illiteracy the Government has attempted to impose a fine upon landowners for each illiterate person over 21 years old working on the property. These fines, under the law, would be reimposed each two years.

In addition to the National Library at Quito are municipal libraries at Quito. Guayaquil, and Riobamba.

TRANSPORTATION AND FINANCE

Transportation.—Guayaquil, situated on the Guayas river some 40m. from the ocean, is the chief port. Almost all of the country's foreign commerce flows through it. The Guayas is navigable for 40m. above Guayaquil. Several other small rivers are navigable, as is the Marañón (the upper Amazon) in the eastern part of the country.

Railways. — Slightly over 600m. of railway are in operation. the most important being the Guayaquil and Quito railway, 297m. in length, which connects the capital with the coast. Its construction. completed in 1908, is regarded as having been one of the most difficult ever attempted. Its cost was in excess of $19,000,000, averaging $68,345 per mile.

Originally a private enterprise, it is now under Government control.

With the exception of the Guayaquil and Quito Railway Company's telegraph and telephones, all the mail service, telegraphs, wireless and telephones of Ecuador are directed by the Ministry of Public Instruction.

Highways. — During recent years new highway construction and rehabilitation of old roads has been pushed extensively. In the single year 1936, the automobile highway mileage increased from 2,428 to 2,710m. or 12%. In 1938 695km. of the Inter-American Highway were open to traffic, and 395km. under construction.

Aviation. — Ecuador has external communication by air with all parts of America, to the north through Colombia, and to the south through Peru. Aviation facilities were materially improved in 1938, when Quito became a regular port of call for north-south aeroplanes.

Revenues. — Revenues and expenditures for the year 1938 were estimated at 120,700,000 and 127,300,000 sucres respectively, a deficit of 6,600,000 sucres for the year. The ordinary budget for 1939 was estimated to balance at 130,950,000 sucres, 9% over the 1938 budget, and nearly 50% in excess of the original budget for 1937.

Decline of the sucre in international exchange was partially responsible for the increase in terms of sucres.

Revenues for 1939 were estimated to come from the following sources: taxes on State monopolies, 25%; import duties, 24%; consular fees, 6%; petroleum taxes, 5%; substitute for sales tax, 5%; income tax, 5%; port duties, 4%; postoffice, 4%; stamp tax, 3%; rural property tax, 3%; telephone and telegraph, 1%; miscellaneous, 15%. Expenditures mere allotted in the following proportions: national defence, 22%; public works and communications, 15%; education, 15%; treasury, 9%; interior, 9%; social welfare. 7%; public debt, 6%; foreign affairs, 5%; general expense, 4%; State pensions, 4%; judiciary, 2%; others, 2%. Three extraordinary budgets for 1939 were also authorized: 4,745,590 sucres for the State railways, which were placed on an autonoinous basis; 2,800,000 sucres for the construction and maintenance of highways, to be financed by special taxes; and 495,000 sucres for the maintenance of rural schools.

Public Debt. — The public debt of Ecuador includes $12,262,700 in dollar bonds; £71,300 railway bonds, guaranteed by the Government; 8,974,500 francs of Government-guaranteed railway bonds; and 26,800,000 sucres in internal debt. Ecuador has the longest present record of default of any Government in South America, dating back as far as 1915. Overdue interest on some bonds now equals the principal.

Currency-exchange. — Ecuador was on a gold standard, adopted in 1898, until 1912, when payments in gold were stopped by decree. Although the bank-note circulation increased to a considerable extent after 1914 (41,698,991 sucres on Aug. 10, 1927) the exchange rate was maintained with very light fluctuations at about the legal parity of $0.4867 to the sucre, until in the middle of 1918 it declined in value to 35 cents U.S.A. This situation was due to the effects of the war and to the passage of the "law of the inconvertibility of bank notes" which was really a moratorium. This law probably saved the banks, particularly the Banco Comercial y Agricola of Guayaquil as it absolved them from paying gold for their notes, but certainly did great injury to the country at large. In Nov. 1918, the sucre suddenly rose in value to 45 cents and held this to the beginning of 1920 when it was quoted at 47½ cents. The exchange market then broke suddenly

and the sucre depreciated in value until it reached 18½ cents, when. by executive decree of Nov. 16, 1922, the Government took over the monopoly and complete control of all foreign bills of exchange, fixing the rate of exchange at about 47 cents. This official rate was subsequently reduced to approximately 33 cents and, eventually, to 25 cents, remaining at the latter level until official control was abolished in Oct. 1924.

Meanwhile, in the open market, the sucre had fallen as low as 17 cents; following abolition, however, it rose as high as 25.6 cents before beginning a slow decline which carried it to approximately 16 cents.

On the recommendation of the American Commission of Financial Advisers, the sucre was stabilized at 20 cents gold U.S.A. The monetary system was fundamentally reformed by a law treating a central bank and by a monetary law, both of which were approved and issued on March 4, 1927. Under these provisions the sucre was placed on a gold basis, at the rate of five sucres to the then current U.S. dollar. In Feb. 1932, however, due to world-wide depression conditions, the gold standard was abandoned, and the sucre began a steady decline. Attempts at exchange control, made in 1935, were abandoned the following year, resumed, and again abandoned in July 1937. The system of import permits was then used for a while, suspended for a time, and again placed in operation toward the middle of 1938 in order to arrest the country's mounting import balance. The sucre was then controlled at approximately 15 to the dollar until May 1940, when the ratio was changed to 18 to 1.

By executive decree of Dec. 30, 1937, the Central Bank of Ecuador was reorganized on a more conservative basis than formerly. Its function is to control credit in the country by restricting the credit flow to member banks, by limiting credit to the Government, and through use of flexible rates of rediscount and interest.

Production and Commerce. — Ecuador's chief product is cocoa, in which it is third in world production. Cocoa beans were exported to Europe as early as the 16th century, and until the present century Ecuador was the world's leading producer. By the second decade of the century, however, it had been exceeded by Brazil, and more recently by the Gold Coast of Africa as well. This relative decline is due not only to increased production elsewhere, but to local difficulties as well. especially to the ravages of the fungous witchbroom disease and of the monilia disease. By 1936 production had fallen from a former high of 16% of world output to 2·7%. Nevertheless, in 1937 cocoa accounted for 30½% of the country's exports. and the country's prosperity still depends primarily on cocoa.

Coffee now ranks second among exports of the country, accounting in 1937 for 15% of all exports. Bananas have been exported since 1931, and comprised 3·4% of the total exports in 1937. Most of the banana holdings are in foreign hands, but a Government decree of July 8, 1938 restricted the holdings of a single company to 80,000 hectares, and required the sale of any excess to Ecuadorian citizens within five years.

Another industry of Ecuador is the production of tagua, or vegetable ivory, a palm fern whose fruit is used as a substitute for the elephant tusk product. The toquilla, or "Panama" hat, so called because exports enter world trade through Panama, is made from the straw of a native plant (*Carludovica palmata*). Exports of tagua comprised 11·1% of all exports in 1937, of toquilla 4·9%. Sugar and cotton are also produced, but have not been developed to the extent that the soil and climate permit.

Mineral Production. — Gold production has, in recent pears, been stimulated by the decline of the sucre, but is still small. In 1938 it aggregated 824,207 grams.

Development of petroleum resources began in 1925. In that year 144,943bbl of crude petroleum were produced, and the output has steadily increased until it is between two and three million barrels annually (2,249,740bbl. in 1938). Around 95% of the production is in the hands of one British company, whose royalties and other payments to the Government averaged £39,544 annually from 1927 to 1936 inclusive. The rate of payments was increased by agreement in 1938. These receipts are an important part of the national revenues, but the country gets little benefit from the oil industry otherwise. Approximately a sixth of production is refined in the country, sufficient to supply domestic needs.

Petroleum aggregated 10·5% of exports in 1939. Cyanide precipitates, exported entirely to the United States, accounted for another 11%. Because these two commodities and gold are produced almost exclusively by foreign interests and their export does not provide exchange, they are reported separately from other exports.

Foreign Commerce. — In terms of sucres, Ecuador's foreign commerce has been on the increase in recent years, but actually this has been due to the fall of the sucre. Exports and imports in recent years (expressed in dollars) were as follows:

	1936	1937	1938	1939
Exports . .	13,493,000	14,928,000	12,614,000	11,341,000
Imports . .	10,857,000	11,980,000	11,064,000	10,173,000

The principal countries of origin and destination during those years, with the percentage going to each, were as follows:

	Exports				Imports			
	1936	1937	1938	1939	1936	1937	1938	1939
United States .	23·0	21·7	37·5	49·1	22·5	25·2	34·6	48·7
Great Britain .	21·8	19·6	4·6	3·7	17·1	15·7	7·7	5·5
Germany . .	8·3	9·2	17·5	6·8	16·6	16·4	24·1	18·1
France . . .	5·5	4·4	8·0	6·5	3·5	3·1	4·4	5·0
Italy . . .	2·3	3·8	1·5	2·2	2·6	2·9	3·2	3·0
Japan . . .	2·1	1·9	2·4	3·9	3·1	2·8	7·4	5·2

The rise in trade with Germany has been due primarily to the use of aski marks, but considerable friction has arisen over what Ecuador has regarded as bad faith in re-exporting the goods purchased and selling in competition with Ecuador.

Imports are foodstuffs, machinery, textiles, and other manufactured goods.

HISTORY

Archaeology and Antiquities. — All that is known about human life in Ecuador up to a few years before the arrival of the Incas, *i.e.*, about two or three generations before the arrival of the Spaniards in 1527 is contained in archaeological and linguistic remains, for writing of any kind mas not only unknown to the earliest inhabitants but even to the Incas themselves.

At various places in the western lowlands, in the central highlands and even in the forests east of the Andes are found archaeological remains, which prove the existence at certain times of a considerable culture. Although objects have been found which according to Uhle point to a relationship with the Maya civilization in Central America. which was flourishing as early as A.D. 68 and probably much earlier, other objects indicate the presence of man in Ecuador several thousand years ago.

The pre-Inca archaeological remains of Ecuador are of three non-related types of culture. One, peculiar to the high Andean valleys, a second. to the Pacific coast lowlands, and a third, to the forested region east of the Andes. The first two types prove, says Uhle, that two, perhaps independent, migrations from Central America took place, and that the emigrants were profoundly influenced afterward by a widely different environment. The region east of the Andes has furnished little archaeological material, but this shows a close affiliation with objects found in the great forest area along the upper Amazon, whose inhabitants Uhle believes migrated from Central America, but turned eastward from the isthmus of Panama to follow the north coast through Colombia, Venezuela and the Guianas to the mouth of the Amazon, which they ascended Perhaps at the same time there was a contemporaneous filtration of people south by way of the numerous waterways which drain into the Caribbean sea. The first type of remains, *i.e.*, those peculiar to the high Andean valleys of Ecuador, may be subdivided into three minor classes in each of

which the remains show a more or less centralized development. Remains of the first subdivision are found in the three northern provinces, Carchi, Imbabura and Pichincha. Those of the second class come from the region near the volcanoes, Tungurahua and Chimborazo, and those of the third subdivision from the provinces of Cañar, Azuay and Loja in southern Ecuador.

The most noteworthy features of the ceramic art of the first subdivision are long slender vessels found in large numbers in the deep, well-like tombs at Angel and vicinity, and bowls painted with many motifs of great interest in aboriginal decoration. The second subdivision is characterized by vessels with thin walls, ornamented with straight or wavy parallel lines. This is the most important of all the ancient culture centres of the Andes because of the stratified sequence revealed in excavations, where six horizons have been recognized, according to Uhle. The lowest of these, which is called the Proto-Panzaleo, no. 1, shows profound Central American influence, as Uhle has declared. The Proto-Panzaleo, no. 2, which overlies the first, is a continuation of the first but with marked traces of a new influence from the north. The Tuncahuán overlying this is thinner and therefore indicates a period of shorter duration than the others, but it is more widespread, being found over almost the entire Andean region of Ecuador. It is marked by the disappearance of tripod vessels, by abundance of negative painting, and by the first white pottery ornamentation. Here also appear objects of copper. The next, or San Sebastián layer, contains new types of pottery vessels, and here progress was made in architecture, as shown by the ruins near Guano. In the fifth horizon from the bottom the art of Chimborazo reached its highest development. Negative and positive painting of earthenware flourished, and jars with conventional human faces and arms, placed in low relief on the necks and upper body parts of the vessels are characteristic. In this restricted region there is much pottery of this style, but none has been discovered beyond. Human bones and innumerable small shell beads have been found in some vessels, while in others yellow powder reveals Chicha sediment showing that they had been filled with liquid for the refreshment of the deceased with whom the receptacles had been buried. Many copper ornaments are in this horizon. This is the art of the Puruha who lived as late as the time of the Spanish conquest. The sixth horizon, *i.e.*, the most recent, is called the Huavalac and is characterized by "lost colour" ware.

CENTRAL AMERICAN INFLUENCE

Near Cañar, Azuay and Loja, a high degree of culture is revealed, of marked Central American influence. says Uhle. Here architecture reached a high plane as the ruins of splendid fortresses and other edifices attest. A wealth of gold ornaments and implements has been found in tombs at Chordeleg and Sigsig. In the second great cultural area, viz., that of the Pacific coast, climatic conditions were very different from those in the highlands, for the region is comparatively low and almost entirely covered with forests. This zone contains two cultural centres, one extending from what is now Esmeraldas south 150 m., and the other in the province of Manabi with its alternate arid and humid climatic conditions. These two cultures, says Saville, prove the existence of two distinct peoples whose occupancy extended over a considerable period, and whose highest development seemingly mas reached long before the coming of the Spaniards. Their cultures differ widely from those represented by the artifacts of the highlands, and apparently there was no connection between the two

In some respects the most interesting culture in Ecuador is that of Esmeraldas. Prominent features are the surprising advancement it shows in modelling clay figures and the great progress in gold working. A dominant feature is the almost microscopic character of many of the objects fashioned in filigree; another is the occurrence of jewels of pure platinum or of platinum and gold filigree. Many pieces are so closely allied to Mayan artefacts as to be almost indistinguishable. The type of culture in general is intermediate between the Mayan and that of the Peruvian coast.

Of the Manabi culture, the outstanding feature is the development of stone architecture, almost entirely unknown in the interior highlands and entirely on the Esmeraldas coast. The Manabi sculptures are unique in South America, says Saville, and have been found in the ruins of houses in hilltop villages and in a few town sites on the arid plains of Manabí. These sculptures include stone seats, believed to have been used ceremonially in household sanctuaries, sculptured slabs of stone, or bas-reliefs, representing female deities, etc., columns recalling those of Costa Rica, birds, animals and human figures in stone. A few pieces of copper and some ornaments of gilded copper are the only examples that have been discovered thus far of the metal work of the ancients of Manabi. In their towns the dead were buried in bottle-shaped tombs cut into the solid rock as well as in mounds or "tolas."

The third great zone of culture east of the Andes, has not been studied. It is represented by a few remains in the Napo region which distinguish it from that of the neighbouring highlands and the Pacific coast; it is apparently related to one farther east near the mouth of the Amazon.

Writing was unknown before the Spanish conquest. At the time of the arrival of the Incas in Ecuador, a number of languages were spoken. Several of these survived the super-position of the Inca language, *i.e.*, the Quéchua, to the time of the arrival of the Spaniards. One, the Esmeraldas, has died out only in recent years, while two, the Cayapa-Colorados and the Jibaro still survive owing to their existence in inaccessible regions. On the basis of geographic names as well as the vocabularies of the three known pre-Inca languages above mentioned, the following languages are recognized as having been in existence at or shortly before the arrival of the Incas:

Quillacingas, Pastos, Caranquis (or Imbaburas or Cayapa-Colorados), Tacungas or Panzaleos, Puruhaes, Cafiaris, Paltas and Jibaros, Bolona (Rabona and others), Esmeraldas, Manabitas or Mantenos and Mochica (or Yunga).

Sefior Jijón y Caamafio thinks that the oldest types represented in Ecuador were the Cayapa-Colorados, the Jibaros and the Chimús and that the others represent modern elements in Ecuadorian ethnology. For Inca history see INCAS.

SPANISH CONQUEST

Spaniards' Arrival. — In 1526 Bartolomé Ruiz, the pilot of Francisco Pizarro, having been sent south from the main base of the second expedition for the conquest of Peru, at that time situated at the mouth of the San Juan in what is now Colombia, rounded Cape Pasado to 1° S. and returned. He was thus the first European to cross the Equator on the Pacific coast of South America, and to see the shores of what is now Ecuador. Ruiz first reached the Esmeraldas where the present town of Esmeraldas is situated and discovered there three large settlements of Indians who received him in a very friendly manner. They wore jewels of gold and three of the Indians who came out in canoes to receive Ruiz, wore golden diadems on their heads.

Ruiz on his return to the San Juan informed Pizarro of his discoveries, and then, joined by Pizarro and Almagro, made a second voyage as far south as Atacames, discovering more large towns, much cultivated ground and a formidable array of well-armed Indians. Returning to the island of Gallo, in 1° 57' N., they sought reinforcements. Early in 1527 Pizarro sailed to the gulf of Guayaquil opposite the town of Tumbez where they saw the undoubted signs of a great civilization, confirmed by a cruise as far south as Santa (9° S.). Pizarro returned to Spain where, by the contract between himself and the Crown, dated July 26, 1529, he was appointed captain general and "adelantado" of the region. He returned, this time with a large retinue, among them his four brothers, his young cousin Pedro Pizarro, the future historian, and several Dominican priests. He sailed from Panama on Dec. 28, 1531, with three small vessels carrying 183 men and 37 horses, and in 13 days arrived at the bay of San Mateo, in northern Ecuador, where he landed his forces and commenced a devastating march along the entire western coast to the gulf of Guayaquil. He crossed this in boats to Puná, where a destructive war was waged with the unfortunate natives. After subjugating them Pizarro crossed over in ships to the mainland where now is

situated the town of Thmbez. Pizarro and his forces left Thmbez on May 18, 1532, founded the city of San Miguel, marched onward in search of the Inca Atahuallpa, made him prisoner and massacred his forces. Atahuallpa was executed in the square of Caxamarca on Aug. 29, 1533, and the Inca empire came to an end.

Pizarro, desirous of forbidding the entrance of adventurers into Peru to make discoveries on their own account, sent Sebastián de Benalcázar as his representative to govern San Miguel which was at that time the key to Peru. In Nov. 1533, Benalcázar learned that Pedro de Alvarado, one of the conquerors of Mexico, had sailed from Guatemala to take the kingdom of Quito, which was famous for the riches of Atahuallpa. Benalcázar collected a few Spaniards and Indians, marched from San Miguel in the last days of 1533 and crossed the cordillera of the Andes to the great highway of the Incas in the province of Loja, now Ecuador, at that time inhabited by peaceful tribes of Palcas. Following this north without opposition, he reached the pueblo of Tomebamba in the country of the Cañaris and persuaded these tribes to join forces with him against their enemies to the north. He then marched north through the "province" of Azuay, defeated the Indians at Riobamba and finally in May or June 1534 arrived at the "city of Quito" which he found in ruins. He then continued north to Cayambe where he received word that Almagro had been sent by Pizarro to join forces with him in opposing the expedition of Pedro de Alvarado, which had landed at Puerto Viejo March 1534 and which was proceeding with frightful hardships straight east from the coast through unknown forests to ascend the west slope of the Andes where no trails even existed. Returning to Riobamba, Benalcázar met Almagro and they founded the "city of Santiago de Quito" on Aug. 15, 1534, as an evidence of formal possession of the territory by Pizarro. This then was the first "city" to be founded in Ecuador. Alvarado when he finally reached the summit of the Andes, after one of the most extraordinary expeditions of the Spanish conquest, found that he had been outmatched. On Aug. 26, 1534, Alvarado agreed to retire from Peru.

Pizarro then proceeded to pacify Ecuador. The city of Santiago de Quito, founded near the present site of Riobamba, was moved to the present site of Quito, on Aug. 28, 1534 and the name changed to San Francisco de Quito. The territory embracing the most northern limits of the Inca empire was soon conquered and finally the conquest continued north into what is now Colombia. It was then continued east of the Andes. Lured by the account of fabulous riches, Francisco Pizarro appointed his brother Gonzalo, Governor of Quito on Dec. 1, 1540, and the final conquest of Ecuador took place. Leaving Quito in Feb. 1541, Gonzalo Pizarro crossed the Guamani pass of the Andes, 13,350 ft. above the sea, wandered in the forests east of the Andes many months and finally, after a feat of exploration which brought him to the Amazon and permitted Orellana, one of his lieutenants, to descend it to its mouth, returned to Quito in rags and with but 97 men, leaving his companions in unmarked graves in the forests east of the Andes.

Conquerors' Discords.—The period of conquest was followed by civil war among the conquistadores. Diego de Almagro and Francisco Pizarro perished by assassination and Gonzalo Pizarro rebelled against Spain. All the new possessions in South America were now erected by the Crown into the "viceroyalty of Peru" and in this governmental body was concentrated the executive power. To this was added a judicial body, the audiencia, and the first viceroy was the president of the first *audiencia* of Lima. In addition, Roman Catholicism, the State religion, was put in charge of a bishop; the first bishopric embraced practically all the viceroyalty. The first viceroy, Blasco Núñez Vela, arrived in Ecuador en route to Peru, but was defeated by Gonzalo Pizarro at the battle of Inaquito, near Quito, Jan. 18, 1546 He himself was killed and his head exhibited at Quito. Gonzalo Pizarro, however, did not long enjoy the fruit of his rebellion, for a new royal representative, Pedro de la Gasca, met and defeated him at Jaquijaguana, Peru, on April 9, 1548. Surrendering, he was executed almost forthwith.

The Government by viceroys continued for 274 years. For the first few years after the establishment of the Viceroyalty of Peru, the territory now known as Ecuador was ruled by its representatives in the "cities" of Quito, Guayaquil, Puerto Viejo, Loja and Cuenca. In 1545, the bishopric of Quito was formed of that portion of the bishopric of Cuzco extending from Payta north into what is now Colombia, and on Aug. 29, 1563, the audiencia of Quito was established with judicial authority over the region from Carchi on the north to Buenaventura on the Pacific and to far east of the Andes, covering all the explorations of Gonzalo Pizarro in 1541, south as far as the latitude of Payta, thus embracing the bishoprics of Quito and Popayán. Because of the isolation of the region from viceregal authority and the presence of the governor as president of the *audiencia,* that body came to be not only judicial in nature but administrative as well.

The audiencia, or presidency, of Quito, as it was almost interchangeably called, remained a part of the viceroyalty of Peru until, by royal edict of May 27, 1717, it was transferred to the newly created Viceroyalty of Nueva Granada, whose seat was at Bogotá. Six years later, the new viceroyalty was abolished, and Quito returned to the authority of the viceroy of Peru, but in 1740, when the viceroyalty of Nueva Granada was restored, Quito was again put under its jurisdiction, where it remained until the end of Spanish domination.

Independence.—The ultimate phase of colonial history, viz., the movement for independence, had its birth in the activities of Espejo (born in Quito, 1747), Antonio Ante, Juan Pio Montufar, and others. The first blow was struck in Quito on Aug. 10, 1809 but the new revolutionary government established soon perished and on Aug. 2, 1810. most of the leaders responsible for it were massacred in Quito. A second attempt on Oct. 11, 1810 set up the "Eight Provinces of the State of Quito" which fell in Dec. 1812. The royalists then maintained their power until May 24, 1822 when, with the assistance of Sucre sent by Bolivar the republican forces defeated the royalists at the battle of Pichincha and two days later Aymerich, the last president of the *audiencia,* capitulated. Ecuador, under the name of "department of the south," now joined with Venezuela and Colombia in the confederacy known as the republic of Colombia.

RULE OF THE PRESIDENTS

The efforts of Bolivar to maintain this greater republic were unsuccessful. Although Bolivar defeated Peru in 1829, fixing the limits between Peru and Colombia as those of the old viceroyalties of Lima and Bogotá, Venezuela soon after withdrew from the confederacy (Nov. 29, 1829) and at a constitutional convention in Riobamba (Aug. 14 to Sept. 28, 1830) the three departments of Azuay, Guayas, and Quito formed themselves into an independent State called "Estado del Ecuador en Colombia" and adopted the first constitution of what is now Ecuador.

The history of Ecuador since its separation from Bolivar's great State has been very largely that of its great dictators, of whom three stand out most prominently: Juan José Flores, Gabriel Garcia Moreno, and Eloy Alfaro. Its course has been complicated by internal struggles of Liberals against Conservatives, of sections against sections, and, particularly in the 20th century, by economic factors.

The first president of the new republic was General Juan José Flores, a Venezuelan by birth, who had identified himself with Ecuador and had led the movement for separation. President Flores represented a Conservative group, whose stronghold was inland Quito, conservative, aristocratic, and devoutly loyal to the Roman Catholic Church, in politics as well as in religion. There were, however, particularly in Guayaquil, elements in whom the liberal ideas of the 18th century ran strong. Coupled with this was sectional rivalry between Guayaquil and Quito.

By 1833, opposition to Flores, headed by Vicente Rocafuerte, became formidable, and soon revolt broke out. After over a year of indecisive civil war, the two rival leaders effected a compromise whereby Flores agreed to acquiesce in Rocafuerte's election as his successor in 1835. Four years later (1839) Flores returned as president, but soon had difficulties with congress, and after further disorders accepted exile in 1845, going to Spain. where he involved himself in plans for restoration of Spanish control. In

1851 he made an unsuccessful attempt to return to power.

Meanwhile, president had followed president, with only the exceptional one serving his full term. In Jan. 1860, while Ecuador was torn by internal dissensions, Peruvian warships blockaded Guayaquil and forced acceptance of a treaty recognizing Peru's boundary claims. This treaty was repudiated shortly, however, when the Government signing was overthrown in Sept. 1860 by a revolution headed by Gabriel Garcia Moreno, son-in-law of Flores, and one of the most distinctive figures in Ecuadorian history.

Gabriel Garcia Moreno (1821–1875) whose length of service amounted to 10 years and nearly 5 months (two terms), held power longer than any other president. He was starting a third term when he was assassinated on Aug. 5, 1875, thus having the second distinction of being the only president to die by assassination while in office. His period of power brought the Church Party to its zenith in Ecuador, so much so that Garcia Moreno's presidency was often referred to as a Jesuit Government. He perhaps did more for Ecuador than any other president, for he gave it the greatest blessing one can bestow on Ecuador—a strong government and peace. He caused the Roman Catholic Church to send out from Europe a number of Jesuit priests, eminent in science, to become teachers. Among these were Theodor Wolf, the geologist, Sodiro, the botanist, Menten, the astronomer, Dressel, the chemist and Kolberg, mathematician. He was a great patron of science, a man of extraordinary energy and a strict ruler. The reaction from his policy carried successive governments to greater and greater "liberalism" and finally to the deprivation of the Catholic clergy of their extensive landed properties, to the establishment of civil marriage and to freedom of worship.

The years following Garcia Moreno's death were marked, initially, by a reaction against the extreme clericalism of his time, but not for long. The issue of separation of Church and State continued to be bitterly fought, amid nearly constant internal disturbance. Not until the rise to power of Eloy Alfaro in 1895 did order and relative stability return to Ecuador. During his presidency (1895–1901) various restrictions upon clerical activity were enacted into law, comparable in most respects to those exercised by Spain during the colonial régime. His successor, Leónidas Plaza Gutiérrez, went further, and under him civil marriage and divorce were legalized and control of education taken from the hands of the church.

In 1906, former President Alfaro returned to power, and was elected president for a second constitutional term. Under him a new constitution was promulgated. It made the Government more centralized, forbade immediate re-election of a president, and set forth various liberal reforms. This constitution, the country's 12th in 86 years, lasted for 22 years, longer than had any of its predecessors. Under Alfaro, too, the railway from Guayaquil to Quito, first in the country, was completed (1909). In 1911, during a revolution against Alfaro's successor, the former president was arrested, and a few months later was dragged from his prison and murdered by a mob (Jan. 1912).

At the outbreak of the war of 1914–18, Ecuador proclaimed her neutrality, but after entrance of the United States into the conflict, relations with Germany were broken off and German shipping in Ecuadorian harbours seized.

A coup d'état in 1925 brought into power a "Junta" which dissolved Congress. Subsequently a military board assumed control and made Dr. Isidro Ayora president. In 1929 constitutional forms were resumed and Ayora's authority was confirmed by election. His administration, however, lost its army support by its budgetary policy and in 1931 Ayora resigned. Factional strife and minor uprisings, partly due to economic depression thereafter prevailed. In Aug. 1935, President Velasco Ibarra was deposed by the army, and a junta set up, with Federico Páez as its nominal head. The new government sternly repressed adverse criticism but, as internal unrest continued, Páez was forced to resign (Oct. 24, 1937), being succeeded by his war minister, Alberto Enriquez. Enriquez served until a constituent assembly, meeting Aug. 10, 1938, chose Dr. Manuel Maria Borrero and, subsequently (Dec. 1), Dr. Alberto Mosquera Narváez. Narváez, fourth president in 14 months, was able to retain his position only by force, crushing a revolution with artillery after two days' fighting, and died in office Nov. 17, 1939. His successor, Dr. Carlos Arroyo del Rio, resigned in favour of Andrés F. Córdova (Dec. 11) to run at the Jan. 1940 presidential elections. Elected, he took office Sept. 1940. Meanwhile, a serious revolution in January, headed by former President Jose Maria Velasco Ibarra, opponent of Dr. Arroyo del Rio in the elections, was suppressed, but unrest continued.

Behind the political unrest—aside from generally unsatisfactory world economic conditions, which hit Ecuador especially hard—was popular dissatisfaction over the lack of progress in settling the acute boundary dispute with Peru. Further complicating the situation was the fact that no one political leader could command general support from the country.

Despite political instability, the country has, since 1931, put into effect many reforms, most of them looking toward State control of resources and toward improvement of education. At the outbreak of the European war in 1939, Ecuador declared her neutrality, and collaborated closely with the United States in its policies of hemisphere defence.

ECZEMA, a common and important inflammation of the skin originating without visible external irritation, and characterized in some stage of its evolution by a serous exudation. For an attack of eczema two conditions are necessary; a predisposition or special irritability of the skin, and a directly exciting cause. The first condition is usually inherited or depends on some underlying constitutional state. The number of such states inculpated and their diversity are expressions of our ignorance of the real causation, but there is an undoubted relationship between eczema and certain forms of functional neurosis, particularly asthma. Sufferers from rheumatism and gout are also prone to eczema, though the exact relationship is much disputed. Eczema is not contagious, though when complicated by pyogenic micro-organisms (impetigo), it is both auto-inoculable and contagious. Females (except when menstruation is becoming established, and at the menopause) are less liable to be attacked than males. In old age the sex influence is lost.

An attack of eczema is usually described as acute or chronic, but the only distinction lies in its greater or less intensity at the time of description; it has nothing to do with the length of time that the disease has lasted. It usually begins with local itching and burning and an erythematous blush, on which numerous tiny vesicles form. The vesicles grow larger, run together, and either burst or are broken by the patient's scratching, a clear fluid exuding which stiffens linen. The discharge does not dry up at once, but continues to exude—hence the name of "weeping eczema" when this is a prominent symptom. In some cases papules predominate, in others, especially when the face is attacked, erythema is more marked. The general health seldom suffers appreciably, unless the itching is so bad as to make sleep impossible. The irritation and local heat may be out of all proportion to visible changes in the skin, and in neurotic patients the nervous excitement may be extreme. The attack may affect any part of the body, but it usually begins at one of the following sites: the bends of the elbows or knees, the groins, between the buttocks, the groove behind the ears, the scalp, the palms or the soles, and the breasts of women. According to its position the form of the eczema is somewhat modified. On the front of the legs and arms, there is uniform redness. On the scalp it is generally seborrhoeic, and in children, especially when pediculi are present, it will become pustular. On the palms and soles it brings about thickening of the epidermis and the formation of cracks.

Treatment is unsatisfactory. Some cases are benefited by X-rays, others by alkaline bicarbonates or calomel, but the condition seems to wax and wane, or even disappear in an arbitrary way and the last treatment employed is given the credit. The only safe statements are *(a)* that the inflamed area should be protected from air and irritation and (b) that highly seasoned foods should be avoided.

EDAM, a town in the province of North Holland, close to the Zuider Zee, about 13 mi. NNE. of Amsterdam. It is connected with the Zuider Zee by a fine canal protected by a large sea-lock (1828). Pop. (1940) 8,941. Germany occupied Edam in 1940.

Edam took its name and origin from the dam built on the Ye, which joined the Purmer lake close by. Free access to the Zuider Zee was obtained by the construction of a new dock in 1357, when the town also received civic rights from William V. of Bavaria, count of Holland. Owing to the danger of the extension of the Purmer and Beemster lakes, Philip II. of Spain caused a sluice to be built into the dock in 1567. In the next century Edam was a great shipbuilding centre, and nearly the whole of de Ruyter's fleet was built here; then the harbour began to get silted up, and commercial and industrial activity slowly waned. The Great Church (St. Nicholas) probably 14th century, was largely rebuilt after a fire in 1602, which destroyed nearly the whole town. It contains some fine stained glass and carved woodwork of this period. The Little Church (15th century) was demolished in 1883, except for a portion of the nave and the old tower and steeple. The town hall dates from 1737, and there is a museum founded in 1895. Cheese making is important and Edam gives its name to the "sweet-milk cheese" *(zoetemelks kaas)* made throughout North Holland.

EDDA, the title given to two very remarkable collections of old Icelandic literature. Of these one bears that title from the middle ages; the other is called *Edda* by a comparatively modern misnomer. The word is first met with in *Rígspula,* a fragmentary poem dating from the first half of the 10th century, where it is introduced as the name or title of a great-grandmother. From the 14th to the 17th century, this word—but no one has formed a reasonable conjecture why—was used as a synonym for the technical laws of the Norwegian Court-metre, *Eddu regla,* and "never to have heard or seen Edda" signified "never to have learned the art of poetry." The only known work by the name in the middle ages was the miscellaneous group of writings composed by Snorri Sturluson *(q.v.;* 1179–1241), the greatest name in old Scandinavian literature. It is believed that the *Edda,* as he left it, was completed about 1222. Whether he gave this name to the work is doubtful; the title first occurs in the Uppsala Codex, transcribed about 50 years after his death. The collection of Snorri is now known as the *Prose* or *Younger Edda,* the title of *Elder Edda* being given to a collection of mythological and heroic poems, discovered by the Icelandic bishop of Skblaholt, Brynjólfr Sveinsson, in 1643 and erroneously named by him the *Edda of Saemundr.*

The Prose Edda.—Properly known as *Edda Snorra Sturlusonar,* this was undoubtedly written by Snorri Sturluson. It is divided into five parts, the Preface or *Formáli, Gylfaginning, Bragaroebur, Skáldskaparmál and Hdttatal.* The Preface bears a very modern character and simply gives a *résumé* of the biblical story of the creation and the flood, with a brief account of the rise and spread of paganism. *Gylfaginning,* or the Delusion of Gylfi, on the other hand, is the most precious compendium which we possess of the mythological system of the ancient inhabitants of Scandinavia. The *Bragaroeður,* or sayings of Bragi, are further legends of the deities, attributed to Bragi, the god of poetry. The *Skáldskaparmál,* or Art of Poetry, commonly called *Skdlda,* contains the instructions given by Bragi to Aegir, and consists of the rules and theories of ancient verse, exemplified in copious extracts from Eyvindr Skáldaspillir and other eminent Icelandic poets. The fifth section of the *Edda,* the *Hdttatal,* or Number of Metres, is a running technical commentary on the text of Snorri's three poems written in honour of Hákon, king of Norway. Affixed to some mss. of the *Younger Edda* are a list of poets and a number of philological treatises and grammatical studies. These belong, however, to a later period than the life of Snorri Sturluson

The three oldest mss. of the Prose *Edda* all belong to the beginning of the 14th century. The Wurm ms. was sent to Ole Wurm in 1628; the Codex Regius was discovered by the indefatigable bishop Brynjólfr Sveinsson in 1643. The most important. however, of these mss. is the Uppsala Codex, an octavo volume written probably about the year 1300. There have been several good editions of the *Edda Snorra Sturlusonar,* of which, perhaps, the best is the edition published by the Arnamagnaean Society in Copenhagen in 1848–52, edited by a group of scholars under the direction of Jón Sigurðsson, and the more recent Danish (1900) and Icelandic (1907) editions of Finnur Jónsson. There are English translations by T. Percy, *Northern Antiquities,* from the French of P. H. Mallet (1770); by G. Webbe Dasent (Stockholm, 1842); by R. B. Anderson (Chicago, 1880); by A. G. Brodeur (1916). The last-named version contains the whole of the *Prose Edda,* with the exception of the very technical and

practically untranslatable *Háttatal.*

The Elder Edda, Poetic Edda or *Saemundar* Edda *hins* frdda was entirely unknown until about 1643, when it came into the hands of Brynjolfr Sveinsson, who, puzzled to classify it, gave it the title of *Edda Saemundi multiscii.* Saemundr Sigfússon, who was thus credited with the collection of these poems, came of an old and distinguished Icelandic family, and lived from about 1056 to 1133. The poems themselves are many of them only fragments of longer heroic chants now otherwise entirely lost. They treat of mythical and heroic legends of an early Scandinavian civilization, and are composed of the simplest and most archaic forms of Norse verse. They present many difficult problems upon which scholars have expended an inexhaustible but not always conclusive erudition.

It may be said with some confidence, however, that the 34 poems usually included in the Edda were composed between the 9th and 12th centuries, and that they were the composition of poets, whose very names are unknown, but who were certainly Norwegians by birth or descent and shared the same religious and poetic convention. These poets were not uncultured; they were affected by the beliefs of the Christianized peoples of western Europe; they used as material for their art Danish and German legends; they were influenced by the Anglo-Saxon and Irish literatures. Irish influence is marked in *Rígspula;* to what extent it affected the Edda as a whole is debatable. The honour of having been the home-land of the Edda has been claimed in turn for Norway, Iceland, the British Isles and Denmark. The two Atli poems can be assigned with certainty to Greenland; *Grímnismál* appears from internal evidence to have been composed in Norway, and *Grípisspá* in Iceland; *Rígspula* may have been composed in Ireland or in northern England. The meaning of the title "Edda" is still in doubt; it has been variously explained by scholars as "Tales of a Grandmother," "Poetics," "The Book of Oddi"—Saemundr resided at Oddi—"Poems of Death and Destruction," from the Irish word aitte, signifying "deaths." The poems appear to have been collected from oral tradition and committed to writing in the 12th century, probably in Iceland and possibly by Saemundr.

The most remarkable of the poems in this priceless collection is the *Völuspá,* or prophecy of the Völva or Sibyl. In this chant we listen to an inspired prophetess, "seated on her high seat, and addressing Odin, while the gods listen to her words." She sings of the world before the gods were made, of the coming and the meeting of the Aesir, of the origin of the giants, dwarfs and men, of the happy beginning of all things, and the sad ending that shall be in the chaos of Ragnarok. The melodies of the verse, exquisite in their extreme and severe simplicity, are wholly rhythmical and alliterative, and return upon themselves like a solemn incantation.

Hávamál, the Lesson of the High One, or Odin, follows; this contains proverbs and wise saws, and a series of stories, some of them comical, told by Odin against himself.

In *Hyndluljóð,* the Lay of Hyndla, the goddess Freyja rides to question the volva Hyndla with regard to the ancestry of her young paramour, Ottar. With this poem, the first or wholly mythological portion of the collection closes. What follows is heroic and pseudo-historic. The Volundarkviba, or Song of Völundr, is engaged with the adventures of Volundr, the smith-king. during his stay with Nidudr, king of Sweden. Volundr, identical with the Anglo-Saxon Wêland and the German Wieland (O.H.G. *Wiolant*), is sometimes confused with Odin, the master-smith. This poem contains the beautiful figure of Svanhvit, the swan-maiden, who stays seven winters with Volundr, and then, yearning for her fatherland, flies away home through the dark forest. Helgakvida *Hjörvarðssonar,* the Song of Helgi, the Son of Hjörvarð, celebrates the wooing of Helgi of Svava, who, like Atalanta, ends by loving the man with whom she has fought in battle. Two Songs of Helgi the Hunding's Bane, Helgakvida *Hundingsbana,* open the long and very important series of lays relating to the two heoric families of the Volsungs and the Nibelungs. A very curious poem is the Song of the Sun, *Sólarljóð,* which forms a kind of appendix to the Poetic Edda. In this the spirit of a dead father addresses his living son, and exhorts him, with maxims that resemble those of *Hávamál,* to righteousness of life. Though found only in the 17th century copies of the Edda, *Sólarlióð* appears from internal evidence to have been written in the 11th century, and to have been the composition of a Christian mystic who had not completely shed heathen modes of thought and expression.

The principal ms. of this *Edda* is the Codex Regius in the royal library of Copenhagen, written continuously, without regard to prose or verse, on 45 vellum leaves. This is that found by Bishop Brynjólfr. Another valuable fragment exists in the Arnámagnaean collection in the University of Copenhagen, consisting of four sheets, 22 leaves in all. These are the only mss. older than the 17th century which contain a collection of the ancient mytho-heroic lays, but fragments occur in various other works, and especially in the *Edda* of Snorri. The text of the *Poetic Edda* has been edited by Mobius, Sophus Bugge, Hildebrand, Sijmons and Gering, Finnur Jónsson, Neckel, Detter and Heinzel (1903), and Sievers (1923). Twelve poems from the *Poetic Edda* were translated into English verse by Amos Cottle in 1797; the poet Gray produced a version of the *Vegtamskvistra;* but the first translation of the whole was that published by Benjamin Thorpe in 1866; the most recent English versions are those of Olive Bray (1908) and H. A. Bellows (1923).

The Eddic poems were rearranged, on *a* system of their own, which differs entirely from that of the early mss., by Gudbrand Vigfússon and F. York Powell, in their *Corpus poeticum boreale* (1883). This is a collection, not of *Edda* only, hut of all existing fragments of the vast lyrical literature of ancient Iceland.

(X.; R. P. Co.)

EDDINGTON, SIR ARTHUR STANLEY (1882–), British astronomer, was born at Kendal, England, Dec. 28, 1882. He mas educated at Owen's college, Manchester, and Trinity college, Cambridge, where he was Senior Wrangler in 1904 and Smith's Prizeman in 1907. In the latter year he was elected fellow of his college. From 1906 to 1913 he held the post of chief assistant at the Royal observatory at Greenwich; and in 1913 he became Plumian professor of astronomy at Cambridge. In 1914 he was made director of the observatory at Cambridge, and in the same year was elected fellow of the Royal Society.

He is a member of many British and foreign scientific societies and was awarded the Hopkins prize of the Cambridge Philosophical society (1918–21), the Pontécoulant prize of the French academy (1919), the gold medal of the Royal Astronomical society (1924), the Bruce medal of the Astronomical Society of the Pacific (1924), and others. He was knighted in 1930 and was awarded the Order of Merit in 1938.

Eddington's principal researches are on the motions of stars, stellar evolution and relativity. His first published paper in 1906 was on the systematic motion of stars; this was followed during the next nine years by a series of papers on the structure of the heavens. "The Systematic Motions of the Stars of Professor Boss's Preliminary General Catalogue" appeared in 1910; in this paper Eddington analyzed this catalogue of 6,188 stars and some of his later researches are based on this analysis. In 1916–17 he published papers on "the radiative equilibrium of the stars," dealing with the interior of a star. Eddington grasped the significance of the theory of relativity at an early stage of its development, and, by means of articles, books and lectures, gave a clear exposition of the theory. His own contribution to this theory is embodied in a paper published in 1921 on "a Generalisation of Weyl's Theory of the Electromagnetic and Gravitational Fields." He collaborated in the preparation of this *Encyclopædia.*

His published works include *Stellar Movement and the Structure of the Universe* (1914), *Report on the Relativity Theory of Gravitation* (1918), *Space, Time and Gravitation* (1920), *The Mathematical Theory of Relativity* (1923), *Stars and Atoms* (1927), *The Expanding Universe* (1933). *(See* ASTRONOMY.)

EDDIUS or **AEDBI,** a Kentish choirmaster, was employed by Wilfrid (c. 634–709), bishop of York, to organize services in Northumbria. His Life of Wilfrid is the earliest extant work of an Anglo-Saxon author. It is invaluable for its period, though strongly partisan in feeling, and was used by Bede for his *Historia.*

See Eddius, *Vita Wilfridi* (Rāine, *Historians of Church* of *York,* London, 1879–94, 14); ed. with trans. and notes by B. Colgrave (Cambridge, 1927); Bede, *Hist. Eccl.* (edit. Plummer, Oxford, 1896), iii., 2.

EDDY, MARY BAKER (1821–1910), the founder and leader of the Christian Science movement, was born on July 16, 1821, at Bow, near Concord, New Hampshire, U.S.A. She was the youngest of the six children of Mark Baker and Abigail Ambrose Baker. Her father was a man of local prominence, first at Bow and later at Tilton, New Hampshire; a landowner, a justice of the peace, a member of the committee having charge of the public schools and a deacon of the Congregational Church. Her mother was the daughter of Deacon Nathaniel Ambrose, of Pembroke, New Hampshire, who also represented the same type of citizenship.

In 1843 Mary Baker married Major George W. Glover, a native of Concord, New Hampshire, but a resident of Charleston, S.C. By occupation a contractor and builder, he had an honorary title "by appointment to the staff of the governor of South Carolina." Major Glover died six months after their marriage while they were at Wilmington, N.C. Her only child (also named George W. Glover) was born three months later, after she had returned to New Hampshire. During the next nine years she lived at Tilton, New Hampshire, with her father, or with her sister Mrs. Abigail Tilton, and occupied herself to the extent allowed by delicate health in caring for her child and in teaching. For a time she conducted a private school for young children; at other times she was an extra teacher in a New Hampshire Conference Seminary.

In 1853 Mrs. Glover married Dr. Daniel Patterson, of Franklin, N.H., a dentist. This marriage proved to be extremely unfortunate. After ten years of alternate care and neglect, he finally deserted her at Lynn, Mass., whither they had removed from New Hampshire. Ten years later (at Lynn, in 1873) she obtained a divorce from him for desertion following after adultery. In 1877 Mrs. Glover (Mrs. Patterson having resumed this name) married Asa Gilbert Eddy, of Lynn, an ardent Christian Scientist and the first of her followers to engage in the public practice of Christian Science. After his death (at Lynn, in 1882) Mrs. Eddy continued as a widow until she died at Chestnut Hill, Mass., near Boston, on Dec. 3, 1910.

Considering that educational facilities for women were limited when Mrs. Eddy was young and that her attendance at school was interrupted by delicate health, the education she obtained was exceptionally liberal. In addition to attending ordinary schools, she attended the Academy at Tilton and received instruction from tutors. An extensive reader of good literature, she also wrote acceptable poetry and prose which appeared frequently in New England publications long before her discovery of Christian Science. After her discovery of Christian Science, she contributed the principal literature of this subject, employing for this purpose a distinctive literary style, as well as a notable ability to elucidate metaphysical and religious topics.

As a child and as a young woman, Mrs. Eddy showed an exceptional interest in religious subjects. In the development of this interest she was aided by her devout and intelligent mother, as well as by the Congregational pastors at Bow and Tilton and by other ministers whom her parents frequently entertained. At the age of 12, she had the courage and independence to dispute a point in theology when she was examined for church membership. Between then and her first marriage, she often discussed religious topics with her parents and with ministers, exhibiting a comprehension which they regarded as remarkable. Shortly before her first marriage, one of her pastors who also tutored her for six or seven years (Rev. Enoch Corser) predicted for Mrs. Eddy a great future and spoke of her as "an intellectual and spiritual genius."

The beginning of Mrs. Eddy's interest in religious or spiritual healing can be traced to an incident which occurred when she was 12 years old, immediately before her examination for admission to the Congregational Church. During a fever her mother commended prayer to God. Then, as Mrs. Eddy has related, "I prayed; and a soft glow of ineffable joy came over me. The fever was gone, and I rose and dressed myself, in a normal condition of health" (*Retrospection and Introspection*, p. 13). This incident, together with others of an extraordinary nature, is believed to have contributed to the observation and study which resulted ultimately in Mrs. Eddy's discovery of Christian Science.

Mrs. Eddy regarded her discovery of Christian Science as resulting directly and immediately from an incident which occurred at Lynn in 1866. While returning from a meeting of Good Templars, she fell on an icy street and was injured severely. Carried to a nearby residence, she was attended by a physician and cared for during the night. The next day she was removed to her home, as a local newspaper reported at the time, "in a very critical condition." On the third day after this injury, having obtained little or no relief, Mrs. Eddy asked for her Bible, opened it so that she read an account of Christian healing (Matt. 9:2) and again experienced an immediate recovery.

Concerning the study which then ensued, Mrs. Eddy has written: "The Bible was my textbook. It answered my questions as to how I was healed; but the Scriptures had to me a new meaning, a new tongue. Their spiritual signification appeared; and I apprehended for the first time, in their spiritual meaning, Jesus' teaching and demonstration, and the Principle and rule of spiritual Science and metaphysical healing,—in a word, Christian Science."

Mrs. Eddy's published works on Christian Science began with a pamphlet copyrighted in 1870, entitled *The Science of Man*, of which only one small edition was printed. In this pamphlet she said, "In the nineteenth century I affix for all time the word *Science* to *Clzristianity;* and *error* to *personal sense;* and call the world to battle on this issue." Her principal work, the Christian Science textbook, first entitled *Science and Health* but afterward entitled *Science and Health with Key to the Scriptures*, was issued in 1875. Occasionally revised by the author, "only to give a clearer and fuller expression of its original meaning," and finally revised in 1907, this book continues to be the fundamental and standard statement of Christian Science. Other published works by Mrs. Eddy include *The People's Idea of God* (1886), *Christian Healing* (1886), *Unity of Good* (1891), *Rudimental Divine Science* (1891), *Retrospection and Introspection* (1891), *No and Yes* (1891), *Church Manual* (1895–1910), *Miscellaneous Writings* (1896), *Christ and Christmas* (1897), *Christian Science versus Pantheism* (1898), *Pulpit and Press* (1898), *Messages to The Mother Church* (1900; 1901; 1902), *The First Church of Christ, Scientist, and Miscellany* (1913).

Naturally, Mrs. Eddy was the first practitioner and the first teacher of her religion. As a practitioner, she demonstrated her religion by healings in many cases, until duties which could not be left to others required all of her time. As a teacher, she taught students until she was obliged to leave class teaching to students whom she selected for this work. She began to organize the Christian Science movement in 1876 when she and a few of her students formed the Christian Science Association. After three years she and a selected number of her followers organized the Church of Christ, Scientist, into which the earlier Association was merged. In 1892, she and a selected number of her followers organized the Christian Science mother church, the First Church of Christ, Scientist, in Boston, which succeeded the earlier church. The Mother Church, together with the branch churches or local congregations throughout the world, constitutes the present organization. In 1892 Mrs. Eddy also founded the Christian Science Publishing Society as an agency of her Church.

Next to what Mrs. Eddy did as the discoverer and founder of Christian Science, her greatest work was done as the leader of the Christian Science movement. Although living a rather secluded life (at Lynn until 1882; in Boston from then until 1889; at Pleasant View, near Concord, N.H., from then until 1908; and afterward at Chestnut Hill, near Boston), she initiated and either directed or supervised every important activity of her Church; and she formulated the plan, set forth in the *Church Manual*, by which its affairs are to be conducted permanently. From the general point of view, Mrs. Eddy was a remarkable woman, for it was no light task to propose a new system of religious philosophy which was at the time and is even now so radically at variance with much of prevailing orthodox beliefs. She was 57 when she founded the Church of Christ, Scientist, which in half a century extended its branches throughout the world totalling (1928) 2,370 churches and societies. She followed this with the founding of the *Chris-*

tian Science Journal, a monthly magazine which she edited for 11 yrs.; and 15 yrs. later she founded the *Christian Science Sentinel,* a weekly. In 1908, when Mrs. Eddy was 87, she established the *Christian Science Monitor,* a successful daily newspaper, giving news free from sensation and scandal. Nor did Mrs. Eddy, at these times, relinquish her other activities. Her own life illustrated and demonstrated her proposition that "prayer, watching and working, combined with self-immolation, are God's gracious means for accomplishing whatever has been successfully done for the Christianization and health of mankind" *(Science and Healtlz,* p. 1). *See* CHRISTIAN SCIENCE. (C. P. S.)

EDE, a town in the province of Gelderland, the Netherlands, on the railway Utrecht-Arnhem. Pop. (1940) 34,567. Ede is the seat of the important Dutch Enka rayon-silk industry. At 3 mi. distance is the castle of St. Hubertus, containing the modern art collection of Rroller-Muller, which gained special fame for its outstanding collection of paintings by Vincent Van Gogh.

EDELINCK, GERARD (1649–1707), Flemish copper-plate engraver, was born in Antwerp on Oct. 20, 1649. He learned the rudiments of the art in his native town under Gaspard Huybrecht. He then went to Paris in 1665 and worked under de Poilly. On the recommendation of Le Brun, he was appointed teacher at the academy established at the Gobelins to train workers in tapestry.

Edelinck with Nanteuil and Masson formed the great triumvirate of the best period of French portrait engraving. He excelled in rendering light and shade, colour and the texture of surfaces. He was the first to execute prints in the lozenge shape. Among his works, which number 341, are a "Holy Family," after Raphael; a "Penitent Magdalene," after Charles le Brun; "Alexander at the Tent of Darius," after Le Brun; a "Combat of Four Knights" after Leonardo da Vinci; "Christ Surrounded by Angels"; "St. Louis Praying"; and "St. Charles Borromeo before a Crucifixn — the last three after Le Brun. Edelinck engraved portraits of Louis XIV, Le Brun, Rigaud. Philippe de Champaigne (which the engraver thought his best), Santeul, La Fontaine, Colbert, John Dryden, Descartes, etc. He died in Paris on April 2, 1707. His two brothers, Jean and Gaspard François, and his son Nicolas, were also engravers, but did not attain to his excellence.

EDELWEISS (*Leontopodium alpinum*), a perennial plant of the composite familv (*Compositae*), native of the Alps and the Andes. It is a 'small herb reaching about 6 in. high, with narrow white woolly leaves, and terminal flowerheads enveloped in woolly bracts. The woolly covering is assumed to protect the plant, in the exposed situations in which it is found, by preventing its drying up through excessive loss of moisture. It is much sought after by some visitors to the Alps but although rather sporadic in its distribution it is not rare and grows readily in gardens under lowland conditions.

EDELWEISS. A HANDSOME WOOLLY PLANT, FOUND IN THE ALPS OF CENTRAL EUROPE, OFTEN GROWN IN ROCK GARDENS

EDEN, SIR ASHLEY (1831–1887), Anglo-Indian official and diplomatist, third son of Robert John Eden, third Lord Auckland and bishop of Bath and Wells, was born on Nov. 13, 1831, and entered the Indian civil service in 1852. In 1855 he helped to suppress the Santal rising, and from 1860 to 1871 was secretary to the Bengal government with an *ex officio* seat on the legislative council. Eden was (1871) the first civilian governor of British Burma; in 1877 he became lieutenant-governor of Bengal. He returned to England on his appointment (1882) to the council of the secretary of state for India, of which he remained a member till his death on July 8, 1887.

EDEN, though often used as the name of the garden in which, according to Gen. ii and iii, lived the first man created, is strictly the name of the region in which that garden was situated. The garden contained beautiful fruit trees providing food for the man whom God had appointed to till it. In it, too, were "the tree of the knowledge of good and evil" and "the tree of life," magical trees conferring upon those who ate of their fruit wisdom and immortality. The man and his wife were expelled from the garden because, having tasted, contrary to the divine command, of the fruit of the former, God feared that they might eat also of the other tree's fruit. The story blends many mythological conceptions which belong to the primitive age of Semitic religion. Close study of the story reveals that it is compounded of at least two traditions, one concerned with the tree of knowledge, the other with the tree of life. Prof. H. T. Obbink of Utrecht has suggested that the narrative has been generally misunderstood. His view is that the tree of life was really intended to furnish divine food by which the first man maintained his immortality, and that he was evicted from the garden to cut him off from this nourishment.

Many speculations have been made as to the site of the garden, which seems to be thought of as an oasis in a barren region According to Gen. ii 8 it was "eastward": verses 10–14 describe a river as flowing forth from it, and dividing into four streams One of these is the Euphrates, and another, "Hiddekel," almost certainly the Tigris. This would suggest a site north of Babylon. It is true that the Euphrates and the Tigris near Baghdad approach so closely together that the former discharges water through canals into the latter. Eut even if it be supposed that these two rivers might be regarded as coming from a common source no satisfactory explanation of the two reinaining rivers is offered. To define the site from these details is impossible; it is obvious, moreover, that verses 10–14 are a learned note intruded into the simple story. The attempt to locate a mythological garden is bound to be attended by considerable difficulty, and all that can be safely said is that the story in its present form combines two traditions, one of which placed the garden in the far east, the other in the far north, where, according to Babylonian tradition, the garden of the gods was to be found. Yet another tradition as to the garden, which underlies Ezek. xxviii 12–19, connects it with the mountain of God, placed by Isa. xiv 13 in the "sides of the north." (W. L. W.)

EDENBRIDGE, a market town in the Sevenoaks parliamentary division of Kent, England, 28½ mi. S.S.E. of London on the Southern railway, and 10 mi. W. of Tonbridge on the line to Redhill. Pop. of civil parish (1931) 3,254. It is pleasantly situated on the river Eden, an affluent of the Medway, in a valley between the Ragstone hills and the Forest ridges, on the Surrey border. The church of St. Peter and St. Paul is principally Perpendicular. The town has considerable agricultural trade and a chalybeate spring which is little used. Hever castle, 2 mi. S.W., is a beautiful moated mansion of the 15th and 16th centuries, but occupying the site of an earlier structure. This was rebuilt by Sir Geoffrey Boleyn, whose grandson, Sir Thomas, was father of Anne, second wife of Henry VIII, who here spent much of her life before her marriage and was visited by the king. There is a chapel of her family in the fine parish church of Hever. Not far distant is the modern Chiddingstone castle, on an ancient site. A block of sandstone in the park is called the "chiding stone," tradition asserting it to be a prehistoric seat of judgment.

EDEN HALL, LUCK OF, an old painted or enamelled glass drinking goblet preserved at Eden Hall, Cumberland, the seat of the Musgrave family, perhaps of the 10th century. It has the letters I.H.S. on the top. Round the vase is the verse given below. In the grounds of Eden Hall is a spring called St. Cuthbert's Well, and the story is that one of the early Musgraves surprised the fairies making merry at the well, and seized the goblet from the fairy king, who eventually acknowledged his

defeat and gave him the cup, but warned him:

> When this cup shall break or fall,
> Farewell the luck of Eden Hall.

Possessed of the cup, the knight of Musgrave is said to have at once prospered in a love-suit. There is a poem on the cup called "The Drinking Match at Eden Hall," by Philip, duke of Wharton, a parody on the ballad of Chevy Chase, reprinted in Edward Walford's *Tales of Great Families* (1877, vol. xi), as "The witty Duke of Wharton."

EDENKOBEN, a town of Germany, in the Bavarian Palatinate, 6 mi. N. from Landau, on the railway to Weissenburg. Population 5,218. It has a sulphur-spring. Its industries comprise iron orks, and the manufacture of machinery, furniture and cigars. It has also a large trade in wine, and is frequented for the grape-cure.

EDENTATA, an order of Mammalia (*q.v.*) comprising the sloths, ant-eaters and armadillos restricted to the warmer parts of America. But this name, meaning toothless, applies only to the ant-eaters. The teeth of sloths and armadillos, however, are abnormal in being of persistent growth, seldom differentiated, without enamel and invariably absent in the fronl of both jaws. A character distinctive of the order is the presence of accessory articular processes on some of the vertebrae. From this the name Xenarthra has been given to these groups to distinguish them from the pangolins and aard-varks of the Old World which were formerly associated with the American edentates as Nomarthra on account of the normal construction of the vertebrae. There is, however, no evidence of kinship between the ant-eaters of the Old and New Worlds, such resemblances as they exhibit being superficial adaptations to diet. The Pangolins and aard-vark are therefore dealt with separately in this article.

The existing edentates are divided into two sub-orders, the Pilosa or Anicanodonta and the Loricata or Hicanodonta.

Pilosa.—In the Pilosa the anus and external genitalia are close together on a common eminence or enclosed in a fold of skin, both the clitoris and penis being quite short, and there is no exoskeleton of dermal bones. There are two well defined tribes, the Tardigrada or sloths and the Vermilingua or ant-eaters. In the Tardigrada the jaws are short, strong and the wide mouth is provided with teeth and a short flat tongue; the tail is short or absent and the limbs are long and slender, the fore and hind feet are similar in being long and narrow and in having the two or three digits compactly united and furnished with long, curved, equal claws. In the skull the zygomatic arch is branched.

The existing sloths feed upon leaves and are entirely arboreal. Their limbs are especially modified to enable them to climb or hang back downwards on branches, and their long coarse hair harbours microscopical green algae which serve to conceal them in the trees.

The sloths are referred to two families, the Bradypodidae and the Choloepidae. In the Bradypodidae, or three-toed sloths, all the feet are furnished with three digits, and the soles are almost entirely hairy; there is a distinct tail; the hair on the head grows forwards, forming a frill round the face, the nostrils are small and the ears very simple. Sometimes known as aïs, they are found in the tropical forests of South and Central America. The few known species are referred to two genera, *Bradypus* and *Scaeopus*.

The Choloepidae or two-toed sloths, also known as unau, have only two digits on the fore foot; the soles are quite naked; there is no external tail, the hair on the head grows backwards, the nostrils have a thickened margin and the ear is provided with a valvular flap. The single genus *Choloepus*, represented by a few species, ranges from Nicaragua to Brazil.

In the Vermilingua or ant-eaters the snout is elongated and down-curved, the mouth has a very short gape, a long worm-like tongue and no teeth; the fore and hind feet are dissimilar and the digits of the fore foot are unequal in size, the third being the largest and armed with a great falcate claw and the tail is very long. In the skull the jaws are weak and the zygomatic arch is slender and unbranched. The ant-eaters are assigned to two families, the Cyclopedidae and Myrmecophagidae.

In the Cyclopedidae, containing *Cyclopes* (*Cycloturus*) *didactylus*, the silky or two-toed ant-eater, the limbs are adapted essentially for climbing. The fore foot has only two digits with strong claws which close upon a large cushion-like pad, the hind foot has four fused digits, each with a long claw, and capable of folding down on to the heel for grasping; the tail is prehensile and naked at the tip beneath but otherwise covered, like the head and body, with long silky hairs which on the head conceal the simple ears. The jaws and other parts of the skull are less specialized than in the next family. This little arboreal ant-eater, which is no bigger than a rat, is found in tropical South and Central America.

The Myrmecophagidae contain two very distinct forms, the great ant-eater (*Myrmecophaga jzcbata*) and lesser ant-eater or tamandua (*Tamandua tetradactyla*). The feet are adapted for progression on the ground, although in the tamandua they also serve for climbing. The fore foot has four clawed toes, and on its outer side a large supporting pad; the hind foot has five toes, with short claws, and is plantigrade; the hair is not silky and on the head is quite short so that the better developed ears are prominent. The skull differs from that of *Cyclopes* in having a weaker mandible and in the fusion of the pterygoids to prolong the narial passages. In the tamandua the tail is prehensile and covered mostly with small scales and short hairs, the hair of the body is short and smooth and the fore foot has a large carpal pad confluent with the ambulatory pad. This ant-eater, which is about the size of a cat, lives in the forests of tropical America.

The great ant-eater (*Myrmecophaga jubata*), standing over two feet high, is purely terrestrial in habits. The hair on the body and tail is long, shaggy and coarse, the tail is rigid and not prehensile, the fore foot has a very large ambulatory pad and a small isolated carpal pad and the snout is much longer than in the tamandua. It lives in the swampy savannahs and forests of tropical America, feeding, like the other ant-eaters, mainly on termites, the nests of which it rips open with the great falcate claws of the fore feet.

Loricata.—In the Loricata the external genitalia are long and not associated with the anus, as in the Pilosa; there is a dermal bony exoskeleton and the hairy covering is usually scanty. The Armadillos which constitute this sub-order are divisible into several families.

In the Dasypodidae the bony exoskeleton consists of a head-shield, one or more free bands on the neck, a large compact scapular shield encasing the fore quarters, followed by from 6 to 13 free dorsal bands and a large solid pelvic shield over the hind quarters, the scutes of these areas being tolerably alike in size and shape; the flexible tail tapers to a point and its bony rings never consist of more than two rows of scutes; the skin of the lower surface is scantily hairy and tubercular; the legs are scaly above and there are five toes on each foot, those of the fore foot being provided with fossorial claws, the fourth toe being the longest, while on the hind foot the third and fourth are subequal and all the claws are smaller; the ears are large, situated on the sides of the head some distance behind the eye.

There are two subfamilies, the Dasypodinae and the Cabassoinae. The Dasypodinae have from six to eight dorsal bands, one neck band; the scutes are coarsely sculptured, and the tail has jointed rings. To this sub-family belong the six-banded armadillo (*Dasypus sexcinctus*) of Paraguay and Brazil, and many related species. A remarkable Brazilian species (*Scleropleura bruneti*) has the dermal scutes defective, especially on the back. These armadillos are active animals of small or medium size, ranging in length of head and body from about six inches in the pichi to a foot or rather more in the six-banded armadillo.

In the Cabassoinae there are from 11 to 13 dorsal and from three to four neck bands, the scutes are often polished; the scutes of the tail are not arranged in distinct rings and may be defective; and the fore feet are more fossorial, the claws of the third or third and fourth being specially enlarged. To this group belong the tatouay (*Cabassous unicinctus*) of Brazil and Surinam, and the giant armadillo (*Priodontes gigas*) of Brazil, which may reach a length of three feet.

The family Tatuidae contains the peba or nine-banded arma-

dillo (*Tatu* or *Tatusia*) which differs from the Dasypodidae in having the ears set close together on the top of the head, no bands on the neck, the scutes of the dorsal bands larger and differently shaped from the small scutes of the scapular and pelvic shields; the bands on the long tail are composed of three rows of scutes; in the fore foot the fifth toe is absent and the third is as large as or larger than the fourth, and the five toes of the hind foot are symmetrically arranged, the third being median. The genus ranges from Texas to the Argentine and is represented by a few species of which the best known is *Tatu novemcincta.* A rare species, the hairy peba (T. *pilosa*), is remarkable for having a coat of long hair concealing the scutes. It has been referred to a distinct genus *Cryptophractus.*

To the family Tolypeutidae belong the apars or ball armadillos, so-called from their power to roll up into a compact sphere. In adaptation to this protective habit there is beneath the very large pelvic and scapular shields a deep recess into which the limbs can be withdrawn. The tail is very short and rigid. They also differ from the Dasypodidae in having from two to four dorsal bands and in being more digitigrade, the second, third and fourth toes of the hind foot, which have broad hoof-like claws, and the tips of the long claws of the third and fourth digits of the fore foot resting on the ground during progression. The toes vary from five to three. A few species of the genus *Tolypeutes* are admitted. The best known is the common three-banded armadillo (T. *tricinctus*) from the Argentine.

The little silky armadillo or pichiciago (*Chlamyphorus truncatus*), the type of the family Chlamyphoridae, differs from all existing armadillos in having a continuous series of scutes, forming transverse bands, extending from the head-shield to the pelvic shield, the latter forming a vertical semicircular disc giving a truncated appearance to the hinder end of the body; in having the dorsal bands attached to the body along the middle of the back and overlapping its sides, which, like the ventral surface and legs, are clothed with silky hair, like a cloak; in the reduction of the ear to a tiny lobe close to the eye and in having the tail spatulate. The feet nearly resemble those of the Dasypodidae but have larger falcate claws. This armadillo, which is found in the sandy deserts of the Argentine, is an expert digger and largely subterranean in habits. A related genus, *Burmeisteria,* found in Bolivia, differs in having the shell adherent to the sides of the body and the bony scutes of the pelvic shield defective.

Extinct **Edentates.**—The fossile remains of edentates, found in abundance in Tertiary deposits of North and South America, show that the existing sloths, ant-eaters and armadillos are the widely divergent survivors of a great, and now waning, group represented in the past by large numbers of highly diversified genera, some of the species of which were colossal in bulk. Some of these fossils serve to link in a measure, not only the sloths with the ant-eaters, but the armadillos with both these groups.

Taking first the Pilosa, the discovery of sloths and ant-eaters, differing but little from existing species, in Pleistocene deposits of South America, needs only passing reference. Of far greater interest are the ground sloths, the Gravigrada, standing between the Tardigrada and the Vermilingua, with skulls and teeth as in the farmer and the rest of the skeleton more as in the latter. The known genera are grouped round three main types *Megatherium, Mylodon* and *Megalonyx.*

Megatherium had a longish, very strong tail, broad hips and very stout hind limbs, with a huge heel and only three toes, the third alone being armed with a large claw; the fore limbs were long and strong, and four-toed, the second, third and fourth toes being armed with claws, that of the third being exceptionally large; there were well developed collar bones; the skull had anteriorly protruding massive jaws, with a thick, branched zygomatic arch. There is no doubt that this great beast, measuring 18 ft. long, the skull being about two feet, fed upon foliage and twigs which he reached by rearing up against a tree trunk, supported on his hind legs and tail, and using his fore legs to pull down the branches, and a long flexible tongue to gather the leaves into his mouth. It also seems clear that in standing and walking on the ground he rested on the outer side of both fore and hind feet. The remains of *Megatherium* itself are found in Pleistocene deposits of the southern United States and South America. Related forms occur in the Pliocene of Argentina, and considerably smaller forms, regarded as ancestral, occur in Miocene beds of Patagonia.

Mylodon, although smaller, with the skull about a foot and a half long, closely resembled *Megatherium* in general form, but had weaker, short jaws, differently shaped, smaller teeth, and five toes on the fore foot and four on the hind, but evidently walked on the outer side of both feet, like *Megatherium.* Its remains are found in Pleistocene beds of North and South America. There are many related genera, also Pleistocene. Of particular interest was *Glossotherium* on account of the presence of bones in the skin beneath the hair, recalling the exoskeleton of the armadillos. Supposedly ancestral forms of *Mylodon* and its allies are found in Miocene deposits of Patagonia.

Megalonyx, with the skull a foot or more in length, found in Pleistocene and Pliocene deposits of North America, is distinguished from the preceding genera by having the first of the five upper teeth large, tusk-like and isolated. A large number of related genera from Miocene deposits in Patagonia are smaller and less specialized.

It is amongst the earlier Miocene forms of Gravigrada that we find evidence of convergence between the sloths and ant-eaters. Not only are they smaller than the later evolved forms but their limbs are more slender and their feet more normal, in the number and size of the digits, and in the hind feet being plantigrade, as in the great ant-eater.

With regard to the Loricata, many existing genera occur in the Pleistocene of Argentina and Brazil; and Pleistocene and Pliocene beds have yielded remains of a huge armadillo (*Chlamydotherium*), comparable to a rhinoceros in size and with teeth less simplified than in surviving species. A large number of genera approximating to existing forms have also been found in Miocene and earlier deposits in Patagonia. One of these, *Stegotherium,* is of particular moment from possessing long, narrow jaws with a few minute, simple teeth at the back of the mouth, thus approaching the long-jawed toothless ant-eaters. But excelling all in interest are the Glyptodonta, a tribe of extinct, highly specialized armadillos distinguished by having the entire body encased in an unjointed bony cuirass, in the fusion of the vertebrae of the back, the peculiar jointing of the neck so that the head could be withdrawn into the shell, and in the structure of the skull which was remarkably like that of *Megatherium,* in general appearance. To support the great weight of the cuirass the feet were short and broad with hoof-like nails especially on the hind feet; and the long tapering tail was jointed, with bony rings in its basal portion and encased in an unjointed sheath at the end. Some of these armadillos, like *Glyptodon* and *Panochthus,* from the Pleistocene of South America, were eight or nine feet long and about four feet high and they moved about slowly, grazing on herbage like huge tortoises. They died out in the Pleistocene; but the group is traceable through the Pliocene back to Miocene deposits of Patagonia.

Another group of extinct mammals, shown by the structure of their vertebrae to belong to the edentate stock, is the Taeniodonta or Ganodonta whose remains occur in Lower and Middle Eocene deposits in North America. In the structure of the skull and of the massive limbs this sub-order shows considerable resemblance to the Gravigrada; but although the median incisor teeth, both above and below, seem to be missing, the rest of the dentition is quite unlike that of typical edentates in being heterodont, with large canines and cusped, usually rooted cheek-teeth, all more or less covered with enamel. The best known forms are *Conoryctes, Psittacotherium* and *Hemiganus.*

The Lower Eocene of North America has yielded yet another group, the Palaeonodonta (*Palaeonodon, Metachiromys*), which has been claimed to be ancestral to the edentates. It is said to resemble the Loricata in the structure of the feet and other respects, such as the absence of incisor teeth, but differed in the absence of dermal bones and of cheek-teeth and the presence of large cutting canines. Since, moreover, the vertebrae were normally constructed and there was no union between the poste-

rior part of the pelvis and the anterior vertebrae of the tail such as is found in all typical Edentata, it is difficult to justify this classification.

PHOLIDOTA

The pangolins (*q.v.*) or scaly ant-eaters of Africa and tropical Asia were at one time associated with the Edentata mainly on account of their likeness to the South American ant-eaters in the absence of teeth, the weakness of the jaws, the enlargement of the salivary glands, and the length of the vermiform, extensile tongue; and to the armadillos in the possession of a hard dermal exoskeleton. But the resemblances to the former group are adaptive and due to similarity of diet and the exoskeleton is of a totally different type from that of the armadillos, since it consists of large, erectile, overlapping horny scales, composed of cemented hairs, there being no trace of bony matter in the skin. They show, indeed, no resemblances to the cdentates of any systematic importance and differ from them fundamentally in many characters, such as the absence of extra articular processes in the spinal column, the presence of a bicornuate, instead of a globular, uterus, of a diffused, non-deciduate, instead of a dome-shaped deciduate, placenta, etc.

The head is short and conical, with functionless facial vibrissae and a moist normal rhinarium as in *Myrmecophaga;* the ear sometimes has a distinct pinna but may be represented by a vertical slit only. The legs are short but the feet vary in structure according to habit. The fore foot has five toes of which the second, third and fourth are always armed with large claws, the largest being on the third; the first and fifth digits are very variable in size and are usually small clawed. The hind foot also has five toes which vary in size and in the size of the claws. The tail is also variable, sometimes being excessively long and prehensile, sometimes comparatively short and forming, with the hind legs, a kind of tripodal support; at other times it is intermediate in structure. The anus and external genitalia are situated close together on an eminence formed mainly by the enlarged anal glands, and the anus is sunk in a depression into which the ducts of the glands open; both the penis and clitoris are quite small.

Pangolins range in Asia from north India and south China to Ceylon and Borneo and in Africa from Sierra Leone and Uganda to the Cape. There are several different kinds. Some are almost entirely arboreal, some purely terrestrial, while others which live in the main on the ground also climb trees as well. Otherwise their habits are very similar. They feed mostly on termites, ripping open the nests of these insects with the strong claws of the fore feet. Their means of defence are the emission of a repulsive odour from the large anal glands and rolling into a compact ball with the hard, often sharp, erected scales presented to the enemy and protecting the soft-skinned hairy underside of the body from injury.

There are several species and genera, all referred to the family Manidae. But this is divisible into three sub-families. In the Asiatic species, the Maninae, the hinder end of the sternum or breast-bone is shaped like the blade of a spade, having a convex posterior edge and two forwardly directed spiniform angles. To this group belong the north Indian and Chinese eared pangolin (*Manis pentadactyla*), the Indian and Ceylonese thick-tailed pangolin *(Phatages crassicaudata)* and the Javanese and Bornean pangolin *(Paramanis javanica)*, which differ in many external characters.

In the African pangolins the end of the breast-bone is prolonged into two long rods running back to the posterior ribs. There are two well defined sub-families differing in habitat and correlated structural characters. The Smutsiinae, containing the genus *Smutsia* with the two species *temminckii* and *gigantea,* are terrestrial with the feet and tail adapted for ground life; and the Phataginae, containing the two small west African pangolins, *Phatagginus tricuspis* and *Uromanis longicaudata,* which differ from all other pangolin; in being adapted to arboreal life, their tails being exceedingly long and prehensile, and the feet with only four functional toes, the upper side of the fore foot being without scales.

Extinct Pangolins. — Bones of a large pangolin, indistinguishable from the African giant pangolin, have been found in a cave in Madras; in Lower Pliocene deposits of Samos occur *Palaeomanis* and earlier still are *Leptomanis* and *Necromanis* from the Upper Eocene phosphorites of Quercy.

TUBULIDENTATA

To the order Tubulidentata belongs the aard-vark (*q.v.*) or African ant-bear, *Orycteropus,* representing the family Orycteropodidae, which was formerly associated with the Ameriean edentates and the scaly ant-eaters because, feeding on termites, it has a longish snout, a long, extensile tongue, a small gape, no teeth in the fore part of the jaws and cheek teeth defective in enamel and of persistent growth. In no other respects does it resemble the edentates; and although it is like the scaly ant-eaters (Pholidota) in having normally articulated vertebrae and a bicornuate uterus, these are characters common to many orders of mammals. The aard-vark is a burrowing, heavily built animal, about six feet long, scantily covered with hair, with a long narrow head carrying huge rabbit-like ears and ending in a swollen mobile snout with terminal valvular nostrils closed with long hair. The tongue, although long, is not vermiform. The feet are powerful and very much alike except that the fore foot has no first toe; the toes are long, armed with huge flattened claws, and the second and third, which are the longest, are united by a deep and wide web; the fore foot is plantigrade, the hind digitigrade. The tail is long, stout and tapering; and the external genital organs are situated on a preanal eminence containing a pair of scent glands opening at the sides of the short penis and of the vulva, which is provided with a cordate flap-like clitoris. The teeth of the permanent set are unlike those of other mammals in being traversed by many tubules radiating from a central pulp cavity. They represent molars and premolars, the latter having milk predecessors; but in the newly born young traces of incisors and canines which never cut the gum have been discovered. There is evidence indeed that the ancestor of *Orycteropus,* before degeneration of the teeth set in, had no fewer than three incisors, one canine, five premolars and five or six molars on each side above and below, a larger number than is found in any order of mammals with typical heterodont dentition.

Aard-varks are found in Africa south of the Sahara both in deep forest and in the open. There are only two or three species known to be in existence.

Extinct **Aard-varks.**—A species, **O.** *gaudryi,* nearly allied to the living forms, occurs in Lower Pliocene deposits of Bessarabia and Samos; and a distinct genus, *Palaeorycteropus,* has been recorded from the Upper Eocene phosphorites of Quercy. Finally, it may be added, certain bones from the Miocene of Europe have been claimed to indicate a common ancestry for the armadillos, scaly ant-eaters and aard-varks; but the indications ard too doubtful to be trusted. **(R. I.** P.)

EDENTON, a city of north-eastern North Carolina, U.S.A., on an inlet of Albemarle sound, near the mouth of the Chowan river; the county seat of Chowan county. It is served by the Norfolk Southern railroad and river transportation. The railroad bridge across Albemarle sound is 4·8 mi. long. The population was 3.563 in 1930; in 1940, 3,835. Shad and herring fisheries are an important industry. and there is a U.S. Fish hatchery near by. The city is a large peanut and watermelon market. Edenton has some fine old homesteads and many historical associations. It was settled about 1658, and through the 18th century was a place of considerable social and political importance. The legislative assembly met here occasionally, and here lived the royal governors and various prominent citizens of the province, including Joseph Hewes, James Iredell, father and son, and Samuel Johnston. St. Paul's church was built in 1736; the court-house in 1767. In a house facing the court-house the "Edenton Tea Party" was held on Oct. 24, 1774, by 51 ladies, who signed resolutions that they would refrain from using tea or anything manufactured in England until the tax on tea should be repealed. On May 5, 1864, a naval engagement was fought near Edenton between the Confederate ram "Albemarle" and the Union "Sassacus," a wooden side-wheeler, resulting in favour of the Confederate ironclad.

EDESSA, the ancient capital of Macedonia (an older name is Aegae), situated 46 m. W. of Thessalonica on a beautiful stream in the centre of the kingdom, commanding the approaches from the coast to the interior. It was the original residence of the Macedonian kings; and after the seat of government was removed by Philip II. to the more accessible Pella, it continued to be the royal burial-place. At the celebration of his daughter's marriage here, Philip II. was murdered by Pausanias in 336 B.C. Though Alexander was buried at Alexandria the bodies of Eurydice and her husband Arrhidaeus were removed by Cassander to the ancestral sepulchre. On the occupation of the town by Pyrrhus the royal tombs were plundered by Gallic mercenaries. Owing to its position commanding the Via Egnatia, the town retainedits importance during the Roman and Byzantine periods. For its present condition, see VODENA.

EDESSA, the Greek name of an ancient city of N. W. Mesopotamia (in 37° 21′ N. lat. and 39° 6′ E. long.), suggested perhaps by a comparison of its site, or its water supply,[1] with that of its Macedonian namesake. It still bears its earlier name, Urhāi, modified since the 11th century (by the Turks?) to Urfa.

The oldest certain form is the Aramaic *Urhāi* ("Western" pronunciation Urhōi), which appears in Greek as an adjective as Ὀρροηνή,[2] -νοι[3] (perhaps also as a fortress with spring, as Ὀρρά[4]), and in Latin as *Orr(h)ei*,[5] and (in the inscription on Abgar's grave) *Orrhenoru(m)*.[6] The Syriac Chronicle ascribed to Dionysius of Tell-mahrē derives the name from a first king Urhāi, son of Hewyā (*i.e.* "Snake"), but neither this nor any other derivation hitherto suggested is satisfactory. The district name Osroēnē (for Ὀρροηνή) is in Syriac Bēth-Urhāyē. The Arabs pronounced the name er-Ruhā, and that form prevailed till it gave place to Urfa in the 15th century.

According to Pliny, v. 86, Edessa was also called Antioch, and coins of Antiochus IV. Epiphanes with the legend "Antioch on the Callirrhoe" may imply that he rebuilt and renamed the place (so Ed. Meyer in Pauly-Wissowa, Realencyclopadie, col. 1933, 66). Pliny indeed seems to call the city itself Callirrhoe, but K. Regling (Klio, i. 459, n. 1) may be right in his emendation which applies the title in Pliny to the sacred spring.

History.—Edessa-Urhāi is important mainly as the earliest seat of Syriac-speaking Christianity. About 132 B.C., when the Hellenistic empire of the Seleucids was breaking up, a native non-Greek dynasty succeeded in establishing a more or less independent State with Edessa as its capital on what came to be the frontier between the Roman and the Parthian dominions. The names of some 30 local kings survive, but little is known of its history, and the true tale of the planting of Christianity in this region is lost in the mists of legend. In A.D. 114 king Abgar VII. entertained Trajan on his way back to Syria (Dio Cass. xviii. 21), but in 116 after a general rising the Consul L. Quietus sacked the city and made the State tributary. Hadrian, however, restored the dynasty of Edessa, but made it a dependency of Rome. When L. Verus (163–165) recovered Mesopotamia from Parthia, it was not Edessa but Harriin that was chosen as the site of a Roman colony and made the metropolis by Marcus Aurelius (172). The fact that these decisive events have left no trace in the Christian traditions suggests that Christianity had not yet arrived at Edessa. The native religion of Edessa, according to Christian tradition, was connected with the Planets. In the *Doctrine* of Addai 24 Venus appears to be called Bath Nikal, a name for Ishtar of Babylonian derivation ("daughter of Nin-Gal": see C. Winckworth in J. *Th.* St. xxv. 402). One or both of the pools below the citadel containing sacred fish may have been sacred to Atargatis (*q.v.*), an Ishtar-Venus deity. In the citadel itself are still standing two pillars—there may once have been more—both 50 ft. high; on one of them is a pre-Christian Syriac inscription, which states that it was set up for Shalmat the queen, daughter of Ma'nu the viceroy (paṣgrība), together with a bas-relief or statue, now effaced. The fact that this inscription is in Syriac is a testimony to the Semitic tone of the culture of the little state; "Syriac," in fact, is the dialect of Aramaic then spoken in Edessa and its neighbourhood.

Before Christianity arrived at Edessa the more important parts of the Old Testament had been translated into Syriac by Jews, either at Edessa itself or in Adiabene under the encouragcinent of the then reigning house (Josephus, Bell. Jud. ii. 19, 4). This translation, slightly revised and supplemented, is still used by the Syriac-speaking churches and is known as the Pĕshīttа (*i.e.* the Simple version). Tradition connects the founding of Christianity in Edessa with Addai, a missionary sent by St. Thomas himself, who converted Abgar the king and many of the inhabitants. As, however, he is also said to have brought the Gospel in the form of the Diatessaron, and we know from Epiphanius (Haer. 46) that Tatian, the author of the Gospel Harmony called Diatessaron, returned to his Mesopotamian fatherland about 170 as a missionary, it seems reasonable to identify "Addai" with Tatian himself (see J. *Th.* St. xxv. 128–130). About the end of the 2nd century Edessene Christianity seems to have made a fresh beginning: the ordination of Palūt by Serapion of Antioch may mean that things ecclesiastical took a westward trend, and it is possible that a complete version of the Four Gospels (the "Old Syriac") was now introduced. Mention should here be made of Bardaiṣān (*q.v.*; Bardesanes) known as the Aramaean philosopher. He became a Christian, and is famous for his cosmological speculations (see C. W. Mitchell, *Ephraim's* Refutations, p.cxxii. ff.), but was reckoned heretical. He was a contemporary of Abgar IX., at whose court Iulius Africanus stayed for a while. A Syrian official record from this reign, preserved in the *Edessene* Chronicle, gives a somewhat detailed account of a violent flood (Nov. 201) of the Daiṣān river which did much damage, destroying amongst other things "the palace of Abgar the Great," rebuilt as a summer palace by Abgar IX., and "the nave of the church of the Christians." The form of this last statement shows that at the time of writing (206) the rulers had not adopted Christianity themselves. Abgar IX. is now commonly supposed to be the ruler to whom the famous legend was first attached (see ABGAR); but though he visited Rome there is no proof that he ever became a Christian (Gomperz, in *Archäologisch-epigraphische Mitteilungen aus Österreich-Ungarn*, xix. 154–157). It was at Edessa that Caracalla, who made it a military colony (Colonia Marcia Edessenorum), spent the winter of 216–17, and near there that he was murdered. The religious philosophical treatise known as the Book of the Laws of Countries was produced at this time by a pupil of Bardesanes. The Acts of *Thomas* in its original form may have followed not long after: this work contains the finest Syriac poem extant, commonly called the "Hymn of the Soul." Bardesanes has been conjectured to have been its author on insufficient grounds (see Mitchell, *op. cit.*, p.cxxix.).

Sassanian Period.—In 226 the Parthian empire gave place to the new kingdom of the Sassanidae, whose claim to the ancient Achaeinenian empire led to constant struggle with Rome in which Edessa naturally suffered. The native State was restored by Gordian in 242; but in 244 it became again directly subject to Rome. The legendary Edessan martyrs Sharbēl and Barsamyā may have perished in the Decian persecution. In 260 the city was besieged by the Persians under Shapur I., and Valerian was defeated and made prisoner by its gates. Odaenathus of Palmyra (d.267), however, wrested Mesopotamia from the Persians; but Aurelian defeated his successor Zenobia at Emesa (273), and Carus, who died in 283 in an expedition against the Persians, and Galerius (297) carried the frontier again to the Tigris. During the Diocletian persecution Shmōna and Garia (Nov. 15, 309) and Habbib (Sept. 2, 310), the "Confessors of Edessa" were martyred; but the bishop Qōna, who laid the foundations of "the great church" by the sacred pool, somehow escaped. Edessa can claim no share in "the Persian Sage" Aphrahat (Aphraates); but Ephrem, after bewailing in Nisibis the sufferings of the great Persian war under Constantius and Julian, when Jovian in 363 ceded most of Mesopotamia to Shapur II., the persecutor of the

Christians, settled in Edessa, which as the seat of his famous school (called "the Persian") grew in importance, and attracted scholars from elsewhere. He taught and wrote vigorously against the Arians and other heretics, and although just after his death (373) the emperor Valens banished the orthodox from Edessa, they returned on the emperor's death in 378. Rabbtila, bishop of Edessa from 411 to 435, was a great organizer, but he won from the Nestorians the title of the Tyrant of Edessa. In particular he exerted himself to stamp out the use of the Diatessaron in favour of the four Gospels, of which he issued a revised Syriac translation, which is the final form of the Pĕshīttа. The sojourn in Edessa of the "Man of God" (Alexis) belongs to Rabbiila's episcopate, and the oldest surviving dated Syriac ms. was written in the year he became bishop. When Nestorianism was condemned at Ephesus (431) it began to gravitate eastwards, Nişībis becoming its eventual headquarters; but Edessa and the western Syrians refused to bow to the Council of Chalcedon (451) when it condemned Monophysitism.[1] Zeno's edict (489) ordered the closing of the school of the Persians at Edessa, and East and West drifted apart more and more; Narsai, the leading Nestorian teacher, fled to Nişībis about 489. Till about this time Syriac influence was strong in Armenia, and some Syriac works have survived only in Armenian translations. In the opening years of the 6th century the Persian-Roman War (502–506) found a chronicler in the anonymous Edessene history known till recently as the Chronicle of Joshua Stylites. Whether Edessa received from the emperor Justin I. the additional name of Justinopolis may be uncertain (see Hallier, *op.cit.* p.128); but it seems to have been renewed and fortified after the "fourth" flood in 525 (Procop. *Pers.* ii. 27; *De aedific.* ii. 7). About this time, according to Noldeke, an anonymous Edesserie wrote the Romance of Julian the Apostate, which so many Arab writers use as a history. Chosroes I. Anushirwān succeeded in 540, according to the last entry in the Edessene Chronicle, in exacting a large tribute from Edessa; but in 544 he besieged it in vain. A few years later Jacob Burd'āra (Baradaeus), with Edessa as his nominal bishopric, was carrying on the propaganda of Monophysitism, which won for the adherents of that creed the name of Jacobites (see JACOBITE CHURCH). The valuable Syriac Chronicle just referred to probably was compiled in the latter half of this century.

Islam. — In the first decade of the next century Edessa was taken by Chosroes TI., and a large part of the population transported to eastern Persia. Within a score of years it was recovered by the emperor Heraclius, who reviewed a large army under its walls. The prophet of Islam was now, however, building up his power in Arabia, and a few years later (636?) Heraclius's attempts, from Edessa as a centre, to effect an organized opposition to the victorious Arabs were defeated by Said, and he fell back on Samosiita. The terms on which Edessa definitely passed into the hands of the Moslems (638) under Riyād are not certain (Balādhurī). As it now ceased to be a frontier city it lost in importance. In 668 occurred another destructive flood (Theophanes, p. 537), and in 678 an earthquake which destroyed part of the "old church," which the caliph Mo'āwiya I. is said to have repaired. To the latter part of the century belongs the activity of Edessa's bishop Jacob, whose chronicle is unfortunately lost. It may have been the impulse given by the final supremacy of the caliphate to the long process which eventually substituted Arabic for Aramaic (which had now prevailed for a millennium and a half), that led Jacob to adopt Greek vowel signs for use in Syriac. Yet a century later Theophilus of Edessa (d.785), author of a lost history, translated into Syriac "the two books of the poet Homer on the conquest of the city of Ilion." When the Baghdad caliphs lost control, Edessa shared the fortunes of western Mesopotamia, changing with the rise and fall of Egyptian dynasties and Arab chieftains. In the 10th century al-Mas'tidi, writing in the very year in which it happened, tells how the Mohammedan ruler of Edessa, with the permission of the caliph, purchased peace of the emperor Romanus Lecapenus by surrendering to him the napkin of Jesus of Nazareth, wherewith he had dried himself after his baptism. The translation of the Holy Icon of Christ from Edessa is commemorated on Aug. 16 (Cal. Byzant). A few years later Ibn Haukal (978) estimates the number of churches in the city at more than 300, and al-Mokaddasi (985) describes its cathedral, with vaulted ceiling covered with mosaics, as one of the four wonders of the world. In 1031 the emperor recovered Edessa; but in 1040 it fell into the hands of the Seljuks, whose progress had added a large element of Armenian refugees to the population of Osrhoene. Maqrīzī tells us that the Armenian minister Badr al-Gamāli employed architects from Edessa to build three of the fine city gates of Cairo (1087–91). The empire soon recovered Edessa, but the resident made himself independent In 1098, in the First Crusade, Baldwin, brother and successor of Godfrey of Bouillon took possession of the town and made it the capital of a Burgundian countship, which included Samosāta and Sartig, and was for half a century the eastern bulwark of the kingdom of Jerusalem.[1] The local Armenian historian, however, Matthew of Edessa, tells of oppression, decrease of population, ruin of churches, neglect of agriculture. With the campaign of Maudud in 1110 fortune began to favour the Moslems. Edessa had to endure siege after siege. Finally, in 1144 it was stormed, Matthew being among the slain, by Imad ud-Din Zengi, ruler of Mosul, an achievement celebrated as "the conquest of conquests," for which an Edessan monk, John, bishop of Ḥarrān (d.1165) laid the responsibility not on God but on the absence of the Frankish troops. Edessa suffered still more in 1146 after an attempt to recover it. Churches were now turned into mosques. The consternation produced in Europe by the news of its fate led to "the second Crusade." In 1182 it fell to Saladin, whose nephew recovered it when it had temporarily passed (1234) to the sultan of Rum; but the "Eye of Mesopotamia" never recovered the brilliance of earlier days. The names it contributed to Arabic literature are unimportant. By timely surrender (1268) it escaped the sufferings inflicted by Hūḷākū and his Monguls on Sariig (Barhebraeus, *Chron.* Arab., Beirūt ed , 486). Mostaufi describes a great cupola of finely worked stone still standing by a court over a hundred yards square (1340). Ali b. Yazd in his account of the campaigns of Timūr, who reduced Mesopotamia in 1393, still calls the city (1425) Ruhā. In 1637, when Amurath IV. conquered Baghdad and annexed Mesopotamia, it passed finally into the hands of the Turks, by whom it is called Urfa.

Modern City. — The city occupies an important position as one of a line of frontier forts which hold the entrance from the foothills to the plain. It is in addition an important point of transit along the northern and safer route from Mosul to Aleppo, being now on the railway. At this point the land routes westwards divide, one going south to Aleppo, another west to Adana. It is the centre of a wheat district but is not concerned in any industry. The population is uncertain; it probably numbers about 40,000 and includes Kurds, Turks and Armenians.

The town itself is of considerable interest. It is surrounded by a wall, with square towers at intervals. On the western part of the town lies the old citadel, with two great Corinthian columns, known as the "throne of Nimrod." Between the citadel and the town are the springs, from which it probably derived its name of *Callirhoë.* The water from these springs forms two ponds, on the edge of the larger of which is the great Mosque of Abraham. The largest mosque however is in the middle of the town, probably on the site of the once famous Christian church. The Kara Kuyun (Σκίριος) runs in a moat round the town, and this and the other streams serve to irrigate the gardens, vineyards and mulberry orchards. In addition to its stormy history in earlier times Edessa towards the end of the last century incurred an unfor-

[1] The oldest surviving *dated* ms. of *a* portion of the Bible in any language was written at Amid (Diarbekr) in A.D. 464.

tunate reputation as the seat of Armenian massacres.

EDFU, in Coptic *Atbō,* a town of Upper Egypt, 484 m. S.S.E. of Cairo by rail, on the W. bank of the Nile, the railway station being on the opposite side of the river. The inhabitants manufacture earthenware. which finds ready sale all through Egypt, The ancient Atbō (*Apollinopolis Magna)* was capital of the second nome of Upper Egypt. The great Ptolemaic sandstone temple is practically complete. The central part of the building, begun by Ptolemy III. Euergetes in 237 B C., was finished by his successor in 212; the portico, court, pylons and surrounding wall were added by Ptolemy Euergetes II., Soter II. and Alexander I.; but the decoration was not finished till 57 B.C. in the reign of Ptolemy XIII. Neos Dionysus. The god of Atbō was a form of Horus (Xpollo) as the sun-god; his most characteristic representation is as the disk of the sun with outspread wings, Population 15,000.

EDGAR (EADGAR), king of the English (944–975), was the younger son of Edmund the Magnificent and Aelfgifu. As early as 955 he signed a charter of his uncle Eadred, and in 957 the Mercian nobles, discontented with the rule of his elder brother Eadwig, made him king of England north of the Thames. On the death of his brother in Oct. 959 Edgar became king of a united England. Immediately on his accession to the throne of Mercia Edgar recalled St. Dunstan from exile and made him first bishop of Worcester, and then of London. In 961 Dunstan was translated to Canterbury, and throughout Edgar's reign he was his chief adviser, and to him must be attributed much of the peace and prosperity of this time.

The reign of Edgar was somewhat uneventful, but two things stand out clearly: his ecclesiastical policy and his imperial position in Britain. Edgar and Dunstan were alike determined to reform the great monastic houses, to restore them to their true owners, and to remove them from the lax discipline of the secular priests or *canonici.* The priests of the old and new monasteries at Winchester, Chertsey and Milton Abbas were replaced by monks, and the old rule of St. Benedict was strictly enforced.

The coronation of Edgar, delayed for some unexplained reason till 973, took place with much ceremony at Bath, and was followed shortly after by the submission of eight kings, including the kings of Scotland and Strathclyde, to Edgar at Chester. In 967 an outbreak against Edgar in Northumbria was put down by Thored, the son of Gunnere, steward of the king's household.

Edgar's death took place in the year 975, and he was buried at Glastonbury. By his vigorous rule and his statesmanlike policy Edgar won the approval of his people; the only fault ascribed to him is a too great love for foreigners and for foreign customs. Edgar strengthened the hands of the provincial administration, and allowed the northern Danes a certain degree of self-government.

Edgar is said to have formed an irregular union in 961 with Wulfthryth, an inmate of the convent at Wilton, who bore him a daughter Eadgyth but refused to marry him. He married Aethelflaed, "the white duck," daughter of Earl Ordmaer, who bare him a son, known as Edward the Martyr. Finally he was united (964) to Aelfthryth, daughter of Earl Ordgar, who became the mother of the Aetheling Edmund (d. 971) and of Aethelred the Unready.

See *The Anglo-Saxon Chronicle* (ed. Plummer, 1892–99), *sub. ann.; Vita Sancti Oswaldi (Historians of the Church of York,* ed. Raine, Rolls Series); William of Malmesbury, *Gesta regum* (ed. Stubbs, Rolls Series); Birch, *Cartulurium Saxonicum,* vol. iii. Nos. 1047–1319; F. Liebermann, *A.-S. Laws,* i. 192–216; "Florence of Worcester" *(Mon. Hist. Brit.)*; E. W. Robertson, *Historical Essays,* pp. 189–215.

EDGAR or **EADGAR** (c. 1050–*c.* 1130), called the Aetheling, was the son of Edward (the exile), a son of the English king Edmund Ironside, by his wife Agatha, a kinswoman of the emperor Henry II., and was born probably in Hungary some time before 1057, the year of his father's death. After the death of Harold in 1066, Eadwine and Morkere desired to make him king, but on the advance of William I, Edgar and his supporters made their submission. He took part in two unsuccessful risings in the north (1068 and 1069), afterwards taking refuge in Scotland, where his sister Margaret married the Scottish king, Malcolm Canmore. In 1074 he went to Normandy and made peace with William. In 1093 he made a successful attempt to set his nephew Edgar on the throne of Scotland, and in 1099 went to the crusade. He returned to England in Henry I.'s reign, but sided with Robert of Normandy against the king in their last war, and was taken prisoner at the battle of Tinchebrai in 1106. He was soon released. and lived in obscurity until his death, the date of which is uncertain.

EDGECUMBE or EDGCUMBE, the name of a celebrated west of England family, taken from the manor of Edgecumbe in Cornwall. One of its earlier members was Sir Richard Edgecumbe (d. 1489), who was descended from a Richard Edgecumbe who flourished during the reign of Edward I. Richard was a member of parliament in 1467; afterwards he joined Henry, earl of Richmond, in Brittany, returned with the earl to England. and fought at Bosworth, where he was knighted. He was richly rewarded and sent by Henry VII. on errands to Scotland, Ireland and Brittany; he died at Morlaix on Sept. 8, 1489. His son and successor, Sir Piers Edgecumbe (d. 1539) went to France with Henry VIII. in 1513. His son Sir Richard Edgecumbe (1499–1562), a cultured and hospitable man, is celebrated through Richard Carew's *Friendly Remembrance* of *Sir Richard Edgecumbe.* Sir Richard's eldest son, Piers or Peter Edgecumbe (1536–1607), was a member of parliament under Elizabeth for about 30 years.

Another famous member of this family was Richard, 1st baron Edgecumbe (1680–1758), a son of Sir Richard Edgecumbe. Educated at Trinity college, Cambridge, he was successively member of parliament for St. Germans, Plympton and Lostwithiel from 1701 to 1742, on two occasions served as a lord of the treasury, and from 1724 to 1742 was paymaster-general for Ireland, becoming chancellor of the duchy of Lancaster in 1743. He managed the elections for the Cornish boroughs in the interests of Sir Robert Walpole and his elevation to the peerage, which took place in 1742, was designed to prevent him from giving evidence about Walpole's expenditure of the secret service money. His son and successor, Richard, the 2nd baron (1716–61), was comptroller of the royal household, a member of parliament, and a major-general in the army.

Richard's brother George (1721–95), was a naval officer during the Seven Years' War. Succeeding to the barony on the and baron's death in 1761 he became an admiral and treasurer of the royal household, was created Viscount Mount-Edgecumbe in 1781 and earl of Mount-Edgecumbe in 1759.

EDGE HILL, an elevated ridge in Warwickshire, England, near the border of Oxfordshire. The north-western face is an abrupt escarpment of the Lias, and the summit of the ridge is almost level for nearly 2m., at a height somewhat exceeding 700ft. The escarpment overlooks a rich lowland watered by streams tributary to the Avon; the gentle eastern slope sends its waters to the Cherwell, and the ridge thus forms part of the divide between the basins of the Severn and the Thames. Edge Hill gave name to the first battle of the Great Rebellion (*q.v.*), fought on the 23rd of October 1642.

EDGE TOOLS. A general term which includes cutting and scraping tools, as distinguished from those of percussive type, as hammers, and of lever type, as spanners. Edge tools date from the remote palaeolithic age when rough axes were chipped from flints, to be improved by neolithic men who ground and polished their celts. The true chisel, thrust by hand, appears to have developed in the bronze age. The basic difference between an axe and a chisel is that the one is doubly bevelled, the other singly. The result is that the axe does not possess good guidance on the wood, while the flat face of the chisel acts as a guide, helping to cut true surfaces. An adze is of the chisel class, and is used by the carpenter and shipwright to true baulks and other large areas. The carpenter's plane gives still better control by means of the sole sliding along the wood, while in machine tools for wood and metal the guidance becomes perfect.

The keenness of an edge tool, or its "cutting angle" is nearest to that of the razor in the woodworker's chisels. gouges, carving-tools and plane irons, as well as in certain machine knives. Hard or tough wood tends to turn over a fine edge or break it, consequently the angle of the two faces meeting at the edge must be

increased. The same rule applies to cold chisels for metals. In the tools used in metal-working machines, as the lathe, drill, planer, shaper and slotter and the milling and sawing machines, the edges must be ground more keenly for the fibrous metals and alloys, as wrought-iron, mild steel and copper, but less keenly for the crystalline kinds, as hard steel, cast-iron and brass. Chilled cast-iron, for the rolls of rolling-mills, is very difficult to turn, and the tool faces meet at an angle of near 90°, the action being merely slow scraping. Nevertheless this tool is a wedge, in principle, just as much as the finest chisel for soft wood, penetrating and forcing aside the metal. (*See* also FILE; MACHINE KNIVES; MILLING-CUTTERS; PUNCHING AND SHEARING MACHINES; SAWS; TAPS AND DIES, and general article TOOL.)

EDGEWORTH, MARIA (1767–1849), Irish novelist, second child and eldest daughter of Richard Lovell Edgeworth (*q.v.*) and his first wife, Anna Maria Elers, was born in the house of her maternal grandparents at Black Bourton, Oxfordshire, on Jan. 1, 1767. She had ample opportunities for society among her father's neighbours in Ireland, among whom were the second Lord Longford, whose daughter, "Kitty" Pakenham, became later duchess of Wellington; Lady Moira at Castle Forbes; and Maria's aunt, Margaret Ruxton, at Black Castle. She gained a first-hand experience of the Irish peasantry by acting as her father's assistant in the management of the estate. The Edgeworths were in Ireland from 1793 onwards through that dangerous period, and Maria's letters, always gay and natural, make very light of their anxieties and their real perils.

It has been the fashion to regard Mr. Edgeworth's influence over Maria's work as altogether deplorable, but she undoubtedly derived a stimulus from his powerful mind. Her first publication was a plea for the education of women, *Letters to Literary Ladies* (1795), and in 1796 appeared *The Parent's Assistant* (2nd ed., 6 vols., 1800), a collection of stories which had been submitted as they were written to the juvenile critics of the Edgeworth nursery. They were therefore children's stories for children, even though the morals were Mr. Edgeworth's. *Practical Education* (2 vols., 1798) was written in conjunction with her father, who also collaborated with her in the *Essay on Irish Bulls* (1802). Miss Edgeworth's first novel, *Castle Rackrent,* appeared anonymously in 1800. It is the story of an Irish estate and its owners, the Rackrents, as told by Thady, the steward. Its success was immediate, and a second edition soon appeared with the author's name. The personages appear to be drawn immediately from the natives of Edgeworthstown, though Miss Edgeworth asserts that only Thady himself was an actual portrait. The book influenced Scott. In the "Postscript, which should have been a preface," in the original edition of *Waverley,* Scott describes his aim as being "in some distant degree to emulate the admirable Irish portraits of Miss Edgeworth, so different from the 'Teagues' and 'dear joys' who so long, with the most perfect family resemblance to each other, occupied the drama and the novel." *Belinda* (1801) is a society novel, and one of her best books. Saintsbury thinks that Miss Austen's heroines owe something of their naturalness to Belinda, who was one of the earliest to break with the tradition of fainting and blushing. *Moral Tales for Young People* (5 vols.) and *Early Lessons,* which included "Harry and Lucy," "Rosamond" and "Frank," appeared in 1801.

In 1802 the Edgeworths went abroad, first to Brussels and then to Paris. They had already connections in Paris through their kinsman, the abbé Edgeworth de Firmont, who was, however, then in exile. They met all the notabilities in Paris, and Maria refused an offer of marriage from a Swedish count named Edelcrantz. Although *Leonora,* not published until four years later, is said to have been written to meet his taste, she apparently remained then and always heart-whole; hut her stepmother thought otherwise and maintained that she suffered severely for her decision (*Memoir,* i. 144). Returning to Edgeworthstown, Miss Edgeworth resumed her writing, which was always done in the rooms commonly used by the whole family. *Popular Tales* was published in 1804, and *The Modern Griselda* in the same year; *Leonora* in 1806; and in 1809 the first series of *Tales of Fashionable Life,* three volumes containing "Ennui," "Madame de Fleury," "Almeria," "The Dun" and "Manoeuvring"; the second series (3 vols., 1812) included "The Absentee," one of her best tales, which was originally designed as a play, "Vivian" and the clever study of émigré life, "Émilie de Coulanges." In 1813 Maria and her parents spent a considerable time in London, and her society was much sought after. When *Waverley* was published, Miss Edgeworth received a copy from the publishers, and at once recognized the authorship. She wrote a long letter of appreciation (Oct. 23, 1814) to "the author of *Waverley,*" which she began with the phrase *aut Scotus, aut diabolus,* but the letter was merely acknowledged by the publishers. *Patronage* (4 vols., 1814), the longest of her novels, and *Harrington, a tale,* and *Ormond, a tale* (3 vols., 1817) complete the list of the works which received what her father called his *imprimatur.*

After his death in 1817 Miss Edgeworth occupied herself with completing his *Memoirs,* which were published in 1820. In 1820 she was again in Paris, and in 1823 she spent a fortnight with the Scotts at Abbotsford. In 1825 Scott went to Edgeworthstown, and their relations were always cordial. Miss Edgeworth's production was less after her father's death. Sequels to "Rosamond," "Frank," "Harry and Lucy" in the *Early Lessons* were published in 1822–1825. *Comic Dramas* appeared in 1817, and *Helen* in 1834. In 1846 she worked strenuously for the relief of the famine-stricken Irish peasants. She died on May 22, 1849.

Miss Edgeworth's novels are distinguished by good sense, humour and vivacious dialogue. She expressly calls some of her stories "Moral Tales"; but the freshness of her stories, her insight into character, lively dialogues, originality of invention and delightfully clear style render it quite possible to read her works in succession without any sense of weariness.

See *A Memoir of Maria Edgewortk, with a Selection from her Letters* (1867), by her stepmother, F. A. Edgeworth, privately printed. A selection from this was made by Augustus J. C. Hare, and printed under the title of *The Life and Letters of Maria Edgeworth* (2 vols., 1894). *See* also *Maria Edgeworth* (1883), by Helen Zimmern, in the "Eminent Women" series; Grace A. Oliver, *A Study of Maria Edgeworth . . .* (3rd ed., Boston, U.S.A., 1882); and *Maria Edgeworth* (1904), by the Hon. Emily Lawless in the "English Men of Letters" series. Also George Saintsbury in *Macmillan's Magazine* (July 1895), the preface supplied by Lady Thackeray Ritchie to Macmillan's edition of the novels (1895); C. Hill, *Maria Edgeworth and her circle* (1909); *The Black Book of Edgeworths Town* (1585–1817), ed. H. J. and H. E. Butler (1928).

EDGEWORTH, RICHARD LOVELL (1744–1817), British writer, was born at Bath. The greater part of his life was spent at Edgeworthtown, or Edgeworthstown, in the county of Longford, Ireland. He was educated at various schools in England and Ireland, and entered Trinity college, Dublin, in April 1761, but was transferred to Corpus Christi college, Oxford, in October of the same year. While still at college, he made a runaway match, marrying at Gretna Green, Anna Maria, one of the daughters of Paul Elers of Black Bourton, Oxon, an old friend of his father. Edgeworth devoted much of his time to scientific reading and experiments; and he made an attempt to establish telegraphic communication (*Memoirs,* 2nd ed., i. 144). In the pursuit of his mechanical inventions he visited Erasmus Darwin at Lichfield, where he met Anna Seward, and her cousin, Honora Sneyd. He kept terms at the Temple, and formed the greatest friendship of his life with Thomas Day, the author of *Sandford and Merton,* which was written at Edgeworth's suggestion. In 1769, on the death of his father, he gave up the study of law, and spent a considerable time in England and France, mainly in Day's company. He was summoned to England by the death of his wife (March 1773), with whom he had been far from happy. Edgeworth hurried to Lichfield, to Dr. Erasmus Darwin's, and at once declared his passion for Honora Sneyd, which had been the cause of his flight to France two years before. Miss Sneyd had been the object of attention from Thomas Day, but her views on marriage were not submissive enough to please him. She had other suitors, among them the unfortunate Major André. She married Edgeworth (July 1773), and after residing at Edgeworthstown for three years, they settled at Northchurch, in Hertfordshire. Honora Edgeworth died in April 1780, recommending her husband to marry her sister Elizabeth, and they

were actually married on Christmas day, 1780. She died in 1797.

Practical Education (1798) was written in collaboration with his daughter Maria, and embodied the experience of the authors in dealing with children. This book, generally regarded as old-fashioned, has a real value in the history of education. Their views had been inspired by Rousseau, and by Thomas Day. The Edgeworths brought a scientific method to their work. The second Mrs. Edgeworth (Honora Sneyd) began the collection of actual examples of conversations between the children and their elders. This was continued by the writers of the book, and their reasonings were thus founded on an accurate record of childish methods of thought. They deprecated especially any measures that interrupted the child's own chain of reasoning. The chapters on special subjects of study, chronology, geometry, etc., were written by Richard Lovell Edgeworth; those on toys, on rewards and punishments, on temper, etc., by his daughter.

In 1798 Edgeworth married Miss Beaufort, and was elected M P. for the borough of St. John's Town, Longford. During the formidable rebellion of that year the Edgeworths took refuge in Longford. The winter of 1802 they spent in Paris. In 1804 the Government accepted his telegraphic apparatus, but the installation was left incomplete when the fear of invasion was past. In 1806 Edgeworth was elected a member of the board of commissioners to enquire into Irish education. From 1807 till 1809 much of his time was spent on mechanical experiments and in writing the story of his life. He died on June 13, 1817, and was buried in the family vault in Edgeworthstown churchyard. Edgeworth's works include *Poetry Explained for Young People* (1802), *Professional Education* (1808); *Readings in Poetry* (1816).

See *Memoirs of Richard Lovell Edgeworth, Esq.,* begun by himself and concluded by his daughter, Maria Edgeworth (2 vols., 1820, 3rd and revised ed., 1844). *Richard Lovell Edgeworth* (1896), edit. Mrs. Lionel Tollemache, is a selection from the *Memoirs. See* also *The Black Book of Edgeworthstown . . . (1585–1817)*, edit. *H. J.* and H. E. Butler (1928).

EDGEWORTH DE FIRMONT, HENRY ESSEX (1745–1807), last confessor to Louis XVI., was the son of Robert Edgeworth, rector of Edgeworthstown in Ireland, his mother being a granddaughter of Archbishop Ussher. His father resigned his living and emigrated to Toulouse, where the boy was brought up by the Jesuits. On taking orders he assumed the additional surname of de Firmont, from the family estate of Firmount near Edgeworthstown. In 1791 he became confessor to the princess Elizabeth, sister of Louis XVI., and then to Louis himself. After Louis' condemnation he obtained permission to celebrate mass for him and attend him on the scaffold, where he recommended the king to allow his hands to be tied, with the words: "Sire, in this new outrage I see only the last trait of resemblance between your Majesty and the God who will be your reward." The abbé himself denied that at the moment of the execution he uttered the celebrated words: "Son of St. Louis, ascend to heaven." Edgeworth continued to correspond with Madame Elizabeth. In 1795, his mother having meanwhile died in prison, where his sister was also confined, he escaped to England, carrying with him Elizabeth's last message to her brother, the future King Charles X. He afterwards went with some papers to Monsieur (Louis XVIII.), then at Blankenburg in Brunswick, and was induced to accompany him to Mittau, where, on May 22, 1807, he died of a fever contracted while attending some French prisoners.

Edgeworth's *Memories,* edited by *C.* S. Edgeworth, were first published in English (London, 1815), and a French translation (really the letters and some miscellaneous notes, etc.) was published in Paris in 1816. A translation of the *Lettres de l'abbt Edgeworth avec des mémoires sur sa vie* was published by Madame Elise de Bow in Paris in 1818, and *Letters from the Abbt Edgeworth to his Friends, with Memoirs of his Life,* edited by T. B. England, in London in 1818.

EDGREN-LEFFLER, ANNE CHARLOTTE, duchess of Cajanello (1849–1892), Swedish author, daughter of the mathematician Prof. C. O. Leffler, was born on Oct. 1, 1849. Her first volume of stories appeared in 1869, but the first to which she attached her name was *Ur Lifvet* ("From Life," 1882), a series of realistic sketches of the upper circles of Swedish society, followed by three other collections with the same title. Her earliest plays, *Skådespelerskan* ("The Actress," 1873), and its successors, were produced anonymously in Stockholm, but in 1883 her reputation was established by the success of her comedies *Sanna Kvinnor* ("True Women") and *En Raddande engel* ("An Angel of Deliverance"). *Sanna Kvinnor* is directed against false femininity, and was well received in Germany as well as in Sweden. Anne Leffler had married in 1872 G. Edgren, but about 1884 she was separated from her husband, who did not share her advanced views. She spent some time in England, and in 1885 produced her play *Hur man gor godt* ("How Men do Good"), followed in 1888 by *Kampen for lyckan* ("The Struggle for Happiness"), a drama in which she had the help of Sophie Kovalevsky. Another volume of the *Ur Lifvet* series appeared in 1889 (both) volumes were reprinted in 1915; and *Familjelycka* ("Domestic Happiness," 1891), a drama in 3 acts, was produced in the year after her second marriage, with the Italian mathematician, Pasquale del Pezzo, duca di Cajanello. She died at Naples on Oct. 21, 1892. The masculine directness, freedom from prejudice, and frankness of her work gave her a high place in Sweden. Her last book was a biography (1892) of her friend Sophie (Sonya) Kovalevsky, by way of introduction to Sonya's autobiography. An English translation (1895) by A. de Furnhjelm and A. M. Clive Bayley contains a biographical note on Fru Edgren-Leffler by Lily Wolffsohn, based on private sources.

See also Ellen Key, *Anne Charlotte Leffler* (1893); *O.* J. Levertin, *Sveriges National-Literatur, 1500–1900,* vol. 18 (1907).

EDHEM PASHA *(c.* 1815–1893), Turkish statesman, of Greek origin, entered the Turkish government service and rose to high office, being successively minister of public works, grand vizier for 11 months (1878), ambassador at Vienna (1879) and minister of the interior. He left a reputation of unblemished honesty and uprightness.

EDIBLE BIRD'S-NEST, the nest of a species of swift of the genus *Collocalia,* composed chiefly of the saliva of birds. They are to be found in the East Indies and Australia and are valued by the Chinese as an article of food. *See* SWIFT.

EDICT, an order or proclamation issued under authority and having the force of law. The word is especially used of the promulgations of the Roman praetor (*q.v.*), of the Roman emperors, and also of the kings of France *(see* ROMAN LAW).

EDINBURGH (ĕd'in-brŭ), city and royal burgh, capital of Scotland, county town of Midlothian or Edinburghshire, south of the Firth of Forth, 393 m. by rail N.N.W. of London. The old Royal Observatory on Calton Hill stands in 55° 57′ 23″ N. and 3° 10′ 46" W. Edinburgh occupies a group of hills and valleys. In the centre is a bold rock, crowned by the castle, between which and the new town lies a ravine that once contained the Nor' Loch, but is now covered with the gardene of Princes Street. To the east rises Calton Hill (355 ft.) with the old prison and the Calton cemetery. On the south-east, beyond the Canongate limits, stands the hill of Arthur's Seat (822 ft.). Towards the north the site of the city slopes gently to the Firth of Forth and includes the port of Leith; while to the south, Liberton Hill, Blackford Hill, Braid Hills and Craiglockhart Hills roughly mark the city bounds, as Corstorphine Hill and the Water of Leith do the western limits. Its situation, general plan and literary, associations gave Edinburgh the name of "the modern Athens"; but it has a homelier nickname of "Auld Reekie," from the cloud of smoke (reek) over the low-lying quarters.

Chief Buildings.—In the castle, the oldest building is St. Margaret's chapel, believed to be the chapel where Queen Margaret, wife of Malcolm Canmore, worshipped, and belonging at latest to the reign of her youngest son, David I. (1124–1153). Near it the parliament and banqueting hall contains a fine collection of Scottish armour, weapons and regimental colours. The heraldic bearings of royal and other figures distinguished in national history are emblazoned in the windows. Other buildings in the Palace Yard include the apartments occupied by the regent, Mary of Guise, and her daughter Mary, queen of Scots, and the room in which James VI. was born. Here also are deposited the Scottish regalia ("The Honours of Scotland"), with the sword of state presented to James IV. by Pope Julius II., and the jewels

restored to Scotland on the death (1807) of Cardinal York, the last of the Stuarts. The remains of King David's tower, the ancient keep, were hidden by the Half Moon battery, but were revealed in 1912. In the armoury is a collection of arms of various dates; and on the Argyll battery stands a huge piece of ancient artillery, called Mons Meg, of which repeated mention is made in Scottish history. The large arsenal on the west side of the rock is modern; but the castle garrison was withdrawn in 1923. A war memorial, a shrine and gallery of honour, was unveiled in Crown Court in 1927.

Holyrood palace was originally an abbey of canons regular of the rule of St. Augustine, founded by David I. in 1128, and the ruined nave of the abbey church still shows parts of the original structure. Connected with this is a part of the royal palace erected by James IV. and James V., including the apartments occupied by Queen Mary, the scene of the murder of Rizzio in 1566. The abbey was sacked and burnt by the English under the earl of Hertford in 1544, and again in 1547. Recent excavation has revealed much of the early foundations. In a map of 1544 the present north-west tower of the palace is shown standing apart, and joined to the abbey by a cloister. Beyond this was an irregular group of buildings replaced later by additions more in accordance with a royal residence. The whole of this latter structure was destroyed by fire in 16jo while in occupation'by the soldiers of Cromwell; and the more modern parts were begun during the Protectorate, and completed in the reign of Charles II. by Robert Milne, after the designs of Sir William Bruce of Kinross. They include the picture gallery, with 106 mythical portraits of Scottish kings, and a triptych (c. 1484) containing portraits of James III. and his queen, believed to have formed the altar-piece of the collegiate church of the Holy Trinity, founded by the widowed queen of James II. in 1462, demolished in 1848, and afterwards rebuilt, stone for stone, in Jeffrey Street. The picture gallery is associated with the festive scenes that occurred during the short residence of Prince Charles in 1745; and in it the election of representative peers for Scotland takes place. Escaping from France at the revolution of 1789, the comte d'Artois, afterwards Charles X. of France, had apartments granted for the use of himself and his suite, who ccntinued to reside in the palace till August 1799. When driven from the French throne by the revolution of 1830, Charles once more found a home in the palace. George IV. was received there in 1832, and Queen Victoria and the prince consort occupied the palace on several occasions; in 1903 Edward VII., during residence at Dalkeith Palace, held his court within its walls; and King George V. and Queen Mary stayed there in 1927. The state apartments were redecorated under the queen's guidance. A fountain, after the original design of that in the quadrangle of Linlithgow Palace, was erected in front of the entrance by the prince consort. Iron gates enclosing the forecourt, and a statue of Edward VII., form the national memorial to that king. The royal vault in the Chapel Royal, which was dilapidated, has been put in order; Clockmill House and grounds have been added to the area of the parade ground, and the abbey precincts generally and the approaches to the King's Park have been improved. With the abolition of imprisonment for debt in 1881 the old privileges of sanctuary came to an end.

Parliament House, begun in 1632 and completed in 1640, in which the later assemblies of the Scottish estates took place until the dissolution of the parliament by the Act of Union of 1707, has since been the meeting-place of the supreme courts of law. The great hall, with its fine open-timbered oak roof, is adorned with a splendid stained-glass window and several statues, including one by Louis François Roubiliac of Duncan Forbes of Culloden, lord president of the court of session (1685–1747), and now forms the ante-room for lawyers and their clients. The surrounding buildings, including the court-rooms and the Advocates' and the Signet libraries, are modern. The Advocates' library is the finest in Scotland. It was founded in 1682 and presented to the nation by the faculty of advocates in 1924, endowed by Sir A. Grant with £100,000 for maintenance. It is one of the five entitled by the Copyright Act to receive a copy of every work puhlished in Great Britain.

The General Register House for Scotland, begun in 1774 from designs by Robert Adam, stands at the east end of Princes Street. It contains, in addition to the ancient national records, accommodation in fireproof chambers for all Scottish title-deeds, entails, contracts and mortgages, and for general statistics, including those of births, deaths and marriages.

The Royal Institution, in the Doric style, surmounted by a colossal stone statue of Queen Victoria by Sir John Steell, formerly accommodated the Board of Trustees for Manufactures and the Board of Fishery, the school of art, the Royal Society of Edinburgh (founded in 1783) and the Society of Antiquaries of Scotland (founded in 1780). In 1910 it was renamed and appropriated to the uses of the Royal Scottish Academy of Painting, Sculpture and Architecture, instituted in 1826, and incorporated by royal charter in 1838, on the model of the Royal Academy in London. It is situated on the Mound close to the National Gallery (1850). These collections are especially rich in Raeburn's works and include also Alexander Nasmyth's portrait of Robert Burns and Gainsborough's "The Hon. Mrs. Graham." The National Portrait Gallery and Antiquarian Museum are housed in Queen Street. St. Giles' cathedral, restored (1879–83) by the liberality of Dr. William Chambers, the publisher, has many historical and literary associations. The regent Moray, the marquess of Montrose, and Napier of Merchiston were buried within its walls and are commernorated by monuments, and among the memorial tablets is one to R. L. Stevenson. The choir (restored in 1873 by public subscription) is a fine example of 15th-century architecture, and the Gothic crown surmounting the central tower is a feature in many views of the city. Just outside the church in Parliament Square, the supposed grave of John Knox is indicated by a stone set in the pavement bearing his initials, and in the psvement to the west a heart indicates the site of the old Tolbooth, which figures prominently in Scott's Heart of *Midlothian*. The original Tolbooth was completed in 1501, but a new one took its place in 1563–1564. At first occupied by the parliament and courts of justice, it served later as a prison, and was removed in 1817. Other churches having historical associations are the two Greyfriars' churches, which occupy the two halves of .one building; Tron church, the scene of midnight hilarity at the new year; St. Cuthbert's church; St. Andrew's church in George Street, whence set out, on a memorable day in 1843, that long procession of ministers and elders to Tanfield Hall which ended in the founding of the Free Church; St. George's church in Charlotte Square, a good example of the work of Robert Adam. The United Free Church claims no buildings of much historic interest, but St. George's Free has many associations. The finest building belonging to the Scottish Episcopal Church is St. Mary's cathedral (1879). The mansion of East Coates (17th cent.), stands in the close, and is occupied by functionaries of the cathedral. The Catholic Apostolic church at the foot of Broughton Street has a set of mural paintings by Mrs. Traquair. The Central Hall at Tollcross testilies to Methodist energy. John Knox's house at the east end of High Street is kept in repair, and contains articles of furniture that belonged to the reformer. The Canongate Tolbooth adjoins the parish church, in the burial-ground of which is the tombstone raised by Burns to the memory of Robert Fergusson; here Dugald Stewart, Adam Smith and other men of note were buried. Almost opposite to it stands Moray House, from the balcony of which the 8th earl of Argyll watched Montrose led to execution (1650). The gaol (no longer used as such), is a castellated structure on the black rock of Calton Hill. Usher Hall (1914), a very fine meeting-hall in Lothian Road was built on the bequest of £100,000 by Andrew Usher (1826–98). The library of the solicitors to the supreme courts presents to the Cowgate a high frontage in red sandstone. The Sheriff Court Buildings stand on George IV. Bridge, and facing them is Andrew Carnegie's free library (1887–1889). At the corner of High Street and George IV. Bridge stand the County buildings. The Scotsman, the principal daily newspaper, is housed in an ornate office in North Bridge Street. Ramsay Gardens, a student's quarter fostered by Prof. Patrick Geddes (b. 1854), grew out of the "goose-pie" house where Allan Ramsay lived. The Outlook Tower on Csstle Hill houses collections, partly

illustrating town-planning, by Prof. Geddes. The old City Cross (restored at the cost of W. E. Gladstone) stands in High Street, adjoining St. Giles's. Several quaint groups of buildings have been carefully restored, such as the White Horse Close in the Canongate; the mass of alleys on the north side of the Lawnmarket, from Paterson's Close to James's Court have been connected, and here Lord Rosebery acquired and restored the 17th-century dwelling which figures in the legend of *My* Aunt Margaret's Mirror. It is used as a branch museum. Another model restoration of a historic close is found in Riddle's Close, which contains a students' settlement. The changes in the Old Town (many of a drastic nature) have been carried out with due regard to the character of their environment.

Monuments — The Scott monument in East Princes Street Gardens was designed by George Meikle Kemp (1795–1844). A column surmounted by a colossal figure of Viscount Melville, Pitt's first lord of the Admiralty, rises from the centre of St. Andrew Square. Burns's monument, in the style of a Greek temple, occupies a prominent position on the Regent Road, on the southern brow of the lower terrace of Calton Hill. It was originally intended to form a shrine for Flaxman's marble statue of the poet (now in the National Portrait Gallery), but it proved to be too confined to afford a satisfactory view of the sculptor's work and was converted into a museum of Burnsiana (afterwards removed to the municipal buildings). On Calton Hill is the national monument to commemorate the victory of Waterloo, originally intended to be a reproduction of the Parthenon. The plan was abandoned for lack of funds, after twelve out of the twenty-four Greek pillars had been erected, but it is perhaps more effective in its unfinished state than if it had been completed. The Nelson monument, an elongated turreted structure, stands on the highest cliff of the hill. Close by is the monument to Dugald Stewart, a copy of the choragic monument of Lysicrates. Sir John Steell's equestrian statue of the duke of Wellington stands in front of the Register House, and in Princes Street Gardens are statues of Livingstone, Christopher North, Allan Ramsay, Adam Black and Sir J. Y. Simpson, and a memorial to the Scots Greys who fell in the Boer War. In George Street are Chantrey's figures of Pitt and George IV., and a statue of Dr. Chalmers; the 5th duke of Buccleuch stands beside St. Giles's. Charles II. surveys the spot where Knox was buried; the reformer himself is in the quadrangle of New College: the statue of Sir David Brewster has been moved from the quadrangle of the university to the new buildings at West Mains; Dr. William Chambers is in Chambers Street, and Frederick, duke of York (1763–1827), and the 4th earl of Hopetoun are also commemorated. The Gladstone Memorial in St. Andrews Square was unveiled in 1917.

Cemeteries. — In Greyfriars' churchyard the Solemn League and Covenant was signed, and among its many monuments are the Martyrs' monument, recording the merits of the murdered covenanters, and the tomb of "Bluidy" Mackenzie. There are interesting memorials in the churchyards of St. Cuthbert's and the Canongate. In the Calton burying-ground are the Roman tomb of David Hume, the obelisk raised in 1844 to the memory of Maurice Margarot, and the graves of Thomas Muir (1765–1798), Thomas Fyshe Palmer (1747–1802), William Skirving and Joseph Gerrald (1765–1796), the political martyrs transported towards the end of the 18th century for advocating parliamentary reform. The Scottish dead in the American Civil War are commemorated in a monument bearing a life-sized figure of Abraham Lincoln and a freed slave.

Parks and **Open** Spaces. — The older open spaces are Princes Street Gardens, Calton Hill, the Meadows and the Bruntsfield Links. On the southern side is Blackford Hill with the Royal Observatory. Harrison Park is in the congested district of Fountainbridge. The park at Saughton Hall was opened in 1905, for the western district of the city, and Hillend Park on the Pentland slopes, in 1924. The fine zoological park of 74 acres is beyond Murray field. To the north of the Water of Leith lie Inverleith Park, the Arboretum and the Royal Botanical Garden which includes a herbarium, hot-houses, and a museum of economic botany. Near it is the Stevenson Memorial house in Howard Place. The most extensive open spaces surround Arthur's Seat (822 ft.). This is a basaltic hill, said to commemorate King Arthur, who from its height watched the defeat of the Picts by his followers. It is separated from the narrow valley in which lie the Canongate and Holyrood Palace by Salisbury Crags. Adjoining Nolyrood Palace is the King's Park, used as a parade ground Facing the crags on the south-west are the spots familiar to readers of The Heart of *Midlothian,* where stood Jeanie Deans's cottage, and between the crags and Arthur's Seat lies Hunter's Bog, used as a shooting range. Near here too are three small lakes, Duddingston, Dunsappie and St. Margaret's, the last overlooked by the ruins of St. Anthony's chapel.

Environs.—Leith (*q.v.*), the port of Edinburgh, was incorporated with the city in 1920. Newhaven, so called from the harbour constructed in the reign of James IV., had a shipbuilding yard of some repute in former times. The village has always been a fishing-place of importance, and the fishing population still live markedly to themselves. To the west lies Granton, where the 5th duke of Buccleuch constructed a fine harbour. Still farther west lies the village of Cramond, at the mouth of the river Almond, where Roman remains have often been found; Lauriston Castle is situated in the parish. Cramond Brig was the scene of one of the "roving" adventures of James V., when the life of the "Gudeman of Ballengeich" was saved by Jock Howieson of the Braehead. Here are Craigcrook Castle, where Lord Jeffrey spent many years, and Ravelston House, the home of the Keiths. To the south of the metropolis are Colinton, on the Water of Leith, and Currie, which was a Roman station and near which are Curriehill Castle (held by the rebels against Queen Mary), the ruins of Lennox Tower, and Riccarton. At Dalmahoy Castle, near Ratho (pop 1,672), the seat of the earl of Morton, are preserved the only extant copy of the Bible of the Scottish parliament and the original warrant for committing Queen Mary to Lochleven Castle in Kinross-shire. Craigmillar has a picturesque castle, part of which probably dates from the 12th century. Duddingston, once a quiet village, has become a centre of the distilling and brewing industries. Duddingston House is a seat of the duke of Abercorn. Restalrig, between Duddingston and Leith, was the home of the Logans, from whom the superiority of Leith was purchased in 1553 by the queen regent. Sir Robert Logan (d. 1606) was alleged to have been one of the Gowrie conspirators and to have arranged to imprison the king in Fast Castle. This charge was made three years after his death, when his bones were exhumed for trial. He was found guilty of high treason and sentence of forfeiture was pronounced. A small chapel adjoining the old church covers the healing well of St. Triduana. Liberton, a name that recalls the previous existence of a leper's hospital, is situated on the rising ground south of Edinburgh, the parish church being a conspicuous landmark. Portobello is a popular seaside resort within 3 m. of the centre of the city. Its beautiful sands are flanked by a promenade extending to Joppa. The town dates from the middle of the 18th century, when a cottage was built by a sailor and named Portobello in commemoration of Admiral Vernon's victory in 1739. The place does a considerable trade in the making of bricks, bottles, earthenware, tiles and paper and a large electric power station was opened in 1923. Joppa, which adjoins it, has salt works, but is chiefly residential. Lasswade, partly in the Pentlands, famous for its oatmeal, was often the summer resort of Edinburgh worthies. Melville Castle and Auchendinny are in the neighbourhood. Most famous among the environs of Edinburgh are Roslin and Hawthornden. Roslin Castle, on the beautifully wooded precipitous banks of the Esk, dates from the 12th century. The fine chapel, higher up the bank, founded in 1446 by William St. Clair, 3rd earl of Orkney, is believed to be the chancel of what was intended to be a large church; it suffered at the hands of revolutionary fanatics in 1688. The Gothic details, especially the wreathed "Prentice's pillar," are finely carved. The walk to Hawthornden, about 1½ m. distant by the river-side leads to the mansion of the Drummonds, on a lofty cliff ialling sheer to the stream. The caverns in the sides of the precipice are said to hsve afforded Wallace and others refuge in time of trouble, hut the old house is most memorable as the home of the poet William Drum-

mond. The Pentland range contains many points of interest and beauty; Habbie's Howe is some 2 m. from Carlops, and Rullion Green is noted as the field on which the Covenanters were defeated in 1666. Penicuik has paper mills and stone quarries.

ADMINISTRATION AND EDUCATION

Communications. — Both L.M.S.R. (Princes St. Station) and L.N.E.R. (Waverley Stationj serve Edinburgh. Besides Leith, Granton and Grangemouth serve as passenger seaports for Edinburgh. Tramways connect all parts of the city, including Leith, Newhaven, Portobello and Joppa; and a suburban railway, start* ing from Waverley station, returns by way of Restalrig, Portobello, Duddingston, Morningside and Haymarket. In summer, steamers ply between Leith and Aberdour and other pleasure resorts; and there is also a service to Alloa and Stirling.

Population. — In 1801 the number of inhabitants was 66,544; in 1851 it was 160,302; in 1881 it was 234,402; in 1921, the figure was 420,264. and in 1938, 469.448.

The area of the city has been enlarged by successive extensions of its municipal boundaries. In 1896 portions of the parishes of Liberton and Duddingston and the police burgh of Portobello were incorporated and in 1900 a further addition was made including Granton, Restalrig, and parts of South Leith and Duddingston. In 1920 Leith and the parishes of Corstorphine, Cramond, Libertan and Colinton, including many villages to the south and west of the city, were incorporated with it.

Government. — By the Redistribution Act of 1918 the city with Musselburgh, was divided for parliamentary purposes into five divisions, each returning one member. Leith also returns a member. The town council, which has its headquarters in the Municipal Buildings in the Royal Exchange, consists of 71 members, a lord provost, 10 bailies, a dean of guild, a treasurer, a convener of trades, seven judges of police, and 53 councillors. The corporation has acquired the gas-works, the cable tramways (leased to a company), the electric lighting of the streets, and the water-supply from the Pentlands.

May Meetings. — During the establishment of Episcopacy in Scotland, Edinburgh was the seat of a bishop, and the collegiate church of St. Giles became a cathedral. But the annual meeting of the General Assembly of the Church of Scotland at Edinburgh is now the public manifestation of the predominance of Presbyterianism as the national church. In May each year the sovereign appoints a representative as lord high commissioner to the General Assembly of the Established Church, who takes up his abode usually in the palace of Holyrood, and thence proceeds to the High Church, and so to the assembly hall on the Castle Hill when the lord provost and magistrates offer to him the keys of the city. The General Assembly of the United Free Church is usualiy held at the same time.

University. — Edinburgh University, the youngest of the Scottish universities, was founded in 1583 by a royal charter, dated 1582, granted by James VI. In 1621 an act of the Scottish parliament accorded to the university all rights and privileges enjoyed by other universities in the kingdom, and these were renewed under fresh guarantees in the treaty of union between England and Scotland, and in the Act of Security. Important changes were made in the constitution by acts passed in 1858 and 1889. It was one of the first universities to admit women and in 1916 three hostels for women were built. The students number about 4,000. As a corporation it consists of a chancellor, vice-chancellor, lord rector (elected by the students every three years), principal, professors, registered graduates and matriculated students. With St. Andrews, Glasgow and Aberdeen it sends three members to parliament. While the college, as such, bears the name of the College of King James, or King's college, and James VI. is spoken of as its founder, it really originated in the liberality of the citizens of Edinburgh. William Little of Craigmillar, and his brother Clement Little, advocate, along with James Lawson, the colleague arid successor of John Knox, may justly be regarded as true founders. In 1580 Clement Little gave all his books, three hundred volumes, for the beginning of a library, and this was augmented by other valuable benefactions, one of the most interesting of which was the library of Drummond of Hawthornden. The older buildings of the university occupy the site of the ancient collegiate church of St. Mary in the Field (the "Kirk of Field"), the scene of the murder of Darnley. The present structure dates from 1789. The Royal Scottish Museum is structurally united to the university and Minto House college and Hcriot-Watt college are practically adjuncts of the university. The medical school stands in Teviot Row, adjoining George Square and the Meadows. The magnificent M'Ewan hall is used for academic and public functions. Closely associated with the medical school, and separated from it by the Middle Meadow Walk, is the Royal Infirmary, designed by David Bryce, B.S.A. (1803–1876), removed from Infirmary Street. Its wards are lodged in a series of turreted pavilions, and cover a large space of ground on the margin of the Meadows, from which, to make room for it, George Watson's College — the most important of the Merchant Company schools — was removed to a site farther west, while the Sick Children's hospital was moved to the southern side of the Meadows. Since 1910 chairs have been established in bacteriology, chemistry, therapeutics, commerce, etc. In 1919 the university acquired 115 acres of land at Liberton, and the new King's Buildings of the university, containing chemical laboratories, etc., were opened at West Mains in 1924; a new zoological department also is planned.

Scientific Institutions. — The old Observatory, on Calton Hill, overlooks the district at the head of Leith Walk. The City Observatory stands close by, and on Blackford Hill is the newer building of the Royal Observatory.

The museum and lecture-rooms of the Royal College of Surgeons occupy a classical building in Nicolson Street, The college is an ancient corporate body, with a charter of the year 1505, and exercises the powers of instructing in surgery and of giving degrees. Its extra-academical courses are recognized, under certain restrictions, by the University Court, as qualifying for the degree of doctor of medicine.

The Royal College of Physicians is another learned body organized, with special privileges, by a charter of incorporation granted by Charles II. in 1681. In their hall in Queen Street are a valuable library and a museum of materia medica. But the college as such takes no part in the educational work of the university.

Educational **Institutions.**—After the Disruption in 1843, and the formation of the Free Church, New College was founded in connection with it for training students in theology. After the amalgamation of the United Presbyterian and the Free Churches, under the designation of the United Free Church of Scotland, New College was utilized by both bodies. The Royal high school, the burgh school par excellence, is an ancient foundation, and the Grecian buildings (1829) on the south of Calton Hill, are its third habitation. Edinburgh Academy was opened in 1825. Fettes Colliege and Merchiston Academy are organized on the model of the! great English public schools. For many geherations the charitable foundations for the teaching and training of youth were a conspicuous feature in the economy of the city. Foremost among them was the hospital founded for the maintenance and teaching of poor fatherless sons of freemen by George Heriot — the "Jingling Geordie" of Scott's *Fortunes* of *Nigel*—the goldsmith and banker of James VI. The quadrangular building in Lauriston, sometimes ascribed to Inigo Jones, is one of the noblest in the city. Even earlier than Heriot's hospital was the Merchant Maiden hospital, founded in 1605, which gave to the daughters of merchants similar advantages to those which Heriot's secured for burgesses' sons. In 1738 George Watson's hospital for boys was founded; then followed the Trades' Maiden hospital for burgesses' daughters, John Watson's, Daniel Stewart's, the Orphans', Gillespie's, Donaldson's hospitals, and other institutions founded by successful merchants of the city, in which poor children of various classes were lodged, boarded and educated. As the New Town expanded, the Heriot Trust — whose revenues were greatly benefited thereby — erected day schools in different districts, in which children received a free education, and, in cases of extreme poverty, a money grant towards maintenance. Public opinion as to the "hospital" system of board and education, however, underwent a revolutionary change after the Education Act of 1872 introduced school boards. The govern-

ing body was reconstituted in 1885, and the income of the trust is now applied for the upkeep of a day school at Heriot's hospital, and of the Heriot-Watt college as a technical school, and for the provision of scholarships here and elsewhere. The Church of Scotland has a training college; there is a large training college for teachers in Holyrood Road, and a Roman Catholic college (1920) in Colinton Road.

Besides the Royal Infirmary there are a considerable number of more or less specialized institutions, two of the most important being situated at Craiglockhart. Though Trinity hospital, the oldest charity in the city, no longer exists as a hospital with resident pensioners, the trustees disburse annually pensions to certain poor burgesses and their wives and children; and the trust controlling the benevolent branch of the Gillespie hospital endowment is similarly administered.

Industries.— Edinburgh is residential rather than manufacturing or commercial, but from 1507, when Walter Chapman set up the first press, to the present day, printing has enjoyed a career of almost continuous vitality. Publishing, on the other hand, has drifted away, only a few leading houses—such as those of Blackwood, Chambers and Nelson—still making the city their headquarters. Mapmakers, typefounders, bookbinders and lithographers all contribute their share to the prosperity of the city. Brewing is a strong industry, Edinburgh ale being proverbially good. The arts and crafts associated with furniture work, paper-making and coach-building may also be specified, whilst tanneries, distilleries, factories for india-rubber goods, electric fittings, rope, hosiery, soap and iron and brass-founding, are prominent. Stone quarrying is carried on, but the vast quarry at Craigleith, from which the stone for much of the New Town was obtained, is abandoned. Owing to the great changes effected during the latter part of the 19th century, some of the old markets were demolished and the system of centralizing trade was not wholly revived. The Waverley Market deals in vegetables and fruit and is used for meetings and concerts. Slaughter-houses, cattle markets and grain markets have been erected at Gorgie, thus obviating the driving of flocks and herds through the streets.

HISTORY

A fort or camp set up on the rock on which Edinburgh Castle now stands was probably the nucleus around which, in prehistoric time, grew a considerable village. Under the protection of the hill-fort, a settlement was established on the ridge running down to the valley at the foot of Salisbury Crags, and another hamlet, according to William Maitland (1693–1757), the earliest historian of Edinburgh, was founded in the area at the north-western base of the rock, a district that afterwards became the parish of St. Cuthbert, the oldest in the city. The Romans occupied the country for more than three hundred years. When they withdrew, the British tribes reasserted their sway. The southern Picts ultimately subdued the Britons, and the castle became their chief stronghold until they were overthrown in 617 (or 629) by the Saxons under Edwin, king of Northumbria, from whom the name of Edinburgh is derived. Symeon of Durham (854) calls it Edwinesburch, and includes the church of St. Cuthbert within the bishopric of Lindisfarne. Its Gaelic name was Dunedin. In the 16th century the latinized form Edina was invented. Long after Edwin's conquest the lowland continued to be debatable territory held by uncertain tenure, but at length it was to a large extent settled anew by Anglo-Saxon and Norman colonists under Malcolm Canmore and his sons.

In the reign of Malcolm Canmore the castle included the king's palace. There his queen, Margaret, grand-niece of Edward the Confessor, died in 1093. It continued to be a royal residence during the reigns of her three sons, and hence the first rapid growth of the upper town may be referred to the 12th century. The parish church of St. Giles is believedrto have been founded in the reign of Alexander I., about 1110, and the Norman keep of the castle, built by his younger brother, David I., continued to be known as David's Tower till its destruction in the siege of 1572. Soon after his accession to the Scottish throne David I. founded the abbey of Holyrood (1128), which from an early date received the court as its guests. But the royal palace continued for centuries to be within the fortress, and there both the Celtic and Stuart kings frequently resided. Edinburgh was long an exposed frontier town within a territory only ceded to Malcolm II. about 1020; and even under the earlier Stuart kings it was still regarded as a border stronghold. Hence, though the village of Canongate grew up beside the abbey of David I., and Edinburgh was a place of sufficient importance to be reckoned one of the four principal burghs as a judicatory for all commercial matters, nevertheless, even so late as 1450, when it became for the first time a walled town, it did not extend beyond the upper part of the ridge which slopes eastwards from the castle. So long, however, as its walls formed the boundary, and space therefore was limited, the citizens had to provide house-room by building dwellings of many storeys. These tall tenements on both sides of what is now High Street and Canongate are still prominent in the Old Town. The streets were mostly very narrow, the main street from the castle to Holyrood Palace and the Cowgate alone permitting the passage of wheeled carriages. In the narrow "wynds" the nobility and gentry paid their visits in sedan chairs.

The other three royal burghs associated with Edinburgh were Stirling, Roxburgh and Berwick; and their enactments form the earliest existing collected body of Scots law. The determination of Edinburgh as the national capital, and as the most frequent scene of parliamentary assemblies, dates from the death of James I. in 1436. Of the thirteen parliaments summoned by that sovereign, only one, the last, was held at Edinburgh, but his assassination in the Blackfriars' monastery at Perth led to the transfer of the court and capital from the Tay to the Forth. The coronation of James II. was celebrated in Holyrood Abbey instead of at Scone, and the widowed queen took up her residence, with the young king, in the castle. Of fourteen parliaments summoned during this reign, only one was held at Perth, five met at Stirling and the rest at Edinburgh; and, notwithstanding the favour shown for Stirling as a royal residence in the following reign, every one of the parliaments of James III. was held at Edinburgh. James II. conferred on the city various privileges relating to the holding of fairs and markets, and the levying of customs; and by a royal charter of 1452 he gave it pre-eminence over the other burghs. Further immunities and privileges were granted by James III.; and by a precept of 1482, known as the Golden Charter, he bestowed on the provost and magistrates the hereditary office of sheriff, with power to hold courts, to levy fines, and to impose duties on all merchandise landed at the port of Leith. Those privileges were renewed and extended by various sovereigns, and especially by a general charter granted by James VI. in 1603.

James III. was a great builder, and, in the prosperous era which followed his son's accession to the throne, the town reached the open valley to the south, with the Cowgate as its chief thoroughfare. After Flodden the citizens hastened to construct a second line of wall, enclosing the Cowgate and the heights beyond, since occupied by Greyfriars churches and Heriot's hospital, but still excluding the Canongate, as pertaining to the abbey of Holyrood. In the 16th century the movements connected with John Knox and Mary, queen of Scots, caused much activity at Edinburgh Castle. With the departure, however, of the sixth James to fill the English throne in 1603, the town lost its prestige for a long period. Matters were not bettered by the Act of Union signed in a cellar in High Street in 1707, amidst the execrations of the people, and it was not till the hopes of the Jacobites were blasted at Culloden (1746) that the townsfolk began to accept the inevitable. This epoch, when grass grew even in High Street, long lingered in the popular memory as the "dark age."

By the accession of George III. (1760), Edinburgh showed signs of revived enterprise. In 1763 the first North Bridge, connecting the Old Town with the sloping ground on which afterwards stood the Register House and the theatre in Shakespeare Square, was opened; a little later the Nor' Loch was partially drained, and the bridging of the Cowgate in 1785 encouraged expansion southwards. Towards the end of the 18th century the New Town began to take shape on the grand, if formal, lines planned by James Craig (d. 1795) and the erection of Regent Bridge in Waterloo

place (1819) gave access to Calton hill. The creation of Princes street led to further improvement. The earth and débris from the excavation of the sites for the houses in this and adjoining streets had been "dumped" in the centre of the drained Nor' loch. This unsightly mass of rubbish lay for a while as an eyesore, until it was converted into a broad may joining the new road at Hanover street with the Old Town at the Lawnmarket. Upon this street, which received the title of the Mound, were erected the National gallery and the Royal institution. Speaking generally, the New Town was resorted to by professional men — lawyers. doctors and artists, — and in its principal streets are found the head offices of the leading banks and insurance offices.

The progress of letters, science and learning manifested the recovery of the city. The names of Knox (d. 1572), Buchanan (1582), Alexander Montgomery (160j), Drummond of Hawthornden (1649), Allan Ramsay (1757), Smollett (1771), Fergusson (1774) and Burns (1796), carried on the literary associations of the Scottish capital nearly to the close of the 18th century, when various causes combined to give them new significance and value. The university was served by a body of teachers and investigators who won for it a prominent position among European schools. Then succeeded the era of Scott's *Marmion* and *The Lady of the Laka,* followed by the Waverley novels and the foundation of *Blackwood's Magazine* and the *Edinburgh* **Review.** The influence of the past survives in many ways, and strong local patriotism, together with certain old-fashioned traits in Edinburgh society, remain characteristic and no less admirable.

EDINBURGHSHIRE: *see* MIDLOTHIAN.

EDISON, THOMAS ALVA (1847–1931), American inventor, born at Milan, O., Feb. 11, 1847, of Dutch ancestry on his father's side and Scottish on his mother's. His education was limited to three months in the public school of Port Huron, Mich. At 12 he became a railroad newsboy and after 1j earned his living as a telegraph operator in various cities, always studying and experimenting in his spare time. In 1868 he took out his first patent for an electrical vote recorder. During the next few years he devised stock tickers, duplex, quadruplex and automatic telegraph systems, and incidentally the electric pen, which developed into the mimeograph, for the multiplication of typewriting. His invention (1877–78) of the carbon transmitter, in which compressed lamp-black buttons were used to obtain the necessary variable resistance in the circuit, marked a real advance in the art of telephony and aided materially in bringing the Bell telephone into practical use.

Most modern inventions result from the contributions of many minds, and it is often difficult for the courts to determine priority, but when Edison made application in 1877 for a "phonograph or speaking machine," the U.S. patent office could discover no previous record of this sort. The original model, costing $18, was a cylinder covered with tinfoil and turned with a hand crank. Ten years afterwards he developed a motor-driven machine with cylindrical wax records which speedily became popular. Later he invented a disk form reproducing with a diamond point for music, and the "Ediphone" for office dictation.

On Oct. 21, 1879, after expending more than $40,000 in fruitless experiments, he succeeded in making an incandescent lamp in which a loop of carbonized cotton thread glowed in a vacuum for over 40 hrs. The following decade was devoted to the invention and exploitation of methods for the generation and distribution of electric light, heat and power, including three-wire system, underground mains, improved dynamos and motors, and an electric railway for carrying freight and passengers. From 1891 to 1900 he was chiefly engaged on a magnetic method of concentrating iron ores, and from 1900 to 1910 in the development of a new kind of storage battery, using an alkaline solution with nickel hydrate as the positive and iron oxide as the negative material. In 1891 he applied for a patent on a "kinetescopic camera" for taking motion pictures on a band of film to be viewed by peeping into a box, and later for projecting them on a screen.

In the *Scientific American,* Dec. 25, 1875, he described an unknown "etheric force," which manifested itself by sparks passing between carbon points at a distance from an interrupted current. In 1883 he patented what became known as "the Edison effect," the passage of electricity from a filament to a plate of metal inside an incandescent lamp globe (a forerunner of the radio tube), and in 1885 a method of transmitting telegraphic signals from moving trains or between ships by induction. During World War I he worked on naval problems for the government and on the production of phenol and other chemicals. In 1927 he was admitted to the National Academy of Sciences.

In his combined workshop and laboratory at Menlo Park and later at Orange, N.J., Edison had been incessantly engaged in various forms of invention for more than 50 years and had taken out 1,033 patents up to April 1928. He died Oct. 18, 1931.

See Frank L. Dyer and Thomas C. Martin. *Edison, His Life and Inventions* (1910, authorized biography with list of patents); W. H. Meadowcroft, *The Boy's Life of Edison,* Harper (1921); *A Popular History of American Invention,* edited by Waldemar Kaempffert, Scribners (1924). (E. E. SL.)

EDMONTON, a municipal and parliamentary borough of Middlesex, England, 79 mi. N. of London bridge, with four stations on the L.N.E.R. Pop. (1938) 103,200. Area 6.09 sq mi. Edmonton, consisting of Upper and Lower Edmonton, lies along the Old North road between Tottenham and Enfield, with the river Lea for its eastern boundary. It has grown very rapidly as an industrial area on account of its numerous factories, including gas meter and gas stove works. Market-gardening is also carried on there. The Church of All Saints, extensively restored, retains Perpendicular and earlier portions and some brasses of interest; in the churchyard is the memorial of Charles Lamb, who lived and died (1834) at Edmonton, and his sister. Cowper and Keats were also residents, and the Bell inn is famed through Cowper's poem *John Gilpin.* Open spaces in Edmonton include Pymmes park (53 ac.) and others. Among buildings are the town hall and public libraries, a technical institute (1912–13), Latymer's school (1624) and the county school (1931). Edmonton was incorporated in 1937 and returns one member to parliament.

EDMONTON, capital of the province of Alberta, Canada. Pop. (1901) 2,652; (1941) 93,817. The city takes its name from Fort Edmonton, a Hudson's Bay company post built in 1795, 20 mi. farther down the North Saskatchewan river, where the great rival fur company, the North West Fur company, also had a fort called Fort Augustus. Both forts were destroyed by the Indians in 1807 and the companies built new ones with the same names on the present site of Edmonton. The rapid Saskatchewan river, flowing, as is usual with rivers of the prairie provinces, in a wide trench, was navigable with difficulty up to Edmonton, which was near the southern limits of the wooded country, and became important as a supply and receiving point for the fur trade of the far northwest. The Canadian National railway, which reached the city in 1905, heads straight for the valley of the upper Athabasca, and the easiest of the Rocky mountain passes—the Yellowhead. The old northern fur trade connections have their counterpart in the line to Grande Prairie and the Peace river settlements, and that to the navigable Athabasca river at Ft. McMurray. Precipitation is heavier at Edmonton than in southern Alberta, and it is the centre of an important mixed farming area, extending as far north as the Peace river country. Both the provincial parliament buildings and the University of Alberta are situated there, the latter including departments in arts, agriculture, medicine and mining. The city is the centre of an important coal mining district but for domestic use the prevalent fuel is natural gas supplied from the immense deposits in the Viking, Kinsella and Fabyan fields to the east. With the rapid increase in the city's population, and that of its vast hinterland, manufacturing has developed to a marked degree, particularly in packing plants, which reached in 1942 the largest output of any city in Canada, supplying more than 20% of the total bacon quota for Britain. Adjacent to Edmonton an the Athabasca river at Ft. McMurray are the immense tar sand deposits, the largest known reservoir of oil in the British empire. These deposits are being developed on a large scale, and besides the production of gasoline, will supply the bituminous road surfacing material for western Canada. Other industries are milling, lumbering, furniture and bedding, men's and women's garments, egg powdering plant, cereals and biscuits. It is a large distributing centre both for the surrounding agricultural area and the extensive mining developments to the north, where the range of ore discoveries is remarkable, including precious metals and radium, also oil. Several railways radiate from this city, and two transcontinental lines. together with lines serving the north country, including the new Alaska highway. The city owns all its utilities including the production and distribution of electricity, waterworks, street railway and telephone systems. Edmonton with its strategical location on the great circle route to the orient has long been to the forefront in the matter of aviation, and was the first city in Canada to establish a municipal airport. There are seven air companies including five of the largest United States airways operating daily in every direction including Alaska, Northwest Territories, Transcontinental and the U.S.A. With the advent of the war and the completion of the Alaska highway and other large northern projects, air traffic has been stepped up enormously, and the twice enlarged air field is taxed to capacity. It is served with ten hangars together with machine shows and repair facilities for the largest modern aeroplanes.

EDMUND, SAINT [EDMUND RICH] (*c.* 1175–1240), English saint and archbishop of Canterbury, was born at Abingdon, near Oxford. His father was a merchant who retired, with his wife's

consent, to the monastery of Eynsham, leaving in her hands the education of their family. Edmund began his education in a grammar school at Oxford, and at the age of twelve took a vow of perpetual chastity in the Virgin's church at Oxford. After graduating at Paris, for six years he lectured in the liberal arts, partly in Paris and partly in Oxford where he was the first to lecture on Aristotle. He then returned to Paris for his theological studies. He again lectured at Oxford on theology until *c.* 1222 when he accepted the treasurership of Salisbury cathedral. Little is known of his life for the next ten years. But he attracted the notice of the Roman court, and was appointed in 1227 to preach the crusade in England.

In 1233 he was elected archbishop of Canterbury at the express suggestion of Gregory IX., after the monks of Canterbury had in vain suggested three other candidates for the pope's approval. Edmund at once leaped into prominence by the outspoken manner in 'which he rebuked the king for following the advice of foreign favourites. In common with the baronial opposition he treated Henry III. as responsible for the tragic fate of Richard Marshal, earl of Pembroke, and threatened the king with excommunication. The king bowed before the storm, dismissed the foreign counsellors, made peace with Marshal's adherents, and was publicly reconciled with the barons. But it was with the object of emancipating himself from Edmund's control that the king asked the pope to send him a legate (1 236). On the arrival of Cardinal Otho (1237) the archbishop found himself thwarted at every point. The marriage between Simon de Montfort and the Princess Eleanor, which Edmund had pronounced invalid, was ratified at Rome upon appeal. The king and legate upheld the monks of Canterbury in their opposition to the archbishop's authority. On all public occasions the legate took precedence of the archbishop. By the advice of his suffragans Edmund laid a protest before the king, and excommunicated in general terms all who had infringed the liberties of Canterbury. These measures led to no result, and after the papal encroachments of 1240, when the English clergy were required to pay a subsidy of a fifth for the war against Frederick II., and simultaneously three hundred Romans were "provided" with English benefices in return for their political services to the Holy See, Edmund withdrew to Pontigny. The state of his health drove him later to Soissy (near Provins), where he died on Nov. 16, 1240.

His canonization was at once demanded by his admirers, and only delayed (till 1247) through the opposition of Henry III. Edmund is one of the most saintly and attractive figures of the English church. As archbishop he showed no great capacity, but the purity of his motives and the loftiness of his ideals commanded universal respect. It was his misfortune to be placed at the head of the national hierarchy in a crisis for which he had not been prepared by practical experience.

Edmund's *Le Merure de Seinte Eglise* was last edited by H. W. Robbins (Lewisburg, 1925). *See* the Life printed by Martène and Durand in the *Thesaurus novus anecdotorum* (1717). Other lives exist in ms., at the Brit. Museum, in Cambridge univ. library and in that of St. John's college, Cambridge. The last-named is printed by W. Wallace in his *Life of St. Edmund* (1893). *See* also B. Ward, *St. Edmund* (1903); Baroness Faravicini, *St. Edmund of Abingdon* (1898), and the *Eng. Hist. Review*, xxii.

EDMUND, king of East Anglia (c. 840–870), succeeded to the East Anglian throne in 855 while yet a boy. According to tradition he was born at Nuremberg, and was the son of King Alkmund and Queen Scivare. Offa, king of the East Angles, visited Alkmund on his way to the Holy Land, and adopted Edmund as his heir. Edmund succeeded him in 855, landing at Hunstanton. His coronation took place in the next year at "Burna" (*i.e.*, probably Bures St. Mary, Suffolk), which was then the royal capital.

Of the life of St. Edmund during the next 14 years we know nothing. In 870 the Danes, who had been wintering at York, marched through Mercia into East Anglia and took up their quarters at Thetford. Edward engaged them fiercely in battle at Hoxne, but the Danes under their leaders, Ubba and Inguar, were victorious. The king himself was slain, whether on the actual field of battle or in later martyrdom is not certain, but the version of the story which makes him fall a martyr to the Danish arrows when he had refused to renounce his faith or hold his kingdom as a vassal from the heathen overlords, may be true. The king's body was ultimately interred at Beadoricesworth, the modern Bury St. Edmunds. The shrine of Edmund soon became one of the most famous in England, and the reputation of the saint was European. The date of his canonization is unknown, but churches dedicated to his memory are found all over England.

See *Asser's Life of Alfred*, ed. *W. H.* Stevenson; *Annals of St. Neots; Saxon Chronicle; Memorials of St. Edmund's Abbey* (Rolls Series), including the *Passio Sancti Edmundi* of Abbo of Fleury; and the *Corolla Sancti Eadmundi*, ed. Lord Francis Hervey (1907).

EDMUND I., king of the English (d. 946), was the son of Eadgifu, third wife of Edward the Elder, and half-brother to his predecessor Aethelstan. He succeeded to the throne in 940, but had already played an active part in the previous reign, and fought with Aethelstan in the great battle of Brunanburh.

In the first year of Edmund's reign Olaf or Anlaf Sihtricsson, called Cuaran, who had crossed from Ireland, had been chosen king by the Northumbrians. Anlaf took York, besieged Northampton and destroyed Tamworth, but was met by Edmund at Leicester. A peaceful settlement was made by the good offices of Odo of Canterbury and Wulfstan of York. Simeon of Durham's statement that the kingdom was now divided between Anlaf and Edmund and his story of the reconquest of Northern Mercia by Edmund probably refer to the compact with Anlaf, made as a result of the campaign. All Mercia south of a line from Dore (near Sheffield), through Whitwell to the Humber, was now in Edmund's hands, and the five Danish boroughs, which had for some time been exposed to raids from the Norwegian kings of Northumbria, were now freed from that fear. The peace was confirmed by the baptism of Kings Anlaf and Raegenald, Edmund standing as sponsor, but in 944 or 945 the peace was broken and Edmund expelled Anlaf and Raegenald from Northumbria.

In 945 Edmund ravaged Strathclyde, and entrusted it all to Malcolm, king of Scotland, "on condition that he should be his fellow-worker by sea and land," the object of this policy being apparently to detach the king of Scots from any possible confederacy such as had been formed in 937.

On May 26, 946, Edmund's brief but energetic reign came to a tragic conclusion when he was stabbed at the royal villa of Pucklechurch, in Gloucestershire, by an exiled robber named Liofa. Edmund, the "deed-doer" as the chronicle calls him, "Edmundus magnificus" as Florence of Worcester describes him, perhaps translating the Saxon epithet, was buried at Glastonbury, an abbey which he had entrusted in 943 to the famous Dunstan.

Edmund was twice married; first to Aelfgifu, the mother of Eadwig and Edgar; secondly to Aethelflaed "aet Damerhame" (*i.e.*, of Darnerham, Co. Wilts). Aelfgifu died in 944, according to Ethelwerd.

See *The Anglo-Saxon Chronicle* (ed. Plummer, 1892–99); *Simeon of Durham* (Rolls Series); *A. S. Laws*, ed. Liebermann, pp. 184–191; Birch, *Cartularium Saxonicum*, Nos. 745–817; *Dictionary of National Biography*, *s.v.*

EDMUND or **EADMUND** (c. 980–1016), called IRONSIDE, king of the English, was the son of Aethelred II. (the unready) by his wife Emma, or Aelfgifu. When Canute invaded England in 1015, Edmund was betrayed and deserted by the ealdorman Edric, who went over to Canute, and Wessex submitted to the Danish king. Next year Canute and Edric together harried Mercia, while Edmund with infinite difficulty gathered an army. His attack on the invaded districts of Northumbria was brought to an end by Canute's northward march, and he was forced to return to London. The death of Aethelred on April 23, 1016, was followed by a double election to the English crown. The citizens of London chose Edmund; the rest of the Witan meeting at Southampton elected Canute. In the warfare which ensued Edmund fought at the severest disadvantage, for his armies dispersed after every engagement. Canute besieged London, but the citizens successfully resisted all attacks. Edmund meanwhile received the submission of Wessex. At Pen in Somersetshire he engaged the Danes and defeated them. Canute now raised the siege of London and,

after beihg defeated by Edmund at Pen, came into conflict with him again at Sherston in Wiltshire. The battle was indecisive, but Canute left Edmund in possession of Wessex. Edmund hastened after him and relieved London, which Canute was besieging. He defeated the Danes at Brentford and at Otford, and drove them into Sheppey. He was now joined by Edric, with whom he followed the Danes into Essex, overtaking them at Assandun (or Ashington). In the battle which. ensued Edric again played the traitor, and the English were routed. Edmund retired into Gloucestershire, whither he was followed by Canute. Edric and the Witan then persuaded Edmund to accept a reconciliation, which took place at Olney. The kingdom was divided—Canute taking the north, Edmund the south. Soon afterwards Edmund died (Nov. 30, 1016), probably from natural causes, though later historians hint at foul play.

EDMUND (CROUCHBACK), king of Sicily and earl of Lancaster (1245–96), was the second son of Henry III. of England by Eleanor of Provence. At ten years of age Edmund was invested by Pope Alexander IV. with the kingdom of Sicily (April 1255); the pecuniary obligations which Henry III. undertook on his son's behalf were among the causes which led to the Provisions of Oxford and the Barons' War. Alexander annulled his grant in 1258, but still pressed Henry for the discharge of unpaid arrears of subsidies. In 1265, after Montfort's fall, Edmund received the earldom of Leicester, and two years later was created earl of Lancaster. He joined the crusade of his elder brother, the Lord Edward (1271–72), and supported him on his accession. In 1275, two years after the death of his first wife, Aveline de Fortibus, Edmund married Blanche of Artois, the widow of Henry III. of Navarre and Champagne. Although the county of Champagne was held by his wife in custody for her infant daughter, Joan, Edmund assumed the title "Count Palatine of Champagne and Brie." This he was compelled to renounce upon the marriage of Joan to Philip the Fair, the heir to the crown of France; but he retained the possession of his wife's dowerlands in Champagne. He was employed by his brother as a mediator with Philip the Fair in 1293–94. When Philip's court pronounced that the king of England had forfeited Gascony, Edmund renounced his homage to Philip and withdrew with his wife to England. He was appointed lieutenant of Gascony in 1296, but died in the same year, leaving a son Thomas to succeed him in his English possessions.

See W. E. Rhodes, "Edmund, Earl of Lancaster," in the *English Historical Review*, **vol. x. pp.** 19, 209.

EDMUNDS, GEORGE FRANKLIN (1828–1919), American lawyer and political leader, was born in Richmond, Vt., on Feb. 1, 1828. He began the practice of law in 1849. He was a member of the Vermont house of representatives (1854–59), acting for the last two years as speaker, and was a member and president *pro tem.* of the state senate (1861–62). In 1866 he became a member, as a Republican, of the U.S. Senate. where he remained until 1891, when he resigned in order to have more time for the practice of his profession. He took an active part in the attempt to impeach President Johnson, He was influential in establishing the electoral commission to decide the disputed presidential election of 1876, and became one of the commissioners. In the national Republican nominating conventions of 1880 and 1884 he was a candidate for the presidential nomination. From 1882 to 1885 he was president pro tern. of the Senate. As senator he was conspicuous on account of his legal and parliamentary attainments, his industry and his liberal opinions. He was the author of the so-called Edmunds Act (1882) for the suppression of polygamy in Utah, and of the anti-trust law of 1890, popularly known as the Sherman Act. He died in Pasadena, Cal., on Feb. 27, 1919.

EDO, a southern Nigerian tribe (sub-tribes: Bini, Esa, Kukuruku, Sobo), living in the provinces of Benin, Ondo, Owerri and Warri. Their language resembles Ewe. The tribe became a powerful kingdom in the 15th century and the chieftainship (Obba) became hereditary in the 17th. The chief is surrounded by high court functionaries, and the provinces are administered by territorial chiefs The extended family is disintegrated. Marriage is prohibited between members of the extended family group; descent is sometimes patrilineal, sometimes matrilineal. Inheritance passes to the son, whom failing, the brother. The son takes the wives of his father (his own mother excepted) if they are childless. The Edo are organized in age classes and in secret societies, and practise husbandry and arboriculture. They are animists and show traces of totemism.

See P. Amaury Talbot, *The Peoples* of *Southern Nigeria* (1926).

EDOM (Greek *Idumaea*), the district situated to the south of Palestine, between the Dead sea and the Gulf of 'Akaba, the inhabitants of which were regarded by the Israelites as a "brother" people (see ESAU). On the east it touched Moab, the tribes of the great desert and the northern part of Arabia; on the west its boundaries were determined by the Sinaitic peninsula, Egypt and Israel. Both Kadesh and Mt. Hor (perhaps Jebel Mādera) are represented as lying on its border (Num. xx 16, 22), and the modern Wadi el-Fikreh, in which the "Scorpion pass" was probably situated (Judg. i 36; Num. xxxiv 4), may have marked its limits from Jebel Mādera northwest toward the southern extremity of the Dead sea. The precise borders, however, must have been determined by political conditions: by the relations between Edom and its neighbours, Judah, the Philistine states, Moab and the restless desert tribes with which Edom was always very closely allied.

The early history of Edom is obscure; Egyptian references to it are few and do not give much light regarding the early inhabitants. In the early records of the Pentateuch, the country is often referred to by the name of Seir, the general name for the uhole range of mountains on the east side of the Jordan-Araba depression south of the Dead sea. These mountains were occupied by a cave-dwelling aboriginal race, the Horites. According to Old Testament tradition, the Edomites were a new race who drove out the Horites from Mt. Seir.

The occupants of Edom during practically the whole period of Biblical history were the Bedouin tribes which claimed descent through Esau from Abraham, and were acknowledged by the Israelites (Deut. xxiii 7) as kin. Among the peculiarities of the Edomites was government by certain officials known as אַלּוּפִים, which the English versions translate "dukes." The now naturalized word "sheikhs" would be the exact rendering. In addition to this Bedouin organization there nas the curious institution of an elective monarchy. A list of eight kings, who reigned before the Israelite monarchy is preserved in Gen. xxxvi. Saul. the first king of Israel, conquered Edom (1 Sam. xiv 47), as did David, the second king.

After David's conquest, the Edomite prince Hadad escaped to Egypt, where he remained until the death of David. If, as the narrative of Kings xi implies, he became a troublesome adversary to King Solomon, nothing is known of his achievements, and if Solomon's trading-journeys from Ezion-geber were maintained, Edom must have been weak. Edom aas under the rule of Jehoshaphat of Judah, who, with Israel held Ezion-geber (1 Kings xxii 47 sqq.; 2 Chron. xx 35 sqq.). Some catastrophe befell the fleet, and shortly afterwards Jehoshaphat's son Jehoram had to face a revolt in which Edom and the men of Libnah (the Philistines) were concerned. It was about this period that Israel had conquered Moab, thrusting it farther south towards Edom, and the subsequent success of Moab in throwing off the yoke, and the unsuccessful attempt of Jehoram of Israel to regain the position, may show that Edom was also in alliance with Moab. In the time of Adad-nirari of Assyria (811–782 B.C.) Edom is mentioned as an independent tributary with Eeth-Omri (Israel) and Palashtu (Philistia). The absence of Judah is noteworthy. Amaziah of Judah had gained a signal victory over Edom in the valley of Salt (2 Kings xiv 7), but after his defeat by Jehoash of Israel there is a gap and the situation is obscure. Consequently it is uncertain whether Edom was the vassal of the next great Israelite king Jeroboam II, or whether the Assyrian evidence for its independent position belongs to this later time. However, Uzziah, a contemporary of Jeroboam II, and one of the most successful of Judaean kings. overcame Edom and its natural allies (2 Chron. xxvi 6 *sqq.*), and at this stage Edomite history becomes more

prominent. It joined the great coalition in which Philistia and Israel were leagued against Assyria, and drove out the Judaeans who had been in possession of Elath (2 Kings xvi 6). On the events that followed see AHAZ; HEZEKIAH; PHILISTINES. In the middle of the 7th century both Edom and Moab suffered from the restlessness of the desert tribes, and later joined in the attempt made by Zedekiah of Judah to revolt against Nebuchadrezzar (Jer. xxvii 3).

Edom in alliance with the tribes along the trade-routes (Philistines, Moabites, etc.) was responsible for many attacks upon Israel, carrying away prisoners as slaves for Gaza and Tyre (Am. i 6 *seq.*, 9). As an ally or vassal Edom was in touch with the wealth of Arabia (Ezek. xxvii 16, read "Edom" for "Aram"), and Judah and Israel as well as Gaza and Damascus enjoyed the fruits of its commerce. Edomite and allied tribes were famed for their wisdom (Ob. 8, Jer. xlix 7 seq., Baruch iii 22), and besides the possibility of Arabian influence upon Israelite culture, the influence of Midian and related tribes is certain from the traditions of Moses and of his work (see JETHRO; KENITES; MOSES), and the Edomite district was a traditional home of Yahweh himself (Deut. xxxiii 2; Judg. v 4; Hab. iii 3). It should be added, however, that the Edomite names and other evidence point to the cult of other gods.

In the last years before the fall of Jerusalem many of the Jews found a refuge in Edom (Jer. xl 11), although other traditions throw another light upon the attitude of Edom during these disasters. It is said that Edomites burned the temple after the destruction of Jerusalem (1 Esd. iv 45, *cf. v.* 50), and naturally the weak state of Palestine invited attacks from the outlying tribes; but the tone of certain late writings implies a preliminary period of, at least, neutrality (*cf.* Deut. ii 4 *sqq.*, xxiii 7 *seq.*; the omission of Edom in xxiii 3; Neh. xiii 1; and in Ezra ix 1—contrast 1 Esd. viii 69). Edom is execrated for revengeful attacks upon the Jews, and its speedy destruction is foretold; but the passages appear to be later than the disaster of 586 B.C., and may even imply conditions after the restoration (Ob. 10 *sqq.*; Ezek. xxv 12–14; Jer. xlix 7; Ps. cxxxvii 7; Lam. iv 21 *seq.*, v 2 *sqq.*). Eventually the constant westward pressure of the eastern Arabs forced the ancient Edomites across the Jordan-Araba depression. With their name they migrated to the south of western Palestine. In 1 Maccabees v 65 they are at Hebron, and this is one of the first indications of the cis-Jordanic Idumaea of Josephus and the Talmud. *See*, for the later history, HEROD; JEWS.

Josephus used the name Idumaea as including not only Gobalitis, the original Mt. Seir, but also Amalekitis, the land of Amalek, west of this, and Akrabatine, the ancient Acrabbim, S.W. of the Dead sea. Jerome describes Edom as extending from Beit Jibrin to Petra, and ascribes the great caves at the former place to cave-dwellers like the aboriginal Horites. Ptolemy's account presents the last stage, in which the name Edom is entirely restricted to the cis-Jordanic district, and the old trans-Jordanic region is absorbed in Arabia.

Levy in *Rev. d'etudes juives* (Jan. 1906). For the history and culture of the latest period, see J. P. Peters and Thiersch, *Painted Tombs in the Necropolis of Marissa* (1905), ch. i. (S. A. C.; R. A. S. M.; X.)

EDRED (EADRED), king of the English (d. 955), was the youngest son of Edward the Elder and his wife Eadgifu. He succeeded his brother Edmund in the year 946 and received the formal submission of the Northumbrians and Scots. In the next year Edred went to Tanshelf in Yorkshire, where he received from Wulfstan, archbishop of York, and the Northumbrian "witan" confirmation of their submission. Shortly after they threw their pledges to the winds and took the Norwegian Eric Bloodaxe, son of Harold Fairhair (Harald Harfagar), as their king. Edred recklessly ravaged all Northumbria in revenge, burning Ripon during his march. On his return home Edred's rearguard was attacked at Castleford, and he once more turned to ravage Northumbria, which was only saved by its abandonment of Eric and by compensation made to Edred. Archbishop Wulfstan seems to have been *a* centre of disaffection in the north, and in 952 Edred caused him to be imprisoned in the castle of "Judanburh," while in the same year the king, in revenge for the slaying of Abbot Eadelm, slew many of the citizens of Thetford. After the brief rule of Anlaf Cuaran in Northumbria, Eric was once more restored, probably in 950, only to be expelled again in 953 or 954, when Edred took the Northumbrian kingdom into his own hands. In the same year Wulfstan was liberated and appointed to the Mercian bishopric of Dorchester. Edred died on Nov. 23, 955, at Frome, in Somersetshire, and was buried in the old minster at Winchester. During the whole of his life Edred was troubled by ill-health, a fact which may help to explain some of the more passionate acts of violence attributed to him. The king was throughout his life on terms of personal intimacy with St. Dunstan, and his public policy was largely guided by that prelate and by his mother Eadgifu. It is not known that Edred married.

EDRIC (or EADRIC), STREONA (d. 1017), ealdorman of the Mercians, was a man of ignoble birth who was advanced to high dignity through the favour of the English king Aethelred II. In 1007 he became ealdorman of the Mercians, and in 1009 married Aethelred's daughter Eadgyth. In the struggle between the English and the Danes he appears in the character of an arch-traitor. When Aethelred in 1009 proposed a great attack on the Danes, Edric dissuaded him from carrying it into effect. At the "witan" held in Oxford in 1015 Edric had Sigeferth and Morkere slain by treachery. In the same year Canute invaded England; Edric, who had joined Edmund Ironside, subsequently quarrelled with him and went over to Canute. After the battle of Otford he returned to Edmund, but only to secure the utter defeat of the national cause by his treachery at the battle of Assandun. After Edmund's death Canute restored to Edric the earldom of Mercia; but in 1017, fearing further treachery, he had him slain.

EDUCATION. The subject of Education is treated in this introduction under the following heads: I. Educational Theory. II. Psychology and Ancillary Sciences. III. Science of Education. IV. Educational Experiments, followed by sections on History and National Systems.

I. EDUCATIONAL THEORY

Definition.—Many definitions have been given of the word "education," but underlying them all is the conception that it denotes an attempt on the part of the adult members of a human society to shape the development of the coming generation in accordance with its own ideals of life. It is true that the word has not infrequently been used in wider senses than this. For example, J. S. Mill included under it everything which "helps to shape the human being"; and, with some poetic licence, we speak of the education of a people or even of the whole human race. But all such usages are rhetorical extensions of the commonly accepted sense of the term, which includes, as an essential element, the idea of deliberate direction and training. No doubt, all education is effected through the experiences of the educated, but it does not follow that all experiences are educative. Whether an experience is part of an individual's education or not, depends upon whether its form has been arranged by those who are concerned with the training of him whose experience it is. It follows that an education may be good or bad, and that its goodness or badness will be relative to the virtue, wisdom and intelligence of the educator. It is good only when it aims at the right kind of product, and when the means it adopts are well adapted to secure the intended result and are applied intelligently, consistently and persistently.

Education is, thus, a definitely personal work, and will vary between wide extremes of effectiveness and worth in any given society. For in all times and places there are wide differences in virtue, wisdom and capacity among those who have in their hands the care and nurture of the young. Yet, despite these differences every teacher expresses, more or less perfectly and clearly, the current conception and outlook of his age and country. The first essential for successful educative effort is, then, that the

community as a whole should have a true estimate of the nature and value of education.

Assuming, however, a well-inspired community and teachers capable of fulfilling its will, it is not possible to say, except in most general terms, how it will educate its children. For although looking at the individual to be educated, we may say with Plato that the aim of education is "to develop in the body and in the soul all the beauty and all the perfection of which they are capable," this leaves quite undecided the nature and form of that beauty and perfection, and on such points there has never been universal agreement at any one time, while successive ages have shown marked differences of estimate. Individual beauty and perfection are shown, and only shown, in actual life, and such life has to be lived under definite conditions of time, place, culture, religion, national aspirations and mastery over material conditions. Perfection of life, then, in the Athens of the age of Plato would show a very different form from that which it would take in the London, Paris or New York of to-day. Hence, so far as any conception of education can give guidance to the actual process it must be relative in every way to the state of development of the society in which it is given.

Education and **the** Community. — There is one respect in which the constitution and general outlook of a community are especially likely to affect the character of its education. Education aims at conserving and perfecting the life of the community, but that life is nothing other than the life of its individual members. In an ideal community there would be complete identification between the interests of every unit and of the whole; but history records no ideal communities. In practice there are always divergences, leading to exploitation here and sacrifice of development there. Societies in different times and places differ from one another, then, in their degree of success in reconciling the interests of the whole with the claims of individual development, or in their willingness to subordinate the latter to the former; and their educational conceptions naturally reflect these differences. The primitive tendency in communities is towards the complete subordination of the individual, but in the western peoples that tendency has, since the advent of Christianity, been checked and modified by an increasing valuation of the individual life. It is an apparently paradoxical, but easily intelligible, fact that the World War, by its startling revelation of the immense range, the intimate closeness and the vast complexity of modern social organization, actually stimulated the reaction against the primitive tendency and the educational ideas which expressed it. Educational theory must always be more or less "paidocentric"—that is, must focus its attention in the first place upon the single child and upon the gifts and powers which make him educable; but in its recent trend it goes beyond that, and tends to regard the perfection of the individual as the proper end of educational efforts. This does not imply a disregard of social claims or point towards social disintegration; the view is that the best forms of communal life will be fostered by an education which regards social activities as a necessary medium for the development of the higher stages of individual life rather than something to which the claims of individual development must be subordinated. This conception, held with more or less conscious clearness, has guided much of the typical development which, prominent in America *(see* EDUCATION: *Science of* and *History of Education, United States)* and to a less extent in Britain before the war, has since 1918 proceeded apace in most civilized countries.

The most striking sign of the change of view here in question is afforded by the reorganization of public education now going on in the more progressive lands. Its distinctive feature is the replacement of the old conception, in which elementary and secondary schools corresponded mainly to social stratification, by the idea that children of all classes should have the opportunity of a primary education, designed to meet the needs of childhood, followed by a post-primary or secondary education adjusted to the needs of adolescence. In the United States this idea is embodied in the system of primary schools (*q.v.*) followed by junior and senior high schools (*q.v.*) on the "six-three-three" principle. (*See* ELEMENTARY EDUCATION IN THE U.S. and SECONDARY EDUCATION IN THE U.S.) In England it underlies the proposals of the Report of the Consultative Committee of the Board of Education on the Education of the Adolescent (1926). It has also inspired the post-war changes in the State systems of the German *Reich.* In part these developments have no doubt come about because modern industry and forms of government demand in the average citizen a higher standard of knowledge and training than formerly sufficed. But the fundamental explanation is to be found in the conception that a community should place the best opportunities of self-development and realization within the reach of all of its members who are capable of profiting by them.

Curriculum. — (For *United States* see below.) From these considerations it is natural to descend to the curriculum. What ought boys and girls to learn at school? The principle underlying any sound answer to this question follows from what has already been said about the purpose of education. It is the function of the school, continuing, supplementing and (too often) correcting the influences of family life, to bring to bear upon the pupil the spiritual forces which are typical of the national *ethos* and to train him to take his part in conserving and developing the life of the community.

To perform that function a school must, in the first place, be a genuine society inspired by the best ideals of the national character and therefore able to transmit to and confirm in its pupils the traits which enter into those ideals. The so-called "public schools" (*q.v.*) of England have won their repute mainly because they are deemed to have been successful in this fundamentally important part of the work of a school. It is well-known that respect for physical vigour and prowess, good manners, public spirit, self-restraint and a training in the responsible use of freedom and self-government are the main ingredients fused in the powerful social ideals of those schools. All these are valuable elements in the formation of any citizen, and should, accordingly, find their place in the life of schools of every type.

In the second place the school must offer its pupils instruction in a number of "subjects." Here the principle we follow admits of a variety of interpretations. One may take either a short or a long view of the life and needs of the community. Upon the Short view the community requires at the moment certain kinds of knowledge and skill to carry on its economical and other activities; and it is the business of the schools to turn out young people equipped with such forms of knowledge and skill. Upon the long view it is less important to consider the utilitarian needs of the present day than to bring the pupil into fruitful contact with those elements which are deemed to have most enduring and vital significance in the historic life of the people. The contrast between these views develops in different ways into the antitheses between a "vocational" and a "liberal" education, between a "modern" and a "classical" education and, less directly, between an education that stresses the value of knowledge and one that emphasizes the importance of "mental training" or "discipline."

A well-based theory of the curriculum should find a place for all that is sound in the conflicting ideas involved in these antitheses. Such a theory must undoubtedly start from what was called above the long view. In other words its leading principle will be that the school society must include among its formative influences all those modes of intellectual, aesthetic and practical activity which have played a major part in the evolution of the human spirit and have shaped the mind of the present age. Letters and art, music and handicraft, mathematics and science, geography and history are thus indicated as necessary constituents of the complete curriculum; but not only may they enter into it in a variety of ways, they must do so if the principle is to be elastic enough to fit the varying needs of different types of scholars. For instance, training for a specific vocation conforms with the principle if it aims not merely at imparting skill in the use of tools or empirical technical knowledge, but at putting the learner to school in the ethical and scientific or aesthetic traditions of some essential occupation or profession which has played and continues to play an important part in our civilization. Thus conducted, a vocational training may be, for large sections of the population, the appropriate way af completing and rounding off

a truly liberal education. On the other hand a training based mainly upon the study of the ancient classics is not entitled to be called liberal unless given in such a way as to make the student a freeman of the modern world, sensitive to its ideas and awake to the significance of its intellectual and social movements.

The idea that the cultivation of mental training or discipline is one of the chief aims of education has played and continues to play so large a part in educational theory and practice that it needs careful analysis. It is expressed in a popular and epigrammatic form in the statement that a man's education consists in what he retains after he has forgotten everything he learnt at school. But the interesting question is: What does he retain? According to the cruder view school studies serve to develop certain faculties or powers of the mind, and that development is the real reason for pursuing them. For instance, the Latin verses a boy learns daily may all be forgotten soon after he leaves school, but (it is held) the learning has served to strengthen his memory, and that is its sufficient justification; he may never have occasion to use the knowledge of chemistry and physics he has acquired, but that does not matter if he has gained from those studies powers of observation and inference which are universally valuable and the habit of applying the scientific method to all subjects of discussion. Similarly, geometry is held to train one's reasoning powers and algebra to develop mental accuracy. The assumption made here is that the strength or training a faculty acquires by being exercised upon a particular kind of material fits it to deal competently with any other kind of material to which it can be applied. The weakness of the argument is that in the eyes of modern psychology this assumption is, to say the least, very questionable. It has, for instance, been shown clearly by most careful experiments that a person who "trains" his memory by (say) prolonged exercise in learning verse is no better able than before to remember the substance of a prose passage. Similarly there is no reason to believe that an acute observer in the field of botany or geology has acquired by his training a quickness and sureness of eye that will serve him usefully when he drives a motor-car through the streets of London. Ascertained facts and general considerations such as these have tended greatly to discount the idea of mental training; yet it is difficult to suppose that there is nothing in a notion which has been held not only by thinkers of the eminence of John Locke but also by a long line of able and experienced schoolmasters. The clue to the right view of the matter was given by Herbert Spencer who, in his famous work on Education, declared, in effect, that the antithesis between the knowledge-value and the training-value of school studies was a false one. If, said Spencer, we give our pupils the knowledge which is "of most worth" — that is the knowledge which has indispensable practical value in regulating the affairs of life—we shall at the same time give them the best possible mental training; for it is incredible that the pursuit of the best kind of knowledge should not also afford the best mental discipling. This interesting dogma must, as far as Spencer himself is concerned, be regarded as part of the faith of an evolutionist; but it may also be regarded as following from the general principle of the curriculum stated above. The most educative activities, it was said, are those which have made the most essential and enduring contributions to the tissue and growth of civilization. Those contributions have actually been brought about by the geniuses of the race: the great artists. craftsmen, poets and men of letters, musicians, men of science, statesmen. They have shaped and refined the activities to which they gave themselves and have thus created traditions of activity, intellectual, aesthetic, practical, having definite and characteristic forms. In this way the traditions of poetry and fine letters have grown up out of the universal habit of communication by speech, architecture and the crafts out of the universal needs of the physical life, science out of the universal gift of curiosity and the equally universal need of exact knowledge for endless practical purposes. and so with the other cardinal activities represented in the curriculum. In so far as a pupil's studies tend to affiliate him lo these traditions or to enable him to absorb them, so far his mind acquires the form and habit of the great minds that fashioned them and is *disciplined*. In short, the discipline of school life and studies consists in learning to become in a small way a brother-poet to the poets, a fellow-craftsman with the craftsmen, an inquirer looking out upon the world through the eyes of the men of science, and a citizen following the civic ideals of the great citizens. Discipline or training of this kind is concrete, not abstract, and is of universal value because the activities which give it are the fundamentally important activities of civilized life.

Nothing has hitherto been said about religious instruction as an item in the school curriculum. Little can be usefully said in a brief review, partly because the term religion embraces so immensely complicated a mass of phenomena, partly because men's attitudes towards religion are so varied and are often in such deeply felt opposition. Besides the adherents of warring creeds there are many (by no means necessarily disciples of Karl Marx) who would teach morality without religion because they hold religion to be a spiritual disease or at best an illusion of the childhood of humanity which should disappear from modern life. Persons who hold that extreme view would exclude religious instruction upon the principle which would normally be thought to make its presence in a school essential — for they deny that it represents a factor of vital and enduring value in the life of nations. It may nevertheless be maintained that even these intransigents live by a faith which sees supreme value in certain ideals, recognizes that those ideals rightly demand service, and has some influence in "cleansing the inward parts." If it be granted that any such faith must be called religious because it is of the essence of all true religion, then the doubt whether the general principle of the curriculum applies to religious instruction disappears; for it must be admitted that religion in this wide sense is one of the cardinal factors in the maintenance and development of human communities, and therefore that religious instruction must necessarily be a factor in the school society. But there remains the question of the relation between religious instruction, in the very general sense here given to the name, and the specific creeds, and this is one upon which agreement is not easily to be reached, even in principle. Probably the proposition that will be most widely accepted is one which seems to follow from what is now known about the general features of mental development: namely, that the credal elements in religion, being of the nature of an organized theory about the sources and objects of religious devotion, should at least be little emphasized until the age of adolescence. But even if this proposition be granted, its application leaves abundant room for controversy.

Coeducation. — A further general question arises in connection with the conception of the school as a society that aims at realizing an idealized epitome of the community of which it is a part and an organ. In the outer world the interactions between the sexes play a rôle of immense importance, and there is no *région* of life where it is more essential that the highest traditions should prevail. Does it not follow that both sexes must necessarily be brought up together at school? The advocates of coeducation (*q.v.*) base their affirmative answer to the question upon the grounds just indicated, and their arguments have in recent years made some headway in countries where, as in England, the custom has been, on the whole, to separate the sexes for education after infancy. On the other hand, defence of the customary separation upon theoretical as well as practical grounds is not lacking.

School Government. — Somewhat the same theoretical difficulty arises in connection with the broader question of school government. There is no ignoring the fact that the school society rests upon an artificial form of compulsion essentially different from the compelling forces which bear upon the citizen of the great society. In brief, the essence of the school polity consists in a regulation of the lives of the young by adults for purposes which the adults have selected Yet since the chief of these purposes is that boys and girls may learn to live worthily, as men and women, the common life of the great society, it would seem that the fundamental features of that life should in some form be represented in the school society. The uncertainty about the application of this principle is naturally greatest where the democratic faith still prevails. In recent years a good many attempts

CLASSES IN PHYSICAL AND VOCATIONAL EDUCATION

1. Class in costume designing at the School of the Art Institute, Chicago
2. Physical education class for girls in the Evander Childs High School gymnasium, Bronx, N. Y.
3. Boys making games in manual training shop of Neighborhood House, Washington, D. C. Classes for boys and girls in music, crafts, and painting are also held
4. Gymnastikuppvisning (Stockholm), a formal drill in Swedish gymnastics, demonstrated by a class of high school girls. The public schools in Sweden place special emphasis on physical education throughout the elementary and high school years
5. An art class working from casts in the Museum of Fine Arts, Boston
6. Class in basket weaving in Milwaukee, Wisconsin. Instruction is being given in the making of baskets and other articles from reeds

have been made in England, the United States, Germany and elsewhere, to conduct school government upon a thorough-going democratic basis, the pupils exercising, together with their teachers, the functions of the legislature and the judiciary in their little state. Experiments of this kind, opposed as they are to deeply engrained traditions concerning the upbringing of children and (some psychologists would add) to deeply rooted impulses towards the exercise of power, were bound to meet with great difficulties. They seem to have been most successful where it was a question of redeeming young delinquents whose faults were due less to corruption than to the misdirected actions of authority, Elsewhere authority has tended to slip back into the hands of the adult members of the school society by whom it was delegated, Nevertheless a comparison, at any rate in England, between schools to-day and the schools of the last generation shows that there has been a notable general advance in the direction which the bolder reformers may have followed too far. The autocratic attitude once generally characteristic of teachers has been sensibly modified; in effect they act not as absolutists imposing their will upon their subjects but rather as the natural guardians of an order which it is the interest of all to have maintained. And in addition to this implicit but very real appeal to the consent of the governed there is in schools of all kinds an increasing tendency to entrust authority and management to pupils who are old enough to understand and to bear the responsibilities involved. Here is a principle which goes a good deal farther than the oligarchical principle of prefect-government as Arnold (*see* ARNOLD, THOMAS) conceived it; for it recognizes that self-responsibility, exercised under adequate adult supervision, is highly educative at all stages in the growth of character.

Punishment. — An important change of attitude with regard to the theory of the government of children entails a change, equally radical, in one's attitude towards punishment; for punishment (whatever else it may be) is an instrument of government. It is scarcely if at all too much to say that it was once the main instrument of government in schools; but the schoolmaster no longer uses it, especially in its more violent forms, with the old confidence in its propriety and efficiency. This is not due merely to the humanitarianism of the age, for, with increasing understanding of the theory of his profession, the teacher feels with increasing discomfort that the necessity of punishment is often a symptom of discordance between the true needs of his pupils and the general conditions of school life—a discordance for which he is largely responsible. Accordingly he is less prone to turn to repression as a remedy for evil than to seek to amead those conditions. Such a policy is in conformity with the general principle that the function of the school is to encourage positive activities of a wholesome and valuable kind and that moral as well as mental discipline comes by learning to do the right thing in the right way. No doubt perversity will crop up in a school no matter how scientifically it may be conducted; for the schoolmaster has to reckon not only with his pupils' human tendency to err but also with the unwisdom of parents in their early dealings with that tendency; the elimination of wrong-doing and its correlative punishment is accordingly a consummation which no one is likely ever to see, however devoutly it may be desired. Nevertheless the treatment of youthful wrong-doing without sentimentality, along scientific lines, promises a vastly greater amelioration than blindly repressive methods ever secured.

II. PSYCHOLOGY AND ANCILLARY SCIENCES

By Plato and Aristotle the theory of education was considered in close connection with political theory and in the foregoing discussion the lead given by those great thinkers has again been followed; it was, however, not easy to exclude references to other sciences whose development has had to await modern times. Of these sciences ancillary to the theory and practice of education the most obvious is psychology. To psychology all writers on education have had to make some appeal, since all have been compelled to recognize that teaching and training cannot be effective in the absence of knowledge about the mind which is to receive them. It must nevertheless be admitted (though the criticism does not justly lie against Aristotle) that until recently the professional psychologists, owing to their preoccupation with the purely intellectual processes, have given less help than might have been expected in the elucidation of educational problems. The pedagogy of Herbart and his successors threw valuable light, it is true, upon the nature of interest, and prepared the way for the modern treatment of this centrally important topic; but academic psychology had, on the whole, comparatively little to give the educator until it was fertilized by contact with the conceptions of biology—especially with master-conceptions of growth and development and the notion that mental, like physical, behaviour is to be regarded as a reaction to environment. Herbert Spencer, whose *Principles* of *Psychology* first appeared in 1855, must receive credit for initiating the new orientation of psychology. In James Ward's famous article in this Encyclopædia (1886) there was effected a fusion between some of Spencer's ideas and the conceptions of Kant and the German school of psychologists, while in William James's unsystematic but vastly influential *Principles* of *Psychology* (1891) the influence of biological science was strong and apparent. The "child study movement" in America *(see* EDUCATION, SCIENCE OF) and elsewhere was a significant expression of the new tendency to look at human behaviour and development from the biological point of view; it produced in Stanley Hall's *Adolescence* (1904) a monumental work in which that tendency dominated almost every page. The same tendency was expressed more formally in William MacDougall's theory of instinct, first worked out fully in his Social *Psychology* (1908). The trend of the biological school of psychologists towards external observation as opposed to the introspection of the older school has in recent years reached its extreme limit in the "behaviourism" of the American psychologist J. B. Watson and his followers. Behaviourism rejects introspection as a means of gaining psychological knowledge, substituting observation of the reactions of human beings under clearly defined experimental conditions. The investigations in the laboratory of the reactions of very young children now being conducted by workers in this typically modern school may lead to interesting results. Meanwhile it is claimed, with some justice, that some of the most useful applications of modern psychology to education—especially the whole field of "mental tests" *(see* EXAMINATIONS)—are, in principle, applications of behaviourism, in as much as they consist in the study not of events supposed to occur in the child's mind but of his observable reactions to situations deliberately arranged.

Among the features in current educational psychology which derive from the influence of biology are the studies that have been made of the meaning and function of play, the rôle of imitation and suggestion in the genesis of individuality, and the exploitation of McDougall's theme that the complexities of adult human behaviour are developed from a moderate number of distinct sources of energy—the instincts—which, unlike the corresponding instincts in the animals, are indefinitely plastic and capable of entering into the permanent systems called by Shand "sentiments," and regarded by him as the main constituents of human character. From biology, again, came the "functional psychology" of John Dewey, his pragmatic theory of reasoning, and the applications of his doctrines in pedagogy (see below).

It may also be remarked here that hygiene, which must be included among the sciences ancillary to the theory and practice of education, has tended in recent years to be not merely a body of applications of human physiology but to derive from biology a broader outlook. It is, in brief, becoming a study of the best conditions and ideal development of the physical human life as a biological process.

In spite of a good deal of hostile criticism the movement which may be called comprehensively, if not very accurately, the psychology of the unconscious (*q.v.*), is now seen to have increasing importance for educational psychology. In this field the discoveries and doctrines of Freud attracted most attention, though those of Jung and Adler are not to be ignored. It is well known that Freud attached very great importance to the rôle of sexuality (defined in an extremely wide way) in the development of mind

and character, and referred most disturbances of that development to deviations from sexual normality in the earliest stages of life. It remains to be seen whether his interpretations will survive further knowledge and criticism without considerable modification; but there can be no doubt about the general truth of his conceptions of the influence upon behaviour of unconscious factors, of the early origin and persistent activity of some of these factors, of the harmful effect of unconscious mental repressions and conflicts, and of their profound bearing upon the happiness, conduct and mental efficiency of boys and girls as well as of adults. Further it can hardly be questioned that many of the perversities which bring young people into conflict with authority and many weaknesses and misdirected developments of character are first caused by unwise or wrongly motived parental treatment, or, in general, by abnormality in the relations between young children and those upon whom they are dependent. In his later works, too, Freud had begun to work out ideas upon the nature and growth ot the ego or self which seem likely to have much value for educators.

Experimental psychology, if it has not fulfilled the rather extravagant expectations of some optimists, has nevertheless made some useful contributions to educational science. It has thrown valuable light upon processes of memorization and learning and the nature of some of the higher intellectual processes; it has exploded some fallacies on the subject of mental training; above all it has given birth to the idea and guided the practice of mental tests. Possibly of more far-reaching importance than the practical applications of experimental psychology in education are the developments of theory to which it has led. Among them a prominent place must be given to Spearman's "two factor" theory of intellectual ability, his formulation of the three noegenetic laws in terms of which he analyses all mental processes, and the "form-psychology" of some recent German writers. All these have an important bearing upon general educational theory or upon the principles of teaching.

Comparative psychology is a science which throws useful sidelights upon educational problems, particularly through its studies of the growth of habits and of rudimentary reasoning in the higher animals. Mention must also be made of anthropology and the psychology of primitive races. These branches of learning, though still young, promise to illuminate not only questions concerning the education of the races for whose welfare the more civilized nations have accepted responsibility, but also to bring into relief principles that have importance for education wherever it is practised: for instance, the necessity of relating instruction to the actual needs and conditions of life of a people, and the influence of differing mental backgrounds upon the attitude of men towards their fellows and towards nature. (T. P. N.)

III. SCIENCE OF EDUCATION

The science of education is the systematic study by exact methods of all phases of the educative process, and is being rapidly extended. One of the earliest advocates was Herbart, the German philosopher and educator. He took the position that if education is to be scientific, it must be guided by psychology, the science of human nature, and by ethics, the science of social behaviour. The psychology and ethics of his day, however, were so theoretical and so deficient in scientific methods that he found it impossible to justify the practical suggestions which he made regarding educational methods. It remained for a later generation, and for the educators of America to develop a science of education.

One group of followers of Herbart did much to improve methods of teaching. Another endeavoured to improve the technique of scientific investigation of mental phenomena. As a result of the efforts of this second group empirical psychology was developed. Wundt, the founder of modern experimental psychology, frequently acknowledges his indebtedness to Herbart and the investigators who adopted Herbart's methods of psychological analysis. It was not, however, until empirical psychology was transplanted to America during the '80s, that it became possible to apply psychology to the study of school prwcedures and results. The schools of Europe were and are conducted under the direct supervision of the central Government, and are not readily subjected to critical examination by scientific methods. American schools, on the other hand, are locally controlled and are so variable in their practices that they encourage studies of their relative efficiency.

G. Stanley Hall, an American who had been trained in the psychological laboratory of Wundt, undertook in 1883 the study of education by methods borrowed from psychology. He initiated the "Child Study" movement and later worked toward the establishment of a scientific basis for education. His chief contribution was a treatise entitled, ***Adolescence*** (1904). In this he points out the biological and psychological changes which mark the transition of children from the period of elementary education to the period of secondary education. In securing information about children, Hall and his followers enlisted the co-operation of parents and teachers. Lists of questions were submitted without discrimination to all kinds of observers. The lack of scientific training on the part of many interested in child study and the extravagant and unfounded generalizations indulged in by the leaders of the so-called science soon discredited the whole movement and very few contributions to the science of education are directly traceable to it. The indirect influence of child study was, however, very large. During the late '80's and the early 'go's widespread interest was aroused in educational problems, and gradually better methods of investigation were evolved.

Systematization. — During the decade of the '90's a number of other influences operated to promote the rise in the United States of a true science of education. Four of these were of major importance. First, the effort was made by national agencies to define with precision the terminology and practices of education. A Committee of Ten, under President Eliot of Harvard university made a report in 1892 which defined the units of instruction in the high school. In 1895 the Committee of Fifteen, under the chairmanship of William T. Harris, U.S. Commissioner of Education, made an effort to define the functions and content of elementary education. Second, under the leadership of J. McKeen Cattell, at that time professor of psychology at Columbia university, the effort was made to develop tests of mental ability by means of which the differences between individuals could be compared and the changes through which individuals pass in the course of development measured. The early results of such tests, later designated as general intelligence tests, were relatively unsatisfactory; but the tests have been perfected to a point where they are now standard instruments of measurement both for psychology and education. Third, John Dewey, Col. Francis Parker and other educators initiated a movement for the socialization of education. These reformers emphasized the need, pointed out by Herbart, of regulating education in accordance with the laws of social evolution as well as in accordance with those of mental growth. The discussions of Dewey and Parker served to stimulate much wholesome thinking on educational problems. Fourth, J. M. Rice, at that time editor of the *Forum*, demonstrated late in the 'go's a highly important method of evaluating the results of education. He obtained permission to test pupils in a number of school systems with lists of words to be spelled and with series of arithmetical examples to be solved. In 1897 under the title, "The Futility of the Spelling Grind," he published an article which pointed out the necessity of exact scientific testing of school results. In 1901 he published an article on the results secured with tests in arithmetic.

Social influences were also stimulating education. The school population was increasing and the demand for more variety in the content of instruction was making itself felt. By the beginning of the 20th century the demand for a science of education was fully established and some of the methods of scientific investigation perfected far enough to render available exact information on which to base scientific conclusions. Since 1900 the development of a science of education has been comparatively rapid, but its progress has been less rapid than it might have been if parents and teachers were fully converted to the idea that education should be guided by science rather than by tradition.

STUDIES AND TESTS

Pupil-administration is one of the fields in which this science has been productive. It was discovered that a great many pupils make progress through the school more slowly than is normally to be expected. If pupils enter the first grade of the elementary school at six years of age, they ought to reach the beginning of the fourth grade at nine years of age. As a matter of fact, many pupils do not reach the fourth grade until they are 10, 11 or 12 years of age. Such pupils are said to be retarded. The facts of retardation were clearly pointed out and extensively studied and radical reforms were introduced in the organization of schools in order to remedy the difficulty. The technique of comparison which was developed by studies of retardation was the technique of statistical comparison. It is one of the most widely employed devices of scientific study of school problems.

The Binet Scale.—A second group of scientific studies employed tests of various types. Certain of these are designed to reveal differences in the abilities of individuals. Binet, the noted French psychologist, discovered that there are certain kinds of knowledge which the ordinary child of three normally possesses, such as the knowledge of the names of different parts of the body. The child of four years of age possesses additional items of knowledge and so on. By arranging the items found to be normally exhibited by children of various ages, it is possible to devise a scale by which normal intelligence can be determined. The so-called Binet scale was perfected in 1905. It was introduced in America and is now extensively used. To arrive at a simple expression for the results of measurements made with the Binet scale, the so-called *intelligence quotient,* usually written I.Q., was devised. The I.Q. is arrived at by dividing the score made on the Binet scale by any given child by his chronological age. Thus a child who passes the 10-year old standard test and is 10 years of age has an I.Q. of 100 per cent. The child who passes only the nine-year test and is 10 years of age has an I.Q. of 90. The child who passes the 11-year test and is 10 years of age has an I.Q. of 110.

Following the appearance of the Binet scale a large number of standard tests were devised. Series of examples in arithmetic were prepared and the rate and degree of accuracy with which these were solved by pupils in different grades were determined. The average achievement of pupils in different grades is a reasonable standard of expectation for all pupils of similar advancement in the school. In this way standards of achievement and standard tests have been produced in all the fundamental school subjects.

Thorndike and Ayres.—In addition to standard tests, scales have been devised in various fields. Thorndike devised, in 1910, a scale for judging specimens of handwriting. He collected a number of specimens of handwriting of varying degrees of excellence. Thorndike secured the judgments of expert teachers of handwriting and arranged specimens in a series of 18 steps. With the aid of this scale, scores can be assigned to any specimen of handwriting, progress measured and the writing of different individuals compared. Ayres devised in 1915 a scale of words to be taught in spelling. He secured exhaustive tests of the words used in correspondence, in the English Bible and in an edition of a newspaper. He then required the pupils in the various grades of a number of schools to spell the words found to be in common use. He was able at the conclusion of his tests to make lists of words in common use which should normally be mastered by pupils in the various grades. The preparation of this spelling scale has completely transformed the methods of selecting words used in spelling lessons in schools.

The World War gave a great impetus to the testing movement. The psychologists of the United States employed the experience which had been accumulated regarding methods of testing general intelligence and special abilities and devised series of tests by means of which they were able to select abnormal individuals and eliminate them from the service and to select for special forms of service those who were competent. So successful was the application of tests during the war that industry has adopted very similar methods, and schools have adopted tests for determining the grading and classification of pupils. In fact the measurement movement in education is regarded by some of its exponents as the essential part of the science of education.

A reaction has arisen against the testing movement on the ground that it has led certain educators to adopt a fatalistic or deterministic theory of education. It has been held by some extremists that a poor score on certain tests is sufficient indication of deficient mental ability to justify exclusion of the pupil making such a score from the advantages of a higher education. The opponents of educational determinism have adduced evidence to show that poor scores are often traceable to lack of educational opportunity rather than to native mental deficiency. It is contended on such grounds that even pupils with low scores in tests have a right to the opportunities of higher education.

Laboratory Experimentation is a type of scientific study of educational problems which developed more slowly than did standard tests but has proved to be highly productive; it originally borrowed its methods from experimental psychology. Laboratory investigations of educational problems are either general, dealing with such matters as the laws of learning, or specific, dealing with the habits cultivated in the acquisition of handwriting or reading or some other school subject. One of the earliest investigations of the general type was that of Bryan and Harter. In 1897 these investigators measured the progress from week to week of several persons who were learning to send and receive telegraphic messages. They found that the rates of progress in learning to send messages were not the same as the rates of improvement in learning to receive messages. Furthermore, they found that there are periods in learning to receive messages where for a time the learner seems to make little or no progress.

General Principles.—Later investigators have discovered many important facts about the learning process. It has been found that in committing to memory a poem or series of passages it is better to read repeatedly the whole poem or series of passages rather than to commit to memory one line at a time. "Whole learning," as the method of reading the poem through is called, has the advantage of giving the learner from the outset the general idea which the passage is intended to convey and prevents the mere revolving of attention around a single line. Another important discovery is that pauses between periods of learning are advantageous. Long periods of continuous effort in learning evidently set up certain conflicts which defeat the learning process. It has also been found that mere repetition without careful attention to the material which is being repeated is not favourable to learning.

Transference.—In addition to the establishment of such general principles, experimental investigations have measured the extent to which knowledge or habits of action acquired under one set of conditions will transfer and guide the learner under other sets of conditions. A vigorous dispute has been carried on between those who interpret their results in regard to transfer as showing that all learning is specific, that is, that there is no transfer and those who find that the human mind is capable of many forms of generalization. Extreme believers in the necessity of specific training hold, for example, that every possible number combination to be encountered in practical life should be explicitly attended to and taught in the schools. On the other hand, it is believed by those who find evidence of generalization, that when a pupil has learned the meaning of number combination by dealing with a limited number of cases, he will be able to carry over the general principles of combination into number fields in which he has had no specific training.

METHODS AND ERRORS OF PUPILS

The laboratory analysis of methods exhibited in learning constitute the most productive application of experimental methods. A common method to study reading is to photograph the movements of a reader's eyes as he looks along a line of printed matter. The movements of the eye are much better indicators of what is going on in the reader's nervous system when he tries to recognize and interpret printed words than are the movements of articulation which the reader makes in pro-

nouncing words orally. Oral pronunciation is a remote process following the recognition of words after so long an interval that other factors such as the physiological limitations of vocal action obscure the true reading process. Eye movements, on the other hand, are very closely related to the reader's efforts to comprehend passages. Photographic records of the eye movements show among other facts that there is a marked difference between the individual's mental processes when he is reading silently and when he is reading orally. Silent reading makes possible attention to large units. Whole phrases are apprehended at a single glance. In oral reading, on the other hand, attention is relatively fragmentary, controlled by the necessity of separate pronunciation of each sound. The discovery of this fact has had a profound effect on school practice. It was formerly the universal practice of schools to limit instruction in reading to oral reading. The newer reading books and reading courses of the elementary schools are organized with a view to encouraging pupils at an early age to read silently.

Similar methods of investigation have been employed in investigating the habits of pupils in dealing with foreign languages. It has been found that high-school pupils in the United States rarely reach the stage in the study of Latin where they read the sentences. They are evidently preparing, each time they look at a Latin word, to fix it in mind, not as part of a sentence but as a separate item to be carried in the mind long enough to be related to the vocabulary at the back of the book. The investigations of the results of instruction in French show that in this case pupils approach more nearly to the type of reading which they exhibit in dealing with the vernacular.

Experimental analyses of the habits of pupils in handwriting show that when pupils first begin to write, their movements are without rhythm and their co-ordinations are undeveloped. Their muscles are tense and diffusion of nervous impulses throughout the whole body results in contractions of muscles which are in no wise involved in the writing of a mature individual. It has been possible to arrange a series of training exercises which develop in pupils proper habits of fluent movement much more economically than was possible under old systems of training.

Analyses of the learning processes in all branches of mathematics are very difficult because there are very few external manifestations of behaviour accompanying the mental steps involved in solving a mathematical problem. In spite of the difficulties, some progress has Ecen made in this field. Especially has it been possible to deal with the simplest phases of number experience. The rate of counting has been measured under different conditions. It has been found, for example, that counting a series of sounds is more fluent and accurate than is the counting of a series of flashes of light. Counting a series of tactile experiences is very uncertain. These and similar facts show the complete dependence of number experiences on training. The reason why sounds are easier to count than are other forms of sensory experience is that sounds are far more often associated in a child's experience with number names than are the other forms of sensation. The more elaborate processes of arithmetical manipulation have been analyzed by securing from learners descriptions of their methods of solving problems. Adequate laboratory experiments have not been devised for the analysis of the processes of reasoning such as those which appear when a verbal problem is attacked. Passing from arithmetic to the higher branches of mathematics, it is possible to give a fairly complete account of the way in which pupils acquire notions of space and to discover the mental processes which are involved in the study of geometry. Here again the higher processes of reasoning are too complex to be readily investigated.

Classification of Errors.—A prodactive method of study which has been employed in all fields is that of recording and classifying the errors which pupils make. **A** mistake made by a pupil is revealing because it supplies a contrast through which investigators can gain much information about normal processes, and also because it throws light on the effectiveness or ineffectiveness of school methods. A number of contributions to educational literature have concerned themselves with cataloguing the typical mistakes made by pupils in different subjects and with the discovery through trial of so-called remedial measures by means of which errors may be corrected or avoided. **A** wide variety of causes of mistakes have been discovered. Defective vision or hearing may cause mistakes. Emotional disturbances are fruitful causes of distraction. Distractions of many different kinds interfere with the progress of the learning process. When the causes of mistakes can be definitely located, it is possible ta adjust instruction to the needs of pupils much more specifically than when all mistakes are classified as belonging together in a vague, general way and when teachers think of them as purely negative facts.

FIRST RESULTS

New methods of teaching that have been developed through these tests and analyses have been extensively employed since about 1900. Confidence in conventional school practices has been so weakened that the demand has been emphasized for new forms of teaching. These demands for new adjustments of school practices have been powerfully reinforced by the fact that modern civilization has created a series of new intellectual demands. While formerly there were only three learned professions, to-day industry has its engineers and commerce has its professional experts. In short, the modem world is calling for higher types of training in fields which formerly were not thought of as especially affected by school training. It has followed naturally that the system of education has found itself confronted with the necessity of extensive reconstruction of the school curriculum. Since about 1918 the interest of teachers and school administrators has been largely centred on curriculum problems. A number of the leading school systems and practically all the educational associations of the country have organized committees on curriculum revision. Various techniques have been employed in the studies of the curriculum. One of these consists in a tabulation of all of the forms of knowledge used in common life; another, in the analysis of the mature sciences in order to discover the fundamental lines of thought to which one should be introduced if he is to be intelligent about modern issues. Thus, it is asked, what are the economists and sociologists discussing in their mature sciences? Having found the answer to this question, one may, it is held, undertake to rewrite the text-books used in the schools. **A** third technique consists in a so-called "job analysis" of various trades and practical activities of life. The phrase "job analysis" has been extended to cover such general matters as the activities of women who have charge of homes and the professional activities of doctors and lawyers as well as the manual skills of tradesmen and mechanics. **A** job analysis having been made, the second step in curriculum construction is to discover the methods of intellectual adaptation which are necessary to the successful mastery of the demands of the job.

It is significant that curriculum reconstruction is engaging the attention not only of the directors of the lower schools but of the institutions of higher learning and of the professional schools. National commissions are engaged in making elaborate studies of the curriculums of engineering schools and schools of medicine.

The types of scientific work which have been described have at times been combined in what are known as school surveys. **A** survey is an examination, by means of the most exact methods available, of the conditions which obtain in any given school system. In many cases the survey originates in dissatisfaction with existing local conditions. The citizens of a community, for example, are doubtful whether the efficiency of their schools has improved at a pace commensurate with the mounting costs; they accordingly invite an expert or a group of experts to test their system of education. Surveys of schools have been common since about 1912. There is a great volume of published material reporting surveys of State systems of education and of smaller units of school organization down to the single school.

Agencies.—In its beginnings the science of education was hardly more than a series of practical applications of psychology or at most a special branch of that science. A few psychologists devoted themselves to the cultivation of the new science, School administrators and classroom teachers were at first very little concerned with it. 'They were absorbed in the routine duties of con-

ducting school. The first great impetus to the new science was given by Clark university and Teachers' college of Columbia university. The first was organized in 1887 and the second was reconstructed and made effective at a somewhat later period. These two institutions graduated groups of students who have since been leaders in the development of the science of education. Not only so, but they set an example which has been extensively imitated until there are very few institutions of higher learning which do not have at least one representative of this science on the faculty, and in many instances instruction and research in education are organized in a separate school or college.

While the higher institutions are thus providing centres for research and instruction, school systems are beginning to feel the influence of the developing science. Gradually the organization of the leading school systems of the country have been enlarged so as to include what is known as a division of tests and research or a bureau of efficiency. A recent report indicated that (1927) there are 200 or more such scientific agencies within public school systems. In many cases the heads of these scientific divisions of the school system rank as assistant superintendents.

A highly effective agency for the support of scientific work in education is the Bureau of Research of the National Education Association. The example of the National Teachers Association in conducting scientific studies has been imitated by a number of State educational associations. The teaching profession has thus taken an active part in the development of educational science. Another central agency for the collection and interpretation of scientific information is the U.S. bureau of education of the Department of the Interior. This bureau has long been occupied in the colfection of statistics regarding the schools of the country. Congress has enlarged its resources and it is now the leading public agency for the conduct of surveys and one of the most important centres for the collection of information and for the conduct of scientific studies.

IV. EDUCATIONAL EXPERIMENTS

Educational experiments in England and Wales are usually suggested by the needs of the moment. (For America see "Educational Experiments in the U.S.") Those who conduct them do so to overcome a recognized difficulty or to achieve a better way of teaching. In one department, that of intelligence testing (see EXAMINATIONS), research experiments are tried and it is here that, in the strict sense of the term, experiment takes place. The importance of this subject led to its being referred to the consultative committee of the Board of Education which issued a report on it in 1924. Their findings were not conclusive, but they recognized the importance of these tests.

Central Schools.—Of experiment in a wider sense there is a great deal. The Board of Education itself has encouraged an experiment on a very large scale in urging local education authorities and school managers to set up central schools, to which boys and girls in elementary schools are transferred at or about the age of 11 for a course of study specially designed to cover the years up to 15 and even 16, selection being either by age alone, or through examination. The establishment of central schools has been proceeding for some years but wili henceforward be part of the reorganization of schools recommended by the Consultative Committee of the Board of Education in their report on the Education of the Adolescent (1926). The main position taken in the report is that the primary age ends or should end at 11, with a fair equipment in the tools of learning; and that all teaching beyond that age should be post-primary in character.

Where the central or modern schools are of the selective type, provision must be made for the scholars over the age of 11 who are not transferred to them or to a secondary school. The schools (the report calls them senior schools) that are being established for this purpose offer an interesting and important field for experiment which has hitherto hardly been touched.

Experiments in *Infant* Schools.—Apart from organization, one of the mcst striking waves of experiment has taken place in infants' schools and classes. Where formerly the three R's in a dull form were the staple of instruction, modified by some artificial exercises denominated "Kindergarten," the school now tries to cultivate speech besides reading and leading "up to reading," activity instead of immobility, self-help instead of formal instruction. This new orientation in fact preceded the spread of Montessori doctrines, but it was strongly reinforced by them (see MONTESSORI SYSTEM), even where they were not accepted in full. The infants' school and class become now more of a social agency and a centre of education than a centre merely of instruction. (See also NURSERY SCHOOLS.)

School Experiments.— Another movement has grown quietly without the support of a great name, but spreading by its own reasonableness. This is the "ruralizing" of many schools, not only in the country but also in many towns. When this goes no further than nature study, it is a recognition that school lessons should be related to the child's surroundings. But gardening is very popular and a school often includes bee-keeping and even poultry-keeping. The Welsh Department of the Board of Education have stimulated the extension of the idea that rural lore, including history, antiquities, architecture, folk-song and speech, should be cultivated in country schools. Connected with this trend is the tendency to localize the geography teaching on the one hand, by studying closely the geography of the town, village or region, and on the other to supplement the local study by school journeys. School journeys are not for all, since their management requires very special organizing and personal care. In small numbers they preceded the Boy Scout movement (see BOY SCOUTS), but the proved practicability of school journeys reinforced the camping idea of the Scouts, and camps grew in popularity. One annual camp under the patronage and the personal attention of the Duke of York, combining boys from the public schools and boys brought up in elementary schools, is a noteworthy example of an attempt to create a sympathy between classes brought up very differently. Both secondary and primary schools have organized school journeys and school camps in other countries. The great extension of self-government (*see* above) in elementary schools and the movement for providing playing fields for elementary pupils has had a most profound effect on the character and physique of the younger generation. Within the school itself the holding of school exhibitions and open days for parents are forging a valuable link between home and school.

Handicraft Work.—The progress of instruction in handicrafts is on the whole slow, for this form of instruction is apt to be expensive. But the idea that handicraft for girls, as well as for boys, is an essential element in education has undoubtedly grown. Handicraft for boys means usually work in wood and metal; and for girls besides needle work and cookery, laundry work, housecraft and the simpler beginnings of crafts like weaving, basketry, embroidery, lace making and pottery.

Cinema, Gramophone and Radio.—These are past the stage of experiment. Schools are considering and trying experiments in new fields with results which are not yet firmly established, experiments with the gramophone, the radio and the cinema. The gramophone has practically won its way to a position of limited but decided usefulness. It becomes more and more used for music, and the introduction by its means of a wide variety of good music into the schools means an increase of music and the appreciation of it as a liberal factor in education. It is also used in the teaching of languages. Radio reception is on its trial (see BROADCASTING); every day at fixed hours in the afternoon lectures and talks are broadcast from the various studios and schools, and the teachers are asked to co-operate by giving the children who listen appropriate revision and appropriate exercises, talks on literature, history, simple science, especially natural history which in this way may gain a larger place in children's education, and,

of course, music. The value of the cinema is still the subject of educational thought. It appears as yet—with some notable exceptions—to be of use (where it can be used) specially as a recreative aid or as giving a pictorial impression of matter, the mass of which has been communicated by word of mouth or reading.

The Dalton System.—Mention must be made of experiments in teaching such as the Dalton plan with its system of independent work and assignment. In a few schools this is followed very thoroughly: in more, adaptations of it are made to meet special conditions, in part of a school, or in some subjects only. The experiments so far have hardly been crucial enough for a final verdict to be passed. The plan was started originally in secondary schools, but it has also been adopted experimentally in a few elementary schools. In the Howard plan the Dalton system of individual work and assignment is combined with the temporary dropping, generally for a term, of some subject or subjects in order to allow of an intensive study of others. The direct method of teaching foreign languages is another example of a movement which has passed the stage of experimentation in one sense. Its principle is fairly well accepted; but it is carried out not always in its purist form but modified to suit the circumstances of pupils. At the Perse School, Cambridge, it is used for Latin and Greek but it has not found much favour among classical teachers.

UNITED STATES

In America experimentation has become a normal function not only of individual schools and colleges but of whole systems of education. The experimental movement has coincided with the rapid quantitative expansion of educational facilities which has marked the first part of the 20th century. The movement owes its impetus primarily to the university schools devoted to the scientific study of education which prepare for professional service an ever-increasing number of school administrators. More recently normal schools and teachers' colleges, philanthropic foundations and special research bureaux maintained in connection with State and city systems have likewise made important contributions to the movement. Not only have these latter agencies extended the range and variety of experiments, but they have also done much to inoculate the whole teaching profession with the experimental point of view.

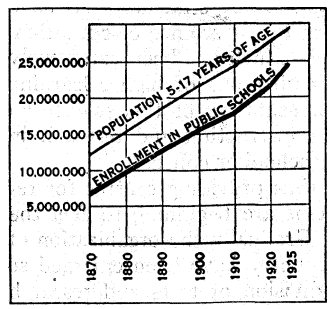
The most significant educational experiments may be classified for convenience as (1) experiments based on psychological investigations, (2) experiments dealing with the reconstruction of the curriculum and (3) experiments bearing on the reorganization of the educational system.

Experiments Based on Psychological Investigations, Educational psychologists have been concerned with developing two kinds of measures: measures of native capacity and measures of intellectual achievement. Since the World War the measures of native capacity, the so-called intelligence tests (*q.v., see* also EXAMINATIONS), have come into general use in schools of all grades. They have been steadily refined and improved, but are still regarded as in the experimental stage. In the classification of pupils and their selection for special treatment, in comparing the progress of different groups of children, and in a wide variety of studies of the educational process, the tests find constant application. They have been adopted by many colleges as part of the matriculation machinery.

The effort to invent objective measures of achievement in school subjects has produced a series of new devices called scales or standard tests. These are designed to estimate the results of the work done in the schools more reliably than is possible by means of the conventional examination. By the correlation of the scales and standard tests with the age of the pupils, tentative norms of achievement at different stages of school life are being established. Scales or standard tests and intelligencetests are now being used in conjunction, with a view to determining the respective rates of progress of children of different mental endowments. Scales and tests of proved reliability are already available in most of the school subjects.



GRAPH SHOWING PUPILS ENROLLED IN ELEMENTARY AND SECONDARY PUBLIC SCHOOLS OF THE UNITED STATES

The whole testing movement has led teachers and administrators to appreciate more fully the essential importance of adapting school procedures to individual differences. Thus in spite of the great growth in the school population, devices for individualizing instruction are becoming more numerous and more effective. The defective or subnormal child (*see* MENTAL DEFICIENCY) was the first to receive special attention. More recently, however, the realization has grown that the gifted child suffers quite as much from subjection to an inflexible régime designed for the mediocre and that society suffers still more from a training process that hampers the full development of the superior individual. Hence a variety of experiments are in progress throughout the United States which have as their object the identification and the appropriate education of the gifted pupil. In these experiments colleges and universities are beginning to participate through the establishment of so-calledhonours courses and through devices for segregating and stimulating the superior student.

Experiments in the Reconstruction of the Curriculum.—For some years the conviction has been gathering momentum that the curricula of schools at all levels are not only out of harmony with the requirements of modern life, but that they are also at variance with the laws of mental growth and of learning which the psychologists have been discovering. Modern living conditions have transferred to the schools a multiplicity of tasks previously performed by other agencies. The social aims of education have also become more prominent at the same time that the necessity of recognizing the idiosyncrasies of the individual has been revealed. The problem of reconstructing the curriculum is now the central problem of American education. It is being attacked in hundreds of schools. Certain experiments have seemed promising enough to be widely imitated, with some local modification. One of these is the Dalton plan and another is the platoon or work-study-play plan. Under the latter plan, half the children are in classrooms while the other half are at work or at play in school shops, laboratories, studios, on the playground or in the auditorium. Decreased classroom space and greatly increased facili-

ties for work and play are features of the physical plants of schools that operate on this plan. The school day is lengthened and the school becomes responsible for the child during the major part of his waking hours.

Cutting across schemes like those just mentioned, which involve complete reorganization of the school is the project method. This method focuses instruction around typical problems actually encountered in life outside the school. In the course of solving these problems, or working out the projects, principles are discovered and learned. The topical organization of instruction largely disappears. The pupils actively seek the solution of the problem wherever the search may lead, even outside the confines of the school. Experiments with the project method are numerous. Some schools have applied it in a few subjects, some in practically all subjects. Instruction in vocational subjects is now largely dominated by some form of the project method. The system of co-operative part-time instruction, first developed in the engineering school of the University of Cincinnati and now followed in many other engineering schools and industrial schools, is founded on the same underlying concept.

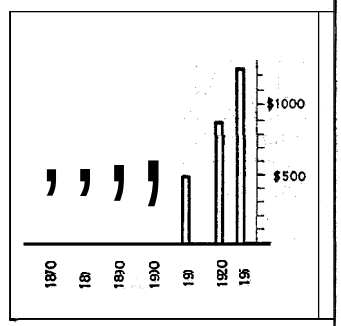
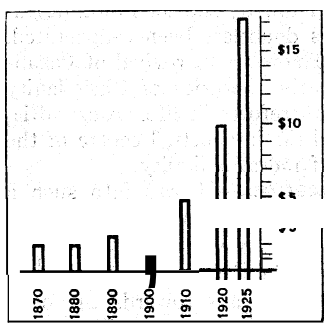
Experiments in the reconstruction of the curriculum are not confined to schools or school systems that are committed to some new departure in method or in organization. In many institutions where the older type of school regimen has not been radically changed, the curriculum is being experimentally revised by the introduction of new material, the elimination of old material and the alteration of the order of presentation.



GRAPH SHOWING AVERAGE SALARY OF TEACHERS IN ELEMENTARY AND SECONDARY PUBLIC SCHOOLS OF THE UNITED STATES

Numerous private schools have sprung up which are frankly experimental. These have come to be known as progressive schools. For the greater part they have been inspired by the educational philosophy of John Dewey. They have been quick to take up and test under the most favourable conditions any methods, materials or plans of organization that muster substantial scientific support. Devices that have proved successful in the progressive schools constantly find their way into the more conservative public institutions.



GRAPH SHOWING EXPENDITURE PER CAPUT FOR PUBLIC EDUCATION IN THE UNITED STATES 1870–1925

Experiments in Reorganizing the Educational System. —The typical organization of the American system consisting of an eight-year elementary school, a four-year high school and a four-year college, with entrance upon professional study coming either at the end or in the middle of the college course, has long been criticized. The several institutional units are the product of diverse influences, mostly foreign. The welding of them into a system was largely accidental. It is generally believed that the period devoted to secondary education is too short, that it should begin earlier and that secondary education should embrace much of the present content of the college curriculum. Educators commonly hold that with a rational organization of the system and with an altered and condensed curriculum, time can be saved and educational results improved.

Two experimental movements looking toward the accomplishment of these reforms are now well under way. One of these involves the reorganization of the elementary and secondary schools and has come to be known as the junior high school movement (*see* SECONDARY EDUCATION). At the other end of the conventional secondary school period another new institution is evolving, the junior college. The typical junior college offers the first two years of the usual college course, with certain modifications dictated by its local environment. There are (1928) more than 300 independent junior colleges in the United States; the majority are private institutions but a large minority are attached to city school systems. Whether the junior college as a separate institution is a transitory phenomenon it is too early to say. Its appearance has had one noteworthy effect upon universities, however. It has led a considerable number of them to divide their colleges of liberal arts into junior and senior colleges and to organize the programme of instruction so that the end of the junior college period marks the completion of general education of a secondary character and the beginning of university specialization. This tendency, together with the multiplication of junior colleges as upward extensions of public school systems, seems to point to the ultimate assimilation of the work of the first two years of the American college of liberal arts into the scheme of secondary education.

HISTORY

Ancient Greece.—In ancient Greece the supremacy of the State was generally unquestioned, and, especially in the earlier times, the good man was identified with the good citizen. The highest life was one of cultured leisure in which the energies were mainly concentrated on the pursuit of knowledge for its own sake. But this life was only for the select few; for the undistinguished many the fulfilment by each of the duties of his station remained the measure of worthy life. For those, therefore, who devoted their lives to the highest culture, the essential preliminary condition was the existence of such a State as would form the most favourable environment for their leisured life. Thus Greek thought was saturated with the conception of life as essentially a set of relations between the individual and the city State of which he formed an integral part. The first aim of education was, therefore, to train the young citizens. (For the evolution of the school from early times, see SCHOOLS.)

Each State, however, had its special character, and to this character the education given in it must conform if it were to be an effective instrument for training the citizens. From these fundamental conceptions flowed the demands of Plato and Aristotle that education should be regulated in all its details by the State authority, should be compulsory on all free citizens, and should be uniform—at any rate in its earlier stages—for all. In the Republic and the *Laws*, Plato shows to what extreme lengths theory may go when it neglects to take account of some of the

most pertinent facts of life. For the guardian-citizens of the ideal State, family life and family ties are abolished. Aristotle, indeed, did not go to these extreme lengths; he allowed the family to remain, but he seems to have regarded it as likely to affect children more for evil than for good. Neither philosopher, however, was at variance with the accepted Greek theory on the subject, although the actual practice of Greek States departed, and often widely, from this ideal, for, especially in later centuries, the Greek always tended to live his own Life. The nearest approach to the theory was found in Sparta, where the end of the State as a military organization was kept steadily in view, and where, after early childhood, the young citizens were trained directly by the State in a kind of barrack life — the boys to become warriors, the girls the mothers of warriors. It was this feature of Spartan education, together with the rude simplicity of life it enforced, which attracted Plato, and, to a less extent, Aristotle. In Athens there had of old been State laws insisting on the attendance of the children of the free citizens at school, and, in some degree, regulating the schools themselves. But at the time of Plato these had fallen into desuetude, and the State directly concerned itself only with the training of the ephebi (*q.v.*) in intellectual and physical pursuits. For children and youths under the ephebic age there was no practical regulation of schools or palaestra by the State. Yet there is no doubt that the education really given was in conformity with Athenian ideals of culture and life, and that it was generally received by the children of free citizens, though of course the sons of the wealthy, then as now, could and did continue their attendance at school to a later age than their poorer brethren. The education of girls was essentially a domestic training. What Plato and Aristotle, with the theorist's love of official systematic regulation, regarded as the greatest defect of Athenian education was in reality its strongest point. In practice, the harmony between individual liberty and social claims was much more nearly attained under a system of free working out of common thoughts and ideals than would have been the case under one of the irresistible imposition from without of a rigid mould.

The instruments of education everywhere found to be in harmony with the Greek conception of life and culture were essentially twofold — "music" (μουσική), or literary and artistic culture, for the mind, and systematic gymnastic (γυμναστική) for the body. Plato, in the Republic, shows that the latter, as well as the former, affects the character, and doubtless, though not formulated, this was generally more or less vaguely felt. But Greek gymnastic was really an individual training, and therefore made only indirectly for the aim of cultivating the social bonds of citizenship. The "musical" training was essentially in the national literature and music of Greece, and this could obviously be carried to very different lengths. The essential purpose throughout was the development of the character of a loyal citizen of Athens. As Athenian culture advanced, increasing attention was paid to intellectual studies, especially in the ephebic age, with a corresponding decrease of attention to merely physical pursuits; hence the complaints of such satirists as Aristophanes of a growing luxury, effeminacy and corruption of youths; complaints apparently based on a comparison of the worst features of the actual present with an idealized and imaginative picture of the virtues of the past. But a disintegrating force was already at wark in the educational system of Greece which Plato and Aristotle vainly opposed; this was the rhetorical training of the Sophists. In a democratic city State the orator easily became a demagogue, and oratory was the readiest path to influence and power. Thus oratory opened the way to personal ambition, and young men who were moved by that passion eagerly attended the Sophist schools where their dominant motive was strengthened.

Further, the closer relations between the Greek States, both in nearer and farther Hellas, led naturally to the diminution of differences between civic ideals, and, as a consequence, to a more cosmopolitan conception of higher education, This process was completed by the loss of political independence of the city States under the Macedonian domination. Henceforth, higher education became purely intellectual, and its relation to political and social life increasingly remote. The University of Athens was the outcome of a fusion of the private philosophical schools with the State organization for the training of the ephebi, and there were other such centres of higher culture, especially in after years at Alexandria, where the contact of Greek thought with the religions and philosophies of Egypt and the East gave birth in time to the more or less mystical philosophies which culminated in Neo-platonism. But at Athens itself education became more and more a mere training in unreal rhetoric, till the dissolution of the university by Justinian (A.D. 529).

Ancient Rome. — Thus when Rome conquered 'Greece, Greek education with which it came in contact was an education which had largely lost its life-springs. In the earlier centuries of the republic, Roman education was given entirely in family and public life. The father had unlimited power over his son's life, and was open to public censure if he failed to train him in the ordinary moral, civic and religious duties. But it is doubtful if there were any schools, and it is certain there was no national literature to furnish an instrument of culture. A Roman boy learnt to reverence the gods, to read, to bear himself well in manly exercises, and to know enough of the laws of his country to regulate his conduct. This last he acquired directly by hearing his father decide the cases of his clients every morning in his hall. The rules of courtesy he learnt similarly by accompanying his father to the social gatherings to which he was invited. Thus early Roman education was essentially practical, civic and moral, but its intellectual outlook was extremely narrow.

When a wider culture was imported from Greece, the instrument of education first introduced was Greek literature, much of which was soon translated into Latin. In time the schools of the *grammatici,* teaching grammar and literature, were supplemented by schools of rhetoric and philosophy, though the philosophy taught in them was itself little more than rhetorical declamation. These furnished the means of higher culture for those youths who did not study at Alexandria or Athens, and were also preparatory to studies at those universities. Under the empire the rhetorical schools were gradually organized into a State system. This widening of culture affected both boys and girls, the domestic education of the latter being supplemented by a study of literature. But it is the higher training in rhetoric which is especially characteristic of Hellenized Roman education.

The conception of a rhetorical culture is seen at its best in Quintilian's *Institutio oratoria,* the most systematic treatise on education produced by the ancient world. With Quintilian the ideal of an orator was a widely cultured, wise and honourable man. And at first the teaching of rhetoric undoubtedly made for higher and true culture. But with the autocracy, soon passing into tyranny, of the empire, rhetoric ceased to be a preparation for real life. Nor was there anything in the general conditions of society to counterbalance the ill effects of such an unreal education. Quintilian lamented that, even in his time, the old Roman family education by example was corrupted; and the moral degradation of later times, though it has doubtless been exaggerated, was certainly real and widespread. The religious revival of Pagan ism which synchronized with the early centuries of Christianity does not appear to have effected any reform in life. Alexandria, the birthplace of Neo-platonism and the intellectual centre of the later empire, was also a very sink of moral obliquity.

Christianity and Pagan Education. — It was into such a decaying civilization that Christianity brought new life. Of course, careful instruction in the Faith was given in catechetical schools, of which that at Alexandria was the most famous. But the question as to the attitude of Christians towards the ordinary classical culture became of growing importance. The Greek Fathers,' especially Clement of Alexandria (150–217) and Origen (185–253), regarded Christianity as essentially the culmination of philosophy, to which the way must be found through liberal culture. Without a liberal education the Christian could live a life of faith and obedience but could not attain an intellectual understanding of the mysteries of the Faith. On the other hand, Tertullian (160–240) was very suspicious of Pagan culture; though he granted the necessity of employing it as a means of education, yet he did so with regret. Many of the cultivated

Christians of the 3rd and 4th centuries were little more than nominal adherents to the Faith, and the intercourse between Christian and Pagan was often close and friendly. The general attitude of Christians towards the traditional education is evidenced by the protest raised against the edict of Julian, which forbade them to teach in the public schools, The ultimate outcome seems to be fairly expressed in the writings of St. Augustine (354–430) and St. Jerome (346–420), who held that literary and rhetorical culture is good so long as it is kept subservient to the Christian life.

In another way Greek philosophy exercised a formative influence over the culture of future ages, in the case of the Eastern Church through Neoplatonism, the last effort of Paganism to attain a conception of life and of God. In the West, this formulation had to be translated into Latin, for Greek was no longer generally understood in Italy, and thus the juristic trend of Roman thought also became a factor in the exposition of Christian doctrine. This formulation of the Faith was one of the chief legacies the transition centuries passed on to the middle ages. Had classical culture been less formal than it was during the early centuries of Christianity, the innate antagonism of the Pagan and Christian views of life and character must have been so apparent that the education which prepared for the one could not have been accepted by the other. Thus the Pagan ideal of life, especially as it had been developed in the individualistic ethics which had prevailed for more than six centuries was antithetical in essence to that of the Christian Church. The former was essentially an ethics of self-reliance and self-control showing itself in moderation and proportion in all expressions of life. An essential feature in such a character was high-mindedness and a self-respect which was of the nature of pride. On the contrary, Christian teaching exalted humility as one of the highest virtues, and regarded pride and self-confidence as the deadliest of sins. The highest state attainable by man was absorption in loving ecstasy in the mystic contemplation of God. The practical attempt to realize this gave rise to monasticism, with its minutely reguiated life expressing unlimited obedience and the renunciation of private will at every moment. The monastic life was regarded as the nearest approach to the ideal which a Christian could make on earth. Naturally, as this conception gathered strength in generations nurtured in it, the value of classical culture became less and less apparent, and by the time of St. Gregory the Great (d. 604) the use of classical literature as a means of education was discouraged.

Of course, during these centuries, the gradual subjugation of the western empire by the barbarians had been powerfully operative in the obscuring of culture. Most of the public schools disappeared, and such light of learning as was kept burning in the monasteries was mainly confined to monks and novices. Though the barbarians absorbed the old culture in various degrees of imperfection, yet the four centuries following the death of St. Augustine were plunged in intellectual darkness, relieved by transitory gleams of light in Britain and by a mote enduring flame in Ireland. The utmost that could be done was to preserve to some extent the heritage of the past. This, indeed, was essentially the work of men like Boethius, Cassiodorus, Isidore and Bede.

Modification of Latin — During these same centuries another process had been advancing with accelerating steps. This was the modification of the Latin language. Thus, with Christian writers, slavish imitation of the past gradually gave way to the evolution of a new and living Latin, which showed itself more and more regardless of classical models. This Christian Latin was a real living instrument of expression, which conformed closely in its structure to the mode of thought and expression of actual life. It is the Latin in which St. Jerome wrote the Vulgate. But with the obscuring of culture during the barbarian invasions this current Latin became more and more oblivious of even such elements of form as grammatical inflexions and concords.

It was to the reformation of this corrupt Latin by a return to classical models, and to the more general spread of culture, especially among clergy and nobles, that the Carolingian revival addressed itself. The movement, essentially practical and conservative, was directed by Alcuin (735–804), who was Charlemagne's educational adviser and chief executive officer in scholastic matters. Its most valuable outcome was the establishment of the palace school, and of bishops' schools and monastic schools throughout the empire. Thus, the educational system north of the Alps was pre-eminently ecclesiastical in its organization and profoundly religious in its aims. For two centuries the new intellectual life was obscured by the troubled times which followed the death of Charlemagne, but the learning which the Carolingian revival had restored was preserved here and there in cathedral and monastic schools, and the sequence of well-educated ecclesiastics was never altogether interrupted.

Mediaeval Curriculum.—The scope of that learning was cbmprised within the seven liberal arts and philosophy, on the secular side, together with some dogmatic instruction in the doctrines of the Church, the early Fathers, and the Scriptures. Theology was as yet not organized into a philosophical system: that was the great work the middle ages had to perform. The seven liberal arts (divided into the *Trivium*—grammar, dialectic, rhetoric; and the more advanced Qzcadrivium—geometry, arithmetic, music, astronomy) were a legacy from old Roman education through the transition centuries. They appear in the *Disciplinarum libri IX.* of Varro in the 2nd century B.C. But they reached the middle ages chiefly through the summaries of writers in the transition centuries, of which the best known were the De *nuptiis Philologiae* et *Mercurii* of the Neoplatonist Martianus Capella, who wrote probably early in the 5th century; The *De artibus* ac *disciplinis liberalium litterarum* of the Christian Cassiodorus (*c.* 490–*c.* 585); and the *Etymologiarum libri XX* of St. Isidore of Seville (570–636).

The scope of the arts was wider than their names would suggest in modern times. Under grammar was included the study of the content and form of literature; and in practice the teaching varied from a liberal literary culture to a dry and perfunctory study of just enough grammar to give some facility in the use of Latin. Dialectic was mainly formal logic. Rhetoric covered the study of law, as well as composition in prose and verse. Geometry was rather what is now understood by geography and natural history, together With the medicinal properties of plants. Arithmetic, with the cumbrous Roman notation, included little more than the simplest practical calculations required in ordinary life and the computation of the calendar. Music embraced the rules of' the plain-song of the Church, some theory of sound and the connection of harmony and numbers. Astronomy dealt with the courses of the heavenly bodies, and was seldom kept free from astrology. In philosophy the current text-books were the *De* consolatione *philosophiae* of Boethius (470–524), an eclectic summary of pagan ethics, and the same writer's adapted translations of the Categories and *De interpretatione* of Aristotle and of Porphyry's *Introduction* to *the* Categories.

Scholastic Revival.—In the 11th century Europe had settled down, after centuries of war and invasion, into a condition of comparative political stability, ecclesiastical discipline and social tranquillity: the barbarians had been converted, and civic life had developed in the fortified towns of Italy, raised as defences against the pressure of Saracen and Hungarian invasions. Soon. communication with the East by trade and in the crusades, and with the highly cultivated Moors in Spain, further stimulated the new burst of intellectual life. Arabic renderings of some of the works of Aristotle and commentaries on them were translated into Latin and exercised a profound influence on the trend of culture. A new translation of Aristotle's Metaphysics appeared in 1167, and by the beginning of the 13th century all his physical, metaphysical and ethical treatises were available, and during the next half century the translations from Arabic and other Semitic versions were superseded by renderings direct from the original Greek. It was only when the real Aristotle was known that it was found possible to bring the Peripatetic philosophy into the service of theology. There were thus two broad stages in the educational revival commonly known as scholasticism. In the first the controversies were essentially metaphysicsl, and centred

round the question of the nature of universals; the orthodox theological party generally supporting realism, or the doctrine that the universal is the true reality, of which particulars and individuals are only appearances; while the opposite doctrine of nominalism—that universals are "mere sounds" and particulars the only true existences—showed a continual disposition to lapse into heresies on the most fundamental doctrines of the Church. The second stage was essentially constructive; the opposition of philosophy to theology was negated, and philosophy gave a systematic form to theology itself. The most characteristic figure of the former period was Abelard (1079–1142), of the latter St. Thomas Aquinas (1225–74). The former knew little of Aristotle beyond the translations and adaptations of Boethius, but he was essentially a dialectician who applied his logic to investigating the fundamental doctrines of the Church and bringing everything to the bar of reason. This innate rationalism appeared to bring theology under the sway of philosophy, and led to frequent condemnations of his doctrines as heretical. With St. Thomas, on the other hand, the essential dogmas of Christianity must be unquestioned. In his *Summa theologiae* he presents all the doctrines of the Church systematized in a mould derived from the Aristotelian philosophy.

It is evident, then, that during the period of the scholastic revival, men's interests were specially occupied with questions concerning the spiritual and the unseen, and that the great instrument of thought was syllogistic logic, by which consequences were deduced from premises received as unquestionably true. There was a general acceptance of the authority of the Church in matters of belief and conduct, and of that of Aristotle, as approved by the Church, in all that related to knowledge of this world.

Before the rediscovery of Aristotle exerted such a general influence on the form of education, there was a real revival of classical literary culture at Chartres and a few other schools, and John of Salisbury (d. 1182) in his *Metalogicus* advocated literature as an instrument of education and lamented the barrenness of a training confined to the subtleties of formal logic. But the recrudescence of Aristotle accelerated the movement in favour of dialectic, though at the same time it furnished topics on which logic could be exercised which only a bare materialism can esteem unimportant. The weaknesses of the general educational system which grew up within scholasticism were that haste to begin dialectic led to an undue curtailment of previous liberal culture, and that exclusive attention to philosophical and theological questions caused a neglect of the study of the physical world and a disregard of the critical functions of the intellect. Doubtless there were exceptions, of which perhaps the most striking is the work in physical science done at Oxford by Roger Bacon (1214–94). But Albertus Magnus (1193–1280), the master of St. Thomas, was also a student of nature and an authority for his day on both the natural and the physical sciences. And the work of Grosseteste (d. 1253), as chancellor of the University of Oxford, shows that care for a liberal literary culture was by no means unknown. Probably the most striking instance of the stunting effect of this premature specialization may be found in the fact that the encyclopaedias of general information which were in general use during the middle ages show little or no advance in positive knowledge upon the treatment of similar subjects in Isidore of Seville.

Foundation of Universities.—The services of scholasticism to the cause of education, however, cannot well be overestimated, and the content of scholastic studies was in fundamental harmony with the intellectual interests of the time. Above all other benefits owed by future ages to scholasticism is the foundation of the universities of western Europe. (See SCHOOLS and UNIVERSITIES.)

The concentration of higher instruction in universities was not antagonistic to the mediaeval conception of the Church as the teacher of mankind. University life was modelled on that of the cloister, though the monastic ideal could not be fully realized, and the scholars not infrequently exhibited considerable licence in life. This was inevitable with the very large numbers of the scholars and the great variations of age among them. Moreover, students. and to a less extent teachers, passed from university to university, so that the universities of mediaeval Europe formed a free confederacy of learning in close relation to the Church but untrammelled by State control. Nevertheless, the introduction of studies derived from the Greeks through the Arabians led to an increased freedom of thought, at first within authorized limits, but prepared, when occasion served, to transcend those limits. The scheme of instruction was arranged on the assumption that special studies should be based on a wide general culture. Thus of the four faculties into which university teaching was organized, that of arts, with its degrees of Baccalaureus and *Magister,* was regarded as preliminary to those of theology, law and medicine. It often included, indeed, quite young boys, for the distinction between grammar school and university was not clearly drawn. Little or no attempt was made to extend the bounds of knowledge: the aim was to pass on a body of acquired knowledge regarded as embracing all that was possible of attainment, and the authority of Aristotle in physics as well as in philosophy, and of Galen and Hippocrates in medicine was absolute. The methods of instruction—by lecture, or commentary on received texts; and by disputation, in which the scholars acquired dexterity in the use of the knowledge they had absorbed—were in harmony with this conception, and were undoubtedly thoroughly well suited to the requirements of an age in which the ideal of human thought was not discovery but order, and in which knowledge was regarded as a set of established propositions, the work of reason being to harmonize these propositions in subordination to the authoritative doctrines of the Church.

Such an extension of the means of higher education as was given by the universities was naturally accompanied by a corresponding increase in schools of lower rank. Not only were there grammar schools at cathedral and collegiate churches, but many others were founded in connection with chantries, and by some of the many gilds into which mediaeval middle-class life organized itself. In addition to the grammar schools were writing and song schools of an elementary type, in which instruction was usually in the vernacular. Girls were taught in women's monasteries and in the home, and those of the upper classes, at least, very generally learned to read, write and keep accounts, as well as fine needlework, household duties and management, and such elementary surgery and medicine as served in cases of slight daily accidents and illnesses. Even those boys and girls who did not receive formal scholastic instruction were instructed orally by the parish priests in the doctrines and duties of the Faith; while the pictures and statues with which the churches were adorned aided the direct teaching of sermons and catechizing in giving a general knowledge of Bible history and of the legends of the saints.

No doubt, in times of spiritual and intellectual lethargy, the practice fell short of the theory; but on the whole it may be concluded that in mediaeval times the provision for higher instruction was adequate to the demand, and that, relatively to the culture of the time, the mass of the people were by no means sunk in brutish ignorance. Indeed, especially when the paucity of books before the invention of printing is borne in mind, the number of people who could read the vernacular, as evidenced by the demand for books in the vulgar tongue as soon as printing made them available, is clear proof that the latter part of the middle ages was by no means a time of general illiteracy.

Feudalism, the other characteristic aspect of mediaeval society, had also its system of education, expressing its own view of life, and preparing for the adequate performance of its duties. This was the training in chivalry given to pages and squires in the halls and castles of the great. This training was not in opposition to the spirit of religion which animated the scholastic education which went on side by side with it. Throughout chivalry was sanctified by the offices of the Church. The education of chivalry aimed at fitting the noble youth to be a worthy knight, a just and wise master, and a prudent manager of an estate. Much was acquired by daily experience of a knightly household, but in addition the page received direct instruction in reading and writing; courtly amusements, such as chess and playing the lute, singing and making verses; the rules and usages of courtesy; and the knightly conception of duty. As a squire he practised more assiduously the knightly exercises of war and peace, and in the man-

agement of large or small bodies of men he attained the capacity of command.

With the unification of existing knowledge and the systematization of theology the constructive work of scholasticism was done. At the same time the growth of national feeling was slowly but surely undermining feudalism. Moreover, deep resentment was accumulating throughout western Europe against the practical abuses which had become prevalent in the Church, and especially in the court of Rome and in the prince-bishoprics of Germany. In such conditions, the customary and traditional education of school and university tended to lose touch more and more completely with the new aspirations and views of life. Had a new cultural movement not begun, the education of Europe threatened to become as arid as the rhetorical education of the last centuries of the Roman empire had been. From this it was saved by the renaissance of classical studies which began in the 14th century.

The Renaissance. — Ever since the 11th century the cities of northern Italy had been in advance of Europe beyond the Alps both in culture and in material progress. The old classical spirit and the feeling of Roman citizenship had never quite died out, and the *Divina Commedia* of Dante (1265–1321) furnishes evidence that the poet of the scholastic philosophical theology was also a keen student and lover of the old Latin poets. But the greatest impulse to the revived study of the classics was given by Petrarch (1304–74) and Boccaccio (1313–75). Generally throughout western Europe the 14th century, though full of war and political unrest, was a time of considerable intellectual activity, shown in the increase of schools and universities. as well as in the literary and artistic revival in Italy, in the social and theological movement in England and Bohemia associated with the names of Wycliffe and Huss, and in the more or less complete substitution of Roman law everywhere except in England for the law of custom which had hitherto prevailed.

But it was the literary movement which most affected education, and, indeed, the whole life of Europe. A decisive step was taken when Manuel Chrysoloras was invited to teach Greek in the University of Florence in 1397. The enthusiasm for classical culture, to which Petrarch had given so great an impetus, gathered force and extended over the whole of Italy, though, of course, felt only by a select few and leaving the mass of the people little, if at all, affected. From Italy it spread gradually to countries north of the Alps. In the old writers men found full expression of that new spirit of self-conscious freedom which was vaguely striving for expression throughout the whole of Christendam. In the free political atmosphere of the Italian communes, with their wealthy and leisured merchant class, that spirit could flourish much more readily than in the feudalized Europe across the Alps. Moreover, the antique spirit was in direct line of ancestry with that of mediaeval Italy. Thus, for a couple of centuries, Italy stood in the van of European culture.

It is the spirit of the new movement which is of interest to the student of education. And that spirit was essentially one of opposition to authority and of assertion of individual liberty, which worked itself out in various forms among peoples of different temperaments. In Italy the form was literary and artistic, and the full development of the Renaissance spirit was seen in a practical Paganism which substituted the attractions of art for the claims of religion and morality, and eventuated in deep and widespread immorality and a contemptuous tolerance of the outward observances of religion without faith in the doctrines they symbolized. The most valuable service of the Italian humanists to Europe was the restoration to man of the heritage of knowledge which he had allowed to slip from his grasp, and the leading the way to a freer intellectual atmosphere. In Germany the spirit manifested itself in a rebellion against the doctrinal system of the Church as the only effectual means of attaining reform of ecclesiastical abuses. The Protestant Reformation of Luther was the real German outcome of the Renaissance. In no other country of Europe did the movement take so distinctive a form.

The revival of interest in classical studies was, therefore, only a first step. These newly discovered literatures responded to the intellectual and moral cravings which had been blindly gathering force for generations, as they encountered in them the pagan view of life with its assumption of the essential worth and self-reliance of the individual and its frank delight in all the pleasures of existence. It was in just this Pagan view of individual worth and the supremacy of the human intellect, that the Church gradually realized the supreme danger to herself.

At first the revival of interest in the classical literatures did not show any antagonism to Catholic faith and practice, and its warmest supporters were faithful sons of the Church. The view of the relation of classical literature to Christianity adopted by the great humanist schoolmaster, Vittorino da Feltre (1378–1446), was broadly that of the early Fathers, and in his school at Mantua he showed that culture was not inconsistent with loyalty to the Church or with purity of life. With him classical literature was not the end and sum of education, but was a means of implanting ideas, of developing taste and of acquiring knowledge, all as helps and ornaments of a Christian life. The school at Mantua may, indeed, be said to have exhibited in practice a Christianized application of the doctrines of Quintilian and Plutarch.

So was it in the other countries of Christendom. In the Netherlands the Brethren of the Common Life introduced humanistic studies into their schools side by side with definite religious teaching and observances and their work was always dominated by the Christian spirit. The earlier German humanists, such as Nicholas de Cusa, Hegius, Agricola and Wimpheling, adopted the same attitude, and Erasmus himself, bitterly as he attacked the practical abuses of the Church, remained in communion with it, and aimed at harmonizing classical culture with the Christian life. In England the same love of culture combined with devotion to the Church was seen in Selling, prior of Christ Church, Canterbury, the first real English humanist; in Grocyn, Linacre, More, Fisher, Colet and many others whose enthusiasm for culture was as undoubted as was their loyalty to Catholicism. It seemed, then, at first as if the greatest educational effect of the classical revival would be the deepening of literary culture, and the substitution of real enquiry for dialectic subtleties in the courses of schools and universities, without any break with established religious teaching. It is true that the majority of schools were but little affected, and many of the universities had given but a half-hearted welcome to humanistic studies when the religious revolt in Germany under the leadership of Luther threw the whole of Europe into two hostile camps. But even the conservative University of Paris — the headquarters of scholastic philosophical theology — had permitted the teaching of Greek as early as 1458, and both Oxford and Cambridge had welcomed the new studies.

The Reformation. — The immediate effect of the religious controversies of the 16th century on education was disastrous. The secularization of ecclesiastical property too often absorbed the endowments of the schools, so that, both in Germany and in England, the majority of grammar schools either disappeared or continued a starved existence with diminished funds; the doctrine of salvation by faith alone and the futility of good works dried up the source from which such endowments had flowed; the violent fulminations of the German reformers against the universities as the homes of the hated scholastic theology and philosophy led to wholesale abstention from those seats of learning; while the theological speculations and quarrels led those few who did resort to the universities to devote their energies to interminable wrangling over controversial points. This decadence in culture was attended by an outbreak of licence and immorality, especially among the young, which called forth violent denunciations from Luther and many of his followers in Germany, and from Latimer and other reformers in England. Humanism and Protestantism, which had so far diverged that Erasmus (1467–1536) had declared that where Lutheranism flourished learning decayed, were brought together again by Melanchthon (1497–1560), under whose influence universities were founded or reorganized and schools re-established in Protestant German States; and in England the reign of Elizabeth saw the creation of a certain number of new

foundations, But this restoration of the means of education was only partial, and the doctrine of the worthlessness of "carnal knowledge," which led the Barebones Parliament to propose the suppression of the English universities, was held by many fervent Protestants both in England and in Germany all through the 17th century.

Moreover, the schools continued to ignore the new directions of men's thoughts and the new view of knowledge as something to be enlarged, and not merely a deposit to be handed down from generation to generation. The later humanist theories of education, which the schools continued to follow generally for over two centuries, and in many cases for another hundred years after that, were drawn mainly from Erasmus and Melanchthon, who found in the classical languages and literatures, and especially in Latin, the only essential instruments of education. General knowledge of natural facts might be desirable to the cultured man as ornaments to his rhetoric, but it was to be sought in the writings of antiquity. Even so revolutionary a thinker on education as Rabelais (1495–1553) with all his demand for an encyclopaedic curriculum, held the writings of the ancients as authoritative on natural phenomena. Nelanchthon exercised enormous influence, both directly and through such disciples as Trotzendorf and Neander, but especially through his friend Sturm (1507–89), whose Latin gymnasium at Strasbourg became the model which the grammar schools of Protestant Europe strove to imitate. In this school nearly the whole of the energies of the boys was given to acquiring a mastery of the Latin language after the model of Cicero.

In Catholic countries the Church retained control of education. The practical reformation of abuses by the Council of Trent, and the energy and skill of the Society of Jesus, founded by St. Ignatius Loyola, in 1534, brought back most of south Germany into the fold of the Church. Everywhere Catholic universities were mainly taught by Jesuit fathers; and under their influence, scholasticism, purged from the excretions which had degraded it, was restored. Everywhere the society established schools, which, by their success in teaching and the mildness of their discipline, attracted thousands of pupils who came even from Protestant homes. Their curriculum was purely classical, but it was elaborated with much skill, and the methods of instruction and discipline were made the subject of much thought and of long-continued experiment. All Jesuit fathers being trained, the teachers in Jesuit schools attained a degree of skill in their art which was too generally wanting elsewhere.

Decadence of **Schools** and ***Universities.***—Mulcaster (1530–1611) pointed out that Latin was not of value to the majority of boys. For them he urged an elementary education in the vernacular; but neither in this nor in his advocacy of the training of teachers was his advice followed. In the 17th century the dislocation between the Latin schools and the needs of life began to be accentuated as Latin gradually ceased to be the language of learning; and, as a consequence, the numbers attending the schools decreased, and the mass of the people sunk continually lower in ignorance. In vain Hoole urged the establishment of a universal system of elementary schools giving instruction in the vernacular, Petty put forth his plan for elementary trade schools, and Cowley proposed the establishment of a college devoted to research. Ideas of reform were in the air, but the main current of scholastic practice flowed on unaffected by them. Some attention was, indeed, paid to the conservative reforms advocated by the Port Royalists, of which the most important was the inclusion of the vernacular as a branch of instruction, but the cry for more fundamental changes based on the philosophy of Bacon was unheeded. Of these, none was a more active propagandist than Comenius (1592–1670). Unfortunately his Great Didactic, in which he set forth his general principles, attracted little attention and won less adherence, though his school books, in which he attempted with very little success to apply his principles, were widely used in schools. But these were little more than bald summaries of real and supposed facts, stated in Latin and the vernacular in parallel columns. In content they differed from such mediaeval summaries of knowledge as the well-known work of Bartholomew Anglicus, which had been widely used since the 13th century, chiefly by their greater baldness and aridity of statement.

In the universities, too, the 16th and 17th centuries saw a continuous decadence. The 16th century was not ripe for real intellectual freedom; and Protestantism, having based its revolt on the right of private judgment, soon produced a number of conflicting theological systems, vying with each other in rigidity and narrowness, which, as Paulsen says, "nearly stifled the intellectual life of the German people." Further, the idea of national autonomy, which exercised so great an effect on the politics of the time, included the universal adherence of the citizens to the religion of the State. Hence, till the end of the 17th century the universities of Protestant Europe were regarded mainly as instruments for securing adhesion to the national theological system on the part of future clergy and officials, and the State interfered more and more with their organization and work. In Paris, on the other hand, the faculty of theology had decayed through the withdrawal of those preparing for the priesthood into episcopal seminaries, and the higher studies pursued were mainly law and medicine. Thus, generally, the universities were less and less fulfilling the function of providing a general liberal education. Another change, due to the same causes and making for the same results, was the isolation of universities, often directly fostered by the State governments, which for the universal interchange of mediaeval thought substituted a narrow provincial culture and outlook.

Indeed, from the middle of the 17th century, the main current of intellectual life had drifted away from the orthodox centres of learning. The formation of the Berlin Academy in Germany and of the Royal Society in England, and the refusal of Leibnitz to accept a chair in any German university, were signs of the times. In France, and later in Germany, the education of the noble youth was increasingly carried on apart from the schools, and was really an outgrowth from the education of chivalry. In the 16th century Castiglione and Montaigne had advocated a training directly adapted to prepare for active public life, and Elyot wrote on similar lines. But the most important movement in this direction was the formation of the courtly academies which flourished in France in the 17th century, and were soon imitated in the *Ritterakademien* of Germany. In these schools of the nobility French was more honoured than classics, and the other subjects were chosen as directly adapted to prepare for the life of a noble at the court or in camp. Milton in his *Tractate* advocated the foundation of such academies in England. More and more, too, foreign travel had, from the middle of the 16th century, been looked upon as a better mode of finishing the education of a gentleman than a course at a university.

Revival of University Life.—The later years of the 17th century saw a revival of university life in Cambridge, through the work of Newton and the increasing attention paid to mathematics and the physical sciences, though the number of students continued very small. In Germany, also, a new era opened with the foundation of the Universities of Halle (*q.v.*) in 1694 and Gottingen in 1737, which from the first discarded the old conception that the function of a university is tb pass on knowledge already complete, and so opened the door of the German universities to the new culture and philosophy. It was soon seen that students Could thus be attracted, and the influence spread to the other German universities, which by the end of the 18th century had regained their position as homes of the highest German thought.

At Halle, too, was set the example by Francke of providing for the education of the children of the poor, and to his disciple. Hecker, Germany owes the first *Realschule.* Simultaneous movements for the education of the poor were made by St. Jean-Baptiste de la Salle and the Brothers of the Christian Schools in France, and by the Society for the Promotion of Christian Knowledge in England. Mention should also be made of the Sunday School movement started by Robert Raikes in 1780. But the total results were not great; the mass of the people in every European country remained without schooling throughout the 18th century.

Education in the **18th** Century. — The intellectual movements of that century were, indeed, essentially aristocratic. Voltaire and the Encyclopaedists aimed at the enlightenment of the select few, and Rousseau declared baldly that the poor need no education. That these movements influenced education profoundly is undoubted. The individualistic and abstract rationalism of Voltaire, derived from the sensationist philosophy of Locke through the more thoroughgoing Condillac, and finding its logical outcome in the materialistic atheism of La Mettrie and the refined selfishness of Rochefoucault, infected the more cultured classes. In Lord Chesterfield's *Letters* to *his* Son is shown its educational outcome — a veneer of superficial culture and artificial politeness covering, but not hiding, the most cold-blooded selfishness. Against this fashionable artificiality, as well as against the obvious social and political abuses of the time, Rousseau's call for a return to nature was a needed protest.

Rousseauism, however, was not merely a transitory revolt against a conventionality of life that had become unbearable; it was emphatically the voicing of a view of life and of education which has profoundly influenced Europe ever since. In that Rousseau (1712–78) attempted to look at life as a whole, he was on truer ground than were the intellectualists of the "Enlightenment," especially in his advocacy of the hitherto ignored claims In education of feeling and emotion. His *Émile* may be, in spite of certain crudities, not unfairly described as the charter of childhood. It is, in fact, a declarztion of childhood's rights. On the other hand, his overinsistence on the efficacy of nature, as shown by his theory that man is born good, and if left to his own instincts cannot fail to achieve happiness, is obviously one-sided.

Against this position the educational teaching of Kant (1724–1804), influenced though he was by the *Émile*, is essentially a protest. The most necessary element in education, according to Kant, is constraint, which by the formation of habit prepares the young to receive as principles of conduct the laws at first imposed upon them from without. And the supreme guide of life is the law of duty which is always more or less opposed to the promptings of inclination. The French Revolution — the natural outcome of the teachings of Voltaire and of Rousseau — was the second stage in the movement of which the Reformation was the first. It was essentially the assertion of the natural rights of man, and, as a logical sequence, of the right of every child to be properly trained for life. The gradual recognition of this truth, with the necessary corollary of the establishment of a national system of education, is emphatically the characteristic mark of the educational history of all countries in the 19th century.

The 19th Century. — Preached and practised by Pestalozzi (1746–1827) in Switzerland, the general education of the poor was first made a reality by Prussia after the crushing defeat of Jena. In France and England it remained for nearly three-quarters of the century the work of the Church and other voluntary agencies, though aided by the State. Finally a State system of schools was more or less fully set up in every State of western Europe and in America, and subjected to more or less State regulation and control. Equally marked was the growing care for the education of girls as well as boys, though only in America were the two regarded as practically identical in form and content.

Thus the 19th century saw the final working out of the idea that the State should be substituted for the Church as the official agent of education. Among the principal causes of such a change, was the growing conviction that with the ever-widening distribution of political power, the State has a right to demand a minimum of knowledge from every citizen, while, on the other hand, it is alike to the benefit of the individual and the State that the door of educational opportunity should be thrown as wide open as possible. Equally potent was the idea which had its roots in the Renaissance conception of the right of man to direct his life apart from theological determinations. The more direct outcome of the same idea was apparent in the absolute liberty with which the presuppositions of knowledge were questioned, and the maxim of Descartes — to prove everything by the reason and to accept nothing which fails to stand the test — was acted upon. No greater contrast is possible than that between the mediaeval student and the modern searcher after truth.

The influence of the same spirit has wrought an equally momentous change in the methods of instruction. The impetus given by the doctrine of Rousseau to the view that the nature of the child should determine the means of education, led to more thoroughgoing attempts than had hitherto been made to base educational method on a knowledge of child psychology. Pestalozzi and Froebel (1782–1852), by their insistence on the need of educating a child through his own activity, and by their widespread influence, made the new view of method an actuality. The influence of Rousseau has, thus, passed into modern educational practice in a form that, in its essence, is true, though in practice it has shown itself apt to run into the same excess of emphasis on impulse and feeling which characterizes his teaching. The influence of Herbart (1776–1841) tended to counteract this. The essence of Herbartianism was that mental life consists of presentations, or reactions of the mind on the environment, and that will springs from the circle of thought thus developed. The emphasis was therefore placed on intellect and instruction, while in Froebelianism it was placed on spontaneous activity and on the arrangement of the environment. Each exaggerated the function of the one factor in concrete experience which it made the centre of interest, and each was tinged with the individualistic conception of life which characterized the 18th and early 19th century. NATIONAL SYSTEMS

ENGLAND

Elementary Education. — It was the development of industry and the social unrest at the end of the 18th century, following on the French Revolution, which combined to bring home to the public mind the need of a national system of day schools. Unfortunately, just at this moment the revival of Nonconformity as the result of the religious vitality of the Evangelical movement shattered the religious peace of the early Hanoverian period and divided the nation once more into hostile camps, to which class distinctions lent additional bitterness. The famous controversy between Andrew Bell and Joseph Lancaster and their respective followers in the opening years of the 19th century served to define the religious difficulty substantially in the form in which it existed for over 100 years. Both these remarkable men conceived independently the idea of a national system of popular education upon a voluntary basis. The controversy between them, begun upon personal grounds, resolved itself into a national contest of rival principles of religious teaching. Lancaster as a young Quaker schoolmaster, confronted with pupils drawn from various religious bodies, planned his religious instruction upon the lines of doctrine common to all the orthodox Christian denominations. Thus he is the father of the undenominational religious teaching which later formed the basis of the Cowper-Temple compromise. But whereas the Cowper-Temple clause is purely negative in form and so seems to point to an undogmatic religion, the Lancastrian teaching was essentially positive and dogmatic within its limits. The Church as a whole refused to co-operate in religious teaching upon the basis of a common Christianity, and joined issue with Lancaster and his Whig and Nonconformist following not merely upon the question of the exclusion of dogmatic formularies, but also upon the question of the control of whatever religious teaching should be given. In fact the vital question at this period was whether the clergy of the Established Church were to control the national education. The religious issue was prominent in connection with the remarkable attempt at legislation made by the Whig statesman Whitbread in his Parochial Schools bill of 1807. It was rejected by the Lords, mainly on

the ground that it did not place education on a religious basis or sufficiently secure control to the minister of the parish.

Early Voluntary Schools.—The failure of the liberal proposals of Whitbread, and the strength of the Dissenting opposition to any settlement on purely Church lines (such as that advocated by Bell in 1808 for establishing schools under the control of the parochial clergy), rendered recourse to voluntary effort inevitable. In 1808 the Royal Lancasterian Society was formed to carry on the work of Lancaster, the name being afterwards changed to the British and Foreign School Society. In the following year the National Society for promoting the education of the poor in the principles of the Established Church throughout England and Wales was formed, with Bell as its superintendent. In voluntary effort on a grand scale the Church easily outdistanced her opponents, and in 1831 the National Society was able to show that there were in all over 13,000 schools in connection with the Church, of which 6,470 were both day and Sunday schools, having a total attendance of 409,000.

The rapid development of the voluntary school system was no doubt greatly facilitated by the monitorial plan of teaching, upon which Bell and Lancaster equally relied. This plan never rested upon any educational theory; it was simply a rough-and-ready expedient for overcoming the practical difficulty caused by the dearth of competent teachers. Historically it is important as the precursor of the pupil-teacher system which so long formed the exclusive basis of the English elementary system.

Meantime, Brougham, in 1816, procured the appointment of a general commission of enquiry into endowed charities. The labours of this great inquisition lasted for 20 years and led to the reformation of many cases of abuse or waste of wealthy endowments, and eventually to the establishment of the Charity Commission in 1853. In 1820 Brougham introduced a bill which proposed to require teachers to be members of the Church of England and to be appointed upon a certificate from the parochial clergyman, and on the other hand to prohibit religious formularies and to confine religious instruction to Bible reading without comment. The bill naturally failed through the opposition of the dissenters, and served only to accentuate the religious impasse.

Establishment of State Aid.—In 1832 the Whig Government placed on the estimates a sum of £20,000 for public education, thus initiating the system of the annual grant voted by parliament. The funds thus granted were to be confined to the erection of school buildings, and to be administered only through the National and the British and Foreign School societies. In 1839 Lord Melbourne's Government, by means of an order in council, established a Committee of Council on education, and the sum voted by parliament was increased to £39,000. The original intention of the Government was to establish a State normal school or training college as the foundation of a national system of education. Unfortunately this design had to be abandoned in view of the religious difficulty, with the result that the training of elementary teachers was left in private hands. In view of the limited resources placed at their disposal by parliament, the Committee of Council were at first compelled to confine their assistance to capital grants in aid of the provision of school buildings, but in the distribution of the money three important conditions were at once imposed. In the first place, the continuing right of inspection was required in all cases; secondly, promoters were obliged to conform to a fixed standard of structural efficiency; thirdly, the building must be settled upon trusts permanently securing it to the education of poor children.

By the minute of Aug. 10, 1840, the Committee of Council concluded what came to be known as the concordat with the Church. Under this minute no appointment was to be made of any persons to inspect schools in connection with the Church of England without the concurrence of the archbishop of the province, and. what seems still more extraordinary to modern ideas, any such appointment was to be revoked should the archbishop at any time withdraw his concurrence. The altered financial relations, however, between the State and the voluntary managers brought about by the institution of maintenance grants soon rendered this concordat obsolete,

Among the first acts of the Committee of Council was the promulgation of a set of model trust deeds. The necessary conditions were the permanent appropriation of the site to purposes of education, and the permanent right of Government inspection; a conscience clause was not obligatory, and indeed was only offered in the limited form of exemption from instruction in formularies and attendance at Sunday school or public worship. Special facilities for the conveyance of land for school purposes were afforded to limited owners by the School Sites Acts of 1841 and subsequent years. The landed gentry responded with great public spirit to the call thus made upon their generosity by the State, with the result that the vast majority of rural, and many urban, parishes were freely endowed with sites for elementary schools.

The Grammar Schools Act of 1840, which was passed to deal with the case of the decayed "grammar" (*i.e.*, classical) schools which abounded throughout the country, belongs to the history of elementary rather than secondary education. As a result of this act a considerable number of ancient endowments were reorganized so as to afford an improved elementary instead of an inefficient classical education, and the schemes made under the act constituted an early, but not very successful, experiment in the direction of higher elementary schools.

In 1843 the Committee of Council decided to make grants in aid of the erection of normal schools or training colleges in connection with the National Society and the British and Foreign School societies, thus marking the definite abandonment of the system of relying on voluntary effort for the provision of training colleges.

In 1846 an important step forwards was taken in the foundation of the pupil-teacher system. The regulations of this year inaugurated annual maintenance grants in the form of stipends for apprenticed pupil-teachers'receiving a prescribed course of instruction under the head teacher, and a lower grade of stipendiary monitors in schools where such instruction could not be provided. These regulations inaugurated the system of Queen's scholarships to assist pupil-teachers to proceed to a training college; they also established capitation grants for the support of such colleges, and annual grants to elementary schools under Government inspection of from £1 j to £30 in aid of the salary of every trained teacher employed. Provision was at the same time made for retiring pensions to elementary teachers.

To facilitate the recognition of denominational schools other than Church of England, the Committee of Council in 1847 issued a minute dispensing schools not connected with the Established Church from enquiries concerning their religious condition, and in the same year State aid was extended to Wesleyan and Roman Catholic schools. Jewish schools received recognition in 1851 upon condition that the Scriptures of the Old Testament should be daily read in them.

During the middle years of the century various unsuccessful legislative attempts were made to establish a national system of elementary schools upon the basis of rate-aid. The only one of these attempts which calls for notice here is the bill introduced by Lord John Russell (called the Borough bill, on account of its being restricted to municipal boroughs) in 18 j3, and forming part of a comprehensive scheme of legislative and administrative reform of which a portion was actually carried into effect. The bill as a measure for elementary education was supplemented by an administrative system of capitation grants for rural areas. The Government scheme also comprised a measure dealing with the administration of charitable trusts (which took shape as the Charitable Trusts Act 1853), the constitution of the Department of Science and Art, and university reform upon the lines recommended by the Oxford and Cambridge commissions.

The failure of the Borough bill did not affect the new system of capitation grants which was introduced by minute of the Committee of Council dated April 2, 1853. These grants were fixed at a scale varying from 3s. to 6s. per head, payable upon certain conditions, of which the most important were that the school must be under a certificated teacher, and that three-fourths of the children must pass a prescribed examination. The capitation grant was, by minute of Jan. *26,* 1856, extended to urban areas. As in

the case of all the early grants, the regulations governing the distribution of the capitation grants were framed upon the principle that subventions of public money must be met by local funds derived from voluntary contributions, endowments and school fees; thus the basis of the denominational system as fostered by the State at this stage was one of financial partnership.

In 1856 a purely administrative bill was passed, establishing the office of vice-president of the Committee of Council on education as a minister responsible to parliament. At the same time, the Science and Art department was transferred from the Board of Trade to the Committee of Council.

The Newcastle *Commission.*—The progress of State-aided education during this period may be measured by the increase of the annual parliamentary grant, which rose from £30,000 in 1839 to £100.000 in 1846, £150,000 in 1851, £396,000 in 1855, and £663,-400 in 1858. This expansion was viewed with misgiving by the friends of the denominational system, and by the strong individualist school of that day, who upon wider grounds clung to the old ideal of voluntary initiative. These sections combined with the advocates of further State intervention to press for a commission of enquiry, and a royal commission was appointed in 1858, under the chairmanship of the duke of Newcastle, to inquire into the state of popular education in England, and to consider and report what measures, if any, were required for the extension of sound and cheap elementary instruction to all classes of the people. The Report of the Newcastle commission, issued in 1861, contains an exhaustive account of the existing condition of elementary education, and, with due allowance for the grave defects revealed, and in particular the glaring inefficiency of the numerous little private-venture schools kept by "dames" and others, the graphic picture drawn by the commissioners constitutes a striking tribute to the sterling qualities of self-help and religious earnestness which were so characteristic of the early Victorian period. It was found that in round numbers about 2,500,000 children were attending day schools, the proportion to population being one in seven, as compared with one in nine in France, one in eight in Holland and one in six in Prussia, where education was compulsory. On the other hand, of this number only 1,675,000 were in public schools of all kinds, only 1,100,000 in schools liable to inspection, and 917,000 in schools receiving annual grant. The result was that only one child in every 20 was attending a school whose efficiency could be in any way guaranteed by the State. The commissioners as a body rejected free and compulsory education in view of the religious difficulty and upon general grounds of individualistic principle. In view of the solution adopted in 1902 it is of interest to note that the Newcastle commissioners deliberately rejected the parish as unfit to be taken as the unit of elementary education upon the ground that management by parochial ratepayers must tend to be illiberal and niggardly, and recommended the constitution of county boards with power to levy a rate for the aid of existing voluntary schools.

The one definite achievement of the Newcastle commission was the famous system of payment by results. Impressed by the defects of the existing teaching, the commissioners reported that there was only one way of securing efficiency, and that was to institute a searching examination by competent authority of every child in every school to which grants were to be paid, with the view of ascertaining whether the indispensable elements of knowledge were thoroughy acquired, and to make the prospects and position of the teacher dependent to a considerable extent upon the results of this examination. They recognized that to raise the character of the children, both morally and intellectually, was and must always be the highest aim of education; but they thought that the training in the rudiments of education, which must be the foundation of all teaching, had been lost sight of, and that there was justice in the common complaint that while a fourth of the scholars were really taught, three-fourths after leaving school forgot everything they had learnt there.

Lowe (Lord Sherbrooke), as vice-president of the Committee of Council (1859–64), adopted the system of payment by results in what became famous in history as the Revised Code, issued in 1862. The Revised Code provided for the payment of a grant of 4s. upon the old principle and a further grant of not more than 8s. upon the result of examination. Lowe declared of the system in the House of Commons that "if it was costly it should at least be efficient; and if it was inefficient it should at least be cheap." In fact, it proved to be cheap; the grant fell from £813,-400 in 1861 to £636,800 in 1865. Later, to meet objections, some modifications were introduced in the code under the Conservative Government in 1867. The system of paying grant upon the result of individual examination of the scholars was not finally abolished till 1904.

The Act of 1870 *and Its Effects.*—In 1868 the Conservative Government brought in, but did not proceed with, an education bill deliberately discarding the principle of rate-aid on the ground that it would destroy voluntary contributions and gradually starve out the denominational schools. In 1867 and again in 1868, Bruce (afterwards Lord Aberdare), W. E. Forster and Algernon Egerton introduced a bill which formed the basis of the measure of 1870. As redrafted in 1868 the bill of Bruce and his coadjutors proposed a universal system of municipal and parochial rating with liberty for voluntary schools to unite themselves to the rate-aided system under their existing management, subject to the acceptance of a conscience clause. The bill also proposed to empower town councils to co-opt outsiders upon their education committees. Thus both in the principle of co-optation and in the extension of rate-aid to schools not under public control the bill of these Liberal statesmen in 1868 anticipated certain features of Balfour's Education Act of 1902. In the meantime, in the country the Education League, originated at Birmingham, was carrying on a propaganda in favour of free secular schools, whilst the Education Union, formed to counteract the influence of the league, urged a settlement upon the old lines. As a concession to the popular feeling against secularism, the league proposed to allow Bible reading without doctrinal exposition. Thus opinion was sufficiently focussed to enable Gladstone's administration in 1870 to undertake a comprehensive measure of educational reform.

The Elementary Education Act of 1870 bore in every respect the marks of compromise. As Forster explained in introducing the bill, the object of the Government was "to complete the voluntary system and to fill up gaps," not to supplant it. To this end the Education Department was charged with the duty of ascertaining whether or not there was in every parish a deficiency of public school accommodation, and of making provision for the formation of school boards in every school district (*i.e.*, parish or municipal borough) requiring further public school accommodation. The definition of public elementary school contained in section 7 of the act is still in force (1928). Shortly, a public elementary school is a school subject to a conscience clause entitling scholars to complete exemption from all religious instruction and observance whatsoever. Any religious instruction or observance in the school must be either at the beginning or the end of the school meeting. The school must also be open at all times to the Government inspectors, and must be conducted in accordance with the prescribed conditions in order to obtain an annual parliamentary grant. In the same connection an important change was made in the conditions of inspection by declaring that it should be no part of the duties of the inspector to inquire into religious instruction, whilst a later section of the act provided that no parliamentary grant should be made in respect of any religious instruction.

Three important changes were made in the measure during its passage through parliament: (1) In lieu of the rate-aid as first suggested, the Government proposed an increased grant from the Treasury, that is to say, the voluntary schools were left standing as State-aided schools under private management, side by side with the new rate-supported schools. (2) The character of the religious instruction in the board schools was determined upon an undenominational basis by a provision which has become known to history after the name of its author, as the Cowper-Temple clause (section 14 of the act), directing that "no religious catechism or religious formulary which is distinctive of any particular denomination shall be taught in the school." The clause was not intended to exclude doctrinal exposition, and was in fact a com-

promise not merely between absolute secularism and denominationalism, but between denominationalism and the view of those who would have the Bible read without note or comment. The Apostles' Creed as a symbol common to all denominations of Christians was held by Forster (at Gladstone's suggestion) not to be excluded under the Cowper-Temple clause. The result was the establishment in the schools, upon the lines laid down by Joseph Lancaster at the beginning of the 19th century, of what may be termed the common Protestantism of the English nation. The Cowper-Temple compromise, notwithstanding its inherent want of logic, stood the test of experience for more than a generation against the consistent denominationalists on the one hand and the party of secular education on the other. (3) The third change in the bill was the substitution of the ad *hoc* school board for the municipally appointed board originally proposed. These boards were elected by the system of cumulative voting under which each elector had as many votes as there were candidates to be elected, with liberty to give all his votes to one candidate or to distribute them amongst the candidates as he thought fit. This system was much criticized as being unduly favourable to minorities, whose representation it was devised to secure; it continued, however, until the act of 1902.

School boards were empowered not only to acquire sites for schools under powers of compulsory purchase, but also to take transfers of existing voluntary schools from their managers. The act of 1870 did not introduce either direct compulsory attendance or free education, but it took a distinct step forward in each direction by enabling school boards to frame by-laws rendering attendance compulsory, and also to pay the school fees in the case of poverty of the parent. Building grants were continued temporarily for the benefit of those who applied (as voluntary managers alone could apply) before Dec. 31, 1870. On the other hand, the Education Department was authorized to refuse parliamentary grants to schools established in school board districts after the passing of the act if they thought such schools were unnecessary.

The following figures are of interest as showing the progress made under the act of 1870. In the year 1870 there was accommodation in inspected day schools for about 2,000,000 ehildren; the average attendance was 1,168,000, and the number on the books about 1,500,000. It was computed, however, that there were, exclusive of the well-to-do classes, at least 1,500,000 children who attended no school at all or schools not under inspection In 1876 accommodation had been provided for nearly 3,500,000, and of the 1,500,000 new places nearly two-thirds were provided by voluntary agencies. "These voluntary agencies," says Sir H. Craik, "had received grants in aid for about one-third of the schools they had built, the grants defraying about one-fifth of the cost of the aided schools." On the other hand, the growth of school boards was rapid and continuous, notwithstanding the permissive character of the act and the strenuous efforts of the voluntaryists to keep pace with the new demands. In 1872, 9,700,000 of the population were under school boards, and of these 8,142,000 were under by-laws; in 1876 the numbers were respectively 12,500,000 and 10,400,000. In the same period the annual grants increased from £894,000 in 1870 to £1,600,000 in 1876. The development evidenced by the above figures, and in particular the fact that 52% of the population were subject to by-laws, enabled Disraeli's Government in 1876 to pass a law introducing universal compulsory attendance, with certain exceptions. In order to complete the machinery for compulsion, the act directed that, in every district where there was no school board, a school attendance committee should be appointed by the local authority.

In 1880 Mundella, as vice-president of the Council in Gladstone's administration, passed a short act which made the framing of by-laws compulsory upon school boards and school attendance committees, thus completing the system of universal direct compulsion. Under the acts of 1876 and 1880 the average attendance increased from 2,000,000 in 1876 to 3,500,000 in 1878 and 4,000,000 in 1881; in terms of percentage to population, 8.06 in 1876, 9.60 in 1878, and 10.69 in 1881. In the last-mentioned year the annual grant rose to £2,200,000, having more than doubled in the decade.

In 1887 a royal commission under the presidency of Viscount Cross was appointed to enquire into the working of the education acts. The labours of this commission produced a thorough discussion of the educational problem in all its aspects. political, administrative, scholastic and religious. For any clear recommendations with regard to the reorganization of education generally the moment was not opportune, inasmuch as the commission just preceded the establishment of the new county authorities and the powers with respect to instruction other than elementary which parliament was shortly to confide to them under the Technical Instruction Acts. Nevertheless the report of the majority of the commissioners pointed unmistakably towards the solutions adopted in the act of 1902, and their definite recommendation that voluntary schools should be accorded rate-aid without the imposition of the Cowper-Temple clause, served as the basis of that legislation.

Of the developments which followed the Cross report, it is convenient to mention in the first place, out of chronological sequence, the practical establishment of free education by the act of 1891, not by the absolute prohibition of school fees but by the device of a special grant payable by parliament in lieu of fees, called the fee grant. The result of this legislation and of subsequent administrative action was to place free education within the reach of every child, fees being retained (with few exceptions) only where some instruction of a higher elementary type was given.

Secondary and Technical Education. — The establishment of county councils by the Local Government Act, 1888, introduced a new factor, destined to exert a determining influence upon subsequent developments of public education. In the first place, it at once rendered possible the partial and experimental provision for higher education attempted by the Technical Instruction Acts, which affected secondary education as well as technical education in the proper sense of the term. In order to understand the state of secondary education at this period, it is necessary to refer to the first attempts made at State intervention (for earlier history, see SCHOOLS).

In 1861 the first step was taken by the appointment of a royal commission, presided over by Lord Clarendon, to enquire into the condition of nine of the chief endowed schools in the country, viz., Eton, Winchester, Westminster, Charterhouse, St. Paul's, Merchant Taylors, Harrow, Rugby and Shrewsbury. The report of this commission led to a statute, the Public Schools Act of 1864, which introduced certain reforms in the administration of seven of these schools, leaving the two great London day schools, St. Paul's and Merchant Taylors, outside its operation.

The Schools Enquiry Commission. — In 1864 the Schools Enquiry Commission was appointed under the presidency of Lord Taunton to enquire into all the schools which had not been included either in the commission of 1861 or the Popular Education Commission of 1858. It thoroughly explored the field of secondary education, discussing all the problems, administrative and pedagogic, which the subject presents, and "its luminous and exhaustive report" (to quote the words of Bryce's commission of 1894) remains the best introduction to the problem of public secondary education in England. The existence of numerous and frequently very wealthy endowments arising from private benefactions and bequests has at all times been a feature in education as in other departments of English social life. At the date of the Schools Enquiry Commission the state of the ancient endowments was largely one of abuse. Very many endowments intended for advanced education were applied for instruction of a purely elementary character, and that of an inferior kind; indeed the possession of an endowment in a rural locality not infrequently operated to prevent the establishment of an efficient State-aided school. The evidence showed that the proportion of scholars in the country grammar-schools who were receiving some tincture of the classical education intended by the founders was steadily decreasing, and nothing had been done to bring the curriculum into harmony with the actual needs of the time. In addition to

the general inelasticity of the curriculum, the special evils from which the grammar-schools suffered were the want of effective governing bodies and the freehold tenure of the headmasterships.

The report of the commission was immediately followed in 1869 by the Endowed Schools Act, which conferred upon a special commission (united in 1874 with the Charity Commission) very wide and drastic powers of reorganizing ancient endowments. A direction for extending the benefits of endowments to girls did much to assist the movement for the secondary education for girls. Thanks to their powers in framing schemes for the reorganization of ancient endowed schools the commissioners found themselves able to treat the majority of cases as undenominational. In such cases the general practice was to direct that instruction should, subject to a strict conscience clause, be given in the principles of the Christian faith; this provision, however, did not exclude special doctrinal instruction.

The Schools Enquiry Commission also submitted proposals for the general organization of a system of secondary education. They recommended the establishment of three authorities — (I) a central authority; (2) a local or provincial authority, representing the county or a group of counties, and (3) a central council of education charged with examination duties. Further, it was proposed to raise the level of proprietary and private schools by offering them inspection and examination and by establishing a system of school registration. Lastly, it was proposed to confer upon towns and parishes powers of rating for the establishment of new schools. For these proposals as a whole the time was not ripe. The bill of 1869 attempted to give effect to the suggested creation of a central council, but exigencies of parliamentary time made it necessary to drop this part of the measure; the result was that the plan of the commissioners was only half carried out. Nevertheless the work accomplished was sufficient to exert a considerable influence upon the secondary education of the country. Thus in 189j Bryce's commission was able to report that schemes under the Endowed Schools Acts had been made for 902 endowments in England, excluding Wales and Monmouth, leaving untouched only 546 endowments out of the total of 1,448 endowments in England known to be subject to the Endowed Schools Acts. The total income of the endowments known to be subject to the Endowed Schools Acts, and therefore available for purposes of secondary education, according to the estimate of the Secondary Education Commission, was in 1895 about £735,000 gross.

The creation by the Local Government Act in 1888 of the representative and popular county authorities rendered the municipalization of secondary instruction at last possible. In 1889 the Technical Instruction Act (extended in some particulars by an act of 1891) empowered the councils of counties, boroughs and urban districts to levy a rate (not exceeding a penny in the pound) for the support or aid of technical or manual instruction. Comparatively few councils were prepared to resort to their rating powers. but progress under these acts mas greatly facilitated by the Local Taxation (Customs and Excise) Act of 1890, which mentioned technical instruction as one of the purposes to which the imperial contribution paid to local authorities in respect of the beer and spirit duties might be applied. (See TECHNICAL EDUCATION.) By virtue of the very liberal interpretation given to technical instruction by these acts the financial assistance afforded under them was extended to cover the whole field of mathematical and physical science, as well as modern languages.

At the same time the Department of Science and Art (founded in 1853) gradually utilized its grants to encourage literary studies in secondary schools as well as the scientific and mathematical subjects to the promotion of which it was primarily directed. Thus the combined effect of the local resources available under the Technical Instruction Act and the imperial grant administered by the department was gradually to develop a national system of secondary education with a marked bias on the side of physical science. But the schools giving higher education still practically consisted, apart from the big public schools, of endowed grammar schools, or proprietary schools established by religious bodies or joint-stock companies. No public body had, as yet, the right to build a secondary school.

An undoubted stimulus was given to secondary education in the great centres of industry during the last quarter of the 19th century by the rise of the new university colleges, among which must be reckoned those established expressly for women. At the same time (1889) a beginning was made of State aid to these colleges, through a committee appointed by the Treasury in a minute of July 1 (see UNIVERSITIES). Meanwhile, with the development of elementary education, the great schdol boards found themselves obliged to provide for the further education of their best pupils in what were known as higher-grade elementary schools. These were really secondary schools of the third grade, and, as the commission on secondary education observed, the school boards simply stepped in to fill the educational void which the Schools Enquiry Commissioners had proposed to fill by schools of that name. Their creation was greatly fostered by the upper departments in such schools being recognized for grants by the Science and Art Department. In fact they continued to multiply and prosper till 1901, when the famous judgment in the test case of Rex v. Cockerton pronounced them to be illegal. It was at once recognized that the legislature must, without delay, step in to secure the educational work which the undoubtedly correct principles of judicial interpretation had placed in jeopardy.

Secondary Education Commission. — Aleanwhile, as far back as 1894, a royal commission had been appointed under the presidency of Bryce to enquire into secondary education. The principal recommendations of the commission were: (1) the unification of the existing central authorities, viz., the Department of Science and Art, the Charity Commission (so far as it dealt with educational endowments), and the Education Department, in one central office, and the establishment of an educational council to advise the minister of education in certain professional matters; (2) the establishment of local authorities, to consist of committees of the county councils with co-opted elements; (3) the formation of a register of teachers with a view to the encouragement of professional training, and a system of school registration upon the basis of inspection and examination. The first of these recommendations was carried out by the Board of Education Act 1899, and under the same act an attempt was made to give some effect to the third-named object, which unfortunately fell short of success. The realization of the second, and the most important, of the recommendations was deferred till 1902, when it was brought about as a part of a wider reorganization of the educational system.

In 1896 an endeavour was made to meet the demands of the voluntary managers of elementary schools by means of a bill introduced by Sir John Gorst. This bill with its provision for a special aid grant to be administered by county education authorities, which were to exist side by side with the school boards, represented a kind of compromise between the systems of 1870 and 1902. It encountered opposition in all quarters and was withdrawn. In 1897, however, the position of the denominational schools was strengthened by the Voluntary Schools Act, which provided for a special aid grant of 5s. per head of the scholars in average attendance in these schools.

Partial effect was given to the recommendations of the Secondary Education Commission by the Board of Education Act of 1899, which united the Department of Science and Art with the Education Department in one central office under the title of the Roard of Education, with a president and parliamentary secretary; and provided for the transfer to this board of the powers of the Charity Commissioners in relation to educational endowments; also for a consultative committee, consisting, as to not less than two-thirds, of persons qualified to represent the views of university and other bodies interested in education, for the purpose (1) of framing a register of qualified teachers, and (2) of advising the Board of Education upon any matters referred to the committee by the board. In 1902, a tripartite division was adopted to correspond with the three branches of education with which the Board of Education is concerned, viz., elementary,

secondary and technological. Mention may also be made here of another uncontroversial measure, the Elementary Education Act of 1899, which dealt for the first time, from the point of view of the State, with mental deficiency (*q.v.*).

Education Act, 1902.—NO law, during the last 50 years, with the exception of the Home Rule controversies, excited a more acute or prolonged controversy than the Education Act of 1902. Yet at this distance of time, when the political and religious passions it provoked have practically disappeared, it appears in its true light as the veritable charter of incorporation of English education, hitherto consisting of disconnected and often discordant elements. In the sphere of elementary education it boldly abolished the school boards and made the one authority for every form of education (below the university), the county or county borough, already the recognized authority for technical and, to a limited extent, for secondary education. By putting voluntary and ordinary elementary schools on the same footing, it practically made the standard of the work in the two identical, and eventually built up an almost complete network of well equipped secondary schools, as well as a vigorous system of technical education. Under the impartial administration of the counties, the religious question practically ceased to exist. The act was extended to London in 1903. For framing and carrying it through, special credit is due to Mr. (afterwards Lord) Balfour a113 Sir R. Morant.

Principal *Provisions* of *the* 1902 Act.—Part I. Local Education Authority. The council of every county and of every county borough is the local education authority for higher and elementary education; for the purpose of elementary education autonomous powers are conferred upon boroughs with a population of over 10,000, and urban districts with a population of over 20,000.

Part II. Higher Education. "The L.E A. (local education authority) shall consider the educational needs of their area and take such steps as seem to them desirable, after consultation with the Board of Education, to supply or aid the supply of education other than elementary, and to promote the general co-ordination of all forms of education." The usual conscience clause in schools, colleges or hostels provided by the council is modified by a provision for facilities for any particular religious instruction to be given at the request of parents of scholars.

Part III. Elementary Education. (1) Powers and duties. The L.E.A. are responsible for and have the control of all secular instruction in public elementary schools not provided by them.

(2) Management of schools. (a) For public elementary schools, such number as they may determine. For schools not provided by the L.E.A. (voluntary schools) the act directs that there shall be a body of six managers, of whom four are to be "foundation managers" and two are to be appointed in counties, one by the L.E.A., and one by the minor local authority, and in autonomous boroughs or urban districts both by the borough or urban district council.

(3) Maintenance of schools. (a) Powers. The L.E.A. are required ta maintain and keep efficient all necessary public elementary schools. The managers must carry out the directions of the L.E A. as to the secular instruction to be given in the school, including any directions with respect to the number and educational qualifications of the teachers, and for the dismissal of any teacher on educational grounds. The consent of the L.E.A. is required to the appointment of teachers, but that consent may not be withheld except on educational grounds; and the consent of the authority is also required to the dismissal of a teacher unless the dismissal is on grounds connected with the giving of religious instruction. (b) Liabilities. The managers are required to provide the school premises to the L.E A. for use as a public elementary school free of charge, and, out of funds provided by them, to keep the school premises in good repair and to make such alterations and improvements in the buildings as might reasonably be required by the L.E.A. The L.E.A. are required to make good such damage as they consider to be due to fair wear and tear of rooms used by them. Assistant teachers and pupil teachers may be appointed in voluntary schools "if it is thought fit" without reference to religious creed and denomination; where there are several candidates for the post of pupil teacher, the appointment is to be made by the L.E.A.

Provision of new schools.—New schools may be provided either by the L E.A. or any other persons, subject to the issue of three months' public notice, and to a right of appeal on the part of the managers of any existing school, the L.E.A. (in the case of proposed voluntary schools) or any ten ratepayers of the district, to the Board of Education on the ground that the proposed school is not required. Any enlargement of a public elementary school which in the opinion of the Board of Education is such as to amount to the provision of a new school, and any transfer of a school to or from the L E.A. must be treated as the provision of a new school. In deciding appeals, the board are to have regard to the interest of secular instruction, the wishes of parents as to the education of children, and the economy of the rates, but existing schools are not to be considered unnecessary if the average attendance is not less than 30.

Aid Grant.—Section 10 provides a new aid grant payable to the L.E.A. in respect of the number of scholars in average attendance in schools maintained by them.

Education Committees.—A11 councils having powers under the act, except those having concurrent powers as to higher education only, must establish education committees in accordance with schemes approved by the Board of Education. All matters relating to the exercise by a council of their powers under the act, except the power of raising a rate or borrowing money, stand referred to the education committee. Every scheme must provide (a) for the appointment of a majority of the committee by the council, the persons so appointed to be already members of the council unless the council otherwise determine; (b) for the appointment by the council of persons of experience in education, and of persons acquainted with the needs of the various kinds of schools in the area of the council; (c) for the inclusion of women.

Expenses.—All parliamentary grants were made payable to the L.E.A. instead of, as previously, to the managers. The county council must charge a proportion of all capital expenditure and liabilities, including rent, on account of the provision or improvement of any public elementary school, on the parish or parishes which are served by the school, such proportion to be not less than one-half or more than three-fourths as the council think fit. The county council may also charge on the parishes benefited any expenses incurred with respect to education other than elementary.

Endowments.—The act introduced a new principle into the administration of endowments by directing that their income, so far as necessarily applicable for those purposes of a public elementary school for which the local authority are liable, must be paid to that authority for the relief of the parochial rate.

A number of Nonconformist ratepayers refused to pay the education rate on the ground that their consciences forbade their supporting the religious teaching in denominational schools; and their willingness to become subject to distraint and consequent inconveniences rather than pay the rates became the foundation of a widespread political campaign known as "Passive Resistance." In Wales, where in the rural districts the schools were commonly Anglican whilst the population was Nonconformist, particular difficulties arose in administering the act in consequence of the hostile attitude of the county authorities. Accordingly the Government passed the Local Education (Local Authority Default) Act, 1904, empowering the Board of Education, in the case of default by the local authority to make payments direct to the managers of the school and to deduct the amount from the sums payable to the defaulting authority.

Supplementary Bills.—When the Liberal Party came into power again in 1906, Birrell, as president of the Board of Education in Sir Henry Campbell-Bannerman's administration, introduced a bill to amend the Education Acts, 1902–03, with the object of securing full public control of all rate-aided schools and the appointment of teachers without reference to religious belief. The bill encountered strong opposition from Anglicans and Catholics; it passed the House of Commons by a large majority, but after

unavailing attempts at compromise upon the amendments introduced in the House of Lords, the two houses failed to agree and the measure was lost.

Early in the session of 1908, McKenna introduced a bill containing a scheme for a new system of allocating the parliamentary grant, and proposing to make Cowper-Temple teaching compulsory in all aided schools. The bill was remodelled by his successor, Runciman, but in spite of negotiations with the Church Party, no compromise was reached, and the bill was ultimately withdrawn by the Government when in committee of the House of Commons.

The Education (Provision of Meals) Act, 1906, enabled local education authorities to aid voluntary agencies in the provision of meals for children attending public elementary schools, and in certain cases with the consent of the Board of Education to defray the cost of the food themselves.

In 1907 an uncontroversial act entitled the Education (Administrative Provisions) Act, besides dealing with various matters of technical and administrative detail, laid upon local education authorities the new duty of providing for the medical inspection of all children attending public elementary schools. In connection with this act the Board of Education established a medical department to advise and assist them in supervising local education authorities in carrying out their statutory duties in this regard. The whole departure was significant of the new sense of the importance of hygiene and physical training, which has been one of the remarkable features in recent educational developments.

Other noteworthy developments were the extension in the provision for mentally and physically defective children *(see* MENTAL DEFICIENCY; BLIND, TRAINING OF THE; DEAF AND DUMB, etc.), and a more definite organization of "after care" work, including the finding of employment for pupils on leaving school. The act of 1902, by placing secular education in public elementary schools under the control of strongly organized local education authorities, enabled the Board of Education in the code of 1904 to abolish the last traces of the system of payment by results, by setting forth "a properly co-ordinated curriculum suitable to the needs of the children, with an indication of the relation which the various subjects of instruction should bear to each other, in place of the relatively haphazard list of possible branches of knowledge which were formerly presented to the choice of individual schools or authorities." In the new code also the board for the first time endeavoured to state for the guidance of teachers and parents the proper aim of the public elementary school, laying stress upon that element of the training of character which the system of payment by results had obscured. The new spirit was strikingly manifested in the volume of *Suggestions for the Consideration of Teachers,* issued by the Board of Education in 1905. Apprehension of the true aims of elementary education led to a corresponding development of instruction of a practical character, observation lessons and nature study being treated as a necessary element in the curriculum, while handicraft and gardening, and domestic subjects (for girls), were encouraged by special grants. Increased attention was bestowed both by the central and local authorities upon the problem of rural instruction, though much still remains to be done in this matter *(see* RURAL EDUCATION).

According to the official returns for 1907–08, the total number of scholars on the registers was as follows: council schools, 2,991,741; voluntary schools, 2,566,030; total, 5,557,771; and the total attendance upon which grant was paid was 4,928,659. The percentage of actual average attendance to average number on the registers was 88·50%. The parliamentary grant (England and Wales) for elementary schools, other than higher elementary, amounted to £11,023,433.

A large number of the old higher grade board-schools (declared illegal under the Elementary Education Acts by the judgment in the case of *Rex* v. *Cockerton* in 1901, and legalized temporarily by an act passed for the purpose in the same year) were converted into municipal secondary schools under the act of 1902. In the succeeding years provision was made in the code for higher elementary schools of a specialized and technical type intended only for industrial districts. In 1906, as the result of the recommendations of the consultative committee, a new type of higher elementary school was admitted for children over 12, corresponding generally to the French *école primaire supérieure,* and having "for its object the development of the education given in the ordinary public elementary school, and the provision of special instruction bearing on the future occupations of the scholars, whether boys or girls." (For subsequent history, *see* CENTRAL SCHOOLS.)

The total expenditure (exclusive of capital outlay) of the local authorities (1906-07) in England only, upon elementary education, including "industrial" and "special" schools, was £19,776,733, of which (a) £10,408,242 was met by the ordinary parliamentary grant, and (b) £8,930,468 was the balance required to be met by rates, the difference being represented by receipts from various sources. The average cost per child of elementary schools in England and Wales (including London) was £3 4s.10d., and the average central grant (excluding grants for special purposes) at 41s., leaving 19s. to be raised locally.

Training of *Teachers.—The* training of teachers for the two great branches of public education, elementary and secondary respectively, is an important part of the general administrative problem. Sir Joshua Fitch pointed out that the full appreciation of the importance of training began at the lower end of the social scale. Shuttleworth and Tufnell in 1846 urged the necessity of special training for the primary teacher, and hoped to establish State training colleges to supply this want; but the one college at Battersea which was founded as an experiment was soon transferred to the National Society (the "National Society for educating the poor in the principles of the Established Church": founded in 1811). Before this, Bell and Lancaster had made arrangements in their model schools for the reception of a few young people to learn the system by practice. The religious bodies in England, notably the Established Church, proceeded to avail themselves of the failure of the central Government, and a number of diocesan colleges for men, and separate colleges for women, were gradually established. In 1854 the British and Foreign School Society (founded 1808) placed their institutes at the Borough road and Stockwell, London, on a collegiate footing, and subsequently founded other colleges at Swansea, Bangor, Darlington and Saffron Walden; the Roman Catholic Church provided two for women and one for men; and the Wesleyans two, one for each sex. The new provincial colleges of university rank were invited by the Educational Department to attach normal classes to their ordinary course and to make provision for special training and suitable practice in schools for those students who desired to become teachers. Thus the residential colleges of the old type and the day colleges attached to institutions of university rank, were both subsidized by grants from the Treasury, and regularly inspected. As the need of special training for teachers became further recognized by the consideration of the same question as regards teachers in higher and intermediate schools (Cambridge instituting in 1879 examinations for a teacher's diploma, and other universities providing courses for secondary as well as primary teachers, and establishing professorships of education), the attitude of the Board of Education towards the problem gradually became more and more a subject of controversy and of public interest, as indicated by the clause in the act of 1899 providing for a public registration of qualified teachers and for the gradual elimination from the profession of those who were unqualified. And meanwhile the increased solidarity of the National Union of Teachers (founded in 1870), the trade union of the teachers, brought an important body of professional opinion to bear on the discussion of their own interests.

The question of preliminary education of elementary teachers reached a critical stage in 1909. The history of pupil-teachership as a method of concurrent instruction and employment shows that it was, in its inception, something in the nature of a makeshift, the ideal placed before local education authorities in the regulations of the Board was the alternative system whereby with the aid of national bursaries (instituted in 1907) "the general education of future teachers may be continued in secondary schools

until the age of 17 or 18, and all attempts to obtain a practical experience of elementary school work may be deferred until the training college is entered, or at least until an examination making a natural break in that general education and qualifying for an admission to a training college has been passed." Under the revised pupil-teacher system established by the regulations of 1903, provision was made for the instruction of pupil-teachers in centres which as far as possible are attached to secondary schools receiving grants from the Board of Education under the regulations for secondary schools. Accordingly, the result has been to modify the old system in two ways; first by providing the alternative of a full course of secondary education, secondly by associating pupil-teachership itself as far as possible with part-time attendance at a secondary school. The success of the scheme has been great and, in fact, no better plan could have been devised for breaking down the party-wall between elementary and secondary education. More recently the abolition of the pupil-teacher system has been strongly advocated (see TEACHERS, TRAINING OF).

One of the principal difficulties which confronted the State and the local authorities in their task of organizing an improved system of public education under the act of 1902 lay in the deficiency of training colleges in view of the increased number of teachers. Moreover there was a widespread feeling that the provision of training colleges should be undertaken by the State as a matter of national concern. Accordingly a new system of building grants in aid of the establishment of training colleges was instituted in 1905. In 1906 these grants were raised from 25 to 75% of the capital expenditure, but were limited to colleges provided by local authorities. A further difficulty in view of the municipalization of education arose from the fact that the majority of the residential colleges were in the hands of denominational trusts which did not admit a conscience clause. Under the presidency of McKenna (1907), the Board of Education, in regulations which excited much controversy, "with a view to throwing open as far as possible the advantages of a course of training in colleges supported mainly by public funds to all students who are qualified to profit by it, irrespective of religious creed or social status," laid down that the application of a candidate might in no circumstances be rejected on any religious ground, nor on the ground of social antecedents or the like. The same regulations provided that no new training colleges would be recognized except on terms of compliance with certain conditions as to freedom from denominational restrictions or requirements. The obligation as to religious exemptions has since been limited to 50% of the admissions.

Training facilities for secondary teachers existed at Cambridge as far back as 1890, and the other universities have since followed suit. None the less progress has been far slower than in the elementary sphere, especially as regards the men. Many headmasters, especially in the public schools, still believe that the best way is for the young master to play himself in. With the headmistresses, on the other hand, training is more and more regarded as a sine *quā* non. It is only fair to add, however, that even with the men the pace has accelerated.

The fear that a considerable part of the national expenditure upon elementary education was wasted, for want of an effective system of continuative instruction to be given out of working hours to adolescents engaged in industrial employment, led to an enquiry by the consultative committee of the Board of Education. whose report (1909) recommended a reduction in the size of classes in elementary schools by the new staffing regulations of that year; an increase in hand-work with a view to rendering the curriculum less bookish and more efficient as a training for industrial and agricultural life; and legislation to reform the system of half-time attendance and raise the age of compulsory attendance to 13 and ultimately 14. They further recommended a superstructure of continuative schools or classes, attendance at which up to 17 would be compulsory under by-laws adoptive locally at the option of the local education authorities. In 1906–07 about 21 per thousand of the population of England and Wales attended evening schools and classes inspected by the Board of Education, and grants amounting to £361,596 were paid in respect of 440,718 regular attendants. (See CONTINUATION SCHOOLS.)

The general progress in elementary education, great as it was in the years following the act of 1902, had been outstripped by that made in secondary education. During that period there had been built up a liberal system of local scholarships and free places, amounting since 1907 to 25% or more of the pupils actually in the schools, providing a ladder from the elementary school to the secondary and thence to the university, including, as we have seen, the majority of future elementary teachers. In addition scales of salaries had been introduced by many local authorities, the curriculum rendered far more flexible by the abolition of regulations, the school life lengthened, and an imposing, though still incomplete, network of schools developed throughout the country. By 1910 there were on the Board of Education's grant list, 841 secondary schools with 141,149 pupils, while in addition 87 schools were recognized as efficient, but received no grant. (For the full history of university education up to 1910, see UNIVERSITIES.)

1910–14.—The period of 1910–14 was one of steady progress in education even if somewhat uneventful from the parliamentary point of view. One noticeable matter in that sphere was the Elementary Education Act of 1914 which renewed the act of 1899 (Defective and Epileptic Children) in a more drastic form. Another landmark was the Board's circular on physical exercises in secondary schools, in which Swedish exercises were definitely laid down as the official form of physical training (*q.v.*), similar recognition having already taken place in elementary schools and training colleges. But, in view of subsequent history, the most important event was in the realm of university education when in 1913 the report of the royal commission on London university (*q.v.*), presided over by Lord Haldane, was issued, the commission having been appointed in 1907. One part of the report seriously threatened the existence of the external degree, a danger since averted, but a still more important part of it dealt with the revision of the organization and government of the university, which formed the groundwork of a subsequent commission and parliamentary action.

The World War.—During the period of the World War all grades of work suffered. The elementary schools lost many of their teachers, who were called on for military service. The men's training colleges were seriously depleted, and several were closed or amalgamated, while in the later stages of the war, the boys' secondary schools lost practically all their pupils at the age of 18. A large amount of the teaching was done by women who occupied positions usually held by men teachers. Nevertheless, there is progress to chronicle. In 1917 the Board, which in 1914 had abolished all examinations for lower and middle forms in secondary schools (*q.v.*), established the Secondary Schools Council for coordinating the standards of the remaining examinations in these schools, multiplicity of examinations, with considerable variety in standard, having been in the past a serious flaw in English education. (See EXAMINATIONS.)

Education Acts *1918* and 1921.—The men who returned from the front on the conclusion of the war had realized the need of education as a sine *qua* non to promotion from the ranks. At the same time there had been forming at home a strong body of opinion in favour of insuring, as far as possible, against the inevitable aftermath of post-war unemployment. This opinion may be said to have focused round the report of the departmental committee on juvenile education in relation to unemployment, which, appointed in 1916, reported in 1917, many of its suggestions being embodied in the bill of 1918.

The Education Act of 1918, which was carried through by H. A. L. Fisher, and which was re-enacted, with most of the earlier acts, in consolidated form by the Education Act of 1921, made a determined attempt to improve the state of things in England and Wales. It aimed at the establishment of "a national system of public education available for all persons capable of profiting thereby," and the local authorities were called on to prepare schemes setting out the provision which they had made and proposed to make to this end. The act effected important changes in respect of elementary education (see ELEMENTARY EDUCATION) including the power to establish Nursery schools (*q.v.*) for children between two and five years of age It raised

the compulsory school age from 12 to 14 with power to the local authority to extend that age to 15. It abolished part-time attendance, made provision for central schools for the older and more intelligent children in the elementary schools, and laid emphasis on physical training, enlarged facilities for recreation of all kinds, and the social side of education. The local authorities were to co-operate in providing for the preparation of children for further education in schools other than elementary, and for their transference at suitable ages to such schools. The act also dealt with the supply and training of teachers, and extended the duties and powers of the local authorities with reference to medical inspection and mental deficiency and treatment, to secondary and continuation schools. It removed the limit imposed on rating powers for education other than elementary.

But perhaps the most novel feature of the statute was that which instituted a compulsory system of part-time education after the close of the elementary school period. "Young persons," between the ages of **14** and 18, were required to attend a continuation school for **320** hours in the year, unless able to claim exemption under the act. *(See* CONTINUATION SCHOOLS.) Other movements that have grown out of this legislation, or have received an added momentum from its presence on the statute book, are the Workers' Education Association and the movement for adult education (*q.v.*).

In **1920**, for the first time in the history of English education, a national scheme of salaries for elementary and secondary teachers *(see* SECONDARY EDUCATION) was established under the chairmanship of Lord Burnham, known henceforth as the Burnham scale. Slight modifications were subsequently made in both pension and salary schemes, but the general result of these reforms was to place the position of the teacher on a distinctly satisfactory footing, one direct outcome being the rapid growth of members on the teachers' register that followed, largely due to the efforts of the National Union of Teachers. In 1920, also, the Board started State scholarships to enable the talented children of parents with limited means to proceed to the university. Dropped during 1922–23, they were revived in 1924, and the maximum number offered in 1927 was **200**. Moreover, during the same period (1918–22), the Board published four reports of committees on modern languages, science, classics and English. In **1922** the Board issued a valuable circular on the possibility of co-ordinating the recommendations made in these reports with the claims of other subjects.

Universities After 1918.—If the universities were depleted during the war, they were speedily overcrowded after the declaration of peace. Most of the men who had interrupted their studies to go to the front returned, and a vast number of ex-officers availed themselves of Government grants which were estimated in 1920 for the five years they were to be in force, to amount to £8,500,000, though the total sum was not entirely expended. No less than 23,000 ex-officers availed themselves of this unique opportunity. Those of them who did not go to the universities went to commercial, art and technical schools, or studied for the various professions. The technical institutes of all sorts, therefore, shared to some extent in the general prosperity. The universities also received substantial grants (£500,000 in 1919–20) to set them on their feet. All these grants were made through a standing committee known as the University Grants committee, and not through the Board of Education direct. The creation of this intermediary body has, like the creation of a buffer state, preserved the complete autonomy of the university which has always been such a marked feature in English education. In this connection it is worth noting that Oxford and Cambridge only accepted State aid in 1919, and at first with no conditions attached. All the universities, quite apart from financial help, gained by the work of this committee which, in practice, was largely a co-ordinating and levelling-up committee.

Developments Since 1922.—After 1922 education went through a period of slowing down and consolidation, while at the same time, a large amount of official investigation and research took place. The financial uneasiness may be said to have started with the seventh report of the Select Committee on national expenditure in **1920**, which specially dealt with national education. But the actual financial stress did not make itself felt till **1922** when, with almost dramatic suddenness, unemployment, hitherto at an insignificant figure, bounded up in less than six months to an abnormal height. Among educational developments the scheme for universal day "continuation schools" (*q.v.*) was the first to suffer. Unfortunately, conceived as the prolongation of a general education, they became speedily unpopular with the pupils, parents and the general public. Practically the only schools that survived were the London ones. A certain number of these were saved by being placed on a voluntary basis with a vocational bias, and as such became increasingly popular.

In spite of the financial crisis, elementary schools, secondary schools, universities and technical institutes of all kinds held their ground, and even progressed, though in elementary education, owing to the falling off in the juvenile population from war causes, the number of pupils showed a considerable decrease. In secondary schools the numbers did not decline and there was a substantial increase in the number of pupils over **16** and in those doing advanced work. The Burnham scale was extended to technical institutes. In the universities the organizations for finding employment for graduates continued to extend, many new chairs were created, and the volume of research increased. The university grants were increased also and one of the outstanding features of post-war years was the commissions on Oxford, Cambridge and London universities, appointed by parliament.

Publications by the Board of Education.—Since **1922** the Board has published some exceedingly valuable reports, memoranda and suggestions. Thus in **1922** suggestions were issued on the teaching of gardening and handcraft. In 1923 the consultation committee of the Board published a long report on the differences in curricula between the sexes in secondary schools, recommending *inter alia* greater freedom of curricula and more flexibility in the matriculation, more free periods for pupils in school, a more generous time allowance for music and art, both the latter to be recognized as suitable subjects for the first school examination, with further investigations into the subject of mental and physical fatigue. Two pamphlets which, though published by the Industrial Fatigue Board, have a considerable bearing on education are worth mention—one on performance tests of intelligence (1925) and the other a study in vocational guidance **(1926)**.

The Board also issued reports, circulars or suggestions on the teaching of English and drawing in secondary schools (1924), the teaching of arithmetic in elementary schools and the teaching of science in secondary schools (1925), the position of French in grant-aided secondary schools (1926), short courses for teachers (giving a list of courses available) and a revised edition of the *Handbook of Suggestions* (1927); a *Survey of Technical and Further Education* (1926); *Recent Developments of Secondary Schools*, a history of the subject since 1902 and even earlier; *First Report of the Committee on Education and Industry* (1926), a committee partly appointed by the Ministry of Labour; *Report of an Inquiry into the relationship of Technical Education to other forms of Education and to Industry and Commerce* (1927); *Report of the Departmental Committee on the Training of Teachers* mainly remarkable for the wide divergence of opinion it contained, and the *Report of the Departmental Committee on the Preparation of the Rural Teacher* (appointed 1927). Perhaps the most important report was that on the education of the adolescent —dealing with further education of pupils over 11 *(see* ELEMENTARY EDUCATION).

Since the beginning of the present century there has been great development in elementary education, and consolidation of the whole system. Teachers' salaries have been placed on a satisfactory basis and pensions put on a proper footing; the whole curriculum has been modernized and rendered more elastic, though education in the years after 11 still needs modification in the direction of a more distinct preparation for livelihood. One of the most striking features of the new learning is the way in which the reading habit is being developed, not merely inside and outside the elementary school, but for all grades of education, including secondary and evening students, whether in adult educa-

tion classes, or honours and research students in the universities. (See LIBRARIES.) The whole bias of education is slowly shifting to making the pupil an active co-operator in his own development. (See above *Educational* Experiments.)

A vast deal of quiet experiment is going on; physical exercises, and especially games, have undergone a wide extension; the perfect system has been developed with the happiest results in boys', and to a certain extent in girls', schools; after-care committees, medical inspection, meals for necessitous children, special treatment for mental and physical defectives have become an integral part of national education in the broader sense. Classes have been cut down (in a few years the number of classes with over 60 pupils fell from nearly 7,000 to under 280). Buildings have been modernized to a great extent. The religious question, so rampant at the beginning of the century, is quiescent, thanks to the broad-minded and impartial administration of the local authorities, but the Church people still feel the "intolerable strain" of maintaining their school buildings, and from time to time feelers are thrown out to try to discover some way of handing over the schools while safeguarding the religious teaching. Moreover, the crisis in the Anglican Church (1927–28) only tended to accentuate the difficulty of the whole question. The Central schools (*q.v.*) have more than made good, and their pupils can now stay on till the age of 16. In 1926–27 there were 9,170 Council schools, 11,553 voluntary, and over 15,000 departments in each category, with an average attendance of 3,231,494 in the former and 1,742,162 in the latter, the percentage of attendance being 88·3. The teachers numbered 169,702, including nearly 120,000 certificated teachers, three-quarters of whom were college trained. The uncertificated numbered 33,852, and the supplementary teachers, 8.734. Training colleges have been multiplied. The study of educational science has increased by leaps and bounds. The connection with the university has been greatly extended; many two-year students frequently spend a third year abroad, or at some English institution.

In the sphere of secondary education where there was most leeway to make up, the progress has been immense. In place of a totally inadequate and often poorly staffed number of schools before 1902, the country is practically covered with a network of secondary schools, in many of which advanced courses have been established, and in the majority of which the pupils leave at 16 or even later. The claims of art and music have been increasingly recognized, considerably less, however, in boys' than in girls' schools. The examination figures are eloquent: though more elasticity in the choice of subjects is necessary (see EXAMINATIONS). In 1917–18, 14,232 took the first examination and 550 the second; in 1926–27, 43,752 took the first, 6,691 the second, over 68% passing in each case (see SECONDARY EDUCATION). Games and self-government are everywhere to-day flourishing, in boys' and girls' schools alike. The number going to the universities has increased beyond all comparison—over 3,300 went in 1926. One effect of these increasing numbers is to raise the standard of study in the universities.

Salaries have increased and teachers' qualifications have steadily risen. In 1908 there were only 4,841 men teachers and 4,484 women, of whom 62% of the men and 41·7% of the women were graduates; in 1926–27 the men teachers (full time) had risen to 9,572, the women (full time) to 9,682, and about 80% of the men and 61% of the women were graduates. In the same period there were 1,319 schools on the grant list, with 371,493 pupils (196,289 boys and 175,204 girls), and 59,141 pupils (29,839 boys and 29,302 girls) in other schools merely recognized as efficient. Within a quarter of a century, a comprehensive system has been built up which can challenge comparison with those of older countries, and which recognizes that the most valuable training the school can give is the development of a healthy and public-spirited citizen.

The 20th century has seen a vast extension in the growth of the provincial universities (previously component parts of a joint university). The movement began with Liverpool and Manchester in 1903 and was followed by Birmingham, Leeds, Sheffield and Bristol, while Durham expanded and took in Newcastle, and finally Reading was founded. Meanwhile, London is being again reorganized, having immensely grown in the interval, and Oxford and Cambridge have also greatly expanded, not only in numbers but also in the ever increasing branches of knowledge they teach and in their outside activities (see UNIVERSITY EXTENSION, etc.), their ties and connections with national life being far more close and numerous than in the preceding century. The number of students in the universities in 1927 was 41.606.

Technical educntion (*see* above), whether within or without the university, has also extended its ramifications on specific subjects, while concentrating with advantage the work of many of its institutes. Its lower grades have shown a considerable increase, whether in junior technical schools, art schools or evening classes of all kinds. The total number of students, whether in day or evening institutes or classes in 1926–27 was 843,637. There is probably, however, in spite of these figures, still abundant room for expansion in all grades of this work, which is peculiarly in keeping with the English temper and genius.

A few figures on educational expenditure since 1913–14 may help to provide a rough index of the volume of growth and development, though on the other side a considerable allowance must be made for the increased cost of living. In 1913–14 higher education (secondary and technical) received from the local and central authorities nearly four and a half millions, and elementary education over 25½ millions, or a total of about 30 millions, of which the State found 45.6%; other items must be included in the general expenditure on education, but none the less the comparison with 1925–26 is striking. In that year higher education received 14 millions, elementary nearly 58½ millions, a total of nearly 72½ millions, the percentage of the State contribution having risen to 53·8. This, with other items, brought the total expenditure to £76,549,460.

English education has always been noted for its variety and elasticity. The 20th century has seen the development of a substantially complete system of national education in all grades, in which the new has been skilfully interwoven with the old, without injuring its two predominant qualities. It has been an immense and unparalleled achievement, in which the work of a few men stands out, chief among whom are Lord Balfour who, by the act of 1902, laid the foundations of the present composite structure with the ultimate aim of forming one single edifice; Sir Robert Morant, his chief henchman and architect, and Sir Michael Sadler who, more than anyone living, has heartened and inspired the enormous army of lay and professional workers in the laborious task of consolidating and enlarging the new temple of knowledge. Other notable master builders have been H. A. L. Fisher and Lord Burnham, each responsible for certain valuable additions to the fabric. The building has, indeed, been, like the building of a great mediaeval cathedral, the work of the anonymous co-operation of thousands of men of goodwill. (C. BR.)

WALES

Wales continued to be treated as one with England for purposes of educational administration until, towards the end of the 19th century, the striking revival of Welsh nationality led to a demand among the Welsh people for a national system of higher education. The Welsh Intermediate Education Act (1889) provided for the creation of education committees in every county in Wales (including Monmouthshire). To these committees were entrusted the establishment of intermediate and technical schools and the application of endowments, and the administration of a ½d. county rate, which was supplemented by a Treasury grant, not exceeding the amount raised by the rate. The duties of inspection and examination were entrusted to a Central Education board. The Education committees were superseded (except for the purpose of framing schemes for endowments) by the local education authorities under the act of 1902. The public assistance afforded to secondary education in Wales under the Intermediate Act is supplemented by the grants of the Board of Education, and the board's revised secondary school regulations were applied to Wales in 1908. In 1907 a Welsh department of the Board of Education was established.

There has thus grown up a dual organization of secondary education in Wales: the intermediate (endowed) schools under the central board, and the municipal secondary schools and others under the local education authorities. The intermediate schools, however, accepted the Board of Education grant and inspection under the act of 1902. In 1920 a departmental committee recommended that the Welsh Intermediate Education Act be repealed, and that all types of schools in a district be placed under the same authority. It recommended the formation of a National Council of Education for Wales, with majority representation of the local authorities and further representatives of the university, the teachers, and other educational bodies. Its functions should be mainly advisory, but it should maintain training colleges (for which the county unit is too small) and conduct examinations. Further recommendations were the creation of teachers' councils, an increase in the number of secondary schools so that admission might be on a qualifying rather than a competitive basis, allowances according to the parents' means, and more university scholarships.

These recommendations have not been put into effect, but a system of close co-operation between the inspectorates of the central board and the Board of Education has been adopted. The National Council of Education has not been formed; the Central Board continues its work and enjoys an increased Government grant.

In 1921 Swansea Technical college became a university college of the National university, created in 1893. (See also UNIVERSITIES.)

SCOTLAND

Historical Development. — In Scotland the practical unanimity of the people in religious faith, the wider diffusion of the sense of the value of education, the greater simplicity of life which has rendered all classes largely content to avail themselves of the preparatory education of the common school and favoured the development in the secondary sphere of day rather than boarding schools, have contributed to the early building up of a national system which in some respects resembles the Continental rather than the English type.

Before the Reformation a statute of James IV. (1494) required all freeholders of substance to send their heirs to school and to keep them there until they had perfect Latin. The Reformation put fresh life into the educational aspirations of the people. As early as 1560 the Church Assembly, largely under the influence of John Knox, issued the Book of *Discipline*, providing that "every several kirk" in a town "of any reputation" was to have its Latin school, that the "upaland" or country parts were to have a teacher of the "first rudiments" in every parish, and that each "notable" town was to have "a college for logic, rhetoric and the tongues." Practical effect was later given to this scheme by an act of the Scottish parliament in 1696, under which parish schools were set up in connection with the Established Church of Scotland. This system was extended by an act of 1803, which made better provision for teachers' salaries and also confirmed the position of the parish school as an adjunct of the parish church. The system of inspection and State aid, introduced in England in 1839, was made applicable to Scotland. In 1861 a new act was passed which relaxed, though it did not sever, the ties which bound the parish school to the church.

The Education (Scotland) Act of 1872 set up elective school boards and vested in them the existing parish and burgh schools. A conscience clause, allowing exemption from religious instruction, did little more than confirm existing usage. The school boards were left full liberty as to the religious instruction to be given in their schools, and in practice school boards universally adopted the Shorter Catechism, which was acceptable to all denominations of Presbyterians. The act made the school boards responsible for the supply of school accommodation, and introduced compulsory attendance. By the act of 1901 the age of compulsory attendance was raised to 14, with provision for exemption after 12.

A notable feature, historically, in Scottish education is the extent to which the parish schools supplied their best pupils with higher education. Administrative changes under the code of 1903 and later codes led to a remarkable development of higher-grade schools and departments, organized upon the lines of the higher primary schools of France "to continue a stage further," says the report of the Scottish Education Department, "the general education of that considerable body of pupils who, under new conditions, may be expected to remain at school till 15 or 16."

There has been a gradual abandonment of individual examination as the basis for the payment of grants. Elementary education was generally rendered free by the fee grants under the parliamentary vote, and by the sums accruing under the Local Taxation (Customs and Excise) Act of 1890 and the Education and Local Taxation (Scotland) Act of 1892.

The Act of 1908. — Certain additional powers were conferred upon school boards by the Education (Scotland) Act of 1908, including powers to provide school meals; in outlying parts to provide means of conveyance, or pay travelling expenses of pupils or teachers, or defray the cost of lodging pupils in convenient proximity to a school; to provide for medical inspection; and in the case of children neglected by reason of ill-health or poverty of the parent, to supply food, clothing and personal attention. Perhaps the most noteworthy provision of the act of 1908 is that which enabled (not obliged) school boards to make by-laws requiring attendance at continuation classes up to the age of 17. It laid upon the school boards the duty of making suitable provision of continuation classes in the crafts and industries practised in the district.

The Scottish Education Act of 1872 distinguished certain burgh and parish schools as "higher class public" or secondary schools. The act of 1908 dealt in some detail with secondary education. Secondary schools were distinguished from intermediate, the former being defined as providing at least a five-years' course, the latter as providing at least a three-years' course for pupils who had reached a certain standard of attainment in elementary subjects. Intermediate schools have now been abandoned and a three-years' advanced course from the ages of 12 to 15 is provided at primary schools, leading to the higher day school certificate. A two-years' advanced course leads to the lower day school certificate. The teaching in these advanced courses is partly practical, but includes also morals and citizenship, music, drawing, English, science, mathematics, and physical exercises. It is the aim of the authorities to staff the advanced divisions with teachers as highly qualified as those in secondary schools. A qualifying test at the age of 11 or 12 decides whether a child is to enter an advanced course or proceed to the secondary school. But there are facilities for changing over at a later stage.

The Act of 1918. — By the Education (Scotland) Act of 1918 the machinery of the system of education was reorganized, with a large increase of expenditure, both national and local, partly due to the transfer of voluntary schools to the public authorities. A scale of minimum salaries for teachers was drawn up in 1919. In 1920 the Education Department urged rigid economy, and there followed a reduction in salaries and staffs and an increase in the size of classes. In 1924 the restrictions were relaxed and there was a noticeable increase in educational activity, but in 1925 the urge for economy was again dominant.

The 1918 act swept away the system of parochial school boards. Five large burghs, Edinburgh, Glasgow, Aberdeen, Dundee and Leith, remained separate educational areas (the number was reduced to four by the amalgamation of Leith with Edinburgh in 1920); elsewhere the area is the county, including the burghs within its bounds. Electors to the education authorities are registered local government electors, and voting is conducted on the principle of proportional representation. School management committees, composed of representatives of the education authorities, parents, teachers, and others nominated by local bodies, have limited powers under the education authorities.

Education authorities are required to provide free primary, intermediary and secondary education in all districts, but they may maintain a limited number of fee-paying schools and make grants to others. No pupil, however, must be debarred from con-

tinued education by inability to pay fees, and each education authority has a bursary scheme. They are also empowered to spend money on the provision of food and books for the children, and to give assistance to qualified persons attending the university or training college.

Nearly all the voluntary or denominational schools have been transferred to the education authorities in accordance with the act; the teachers in such schools are appointed by the education authority after being approved, as regards character and religious belief, by the denomination concerned. No child whose parents object to his receiving religious instruction is thereby to lose any other advantage of the school. Voluntary schools which are not transferred to the education authority cease to be eligible for grant from the education fund. A national committee for the training of teachers, established in 1920 and elected by the education authorities, now controls the former denominational training colleges.

The act contemplated an extension of the school age to 15 and the provision of continuation schools giving vocational instruction, besides general education and physical culture. But these provisions have only been partially carried out, and school attendance is compulsory from five to 14, with powers to exempt or allow part-time attendance in special circumstances at 12. The Treasury grant to the universities was largely increased, and since the end of the World War private benefactions have greatly improved the teaching equipment of all four universities, and especially Glasgow and Edinburgh.

The departmental committee on Endowments for Scottish Education, presided over by Lord Mackenzie, reported in Oct. 1927 on endowments whose original purpose had become obsolete. It advised the appointment of an executive commission of seven members to reconsider their use, and suggested the following objects: universities, residential halls for students, central institutions (*i.e.*, advanced technical colleges), hostels for school children, adult education, playing fields, social organization, and nursing.

IRELAND

Historical Development. — In Ireland education has suffered in the past from the general absence of local interest almost as seriously as from the mistakes of the English Government. State intervention is actually of earlier date in Ireland than in Englacd From the reign of Elizabeth onwards English Protestant schools were founded by the Government in an intermittent fashion in pursuance of its anglicizing policy. The Kildare Place Society (founded in 1811) comprised both Roman Catholic and Protestant schools upon a common religious basis of Bible reading without note or comment, and received Government grants until 1833. The religious compromise broke down in consequence of Catholic dissatisfaction. In 1833, as the result of a commission of enquiry (1824) and a select committee of the House of Commons (1828), Stanley inaugurated the national system of grant-aided elementary schools under a board of commissioners nominated from the different denominations. In these schools teachers were paid by the State, but were appointed by the school managers, subject to the commissioners' approval. The Government appears to have aimed at combined secular and separate religious instruction for Roman Catholics and Protestants; at the same time an attempt was made to provide an ethical basis for secular instruction by means of Bible extracts. This solution through common schools with separate religious teaching was advocated by the great Irish educationalist, Sir Thomas Wyse, himself a Roman Catholic. In 1830 he had urged on the Government a kind of local option in education: each parish was to decide for itself whether to establish a school; if it did so, it was to receive Government support. Catholics and Protestants were to be educated together, but each to receive religious instruction from their own pastors. The growing Catholic objection to the Government's policy, however, found expression in a decree of the Roman Congregation De Propaganda Fide of Jan. 11, 1846, declaring that non-sectarian religious instruction was dangerous to youth.

The religious difficulty in Irish elementary education may be said to have been solved in process of time by the conversion of the national system in practice, though not in theory, into a system strongly denominational, separate schools taking the place for the most part of the combined schools of the two creeds. In addition to national schools there were a considerable number of convent or monastery schools, which received capitation grants, but not direct salaries.

In 1845 a bill was passed "to enable Her Majesty to endow new colleges for the advancement of learning in Ireland," based on Wyse's plan of joint secondary schools for Catholics and Protestants with separate religious teaching. But here again there was Catholic opposition, and the schools were declared, in rescripts of the council of cardinals, to be "dangerous to faith and morals." The Irish Education Act of 1892 provided for compulsory attendance in towns and for the adoption of compulsion in other districts. In virtue of the financial sections of the act, which provided an increased grant for salaries, most of the national schools became free.

Agriculture is Ireland's key industry, and towards the end of the last century there was a vigorous movement, led by Sir Horace Plunkett, for improved methods, better technical education and farmers' co-operation. In the parliamentary recess of 1895–96 Sir Horace Plunkett assembled the Recess committee to report on the subject. Its report resulted in the act of 1899, which created a department of agriculture and technical instruction. This department helped to establish continuation schools, technical schools and winter agricultural schools. It also sent out itinerant agricultural instructors.

Irish Free State. — Before the Government of Ireland Act of 1920 there were two central authorities dealing with secondary education, the Intermediate Education Board and the Department of Agriculture and Technical Instruction. The Intermediate Board administered sums available under the Intermediate Education Act of 1878 from the Irish Church surplus, and also the sum allocated under the Local Taxation Act of 1890. The first step of the Free State Government was to unify control, under a Minister of Education, of primary, secondary and endowed schools.

The so-called First Conference of Educationalists met in 1920 and drafted a programme for primary education, which aimed at stirring in the children a consciousness of their national heritage. Irish was to be the medium of instruction. This programme was adopted by the Government in 1922. Difficulties arose in putting it into effect, partly because the Irish language was not familiar to all teachers and pupils. A further conference, representing school managers, teachers in national schools, the General Council of County Schools, and the Gaelic League, and including nominated members, reported in 1926. It praised the new programme as "giving the language, history, music and tradition of Ireland their natural place in the life of the Irish schools." But it recognized the difficulties and recommended that transition to the use of the Irish language should be gradual and that the best Irish teacher in a school should be allocated to the infants, and instruction in other standards given in English where it could not properly be given in Irish. It was proposed to establish six preparatory colleges for candidates for training colleges, five to be situated in districts where Gaelic is still a living language and staffed with teachers capable of teaching the secondary school programme entirely through the medium of Irish.

The old managerial system, under which the power of appointment and dismissal lay, under certain limitations, with the manager of the school (usually a clergyman) was retained. This system means that each religious denomination controls the appointment of teachers in schools attended by children of that denomination. Opportunities must be afforded to the pupils of all schools for receiving such religious instructipn as their parents approve. It is given at a time not counted when computing attendance, and does not come under the supervision of the depart. ment.

As regards secondary education, a wide problem confronted the Government. The Intermediate Education Act of 1878 prescribed

that grants were to be paid on the results of a general public examination. Under the Free State Government this was replaced by a capitation grant, dependent on the reports of inspectors who take into account every feature of the school. The Intermediate Education Act of 1924, embodying recommendations of a commission which reported in 1922, introduced both financial and educational changes. A salary scheme for secondary teachers was adopted. Technical instruction was placed under the control of the Minister of Education, but the organization under local committees was retained.

In the Free State only primary education is gratuitous, but county and county borough councils may levy a rate to provide scholarships in secondary schools. Until the passing of the School Attendance Act of 1926 education was not universally compulsory. That act required attendance for secular instruction from six to 14; and the minister has power to extend the age limit to 16. Parents have the right to object lo any school on religious grounds. Schools are inspected and certified by the minister as suitable for giving elementary instruction.

Northern Ireland. — In 1922 educational services were transferred to the Government of Northern Ireland. The Education Act of 1923 largely gave effect to the recommendations of the Lynn departmental committee of enquiry, which published an interim report in 1922 and a final report in 1923. According to the ministry's report for 1923 the predominant feature of the act is that "it abolishes a highly centralized system of control, and sets up in its place a decentralized system of local control." Later reports describe the policy of amalgamating small primary schools for the sake of greater efficiency; in some cases there were several denominational schools in a single area, rendering less efficient service than one public school could give. The ministry put an end to the system of paying grants to schools conducted for private profit, and successfully encouraged private secondary schools to place themselves under governing bodies of a representative character, and so qualify for grants. Grants to secondary schools are now made by capitation payments, depending on the inspectors' reports, and no longer on the results of examination. The pupil teacher system was so amended that candidates for admission to training colleges complete their secondary school course.

The act of 1923 defines elementary education as education below the age of 14 "both literary and moral, based upon instruction in reading and writing of the English language and in arithmetic." Fees may be charged "if there exists otherwise a sufficient supply of free places." School books may be provided free. Attendance is compulsory from the age of six to 14, and by-laws are allowed lowering the age to five. The education authority may exempt individuals partially for reasons of employment after the age of 12.

Schools may be provided by the public authority, or transferred from voluntary agencies to the education authority. Further, there are voluntary schools recognized as public elementary schools, which receive a 50% grant on maintenance and repairs. In all schools religious instruction must be so arranged as not to put children of any denomination at a disadvantage in the matter of secular education. The education authority does not itself provide or inspect religious instruction, but the clergy of all denominations have access to provided and transferred schools according to the parents' wishes. The education authority appoints the teachers, and there are no religious tests.

Higher education includes preparatory schools, intermediate schools (a three-years' course beyond the primary school), and secondary schools (a five-years' course beyond the primary school). The education authority is empowered to pay for the higher education of all children capable of profiting by it, as also for their continued education at the university or training college.

(M. M. G.)

UNITED STATES

Religious Origin **of** Schools.——Schools of America, as with the older European countries from which the early American settlers came, arose as children of the Church. From instruments of religion they have gradually been changed into instruments of the State. The first schools in America were clearly the fruits of the Protestant revolts in Europe, and were set up by dissenters who had come to America to obtain a freedom in religion which they could not enjoy in their own lands. The reformers had insisted upon the necessity of a knowledge of the Gospels as a means to personal salvation, and the ultimate outcome was the creation of schools to teach children to read. These ideas the early settlers in New England brought with them, and one of their first interests, after they had built their homes and churches and settled the civil Government, was the creation of schools and a college to advance learning in the new land and to provide a supply of literate ministers. With practically all the early religious groups that settled in the central and northern colonies the education of the young for membership in the Church, and the perpetuation of a learned ministry for the congregations, elicited serious attention. Only in the Anglican colonies of Virginia and southward was this early interest in education largely lacking.

Three Type Attitudes. — From the European background of the early colonists three type attitudes toward education were established in the American Colonies. These are of importance because they materially affected the development of education in the States during the early national period. The first was the compulsory-maintenance attitude of the Puritans of the New England colonies, who set up a combined religious and civil form of town government, and by colony legislation in 1642 and 1647 established schools and ordered children to be taught to read and to be given instruction in religion. Still earlier (1635) the beginnings of an English type of Latin grammar school had been made at Boston, and the year following (1636) an English type college (Harvard) had been established by the same people at Cambridge, Mass. The laws of 1642 and 1647 are important, in part because for the first time in the English-speaking world a legislative body representing the State made education compulsory, and also because what the Calvinistic Puritans of Massachusetts established in practice has since been generally adopted by the different American States. This distinctively Calvinistic contribution to the New-World life was one of large future importance.

The second type attitude was what has become known as the parochial-school attitude, and was best represented in Pennsylvania. Unlike New England, no sect was in the majority in Pennsylvania, and Church control by each denomination rather than general colonial action resulted. There was no appeal to the State. Instead, parochial schools were established in connection with the churches and private pay schools were opened in the larger towns. Under the primitive conditions of the time the interest even in religious instruction often declined almost to the vanishing point, and Pennsylvania and the other middle colonies finally settled down to the policy of leaving education to such private and parochial schools as cared to undertake it, a policy that was overcome later only after long and stubborn resistance.

The third type attitude was what was known as the pauper-school non-State-interference attitude, and was best exemplified by Virginia and the southern colonies. Unlike New England, these had been settled by English who had come to America for gain rather than for religious freedom, and the lack of any strong religious motive for education naturally led to the continuation of English practices rather than development on distinctively colonial lines. The tutor in the home, education in small private and select pay schools, or education in the mother country for the sons of the well-to-do planters, with apprenticeship training and a few pauper schools for the children of the poorer classes consequently came to be the prevailing system and, as in the mother country, education was not considered the business of the State, nor did the Church give any special attention to it. As a result in Virginia, and the colonies which followed her example, the English charity-school idea came to dominate such general education as was provided, with the apprenticing of orphans as a prominent feature.

The 17th century was a period of the transplanting of European ideas as to Government and religion and education to the new

American Colonies, and by the 18th century the three type attitudes toward educational responsibility had been clearly established on American soil, deeply influencing subsequent American educational development. In time the first or New England Calvinistic attitude came to be the accepted American conception, and the other two types were subordinated or eliminated. Almost all the early 19th century struggles to establish education in the States were battles between the upholders of these different type attitudes.

Change in Character. — During the 17th century little or no attempt at adaptation or change in English ideas transplanted to the colonies was made. With the coming of the 18th century there was a waning of the old religious interest, a tendency to create native institutions instead of copying those of the mother country, the rise of a civil as opposed to a religious form of government, new interests in trade and shipping, a breakdown in the old aristocratic traditions and customs, and a dawning individualism — all of which tended to weaken the hold of the old religious influences and in turn the interest in the old type of schools and learning. By 1750 the change in religious thinking had become quite marked, the New England religious town had begun to disintegrate, and a native type of district school and academy had arisen to threaten the very existence of the town grammar school. By 1750, too, it was clearly evident that European traditions and ways and manners and social customs and types of schools no longer satisfied. To the North this expressed itself in a tendency to modify all established educational institutions to make them conform more closely to American thinking; to the South in a tendency to discard schools altogether. There were many evidences, in education as in Government, that the end of the colonial period was near at hand, and the Revolutionary War came as the culmination of a process of evolution which had been taking place for some time.

Effect of the War of Independence. — With the outbreak of the war education everywhere suffered seriously. Most of the rural and parochial schools closed, or continued a more or less intermittent existence. In some of the cities and towns, the private and charity schools continued to operate, but in others they were closed entirely, for the war engrossed the energies and resources of the peoples of the different Colonies. In New York city, then the second largest city in the country, practically all schools closed with British occupancy and remained closed until after the end of the war. The Latin grammar schools and academies often closed from lack of pupils, while the colleges were almost deserted; Harvard and Kings, in particular, suffered grievously, and sacrificed much for the cause of liberty. The period from the revolution to the beginning of the national Government (1775–89) was a time of rapid decline in educational advantages and increasing illiteracy among the people. Meagre as had been the opportunities for schooling before 1775, by 1790, except in a few cities and in the New England districts, they had shrunk almost to the vanishing point.

A Half-century of Transition. — The first half-century of America's national life may be regarded as a period of transition from the Church-control idea of education to the idea of education under the control and support of the State. It required time to make this change. Up to the period of the beginnings of national development education had almost everywhere been regarded as an affair of the Church, somewhat akin to baptism, marriage, the administration of the sacraments and the burial of the dead. Even in New England, which formed an exception, the evolution of the civic school from the Church school was not yet complete. A number of nevi forces — philanthropic, political, social, economic — now combined to produce conditions which made State rather than Church control and support of education seem both desirable and feasible. The rise of a new national Government based on the two new principles of political equality and religious freedom, together with the rise of new economic conditions which made some education for all seem necessary for economic as well as for political ends, changed this age-old situation.

For long the Churches made an effort to keep up, as they were loath to relinquish their former hold on the training of the young. The Churches, however, were not interested in the problem except in the old way, and this was not what the new democracy wanted. The result was that, with the coming of nationality and the slow but gradual growth of a national consciousness, national pride, national needs, and the gradual development of national resources in the shape of taxable property, — all alike combined to make secular instead of religious schools seem both desirable and possible to a constantly increasing number of citizens. This change in attitude was facilitated by the work of a number of semi-private philanthropic agencies, the most important of which were: (1) the Sunday school movement; (2) the growth of city school societies; (3) the Lancasterian movement; and (4) the coming of the infant-school societies.

Of these the Lancasterian movement was by far the most important because it, for the first time, made general education for all seem financially possible. All at once, comparatively, a new system of teaching had been evolved which not only improved but at the same time tremendously cheapened education. The new Lancasterian schools materially hastened the coming of the free school system in all the Northern States by awakening thought, provoking discussion and accustoming the people to bearing the necessary costs which public education entail. The city school societies, privately organized associations to provide educational facilities in the cities, formed a connecting link between the Lancasterian schools and the publicly organized schools which followed.

Creation of the American State School. — By the close of the first quarter of the 19th century a great struggle for the creation of a series of tax-supported, publicly controlled and directed, and non-sectarian common schools was in progress, and the second quarter of the century may be said to have witnessed the successful conclurion of the battle. In 1825, always excepting certain portions of New England where the free school system had become thoroughly established, such schools were the distant hope of statesmen and reformers; in 1850 they were becoming an actuality in every Northern State. The 25 years intervening marked a period of public agitation and educational propaganda; of many hard legislative fights; of a struggle to secure desired legislation, and then to hold what had been secured; of many bitter contests with Church and private-school interests, which felt that their "vested rights" were being taken from them; and of occasional referendums in which the people were asked, by vote at the polls, to advise the legislature as to what to do. Excepting the battle for the abolition of slavery, perhaps no question has ever been before the American people for settlement which has caused so much feeling or aroused such bitter antagonisms.

To meet the arguments of the objectors, and to change the opinions of a thinking few into the common opinion of the many, to overcome prejudice, and to awaken the public conscience to the public need for free and common schools was the work of a generation. It was likewise the work of a generation to convince the masses that the scheme of State schools was not only practicable but also the best and the most economical means of giving their children the benefits of an education; to persuade propertied citizens that taxation for education was in the interest of both public and private welfare; to show legislators that it was safe to vote for school bills; and to overcome the general opposition due to apathy, sectarian jealousy and private interests. In time, however, the desirability of common, free, tax-supported, non-sectarian, State-controlled schools came to be evident to a majority of the citizens of the different American States, and as it did so, the American State school, free and equally open to all, was finally evolved and took its place as the most important influence in the national life working for the perpetuation of American democracy and the advancement of the public welfare.

The Struggle for Public Schools. — The problem confronting those interested in establishing State-controlled schools was not the same in any two States, though the struggle in many States possessed common elements, and hence was somewhat similar in character. There were six strategic points in the struggle, which may be described briefly, as follows:

1. *The Battle for Tax* Support. — Land endowments, lotteries, licence taxes, and rate bills were the favourite early means for

raising money for school support. The land endowments made by the early States and by the Federal Government to the hew western States were looked upon as having large potential values. The early idea was that the income from such sources would in time entirely support the necessary schools. Later this idea had to be abandoned when it was seen how little yearly income these sources produced, and how rapidly the population of the country was increasing. By 1825 it was evident to the leaders that the only safe reliance of a system of State schools lay in the general and direct taxation of all property. The cry that "the wealth of the State must educate the children of the State" now became a watchword, and by 1825 to 1830 the battle for direct taxation for education was joined in all the Northern States except the four in New England where the principle had long been established. The struggle was a prolonged and bitter one. "Campaigns of education" had to be prepared for and carried through. Often those in favour of taxation were fiercely assailed and even at times threatened with personal violence. Indiana and New York were the critical battle-grounds, and referendums were taken. In Kentucky a long fight was waged to prevent misappropriation of the school fund and to secure a two-mill (one-fifth of a cent in American currency) tax. The right of the State to tax for education and to compel the duplication of State aid by local taxation was seen to be the key to the whole problem of the creation of a State school system of public instruction. When this key position had been won, as it had been generally in the North by 1850, the process of evolving an adequate State school system became merely that of the further education of public opinion to cover the new educational needs. The development since has followed different lines in different States, and probably no two States stand at the same point in the evolution of a system of school support. Everywhere, though, the New England idea of State support has been accepted, and the New England co-operative-maintenance attitude has been established as the common practice of the different American States. New England Puritanism here makes what is probably its greatest contribution to American life.

2. *The* Battle to Eliminate the *Pauper-School* Idea.—The home of the pauper-school idea was in the old Central and Southern States; it made no headway in the North and the new democratic West would not tolerate it. Its friends were found among the old aristocratic or conservative classes, the heavy taxpayers, the supporters of Church schools, and the proprietors of private schools. Large numbers of those for whom the pauper schools were intended would not brand themselves as paupers by sending their children to them, and those who accepted the advantages offered, for the sake of their children, despised the system. Finally the battle to eliminate the pauper-school idea began in Pennsylvania in 1834 and in New Jersey in 1838, and in each State a victory was won and a State system of schools created only after a most bitter fight in the legislature and at the polls. The idea continued some time longer in Maryland, Virginia and Georgia and at places in other Southern States, but finally disappeared in the South with the establishment of State taxation and with the educational reorganizations following the American Civil War. The rate bill, a per-pupil charge levied on parents to supplement the public funds, lingered a little longer; the cities did away with it first, and by 1871 it had disappeared from every Northern State and the schools of the nation were tax-supported and entirely freed from the pauper taint.

3. The *Establishment* of *Supervision.*—The battle for taxation for education was also indirectly a battle to establish some form of State oversight for the hundreds of systems which had grown up in each of the States. The acceptance of State aid inevitably meant a small but gradually increasing State control. To exercise this control me next find the States creating a series of school officers to represent the State, the enactment of laws extending State control, and a struggle to integrate, subordinate and reduce to some semblance of a State school system the great numbers of small community school systems. The pivotal States in this struggle were Massachusetts, Connecticut, New York, Ohio and Michigan, and the pivotal point in the struggle was the attempt to control the local systems of school organization which had developed and spread with time. In most States the district system had run rampant, and an exaggerated idea as to district rights, district importance and district perfection had become common. In Massachusetts, New York and Indiana, in particular, such systems had almost destroyed the schools. The Massachusetts law of 1826, requiring each town to appoint a town school committee to control the schools; the establishment, in 1834, of the State school fund; and the creation, in 1837, of the celebrated Massachusetts State Board of Education with an appointed secretary—a position held by Horace Mann for 12 years—mark the culmination of the struggle in that State. Connecticut provided for a somewhat similar board in 1839, and Henry Barnard became the first secretary. Michigan and Ohio provided for a State superintendent of public instruction in 1837, and the other States soon followed these examples. From then on State supervision came to be regarded as an established principle, the work of the future being largely an elaboration of the work of Mann in Massachusetts and Barnard in Connecticut,—two men who may be said to have created State supervision in the United States.

4. The *Elimination* of Sectarianism.—So long as there was little intercourse and migration, and the people of a community remained fairly homogeneous, it was perfectly natural that the common religious faith of the people should enter into the instruction of the school. With the coming of foreign immigration, which began to be marked after about 1825, and the intermingling of peoples in the cities, religious uniformity ceased to exist. As necessity compelled the State to provide education for the children, sectarian differences made it increasingly evident that the education provided must be non-sectarian in character. The secularization of education in America thus came about as an unavoidable incident in the development of government among a people, and not as either a deliberate or wanton violation of the rights of the Church. The change to non-sectarian schools came gradually. Beginning early in American national history and in a way a sequel to a waning interest in religion, it was not until the 1840s that the question became at all acute. Then the fight was precipitated in both New York and Massachusetts at about the same time, and with about the same results. Finally, to settle the question, State after State amended its constitution to forbid any division or diversion of the public school fund, and each new State when admitted made similar provision. The matter may now be regarded as settled in the different American States.

5. The Establishment of the High *School.*—The schools established by the early States were almost entirely elementary, or the so-called "common schools." The next struggle came in an attempt to extend the public school system upward so as to provide a more complete education than the common schools afforded. The academy development, beginning about the middle of the 18th century (see SECONDARY EDUCATION), had created a new type of secondary school that was semi-public in control and more democratic in character than the town Latin grammar schools had been, and the development of the academy was marked during the first half of the 19th century. In particular, this institution offered a much broader course of study than did the Latin grammar schools, often was open to girls as well as boys, and aimed to prepare for practical life and for teaching instead of merely for college. One result of this development was a demand that the cities should establish free higher schools of a somewhat similar nature. In 1821 Boston created what is regarded as the first American high school, and in 1827 Massachusetts enacted a law requiring a high school in every town of 500 families or over, in which certain specified modern studies should be taught. In 1835 smaller towns also were permitted to establish such a school. This law marks the real beginning of the American high school as a distinct institution, formed the basis of all subsequent legislation in Massachusetts, and deeply influenced development in other States.

Up to 1840 about a dozen high schools had been established in Massachusetts, and a similar number in other States. The democratic West soon adopted the idea and established high schools as cities developed and the needs of the population warranted their

creation. The struggle to establish and maintain these schools which New York and Massachusetts had undergone was repeated in every new State east of the Mississippi river and north of the Ohio. One of the most important of these conflicts came in the City of Kalamazoo, Mich. This case finally reached the State supreme court of Michigan which, in 1874, handed down a decision which deeply influenced all subsequent development. It confirmed the high school as an integral part of the common school system, and affirmed that the voters might provide for the support of any kind of public instruction authorized by the laws of the State. This decision ranks with the Massachusetts law of 1827 as one of the important milestones in the creation of the American public high school.

6. The State University. — *During* the colonial period of American history nine colleges had been established: Harvard in 1636, William and Mary in 1693, Yale in 1701, Princeton in 1746, Pennsylvania academy and college in 1753–55, Kings (Columbia) in 1754, Brown in 1764, Rutgers in 1766 and Dartmouth in 1769. The religious purpose had been dominant in the founding of each institution, though there was a gradual shading off in denominational control and insistence upon religious conformity after about 1750. Fifteen additional colleges were founded before 1810, though the two dozen colleges then existing did not have all told over 100 professors and instructors, and not over $1,000,000 worth of property. All were small. No one of the 24 admitted women in any way to its privileges. Fourteen more colleges were added before 1820, after which a great period of denominational effort in the founding of new colleges began, and during the next 40 years 196 new colleges were founded in the United States. Though the Federal Government, beginning with Ohio in 1803, had given land to each of the new States to help endow a seminary of higher learning within the State, of the 246 colleges in existence by 1860 but 17 were State institutions.

In 1816 the legislature of New Hampshire attempted to take over Dartmouth college and make of it a State university, but was stopped from so doing, in 1819, by a decision of the U.S. Supreme Court which held that the charter of a college was a contract the obligations of which a legislature could not impair. The effect of this decision was to give a new impetus to the States to extend their public school system upward and to crown it with a State university. It was some time, however, before such institutions became either numerous or important. For long they remained much like the denominational colleges about them—small, poorly supported, and afflicted with denominational and political controversies. Michigan was the first of the State universities to throw off the incubus of political and denominational control. Opened in 1841 at Ann Arbor, Mich., in 1852 it had a faculty of only six, 72 students and a single course of study, but by 1860 it had enrolled 519 students and its remarkable development as a State university had begun. During the next two or three decades most other State institutions followed its example. Large and important State universities are to be found in every State west of Pennsylvania and south of the Potomac, and a few elsewhere. In every State, too, some form of a State college or university now exists.

The Land-grant Colleges (*q.v.*).—In 1862 Congress provided (Morrill Act) for a grant of public land to each State to found a college of agriculture and mechanic arts. The grant was accepted and such an institution was created in every State. 18 States added the land-grant to their existing State universities and combined the two institutions; three of the older States (originally five) gave the grant to private institutions already established within the State; and the remainder established separate agricultural and mechanical colleges.

The financial returns from the land-grants were disappointing, but the educational returns have been very large. Probably no aid given by the national Government to the States has proved so fruitful as have these grants of land, and subsequently of money, for instruction in agriculture and the mechanic arts. New and vigorous colleges have been created (Cornell, Purdue, and the State universities of Ohio and Illinois are examples); small and feeble State universities have been awakened into new life (Vermont and Wisconsin are examples); agriculture and engineering have been developed as new learned professions; and the States have been stimulated to make larger and rapidly increasing appropriations for their universities, until the State universities largely overshadow all but the best endowed of the old denominational colleges. The far-reaching educational importance of the Morrill Act is not likely to be overestimated.

The Free Public School System. — By the close of the second quarter of the 19th century, certainly by 1860, we find the American public school system fully established, in principle at least, in all the Northern States. Much yet remained to be done to carry it into full effect but everywhere democracy had won its fight, and the American public school, supported by general taxation, freed from the pauper-school taint, free and equally open to all, under the direction of representatives of the people, free from all sectarian control, and complete from the primary school through the high school, and in the Western States through the university as well, may be considered as a permanency in American public policy and, with the State university, represents the crowning achievements of those who worked for a State-supported educational system fitted to the needs of great democratic States. Probably no other influences have done more to unify the American people, reconcile diverse points of view, eliminate State jealousies, set ideals for the people, and train leaders for the service of the States and the nation than have the academies, high schools and colleges scattered over the land. They have educated but a small percentage of the population, to be sure, but they have trained most of the leaders who have guided the American democracy since its birth.

New Influences. — Up to the close of the first third of the 19th century American educational development was largely native, modified from time to time during the colonial period by new ideas brought over from England and new plans as to organization from France. The revolution put an end to English influences, and the schools evolving afterward were those adapted to the needs of a new nation on a new continent. They were distinctly of a homespun variety. It was not until the decade of the '20s that educational journalism in America had its beginnings, and not until a decade later that it may be said to have got under way. The first real contact with what Europe had been doing came in 1819 through the publication in America of John Griscom's *A Year in Europe*, in which he described the schools of a number of European countries, and especially the schools and work of Pestalozzi. A few other travellers published their descriptions, and in 1835 a translation of Victor Cousin's *Report* on public instruction in Prussia was printed in New York. The influence of this volume on the new constitution of Michigan, then being formulated, was of great importance. Both Stowe's *Report on Elemerztary Education in Europe*, made to the legislature of Ohio in 1837, and Bache's *Report on Education in Europe* (1839), awakened wide interest. In 1843 Horace Mann spent some months in visiting European schools, and on his return reported at length on what he had seen.

The general results of these various observations by travellers and official *Reports*, extending over nearly a quarter of a century, and the work of the newer educational journals, particularly the work of Henry Barnard, were to give to American educators some knowledge of school organizations elsewhere. They especially gave strong support to the movement, already in progress, to organize the many local school systems into State school systems, subjecting them to State oversight and control; they further stimulated the movement, already well begun, to grade and classify the schools in a more satisfactory manner; they helped to inaugurate a movement for the introduction of Pestalozzian methods to replace the wasteful individual and the mechanical Lancasterian plans which had for so long been in use; and they gave material assistance to the few leaders in Massachusetts and New York who were urging the establishment by the State of professional training for teachers for the educational service.

The training of teachers had been begun in the Lancasterian model schools, about 1810, but the first regular teacher-training school in America was established privately in 1823, at Concord,

Vt., by the Rev. Samuel R. Hall, as an adjunct to his work as a minister. In 1827 New York State, at the instance of Gov. Clinton, provided for teacher training in connection with a few of the academies of the State. The training offered in all these institutions was entirely academic, as there was in America at that time no body of professional knowledge to teach. Practice in the work was obtained by teaching during the winter in the rural schools. Hall, however, tried to tell his pupils how to organize and manage a school, and finally wrote out his ideas in a series of *Lectures on Schoolkeeping* (1829), a little volume that constituted the first professional book on teaching to appear in America in the English language. In 1835, a Dr. Julius, of Hamburg, visited America and described to the Massachusetts legislature the Prussian system of elementary education and teacher training. A State-wide agitation for State training of teachers followed, culminating in the opening of the first American State normal school at Lexington, Mass., in 1839, followed by another at Barre the same year, and a third at Bridgewater in 1840. New York State followed with a similar school in 1844, and Connecticut and Michigan in 1849. By 1860 12 normal schools in nine States, and six private normal schools, had been organized for the training of teachers *(see* NORMAL SCHOOLS).

About 1860, largely through Edward A. Sheldon, of Oswego, N.Y., the introduction of the new Pestalozzian procedures began. Within a few years visitors from near and far came to Oswego to see the work of Sheldon and his teachers. The "Oswego movement," which he inaugurated, during the two decades following almost completely reshaped elementary instruction in the better schools of America. The normal school came into its own, and teacher training by Oswego methods was generally adopted by educationists. Between 1850 and 1880 new subjects of study were introduced in elementary education, the teaching of the older ones was revolutionized, and a new technique—a methodology—for instruction in each subject was worked out. Where before the ability to organize and discipline a school had constituted the chief art of instruction, now the ability to teach scientifically took its place as the prime professional requisite. A new conception of the child as a slowly developing personality, demanding subject matter and method suited to his stage of progress, also replaced the earlier conception of the school. With the addition of new ideas as to the teaching of history and literature, which came in with the Herbartian theories in the '80s, and manual training and home economics instruction, which began about the same time, the most important foreign contributions to the elementary school were made. The kindergarten (*q.v.*), which reached America in the '70s and became well established by the '90s, also should be mentioned among the material contributions from foreign sources.

By 1900 the centre of gravity had been shifted from the subject matter of instruction to the child to be taught. The school, in consequence, had begun to change from a place where children prepare for life by learning certain traditional things to a place where children live life and are daily brought into contact with such industrial, social, community and real life experiences as will best prepare them for the harder problems of living which lie just ahead. These changes in character and purpose, largely due to the teachings of John Dewey, have become dominant purposes of the American elementary school of the 20th century.

Expansion of the High School.—Though dating from 1821, the public high school up to about 1860 had made little headway except in regions where New England people had gone. The Civil War checked development for two decades, but after about 1880 a very rapid growth took place. From about 500 high schools in 1870, and about 2,500 in 1890, some 16,000 had been established by 1925. The old academies were replaced, and the high school has become the accepted American secondary school. Along with this rapid development—in number of schools, teachers and students—a marked change in the high school itself has taken place. The course of study, up to about 1860 essentially a uniform book-study course of three years, after about 1880 was expanded so rapidly by the introduction of new subjects that it was soon lengthened to four years and subdivided into numerous parallel courses. Entirely new types of high schools, too, were created, such as commercial, agricultural and manual arts; and out of this evolution has come the so-called cosmopolitan high school which oifers instruction in many different types of general and special training. With the enactment by Congress of the Smith-Hughes Vocational Education bill (1917), giving aid to the States for agricultural, home economics and industrial education, a vast system of vocational education, secondary and local in character but national in scope and purpose, began to be developed. Hence we find the American high school, as the result of a century of progress and evolution, has developed into a comprehensive system of secondary education which an increasingly large proportion of the youth of the land, of both sexes. attend. Day schools, night schools and continuation schools all form a part of this secondary school system.

University Expansion.—Accompanying the expansion of the high school has come a similar development of college and university training. Since about 1880, when the State universities began to turn their attention to serving and advancing the welfare of the State, both university attendance and university revenues have advanced by leaps and bounds. During the same period a number of new and important endowed university creations have also made their influence felt. Coincident with the rapid increase in students, faculty, schools and courses, has come the greatest number and amount of gifts of money ever made to aid higher education in any land. The States, too, have put millions of dollars into the equipment and maintenance of these higher institutions, believing in them as the creators of advanced public opinion and as training schools for the future leaders of the State.

Educational Reorganization.—Beginning about 1910, a very important reorganization of the upper years of the public school systems in the United States has taken place. Instead of an educational organization consisting of eight years of elementary school and four years of secondary school, there has been evolved a six-year elementary school dealing with the fundamental tools and skills, a three-year junior high school with a greatly enriched course of study designed to meet the special biological and psychological and social needs of young people in their teens, and a three-year senior high school planned for later adolescents. This has substituted a 6–3–3 type of educational organization for the former 8–4 type. Few fundamental changes in educational organization have been accepted more rapidly than this; whereas but two cities had organized junior high schools before 1900, and but ten cities before 1910, 198 cities had organized such schools by 1915, 386 cities by 1920, 704 cities by 1924 and 1,109 cities by 1927. This type of organization promises to become well nigh universal in another decade.

Another administrative reorganization, and one of great importance to the future of public education in America, is the extension upward of the public school system to include the 13th and 14th years of school life—the freshman and sophomore years of the traditional college. A number of American cities have already added these years to their public school system by organizing what has come to be known as a junior college, thus making their public school system a 6–3–3–2 school system. The final result of such a reorganization will be not only a kindergarten—6–3–3–2 school system, or possibly a kindergarten—6–4–4 plan of organization, but also the dropping of the first two years of work from the traditional college and the transformation of the universities of America into what continental European universities have for long been—a group of professional schools beginning with the junior year.

Lateral Expansion of the School.—Along with the vertical expansion of the public school system there has also been a vast lateral expansion of the school. Especially since about 1900 has this been a marked feature of American educational work. Pedagogical and intelligence testing have revealed the need for differentiated instruction, and this has been met by the institution of flexible plans for grading and promotion and the organization of ungraded and special-type classes to meet many varying needs. Classes have been organized for over-age, non-English-speaking, deaf, blind, crippled, tubercular, anaemic, speech-defectives, subnormals and other types of children in need of special attention

and care. The handling of disciplinary cases also has called for the organization of the ungraded room, the opportunity school and the parental school. Industrial classes, trade schools and special vocational and home-making schools have been instituted for other children who cannot profit by the book-work of the ordinary school. Adult instruction has experienced a very marked development. Another aspect of the lateral expansion of the school has been the attention given to problems of health, physical welfare, playground work, nutrition, abnormalities, child care, preventive hygiene and parental guidance and infant welfare. The school physician, the school nurse, the visiting teacher and the compulsory attendance officer have all combined in service to the child who does not make proper progress in the regular school. The school guidance counsellor has also been added to help guide boys and girls into tasks which they can do, and other advisers (deans) to help the youth of both sexes in handling their personal problems. Education in America has thus taken on many new functions of a personal and public welfare character.

Throughout all the reorganizations and expansions of public education one sees a determined effort to readjust the school to meet the changed conditions in national life — social, industrial, political, religious, economic, scientific. While the school systems which have been developed are State school systems, and in their internal organization and administration the States are supreme, many of the difficult social and educational problems America has come to face are national in scope and character and call for general and country-wide solution. To assist in such national solution many nation wide agencies have been set up, and there has been a strong and persistent movement for some national financial aid to the States, and for a secretary of education in the President's cabinet. (E. P. Cu.)

SCHOOLS FOR NON-ENGLISH-SPEAKING ADULTS

In the United States schools are provided for three main lines of educational effort: instruction in English; preparation for naturalization and citizenship; educational service for individual, family and group adjustment. To meet the needs of the foreign-born in adjusting themselves to a new environment and to new culture patterns and forms of behaviour, special materials relating to American history, biography, institutions, traditions, customs, ways of living, geography, industry and other subjects are provided.

These schools range from elementary to higher education. Emphasis is placed upon elementary instruction because of much illiteracy and limited educational attainments among many immigrant groups. Educational facilities include public and institutional evening schools and classes; day classes in schools, libraries, churches, neighbourhood centres and homes; classes in factories, industrial plants, hotels and other places of employment. Special attention is given to home and neighbourhood classes for women and mothers.

Schools for non-English-speaking people are direct results of immigration. Their rapid development is largely due to an Americanization movement during and immediately following the World War. They are regarded as distinct instrumentalities in nation-making. For several years prior to the war, public evening schools, settlements, Y.M.C.A.'s, Y.W.C.A.'s, various social agencies, churches, corporations and other organizations conducted schools and classes for immigrants. Chief attention was devoted to instruction in English. Fear of the foreign-born during and after the war; comparative ignorance about their conditions and needs; the prominence of the foreign-language press and increasing delinquency among the second generation, coloured much of what was promoted as Americanization. Departments, divisions or bureaux of Americanization were created in numerous city and State departments of education. This nationalistic movement has been partially transformed into a definite educational movement for adults of foreign birth and speech with appropriate redirections on emphasis, organization, materials and methods.

Complete and accurate statistics for the country as a whole are difficult to secure. The U.S. Bureau of Education for the year 1925–26 reported 128 public school systems with Americanization classes, employing 262 supervisors and principals and 3.436 teachers. and enrolling 141,064 pupils. To these figures should be added the considerable number of schools and classes conducted by individuals, social organizations, private and semi-public institutions, religious organizations, industries and other agencies. In certain communities, as for instance, New York city, where foreign-born men and women comprise about go% of evening school enrolment, a large proportion of adults enrolled in schools are immigrants.

Community co-operation of various forms — between public and private agencies; between organizations and individuals representing the native and foreign-born — is necessary. Some cities have central co-ordinating organizations. Public responsibility for socialized educational service is increasingly emphasized with larger provisions for schools under competent leadership. In general, local public educational authorities provide funds for supervision and full or part-time teaching according to local demand; local appropriations are commonly supplemented by some form of State aid, in keeping with general educational fiscal policies of the several States.

See Sharlip and Owens, *Adult Immigrant Education* (1925); Cook and Walker, *Adult Elementary Education* (1927); Caroline A. Whipple, *Course of Study for Non-English-speaking Adults* (1927).

FRANCE

France (*q.v.*) presents the most complete type of a state system of education organized under a strongly centralized administration in all grades. This centralized administration in education, as in other departments, represents the Napoleonic heritage of the republic. The teaching profession, both in the primary and higher spheres — and the two are sharply marked off from one another — consists of a highly organized body of state functionaries, united by a strong *esprit de corps* and actuated by ideals and aims which are inspired by the State. The importance of this condition of things lies in the fact that the republic is something more than a form of government; it is the social and moral expression of the democratic ideal as conceived by a people profoundly imbued by tradition with the sense of social solidarity, or collectivism; and nowhere has this expression been more characteristic or more complete than in the domain of public education. Yet the educational system of modern France is by no means exclusively the creation of the Third Republic, and the main stages in its development deserve to be traced historically.

Early Stages of Public Education. — No historical sketch of French education can ignore the great catholic religious educator of the 18th century, Jean Baptiste de la Salle, the founder of *Les Frères de la Doctrine chrétienne,* commonly known as the "Christian Brothers." The brothers were not merely pioneers of elementary education, they may also be regarded (as M. Buisson, formerly director of public instruction, has shown) as the originators of higher primary instruction. Under the restoration they upheld the method of simultaneous teaching against the partisans of the mutual (or monitorial) method, successfully demonstrating the superiority of the trained teacher.

The Revolution. — The constitution of 1791 decreed that primary instruction should be compulsory and gratuitous. In this as in much else the revolution was powerless to do more than enunciate general principles which it left for later generations, in the present instance after the lapse of nearly a century, to carry into effect. True to its theories of individualistic liberty, the revolution admitted liberty of teaching. Napoleon, on the other hand, by the law of 1806, centralized all forms of education in one official teaching body under the name of the Imperial University, thus securing a monopoly of teaching to the state.

Under the restoration education fell inevitably under the control of the church, but under the Liberal monarchy Guizot in 1833 passed a law which laid the foundations of modern primary instruction, obliging the communes to maintain schools and pay the teachers. It is also to the credit of Guizot as an educational reformer that he perceived the necessity for the higher primary as distinct from the secondary school. The higher primary schools

which he founded were unfortunately suppressed by the *Loi Falloux;* their restoration constitutes one of the great positive services rendered by the Third Republic to the cause of popular education.

Loi Falloux.—The *Loi Falloux* of 1850, passed by the Second Republic under the influence of the prince president, is chiefly memorable for its restoration of the liberty of teaching, which in a catholic country means in effect free scope for priestly schools. This law also made provision for separate communal schools for girls, for adult classes, and for the technical instruction of apprentices. In 1854 France was divided for purposes of educational administration into 16 academies, each administered by a rector with an academy inspector under him for each department. This organization survives to-day, with the difference that for each academy (except Chambéry) there is now a local teaching university.

The ministry of the well-known educationist, M. Duruy (1865–69), corresponding to the period of the Liberal empire, rendered primary schools for girls obligatory in communes of over 500 inhabitants. Duruy also provided for the introduction of gratuitous instruction at the option of the commune.

Organization by the State. — The task of educational reform imposed itself upon the republic by a twofold necessity. The wars of 1866 and 1870 were victories for the Prussian school-master, and aroused western Europe to the national importance of popular education. For France the reform of popular education was an essential part of the work of national restoration. For the republic, too, menaced by older and hostile traditions, the creation of a national system of education inspired by its own spirit was an essential condition of the permanence and security of its government and the social ideals of which that government was the expression. Hence the energy with which the republican state addressed itself to the organization of primary instruction, "obligatory, gratuitous, secular."

By the law of June 1, 1878, there was imposed upon the communes the obligation of acquiring their school buildings; and as a grant in aid a sum of £2,400,000 was set aside for this purpose by the State. In 1879 a law was passed compelling every department to maintain a training college for male and female teachers respectively. The two higher normal schools of Fontenay and St. Cloud were also founded to supply the training colleges with professors. During the same period, among other *certificats* or professional diplomas, there were established the *certificat d'aptitude ptdagogique,* which qualifies probationer-teachers (stagiaires) for appointment as teachers in full standing (titulaires), and the *certificat d'aptitude* for primary inspectors and heads of normal schools. The law of June 16, 1881, rendered obligatory for all teachers, whether public or private, the *brevet de capacité.* It was found, however, impracticable to carry this law into immediate effect, though conditions have improved.

The laws making primary education gratuitous, compulsory, and secular are indissolubly associated with the name of Jules Ferry. The law of June 16, 1881 abolished fees in all primary schools and training colleges, the law of 1882 established compulsory attendance, and finally the law of Oct. 30, 1886 enacted that none but lay persons should teach in the public shools, and abolished in those schools all distinctively religious teaching. In the boys' schools members of religious communities were to be displaced within five years, but in girls' schools the religieuses might remain till death or resignation.

Moral Instruction. — Religious teaching was replaced in the state schools under the Ferry law by moral instruction according to official curricula. As regards the character of this instruction, it would seem to have shifted from a Kantian mainly to a sociological basis. Roman Catholic opinion is at least not unanimous in regarding the "lay" or neutral school as essentially or necessarily anti-religious, and plainly there is no inherent reason why the neutrality should not be a real neutrality, but with the existing relations between the catholic church and modern thought in France the influence of the normalist teachers is in fact to be anti-religious, and moreover no system of independent moral doctrine, whether based upon *a priori* or inductive reasoning, can be acceptable to the Roman Catholic church. In whatever degree the blame may be rightly apportionable between church and state, the fact is that the two find themselves in acute conflict. It may be that the mischief would have been mitigated had more moderate counsels prevailed at the time of the Ferry law, and had the church been willing to accept (as the republic might have been willing to concede) right of entry for the clergy into the schools. In the meantime the religious difficulty in the schools divided the nation into two hostile camps (*les deux Frances,* as a Swiss Protestant writer put it) in the shape of the state secular schools on the one side and the private religious schools on the other.

Administration. — In 1889 an important change was made in educational finance by transferring the cost of teachers' salaries in primary schools from the communes to the state, a right consequence of the change which made the teacher a state official. Thus the state assumed the greater part of the burden of primary instruction, leaving to the communes merely the cost of fabric, and to the department the maintenance of the fabric of the normal schools.

Central Authorities. — The minister, the head of the entire hierarchy, is assisted by a *conseil supérieur* consisting of 57 members, of whom the majority are elected by the higher teaching profession. Practically the ordinary work of the council is carried on by a sub-committee consisting of the nine nominees of the president and six others designated for this purpose by the minister. The council has administrative, judicial, and disciplinary, as well as advisory, powers which enable it to exert a direct influence upon the internal organization of schools. There is also a pedagogic *comité consultatif* and a legal *comité contentieux,* whose respective functions are purely advisory.

The *inspecteurs généraux* should "act as the eyes and ears of the central authority." Their main duties are to inspect the normal schools and supervise the work of the ordinary inspectorate. For the purpose of general inspection France is divided into seven districts.

Local Authorities. — As already indicated, for the purpose of educational administration, the departments of France, to which must be added Algiers, are grouped in 17 divisions called academies. At the head of each academy is the rector. He is appointed directly by the president and is not only the head of the local teaching university, but is also charged in a general way with the oversight of all three departments of education — superior, secondary, and primary. The direct share of the rector in administration is mainly confined to the normal schools and the higher primary schools. The rector is assisted by an academic council composed almost exclusively of pedagogic elements.

Each department of France has an academy inspector appointed by the minister. The duties of the academy inspector embrace both higher and primary education. In the latter sphere he is the real head of the local administration, and the primary inspectors are his subordinate officers. He appoints the probationer-teachers and nominates the regular teachers for appointment by the *pre'fet.*

The *préfet,* the chief administrative officer of each department, not only appoints the teachers upon the proposition of the academy inspector, he is also, as president of the *conseil départemental,* concerned generally with the externa of school administration, including the supply of schools. As regards its constitution, the *conseil départemental* is in no sense a municipal body, the representatives of the *conseil général* of the department being greatly outnumbered by the pedagogical members.

The inspectors of primary schools, as has already been stated, act under the academy inspector. They are appointed upon the result of examination, and not by direct nomination as in England. The examination is severe, and it is from the body of the professors of the normal schools rather than from the ranks of the primary teachers that the successful candidates are chiefly drawn.

Very limited powers are entrusted to certain communal and cantonal authorities. The *commission scolaire* is a committee organized in each commune for the purpose of improving school attendance, to which end they administer a *caisse des écoles* or school fund for supplying clothing and meals to needy children The *maire* of the commune has the right of visiting the schools,

but neither he nor any of the minor local authorities can interfere with the teaching. Similar duties are assigned to the *délégués cantonaux* who are appointed by the *conseil départemental* for each canton (a wider area than the commune), and can best be described as local visitors or visiting committees rather than managers in our sense of the word.

Nursery Schools.—Probably the most important modern development in France has been the creation on a large scale of public *e'coles maternelles* (nursery schools).

In the single department of the Nord there are no less than 60 of such schools, more than in all England at the present time. In fact, for all France, the number of pupils in these schools in 1923–24 was 280,768.[1]

SECONDARY EDUCATION

In proceeding to sketch the French system of higher primary and secondary schools, it may be observed that European systems of higher education have generally been framed upon the view that secondary education is a training complete in itself from the preparatory stage to the university, with aims and ideals of general culture which differentiateit radically and at the very outset from education of the elementary type. On the other hand, in the United States, the view has prevailed that the secondary school must be complementary to the elementary school, in which even the Clite must receive their preparatory or elementary training. At any rate, down to the reform of 1902, which will presently be explained, the French system could be regarded as a typical and even extreme example of the European theory, little consistent as this might seem to be with the broader principles of democracy. A further breach has been made in the theory by an augmentation in the number of scholarships since the World War, and by an experiment to amalgamate in country districts small secondary day and higher finishing schools

Higher Primary Schools.—The aim of the *e'coles primaires supérieures* is to fill the void which must otherwise exist for those who need a higher education than the primary school can give. Throughout the organization of primary education the French have kept steadily in view the danger of creating an intellectual proletariat. *Nous poursuivons la culture générale du caractère et de l'esprit, mais nous cherchons en même temps à orienter l'enfant vers la vie pratique,* says an official report. The aim of the higher primary school is to continue education in this spirit up to the age of 16 so as to prepare the scholar to take an honourable place in the higher ranks of skilled industry. Within the limits necessarily marked out for them the higher primary schools of France have aimed at imparting what may be termed a general culture as distinct from purely technical or trade teaching, and this development has been greatly furthered by the separate organization given to the latter teaching in the *e'coles professionnelles.* At the same time, prominence is given in the higher primary schools to practical training of an educational character with special reference to the industries and circumstances of the locality, and in the rural districts a special agricultural bias is imparted to the curriculum. It is interesting to note that the institution of the higher primary schools was due in large part to the spontaneous initiative of the municipalities.

A wider extension has been given to higher primary instruction by the establishment of *cours complémentaires* in certain schools, at centres at which it would be impossible to organize separate higher primary schools. A similar solution of the continuation school problem has recently commended itself to the consultative committee of the Board of Education for England.

Admission to the higher primary schools in France is only accorded to those who have obtained the elementary school leaving certificate, *certificat d'études primaires.* A feature of importance for continuation work in rural districts is the provision made for boarding scholars in attendance at these schools. The boarding arrangements are generally, as in the case of the secondary schools, left to the head teacher, but in some instances municipal hostels have been provided. No fees may be charged for higher primary instruction, and scholarships (bourses) are provided to a certain extent in the form either of boarding scholarships or maintenance allowances to compensate the parent for the loss of the child's labour. The number of scholars in the public higher primary schools for the year 1903–04 was 34,084, and in *cours complémentaires* 21,777, making a total of 55,861. In addition, there were 8,801 scholars in receipt of higher primary instruction in private schools. In 1923–24 there were in these schools 39,309 boys and 34,091 girls.

Lycées and Colleges.—Practically every department has two training colleges for students of the two sexes. While the professors in these colleges receive their preparation in the two higher normal schools of St. Cloud and Fontenay-aux-Roses, French secondary education is given in the *lyce'es,* which are first-grade schools maintained and controlled by the state, and the *collèges,* which are schools of the second grade, maintained partly by the state and partly by the municipality. In both grades of schools the teachers are paid by the state and nominated directly or indirectly by the minister of education. They are required to possess certain specified academic qualifications which can only be obtained from the *université,* but failing teachers with the prescribed qualifications the classes are taught by teachers styled *charge's de cours* as distinct from professors. .

With a view to supplying teachers for the upper classes of the secondary schools, the state maintains the *e'cole normale supérieure,* a college in which instruction, board, and lodging are given free to a number of scholars selected by competition from the best secondary school boys, though residence in the institution is no longer compulsory. The *e'cole normale* has now become practically the college of pedagogy of the university of Paris. Its students are entered as students of the university, and study for their qualifying examination as teachers in secondary schools (*agrégation*) under university professors, partly at the Sorbonne, partly at the *e'cole normale,* while their professional preparation is entrusted solely to the latter institution. Before the World War the profession was the best qualified academically in Europe. With, however, the fall of the franc the recruitment was seriously threatened This danger has been removed by the stabilization and the large rise in salaries.

Secondary Education for Girls.—The foundation of secondary schools for girls was in its way one of the most notable achievements of the republic. It was inaugurated by the law of Dec. 22, 1890, called after its author, *la loi Camille Sée.* At first the curricula were different from those of the boys, and the course of study was only five years. There were no ancient languages, and mathematics were not carried to so high a pitch as in the boys' *lyce'es.* To-day there are three types of establishments: the *cours secondaires* (municipal or private) assisted by the state and regarded as colleges in the making, communal colleges, and *lycées.* Moreover, the pupils can prepare for the baccalauréat on equal terms with the boys. The rest of the girls confine themselves to working for the *diplôme de fin d'études secondaires.* The number of girls following the *cours secondaires* in 1923–24 was over 50,000.

Private Secondary **Schools.**—Until the passing of the Waldeck-Rousseau laws prohibiting religious associations, the number of pupils in the state secondary schools and the private secondary schools were approximately equal, the great majority of the latter schools being in the hands of the religious orders. The Waldeck-Rousseau Act was passed on July 1, 1901, and in 1904, under M. Combes, the religious schools were suppressed by law. Some managed none the less to maintain their ground, but their pupils shrank to a little over 20,000, with 35,000 in the free lay schools (some of these being transformed religious schools), while the numbers in the state schools amounted to about 100.000. In 1912 the number in the religious schools had risen again to 56,000; the number in the free lay schools had fallen to 17,000, while the number in the state schools was stationary. Under the heading of the private secondary schools should be mentioned here *honoris causa, l'école des Roches* founded by M. Demolins (author of *À quoi tient la supériorité des Anglo-Saxons*) and *le Collège de Normandie,*

[1] In this and other cases later statistics are not available owing to the economic crisis which has considerably reduced the staff in French government departments.

founded by M. Duhamel, a former French master at Harrow school, England. The Waldeck-Rousseau Act also caused a temporary decrease in the number of pupils in the religious elementary schools. But here again the impossibility of finding funds for building new schools or providing for new teachers speedily made itself felt, and the numbers rose again. They amounted in 1903–04 to 1,298,571, as against 4,935,000 in the public primary schools. To-day the terrible effects of the World War have markedly affected the numbers in both types of schools. In 1922–24 the numbers in the State primary schools were only 3,175,637, and the numbers in the private elementary schools had proportionately declined.

Secondary School Curriculum. — In 1902 reforms were made in the curriculum. Article 1 of the decree of May 31, 1902, coordinated with primary education so as to constitute a continuation of a course of primary studies of a normal duration of four years. The decree went on to provide for a full course of secondary studies of seven years' duration, divided into two cycles of four and three years respectively. In the first cycle the scholar had two options. In section 1 Latin was obligatory and Greek optional from the beginning of the third year (*classe* iv.). In section 2 there mas no Latin. At the end of the first cycle the state granted a *certificat d'études secondaires du premier degré*. In the second cycle one of four courses might be taken: section 1 with Latin and Greek continued the old classical education; section 2 with Latin and modern languages corresponded to the German Realgymnasium; section 3 with Latin and science; and section 4 with modern languages and science to the Oberrealschule. The *baccalauréat,* or secondary school-leaving examination, conducted by the university, was adapted to all the courses on the principle that courses of study of equal length, whether classical or modern, literary or scientific, were entitled to equal advantages.

Final Re-draft of the Curriculum, 1924.—Since 1910 the most important event in the sphere of secondary education has been the changes in the curriculum. In 1923 the minister of public instruction, M. Léon Bérard, decided to abolish the four alternative sections and make Latin compulsory for four years and Greek for two. for all secondary pupils. The course in science was to be the same for all pupils, and it was only in the year before the baccalauréat that the pupil could choose between classics and a modern course. The Bérard reforms considerably lightened the time-table by cutting down, above all, the mathematics and simplified the over-elaborate choice of studies, but the proposal of classics for all roused the most violent opposition. A change of government made it easy for M. Herriot — the new minister of public instruction — to re-establish the modern Latin-less course, but the others were not revived. Henceforth the pupils have a choice between classics and a modern course, but whichever they choose, for two-thirds of the time-table in such subjects as French, history, geography, etc., they are taken together, though the system is meeting with a good deal of criticism.

Physical Education. — A word must be said here on physical education. Since 1923, two hours a week have been prescribed for pupils of both sexes in the elementary schools. Since Jan. 19,1925, it has been laid down by the ministry that similar time shall be devoted to the subject in boys' and girls' secondary schools. The teaching consists in conferences on health and in practical exercises. Attempts are being made to build up a properly equipped *personnel* by establishing a *certificaf d'aptitude à l'enseignement de la gymnastique,* which is now to be replaced by an examination of more general culture entitled *le certificat d'aptitude au professorat de l'éducation physique*. Meanwhile, the number of secondary pupils playing tennis, football, and basket-ball (the latter being played by both sexes!) has largely increased of recent years.

Technical Schools. — A certain number of technical schools, formerly under the ministry of commerce, have been brought under dependence of the ministry of public instruction. They include six national professional schools, six *e'coles nationales d'arts et métiers,* higher schools of commerce and 84 *écoles pratiques de commerce et d'industrie,* as well as commercial and technical courses followed by some 280,000 students in 1923–24. There are also a network of institutions and schools run by the ministry of agriculture, from the national agricultural institute of Paris, and the national schools of agriculture at Montpellier and Rennes, down to the *fermes-écoles* and the *e'coles pratiques d'agriculture* (over 30 in number with generally a two years' course). There are also some 50 fixed winter schools and more than half that number of travelling winter schools. In addition, there are some 700 continuation classes in agriculture and agricultural economy for adults of both sexes. Various other ministries have professional schools attached to them, the most important being those of the ministry of war *(e'cole polytechnique* for military engineers, *école militaire,* St. Cyr, for ordinary officers, and St. Maixent for non-commissioned officers seeking commissions), the ministry of the marine (naval school), and the ministry of the colonies *(e'cole coloniale,* for the colonial civil service — also French schools abroad). Some of the schools in other countries are also under the ministry of foreign affairs.

The question of restoring some of the religious teaching orders was discussed by the Poincaré cabinet in November, 1928.

As regards higher education and the creation of regional universities in 1896, *see* UNIVERSITIES.

GERMANY

Until the fall of the Empire, education was left to the exclusive control of each of the federated states. The only points of direct contact between the Empire and education lay in the mutual undertaking of the states to enforce the law of compulsory attendance at school and to maintain approximately equal standards in the award of final secondary school certificates. Of far greater moment than these indications was the moral influence exerted on other states by the Prussian hegemony, in virtue of which the Prussian system came to be in all essential characteristics typical and representative of Germany as a whole. Complete and careful though the system was it was not within the power of any government in Prussia to pass a comprehensive education law. The growth was determined by a series of special laws, royal decrees and wise administrative regulations. A detailed historical study would bring out clearly the intimate connection between the development of the educational system and the Prussian state and again between these and the expansion of the national life of the German people.

Latin Schools. — Stress is rightly laid by all educational writers upon Luther's famous letter to the German municipalities in 1524 urging upon them the duty of providing schools and upon parents the duty of sending their children to school. An attempt to carry this into effect was made by the Electoral government of Saxony which issued in 1528 an ordinance, drawn up by Melanchthon, providing for the establishment in every town and village of Latin schools, for the Protestant Reformers were solidly in favour of classical education. It is, therefore, all the more remarkable that the Ordinance issued by the Elector of Wiirttemberg 1559 represented the first systematic attempt to provide both elementary and higher education, directing the establishment of elementary schools throughout the country and of Latin schools (or *Particularschulen*) in every considerable centre of population. These promising beginnings were, however, brought to nought in the troublous times of the Thirty Years' War, and by the desolation and national decadence which that calamity brought in its train. The permanent and positive value of Luther's pronouncement of 1524 lies not so much in its direct effects as in the hallowed associations which it established for Protestant Germany between the national religion and the educational duties of the individual and the state. Thus, doubtless, was created that healthy public opinion which rendered the principle of compulsory school attendance easy of acceptance in Prussia at a much earlier date

than in England. State interference in education was almost coincident with the rise of the Prussian state. In 1717 Frederick William I. ordered all children to attend school where schools existed. This was followed in 1736 by edicts for the establishment of schools in certain provinces and by a royal grant of 50,000 thalers for that purpose in the following year. In 1763 the Landschulreglement of Frederick the Great laid down the broad lines upon which the Prussian state has since proceeded, asserting the principle of compulsory school attendance.

Karl Wilhelm von **Humboldt.**—It was not till after the disaster of Jena (1806) that any effective reorganization of the educational system was carried out. One of the first acts of the great patriotic minister vom Stein in 1807 was to abolish the semi-ecclesiastical *Oberschulkollegium,* and to place education under the ministry of the interior with Karl Wilhelm von Humboldt (*q.v.*) at the head of a special section. Humboldt's greatest positive achievement—the foundation of the university of Berlin—lies beyond the scope of this article. But it may be noted that his policy in secondary education is a compromise between the narrow philological pedantry of the old Latin schools and the large demands of the new humanism of the period. The measure introduced by Humboldt in 1810 for the State examination and certification of teachers checked the then common practice of permitting unqualified theological students to teach in the schools, and at once raised the teaching profession to a high level of dignity and efficiency which of itself sufficed to place Prussia in the forefront of educational progress. It was due also to the initiative of Humboldt that the methods of Pestalozzi were introduced into the teachers' seminaries, through them to vitalize the elementary schools. To the period of the national struggle belong the revival. 1812, of the *Abiturientenexamen* (the school-leaving examination) which had fallen into abeyance, and the institution about the same time of the local authorities called *Schulvorstände* for the country and *Schuldeputationen* for the towns.

Though the period which succeeded the peace of 1815 was one of political reaction, the work of administrative organization was carried on by defining the duties of the *Provinzial-Schul-Kollegium* and the *Regierung.* In 1834 an important development was given to secondary education by making it necessary for candidates for the learned professions as well as for the civil service, and for university studies, to pass the leaving examination of the gymnasia. Thus through the leaving examination the state held the key to the liberal careers, and was thereby able to impose its own standard upon all secondary schools.

Administrative Machinery.— In connection with the *Kulturkampf,* or struggle between the state and the Roman Catholic church, the Schulaufsichtsgesetz of 1872 reasserted the absolute right of the state alone to the supervision of the schools. Nevertheless the Prussian system remained both for Catholics and Protestants essentially denominational. All schools, whether elementary or secondary, were Evangelical, Catholic, Jewish or mixed. In the elementary sphere, in particular, recourse was only had to the mixed school (Simultanschule or *paritätische Schule*), where the creeds were so intermingled that a confessional school was impracticable. In all cases the teachers were appointed with reference to religious faith; religious instruction was given in school hours and inspected by the clergy. Under the ministerium in Berlin stood the *Provinzial-Schul-Kollegium,* the chairman of which was the Ober-Prasident of the province, composed of four or five Rate or councillors, generally selected from the directors of Gymnasien. This body was concerned mainly with higher education.

Each province was divided for purposes of general administration into two *Regierungen* or governments, and in each government there was a section consisting of three or four *Schulräte,* which controlled the elementary schools. This council was usually recruited from the ranks of directors of training colleges and from the inspectorate. The Regierung was divided into *Kreise* or districts, and in each district an administrative officer, called the *Landrat,* represented the Government. The *Landrat* was concerned with the provision and repair of elementary school buildings; as regards internal organization, the elementary schools were under the *Kreisschulinspektor.*

In the Protestant districts the inspectors used often to be Evangelical clergymen but later inspectors with pedagogical qualifications and the status of full government officials were appointed. For every school there was a local inspector (*Ortsschulinspektor*), usually the clergyman of the parish, who discharged the duties of local manager and correspondent.

The official classification or grading according to the type of curriculum of secondary schools in Prussia (and throughout Germany) was very precise. The following were the officially recognized types of the pre-war period. I. Classical schools: (a) *Gymnasium,* with nine years' course; (b) *Progymnasium,* with six years' course. II. Modern schools: (a) with Latin (semi-classical)—(i) *Realgymnasium* (nine years' course), (ii) *Realprogymnasium* (six years' course); (b) without Latin (non-classical)—(i) Oberrealschule (nine years' course), (ii) *Realschule* (six years' course).

This system of educational administration still remained in force, with some modifications, in 1927. The differentiation between the types was the result of a natural educational development corresponding with the economic changes which transformed Prussia from an agricultural to an industrial state. The classical schools long retained their social prestige and a definite educational advantage in that their pupils were alone admissible to the universities. Since the foundation of the Empire (1871) the history of secondary education has been largely concerned with a struggle for a wider recognition of the work of the newer schools. The movement received a considerable impetus by the action of the emperor who summoned a School Conference in 1890, at which he criticised the Gymnasien as lacking a national basis. "It is our duty to educate young men to become young Germans and not young Greeks or Romans." New time-tables were framed in which the hours devoted to Latin were considerably reduced and no pupil could obtain a leaving certificate without a satisfactory mark in the mother tongue. The results satisfied neither party and the reform lasted only a single school generation. In 1900, after a second conference, equality of privileges was granted to three types of schools, subject to certain reservations—The theological faculties continued to admit only students from classical schools, the pupils of the *Oberrealschule* were excluded by their lack of Latin from the medical faculties, but in so far as Latin was required for other studies, such as law or history, it could be acquired at the University itself.

Although the official programmes were binding on the schools, their rigidity was not absolute; experiments were possible, but they were carefully supervised. It was thus that the modifications of the classical school programme known as the Frankfurter system came into being, after a similar experiment had been tried at Altona. The chief innovation—and here the two schemes agreed—was the postponement of the beginning of Latin to Untertertia and the introduction of French as the first foreign language. This enabled parents to defer their decision as to the form of their son's education until he was about 12 years of age.

A further instance of the willingness of the authorities to sanction reasonable changes was seen in the permission accorded to certain schools to vary the course of study in the top classes, as a preparation for the freedom of choice of the university.

Girls' Schools.—In Prussia, as elsewhere, the higher education of girls lagged far behind that of boys and received little attention from the State or municipality, except so far as the services of women teachers were needed in the elementary schools. Thus it came about that in Prussia secondary schools for girls were dealt with administratively as part of the elementary school system. After the establishment of the Empire a conference of directors and teachers of these schools was held at Weimar and put forth a reasoned plea for better organization and improved status. The advocates of reform, however, were not at unity in their aims; some wished to lay stress on ethical, literary and aesthetic training, others on intellectual development, and claimed an equal share in all the culture of the age. But even in the schools the women fought an unequal battle, for all the heads and a large part of the staff were men usually academically trained. The women con-

tinually demanded a larger share of the work, and this was secured by the establishment of a new higher examination for women teachers. University study though not prescribed was in fact essential and yet the women had not the right of access to the university in Prussia. They were allowed to take the *Abiturientenexamen,* for which private institutions prepared them, but their admission to the university rested with the professor.

Economic necessity and the growing strength of the women's movement at last brought the desired change. New programmes were issued in 1908, organizing the girls' schools in two degrees: — the *Lyceum,* a ten-class institution for girls from 6 to 16; and an *Oberlyceum* of three classes, of varying types, one of which might be a training department for teachers, another for home life. But apart from these normal courses, opportunity was given to girls to follow from their 12th or 13th year courses similar to those of the higher schools for boys. The form generally preferred was that of the *Realgymnasium.* At the same time a ministerial decree opened the Prussian universities to women on the same terms as men.

Elementary **Schools.**—In no sphere of public activity did the revolution of 1918 cause more far reaching changes in Germany than in that of education. The ultimate aims which these innovations envisaged have been clearly stated in the Weimar Constitution, and have led to a single system of national education. *(See* Leo Wittmayer, *Die Weimarer Reichsverfassung,* 1922.) It was recognized that this goal could only be reached by gradual steps and the responsibility for educational administration was left with the federated states. The State ministries, however, have to observe the principles enunciated in the Constitution and to conform to the Federal laws enacted to secure the realization of the Republic's ideals.

The elementary school, which under the old régime was a class-school, has become a national institution, serving all and used by all. It has no rivals and private elementary schools are forbidden in those early years for which the common school exists. The *Einheitsschule,* which the popular parties had demanded before the World War, has become an accomplished fact, as far as the first four years of the course are concerned. As a concession, reluctantly granted, specially gifted children may be allowed to complete the course in three years. A further regulation of the school service was promised in the Constitution, but has not proved easy of accomplishment, and. the bill of the Federal Government, brought before the *Reichstag* in 1928, met with considerable opposition on account of its wide concessions to denominational principles. In the main, the schools have remained "confessional" and the *Simultanschulen* or schools of mingled creeds have not so greatly increased in number.

When the *Grundschule* (basic school) has been passed the child may be transferred to a secondary school, which is organized to lead on to the university, or he may go to the *Mittelschule,* if he wishes to enter commerce or industry about the age of 16, or he may remain at the elementary school, if he must enter on employment at the earliest possible age. The bulk of the children accept the third alternative, but the number of pupils in all the higher types of general education have largely increased since 1918. Particularly is this true of the *Mittelschule,* an intermediate type similar in purpose and curriculum to the Central Schools of London. With the ending of compulsory military service there has ceased the unnatural thrust towards the higher school not for the sake of learning but to win the coveted social privilege of one year's military service. In point of fact the Realschule, which bore the greater part of this burden, has in some states practically ceased to exist and the greater part of its former clientele now frequent the Mittelschule.

New Types of Secondary Schools. — This does not imply any underestimation of the value of higher education nor of the national gain to be won by the transference of suitable pupils to the higher schools. The pre-war provision was inadequate but the interests of poor but gifted boys have since been well served. Two new types of schools cater for their particular needs. There is first the *Deutsche Oberschule,* in which, in harmony with the sentiment of the Weimar Constitution, the emphasis is laid on the training of a national spirit, and German history, literature and art are all studied from this national standpoint, though foreign languages are not excluded. These schools have replaced, to a large extent, the old institutions which prepared ex-elementary school pupils for admission to the Training colleges for teachers of primary schools.

The other new type is the *Aufbauschule* ("built-on" or supplementary school). As regards its place in the educational scheme it resembles the High School of the United States in that it only receives pupils who have completed the primary school course. In Saxony and Prussia pupils may leave the elementary school after the seventh class, that is at the age of 13 and attempt to achieve in six years what the ordinary secondary school pupils accomplish in nine. There has recently been opened in Berlin an evening gymnasium for adults, who propose in time to sit for the ordinary leaving examination of a classical secondary school, possibly with a view to a further study at a university.

The old types of the nine year schools have been maintained and it is probable that the pressure of modern studies will decrease the numbers of the *Gymnasien.* In the internal arrangement of the curriculum the schools have a larger measure of freedom to adapt the course to the qualities of their pupils, provided that the central subjects which give the colour to the school's curriculum are maintained at the prescribed level. The old ideal of *allgemeine Bildung,* or general culture, demanding equal service in many branches has been definitely abandoned, not without misgiving on the part of many teachers.

Training of Teachers. — The *Grundschule,* being a new institution, calls for a new race of teachers. The work of preparing these teachers has occasioned the greatest breach with the past. In the old days the elementary school teacher was educated, trained and served his course in isolation, without any contact with any other form of education, unless ambition drove him from the normal course. Under the Republic all is changed, the *Präparandenanstalt* and the *Seminar* alike are gone. For his general education the future elementary school teacher attends one of the recognized types of secondary schools. Both Prussia and the Free State of Saxony require the final leaving certificate of such a school, but while the Prussian candidate goes to a special institution, the *padagogische Akademie,* the Saxon future elementary school teacher proceeds directly to the university; the latter course is not without its dangers and it would seem that the open field is likely to leave the elementary school service with its requirements largely unsatisfied. The *padagogische Akademien* though not strictly university institutions are places of scientific study not in the sense that the students will all be preparing themselves to undertake original research but that they will be encouraged to envisage their work in a spirit of freedom and to build up their practice on a broad and scientific basis. Gone are the old days of *Dressur,* the training to mechanical obedience.

Within the schools too there is new life; in the elementary school the pupil is no longer a passive listener: but is a productive worker, for the principle of the *Arbeitsschule* has found wide acceptance. In the secondary schools more and more attention is given to physical development and many town schools have their country stations to which the pupils are taken in turn. The old one-sided emphasis on intellectual training has disappeared.

(A. E. Tw.)

ITALY

The basis of Italy's modern educational system was the Act of 1859. By the Act of 1908 religious instruction was made optional. It has been widely held that the aesthetic and physical side of education was unduly sacrificed to intellectual training. In 1922 Giovanni Gentile became Minister of Education, and by a series of decrees he transformed the educational system. More manual work, singing, drawing, and games were introduced. Efforts were made to brighten the atmosphere in the primary schools by flowers, pictures, more comfortable seats, and open-air lessons. In the secondary schools each teacher was required to teach more than one subject; a combination of mathematics and physics, for instance, was expected to lead to a more philosophical

and less technical treatment. Compulsory religious instruction was restored "in the form established by Catholic tradition," and exemption was granted only where parents undertook to impart it themselves.

Gentile tried to enforce attendance by warnings and fines. But a number of small schools in thinly populated districts were transferred to private hands, and others were closed. The private schools receive a State subsidy. Compulsion is nominally from six to 14, but Henri Goy, an ardent admirer of Gentile's work, declared that in practice the majority of schools are only organized for the four lower classes. The minister decreed a drastic revision of text books, and established a board of censors. There was also a change in the method of transfer from class to class. Whereas formerly pupils were examined by their class-masters to enable them to pass out of a lower class, they are now examined by State examiners to enable them to pass into a higher class or school. The partially elected local education authorities were replaced by regional inspectors and councils, appointed by the Government.

Secondary education, according to Henri Goy, aims at recruiting a limited élite and separating directors from workers. The number of secondary schools and places, therefore, is strictly limited. Special schools are provided for girls of the wealthier classes. There are also "complementary schools," providing a three-year course after the primary school, and the number of these is not restricted, as is that of secondary schools proper.

A State examination is required for admission to the professions, independent of the university doctorate. The universities are closed to primary teachers, but there are training colleges whose university status is recognized. Gentile retired in 1924, but his decrees remained in force.

In the early years of the present century a demand arose for the training of teachers of domestic economy, and for instruction in rural pursuits among peasant women, who in Italy care for silk-worms and fowls, while the men work in the fields. In 1902 an agricultural school with a domestic economy course was opened at Niguardia. Others followed, and in 1911 an infant welfare school was founded in Rome. These institutions were private, but received Government subsidies. Domestic economy is now a compulsory subject in primary schools. (See also MONTESSORI SCHOOLS.) (M. M. G.)

RUSSIA

Education in Russia is markedly less advanced than in Western Europe. Historical, geographical and economic factors have all helped to retard it. Two centuries of Tatar domination effectually checked intellectual progress and isolated Russia from the western world. Peter the Great made the first effort to organize education, but considered it merely as preparatory to a career in the public service, and this opinion dominated Russian thought until the latter part of the 19th century. Education of a scattered agricultural population is always difficult. In Russia, 90% of the population is agricultural, distances are great, communications are poor, and during the spring floods often cease to exist. Summer is brief and hot and demands exhausting and intensive work, so that the economic value even of a child's work is great, while the general poverty and poor cultural conditions make the long, severe winter a time of great hardship. Here, again, the child's help is valuable for the home industries by which the peasant supplements his income. An added difficulty has been the long serfdom of the agricultural labourer (until 1861). Local Zemstvos (founded 1864) and town councils strove to raise educational standards, but were hampered by poverty, by the fact that the village priest was often the only possible teacher and by the neglect of education on the part of the Imperial Government, which considered the higher grades essentially a class privilege. In 1914 the number of children attending school was 53% of those of school age.

War, foreign intervention and famine (1914–21) destroyed schools far and wide, and some 350,000 children from the devastated and famine stricken areas became homeless vagrants. The new Soviet government was thus faced with great difficulties in its efforts to improve education. Its budget was much less than that of 1913 and it was able to allow only 68% of the pre-war grant to education in 1925, the remaining funds being assigned by local budgets or raised from private funds or school fees. School fees for city children were introduced in 1922–23, though rural children paid no fee, and city schools provided not less than 25% of free places (for children of the soldiers of the Red Army, of the unemployed, the crippled, etc). The results of the financial stringency are difficulties in providing equipment and school buildings and the inadequate payment of the teachers. A large proportion of the education grant has to be set aside to maintain homes for destitute children, which, even so, cannot provide for all the child victims of the tragic 1914–21 years. Education is administered by the People's Commissariat for Education (Narkompros), which controls and administers all forms of education, including universities, museums, art centres and schools of music. This centralized government superimposed by a highly westernized and industrialized group upon a scattered and primitive agricultural population living in different regional conditions is a remarkable educational experiment. Outstanding features of the system are its encouragement of teaching in the vernacular, both for adults and children, among the national minorities, its introduction of politics even to the youngest children, its emphasis on the material side of life, its refusal to recognize spiritual values. These latter aspects are a reaction to the difficult material conditions of life for a very large percentage of the population. None the less, according to official reports, considerable progress in the liquidation of illiteracy has been made and a keen enthusiasm for better educational facilities aroused. Kindergartens, children's hearths and playgrounds are provided for a small but increasing percentage of children from three to seven years of age. First grade schools provide for the children of seven to 11 years, though many children of peasants leave school at 10 years to help their parents. In 1925, first grade schools were attended by 59 5% of the children at this age. Second grade schools provide for a general education up to 15 years, and vocational education from 15 to 17 years. In addition there are workers' faculties for children working in factories, some providing part-time day instruction and some providing evening instruction. The number of universities and higher polytechnics has markedly increased, and industrial undertakings must contribute to their support. Schools, clubs, cottage reading rooms and travelling libraries are provided for adults, and art, music and dramatic clubs are popular everywhere. Russian scientific work, notably Pavlov's neurological work and Glinka's soil survey, is of a very high standard, and the researches of the Russian Geographical Society have led to the publication of a remarkable series of regional monographs.

(R. M. F.)

AUSTRIA

The educational system of Austria in the 19th century was adapted to the training of obedient subjects of a nearly absolute monarchy, and an efficient and docile bureaucracy. After the World War and the collapse of 1918, Austria was transformed at one stroke into a small, impoverished, democratic republic, with some two-thirds of her school population in Vienna. Her first education minister, Otto Glockel, set himself the task of training responsible citizens, men and women capable of judgment and initiative. He was himself a teacher, and he based his reforms on three principles: (1) In the lower forms subject matter was not to be sharply divided, but all treated as part of a unit—the child's own experience. (2) The child's familiar world was, therefore, the point of departure: the geography and natural history of its home, local folk-songs and dances, traditions and history. (3) Education was to be creative activity rather than passive receptivity.

Glockel made plans for transforming the pre-war educational system, based on social distinctions, into the so-called *Einheitsschule,* in which the State primary school would be common to all classes, and access to higher education would depend on the child's aptitudes, rather than on his parents' income. He submitted his new primary scheme to the teachers, and in 1920 it

was adopted experimentally. In that year Glockel resigned, and subsequent Governments were hostile to many of his ideas. But he had taken every step in consultation with the teachers, and they showed remarkable initiative in working out his primary school reforms; in 1926 these were finally established for the first five years of school life.

Glockel realized that his secondary school reforms must be built upon the foundation of a reformed primary system. He contented himself, therefore, with sketching a general plan for the *Einheitsschule,* and transforming six former officers' training schools into experimental secondary boarding schools for children of exceptional ability, who were admitted free. Four of these are for boys and two for girls. The Secondary School Act of 1927 does not carry out Glöckel's scheme, but it provides facilities which approximate to the *Einheitsschule.*

SPAIN

Spain's compulsory education act was passed in 1909, but it was not enforced, and, moreover, the age of compulsory attendance was left blank. In 1910 59·35% of the population were illiterate, and in the years following rural schools were continually being closed for lack of funds.

Of recent years single-class primary schools have been giving way to better-equipped six-class schools, and there is a movement for the introduction of modern methods: activity in place of passive receptivity, school libraries. beauty in buildings and decorations. Particularly in Barcelona there has been a strong forward movement. A commission which reported to the city council in 1908 advocated far reaching reforms, which the council accepted, but the proposal to make religious instruction optional was ruled out as illegal. Barcelona, however, has established open-air schools and holiday colonies for delicate, under-fed children; an apprentices' school and continuation school for girls; and a domestic economy school with evening and Sunday classes. During the last five years (1929) 5,000 new schools have been built and the Government proposes to continue at the same rate till the supply is adequate. There are now 33,000 public primary schools; church schools number 17,000. Illiteracy has fallen, according to the latest official returns, to 40 per cent, and in Castile it is only 15 per cent.

In 1926 a series of decrees reorganized secondary education in all districts under the same authorities as the universities. Admission to the secondary school is by examination; after three years a second examination admits to a further three-years' course, leading to matriculation. One-quarter of the total places must be free. Religious instruction is compulsory, unless the parents expressly appeal. There is a State monopoly of school books, and these must be in Castilian Spanish: a severe blow to Barcelona, where the Catalan dialect is in general use, though Castilian is taught. (M. M. G.)

PORTUGAL

A legally regulated system of education was introduced in Portugal by the marquis of Pombal in 1772; a school was to be established in each locality; but the marquis's fall from power prevented the completion of his work. Under the law of 1881, which devolved authority on the localities, schools sprang up all over the country, but the Central Government resumed control in 1890. School attendance became free and compulsory from six to 12 years. After the proclamation of the republic in Oct. 1910 great educational developments were planned. By the decree of March 29, 1911, primary education became secular and compulsory. Each parish was to have at least one boys' and one girls' school, the cost to be shared between the State and the town councils. The disturbed state of the country, however, largely prevented the realization of these educational aspirations, and, according to the 1920 census, illiterates still numbered 1,838,419 men and 2,438,922 women out of a total population of 5,621,977 (excluding the islands and colonies), though efforts are made to enforce school attendance rigorously. In the year 1918-19 there were 7,007 primary schools with 170,415 pupils, and 32 secondary schools. There are also nursery schools (*q.v.*) for children between three and six years. Bursaries are granted for the two years' course at the teachers' training colleges. Portugal has three universities at Lisbon, Coimbra and Oporto, a technical school at Lisbon, and a higher school of agriculture, besides colleges of music and art at Lisbon and Oporto. (X.; C. Br.)

BELGIUM

It was not till 1914 that primary education became compulsory in Belgium. By the act of 1914 free primary education from six to 14 was made universal. Between the ages of 12 and 14 half-time was allowed. The communes may "adopt" and make grants to private schools which reach a required standard and which exempt pupils from religious instruction at their parents' wish. But 20 parents in any commune may demand the establishment of a public primary school. Schools recognized as qualified for adoption receive a State grant. The size of classes in primary schools is restricted to 50. There are special regulations for bilingual areas (Flemish and French).

An interesting feature in Belgian education is the treatment of the religious question. The law of 1842 obliged the communes to provide primary instruction, which was to be free in the case of poor children. Subject to a conscience clause, religious instruction was obligatory. The law of 1879 removed religious instruction from the curriculum, and provided for facilities to the clergy to give such instruction outside school hours. This law evoked a storm of opposition, and within eighteen months the Catholics founded private primary schools with 455,000 scholars. The law of 1884 gave liberty to the communes to provide for religious and moral instruction, subject to a conscience clause, and the law of 1895 made it obligatory. Under the present law, passed in 1914, it is still obligatory, subject to a conscience clause. It is controlled by the clergy, and all recognized denominations have equal rights in the public schools.

Another interesting feature is the development of *l'enseignement ménager*—instruction in domestic and rural pursuits—which is, perhaps, the best in Europe. It is regulated in the primary schools by the act of 1914. Private schools conforming to the required standard receive a Government grant. There are one and two year courses for girls of the well-to-do classes, and a Higher Normal College of Agriculture and Domestic Economy at Laeken, where women are trained, not only as teachers, but as leaders in agricultural activities. For 33 years Belgium has had itinerant agricultural instructors, and there is one itinerant school for each province, 18 in all.

HOLLAND

The outstanding feature of education in Holland is the strength of the private primary schools. The law of 1878 allowed communes to make grants to private schools on condition of their becoming neutral in the matter of religion. The law of 1889 allowed private denominational schools t o receive Government grants, but forbade further grants to such schools by the communes. Of late years there has been acute strife concerning the demand of religious bodies to maintain denominational schools wholly supported by the State, ending in the Act of 1920 which conceded the demand. The result, according to P. A. Diels, was to duplicate schools by denomination, with a frequent loss of efficiency, and to add to the expense incurred by the State. An outcry for economy followed, and teachers' salaries were lowered, while the size of classes, reduced under the Act of 1920, was again increased.

The 1920 act, further, created the Unitary School, and established parents' committees. Compulsory education is from the ages of seven to 13; the age was lowered to six in 1921, but raised again to seven for reasons of economy in 1924. The Government has now introduced a bill restoring the age of six. Child labour is illegal before the age of 14, so that there is a gap of one year in many cases between leaving school and starting employment. Pupils pass from the primary to the higher schools at 12. Admission to secondary schools is by certificate of capacity from the head of the primary school.

SWITZERLAND

Switzerland's education is based on a democratic system of local authorities. The central authority is the canton. The Federal Constitution states that primary instruction must be compulsory and gratuitous; that the public schools must be open to all without prejudice to freedom of faith and conscience, and religious instruction be optional; forbids the employment of child labour before the completion of the 14th year; and rules that all recruits for the Federal army (in which service is compulsory on a militia basis) shall be examined in their 20th year. The Federal authority also controls the entrance examinations for certain professional studies.

The commune is the unit for primary education, covering the years from six to 14. In the primary schools classes are still large; 70 is not uncommon, and nowhere is the maximum below 50. Several communes in combination form a district authority for the support of higher primary schools *(Sekundarsclzulen)*. The secondary schools are maintained by the cantonal authority. Religious instruction in the Swiss communal schools generally follows the faith of the majority; in a few cantons separate schools are provided for minorities if sufficiently numerous.

Attendance at continuation schools is compulsory for apprentices in most cantons; the cantonal authorities frequently delegate compulsory powers to the communes in the case of other children. It is usual to allow two years to elapse between leaving the primary school and entering the continuation school.

SCANDINAVIA

The three Scandinavian countries are closely akin educationally. All three can boast that State education has banished illiteracy. All three, with Denmark in the vanguard, have developed popular adult education in the form of residential people's high schools. The prevalence of co-education, in Scandinavia as elsewhere, is a measure of economy adopted by peoples resolved to secure educational efficiency in spite of limited means.

Denmark. — Denmark introduced compulsory primary education on paper as early as 1739, but the act was not strictly enforced. An act of 1899 limited the size of classes to 35 in the towns and 37 in the country.

The modern State educational organization is that of the Unitary school. Education is compulsory from the ages of seven to 14. Admission to the secondary school is secured by examination. Primary education in State schools is free. In the higher "examining" schools, fees are graded according to the parents' income. Denmark's woman minister of education, Nina Bang, has introduced two new bills: (1) dealing with the training of teachers; (2) limiting the power of the clergy on the local school committees and establishing joint committees of teachers and parents.

Denmark's great contribution to education, her people's high schools, were inspired by Bishop Grundtvig (1783–1872). The early years of the 19th century were a time of national humiliation and spiritual stagnation for the country. The people's high schools, as Grundtvig conceived them, were to give no vocational instruction, to prepare for no examinations; they were to deepen the moral and spiritual life of the students, and to open to them the treasures of national history and tradition, of poetry and thought, and to show them history as the slow fulfilment of a Divine purpose. They were to depend on the living force of the teacher's words rather than on book learning. In 1844 a successful beginning was made with such a school at Rödding by Prof. Flor. Seven years later Kristen Kold established a school at Funen on simpler and more popular lines. He is described in the English Board of Education *Special Reports* as "a sort of rustic blend of Socrates and Pestalozzi." The people's high schools receive State subsidies and are inspected by the State, but no attempt is made to dictate curricula or interfere with their freedom. They are open to both sexes between the ages of 18 and 25; the men as a rule attend in winter, the women in summer. Since Grundtvig's time there has been a departure from the rule of excluding vocational instruction, and much of the success of Danish agricultural co-operation is attributed to the high educational standard of the farming community, thanks to the people's high schools.

Norway.—Compulsory primary education was established by the act of 1889. The children attend from seven to 14 years of age. The size of classes is limited to 35. Norway, like Denmark, has the unitary school. Primary education is free, as also in many cases secondary education. Teachers' councils are consulted on questions of administration, text books, curricula. There is equality of work and pay between men and women. The act of 1927, passed under the pressure of a demand for economy, deals with the organization of schools in thinly populated areas, with salaries and with State subsidies.

Sweden.—The unitary school is not yet an accomplished fact in Sweden, but the royal commission which reported in 1922 recommended its adoption, and parliament has now sanctioned the scheme. Primary education is regulated by the act of 1921. It became compulsory under the act of 1852, and begins at the age of seven. Under the act of 1918 two years' attendance at a vocational continuation school is compulsory and free for children who do not proceed to secondary schools, and the local authorities may add two years more compulsory attendance at the free Apprentices' schools.

The new scheme sanctioned by parliament in 1927 provides for six years' compulsory attendance at the common primary school; and a four-years' secondary course followed by three years at the gymnasium, which leads to the university. The number of subjects studied is to be reduced and more team work on special research is to be encouraged.

CZECHOSLOVAKIA

Like Austria, the new Czechoslovak republic had to transform an absolutist, bureaucratic educational system into one adapted to train a democracy; like Poland, it had to weld provinces with widely different customs and cultural traditions. Besides Czechs, the republic includes German-speaking Bohemia, with a high cultural tradition, and Slovakia, which was more backward and more illiterate, as under the Magyar régime most Slovak-speaking schools had been suppressed.

School attendance is compulsory from the age of six; for Slovakia compulsion was at first imposed for six years only, for the rest of the republic for eight years; in 1928 the eight years' compulsion was legally extended to Slovakia. In the larger towns the primary course is divided into five years at the primary school proper and three at the higher grade school. Children are admitted by examination at the age of ten to the several types of secondary school, with a seven or eight years' course. The law provides for the establishment of compulsory continuation schools for pupils 14 to 16.

Provision has been made for a gradual reduction in the size of primary school classes; in 1933 a maximum of 60 is contemplated. Religious instruction is obligatory, subject to a conscience clause, and is controlled by the various churches. Private schools are recognized by the State, and in Slovakia there are a large number of denominational primary schools. Educationalists aim at transferring these to the State, since a locality is often less well served by two inferior denominational schools than it would be by concentrating all resources on a single efficient public school. Difficulties arose in Slovakia from the fact that many of the teachers were previously Hungarians who did not speak Slovak. All teachers are now required to learn Slovak, but there has been a shortage. only partially made good by Czech-speaking teachers.

In Prague the Czech university dates from 1348 and the German (added to it in the 18th century) was separated in 1882. The republic founded the universities of Czech Masaryk at Brno (Briinn) and the Slovak Comenius at Bratislava. (M. M. G.)

POLAND

When Poland became an independent State in 1918 she had to weld three provinces, with the widely differing administrative systems of three empires: Congress Poland (Russian), Posen (Prussian) and Galicia (Austrian). In Congress Poland education was rudimentary, and even in 1919–20 there was 50% absenteeism among children of school age. Galicia was accustomed to

far greater local autonomy. Posen had enjoyed efficient German administration and showed only 2% absenteeism before the World War; the fact that the rate had increased in 1919–20 was probably due to the effort at abrupt Polonization.

An act of 1920 brought all education under the control of the minister in Warsaw. The communes were responsible for school buildings and the State for teachers' salaries. Education was made compulsory from seven to 14, but the law was not in full operation in 1928. A public school may provide teaching in a language other than Polish where there is a sufficient number of children with a different mother tongue.

All public secondary schools are required by the Constitution to be free. Admission is open to all who pass a qualifying examination at the end of the sixth year at the primary school. Private schools which conform to Government requirements are given equal recognition with Government schools. Many inefficient schools have been compelled to close.

The new State found universities already established at Cracow, Warsaw and Lwow (Lemberg); it has founded new ones at Poznan and Vilna and a Catholic university has been founded at Lublin. (M. M. G.)

EDUCATION, ARTICLES ON. The main article EDUCATION is divided into the following sections: (1) *Introduction.* (2) *History down to the 19th century.* (3) *Growth of National Systems,* with subheads: England; Wales; Scotland; Ireland; the United States; France; Germany; Italy; Austria; Spain; Portugal; Belgium; Holland; Switzerland; Scandinavia; Czechoslovakia; Poland. (4) *Bibliography.*

For the subject of its curriculum *see* SCHOOL AND CURRICULUM divided as follows: Introduction; Mother Tongue; History; Mathematics; Arithmetic; Science; Geography; Music; Art; Handicraft; Domestic Science; and Religion.

For other articles of a general and particular character *see:* SCHOOLS; UNIVERSITIES; ELEMENTARY EDUCATION; SECONDARY EDUCATION; CLASSICAL EDUCATION; POLYTECHNICS; PHYSICAL CULTURE; COMMERCIAL EDUCATION; EDUCATION AND INDUSTRY; TECHNICAL EDUCATION; WORKERS' EDUCATION; ADULT EDUCATION; EXAMINATIONS; TEACHERS, TRAINING OF; NURSERY SCHOOLS; KINDERGARTEN; MONTESSORI SYSTEM; CO-EDUCATION; BLIND, TRAINING AND WELFARE OF THE; DEAF AND DUMB, EDUCATION AND WELFARE OF THE; MENTAL DEFICIENCY, etc.

For specialized education, *see* AGRICULTURAL EDUCATION; JOURNALISM, SCHOOLS OF; LEGAL EDUCATION; MEDICAL EDUCATION, etc.

EDUCATION, BOARD OF: *see* GOVERNMENT DEPARTMENTS.

EDUCATION, THE UNITED STATES BUREAU OF, established by Congress as an independent department of the Government in 1867 and in 1869 as a bureau in the Department of the Interior, is the principal agency in the United States for educational research, statistics, investigation and general dissemination of information relating to schools. It has no administrative power over State school systems but exercises certain administrative functions in connection with the expenditure of funds appropriated by the Federal Government for the colleges of agriculture and mechanic arts in the States and Territories and is entirely responsible

for the administration of the schools, hospitals and other activities relating to the natives of Alaska. The Bureau of Education had completed (1928) more than 200 formal surveys of school systems, of which 11 have comprised entire States and a considerable number have been national in scope, such as the survey of negro colleges and universities in the United States and the one on land-grant colleges and universities. The most important of its publications is The *Biennial* Survey of Education, a comprehensive statistical and textual review of education in the United States. The bureau possesses the largest and most valuable purely educational library in the United States.

Tigert, "Activities of the United States Bureau of Education," in National education association Addresses and proceedings (1922); D. H. Smith, "The Bureau of education; its history, activities and organization" The Johns Hopkins Press (xiii., 157, p. 80, 1923). (J. J. T.)

EDUCATIONAL ASSOCIATIONS. Many educational and professional associations have been formed since the middle of the 19th century; these have done much to co-ordinate methods of education and to organize the teaching profession as a whole.

GREAT BRITAIN

University teachers of Great Britain are represented by The Association of University Teachers (founded 1919) which has a membership of 1,200 and publishes The Universities Review terminally.

In the sphere of secondary education, there are five important associations: The Head Masters' Conference (founded 1869); membership (187) is restricted to head masters of public schools and is revised periodically, regard being had to the measure of independence enjoyed by the school's governing body and the head master, and to the number of resident undergraduates at Oxford and Cambridge who have been educated at the school. The Association of Head Mistresses Incorporated (founded 1874); its membership is approximately 600 and its objects are to support and protect the status of women teachers and to safeguard professional and educational interests. The Incorporated Association of Head Masters (founded 1890), mainly represents the interests of publicly controlled secondary schools, with a membership of 900; like the Association of Head Mistresses, it has a wide influence on school administration; it issues a review terminally. The Association of Assistant Mistresses Incorporated was founded in 1884, to promote the discussion of educational questions and to improve professional status side by side with the cause of education; it has a membership of 8,300 drawn from 1100 schools. The Incorporated Association of Assistant Masters was founded in 1891; its membership, confined to masters in secondary and public schools, totals over 11,300. It is organized in a central body with 75 branches. Its objects are educational and professional. It publishes a monthly journal, *The* A.M.A., and a Year Book; it has also issued many memoranda on teaching methods.

The four major secondary associations set up a Joint Committee in 1916 under the title The Joint Committee of the Four Major Secondary Associations. This Committee, when united action is required, speaks with the authority arising from a combined membership of over 2,100 secondary school teachers.

Secondary teachers in Wales are mainly enrolled in one or other of the four major secondary associations, but there is also the Welsh County Schools Association (membership 148) for headmistresses and headmasters; this publishes The Welsh *County* Schools Review.

Two other associations connected with secondary education are The Association of Preparatory Schools, founded in 1892, with a present membership of 700, all of whom are or have been headmasters of preparatory schools, and an official organ The *Preparatory* Schools Review; and the Independent Schools Association, with a membership of 750 confined to proprietors; its official publication is The Independent School.

There are three main associations connected with technical education; The Association of Teachers in Technical Institutions was founded in 1904 for the advancement of technical education and the safeguarding of professional interests. It has a membership of 2,300 and issues monthly The Technical Journal. The Association of Technical Institutions includes representatives from 175 technical institutes in Great Britain. The Association of Principals in Technical Institutions has 170 members. There is also the Higher Education Section of the National Union of Teachers with a membership of over 4,000 men and women engaged in higher education.

Associations on the administrative side are: The Association of Education Committees representing 270 local education authorities; it publishes a weekly journal, Education, and organizes annually the North of England Education Conference. The County Councils' Association and the Association of Municipal Corporations also have education committees in constant relationship with the Association of Education Committees and these bodies have considerable influence with the Board of Education. The Association of Directors and Secretaries for Education has a membership of 250.

The more important subject associations are: The Classical Association (3,000 members), The English Association (6,000—English), The Geographical Association (4,400—*Geography*), The Historical Association (4,500 members—many local branches), The Mathematical Association (1,700 members—Mathematical Gazette), The Modern Language Association (2,000—*Modern* Languages), The Science Masters Association (1,650 members—School Science Review) and The National Society of Art Masters (1,130 members). Other subject associations are The Art Teachers' Guild, the Educational Handwork Association, the Music Teachers Association and the Secondary Schoolmasters Physical Education Association.

Bodies of a more general order include: The British Association for Commercial and Industrial Education, The British Association for the Advancement of Science, into which has been merged the British Science Guild (17 sections including educational science), the New Education Fellowship (2,000—New Era, with editions in English, French and German), The National Union of Scientific Workers, The Parents National Education Union, and the Workers Educational Association (27,000 members, over 2,000 affiliated associations and nearly 600 branches).

Most of the above associations are affiliated to the Annual Conference of Educational Associations presided over by distinguished educationists and first held in 1913. The Conference has supplied a rallying place for teachers and administrators of all categories and its comprehensive organization gives a free platform for full discussion of educational questions from all points of view. A full report of the papers and discussions is published yearly.

(G. D. D.)

National Union of Teachers. The National Union of Teachers was constituted in 1870. Its principal objects are to associate and unite the teachers of England and Wales; to provide means for co-operation and the expression of collective opinion upon matters affecting education and the teaching profession; and to secure the establishment of an efficient national system of education. In 1936 the Union achieved a record membership with a total of 159,500 teachers of all types and grades: university professors, secondary, primary and special school teachers, fully qualified instructors in handicraft, domestic science and other special subjects, and student members (6,500) in universities and training colleges.

The controlling body of the Union is an annual conference held at Easter, of about 2,000 delegates, representing 638 local associations which, for the most part, are grouped together in 60 county associations. The executive consists of 38 members, directing a large official and clerical staff.

The headquarters of the Union are situated at Hamilton House, Mabledon Place, London, and housed in the same imposing building are two other bodies which are independently constituted and governed, yet are integral parts of the Union. The Teachers' Provident Society, with accumulated funds of £5,750,000, and nearly 100,000 members, offers friendly society and insurance benefits expressly designed to suit teachers; the benevolent and

orphan fund raises about £50,000 annually for charitable purposes. Minor departments are the Union library, its War Aid fund, which raised £250,000 to assist ex-service men and their dependents, and the Thank-offering fund which was established to augment the small pensions of those teachers who retired under pre-war superannuation schemes. The Sustentation or Defence fund has investments worth £1,340,000. The Union publishes its own journal: *The Schoolmaster and Woman Teacher's Chronicle.*

In recent years successful efforts have been made to establish contact and co-operation with teachers in other lands for educational progress and international goodwill, and the Union is affiliated to the World Federation of Education Associations and to the International Federation of Teachers' Associations.

Working in friendly co-operation with the Union are the Educational Institute of Scotland, the associations of teachers in secondary and technical schools, the National Association of Head Teachers and the National Federation of Class Teachers. The two latter organizations include a large number of teachers in primary and central schools who are employed mainly in the principal urban centres of the country and are usually members of the Union. Both bodies hold annual conferences at which educational and professional policies are formulated, generally in harmony with those proposed by the National Union of Teachers. The relations between the Cnion and the Local Education Authorities are now on a very friendly basis, the change in attitude dating from the establishment of national committees to settle the question of scales of salaries for teachers.

(F. W. G.)

INTERNATIONAL CONFEDERATION OF STUDENTS

The International Confederation of Students (Confédération Internationale des Étudiants [C.I.E.]) was founded at Strasbourg in 1919, with the triple object of creating friendship and understanding between the university students of the world. of co-ordinating student activities in all countries, and of studying international questions relating to the material and intellectual life of the students. As its name indicates, it is a federation of the National Unions of Students in the various countries, and its work is carried on in complete independence of political and religious differences.

The Confederation has at present 32 members, the following countries being affiliated: Albania, Austria, Belgium, Brazil, Bulgaria, Czechoslovakia, Egypt, England & Wales, Estonia, Finland, France, Greece, Hungary, Irish Free State, Italy, Latin Americans abroad, Latvia, Lithuania, Luxemburg, Mexico, New Zealand, Palestine, Poland. Rumania, Scotland, Spain, Switzerland, Turkey, Ukrainians abroad, United States of America, White Ruthenians abroad, Yugoslavia.

The practical work of the Confederation is carried on by permanent Commissions, of which the most important are the office of the Secretary-General (Brussels); the international sports office (Paris); and the office for international relations and travel (London), which does valuable work in encouraging and facilitating student travel. Among its most useful activities are the publication of the *Handbook* of *Student Travel* and the control of the international student identity card.

The students of England and Wales are represented in the International Confederation of Students through the National Union of Students of the Universities and University Colleges of England and Wales, a national federation of the Student Unions and Guilds of Undergraduates in the universities. Since its foundation in 1922 the National Union of Students has developed with great success and rapidity and now occupies a position of no small importznce in the educational world. It has largely concentrated on international work of a strictly practical kind. such as the exchange of university students between different countries, the finding of positions "au pair" both in England and abroad, and the organization of educational travel on a very wide scale. In this way it has achieved a large measure of "intellectual co-operation" between members of the younger generation in different countries. Nationally it acts as a co-ordinating link between the various University Unions and promotes discussion on matters of educational interest.

(I. S. M.)

UNITED STATES

Educational associations of teachers for mutual improvement and for the advancement of the profession were formed very soon sfter education became an established policy of the United States snd a system of training instituted through the interest and vision of such leaders as Horace Mann and Henry Barnard.

The United States has no Federal system of education but does have a distinct American system. It has no governmental authority requiring standard courses of study, teacher training, management, methods or finance as in those countries where education is directed by the central Government. The American system, however, has grown up through the zeal and courage of teachers who have formed local educational associations and overstepped State boundaries to join with their co-workers in conference and in educational investigation. These associations have become clearing houses for educational procedure. Teachers have discussed methods, determined failures and successes, and catalogued educational experiences and results. They have listened to addresses from leaders of the profession and have formed investigating committees until educational methods and standards, materials, processes and attitudes have become greatly unified throughout the States and Territories of the Union.

Educational organizations in the United States are local, state, and national in scope. They may also be classified as general and special, according to their aims and purposes. There is scarcely one of the 3,072 counties of the United States which has not its organization and every city has from one to several. Each State and Territory is organized.

Local associations function in the solution of problems which concern their members in their local relationship. Their programmes vary widely—the nature and scope being determined by the size of the group, the extent of its territory, and the energy and initiative of its members and leaders. No single programme can be cited as typical. Professional improvement, teacher welfare, social betterment, and community service are common objectives to which the various types of local associations have found different avenues of approach. Most local associations are affiliated with the state associations and 588 were affiliated with the National Education Association in 1937.

The activities of State associations include: conventions; publications (every State with the exception of Maine and Maryland has an official organ); legislation; research; field service; public relations; teacher welfare; membership promotion; co-operation with the national organization. Every State association and Alaska, the District of Columbia, Hawaii, and Porto Rico are affiliated with the National Education Association. In this connection the States co-operate in national projects, lend counsel on national policies, assist in the enlistment of members in the national, and send official delegates to the conventions of the national.

The most outstanding and influential educational organization in the United States is the National Education Association, organized at Philadelphia, Pa., in 1857, under the title, The National Teachers' Association. It has held annual meetings since that time. The name was changed in 1870 to the National Educational Association and in 1907, by act of the U. S. Congress. the new charter was adopted designating the organization as the National Education Association of the United States. Its general purposes may be considered the objectives of all educational associations in America. "The purpose and object of the incorporation shall be to elevate the character, to advance the interests of the profession of teaching and to promote the cause of education in the United Stales." It includes the National Council of Education and the following departments: Administrative Women; Adult Education; Art Education; Business Education; Classroom Teachers; Deans of Women; Educational Research; Elementary School Principals; Kindergarten-Primary Education; Lip Reading; Music Education; Rural Education; School Health and Physical Education; Science Instruction; Secondary Education; Secondary School Principals; Social Studies; Special Education; Superintendence; Supervisors and Directors of Instruction; Supervisors and Teachers of Home Economics; Teachers Colleges; Visual Instruction; Vocational Education. Other departments may be cre-

ated by organization or consolidation, and departments already established may be discontinued.

Membership in the National organization is voluntary. Due to increased membership, the Delegate Assembly was created in 1921. Educational organizations — state and local — may have representation according to membership in the national body. These representatives participate in the business sessions and in establishing the general policy. Under this reorganization, the association undertook to carry its influence and its support to every teacher in the United States. The membership has been extended from 8,557 in 1918 to over 200,000 in 1937. There were in 1937, 5,700 life members.

The National Education Association is concerned with promoting teacher welfare, through the establishment of retirement systems for teachers, the assurance of tenure of position, and increased salaries. It stimulates beneficial legislation, research, and the general advancement of learning and culture. It has sponsored many of the most forward movements in education. Through its publications advances in educational procedure are given wide distribution. Under its direction, the first World Conference on Education was called in San Francisco in 1923, which resulted in the organization of the World Federation of Education Associations which now numbers in its enrolment about 1,000,000 of the 5,000,000 teachers of the world.

These associations stand as sponsors for the American public school as the foundation of American democracy. They believe in giving every child an opportunity to secure all the education he is capable of receiving and in making universal education a basic principle of the free institutions of the United States.

In addition to the organizations mentioned, there are many other national organizations representing chiefly special interests. Among the general organizations are the American Council on Education, Progressive Education Association, and the American Federation of Teachers. The latter is affiliated with the American Federation of Labor. Other groups include the Association of American Colleges, the National Council of Teachers of English, the National Catholic Welfare Conference, and many others. (O. C. P.)

EDUCATION AND INDUSTRY (including COMMERCE). The problem of the relations of the school to industry and commerce is only part of the wider question of vocational training (*q.v.*), namely that of co-ordinating the preparation for livelihood (specialized training) with the existing preparation for life (general education), and deciding how much or how little of the former should be given in the schools. The wide-spread neglect of the problem till recent time seems all the more surprising, considering the practical bent that has distinguished the English-speaking peoples. The neglect is mainly due to two reasons, both historical.

The first is the comparative eclipse of the idea of vocational training in the university sphere, an eclipse which lasted from the Renaissance till the closing years of the 19th century. In the middle ages the university was predominantly professional and vocational, its principal object being to turn out doctors in theology, law or medicine; the Latin and later the Greek authors studied were mainly regarded as providing the raw material for the technical equipment of the future graduate whatever his faculty. The Renaissance gave a great impetus to the gospel of the value of learning for its own sake, while in England the increasing resort of the aristocracy to the university that dates from the same period tended to overshadow and obscure the more strictly professional character of its work by the new ideal of its being the finishing school of the scholar and the gentleman. Yet in the case of the latter this seemingly general education was in a very real sense vocational. since the culture of the day and the power to handle his fellows (mancraft) acquired at the university were the indispensable stock in trade of a member of the ruling classes. On the other hand the ordinary mediaeval school, apart from certain monastic and a few other schools, was either preparatory to the university or gave a general education, all technical training in the then existing arts and crafts being provided outside the school by a very complete system of apprenticeship (*q.v.*).

It was just this very system of apprenticeship which explains in its turn the absence until recently of the vocational idea from the purview of education below the university. In fact it was only with the gradual decay of apprenticeship since the beginning of the 19th century, and the increased demand for more scientific training for the higher walks of industry towards the close of the same century that the question came to the fore and efforts were made by the technical Education Acts of 1889 and 1891 and still more by the Education Act of 1902 to deal with the problem on a national scale (see TECHNICAL EDUCATION). Today it is realized that it is no longer a problem of technical education pure and simple, to be dealt with as a separate department, but a much wider one of bringing national education in all its stages, primary, secondary and university, into closer touch with commerce and industry without injuring the general education they provide.

GREAT BRITAIN

The main headings under which the relations between the school and industry may be considered both as regards the present conditions and future developments are as follows: — (I) The contact between the two as at present furnished by official or other machinery for placing out the products of the school in industry and commerce. (2) The contact already set up by means of trade and technical schools and colleges. (3) The contact at present existing in establishments of general education.

On many of these points the report of the committee on education and industry (first part 1927, second part 1928) throws valuable light. For certain reasons however, the committee ruled out of consideration what may be called the counting house side of commerce as well as the university's share in the problem.

Official Machinery. — The first attempts to create official machinery for the placing out of pupils dates from the establishment in 1909 of labour exchanges, subsequently known as employment exchanges, some of which contained not only juvenile departments but also juvenile advisory committees. Various legislative modifications have since taken place, and today the work is either carried on by the Ministry of Labour through its local exchanges or else by local education authorities, where they have decided to undertake it through juvenile employment committees. These local authorities comprised in 1935 10 county councils, 49 county boroughs, 45 boroughs and urban councils, while the Ministry of Labour with 197 juvenile advisory committees is responsible for the rest of the country. The Board of Education assists through inspection and advice on buildings and curricula. Advice and information is furnished to boys and girls while still at school, through school conferences or individual interviews. In both cases particulars are collected from head-teachers on the character, ability and physical capacity of pupils on the leaving list. Other features of the work include the interviewing of applicants, the keeping in touch with employers in respect to vacancies. etc., the putting forward of juveniles for vacancies, the keeping in touch with those who have got jobs, generally known as "after care."

Every juvenile employment committee contains a member of the local education committee and normally representative employers, workers, voluntary social workers and teachers. The amount of after-care work by the committees is of considerable value and volume. The number of situations found in 1935 by the Ministry of Labour and the local authorities committees amounted to the impressive number of 764,000. In addition a large number of posts are found by individual elementary headmasters and headmistresses, especially by those of central schools, and the headmasters and headmistresses of secondary schools generally make a point of keeping in touch with employers. Those in or around London have also joint agencies for placing out boys and girls. Broadly speaking, a pupil completing the course in a secondary school has little difficulty in securing a job. In trade schools and technical institutes the finished products are readily absorbed by the business world. In the universities again appointment boards have been established. There is among certain big trading companies a growing demand for men of a university type, especially for posts abroad, where qualities of character and grit are often a paramount consideration. Increasing numbers of scientific and technically trained graduates such as chemists, en-

gineers, biologists, statisticians and the like are being taken on by the bigger firms in this country, though the intake is still far below that of Germany. This tendency is likely to be further fostered by the growing amalgamations and federations in industry, while still more recently the value of the university student (man or woman) has been appreciated by the larger stores where manners and ability to manage large masses of employees are recognized as a business asset. Mention may also be made of the work of the Institute of Industrial Psychology whose tests have proved to be of the greatest assistance in the sorting out of pupils and the prevention of industrial misfits. The Institute has also done some most valuable research with a view to systematizing the haphazard training given in the workshop or counting house and establishing the principle of a scientific technique. It also conducts courses in Industrial Psychology for London University. It provides classes for social workers, engineers and teachers, and trains business administrators and those in executive positions in the application of industrial psychology to their particular trade or industry. Sooner or later its work of scientific selection will doubtlessly be recognized as an indispensable branch of our educational machinery.

Co-operation **of** Education and Commerce.—For the direct contact already established with trade and commerce through trade schools, including those run by certain big firms, day and evening continuation schools, technical institutions and schools of art and agricultural institutes, *see* the appropriate articles on the subject. Reference should also be made to the juvenile unemployment-centres which were started as a sort of "ambulance" class for juveniles temporarily out of work. The need of some sort of compulsion soon made itself felt. The problem was largely insoluble as long as the school leaving age was 14 and the scheme of national insurance only started at 16. Today the gap no longer exists; the school age has been raised to 15, and even when the pupil has been exempted at 14 from attendance, he at once comes under the insurance scheme as the qualifying age has been reduced to 14 by the acts of 1934 and 1935. The raising of the compulsory age to 15, has by no means settled the problems of adolescence and it still seems that the part time continuation school provides the best solution for its problems. It would be far less costly than raising the compulsory age of the full time school to 16. It would bring the school and workshop into far closer and more fruitful contact than the full-time school can hope to do. It would certainly be more popular with employers (*see* below) and by combining earning and learning makes a special appeal to the young worker and his parents. At present a good deal of the commercial and technical (including artistic) equipment of the elementary or secondary ex-pupil is provided in the evening by the Junior and Senior Commercial Education and the Junior technical and Senior technical Institutes (*see* COMMERCIAL EDUCATION). Probably in no country in the world is there more evening work, ranging as it does from simpler courses in the rudiments of commerce and technology to preparation for the higher walks of commerce and industry, and including university work and even postgraduate research. But the whole is run on a voluntary basis and the leakage especially in the lower grades is, owing to various causes, considerable. It also leads to a good deal of overpressure owing to the long hours of business of many of the students, while in rural districts the problem is further complicated by the difficulties of travelling.

As regards its relations with the elementary school, criticism from the business world of the latter has certainly decreased. Taking the elementary school as it is, the main improvements that seem feasible appear to lie in the provision of more handicraft and domestic work and in some cases a closer relation of the school instruction to the pupils' environment in industrial or rural districts (*see* RURAL EDUCATION), with visits to factories, farms and places of business by the children still at school. One of the most promising developments in this respect has been the policy, especially in East Suffolk, Norfolk and Northumberland, of utilizing more fully the rural environment to provide a basis for the teaching of science and a bias to the curriculum generally, especially in senior and non-selective central schools. It is at long last being realized that of all the books at the disposal of the country child the book of nature is the best, while the slow-motion film of the seasons is most valuable.

The selective central school, especially in the towns, with its technical and commercial bias seems to have established a substantial contact with the business world, which is however capable of further extension. The secondary school, as pointed out elsewhere, incidentally gives in the English, Arithmetic, Geography and other subjects that it teaches a good deal of the technical equipment the pupil will require in commerce and to some extent in industry. Only 15·7% of its pupils enter industrial occupations, of whom only a fraction (1·7%) take up rural occupations as against 43.1% who select professional, commercial or clerical callings. From the point of view of industry and commerce it is clear that a widening of the present form of the school certificate is desirable especially in relaxing the two rigid conditions on which it can be obtained (*see* also EXAMINATIONS), but one is convinced that the necessary elasticity can alone be obtained, when a candidate will be obliged to take only two compulsory subjects (English and Arithmetic) and can select with the consent of his teachers any others on the prescribed list most suitable to his ability. At present a large number of pupils never reach the examination at all. The percentage of failures is exceedingly high, while of those who pass a good many only qualify through the misplaced charity of the examiners. These passes "of no par value" are of no real use to the pupil or to the business man who has been driven to demand the matriculation certificate which does not always test the knowledge he requires from those who desire to enter his office. Ultimately the examination should be so reconstructed and enlarged as to be capable of being taken in their stride, not only by the ordinary secondary pupils but by those of the remodelled central and the newly projected secondary technical schools (*see* below).

Recurring to the secondary schools, it is interesting to note that there is a growing tendency for pupils who have passed the certificate to enter trade and technical schools, and this should increase in the future, while as regards commerce, not only many secondary schools but public schools, like Mill Hill and Rugby, have introduced an element of commercial education into their higher classes and the movement is growing. It is worth noting in this connection the foundation of a Public Schools Business Society in London for helping the public schoolboy to adapt himself to the often unfamiliar conditions of commerce. There is plenty of room for creating similar societies for other types of schools. It has been already indicated that the universities are sending an increasingly larger number into commerce and industry. In some universities the training for the future entrants into the higher walks of commerce is insufficient, especially in usefulness to those who are to specialize in modern languages with a view to going abroad later on. These courses are organized on a narrow linguistic basis rather than the broad cultural one which such candidates really require.

Conclusion.—In spite of much progress in the past, much still remains to be done. While the value of the school has steadily risen in the opinion of the more enlightened members of the business world, a large number of industrialists and traders are still largely unacquainted with the work of the school. To bring the two parties closer together the Ministry of Labour appointed in 1928 two national advisory councils (one for England and Wales and another for Scotland), which have also produced several valuable reports, notably one on courses for the unemployed. Help has likewise been given in the matter by the United Chambers of Commerce. Valuable work has also been done by the British Association for Commercial and Industrial Education, an amalgamation in 1934 of two Societies which were severally interested in industry and commerce. They have either separately or together made some very valuable enquiries, especially into the question of instruction in modern languages (report 1935), and into vocational education after general education up to the age of 16 (report 1936). One very important point emerged from this latter enquiry. A questionnaire which was sent out to the business world elicited some 348 replies. Nearly 50% favour

part-time vocational courses for all classes of workers against about 8% who preferred full time courses—a highly significant indication of the employers' belief in this type of vocational education. Thanks to the Association and other bodies a certificate of efficiency has been established by the Board of Education in the various branches of technology. It has been distinctly successful in the engineering and electrical trades, but less in the chemical and building industries for the simple reason that the possession of a certificate does not exempt a successful candidate from any of the examinations of these latter bodies. The remedy is obvious.

Further Outlook.— Probably one of the most potent ways of furthering commercial and technical education would be to regard the selective central school and the proposed improved trade school (suggested title—technical secondary) as equally important parts of the intermediate state (11+ to 16+) in the national system of education. This would involve the gradual raising of the selective central school in staffing, amenities and salaries to the status of the ordinary secondary school and the extension of the school life and curriculum of the present trade school, (1) by starting the course two years earlier at 11+ and prolonging it to 16+, (2) by reinforcing the proportion of general education, making the instruction in the first two years of the course general and increasing and combining the general subjects more closely with the technical instruction. Instances already exist. The Walthamstow Central School has had its status raised in this fashion. The new Technical Institute at Dagenham contains a day school for pupils from 11+ to 16+ in which the curriculum fulfils the conditions enumerated above, while the Gate House School at Leicester is largely organized on these lines.

The prospects of commercial and technical education have never been brighter, especially in view of the present boom in trade and the intense demand for skilled workers, but there is one lion in the path which has yet to be faced,—the colossal cost of providing adequate technical training for all the various groups of industry and commerce throughout the country. Great as has been the advance of technical education in the past, there are obviously a large majority of business callings which are only imperfectly if at all catered for under the existing provision of technical education. Possibly the cost can only be satisfactorily met if all the main trades and industries of the country both from the side of employers and of trade unions arrange to make some definite financial contribution to the national exchequer in return for the benefits received by their own particular industry.

(C. BR.)

THE UNITED STATES

A study of the educational literature of the last half century reveals that the evolution of American education is rapidly tending toward a proper balance of the cultural and vocational objectives over which there has been so much strife in past decades between the proponents of general and practical education. Progressive leaders in the general education field now insist upon adequate provision for the practical education of all persons seeking occupational preparation, and the ablest vocational educators with equal emphasis insist that all persons seeking vocational preparation should first secure the most thorough fundamental general training which the capacities and resources of the trainees will permit. This balance is being accepted uith a full recognition of the principle that educational adjustments must be made to fit individual needs to the extent that these do not conflict with society's interest in that general education which is essential for the common good of all citizens.

Occupational statistics for the United States indicate clearly that population is shifting from rural to urban centres and that the number of workers in industrial occupations is greatly increasing. This new economic development has brought with it a vigorous demand for industrial education. This demand is being met by both public and private agencies and is resulting in the industrial enlightenment of the general population along two lines, (1) consumption and (2) production.

Education for consumption is largely supported financially through the advertising campaigns of manufacturers who make products of commercial value which satisfy popular wants. In the best elementary and some secondary schools, however, school children are now being taught in carefully prepared lessons the true value of products offered the public to satisfy the desire for food, clothing, shelter, recreation, transportation and other necessaries. This early education in the grades also serves to introduce children to certain general aspects of industrial life and is further strengthened in later grades by handwork courses which develop muscular skill. Interest is also stimulated in the study of occupations through formal courses in the junior high school years and in the practical work of try-out laboratory courses which provide experiences typical and representative of community occupations to adolescents who, in many cases, are seeking early induction into industrial occupations. The steady discharge of juveniles 14 years of age and older from the schools into industry, whether caused by necessity or lack of interest in school work, has led to the further provision for a public guidance and placement service in many American cities, in order that working children may make better occupational adjustments than would be possible for them were they to seek work unassisted. In such communities continuation schools (q *v.*) usually exist to give young workers 14 to 16, 17 or 18 years of age (as the State laws may require) further vocational and civic training on a part-time "learning while earning" programme, which calls for four to eight hours attendance weekly at these schools. This schooling aims to make economic and civic adjustment more satisfactory and certain than is possible when such children drift about in juvenile jobs without any educational guidance whatever.

Great variety characterizes training for productive efficiency. Public senior, technical and co-operative high as well as continuation schools give both trade preparatory and trade extension courses in their day and evening classes for the more well defined trades of industry. While public secondary schools for both part and full time pupils have shops in which to give practical training in the more common occupations, it is, nevertheless, an accepted principle of vocational education, that the most effective practical instruction is given on the job in industry. Such practical training may embrace any practical instruction, requiring in some instances only a few days or even hours to master, as in highly and narrowly specialized operations, or as much as five years in some of the very complex all-round trades. Industry provides the short-time training in vestibule schools and the all-round trade training through apprenticeship under indenture agreements with the trainee. The public day and evening vocational schools give such trainees the necessary related theoretical training.

Private industrial initiative, however, since 1916, has greatly extended educational opportunity in industry. In the larger industrial corporations of international reputation extensive industrial training of workers and executives (see also EMPLOYEES, TRAINING OF) has been undertaken in the form of foreman training classes and corporate trade and engineering schools. One of these, the General Motors Corporation, has established the Institute of Technology at Flint, Mich., to which co-operative engineering students from the many units of the corporation are sent in alternate months for engineering training to supplement the practical instruction received by them in the shops of the units sending them. So great is the need for industrial education on all levels of maturity that even the units of this corporation make use of available training agencies other than their own. Thus, the Frigidaire Corporation, a General Motors unit at Dayton, O., for example, sends co-operative students not only to the institute at Flint, but also to the University of Cincinnati and Antioch college in Ohio and augments this effort further by co-operative relations with the technical high school of the city of Dayton. The Ford Motor Company and the Westinghouse Electric Manufacturing Company are other notable examples of the many other large corporations which have established training organizations to meet their own industrial needs. Industrial requirements are further satisfied by absorbing engineering and technical graduates from State and private universities, where the entire training effort is confined to the class and laboratory work at the univer-

sities. Such graduates, however, seldom find their places in industry without first serving supplementary apprenticeships following their graduation from the universities. Such apprenticeships usually run from one to two years. Students at these universities are usually recruited from the graduates of technical high schools.

Finally, it may be said that the educational opportunities in the United States have been extended and developed to that point where, through public, private and corporate schools, a flexible system now obtains which meets the nation's demand for a citizenry well grounded both in the common essentials and those specialized occupational skills or abilities which ensure economic efficiency. (W. F. R.)

EDUCATION IN ANIMALS. In some birds and mammals it has been observed that the young receive parental education. This varies in its detail in different cases, for it may be little more than the supplying of a liberating stimulus or an incentive to action, while in more complicated expressions the education amounts to careful training in the way in which certain things should be done. It is advantageous in lessening the time required for learning by individual experiment, and in lessening the risks of this self-education. Moreover, there is some profitable handing-on of the gains of parental experience—a simple form of extra-organismal heritage.

To begin with simple cases, we may notice how a dabchick, with its young ones on its back, depresses itself in the stream and thus forces them to begin to learn to find their way about in the water. A grebe has been seen ducking one of its offspring, as if accustoming it to immersion. The great crested grebe often dives after fish while carrying the young ones on its back, and they soon learn their lesson. Although young birds do not require to be taught to fly, the parents may force or encourage them to make a beginning, sometimes tempting them with food. A guillemot may push its young one off the brooding-ledge on to a slope leading steeply to the sea. T. A. Coward notes that "a more usual method is for the old bird to seize the unfortunate by one wing, and, flying out with it until clear of surf and rocks, let it drop." The young bird opens its wings and flutters. It takes its first flight, diagonally down to the sea, where it also takes its first, somewhat compulsory, dive, and follows this by beginning to swim. It is waited on by its parents or by one of them, and gets some help with its meals until it is able to fend for itself. There are several similar cases well authenticated.

Some kinds of education take the form of graduated meals, as has been observed in birds of prey. From prepared pieces of flesh, to begin with, the nestlings are gradually trained to tackle more or less intact booty. L. J. Hobhouse refers to the expertness shown by some young woodpeckers in getting at the seeds of fir-cones, but he points out that the parent woodpeckers bring their young ones first the seeds themselves, then partly opened cones, and finally intact ones. "The method of preparing the family dinner is at least as much a tradition as an instinct." It is the outcome of both teaching and learning.

Among mammals the instruction is almost always on the mother's part. The carnivore often brings a living captive to the den and sets it free in presence of the young ones. This serves as a liberating stimulus to instinctive capacities, but it also affords some training. In many cases, *e.g.*, foxes and stoats, the mother takes her offspring with her on her hunting expeditions, and they gradually learn their business. The instinctive basis is, of course, present, but its exercise under maternal control may continue for months. Tregarthen describes circumstantially the detailed instruction given by the mother otter to her cubs. It includes the long alphabet of country-sounds, the fit and proper ways of diving and lying perdu, the methods of capturing different kinds of booty, and the recognized ways of eating trout, eel and frog. It may be safely said that too little attention has been given to the factor of education in developing animal behaviour. *(See* also PSYCHOLOGY, COMPARATIVE.) (J. A. TH.)
